1819.
GENERATION. 

GENERATION is that function of the animal economy by which the species is perpetuated. Inanimate matter and unorganized bodies are subject to no alterations, and would never change their condition, did not external forces destroy or modify them. On the contrary, organized bodies, very different from these inert masses, are active media of new combinations and changes; they undergo alterations, and are even destroyed by the exercise of their own powers, the entire effusion of which delivers up their spoils to the grand circle of changes, which organized matter is constantly undergoing. Although some of these bodies may last for a century, while the greater number live only for a few years, days, or even hours, this unequal duration, these moments or ages of existence, are nothing with respect to nature, and the death which the allots to man, to the plant or the insect, is not the least necessary and certain. But, if individuals are sacrificed and perished, the species survive and are immortal; by a constant and general law, animated bodies never die altogether, but are renewed and perpetuated by various modes of re-production. Some terminate their vital course while others are beginning it; and never, says Lucretius, does morning or night visit the globe, without having funeral lamentations round a bier, and the plaintive cries of an infant in the cradle. There is a constant alteration of deaths and births, of losses and reparations; and the torch of life is rapidly transmitted in the series of succeeding generations; "quasi currentes vital lampades tradunt." At a certain point of elevation in the scale of animal existence, this object is accomplished by a double series of organs, executing very different functions; and reproduction is effected by a true proof of generation, under the influence of that physical feeling, the Venus, whose universal empire and irresistible attractions are so beautifully delineated by the Roman poet.

"Aeneadum genetrix, hominum divumque voluptas,
Alma Venus! ece subter habentia signa
Que mare navigerum, que terras frugi ferenteis
Concelebras; per Te quoniam genus omne animantium
Concipitur, viuitque exortum lumina solis;
Te, Dea, te fugiant venti, te nubila ecehi,
Adventumque tuum: tibi amitas dedita tellus
Submitit flores; tibi ridens squora ponti,
Phacatumque nitet diffuso lumine eculum.
Nam, simul ac species patetifica eft verna diei,
Et referata viget genetabilia auris Funibii;
Aeris primum volueres, te, Diva, tuamque
Significant initiun, percolis corda tua vi.
Inde ferre pecudes perfaliant pabula beta,
Et rapidos transcant annes; ista, capta lepore,
Ilecebrifique tuis omnis natura animantium
Te sequitur cupide, quo quamque inducere pergis.
Dumique, per maria, ac montes, fluviique rapaces,
Frondiferaque domos avium, camposque virentes,
Omnia incidunt blandum per pectora amorem.
Efficiat, ut cupide generantia fella propagat.

Generation is the greatest mystery presented to our view in the economy of living bodies; and its real nature is still involved in the most complete obscurity. Hitherto no observation authorizes us to admit the simultaneous formation of a living body in all its parts; that is to say, by the union of particles suddenly brought together. The comparison of generation with crystallization is supported by no just analogy: crystals are made up of homogeneous particles, attracting each other indifferently, and agglomerated by their faces,
The origin of the gernis, and the mode of their existence in the female; whether they are originally formed in all their parts in each individual by any vital process, or are all pre-existing, being inclosed in each other, or whether they are differentiated through the body, and require a concourse of circumstances to bring them into a situation favourable for their development, are questions, which it is utterly impossible for us to decide in the present state of our knowledge.

The chief points have for a long time been agitated by phylogenists; but the discussion seems now to be abandoned by universal consent.

The combination of the sexes, and the mode of fertilization, are subjects to great variety. In some instances, the two sexes are united in the same individual, and fertilization is accomplished without any extraneous aid; such are the hermaphrodite and monoeocious plants, the asperatus mollusca, and the echinodermous animals. In others, each individual possesses both sexes, but requires the assistance of another, which it fertilizes, and by which it is fertilized. This is the case with the galatopodous mollusca, and with several worms. There are distinct individuals, male and female, in other classes; as, for instance, in the dioecious plants, in all animals, which have a vertebral column, in the cephalopodous and some galatopodous mollusca, in some worms, in the crustacea, and in insects; in short, in the far largest portion of the animal kingdom.

Fertilization is accomplished in plants by means of a liquor contained in small capsules, which resembles a fine powder in appearance, lodge on the female organs, and, building, deposits their contents. In animals, the liquor is always applied immediately upon or about the germs; and in many cases it is not brought in contact with the ovum, until they have been laid, as in the bony and oviscaporous fishes, and the cephalopodous mollusca; here the males and females have no commerce. Sometimes, as in the frog and toad, copulation is necessary in order to determine the discharge of the ovum and semen, but fertilization is still performed out of the body. Lastly, in the great majority of instances, the seminal liquor, introduced by the male into the body of the female, fertilizes the ovum before they are laid. This is the case in the mammalia, birds, moll reptiles, and some fishes, in the hermaphrodite galatopodous mollusca, in the crustacea, and insects. The union of the two sexes, or the act by which this is accomplished, is called copulation. In all the last-mentioned orders ovum may be discharged without previous copulation, as in the preceding ones. But they receive no further development; nor can they be fertilized when thus voided. The effect of a single copulation varies in its degree; it usually fertilizes one generation only, and produces one pregnancy; but sometimes, as in poultry, several eggs are fertilized, and afterwards discharged successively; still, however, they only form one generation. In a very few instances, one act of copulation fertilizes several generations, which can propagate their species without the aid of the male. In the plant-louse (aphis) the species has been continued through eight generations from one copulation; and in some monoeocious, through twelve or fifteen.

When the germ is detached from the ovum, its means of existence may be more or less complete. In most animals it is accompanied by an organized mass, to which it is connected by means of vessels. The absorption of this sers for its nutrition and development, until the period of its independent existence. It derives nothing therefore from the body of the mother, from which it is separated by coverings, varying in number and solidity. The germ, together with its malls of nourishment, and the surrounding membranes, constitutes an egg, or ovum; and the animals, which produce their young
young in this state, are denominated oviforms. In most of these the germ contained in the egg is not developed, or hatched, until that part has quitted the body of the mother, or has been laid; whether it be necessary that it should be afterwards fecundated, as in many fishes, or that it requires only the application of artificial heat for its incubation, as in birds; or that the natural heat of the climate is sufficient, as in reptiles, insects, &c. These are strictly viviparous animals.

The ovum, after being fecundated, and detached from the ovarium, remains in some animals within the body of the mother, until the contained germ be developed and hatched. There are fowl viviparous, or ovoviviparous. The viper and some fishes afford instances of this process.

The mammalia alone are truly viviparous animals. Their germ poissesses no provision of nourishment, but grows by what it derives from the juices of the mother. For this purpose it is attached to the internal surface of the uterus, and sometimes by accident to other parts, by a kind of root, or infinite ramifications of vessels, called a placenta. It is not therefore completely separated from the mother by its coverings; and it does not come into the world until it can enjoy an independent organic existence. The mammalia cannot therefore be said to poissess an ovum, in the sense that we have assigned to that term.

According to this sketch of the subject, generation may be said to consist of four functions, differing in their importance, and in the number of animals, to which they belong, viz. 1st. The production of the germ, which is a constant circumstance; 2dly. Fecundation, which belongs only to those animals where there is a distinction of sexes; 3dly. Copulation, which is confined to those kinds of sexual generation in which fecundation is accomplished within the body; lastly, Utero-genitation, which belongs exclusively to viviparous generation. The generative organs may be most naturally arranged according to this distribution of the partial functions, which they execute. The simple production of a germ, or oovoviviparous generation, may be accomplished at any point of the body, and has, therefore, no peculiar organs.

Sexual generation demands an organ for the production of germs, and another for that of the fecundating liquor. Modes of union are necessary when copulation takes place; and fertilization requires a receptacle adapted to the abode of the germ. Thus we have preparatory and preparing organs; instruments of copulation; and organs of education. Those of the two first classes are divided into male and female; the last belong to the latter sex only. The preparatory and preparing organs of the males secrete the semen, and the other fluids which are to be mingled with it, and retain these secretions. They confine, in their most complicated form, 1st. Of the vesicles, which prepare the femoral fluid, and conduct it, either into a particular resevoir, or into a canal, from which it is conveyed out of the body, or into a cleaan, from which it is in like manner ejected; 2dly. Of the vesiculae seminales, supposed to be resevoirs for the semen; 3dly. Of the prostatic glands; and, 4thly. Of Cooper’s glands, which secrete a pecurial fluid, mixed with the semen at the time of coition. The vesicles are highest in the last class of the animal kingdom, where generation is performed by a female division of the animals or by florids. They exist in all the classes of vertebral animals; and of the invertebrate division, in the mollusca, crustacea, insects, and most vermes. Their number, structure, &c. differ very much in these various classes. The vesicle, prolate, and Cooper’s glands, being less essential in their functions, are much less generally found, and are chiefly confined to the first classes of the animal kingdom. The preparatory female organs serve the purpose of developing and preparing the germ. Their existence is as general as that of the parts just mentioned; but they are much more simple in the first class of the animal kingdom. They consist of two bodies similar in form, size, and structure, and named by modern physiologists ovaries, in order to express more accurately, than by their old name of vescicles, the function to which they are destined. In fact, if their structure, considered simply in man, and most of the mammalia, leave any doubt concerning their office, their nature is so evident in the other classes, that their function cannot fail to be recognized. In all the classes which succeed the mammalia, the ovary or ovaries serve evidently for the production and preservation of the germ or ovum, which are formed in these bodies previously to the approaches of the male. Analogy leads us to conclude that the same circumstance holds good in the mammalia; and this conclusion is one of the most important results from the study of comparative anatomy and physiology.

The organs of copulation, in the male sex, consist of one or more projecting bodies, called penes, generally perforated by a canal, named the urethra, capable of being introduced into the female organs, in order to convey to them the fecundating liquor, or for the simple purpose of producing an irritation necessary for conception; or they are supernumerary members, enabling the male to grasp and hold the female. In the latter sex, the copulating organs consist of canals, particularly designed to receive the male penis, or give passage to the products of conception; or of cavities, which serve also for other purposes, but which, at the time of copulation, receive the penis, and transmit the fecundating liquor to the educating organs.

The educating organs receive the germ or ovum, after its detachment, from the ovarium, retain it for a shorter or a longer period of time, contribute to it a more or less direct manner to its growth, and convey it out of the body, or they furnish it no moisture, and let it be carried to a temporary lodging. They are, therefore, divided into external and internal parts. The latter may be again distinguished into two kinds. The first of these are simple canals, through which the germ or ovum is to pass, either in order to be conveyed out of the body (as in the egg), or to be transmitted into the parts of the second description. The latter are very dilatable bags, to the partes of which the germ is attached by means of vessels conveying the materials of its nutrition, and preserving it in this way until it has acquired a certain degree of growth. Organs of the first kind are formed in the four classes of vertebral animals; and are called follicular tubes, in the mammalia, ovulatrices, in the birds, reptiles, and fishes. Parts of the latter description belong to the mammalia only, and are the uterus. The external educating organs are, in the mammalia, the mammary glands secreting the milk by which the young are nourished; or receptacles, in which they are retained for a time, in a few genera. One kind of reptiles only poissesses analogous pouches.

To fill up the outline which we have presented to our readers in the preceding sketch, would require a detailed description of organs varying almost infinitely in form and structure in the different classes of organized bodies. These details will be found in the proper articles of the Cyclopaedia, relating to vegetable and comparative anatomy; this general view has been thought sufficient, as introductory and explanatory. The remainder of this article will be devoted to the anatomy and physiology of the generative organs in the human subject. The growth and development of the ovum in the uterus have been considered under the article EMBRYO, and the anatomy of the mammary gland will be found under BREAST.

The preceding account will show what various methods are employed by nature for the perpetuation of the races of orga-
organized beings; this seems to have been a very leading object, and one accordingly, in which the has developed all the fertility of her sources. Searcely can such diversified phenomena be reduced, by artificial classifications, to any common and constituent laws: new facts specifically modify or overturn the previous generalizations; and imagination can scarcely conceive any possible forms of propagation which observation does not soon realize. The generative functions are particularly attended to by those who are employed in delineating the manners of animals. They will probably find that the propinquitities and habits of each are intimately connected with the mode of propagation; and that the character of its wants, pleasures, and labours, its sociability and perfection, and the extent or importance of its relations either to other species or to the various external bodies or agents, particularly depend on the circumstances or conditions to which its reproduction is subjected, and on the disposition of the organs employed for this purpose. This is certainly very much the case with men, which is the object of our present investigation.

Man belongs to one of those classes of the more complicated and perfect animals, where propagation is effected by the concurrence of two beings, whose organization, possessing most circumstances in common, is distinguished by certain particular traits. He quits the womb of his mother with organs capable of fulfilling the impressions of the atmosphere, and of affording food to his own substance: he can already live by his own independent powers. He is not destined to remain, like the oviparous animal, included in a foreign envelop, and to continue for an indeterminate length of time in a state of inaction which hardly differs from non-existence: he does not wait until creative warmth bellows on him motion and life, amid the nutritive fluids prepared beforehand by nature, like those in which the embryo of the serpent, the tortoise, or the bird swims for a long time as an inheriting point. The human fetus has been supported in the uterus by fluids animalized in the vessels of the mother: it subsists, immediately after birth, on milk, prepared in organs yet apart for that office. The duration of gestation, that of infancy, during which the aid of the parents is indispensable, and the epoch of puberty, or the moment at which the generative faculty is manifestly by feasible signs, differ greatly in the different species of animals; these circumstances are not connected together by uniform or constant relations.

Man, like all the more perfect animals, is not born with the power of reproducing the species. The organs, which are at a future period to exercise this function, are now completely inactive, and the properties which fulfill this operation do not exist. The time of puberty — the epoch at which the frame and powers of the being receive their full development, is also the period at which the generative organs, recovered from their lethargy, assume an active state, and become capable of exercising their functions. The duration of infancy is longer, and the age of puberty is later in man than in any animals: although the term of gestation is shorter than in some other species. These circumstances must have a very marked influence on the wants, the faculties, and the habits of the human race.

The characters of the generative functions partake of those which belong to the animal and organic lives. Thus, on one side, all that precedes the union of the sexes, all the impressions made on one by the charms which nature has bestowed on the other, belong to the senses; this very union is an act of the external life, to which animals are impelled by instinct, over which reason presides to a certain degree in man. The influence of habit is also perceived here; but instead of blunting the enjoyment, it renders it rather more acute, and often gives rise to factious wants. On the other hand, the secretion of the fluid, by the emission of which man contributes to the reproductive processes, the mysterious work of conception, the development of the new being, &c. all belong to the organic life.

Sexual Distinctions.—Some ancient philosophers have held on this subject opinions very injurious to the fair sex, and indeed so manifestly whimsical and ridiculous, that a simple statement of them will shew their absurdity. Woman, in the opinion of Aristotle, is an imperfect man, an ill-formed and imbecile individual: while man is characterized by the attributes of strength and power. Galen goes even further, and confounding the sexes in those very parts, where their distinguishing characters are the most unequivocally marked, admits no other differences between the male and female generative organs than such as may be deduced from development and formation. He does not regard even the addition of the uterus in the female as an objection to this opinion, but, bending nature to his hypothesis, he represents this organ as being turned inside outwards in man to envelop the glands in which the seminal fluid is elaborated. This strange paradox has been adopted by numerous writers, and is hardly yet completely abandoned. Daubenton calls the clitoris a penis in miniature; Buffon turns the ovaries into testicles, and endeavours to prove that the addition of the uterus alone constitutes any essential distinction between the male and female parts.

Some resemblance in the unimportant points of form and arrangement gave rise to these unfounded analogies: pride and sexual prejudices, joined to the results of superficial observation, seem to have so far misled true philosophers, whose strange opinions we have just alluded to, as to make them discover, in one of the first productions of nature, a feeble sketch, and a timid production. Woman has appeared to them as a degradation and imperfect copy of the constitution of man, while, in fact, she is the most essential part of the species, as contributing by far the greatest share to the business of reproduction. A more accurate examination will destroy these haphazard analogies, and prove that man and woman do not differ in the relations of more or less, that the structure and functions of their generative organs are different in the kind; that their whole constitution has in each its peculiar type, the distinctive traits of which offer to us a long chain of physical and moral effects more or less immediately dependent on the functions of the organs concerned in the business of generation.

The characters of sex do not therefore shew themselves in any single point; it is not merely a particular organic apparatus, nor those external forms which delight us, that constitute woman; and if she is principally characterized in some parts, where the sexual physiognomy is the most distinctly expressed, if the superficial traits, and the sweetly rounded contours, which constitute her charms, form her most agreeable distinction, she is woman in the eyes of the naturalist and physician, in all her modes of existence, in her moral affections as well as in her physical system, in her enjoyments and pains; in a word, all parts of her existence bear the character of sex, and present a series of contrasts and oppositions with the corresponding points in man.

It is however only at the epoch of puberty, at that period of life called by Buffon "le printemps de la nature, la saison des plaisirs," that the appearance of all the sexual traits is exhibited to our observation; and that man and woman, attuned to each other with different and proportionally as they differ become connected by various relations, which enlarge and exalt the excellence hitherto personal, solitary and isolated. Woman may be distinguished from man by general and particular differences: the latter are so decided as to be easily discernible at all times, while the former, which are our present obj-
GENERATION.

In running through a more detailed sketch of the differences observable in the two sexes, we find them differing in the first place in stature, and in the size and proportions of parts. The height is less in the female, by about one-sixth. The middle of the body in man is at the separation of the lower limbs at the pubis: in woman it is higher, and hence the lower limbs are shorter, while the humerus region is longer. This gives to the female sex in general, and to the Americans and Negresses in particular, that elegant slenderness which distinguishes them. The arm or leg of a woman could be immediately distinguished from those of a man: the form of these parts is much more delicate, and less marked by decided prominences. The bust is not so broad, but more rounded, and particularly distinguished by the size and elegant formation of the breast, which is commonly but little developed in man, where its greater development would be regarded as a deformity. The thighs are much larger, more rounded, and further apart; they approach each other below, so that the knees are slightly turned in. The latter circumstance is seen in the Venus, and the whole formation of these parts is attended with advantages in gait and parturition, although the peculiaritiy in question is not seen in these females which in common opinion are the most formed. The convexities described by the lower limbs at their upper part, and uniting them by a closer, happily rounded form with the trunk, have a very obvious peculiarity of character in the softer sex. They are more prominent, and approach in their contour more to the semispherical form. All other parts of the lower limbs are distinguished by their small round outlines. The foot is smaller, and the base of support for the body is proportionally more narrow. The leg gradually diminishes from above downwards, instead of swelling out abruptly at the calf. The outlines of the upper limbs are equally flowing and soft; thus the arm of woman is fatter and more rounded; the whole upper extremity corresponds in its comparative shortness and smallness to the general difference in stature; and is terminated by a small hand, and short, delicate and flexible fingers.

We may observe further that the head is smaller, the face shorter, and the neck longer in woman. The cheek is not so long, but deeper; the abdomen more prominent and rounded; the shoulders are carried more backwards, and stand out less from the trunk. Hence the breadth of this part is much less considerable than in man, where the shoulders are more fully developed and more widely set off, and conform to their comparatively greater size, a very impressive feature of the superior strength, which is the attribute of the male sex. In the female trunk, on the contrary, the breadth part is below: the pelvis, holding the organs of generation, being principally concerned in the functions of utero-gestation and parturition, being, in short, the seat of those attributes which especially distinguish the female, is much more spacious than in the male. Hence the superior breadth of the female hips: hence the opposite character of the trunk in the two sexes, in respect to size. The trunk of the female is a pyramid, with the breadth part below; that of the male is just the reverse. Camper has shown, that if the body of a well-formed man be delineated on an elliptical area, the shoulders pass out of the ellipse, while the pelvis falls within it; on the contrary, that the hips exceed, and the shoulders fall within the line in woman. (Memoire sur le beau Physique.)

In those specimens of ancient art, which may be regarded as models of the most characteristic formation, the difference of breadth in these parts amounts to one-third: the shoulders being so much broader in the male, and the hips in the female. The greater breadth of the pelvis gives a broader base.
balse of support to the female trunk; and, as it throws the thigh-bones further apart at their upper ends, produces the increased widening of the hips. Hence in progressions the centre of gravity is more sufficiently changed at each step; and there is a perceptible rolling of the pelvis, which characterizes the female gait. The inconveniences of this arrangement counterbalance the advantages which the broader base of support might otherwise have bestowed on the female organization; and the latter is, in truth, an imaginary superiority, since the feet, which are always small in women, offer ultimately a narrow surface for the body to rest on.

The various pieces of the skeleton, by their respective dispositions and junctions, determine the essential form of the body, its position and attitudes, and the extent and variety of its motions. The characters of the general form, which we have already considered, are therefore to be retraced in the bones; and in this point of view a parallel of the male and female organization leads to very important results. It is difficult to meet with a well-formed female skeleton, where the structure can exhibit or recall the leading traits of the female form. After much trouble and observation, Sommerring met with a specimen of what he considered the best and most natural form in a young girl of Mentsy, whose form had not been impaired by absurd modes of dressing, and who had been successfully delivered a short time before her death. A beautiful plate of this skeleton, with its description, is exhibited in his "Tabulae sex dulcitatem, juncta descriptione," folio, 1797. The female skeleton, on the whole, is smaller in all its dimensions, and more slender than the male. The individual bones have fewer inequalities, their prominences are less strongly marked, the grooves or impressions more superficial, all the cavities less deeply hollowed out; hence the surface seems more finely raised, and is distinguished by its smoothness. They are often actually softer, and have on the whole a peculiarly feminine character, which is not confined to the cavities, but is diffused through the entire structure.

The head, with the teeth, bears a greater ratio to the weight of the skeleton, on account of the individual bones being in general more slender: the proportions are 1:6 in the female, 1:8 or 1:10 in the male. The cranium is larger in proportion to the face. The thorax is shorter, more convex in front, and more distant from the pelvis, the space between the last rib and the crista ili being greater. It is less prominent in front; so that while this part of the skeleton is the lowest in the erect or supine position of the male, the symphyses pubis does the same in the female. The humps are longer, and the angle between them and the facium more acute. The disposition of the pelvis is particularly characteristic, as being so immediately connected with the sexual functions. It is larger in all its dimensions. The facium is turned more backwards, is broader, and more concave; the osa coccygis, more moveable and flender, project less into the cavity of the pelvis. The hip-bones (osa innominata) are broader, smoother, and expanded further in the lateral direction: hence their cribs and tuberosities are more diffuse, and hence the space between the osa pubis is greater. The angle formed between the rami and symphyses pubis is larger than between the two bones of the pubes is acute in man, while it is of 80 or 90 degrees in woman; and approaches more nearly to the form of an arch. That the sexual functions are favoured by all these circumstances is very evident; but the advocates of final causes point out more particularly the reason for the wider space under the osa pubis: "Ad virum admittendum intercavernae majores cum infra internum vulnus pubis." (Albinus de sexu, p. 475.) The tuberosities of the ischia are more distant, larger and smoother. The clavicles are less curved, and the shoulder joints are less confined. The acetabula are further apart, and the thigh-bones more oblique in their position: the latter are also more curved forward, and have longer internal condyles.

The muscles of the female are more slender and delicate; they are, in fact, less dense, softer and more pliable. These organs are less prominent, and their feelings, partaking of the general softness of the female constitution, have not that character of vigour which their rough prominences and strongly marked intertissues impress on the frame of a muscular man, in whom the exterior traits of sex have not been destroyed by effeminate manners or sedentary habits. The cellular and adipose tissue is more abundant in the female; and this, joined to the smaller prominence of the muscular biceps, gives to the limbs that soft roundness and delicate contour which characterize female beauty, as expressed in the most celebrated productions of great artists.

The differences just described, the comparative weaknesses of the muscles, the elegance and beauty of the external forms, belong to the very nature of woman. Education and habits may add to these characters; may increase the delicacy of organization; but their influence is not sufficiently powerful to induce us to overlook the existence of a radical innate difference in the physical structure of the sexes, occurring in all ages and amongst every people. That such differences of organization will produce corresponding varieties of function may be readily allowed: but our facts are not quite so indisputable on this point. We could undoubtedly point out many peculiarities in the sensibilities of women, taking the term in its most extensive sense, in their perceptions, their mental operations, and the reactions of the nervous system on the rest of the frame. We could trace many circumstances to the influence of the generative organs, and particularly of the uterus. But the influence of education, habits and customs, is so extensive, that it is difficult to distinguish between the results of these causes, and of the supposed original distinctions in organization.

The reader may refer to this subject to the Histoire naturelle de la Femme, by Moravus, tome 1, p. 112, &c.

We cannot draw any very strong line of distinction between the sexes in the vital and natural functions. We may apply, indeed, to this subject, the philosophical remark of Buffon concerning animals; viz., that they differ from each other more strikingly in proportion as we compare them together in superficial points, which do not affect the nature of their existence so much as its exterior development. Yet the characters of sex are so deeply imprinted, that we find traces of them even in these functions, when submitted to a rigorous examination. The pulse, ceteris paribus, is more frequent; the lungs are smaller, and the chest narrower. The appetite is less; the body grows more rapidly, and the periods of dition, puberty, and adult nature are more early. See for more detailed observation on this head, the work above quoted.

The voice is marked by very characteristic distinctions in the two sexes. In man it is strong, deep, less soft and flexible. In the female it is sharper, and the organs are more flexible, so that articulate sounds can be performed more rapidly. It has also a peculiar quality or tone, which, in many infinances, constitutes an irrepressible attractive charm. "Of all acute voices," says Roufian, "it must be allowed, in spite of the prejudices entertained by the Italians in favour of the castrati, that none are equal to those of women, either in the extent or beauty of the tone." The anatomist, perhaps, will attempt to explain these circumstances by observing, that the glottis is not enlarged at the age of puberty in females, as it is in males; that the larynx is considerably smaller; that the tongue, the muscles, and the organs of speech being
The differences which we have enumerated are not very distinctly perceivable, until the two sexes have reached the epochs of their respective perfect development. They are concealed, in the early periods of infancy, under external forms which are nearly the same in both sexes. It is true, indeed, that we can distinguish a male from a female embryo (see Examine); but the leading sexual distinctions are by no means fully developed until the age we have mentioned. The muscles have not yet produced any remarkable change in the direction of the bones; the glandular and fibrous parts hardly differ either in form or volume; and the skeletons can scarcely be distinguished by the breadth of the hips and pelvis. The like confusion prevails in the moral dispositions of the two sexes: boys are not distinguished in this respect from girls. The appetites, ideas, and passions of both are the same. We cannot at present, nor perhaps shall we ever be able to determine, by what particular action the organs of generation influence the other parts of the body, direct their operations, and modify the character and order of the phenomena relating to them. The fact, however, is evident; and the influence is incontestable. For, when the natural development or actions of the generative organs is impeded, the secondary characters, by which the sexes are distinguished, do not take place.

To illustrate this subject, let us observe, that the several differences of animals may be divided into two classes; the former include the differences in the parts of generation themselves, which are originally formed differently, and belong equally to both sexes; the latter are all the other variations depending on these, not taking place until the parts of the first class are coming into use, and being principally, though not entirely, in the male. One of the most remarkable secondary characters in animals, generally speaking, is the superior strength of make in the male; and this strength is generally directed particularly to the organs employed in fighting. Hence it is especially noticeable in the animals whose females are of a peaceable nature; e.g., the leg of the cock and neck of the bull. But in carnivorous animals, where strength is required by both sexes to kill the prey, the differences in the form of the male and female are not so striking, yet the sexes are still distinguished by some differences in their external covering, as the male lion by his mane, and the cock and hen of many birds by the plumage. The general strength of make, the hairy covering, and the voice distinguishing the male from the female of the human species. Now in all animals, which are not of any distinct sex, no such alteration takes place in the form at the time of puberty. Thus, the free martin, which possesses a mixture of the generative organs of both sexes, does not exhibit in form a resemblance of either the cow or bull. It is very much like the ox or spayed heifer, being considerably larger than either the bull or the cow, and having horns very similar to those of the ox. The voice is similar to that of the ox, and more like that of the cow than of the bull. The billy, like that of the ox or spayed heifer, is generally much fatter in the body, than that of either the bull or cow; it is supposed to exceed that of the ox and heifer in delicacy of flavour, and bears a higher price at market. (See "Account of the Free Martin" in Mr. Hunter's observations on the animal economy, p. 55.) A similar effect is produced, when the sexual parts are removed after birth; the castrated male and the spayed female have both the same common properties, and are very much like the free martin; the artificial removal of the generative organs preventing the occurrence of those changes, which would naturally have occurred at the time of puberty. Thus, by depriving either sex of the true parts of generation, they
they seem to approach each other in appearances, and acquire a resemblance to the hermaphrodite. Reflecting the changes, which occur at puberty, Mr. Hunter says, "It is evidently the male, which at this time in such respects recedes from the female; every female being at the age of maturity more like the young of the same species than the male is observed to be; and if the male is deprived of his testicles when young, he retains more of the original youthful form, and therefore more resembles the female. From hence it might be supposed, that the female character contains more truly the specific properties of the animal than the male; but the character of every animal is that which is marked by the properties common to both sexes, which are found in a natural hermaphrodite, as in a stall, or in animals of neither sex, as the castrated male or spayed female. But, where the sexes are separate, and the animals have two characters; the one cannot more than the other be called the true; as the real distinguishing marks of each particular species, as has been mentioned above, are those common to both sexes; and which are likewise in the unnatural hermaphrodite. That these properties give the distinct character of such animals is evident, for the castrated male and spayed female have both the same common properties; and when I treated of the free stall, which is a monstrous hermaphrodite, I observed that it was more like the ox than the cow or bull; so that the marks characteristic of the species, which are found in the animal of a double sex, are imitated by depriving the individual of certain sexual parts, in consequence of which it retains only the true properties of the species." (See "Account of an extraordinary Phenomen," in Mr. Hunter's observations on the animal economy, p. 75.)

The influence of the generative organs in the development of the body at puberty, and in the modifications which constitute the sexual character, is clearly evinced in the stall, whose amours are conducted in so splendid a style, and evince so remarkable an exuberance of vitality. When he is deprived, at an early age, of the sexual attributes, none of the vigour of the rutting season is displayed; the muscular flesh is softer, and the horns are either arrested in their growth entirely, or are imperfectly formed. Ruffled castrated a very young stall, and no horns appeared; he operated on an older one, and the horn was partially developed. When he removed one testis at a more advanced age, the opposite horn was the most completely formed; the removal of both glands from two adult stags did not prevent the appearance of the horns; but they were shorter, and neither the investing membrane, nor the horn itself, were afterwards separated. (On the Economy of Nature in glandular Diseases.)

Facts very analogous to these may be observed in the human subject. An imperfect original formation of the sexual organs, or the removal of some of them modifies the whole character of the individual, changes the physical constitution in a very remarkable manner, and influences in a no less striking degree the moral habits and dispositions. Observers in all ages have remarked, that mutilated or imperfect animals poise asemblage of peculiar characters, all of which have not a very direct relation to the functions of the generative organs. Not only are the sexual defects entirely lost in these degraded individuals, but the whole of their organization is affected in a very singular way. The cellular texture becomes more abundant and lax, and is more loaded with fat; the muscles are weaker: the voice more acute: and the development of the beard is impeded. The change in the moral dispositions is not less worthy of attention. It was the opinion of the ancients, that masturbation degrades man, and brings animals to perfection; the truth is, that it equally degrades both, since it alters their nature.

But, by weakening an animal, it renders him more docile, and better suited to the purposes of man; by destroying the tie, which connects him the most powerfully to his species, it afflicts in developing those habits of obedience and attention, and those feelings of gratitude and attachment which make him so serviceable to us. A similar effect is produced in man; mutilation separates him in a manner from his species; and the fatal event, which deprives him of the most agreeable relations established by nature, between beings of the same kind, almost extinguishes in his breast the peculiar feelings of humanity.

In those young persons, to whom nature has denied either wholly or in part, the distinguishing powers of the male sex, puberty does not produce its ordinary effects. And moreover, at this time the bony and muscular organs are constantly assuming more and more of the external forms, and general character belonging to the female. These equivocal individuals have an acute voice, weak muscles, and laxity in the general organization. The pelvis, too, has that greater proportional breadth which characterizes this part in women. This circumstance, as well as the consequent breadth, and great roundness of the hips, may be particularly noticed in the castrate. The physical condition is generally accompanied in these individuals with a perfectly corresponding moral state. All these points are fully illustrated in the following account of a marine folder, aged 23, by Mr. Home, (Observations on Hermaphrodites, Philos. Transact. 1799.) "He had no beard; his breasts were fully as large as those of a woman at that age; he was inclined to be corpulent; his skin uncommonly soft for a man; his hands fat and short; his thighs and legs very much like those of a woman; the quantity of fat on the os pubis resembled the mons veneris; the penis was unusually small, as well as short, and not liable to erections; the testicles not larger in size than we commonly find them in the female flat; and he had never felt any passion for women. He was weak in his intellects, and his bodily strength." Mr. Home mentions, in the same place, two other still more striking examples. A woman had three children, of which the first and third were supposed to be hermaphrodites; the second was a perfect female. The eldest, when Mr. H. saw him, was thirteen years of age, "of a most uncommon bulk, which appeared to be almost wholly composed of fat; his body, round the waist, was equal to that of a fat man, and his thighs and legs in proportion; he was four feet high; his breasts as large as those of a fat woman; the mons veneris loaded with fat; no penis; a prepubescence of an inch long; and under it the meatus urinarius, but no vagina. There was an imperfect serotum, with a smooth surface, without a raphe in the middle, but in its place an indented line; it contained two testicles of the size they are met with in the fexitus. He was very dull and heavy, almost an idiot, but could walk and talk. The younger one was six years old, uncommonly fat, and large for his age; more an idiot than the other, not having sense enough to learn to walk, though his limbs were not defective. The external parts of generation differed in nothing from those just described, except in the prepuce being an inch long."

An interesting case is mentioned in the Mémoires de la Société médicale d'Émulation, t. 3, p. 253, which tends to confirm the preceding observations. A young man, aged 23, has no testes in the serotum, which is only indicated by a slight corrugation of the integuments; a very small penis, which never changes its size, and two folds of skin, extending from the latter organ to the anus, and very much resembling the female labia. His stature is below the middle size. The skin is soft, smooth, and entirely free from hair;
the place of the beard supplied by a slight down. The voice habitually hoarse. The muscles not well marked, and the pelvis and chest resembling those of the female. The intellectual faculties are very dull, and the sexual appetite entirely wanting.

The period, and the manner of maturition, have considerable influence on the effects of the procids. The complete removal of all the external organs is a much more decisive method of annihilating the propensities connected with them, than any partial amputation, or compreッション, or ligature of the genitourinary cords. The operation is also more effectual, when performed in early infancy, than after the period of puberty. Venereal desires have been known to habit in considerable force, and with the usual external signs, after the removal of the sexes in the adult. The moral effects of this mutilation have been strongly depicted by Cabaret.

"Eunuchs are the vilest class of the human species; cowardly and knavish because they are weak; vicious and malignant, because they are unfortunate. Their understanding shows the absence of those impressons, which give to the body so much activity, which infuse into it an extraordinary proportion of vital energy, which cherishes all the expansive and generous feelings of the soul, elevates and directs all the thoughts. Nature is almost the only very imposing exception to this rule; he is almost the only eunuch whose man appears with glory in the page of history. Solomon, one of the lieutenants of Belphagor, is another rare example; he exhibited great courage and talents in the war with the Vandals in Africa. How immoral then, how cruel and fatal to society, is the practice of thus degrading and corrupting at pleasure the human species!"

A curious case in the Philosophical Transactions for 1805, pt. 2, in which the ovaria were deficient, shows that such a deficiency occasioned the female to approach in some points to the male formation. The subject of this narrative died at the age of twenty-nine. "Having ceased to grow at ten years of age, she was in stature not more than four feet six inches high. Her breadth across the shoulders was as much as fourteen inches, but her pelvis (contrary to what is usually observed in the proportions of the female skeleton) measured only nine inches from the front across the ilium. Her breasts and nipples never enlarged more than in the male subject; she never menstruated; there was no appearance of hair on the pubes, nor were there any indications of puberty, either in mind or body, even at twenty-nine years of age!"

The removal of the ovaries has been most rarely practiced in the human subject; probably the only case in which it has ever been done is that recorded by Mr. Pot, where their bodies were contained in inguinal hernia. A healthy young woman, aged twenty-three, large breasted, stout, and menstruating regularly, had a painful tumour in each groin, near the abdominal muscles. The ovaria were removed from these tumours by a surgical operation. "She has enjoyed good health ever since, but is become thinner and more apparently muscular; her breasts, which were large, are gone; nor has she ever menstruated since the operation, which is now some years." (Pot's Works, vol. iv. p. 329.) The changes which took place in the latter case seem analogous to what has been observed in some birds. After they have done laying, hen pheasants have been observed to acquire the plumage of the cock in some instances. This has been noticed in wild individuals; but Mr. Harter had three opportunities of ascertaining the fact by his own examination. He further mentions a pheasant, which had produced chickens eight times, and which, after moulting at eleven years old, displayed the feathers peculiar to the other sex. The tail of the cock appeared at the same time. This was repeated for three years, and the furs of the cock appeared also in the third year. The animal never bred after this change of plumage. The same fact has been noticed in the duck, see Home on Hermaphrodism, in the Phil. Transact. 1759. "We may conclude," says Mr. Hunter, "that this change is merely in effect of age, and obtains to a certain degree in every class of animals. We find for things similar taking place even in the human species; for that increase of hair observable on the faces or many women in advanced life, is an approach towards the beard, which is one of the most distinguishing secondary properties of man. Thus we see the fures, which, at an early period, had little to ciftinnish them from each other, acquiring about the time of puberty, secondary properties, which clearly characterize the male and female; the male at this time receiving from the female, and assuming the secondary properties of his sex. The female, at a much later time of life, when the powers of propagation cease, loses many of her peculiar properties; and may be said, except from the mere structure of parts, to be of no sex; even exceeding, in some respects, the original character of the animal, and approaching in age, in many respects, to the male, or rather more properly towards the hermaphrodite." Observations on the Animal Economy, p. 80.

Nothing can be more absurd than to seek for any mechanical explanation of these accidental phenomena, or even of the more regular phenomena, of which they interrupt the course, at the same time that they elucidate the laws. They cannot freely be derived from the structure of the organs to which they belong, nor from the known nature of the quors secreted in these organs. But the consideration of some physiological circumstances, which are very simple in themselves, may enable us to escape from this dark abode of occult causes, to which the theories of the ancients were confined, and which have been little changed, except in name, by the moderns. The latter indeed, by substituting, for the opinions of the ancients, other more dogmatical explanations, have given rise to more important and dangerous errors: they have induced men's minds to the pernicious habit of attempting to determine the nature of causes, where we can only observe effects; and in determining these causes they have often perverted mere abstractions. In the first place, it is a certain fact, however it may be explained, that the muscular fibres are weaker, and the cellular tissue more abundant, in women than in men. Secondly, we cannot doubt that this difference is produced by the influence and influence of the uterus and ovaria; it takes place infallibly when these organs are originally well formed, and are developed in the natural order. This weakness of the muscles imparts an instinctive dislike for violent exercises; it inclines the individual to amusements, and, when the age admits of it, to sedentary occupations. The greater separation of the hips renders progression less easy in the female, on account of the more extensive change of the centre of gravity. The mode of life in the female is thus indicated a priori by a circumstance in their organization, which might be regarded as trivial, and which can hardly be distinctly observed at an early age. Again, the habitual tenes of weakneais inspires less confidence. Not pufhilling the means of acting on surrounding objects by direct force, woman seeks for more indirect methods; in proportion as she finds herself calculated to exit alone, does she attempt to attract the attention of others, and to fortify her own existence by that of those surrounding beings, whom she judges most able to protect her. These observations would be almost sufficient to explain the dispositions, tastes, and general habits of women. They will naturally prefer those employments which require delicate address rather than muscular force;
they will employ themselves on little objects; and their minds will consequently acquire acuteness and penetration rather than extent and depth. Thus, as they lead a sedentary life, to which the nature of their employments confines them as strongly as do the immediate propensities depending on their organization, we see in a manner a new physical and moral system developed in them. They perceive their own weakness; hence the necessity of pleasing: from the latter circumstance arises the continual observation of all that is pleasing around them, also of their disposition, their attentions, their manners, their grace, in a word, their equanimity, which, in the present system of society, must be regarded as the aftereffect or result of their good and bad qualities.

For reasons exactly contrary to those which have been just explained, they acquire the opposite original and characterizing propensities: hence they naturally contract opposite manners and habits. Full of the feeling of their growing strength, and of the wish to exercise it, repose is disagreeable and irksome to them: they want lively motion, and they indulge in it with imperfection. Thus, without entering into further details, we see that the bent of their ideas and the character of their passions are formed directly by their original dispositions, and the kind of amusements or occupations which determine them to prefer. Now, the passions and ideas of the grown man are only those of the child developed and completed by the maturity of the organs, and the personal experience of the individual. See Cabanis, R. sports du physique et moral de l'homme, memoire cinquieme.

But hitherto explains us how modifications of fo general a nature can depend on the conditions of certain peculiar organs. We must then attend a little higher, and require whether the remarkable influence exerted by the organs of generation can be at all elucidated by their structure, their functions, or their physiological relations to the other branches of the system. We see, in the first place, that parts supplied by nerves which come from different trunks, or are formed by different nerves united together, are either more sensible or more irritable, and almost always both at once. Nature seems to have placed the ganglia and plexuses in the neighborhood of the visceras, where the nervous influence must be the most considerable. The epicraniac and hypochondriac regions abound with them; consequently their sensibility is very acute, their sympathies very extensive, and the corresponding portions of the intestinal canal enjoy a degree of irritability hardly equalled by that of the heart. Now the nerves of the generative organs in both sexes, without being apparently very important by their size or number, come from various sources, are connected with those of all the abdominal visceras, and by them, or rather by the great sympathetic, which serves as a general medium of connection, with the most essential divisions of the nervous system.

Secondly, observation shows us that the nervous system (of which the original organization and mode of acting determine the general sensibility of all the organs taken together, and the particular sensibility of each considered separately) may in its turn be powerfully modified by the character of those functions, which perform the most important part in the animal economy; that is to say, in other words, by the habitual impressions conveyed to it from one of its most sensible extremities. The less of one sex does not produce merely an increase of energy or attention in those which remain, and which seem to redouble their efforts in order to supply its place; but it changes the manner in which the nervous system feels and reacts, and hence arise new habits evidently connected with the habitual impressions which these senses then begin to receive. The practice of medicine proves to us, by daily examples, that the affections of various organs have the most marked influence on the tastes, ideas, and passions. The moral dispositions are by no means the same in diseases of the chest, as in those of the spleen or liver. A greater or less propensity towards a particular train of ideas or feelings (as for instance towards those connected with religious belief) is experienced in particular states of languor than in others; and the greatest aptitude to those avocations, which demand either considerable strength and activity in the imagination, or long continued meditation, is often experienced in a state of disease caused by the deranged functions of some of the abdominal visceras. Thus, then, nothing is more conformable to the laws of the animal economy, than that organs, endowed with a singular degree of sensibility, should exercise a very extensive influence on the machine in general; and we perceive immediately that the present is one of the most remarkable phenomena referrible to these laws.

In the work last quoted, Cabanis endeavours to explain this subject further, by observing that those organs, which seem to be the principal seats (foyers) of the peculiar sensibility of the generative apparatus, viz. the ovaries and testicles, are of a glandular structure, that the various parts of the glandular system affect each other very powerfully; and that the condition of this system altogether has a most important influence on the state of the brain, augmenting or diminishing its energy. The latter circumstance will apply with so much the greater force to a cafe, where the glands are distinguished by their great sensibility.

Again, it has been alleged that the seminal fluid formed in these filaments, when absorbed and converted into the circulation, affects the general mass of blood. At all events the commencement of this secretion is marked by important changes in the voice, the muscular motions, and the phlegmatics, by the appearance of the beard, &c. And we have seen, that in animals, the development of particular parts is materially modified by the presence and action of the tube. That an analogous fluid forms in the ovaries, and either furnishes the materials of the embryo, or contributes to their formation, and that its absorption produces analogous effects in the female, to those which we observe in the male, is in truth a mere hypothesis. But the influence of the ovaries in the changes at the time of puberty, whether produced in this way or not, is incontestable. Lastly, in explaining the different influence of these parts in the two sexes, we must ascribe peculiar dispositions in the original formations of the nervous system, as well as in the cellular organ, the muscles, and sense. These must depend on those unknown circumstances which influence the formation, life, and development of the embryo; their explanation must be referred to that of the differences of sex, they must be regarded as fundamental, and be admitted as such, without attempting to trace them any higher.

Hermaphroditism. — Having compared together the two sexes, and mentioned the most remarkable circumstances which distinguish the organization of each, we have to examine further whether nature has in any instances united the attributes of the male and female in the same individuals, so as to form a true hermaphrodite. The resolution of this question, which is not to be considered as satisfying idle curiosity, is equally interesting to the naturalist and the philosopher, and may influence the decisions of judicial tribunals on the important questions of impotence and sterility. The German artists have endeavoured to combine the beauties and properties of the two sexes in the same subject, and have exerted the magic powers of their chisel on figures of hermaphrodites.
maphrodites. Among these ideal productions, we may mention two beautiful statues in a recumbent position in the Florentine gallery. A small hermaphrodite statue is seen in the villa Albani, a very fine one in the villa Borghese, and there is another in an obelisk at Florence, pointing out that it partakes of the two sexes. All these are males in the external appearance of their generative organs, females in the form of the breast, in the features, in the elegance of the figure, and in the softness of the contours. (Winckelmann, Histoire de l'Art, 446. tome 1. p. 364.) These monuments furnish no proof on the subject; they are to be regarded as creations of art, derived from the imagination of the sculptor, and not as the representatives of any real existence. Winckelmann himself, who, in other respects, believes in hermaphrodism, classes the chef-d'oeuvres we have just alluded to among the ideal productions. They exhibit an attempt to form a more perfect being, by uniting together the peculiar excellencies of the male and female, without attending very particularly to the genital organs. The word hermaphrodite then, as applied to these works of art, includes the notion of a very high degree of beauty and elegance, in which all that is most admirable in either sex is combined in one individual; and the works, in which such are represented, may be regarded as the inventions of the greatest masters. (See Caylus's Recueil d'Antiquités, tom 3.) The fabulous account of the transformation of Hermaphroditus and the nymph Salome into a most lovely being, combining the attraction and the powers of both sexes, may be regarded as an expression of the common opinions on the subject.

The vast multitude of observations and histories of hermaphrodites, recorded in various medical works, renders it necessary for us to classify them under certain heads. 18. The true hermaphrodite? There is much reason to believe, that no instance of an hermaphrodite, in the strict sense of the word, has ever occurred in the more perfect quadrupeds, or in the human species. For, when we consider the bones of the pelvis, to which the organs of generation are connected, it is difficult to conceive in what way the complete parts of the male and female could be placed, distinct from each other; and no instance of its having happened is to be found, in any record, which can be depended on. To constitute an hermaphrodite, in the sense we are now considering, it would be necessary that the male organs of copulation and impregnation, such as the testes and their ducts, the vesicle feminales, prostate, urethra, and penis, should exist in the same individual with the organs employed for the purposes of conception, of receiving, nourishing, and expelling the foetus, such as a well-formed vagina, clitoris, labia, Fallopian tubes. The difficulty, and even impossibility of such an union, has been already recognized by Haller and Priest. Medical authors have indeed related cases of women, who, after having many children, had impregnated other females; (see Mollerus, Traité de Hermaphroditique, cap. 2. : Blan- card, Collect. Medico-Phys. cont. 3. obv. 83.) but such narratives are too obviously fabulous to require serious refutation.

The nearest approach to such an occurrence, as we have just alluded to, consists in a partial mixture of the female and male organs. This has been observed, not very rarely, in some animals. Mr. Hunter has given several instances of it in cattle; and it has also been seen in the dog, the ase, and the goat. The individuals, in whom such appearances have been noticed, are so far from having had the properties of both sexes, that they were obviously incapable of executing any sexual function at all. Even in this restricted sense, we believe that no case has occurred in the human species, and that all the supposed hermaphrodites among men have been individuals with imperfect or monstrous formations of some parts. The case mentioned by Petir, in the Memoirs of the Academy of Sciences for 1752, as exhibiting a mixture of organs, was clearly a male: and that related by Maret in the Memoires de Dijon, t. 2. p. 157, belongs to the same class. The following case, related by Giraud of the Hotel Dieu, shews us how careful we should be in drawing conclusions from external appearances, and will convince us that no account of hermaphrodites can be received, except on the faith of description performed by experienced anatomists. The individual was essentially a male, and offered some appearances of the other sex, not from the addition of organs, but from an unnatural distribution of some parts of the male apparatus. He was received in society as a woman, and was connected by a voluntary affection with a man, who had for a long time performed the duties of a husband towards him. This singular character died in the Hotel Dieu. He exhibited, externally, an affinility of the male and female properties. The bust had a completely masculine appearance; the chin was covered with firm hair, very analogous to a beard; the neck was thick, the chest broad, the bosom slightly swoln, and the nipples exactly like those of a man. The lower half of the body presented a contrast to these characters. The soft and delicate contours of the lower limbs, the rounded hips, the broad pelvis, and the greater separation of the thighs, approximated decidedly to the female form. An imperforate penis, two testicles, and an appearance of vulva, were the external generative organs. The testes were well formed, the vesicle feminales imperfect, and the urethra opened at the cul-de-sac, which represented the vagina. Thus, instead of a double sex, the individual was an ill-formed, entirely incapable of any sexual function. See Journal de Médecine par Sédiott, tome 2, p. 319.

The half influence of mixed organs, which we shall quote, is mentioned by Dr. Baillie, to whom it was communicated by Dr. Storer of Nottingham. "The person bears a woman's name, and wears the apparel of a woman. She has a remarkably masculine look, with plain features, but no beard. She had never menstruated; and on this account she was desired by the lady, with whom she lived as servant, to become an out-patient at the Nottingham hospital. At this time she was twenty-four years of age, and had not been sensible of any bad health, but only came to the hospital, in order to comply with the wishes of her mistress. Various medicines were tried without effect, which led to the supposition of the hymen being imperfect, and the menstrual blood having accumulated behind it. She was therefore examined by Mr. Wright, one of the surgeons to the hospital, and by Dr. Storer. The vagina was found to terminate in a cul-de-sac, two inches from the external surface of the labia. The head of the clitoris, and the external orifice of the meatus urinæ, appeared as in the natural structure of a female, but there were no nymphs. The labia were more pendulous than usual, and contained each of them a body resembling a telicile of a moderate size, with its cord. The mammary resembled those of a woman. The person had no desire or partiality whatever for external sex." (Morbid Anatomy of some of the most important Parts of the human Body, 2d ed. p. 416.) This narrative leaves very little doubt, that the individual was a male, with the generative organs imperfect, as not to have exerted their usual influence on the frame in general: there is no evidence of any female organs being present here.

We repeat then, that there is not only no instance recorded, of perfect male and female organs united in the human species, as to constitute an individual capable of exerting
ercing the generative functions of both sexes—of impreg-
inating or being impregnated—but also, that there is no
clearly described instance of the final mixture of organs
in any human person, ascertained by actual dissection,
and testified by persons of competent anatomical skill. All
the supposed instances of hermaphrodists must be traced
to one of the following classes: 1. Those unusual situations
of certain organs and their conformations, various monstro-
lities, or imperfectly developed male organs, or a greater
prominence than usual of some female parts; occasion a de-
viation from the accustomed type, supposing to constitute
hermaphrodism, very capable, when allured by lies and fraud,
of imposing on those who knew nothing of natural appear-
ances, and often mistaken by those who ought to have
known better. Hence have arisen the numerous statements,
contained even in the writings of anatomists and physicians;
and tending to prove the existence of the prodigy, of which
no well authenticated fact has hitherto determined the reality.
A found spirit of criticism, founded on a more accurate
knowledge of natural appearances, reduces to their just
standard those singular deviations from the ordinary type,
which ignorance, credulity, and a love of the marvellous,
have drawn such extravagant and ridiculous con-
sequences.

3d Class.—Male individuals, with unusual formations of
the urinary and generative organs; (androgyne.) Where
the ordinary type is considerably altered, an appearance is
sometimes produced, very capable of deceiving superficial
observers; there is a kind of sketch, or imperfect attempt,
at a double apparatus of organs. But the male sex gene-

erally predominates very clearly in these cases, and the
antiquity depends commonly on the testes being contained in
separate parallel folds of the skin; the penis being imper-
forate; and the urethra opening in the perineum, on the sur-
face of a blind pouch, having a red and tender appearance,
and easily mistaken for the vagina. In such an individual
the penis, being imperfect, and probably smaller than usual,
as considered a large citoris; the folds of skin holding the
testes very much resemble the female labia, and the red flt,
between which the urethra ends, is tolerably analogous
to the vagina. The imperfection of the penis, and the opening
of the ejaculatory ducts near the perineum, at which their
contents escape, deprives these individuals of the power of
procreation; and the facility of their marriages, if they
cnto that state, is quite of their imperfect formation, arises
c. e. from this cause. The testes and seminal vesicles of
males appear to be perfect, in those cases. The individuals
experience the ordinary sexual desires, and the seminal fluids
are expelled at the unnatural opening in the perineum. A
similar deformity occurs not unfrequently in the goat and
sheep; Aridle having observed it in the former. The
reader will find examples in Halter's Commentarii de Her-

maphroditis, where a vast number of instances is quoted;
in Writberg's Commentatio de Singulari genitalium Deform-
itate in puero Hermaphroditum Mentiente; § 7, note 6: in
Moronii Historiae Naturae de la Femme, tom. 1. p. 224: in
Mertrud, Dissertation fur la femme Hermaphrodite,
qui paroit aux yeux du public, Paris 1749, folio: Agoty, Ob-
stractions de l'Histoire Naturelle, la phisique, &c. avec
des plans, des imprimés en couleur, Paris 4to. 1752.

An instance, similar to the kind just described, is related
and drawn by Writberg; in the memoir above quoted, but
there was this difference, that the rectum, as well as the
urethra, opend in the unnatural situation in the perineum;
this male child had been christened by a female nurse.

Other less essential deviations from the accustomed organi-
zation have given rise to the opinion that the individuals were

hermaphrodites. A fissure, of various depths, has existed
in the perineum; covered with a secretion from numerous
sebaceous glands; when all the other organs were perfect in
every respect. Writberg knew an instance of this kind at
Gottlingen: the individual was always deemed an herma-
phrodite, but he had the natural dixics and powers of a
male. The absence of the testes from the scrotum has
given rise to the same opinions. A confinement of the penis
and the urethra, by a particular formation of the integu-
ments, has occasioned persons to be reputed hermaphrodites.
In thefe the urine is in the direction downwards, and the
confinement of the organ will not allow of its performing
the sexual functions. The parts may be set free by a fur-
ged operation.

The last description of males, supposed to be hermaphro-
dites, are those in whom the urinary bladder is deficient,
together with the lower and anterior portion of the abdo-
nal muscles and integuments, and the lymphatic pabul, a
red and felible mass of an irregular and fungous-like sur-
face, with the ureters opening in it, is placed at the lower
part of the abdomen. Considerable alterations take place in
the generative organs, in consequence of this deformity.
The urethra is deficient, and the penis consequently imperfect.
The female ducts open near the fungous mass above-men-
tioned, or on the open surface of the urethra, or even ter-
ting to the bladder external. As the tubercles of the in-
chus are at an unusual distance from each other, the crura
penis are concealed within the body for a greater length,
and the prepuce of the organ is extremely short, fel-
dom exceeding two inches in length, even in the adult.
The urethra appears as if it had been slit open, forming a
band or grooves, instead of a perfect canal, and rendering
the glans penis biffid. The situation of the urethra is also
very remarkable; for, instead of running, as it naturally
does, in the lower angle formed by the junction of the cor-
pora cavernosa, it has commonly passed along the upper
angle, giving the penis and glands the appearance of being
inverted. That the part now described is really the urethra,
is evident from its vesicular surface, with Incime opening
upon it, from the presence of the cappu gallinaginis, and of
the openings of the female ducts. In consequence of the

glands being bifid at its upper surface, the prepuc is at-
tached only to the lower half, and is connected by a frenum,
as usual. The testicles, in some instances, are contained in
the erotonum, in others in folds of integument resembling
the puerine scrotum of the male, and in some do not descend.
The testicles are rarely pendulous, being incrusted in tradition
consequence of the separation of the osa pabul. The sexual
appetite, in some of these individuals, has been weak, in
others strong, in others altogether wanting. It is evident
that they are not capable of procreating the species, in con-
sequence of the shortness and imperfection of the penis,
and the female ducts opening externally. See Dr. Dunlop,
un, on this subject, in the Edinburgh Medical and Surgical
Journal, vol. 17, pp. 423 and 152; where he has collected to-
gather a vast number of cases.

3d Class.—Female individuals; (androgyne.) An un-
usuallv large size of the citoris, is one of those causes
which have led to mistakes concerning the sex. This is not a
common occurrence in these countries, but is said to be much
more frequent in warm climates; insomuch that a surgical
operation for removing the part is described by the Arabs.
Thefe individuals are perfect females in all other cir-
cumstances of their organization, and the mental dischuge
characterizes them. In many of the recorded in-
stances of this description, there is probably exaggeration,
as any enlargement of the citoris can hardly make it suffi-
ciently
G E N E R A T I O N.

Ecently like a penis to give rise to mistakes. A gipfey applied to Columbus for the removal of a clitoris which incommode
d her. The famous hermaphrodite negro of Angola, exhibited in London, was in the same cafe with the gipfey
mentioned by Columbus. Parfons has collected many facts of
this kind. Mr Home relates an instance in a negro.
She was of the M undo nation, 24 years of age; her
breasts were very flat; she had a rough voice; and masculine
countenance. The clitoris was two inches long, and in thick-
ness resembled a common-sized thumb; when viewed at some
distance, the end appeared round, and of a red colour; but, on
a clofer examination, was found to be more pointed than
that of a penis, not flat below, and having neither prepuce
nor perforation; when handled it became half erected, and
was then fully three inches long, and much larger than be-
fore; when she voided her urine, she was obliged to lift it
up, as it completely covered the orifice of the urethra.
The other parts of the female organs were found to be in a na-
tural state." A gentleman, who had practifed midwifery
among the negro women, flated that an enlarged condition
of the clitoris was common among them. Parfons and some
others, in confluence of the ftructure just defcribed,
have defcribed all hermaphrodites to the female sex. Whe-
ther this unusual size of the organ can be produced, " per
feferatum abulum et climitoris" is very doubtful. In order
to avoid all mistake concerning fex in newly born children,
fmall male, or females, that the clitoris is proportionally very
large at that age.

A prolaplus of the uterus is another circumftance which
has occafioned females to be deemed hermaphrodites, and
even to be publicly exhibited as fuch. A perfon of this
kind came to Paris in 1609, dreffed as a man, and wearing a
fword. She pretended to have the organs of both sexes,
and to be able to employ both, and exhibited her perfon to
the curious for a fimilar gratification. Besides the numbers
who took up the common opinion of her being an herma-
phrodite, and who could not be supposed sufficiently well-in-
formed to judge of fuch a subjed, feveral physicians and
furgeon fell in with the vulgar sentiment, and gave certif-
cates which prove incontrovertibly, that a great reputation
may be acquired in the profefion, without any real talents, or
any large stock of folid information. Saviard, after in-
fefting the parts closely, found that the cafe was a pro-
laplus uteri, which he reduced. When the female had re-
covered, she pretend a requief of the king for permiffion
to take again the female dress, in fpite of the magiftrates of
Toulouf, who had ordered her to clothe herfelf as a man.
See Saviard, Recueil d'Oblervations, obf. 15.
An instance of the fame kind is related by Mr. Home.
A French woman had a prolaplus uteri at an early age,
which increafed as she grew up; the cervix uteri was un-
commonly narrow, and at the time I faw her, when she was
about 25 years old, projefted several inches beyond the ex-
ternal opening of the vagina; the surface of the internal
parts, from conflant exposure, had lof its natural appear-
ance, and resembhed the skin of the penis; the orifice of the
os tinent was mistaken for the orifice of the urethra. This
woman was known as a curiofity, and in the course of a few
weeks made 400l. I was induced by curiofity to visit her,
and on the first infpection difcovered the deception; which,
though very complete to a common obferver, must have
been readily detected by any perfon intimately acquainted
with anatomy. To render herfelf full more an objedt of
curiousity, she pretended to have the powers of a male." Phi
cif. Transf. 1759.

We have already mentioned fome infances where the ge-
nerative organs, although belonging clearly to one fex, had
been imperfectly developed, and consequently had not pro-
duced their usual effed in modifying the form of the body,
and imparting it with the sexual character. There are other
infances, in which men or women, having their organs ap-
parently of the accenteded magnitude, partake reftectively
of the charaders of the other fex, probably from the caufe
just alluded to, of the fexual parts not exerting their full
influence on the frame. Such infances may be accounted
for, and, in the human fubjed, to resembide the fexe mar-

*Figuratus urinarius to the clitoris in the female, will afford the
decision, as also the want of power to pass an instrument
towards the situation of the uterus.*

...but not by the female very symmetrical, but fully
found front and warm, but the completely
the fuch fuch rough, but young
...decilion, towards the
...mitts, and the clitoris, and its different flaps;
the connection of its prepuntum to the ayin phr, and the
presence of the latter parts; the separate opening of the vagina
and mammary tubas, and the presence of the hymen; the
abence of teffes, all prove the individual to be a woman.

An adhesion of the labia to each other at their convexities
may cause a difficult in deciding; but here the abence of the
penis and teffes, the discharge of the urine at the upper
end of the labia, and the line of union between these folds,
shew us the nature of the cafe.

Much information on the subject of hermaphrodites may
be gained from the following works. Parsons’ Mechanical
and Critical Enquiry into the nature of Hermaphrodites:

seq. Wrifler, Commentatio de Sigulari genitalium de-
formitate in puer, Hermaphrodism mentente, in his Com-
mentary, vol. i. p. 524, et seq.

Male Organs of Generation.—In the human subject these
consist of the teffes, vehicle feminales, prolate, Cow-
er’s glands, urethra, and penis: making up a secretory ap-
paratus, which is double, consisting of a right and left
organ, in the two former parts, and fingle in the latter.

The peculiarities of the apparatus consist in the small quantity of
fluid which is fennial, in the long periods for which this
fluid is retained in its reticulums; in the particular condition
of the organ destined for its emission, efferently necessary to
that act; and in the physical feeling which accompanies the
act.

The Teffes.—These organs, placed externally to the ca-
vity of the abdomen, and left protected against external
injury more moft other important viscera, are fuffreded, each
by them a considerable vascular bundle, called the sperrra-
tic cord, and contained in a kind of bag or cavity formed of se-
veral membraneous layers. A middle fepiment divides the interior
of the bag, and feparates from each other the right and left teffis,
with their coverings, which are double with the exception of
the outer one. The latter, formed by the integuments,
and called the feroitum or puric (in French les bourses) con-
dittutes a fingle bag, which envelopes all the others.
The feroitum is attached to the upper and front part of the pelvis,
unconnected in every other situation, contiguous laterally to
the inside of the thighs, in front to the penis, and feparated
behind from the anus by an interval of two or three inches,
called the perineum. A fmall fold of the skin under the penis,
a flight groove below, and a prominent line behind, con-
tinued into the raphe of the perineum, mark out fuccedvilly,
on the external surface, the symmetrical division of the
organ. Yet the right fide of the feroitum is almost contantly
more elevated than the left, in conformance of the cor-
responding femeric cord being shorter, and the teffis nearer to the
ring. The feroitum is foft to the feel, and elongated,
so that the teffes appear liden and long low; in warm weather,
in old persons, after cotion, and under the action of any
causes which have a debilitating influence on the frame
in general. It is rough and harder on the surface, and
shorter in cold weather; in young subjects, at the time of
ejacuation, and in a strong, vigorous state of the body; con-
sequently, at such times, it is applied more exactly to the
tefsis, and, drawing these organs gently upwards, shortens the
orbs. The sudden action of cold, and even of fear,
will produce the latter state of the organ. The wrinkles
which it exhibits at such times are effaced by extending it.

The coverings of the teffes succeed each other in the fol-
LOWING order: 1. The cutaneous investment, or feroitum;
2. The cellular layer; 3. Membrane of a fibrous ap-
pearance, common to the teffis and cord; 4. The feros.
membrane. The reason why the dartos is not enumerated
among these covering will appear presently.

The feroitum is continuous with the integuments of the
inside of the thighs, the perineum, and penis. It is distin-
guifhed by a brownish line from the rest of the integuments,
but follows in general the tints of the latter, being always
darker in colour. A few hair are scattered over its
surface, and their bulbs, efferently implanted, form feble
prominences from the thinness of the skin, which are not
effaced by extension of the organ. In its general organization
the feroitum refembles the skin; but it is very thick, fo
that the veins of the subjacent cellular tissue are visible
through it. The vital properties of the feroitum are the
same with those of the skin in general; but the contraction
produced by cold is more manifest in the former than in the
latter. The phenomenon seems to be the fame in both in-
fances. It constitutes the cutis aneriina of the surface in
general. This corrugation of the part has given rise to the
opinion that a muscular expansion is found under the skin in
this situation; and hence have arisen the descriptions of the
dartos. We can, however, clearly distinguish that the
contraction is in the integuments, and not in any more
deply-feated part; they feel denke and firm at this time,
instead of being left and looef, as in their ordinary state.

The teffes and cord are surrounded in their situation by a
continuous and loofe layer of cellular subsifance, placed im-
mediately under the skin, and constituting, where it divides the
tefsis from each other, the leptom feroit. This is rather
more clothed than the other fepiments, and the loofe at the surface of the teffes. Several blood-valls ramify through it, particularly veins; and hence arise an
appearance which may have authorized the opinion concern-
ing a muscular covering on a superficial examination; but
accurate inspection can discover no muscular fibres. Many
nervous filaments are also fen in this subsifance, and enable
us to explain the acute femibility offered on the removal of
the teffis in surgical operations, a little fat is fen near the
ring and the urethra; but it is completely alfrom all other
situations. Here, as in the penis, the eye-lids and
force other parts, the abundant depofition of fat would in-
terfere with the functions of the organ; and its alfrom in
these situations seems to indiate the design and foresight em-
ployed in the construction of the body as fully as the parti-
cular construction of any parts can do. However the size of
the body in general may be increased in corpulent persons,
the feroitum, penis, &c. always retain the fame dimensions.
The alfrom of fat renders these parts more efpicially sub-
ject to the wattery depofitions of affura; such effusions
often overfill themselves in the feroitum, and that organ
is generally very much increased in bulk when the affura is
considerable. The impulion of air through an opening in
the feroitum demonstrates very well the nature and extent of
this cellular layer; by diffusion of this kind it refembles
easton in appearance. Maceration in water may be employed
for...
GENERATION.

for the same purpose; as the fluid penetrates very minutely into the cellular interstices. It is continuous with the similar covering of the penis, and with the cellular substance of the perineum and groins; so that air passes from it into these situations.

The cord and testis are closely enveloped by a condensed cellular covering, which descends from the neighbourhood of the abdominal ring, and includes the organs just mentioned, together with the membranous coverings of the latter; it constitutes the ephithelial or ephithroid coat of some writers. The cremaster muscle is strongly connected with this, and contributes to the formation of the cellular sheath. This part has been described as the tunica vaginalis of the spermatic cord, but it is entirely overlooked by many writers. Its thickness differs considerably in different subjects. It is connected to the cellular substance of the testis externally; and adheres, by cellular connections, to the spermatic vessels, and to the tunica vaginalis testis, on the inside. If air be impelled through a small opening, it is separated from these parts, and may be divided for as to show that it is a distinct membrane. It then appears semi-transparent and thin, and seems to consist of fibres variously interwoven. Its thickness is much increased in ferotal ruptures, to which it gives a complete external covering. Camper has delineated it very well in his posthumous plates edited by Soemerring, and he describes it in the following paragraph: "Cremasteres igitur musculo sunt, ab oblique internum et transverso abdominis orti, per involu'm membranaceum sub cute feroti differt, quorum velamentum efformant, funiculum spermaticum et telem utqueque eingen, quodque in hernia cordium descensum humani testis, et in multa fibri invicem imperfecte laemelis consistit dividum, cum chirurgia hernias attingitum. Velamentum illud facile a fece hermici digitis separatur; formam autem adheret vasa spermaticae." Leen's herniarum, p. 13.

The serous membrane of the testis is called the tunica vaginalis, and the same should be confined entirely to it, as most of the anatomical descriptions apply to this part only. Like all other serous membranes, this forms an entire and unperforated bag. Its arrangement is simple. It forms a pouch-covering, and appearing to include the testis and epididymis, as the heart is included in the pericardium. When an opening is made into it, and air is impelled, it is elevated into a bag on the front and sides of the testis. At the posterior edge of the organ it is reflected over its surface, covering the epididymis, a small portion of the spermatic vessels, and the whole testis; and giving to these parts a smooth external coat. The tunica vaginalis therefore may be said to consist of two parts; viz. an external portion, forming the bag, which includes the testis; and an internal, reflected over the surface of the organ. The two are continuous at the back edge, and at the upper and lower ends of the testis. The bag-like portion of the membrane is covered by the fibrous investment already described; the reflected part adheres very closely to the epididymis and testicle. The tunica vaginalis is very thin, and everywhere cellular on its external surface; internally it is smooth, polished, and moistened by a serous secretion, which, in an increased quantity, constitutes hydrocele. There is hardly any fluid fluid in the ordinary state of the part. Sometimes there are partial adhesions between the opposed surfaces of the two portions of the membrane; and sometimes a general adhesion, by which the cavity is entirely destroyed, is produced by the operation for the radical cure of hydrocele.

In man and quadrupeds the testicle consists of two parts; viz. the proper testis, and the epididymis, which adheres to it behind. Ordinarily the ferotum contains two of these glands, a right and a left one: but this number is not invariable. We shall explain hereafter how it may happen that the ferotum should contain no testis, or only one; and, if authors could be credited, we might cite examples, in which there have been three, four, or even five. We believe that the number never exceeds two, that the statements now alluded to have arisen from the swellings incidental to these parts, being mistaken for testes, and that there is no observation deferring of credit by which this affection can be contradicted. The ordinary size of the gland in the adult is an anatomical fact known to each individual; but there are some varieties in this respect. Long continued abstinence probably causes a shrinking of the organ; and a similar diminution, to a much greater degree, may be occasionally observed in old subjects, when the function of the part has ceased, without any disease. On the contrary, when venereal enjoyment has been habitually indulged, temporary abstinence will cause a swelling of the organ, with some pain; and this may be relieved by a spontaneous discharge of the effusion. Again, there are differences of volume from original formation. The right and left glands are not always of the same size, nor is this size particularly observed to exceed the left, as some have asserted. The figure of the part is pretty exactly oval, with the two ends placed perpendicularly, and the surface flattened in the direction of the small diameter. The extremities, which are distinguished by the epithets superior and inferior, are not in the same perpendicular line; the former is inclined forwards and outwards; the latter backwards and inwards. The two ends are sometimes almost interior and posterior. The flat sides, which are external and internal, are turned, the former towards the thigh of the same side, and the latter towards the corresponding surface of the opposite gland. The edges of the testes, which are anterior and posterior, are placed obliquely, so as to float from above backwards and downwards. The anterior edge is sometimes described as the interior, and the posterior as exterior. The epididymis is a thin and elongated organ, placed along the back edge of the testis, to which it adheres by means of the tunica vaginalis and blood-vessels, smaller in the middle and enlarged at the upper and lower ends, and reflected at the latter, to form the deferens. Its upper extremity is called the caput epididymidis or globus major (vice de l'epididyme); and this adheres very firmly to the upper end of the testis, being placed rather above, as well as behind it. From this point the organ descends in a thin and flattened form, distinctly seen as a separate part in the side of the testis, which is turned towards the thigh, but not on the opposite surface. It swells again at the lower end into the globus minor (queue de l'épididyme) and then turns up to form the vas deferens. The spermatic cord is attached along the posterior edge of the gland, and the greater or left obliquity of the testis depends on the mode of its connection. A cord, composed of the same parts, suspends each testis in its place, but it is rather longer on the left side; a circumstance which has been noticed by painters and statuaries. The pathologist ascribes to this circumstance the more frequent occurrence of varicocele on the left side of the body. The distance of both organs from the ring is variable, and depends on the size of the forotum, and the cremaster muscle. These two parts generally contract together. The concurrence of the gland is felt to the feel. As it is covered almost entirely by the fibrous membrane already described, it acquires from this circumstance a smooth and polished surface; its whiteness arises from the tunica albuginea.

Structure of the Testis.—The glandular part of the organ,
in which the seminal secretion is immediately effected, is a light-brown pulp, considerably softer than the parenchyma of the other glandular organs, contained in a thin fibrous membrane, which determines the exterior configuration of the part, and the consistence which it presents on examination. This membrane is named the tunica albuginea. It is seen through the reflection of the tunica vaginals, which envelops the testicles, and adheres to it very closely. Yet, notwithstanding the strength of this adhesion, the serous layer may be partially separated by dissecting from the epididymis forwards. But, over the general surface the union is too intimate to admit of separation; and consequently the serous layer and the true albuginea are described ordinarily as composing one membrane under the latter name. It is from analogy, rather than the direct testimony of anatomical observation, that we denominate them as distinct parts. Along the posterior edge of the testis, the albuginea is perforated by numerous openings for the passage of the seminal and blood-vessels. From the inner surface of this membrane are detached numerous delicate processes penetrating the substance of the testis, and forming partial septa, by which the glandular mass is slightly subdivided into smaller portions. Some of these processes seem to consist of blood-vessels. The structure of this part differs among the fibrous membranes: it is dense, very firm, of a peculiar white colour, and possessing some blood-vessels. Its external surface is everywhere covered by the reflected tunica vaginalis, except at the back of the testis, and its inner surface is in contact with the glandular substance of the organ. The great elevenses and filaments of its texture explain to us the peculiarly hard feel of the inflated testis, as the membrane yields with difficulty to the detention produced by the swelling of the contained vascular parts. It is manifestly thicker where the fibrous tubes penetrate it; and in this situation we observe the corpus Highneri, concerning which we have further observations to make below. The albuginea possesses extensibility, and the corresponding contractility; the swellings of the testicle, from various causes, swell the former, and its subsequent return to the natural size, as well as the shrinking of the part from age demonstrate the latter. It is very subject to conversion into carthage. Little excrescences are sometimes observed on the surfaces of the gland, about the size of a pin’s head.

The tunica albuginea is filled with a soft pulp, matter, of a light brownish-yellow hue, and divided into small portions or lobuli. Incomplete septa, along which the small arteries and veins run, divide these portions; but the partitions are not merely vascular. They are attached, as we have already observed, to the internal surface of the albuginea. Behind, they unite together in a white cellular layer, running along the back edge of the testicle, from above downwards. Such are the appearances exhibited in the recent organ, without any dilatation or preparation. Its substance is very firm; so that when it loses more than eight-tenths of its weight. A more accurate examination, particularly with the affinities of maceration and putrefaction, discover that all this pulp mass is made up of convoluted serpentine threads possesting some filaments and connected together by a very soft cellular substance. These, which are called the tubuli or ductus seminiferi testis, seem about the size of an ordinary sewing thread, and can easily be drawn out with a needle, after maceration, to the length of an inch and even more. These threads are tubular, cylindrical thick in their coats with small calibre, plentifully supplied with minute vascular ramifications, from which however injected liquors do not pass into the ducts. They do not ramify, but pass in a tolerably direct line to the cellular part at the back of the testis. That they are tubular is proved by the possibility of injecting them with quicksilver from the vas deferens: this indeed often fails, but in some cases the tubuli are filled in this way through the whole testis. The diameter of one of these ducts, according to Monro, is 1.250th of an inch; or 1.125th when injected with quicksilver. By the calculations of the same anatomist, the testis should appear to consist of 62,500 tubes, supposing each to be one inch in length: and consequently, if they were joined into one tube, it would be 5309 feet and 4 inches in length. The convolutions and ramifications of these ducts are so numerous, that they do not continue their course in the same straight line, for more than 1.425th of an inch.

The white and firm cellular line at the back of the testis, just at the adhesion of the epididymis, is called the corpus Highneri. Many anatomists have described it as tubular, and have aligned to it the office of conveying the semen to the epididymis. Such a part obviously exists in the testis, and is still more manifest in animals, as in the boar, than in the human subject. Haller, who has given the most accurate account of this subject, says, “After I had accurately filled the vas deferens with quicksilver, I observed in the corpus Highneri numerous vessels, larger than the tube of the epididymis, running according to the length of the gland, serpentine, easily torn, and communicating with each other.” Elem. Physiol. v. 7. p. 435. In these the tubuli seminiferi testis terminate, and they constitute the rete vasculorum of the organ. The ducts contained in each part of the tubuli seminiferi end in one straight tube, which terminates in the rete testis. A certain number of tubes, called the vasa efferentia, convey the semen from the rete vasculorum to the commencement of the epididymis. Obscure notices of these vessels may be found in various writers, and De Graaf in particular has described them. But the labours of Haller have thrown the greatest light on the subject. “When, after various unsuccessful attempts, the continued labour of an hour or more had enabled me to fill completely the vas deferens, I observed the head of the epididymis to be made up of vascular cones, amounting in number to twenty or thirty, and connected together by cellular substance before any dilatation had been used. Each of these cones is made up of a single small vessel, larger however than the tube of the epididymis, convoluted into innumerable folds. The basis of the cone is turned towards the epididymis; its apex is a vessel proceeding downwards to the testis, perforating the albuginea, and communicating with the rete testis.” Ibid. p. 447.

The epididymis, of which we have already described the position and figures, is distinguished by its greyish colour from the shining whitenss of the testis. Being placed at the point where the cord is attached to the testis, it is surrounded by blood-vessels, of which much are distributed to itself; its surface is partially covered by the reflection of the tunica vaginalis, which adheres to it closely, except at the angle of reflection, where the convulsion is looser. Its structure is much more easily unravelld than that of the testis, for, when filled with quicksilver from the vas deferens, it is proved to consist of a single tube, almost infinitely convoluted upon itself, excepting only a small part of the caput, which is made up of the vascular cones. The latter uniting together form one very small tube, which by its serpentine course and turns, connected to each other by cellular substance, containing the ramifications of blood-vessels,
GENERATION.

Veils, forms the body of the epididymis. As it descends along the back of the testis, it increases in diameter, and at the same time is proportionally less convoluted. In a considerably enlarged state, it is reflected from the lower end of the testis, until a little convoluted at first, but soon forming a straight tube, called the vas deferens. By carefully destroying the cellular substance, which connects together the convolutions of this tube, we can demonstrate the facts now mentioned concerning the structure of this organ. In such a process the tube can be drawn out to a surprising length, as much as 20 feet, according to De Graaf. In 420 times the length of the epididymis in its natural state, according to Heuermann. Monro has taken great pains in measuring and calculating the dimensions of this part: he finds the diameter of the tube, on an average, to be 1/50 of an inch, its length 31 feet, and the number of its turns, as it does not go in a straight direction at any part, for more than 1/20th of an inch, 1100. (De femine et testibus in varius animalibus, p. 31 and 32.) As a further proof, that the organ is made up of a single tube, we may observe, that if we cut it across while we continue to inject quicksilver from the vas deferens, the fluid escapes from one orifice only, and when that is tied, no more runs out.

Thus, the semen, first formed in the small fertile veins (tubuli testis) which make up the pulp masts of the testis, is deposited from these in the straight seminiferous tubes, which convey it into the rete vasculiferum, placed at the back of the testis, and connected to the abbuinica, where it forms the corpus highamori. Hence it passes through the vasa efferentia, or eceretoria testis, about twelve in number, which perforate the abbuinica, at the upper end of the testis, and then form, in a convoluted state, the peripertate vascular cones, which make up the caput epididymis. These unite into a single small tube, which, by its numerous turns, first forms the epididymis, and then ends in the vas deferens. Haller, Programma de vasa seminalia, Gotting, 1745; and in Oper. min. t. 2. p. 5.

From the origin of the convoluted tubuli seminiferi, to the termination of the epididymis in the vas deferens, the semen goes through a series of vesicles, which are folded 169,860 times, and, if extended in a straight line, would exceed 42 feet in length. Monro, lib. cit.

The small ends of these tubes prevents us from ascertaining their texture, or the nature of their fibers. The tubuli testis presents considerable variations, as we may ascertain by extending them until they break, and by observing the column of quicksilver which they support, when we inject them. The tube of the epididymis presents firm and strong fibers, in comparison to its cavity.

A small tube, either straight, or slightly convoluted, is sometimes observed to arise from the epididymis, and after passing to various distances on the cord, to terminate in a cul-de-sac. Its size is equal to that of the tube of the epididymis itself. This circumstance was first noticed by Haller, who called the vesel vaeulum aberrans. (Progr. de vasa seminal.) He did not undertake to determine its termination or nature, observing that it proceeded along the cord, incerto fine: an lymphaticum? The existence of the vaeulum aberrans has been confirmed by Monro, who injected it in four out of fifteen testicles; and he adopts the opinion suggested by Haller, of its being a lymphatic. Mr. Cruikshank takes a different view of the matter. "It is," he says, "a laius nature, and either forms a cul-de-sac, or, after many convolutions, returns back again upon itself, and terminates where it begins. It sometimes mounts four inches upon the cord, and then terminates in a coccus, or blind end. Sometimes it is not a quarter of an inch in length. I have seen it convolute, like the epididymis itself; from which it could not be distinguished, till, by maceration and diffusion, the cellular membrane had been removed. It may be compared with the diverticular illi, so frequently met with in the human intestines." Anatomy of the absorbing Vessels, p. 141.

Tubes of the Testicles: Spematis cord. Under the interior extremity of the kidney, and about the middle of the psoas magnus muscle, we observe a fasciculus of blood-vesseils, lymphatics, and nerves, placed behind the peritoneum, and connected to that membrane by a cellular substance: this is the commencement of the spermatic cord. It descends over the psoas muscle, passing at the same time rather outwards, crosses the ureter, continues its course between the iliacus internus, and arrives at the upper opening of the abdominal ring. Here it is increased by the accession of the vas deferens, from the side of the bladder. It now penetrates the upper aperture of the ring, going under the inferior edge of the obliquus internus, and transversus abdominis: then it turns downwards and forwards in the canal placed between the two openings of the ring, covered in front by the aponeurosis of the obliquus externus, and lying behind on the falcia transversalis. In this part of its course, it is further increased by the accession of the cremaster muscle. The cord finally emerges through the opening in the tendon of the obliquus externus, and then turns suddenly downwards; lying not so much on the bone between the two columns of the ring, as on the outer column itself, so as to cover its insertion into the pelvis. Just at the point, where the cord enters the abdominal canal, it lies on the root of the epigastric artery. As it is placed behind the peritoneum, in the whole of its descent from the loins to the abdominal ring, that membrane is not perforated at the point where the cord leaves the abdomen. Nor is there any sheath continued from the peritoneum, along the cord, to the tunica vaginalis; although such a structure has been ascribed to the human subject from the observation of animals, in which it is really found. In human males, indeed, a membranous cavity, produced by a continuation of the peritoneum, lies over the cord; but this is diseased; and in a particular period of foetal existence, there is a canal leading from the abdomen to the tunica vaginalis, but this is ordinarily closed before birth. Neither is there any foundation for the description of two layers of the peritoneum, of which the ureter is said to be accompanied by the cord. Escaping through the opening in the tendon of the obliquus externus abdominis, the cord descends in a straight course to the testis, covered externally by the fibrous sheaths already described, and growing rather larger as it approaches the organ. Copious soft cellular substance, with very little fat, connects together the component parts of the cord.

The spermatic are the chief arteries for supplying the testes and their coverings. These vessels are the longest in their course, compared to their diameter, of any in the body; they were known to the ancient physicians, and called by them the seminal vessels. They would probably have escaped the diligence of the physician, had not the importance of the part, which they supply, been more attended to, than the size of the tube. They arise, most commonly, from the front of the aorta, between the origins of the renal and inferior mesenteric vessels; either near together, or at a small distance from each other. This is the case in twenty-two out of thirty-five instances. They may arise from the aorta higher or lower than the point, which has been mentioned. The artery of the right side sometimes comes from the right renal; but the left arises much more commonly from the renal artery, infomuch, that this has been described as the accustomed origin. Often a smaller branch from the renal joins

Vol. XVI.
the trunk of the spermatic. It descends at an acute or half-right angle, and goes in front of the vena cava, on the right side of the body; but has been seen behind that vein. Its course is rather tortuous; joining the vein on the psoas muscle, it descends along the cord, and arrives at the testis in two branches. It gives off small twigs to the renal capsule, fat of the ilium, rectus, lumbar glands, and the cord itself. The area of the vessel, instead of being diminished by all these branches, is rather increased. Several ramifications are distributed, below the ring, to the cremaster, tunica vaginalis, and cellular substance of the scrotum. Ultimately it is distributed in numerous branches to the epididymis and testicle; these partly perforate the back of the albunigma, and are employed in supplying the pulpy substance of the organ. Some of the ramifications communicate with branches of the epigastric artery. Smaller arteries come to the spermatic cord, or testicle, from the epigastric, or from the circumflexa abdominis. The testis, and its cellular substance, receive twigs from the arteries of the thigh. 'Hence,' says Haller, "tying the spermatic arteries does not destroy the testicle, on account of the supply derived from the external vessels; but as these are very small, the venerable powers of the organ are loft." Element. Physiolog. v. 7. p. 458.

It has been affected by many anatomists, and some of considerable celebrity, that the spermatic arteries and veins communicated together, and Zuckermann has drawn large communications between them. That injection will sometimes pass from one order of these vessels into the other, when dexterously impelled, is very true, and it holds equally good of other parts; but there is no more than the ordinary kind of communication here.

The spermatic veins, like the arteries, are two in number: the right usually terminating in the front of the vena cava, the left in the renal vein, either alone, or in conjunction with the cephalic, or a lumbar, or the hemiazygus. The left spermatic may end in the vena cava; or the right in the renal vein. Sometimes the vein ends by two, three, or four branches in the cava and renal vein. The size of the vessel is very considerable when compared to that of the artery: its diameter being nearly a line and a half. When the vessel has reached the psoas muscle, it divides into branches, which unite again, and give origin to other ramifications, which also anastomose together, and on: thus a large plexus of veins is formed, constituting the corpus pampiniforme, forming the chief bulk of the cord, and increasing in size as it approaches the testis. Branches corresponding to the arteries, which arise from the spermatica, join the vein. Valves are found in the spermatic veins, but none at their terminations: the tendency to the formation of varices in these vessels, shows the necessity for the existence of valves. The veins of the scrotum, derived from the epigastric, communicate with the spermatic, and with those of the penis.

The absorbers of the testicle are numerous and large, but have not been long known. Nuck had demonstrated them by inflating the spermatic veins; and Monro rejected them when he had thrown quicksilver into the vas deferens. He observed four or five valvular vessels arising from the ret. testis, and ascending the cord. Haller candidly admits that he did not know much of them: 'In homine aliquid visi majuscula, non tam venae numerosa, in fimulculo feminali cum venas ascendentia, valvoluca, ut tamen necque originem, neque finem factis accurate viserem.' (Elem. Physiol. v. 7. p. 436.) Mr. Cruickshank has given us the most perfect account of these vessels. 'The absorbers of the tunica vaginalis,' says he, 'are easily discovered, lying between the reflection of that coat and the tunica albuginea. Though they are thus situated, I know that they belong equally to the body of the testicle; they are in great numbers, and I have sometimes covered the albuginea with absorbers injected with quicksilver; perhaps there is not any part of the body where the absorbers are larger or more numerous, in proportion to the part, than they are here. They soon leave the albuginea, and get upon the cord, where they are joined by others, to be described presently; but the tunica vaginalis has also other absorbers, upon the anterior and lateral parts, which have not the least connection with the body of the testicle, nor with the albuginea, and which also soon blend with the former, on the beginning of the cord. The absorbers, which arise out of the ret. testis, are exceedingly large, and appear to have no connection with its coats. A very beautiful preparation of these vessels I made at Windmill-street, at least ten years ago; I injected the vas deferens with quicksilver, and had in view not only the filling of the epididymis, but the tubuli testis themselves. I had forced the mercury along the epididymis, and was delighted to see it get into the body of the testicle; the mercury continued to descend very quickly through the glads injecting tubes; but I soon found that it was not running into the tubuli testis, but into some vessels, which mounted along the cord: these I soon perceived were absorbers. I have also injected them from every part of the epididymis, from its inferior extremity, from the middle, and from the lower end. The absorbers, having reached the cord, form from six to twelve trunks or more; some of these are sometimes larger than a crow-quill: they do not appear to anastomose with one another as they pass along the cord; at first they run straight upwards, in the direction of the ring of the external oblique muscle; after which they are bent upon themselves, and pass a little way in the direction of the spine of the ilium; after which they are bent as it were a second time upon themselves, and run over the anterior surface of the psoas muscle, and terminate at last in the lumbar glands. The reason of their termination, so distant from their origin, will easily occur to those who reflect that the original situation of the testicle was at this place, and that it was natural for it, like the other vasa, to receive its blood-vessels and nerves from the nearest trunks, and to return its absorbers to the nearest glands.' Anatomy of the absorbing Veins, p. 140.

The nerves, like the blood-vessels of this organ, arise from the trunks contained in the abdomen, and have consequently a long passage to their ultimate definition. They are rather numerous than large. They are produced from the renal plexus chiefly, with additions from the meroenteric and hypogastric plexuses, and from the trunk of the great symphatico. They are closely connected to the vessels in the cord, but can hardly be traced to the testis. The feromut and cremaster are supplied by the lumbar nerves. Although the testis does not possess acute sensibility, compression of the organ causes a peculiar, dull, and intolerable sensation, of the most distressing kind.

Besides the parts just enumerated, the cord contains the vas deferens, which will be presently noticed; and the cremaster muscle, which is described under the article Chemaster. A soft and loose cellular substance unites together the parts which have been just mentioned; it resembles that of the feromut in not containing fat generally; but in corpulent persons small depositions of adipous matter may be observed in it. It does not communicate with that of the feromut, as the fibrous covering of the cord is interposed between them; and it is much less subject than the latter to anatomic affections. Indeed its quantity is proportionately less abundant. Yet in rare cases it has been the seat of aqueous infiltration, constituting a very uncommon kind of hydrocele of the cord: the latter complaint shews itself more frequently
The vas deferens, or deferent, is the tube which conveys the semen from the epiphysis to the urethra. Its figure is for the most part cylindrical, and it consists of a very small tube, which will only admit a large bristle, with very thick sides. Although its caliber is so small, the diameter of the part on a section equals a line. The substance of its sides is very firm, and cuts like cartilage; hence we can dilate it by the feel from the other component parts of the cord, by sliding them between the finger and thumb in the living subject. The internal surface of the tube is smooth. Nothing of a muscular structure can be discerned in its composition.

It arises from the posterior and inferior part of the epiphysis, ascends behind and a little on the inside of that organ, and then continues its course along the spermatic cord behind the vessels to the ring. Compression of this part occasions the same kind of pain as is experienced when the testes are injured; and the very acute suffering observed on tying the cord in calf-latin, has been explained by the circumstance of this tube being included in the ligature. Perhaps this explanation may be doubted, as the nerves of the testes are also among the compressed parts; however, the vas deferens is easily omitted, as its hard feel enables us to separate the vessels which lie in front, and are connected to it by a loose cellular substance. It passes through the abdominal canal, holding the same relative situation to the spermatic vessels. It separates from them behind the opening, and then bends downwards and backwards along the surface of the psoas muscle, and of the iliac vessels, to enter the pelvis. Here it becomes attached to the posterior and lateral part of the bladder, and descends obliquely from without inwards, just in the situation where the peritoneum is reflected to the bladder from the side of the pelvis, connected by cellular substance on one side to the bladder, and on the other to the peritoneum, and situated in front of the rectum. In this course it descends the umbilical artery, behind which it passes; it also crosses the ureter, being placed between the lower extremity of that canal and the bladder. At the lower and back part of the latter organ it turns forwards and inwards, so as to approach towards the canal of the opposite side, still connected to the surface of the bladder; in this direction it continues along the under surface of the organ, within the vesicula seminalis, and connected below by cellular substance to the rectum. In the neighbourhood of the prostate, the two vasa deferentia are placed close together, and each unites just at the surface of the gland, with the anterior extremity of the vesicula seminalis. The canal, resulting from this junction, sometimes called the ejaculatory duct, penetrates the substance of the prostate, from below and behind, upwards and forwards, and opens in the urethra at the side of the verumontanum.

The commencement of the vas deferens is a little convoluted, and rather larger in its calibre: at the upper part of the testis it becomes straight in its course, and its area is diminished. Under the bladder it is considerably enlarged again, where it lies along the inner edge of the vesicula seminalis. It has here sometimes a highly serpentine course, and presents a flattened form. Its cavity is proportionally augmented, and, instead of a cylindrical tube, presents a reticulated texture, like that of the vesiculae masculinae. Its surface is irregular and tuberculated in consequence of this cellular structure. After receiving the tube of the vesiculae masculinae, it is again diminished remarkably in size, and forms a small cylindrical canal.

The vas deferens receives arterial and venous ramifications from the trunks in the neighbourhood of which it passes. Nothing is known of its nerves.

It is by no means common in animals for the vas deferens to join the vesiculae masculinae in the manner already described. In all cases where there are testicles, that duct conveys the secreted fluid into the urethra, there being no vesiculae in some, while in others they terminate by separate openings. The communication between the two parts in man is a very free one; and, although the canal formed by their junction proceeds in a straight direction to its termination in the urethra, yet quicksilver, or any other injected fluid, or air thrown into the vas deferens, paffes into, and diffuses the corresponding vesicula before it gets into the urethra. The composition of the common canal by the firm substance of the prostate, the small size of the tube and of its opening, and a particular turn made by it, have been assigned to explain this fact. If the injection is pushed further, it will go into the urethra. Fluids thrown into the vesicula also diffuse the vas deferens, but are more readily admitted into the urethra, as the capacity of that vesicle is not considerable.

The vesiculae masculinae are two soft bodies, resembling, when undisturbed by dissection, membranous tubes with blind extremities, convoluted, and therefore marked with ridings and grooves on their surface. They are situated under the inferior flattened surface of the bladder, and upon the upper surface of the rectum, being connected to both these organs by loose cellular adhesions. They are pyramidal, with the apex placed forwards, and the basis backwards and convergent from behind forwards. Their anterior extremities, joined, as we have already mentioned, to the vasa deferentia, lie on the upper and back part of the prostate, and would be in contact with each other, were they not separated by the tubes just alluded to. From this point they grow gradually broader and are divergent, terminating behind in rounded ends, which are the most distant from each other. The superior surface, in contact with the bladder, is rather flattened: the inferior, lying upon the rectum, is slightly convex. The vas deferens runs in contact with the inner margin, and the outward edge is turned towards the side of the bladder. The posterior broad and rounded ends are partly in contact with the peritoneum, and lies at the sides of the pouch, formed where that membrane is reflected from the bladder to the rectum. Numerous arterial and venous ramifications, particularly the latter, and a considerable quantity of cellular substance, surround these organs in all directions, and connect them to the neighbouring parts. In some individuals the pyriform shape is not well marked; but the anterior and lower end is always small. The flattened appearance of its surfaces is altered by injection: the whole organ then appears thicker, and the tubercular ridings of the surface are more distinct.

A very different appearance is produced when these bodies are unravelled by the anatomist. Each vesicula is then found to consist of a single tortuous tube, about the size of a writing quill, with a blind extremity, and several lateral appendages, which also end in cul-de-sacs. Sometimes the latter are very few; perhaps one or even none. In other instances they may amount in number to ten, or more. Haller has seen seventeen larger, besides smaller ones. Some of these are simple blind appendages; others, particularly near the anterior end of the organ, again branch out. Sometimes the whole vesicula is hisb almost from its very origin; the varieties, indeed, are so numerous, that
two vesicles will hardly be found exactly resembling each other; but these variations are not important. (See Monro de T. Elhus, 3d ed.) This tube, with its appendages, is so convoluted upon itself, that the turnsings being closely connected together by cellular substance, containing numerous muscular ramifications, that the organ, when undisturbed, is four or five times shorter than the unravelled tube; and a section of it in this state makes it appear to be composed of numerous cells, communicating together. This structure accounts to us also for the knotted appearance of the organ on its surface.

The structure of the vesicles is analogous to that of the vas deferens: its sides are not so thick, but they are still dense and strong. The external coat is of a close texture, and whitish colour, covered with cellular substance externally. Nothing of a muscular nature can be discerned here, although the functions of the organ oblige us to admit that it possesses a contractile power. We cannot otherwise account for the expulsion of the contents of the vesicle. The action of the levatores, and which has been ascribed to them in particular, of this expulsion, is certainly inadequate to account for it; as their ordinary daily exertion is attended with no such effect, when the vesicular organ is not present, and these parts are not exerted in their specific manner. We may observe, moreover, that the perineal muscles contract at the moment of ejaculation; but the contents of the vesicles must be conveyed into the urethra in the previous moments. The internal surface of the vesicle is formed by a mucous lining, connected closely to the preceding tunics. Its colour is whitish, and its thickness not considerable. It is continuous with the lining of the urethra.

Its surface is very minutely reticulated, and marked with extremely small divisions, not to mention the larger septa formed by the turnings and folds of the tube and its appendages. It has, moreover, a convex or villous appearance; a similar structure characterizes that enlarged portion of the vas deferens which lies along the edge of the vesicles. The structure of these parts, as well as the junction of the vas deferens and vesicle at an acute angle, has very considerable analogy to the gall-bladder and ductus hepatice. Both have the same reticulated internal surface; the union of the two tubes, and the fupposed course of the contained fluids, are considered to be similar.

Some anatomists have described glands as being contained in the substance of the coats of the vesicle, and secreting the mucous fluid poured into these organs; but the most careful investigation does not lead us to detect any thing glandular, and the secretion is probably performed by the surface of the parts.

We proceed to describe more exactly the canal by which the vesicle and vas deferens communicate with the urethra. The tube of the former assuming a smooth appearance on its internal surface, and rather diminished in size, converging towards its fellow, joins the corresponding vas deferens at a very acute angle; it is still considerably larger than the latter canal. When the parts are directed, and the connecting cellular membrane removed, as in the hepatic and cystic ducts, the junction appears to be effected at a half right angle. The canal formed by this union, and belonging equally to the vesicle and vas deferens, proceeds more directly in the course of the latter, lies in close contact with its fellow, passes between the prostrate and neck of the bladder, and thus arrives at the under surface of that part of the urethra, which runs through the gland. A small elongated eminence is found in this portion of the urinairy canal, composed of its internal coat, broader behind, where it assumes an oval figure. Towards the front it is continued into a long prominence, which is simply a fold of the urethral lining, and disappears in the bulb, ending in one of the long fins, of which several are seen in the urethra, and sometimes bifid, or even radiated at its extremity. It is called exuvet gallinaeum, or verum montanum. The elevations of the lining of the bladder, continued from the ureters, terminate in this eminence. Its oval portion is hollow, and presents a long slit leading into a cul-de-sac, which can be inflated, but which has no communication with the female passages. On each side of the eminence there is a small oblong opening, the termination of the ejaculatory duct, but much narrower than the calibre of that tube, which is suddenly reflected from within outwards, at nearly a right angle, and pours its contents, by this small opening, into the urethra. There is no valvular structure at these orifices.

The slit and cul-de-sac already mentioned have given rise to an opinion, that the two ejaculatoryducts terminated by a common orifice, which is altogether erroneous.

The prostate is a firm glandular body, placed behind the symphysi pubis, in front of the neck of the bladder, and surrounding the commencement of the urethra. In most animals there are two separate glands in this situation, and the expression prostaticus has been erroneously transferred to the human subject. The size and figure of this part have been not unaptly compared to those of a large chesnut. Its broader end is turned towards the bladder, and is divided by a slight fissure into two lateral lobes, the narrower part is situated forwards. It is considerably thicker from side to side, than in the vertical direction. The superior surface corresponds to the arch of the pubis, but is rather behind that part; it is covered by a strong fibrous expansion, descending from the arch, and named the inferior ligament of the bladder. Below, the gland is connected by close cellular adhesions to the upper surface of the rectum, and the contact of these two parts is more extensive in proportion to the size of the gut, which, when much dilated, rises slightly on each side of the prostate, so as to be endangered in the lateral operation of lithotomy. The convex prominent fides are covered by the anterior fibres of the levator ani. The bafiis, or broad posterior part, which is gently concave, embraces the neck of the bladder, and the small anterior ends of the vesicles externales and vasa deferentia. The cellular substance, which connects it here to the bladder, is very dense and firm, and the muscular fibres of the organ are partly interwoven with it. This part presents the grooves already mentioned as dividing the organ into two lateral lobes. In front, the narrower portion of the prostate is lost indefinitely on the membranous part of the urethra, to which it adheres most firmly. The bulk of the urethra, the fat and muscles of the perineum, cover the part to deeply on its anterior aspect, that it can by no means be felt from the surface: on the upper part of the rectum, however, the gland may be distinctly recognized by the finger introduced into the gut, as nothing but the intelle covers it in this situation; and it projects sensibly into the tube when enlarged.

The urethra, immediately at its origin from the bladder, passes through the prostrate from behind forwards, and the membranous is almost coalesced with the sides of the opening in the gland. This passage does not take place at the centre, but nearer to the superior surface, so that a small portion only of the gland is above the urethra, and the chief bulk of it below and at the sides. At the inferior part of the opening, by which the urethra commences, a small portion of the gland projects slightly towards the bladder; and this
GENERATION.

This part is perforated by the female ducts. It has been particularly described by Mr. Home as forming a third lobe of the prostate. See the description of a small lobe of the human prostate gland in the Philos. Transact. 1826, pt. 1.

The external surface of the prostate is covered by a more or less distinct cellular investment, which is the most complete below, and surrounded by numerous vascular ramifications, particularly of the venous kind. For an account of some muscular fibres connected to it, see Compressors.

Its structure is rather obscure; for it does not constitute a simple gland with one excretory cavity, nor is it separable into smaller distinct portions. It is dense and very firm to the feel, appearing homogenous when cut into, of a light brown colour, and on the whole considerably resembling a fibrous mass. Small cavities are scattered through it, and excretory ducts, from 7 or 8, to 12 or 15 in number, continued from these, open into the commencement of the urethra, on each side of the caput gallinacini. From these openings, a white and thickish fluid may be expressed in considerable abundance; it differs essentially in its colour from that contained in the vesicles of the females.

Cowper's glands, are two small glandular masses, so named from the anatomist who particularly described them, and published figures of them; see his Descriptive glansdularum, quadrum super detectarum, &c. 1792. They have also been called the inferior, or smaller prostates, or glandulae accessoriae; they are of a roundish or oval figure, rather flattened, about the size of a pea, placed on each side of the lower end of the bulb of the urethra, and covered by the accelerator muscle. They may be easily demonstrated by cutting through the middle of that muscle, and reflecting it towards each side: they are of a reddish-grey colour, and composed of many little portions, united together by cellular substance. Each of them has a separate excretory duct, about half an inch in length, running obliquely forwards, and opening into the urethra by an aperture, which will admit a hog's bristle. They secrete a mucous fluid, of a reddish colour, which assists in lubricating the lining of the urethra. According to Morgagni, they are sometimes wanting. Haller has always found them, when he sought for them carefully. Cowper describes a third gland as being placed under the pubes in the curve of the urethra; but this has not in general been admitted.

The Penis.—After this description of the organs, which secrete and preserve the seminal fluid, or form other liquors which are added to the produce of the testicles, we proceed to show how this is conveyed to the place of its destination in the female. The urethra is a common passage for the semen and urine, commencing at the bladder, continued along the penis to its extremity, at which it opens, and facilitating, by its connection with this organ, the transmission of the secreting liquor to the organs prepared in the generative parts of the female. The penis is a very leading character in the structure of the male, and is the f&deg;st of enjoyment in the act of copulation. Its form is elongated, and nearly cylindrical; it is placed at the middle and lower part of the abdomen, in front of the lymphatics, and at the bifurcation of the lower limbs. When not erected it is soft and pendent, hanging in front of the scrotum. Its length and size are not constant, even in this condition, in the same individual: for there are numerous degrees between the considerable diminution of bulk produced by the operation of cold, and the swelling, which precedes erection, in any of which the organ may be found according to circumstances; yet there is a middle state, in which it is commonly found, which is not the same in all individuals. In the erected state it is lengthened, enlarged, changed in its direction, and rendered, by the swelling of the urethra, somewhat triangular; a slight curvature may be observed in it at this time, adapted to the direction of the vagina. The increase in the length and size of the penis is always the same in the same individual; and it is more considerable in proportion as the dimensions of the organ in its state of repose are greater: but this is not constant. We may notice a superior and inferior surface, two sides, an anterior and a posterior extremity.

The upper surface, named the dorsal, or back of the penis, is inclined forwards; it is turned towards the abdomen, and becomes posterior in the erected state. A large vein runs along its middle, and sometimes there are two trunks. The inferior surface, turned backwards, is placed against the front of the scrotum; it forms a prominent line from the course of the urethra, and the integuments in this situation have a longitudinal rough mark, called the raphe, continuous with a similar part in the scrotum. On each side of this middle prominence there is a superficial depression, where the urethra is in contact with the corpora cavernosa. The two sides of the penis are rounded. The posterior extremity, called all the root of the penis, is divided into three portions, which will be presently described, viz. the urethra in the middle, and the two corpora cavernosa, one on each side. The anterior extremity presents the glans and prepuce.

The penis is made up of various parts, each of which serves some particular purpose in the functions of the organ, considered as an instrument of reproduction. It. The corpora cavernosa, making up its chief bulk, soft and loofe in the state of repose, are so organized as to become very suddenly increased in size and hardness, in consequence of the operation of certain stimuli. They are the penis is rendered capable of introduction into the female vagina. 2dly. The urethra, by which the secreting liquor is conveyed, is a membranous canal, surrounded by a vascular substance, called corpus spongiosum, which is susceptible of the same change in erection as the corpora cavernosa. 3dly. The glans is a small organ, consisting of a continuation of the corpus spongiosum, covered by a highly organized and acutely sensitive skin, the excitation of which, in the act of coition, determines the discharge of the seminal fluid through the urethra. The penis poises as external cutaneous covering, which is simply contiguous to the glass, but united to the corpora cavernosa and urethra by cellular substance.

The corpora cavernosa, or crura penis, are two nearly cylindrical bodies, of a very firm texture, united laterally in the greatest part of their length, but separated from each other behind, like the branches of the letter Y, and terminating by slender, conical, and pointed extremities. The fixed behind to the rami of the ischii and pubes, advance forwards and inwards, approximating to each other. In front of the crura cavernosa is the corpora cavernosa, in the plural number; but their conformation into one body has induced Sylvester, and some other modern authors, to admit only a single corpus cavernosum, bifurcated behind for a double insertion into the pelvis. The single body, formed by the union of the two crura, to which the bulk and firmness of the penis are almost entirely owing, is flattened above and below, and presents two surfaces, a superior and an inferior, on each of which there is a longitudinal groove, corresponding to the septum, which is within the corpus cavernosum. That of the upper surface is the final, and lodges the great veins of the penis; the inferior, broader and deeper, receives the urethra, to which it is united.
SIDE of the penis, and all the spongy substance removed; the
septum will then be found continuous, by its two edges, with
the fibrous membrane, and composed of strong whitish fibres,
not forming an entire plane, but leaving intervals be-
tween them, at which the two sides of the corpus cavernosum
communicate freely. From this structure the name of septum
peciforme has been derived. The intervals between the
fibres are larger towards the inferior than the superior edge
of the septum. At the part where the two crus meet to-
gether, the septum is complete, it degenerates into separate
fasciculi towards the opposite end of the organ, and the in-
tervals between these are more considerable, as we approach
neater to the front extremity.

The dimensions of the penis are determined in great mea-
sure by the corpus cavernosum; and to this body the organ
owes that firmness in the erected state, which enables it to
fulfil its office in the business of generation.

Each of the crur penis gives attachment at its origin to a
tolerably strong muscle, named the crus penis, probably,
because when a power, capable of producing the effect in-
dicated by that name, was sought for by anatomists, this
muscle seemed to be their only resource. At present the
name appears very ill adapted, since the muscles in ques-
tion obviously draw the penis downwards and backwards,
instead of upwards and against the pubes. Those who ex-
plain the erection of the penis, by the compression of its vein,
should find out a power capable of elevating the organ
against the bone, and of carrying it forwards. It has a ten-
duous origin, below the attachment of the crus penis, from
the inner surface of the tuberity, and radius of the ilium.
It passes forwards, upwards, and a little inwards, and is firmly
implanted in the fibrous membrane of the crus penis.
It will draw the corpus cavernosum downwards, so as to bring
it more nearly into a direction, suitable to the cavity of the
vagina; it has a finial power of shortening the crus penis,
and thereby expressing the blood into the anterior part of the
organ, so as to increase its turgescence. Its origin and
course render it completely incapable of compressing the
large vein of the penis.

The urethra, which, in the female, belongs only to the urin-
ary passages, constitutes moreover in man an essential part
of the generative apparatus. Its length is very considerable,
and its organization very complicated, in consequence of the
latter office. It has connections with almost all the parts
belonging to this apparatus; the ejaculatory and prolate
ducts open into it; it is closely connected to the corpus
caavernosum, and terminated by the glans. In the male sub-
ject it forms a canal extended from the neck of the bladder
to the end of the penis, and giving passage to the urine and
femen. Its length, which varies in different individuals, and
in subjects of different ages, is about nine or ten inches in the
adult. At its origin it penetrates the prolate, passing for-
wards and downwards; it goes under the symphysis pubis,
and then ascends in front of that part, between the two
crura penis, in order to reach the inferior surface of the
corpus cavernosum, and becomes attached to the channel
which we have already described. Being thus united to
the corpus cavernosum, it runs along the whole length of that
body, and follows its direction. Lastly, it traverses the
glans penis, and opens at its extremity, by a vertical slit
with slightly rounded edges of a bright red colour. Hence
the canal forms in its course curvatures resembling those of
the letter S; but this is only when the penis is relaxed; for,
in the erected state, the curvature in front of the pubes,
of which the concavity is turned downwards, is entirely effaced,
and that only remains, which is below the pubes, and of
which the concavity faces upwards.

The
The canal is divided into three portions, distinguished from each other by their organization. The first, of about an inch in length, which passes through the prostate, has received no name; the second, of about equal extent, continued from the prostate to the bulb, is called the membranous portion; the latter corresponds above to the inferior surface of the symphysis pubis, but is about half or three quarters of an inch below the same. Below it is connected by the circular substance to the surface of the rectum, and at the sides, the front edges of the levatores ani are in contact with it. This part of the canal has been called the membranous portion, from a motion that the membrane of the urethra was covered here by no external investment, but in fact it is closely surrounded by a thick stratum of muscular fibres. The most interior of these are circular, and lie close upon the membrane of the urethra. Mr. Wilson has lately described some fibres, arising from a double tendon from the arch of the pubes, depending on each side of the urethra, and united under the canal. (See the Medico-chirurgical Transactions, vol. i.) These fibres are connected in front with the accelerator urine, and behind with the levatores ani. They will comprise the canal when they contract, and, by closing it at the time of emission, will prevent the seminal fluid from being driven backwards by the action of the accelerator.

The third portion of the urethra, including all the rest of the canal, is called the spongy part. It begins by an oblong rounded portion, named the bulb of the urethra. This is situated below the union of the crura penis, between which it makes a remarkable prominence. Below, and on the sides, it is covered by the accelerator urine (see Accelerator), and by Cowper's glands. Together with the two preceding parts of the canal, the bulb forms the first curvature of the urethra, and its sides are strongly connected to the arch of the pubes by means of a fibrous expansion, termed the triangular ligament of the urethra. The latter part possesses the figure, which its name indicates; the base of the triangle is turned downwards, the apex upwards, corresponding to the junction of the oils, pubes, and the sides are attached to the rami of the pubes. It is perforated by the passage of the urethra, which it holds firmly in its relative situation to the bone. In the rest of its extent, the spongy portion of the urethra corresponds above to the channel in the under surface of the corpus cavernosum. Below, it is covered near the bulb by the accelerator, then by the cellular substance of the serotum, and afterwards by the integuments of the penis.

The diameter of the canal is by no means uniform in its whole length. It is large in the middle of the prostate, and smaller where it enters and leaves the gland. The canal is here rather flattened laterally. In the membranous portion it is perfectly circular, but small in its size; and the narrowest portion of the whole canal is just where the bulb and membranous part join. In the bulb it is again considerably enlarged, and after contracting slightly, prefers a cylindrical figure and uniform size to the base of the glans. There it again dilates, and forms what some anatomists have called the fossa navicularis; its anterior opening is somewhat narrower. Mr. Home took the trouble of ascertaining the dimensions of the canal by filling it with wax, and measuring the cast thus formed. The length was nine inches; from the external orifice to the bulb, seven. The membranous portion was 1½ inch, and the prostatic portion of the canal half an inch. The diameter of the cast, at a of an inch from the external orifice, was 9½ths of an inch in a subject of 80 years, and 7½ths in one of 30 years; at 1¼ inches from the external orifice 7½ths; at the bulb of the urethra 12½ths; in the membranous part, immediately adjoining the bulb, 7½ths; in the middle of the prostate 11½ths; at the neck of the bladder 9½ths. Home on Strictures, vol. i. p. 24, and 25.

The situation of the eminence, on which the ejaculatory ducts open, called the vesicostomum, in the prostatic part of the urethra, and its figure, have been already noticed; as well as the openings of the prostatic ducts in the same part of the canal. In the rest of its extent, the internal surface of the canal possesses a reddish colour. In the membranous and spongy portions, longitudinal folds are observable, disappearing on extension. These are not seen in the prostatic, nor at the glans, because the firm texture of the parts which adhere very closely to the mucous membrane, forms which are constantly smooth. Hence the diameter of these parts is nearly uniform at all times. The sides of the canal exhibit openings of numerous small oblique ducts, frequently named after Morgagni. These are only seen in that part of the urethra which is in front of the bulb, and are sometimes called lacunae; their number and size vary in different subjects. They run from behind forwards, and terminate by simple oblique orifices. They are always very numerous about the fossa navicularis, from which some have explained the circumstance of this part being particularly affected in gonorrhœa. They consist of short canals, formed in the membranous fibres of the urethra, lined by a continuation of the internal membrane of this canal, and about large enough to admit a large hog's bristle. They are of various lengths, but commonly about a quarter of an inch. Sometimes several smaller join into one larger duct. If carefully examined, their whole number will not be found less than 60 or 70. No glandular apparatus can be differentiated connected with them. In these tubes the mucous fluid is secreted, by which the surface of the urethra is lined, and defended from the action of the urine. Where these lacunæ do not exist, as in the bulb, membranous portion and prostatic, a protecting fluid is furnished from other sources, as Cowper's glands and the prostate. The fluid of the lacunæ seems to be a clear viscid secretion, similar in appearance and tenacity to the white of egg. In this form it can be expressed from the openings on the surface of the urethra. Under various circumstances of disease it is increased in quantity, and variously altered from its natural properties, as in gonorrhœa and gleet, and in stricture. In some of these instances, it is a clear, transparent, viscid fluid, being the natural secretion in a more abundant form.

The sides of the urethra are differently organized in different parts; it is lined indeed throughout by a mucous membrane, but this is covered externally by very different structures. Where the canal is passing through the prostate, the sides are formed merely by the mucous membrane, closely united to the gland by a dense cellular texture. The firm substance of the prostate is intimately connected with the canal, and, as it is placed in the bend of the urethra, is particularly liable to injury in the employment of the catheter. Even here the membrane is covered by a dense cellular texture, continued from the prostatic, and by the muscular fibres already described. In the spongy portion of the urethra, the sides of the canal are covered by a substance of peculiar organization, analogous in its effects to that which fills the corpora cavernosa penis. This is called corpus cavernosum urethrae, or corpus cavernosum.
crum penis and below the canal of the urethra, sometimes bearing a slight appearance of furrows through the two lateral parts by a middle line, and terminating behind by a rounded end. The bulb corresponds only to the inferior surface of the urethra; but a thinner layer of the corpora cavernosa, continued from the bulb, covers the urethra on all sides in front of that body to the end of the canal. Here it is again increased in quantity, and reflected over the anterior extremity of the corpus cavernosum penis, to form the glans. The spongy fibres surround the urethra uniformly on all sides. It is closely connected to the corpus cavernosum above by cellular substance, and by vessels which are seen when the urethra is detached from its channel; below and on the sides it is covered by a cellular sheath, common to it with the corpus cavernosum penis. The external surface of the corpus spongiosum consists of a thin but compact fibrous layer; and the interval between this and the mucous membrane seems to be filled by a very fine cellular net-work, the cells of which contain venous blood. The tenacity of the external layer occasions the part to possess a livid colour, as the time is different. This net-work is covered in the glans by a highly organized species of skin, through which the colour of the venous blood is not discernible. The corpus spongiosum does not consist, according to the common opinion, of a cellular texture; but it is made up of very small and repeatedly convoluted veins, as may be ascertained distinctly enough by inspecting attentively the surface of it, when successfully injected: this structure is more evident in some animals, as particularly in the dog.

The bulk of the corpus spongiosum depends on the quantity of blood which it contains; and this part admits of the same distinction, as the spongy substance of the corpora cavernosa penis, and for the same purposes. Air, impelled into any part, finds its way readily over the whole extent of the substance, and the same circumstance may be observed of injection. It may be readily injected from the large vein at the back of the penis; but the valves sometimes prevent the success of this attempt.

The canal of the urethra is lined by a mucous membrane, continuous with the lining of the bladder at one extremity, and with the cutaneous covering of the glans at the other, and sending prolongations into the mucous linings of Morgagni, the ducts of Cowper's glands, the ejaculatory ducts, and those of the prostate. Its surface is perfectly smooth, excepting the longitudinal wrinkles which are effaced by extension. The colour is a bright red at the external orifice, and in the fossula navicularis; in other parts it appears pale, when the blood has been expressed from the corpus spongiosum. But the injection of coloured fluids proves that it receives every where an abundant supply of blood-vessels. Its substance is very thin, and the opinion of its being covered by a continuation of the epidermis does not seem to be at all well-founded, as there is a well marked line of separation at the glans, and no cuticle can be shown in the canal. The external surface is rough and cellular for its connection to surrounding parts. No appearance of muscular structure can be discerned in any part of the membrane. The introduction of an instrument shows this membrane to possess acute sensibility; and the repetition of the practice evokes the force of habit in blunting such feelings. The first time of passing a bougie or sound is sometimes attended with fainting, and almost always with sharp pain, but after a few times, no unpleasant sensation is excited. The passage of the urine is attended ordinarily with no sensation; but this becomes most keenly painful when the membrane is inflamed. It has been much disputed whether or not this canal possesses a contractile power in its own living. The phenomena are strongly in favour of the affirmative, although no muscular fibres have been demonstrated. The temporary obstruction to the flow of urine, under circumstances of distress, and the sudden emission of this incontinence, can hardly be explained without allowing a contractile force to the membrane. The emission of urine from the canal is another phenomenon of the same kind. That the trumpet is extensible, and that it returns again to its original size, improved by the passage of instruments. Haller states that external stimulants will cause it to contract.

The glans is the body surmounting the anterior and upper part of the corpus cavernosum penis, and forming the front extremity of the organ, of which it augments the length in a trivial degree. It has the form of a cone, slightly flattened from before backwards, with its base obviously truncated. Its apex presents the aperture of the urethra already described. Below this, is placed the frenum connecting it to the pre-pucce; and on each side of this fold it fuses into a small convex protuberance (colliculi glandis). This part is called by Haller "fensus acernini fede." The glans cannot be laid to extend below the urethra, as that part belongs to the corpus spongiosum. Since the basis is obliquely truncated, the depth of the organ is very incon siderable at the two convexities already named; but it is much more considerable above, where it is produced over the corpus cavernosum, and terminated by a thick rising edge of a semi-lunar outline, with the convexity turned backwards, called the corona glandis. This margin, sufficiently thick and prominent to elevate the integuments, and cause a perceptible rising externally, forms the front boundary of a cul-de-sac, or gutter, caused by the reflection of the inner membrane of the prepuce over the glans. Below, the corona glandis is interrupted by a small groove, which extends to the orifice of the urethra, and gives attachment to the fold which forms the frenum. In some subjects this groove is hardly perceptible. The colliculi glandis are continuous below with the corpus spongiosum; the basis of the glans is hollowed out, and the anterior extremity of the corpus cavernosum penis is received into the concavity. In consequence of this structure, although the glans appears to be an inch or more in length, it makes very little addition to the length of the penis.

The substance of the organ consists of a spongy matter similar to and continuous from that of the urethra. Air or injected fluids pass readily from one into the other. This matter is made up, as in the urethra, of convoluted veins, and it admits of the same changes of laxity and erection from the same causes. Sometimes there is an appearance as if the corpus spongiosum urethrae and the glans were separated from each other by a septum. The substance of the glans is always more dense, and contains less blood than that of the urethra. The surface of the organ is covered by a very vascular and delicate production of the integuments, continuous towards the apex of the glans with the mucous lining of the urethra, and at its basis with the inner layer of the prepuce. This covering is very thin, and smooth and soft to the touch. Its external surface is composed of a delicate epidermis; this is succeeded by a layer of the true skin, of a very soft and delicate structure, covered with numerous small villous processes, which are most distinctly seen about the corona glandis. The most favourable method of observing these villi is to plunge the part in boiling water, which separates the cuticular covering; they are then visible in vain numbers over the whole surface, giving it an irregularity in its appearance. This circumstance in the structure of the glans was first demonstrated by Albinus (Annot. Academ. Lib. iii.) and is admitted by Ruych and Winflow, although
although some anatomists have questioned it, probably be-cause the demonstration is rather difficult. That the nerves of the organ are contained in these papilles, as they are in the tongue, and that the exquisite sensibility of the glan-des, from this organization, is rather matter of probable conjecture, than the result of direct proof. The blood-vein-els of this cutaneous production are numerous, so that a general redness is produced by minute injections. The op-posed surfaces of the glans and prepuce are fringed over with a white, friable, and mucous substance, of a very pecu-lar colour, moistening the parts and preventing the efflux which might otherwise follow their mutual attrition. In animals there are manifest glands to secrete this substance, and an apparatus of glandular structure defined to the same office has been described in man. This kind of febaceous matter is formed in other situations of the body by peculiar glandular organs, as in the eyelids by the Meibomian glands; and the notion that it is deposited by the urine, which is con-trary to all observation, and to every thing we know of the properties of that fluid, would be immediately overturned by the fact, that a similar deposition occurs under the prepuce in the female, where the urine could not form it. Although in many subjects no glands can be seen, they are occasionally obvious enough, and are now universally admitted, under the name of glands of the glans. Morgagni, in his Adversaria, has given a very particular de-scription of them, and Haller confirms his statements. They are hardish, white, and very small bodies, particularly ob-servable about the corona glandis, and in the channel behind that part, where the prepuce is reflected. Morgagni also mentions them near the frenum in the prepuce. "I have seen," says Haller, "five rows of them in the corona, but their number diminished towards the frenum, so that no more than two rows could be seen." They can be observed most advantageously when the cuticle has been removed. That the orifices of these bodies can be seen, and their sebaceous contents squeezed out, is not so clearly ascertained; but both these facts are affected by competent witnesses. They may be rendered more evident when enlarged in dis-ease; and might be mistaken for venereal pimples, if their symmetrical arrangement did not throw light on the appearance. That the matter secreted by these glands accumulates under the foreskin, in the form of a white, soft, and greasy sub-stance, where the necessary attentions to personal cleanliness are neglected, and that, in hot weather, it may become acid and irritating, so as to produce excoriation and even ulceration, are well known facts. The inhabitants of warm cli-mates are chiefly exposed to these inconveniences, and the most important advantage of circumcision consists in its eli-viating such accumulations. Hence we know that Christians, living under the burning sun of Senegal, submit to this operation, and that uncircumcised Egyptians, living in the Eail, very frequently experience the ill effects arising from the source just alluded to. For this reason Gibbon de Cau-lace, a celebrated surgeon of his time, about the middle of the fourteenth century, observed that circumcision was use-ful to many others besides Jews and Saracens: "propter quod non congregans forditates in radio balnei, et ex tempore, et fecon-dent ipsum." Cirurgius, tr. vi. docir. i. p. m. iii. The glans penis polishes a very exquisite sensibility, particu-larly near the corona where it is most plustly by the pre-puce; this feeling is only observed on certain occasions, and is the source of that physical sensation experienced at the expulsion of the seminal fluid. It swells and becomes firm in the act of erection, as well as the rest of the penis. The cutaneous covering of the penis is continuous, at one end, with that of the frenum and pubes, and at the other with the prepuce. It is thin, furnished with numerous febaceous glands, particularly at the under surface, and marked in that situation by a rough line, called the raphis, running along the middle of the organ, and continued with a similar one on the frenum. It is darker coloured than the integu-ments in general, and has a few hairs towards the root of the organ. The cellular texture connecting the skin to the penis is very loose, and contains no fat except close to the pubes; hence the skin adapts itself with the greatest facility to the varying bulk of the organ, falling into wrinkles in the everted condition. It is continuous with the cellular substance of the frenum, glans, and pubes, and air passes readily between them. Towards the surface of the corpus cavernosum it becomes more dense, and assumes the form of a regular membranous covering; it is more and more loose towards the surface, and has, when inflated, a cottony appearance. The supraperineal ligament of the penis is placed at the root of the organ, which unites to the skin of the pubis. It consists of a dense, cellular, elongated, and flattened band, proceed-ing from the front of the skin of the pubis, running along the cellular tissue of the organ, and expanded under the skin. Its limits and figure are not very determined, and the knife of the dissecteur often influences its size and appearance.

The prepuce or foreskin is a loose fold of the cutaneous covering of the penis, continued over the glans, without adhering to it, and affording a more complete covering to the extremity of the penis. Its length varies in different individuals; sometimes it is produced considerably in front of the glans, and its opening is then generally small. Its ex-ternal surface offers the same structure and appearance as the integuments covering the body of the penis, and is smooth or wrinkled, according to the state of the organ. The inner surface, much softer to the touch, is in contact with the glans, to which it has a membranous attachment below, termed the frenum. The latter is continuous, on one side, with the internal membrane of the prepuce, and fixed, on the other, to the small longitudinal groove which we have described in the under part of the glans; and it ends in this situation by a prominent line fixed to the very opening of the urethra. The frenum limits the extent to which the retroc-ision of the prepuce can be carried; but allows the organ either to be brought sufficiently forwards to cover the whole glans, or to be carried backwards far enough to expose its whole surface. In the latter state the frenum is on the stretch, and, s the prepuce is moved forcibly in this direction, it may even be torn, as is colritio; this accident is particularly likely to occur, if the shortness of the fold allows only a par-tial exposure of the glans. Such a disposition of parts rendering the act of copulation painful, might require a sec-tion of the frenum. The base of the prepuce is attached on the inside, to the base of the glans, behind which it is reflected so as to line the small channel already described in this situation. Its apex forms a large round opening, of a sufficient magnitude, in general, to allow the part to be drawn entirely back behind the glans; and, even where it is more contracted, much larger than the orifice of the urethra. In some cases its opening is so small as not to allow the retrocision of the organ, and even to obstruct the flow of urine: this constitutes phimosis; in others, it can be withdrawn, but the tightness is so great that it may not be possible to reduce it; that is termed paraphimosis. It has been ascribed to some races in the East that the prepuce is unusually long, and that this structure particularly favours the accumulation of the matter secreted by the glandular odoriferous; so that circumcision has been more especially necessary on that ac-count.
The integuments of the penis, having arrived at the base of the glans, are continued forwards to its apex, as far as the opening of the prepuce. There they acquire a different organization, are folded back in a contrary direction, and terminate by a firm attachment round the base of the glans. The two layers, of which the exterior does not differ from the skin of the penis, except in being thinner, are connected by a stratum of very loose cellular substance, perfectly free from fat. The laxity of this cellular matter is so considerable, that, when the prepuce is withdrawn as far as possible, the two component layers are no longer in contact, but separated completely. The surfaces, by which they before adhered, are now applied to the corpora cavernosa, and the integuments of the penis are withdrawn towards the pubes. The prepuce seems designed to protect the glans, and defend it from the effects of contact, and rubbing against external objects. Yet it is not essential to the functions of the organ, that it should perform such a covering, as the destruction of it by circumcision or disease proves. The covering of the glans becomes afterwards thicker and harder, but the peculiar sensibility, excited in the performance of the generative functions, does not seem to be diminished.

The arteries of the male generative organs are chiefly furnished by the trunk of the pudendal; but the prolate and vesicule feminales receive branches also from the vesical arteries. The integuments of the external parts have branches from the perineal artery, and from the vellums of the thigh. The veins of the penis unite, for the most part, into a large trunk at the middle of the upper surface of the organ, which passes under the symphysis pubis, and opens into a large plexus surrounding the prostate and neck of the bladder. These end partly in the hypogastric veins, and partly in the inferior mesenteric. Besides these there are superficial veins in the prepuce and penis, terminating in the saphena and femoral vein. The lymphatics of the penis are divided into superficial and deep-seated. The former arise from the prepuce and integuments, and go to the superficial inguinal glands. The latter, arising from the urethra and corpus cavernosum, enter the pelvis in company with the branches of the pudendal artery, and join the hypogastric plexus. The nerves of the penis are of considerable force, and are derived principally from the 2d, 3d, and 4th sacral pairs.

Development of the Male Generative Organs.—As the function of generation does not commence until a considerable period after birth, the development of its organs in the human subject follows a law derived from this circumstance. They undergo no remarkable change from birth till the age of puberty, at which time the growth of the body is carried on in them with great activity. But they may be observed at an early period in the foetus, where, without having any remarkable advancement over other parts, they are considered as advanced, as if nature, in throwing out the organization, had wished to mark a decisive in the differentiating sexual traits.

In the infant state, we shall describe merely the condition of the teills and spermatic cord, as these are the only parts differing essentially at that time from the flin to which they are found in the newly born child. The size of the generative apparatus undergoes no remarkable changes, until the time of birth, and we shall therefore not notice them until that time.

There is no part in the body which undergoes so remarkable a change in its situation as the testicle; and, if it be interrupted in this process, a particular disease is very commonly occasioned. This organ, which, at its first formation, lies in the abdominal cavity at the inferior margin of the kidney, surrounded by the intestines, passes in the advanced periods of utero-gestation into the ferotum, and, as the canal through which it descended is shut up, never regains its original situation. At the time of birth, or very soon after, man and most other mammals have both testicles in the ferotum. This remarkable change was first noticed and described about the middle of the last century, when many celebrated anatomists turned their attention to it, insomuch that it is difficult to determine with whom the credit of being the first describer rests. The peculiar kind of rupture, called hernia congenita, which takes place when the defect of the testis is not accomplished in the regular manner, was the circumstance which principally led to the discovery, and more minute investigation of the facts. When surgeons began to reason on the causes and forms of ruptures, and the structure of the hernial sac, they naturally turned their attention towards these parts, and soon discovered that kind of the complaint in which the parts occupy the canal formed by the defect of the testis, and to which the name of congenital was given, because the state of parts having its occurrence commonly exists at the time of birth. The examination of the origin and peculiarities of this affection, led to a complete elucidation of the whole affair, in a series of excellent publications.

Reneaulme de la Garaune, a French surgeon, who wrote a treatise on ruptures in 1726, has the first hint on the subject; he speaks of the intestines and omentum escaping through the same canal at which the testis has puffed out. Among the numerous claims, which the great Swiss physiologist Pecquet, to the gratitude and respect of all medical men, is that of having given the first clear account of this matter. Indeed, there is hardly any part of the subject which has not been discussed and explained in the writings of this great man; and, as the observation of La Garaune is a single and indirect hint, we must allude the honour of the discovery entirely to Haller. (See Commerc. litterar. Norimberg. 1733, p. 197; 1737, p. 3. Programma, hernia- rum observationes aliquot. Goetting, 1730. Opuscula pathologica, Lauffame, 1755.) Soon after these publications, the subject was taken up in England by the Hunters. Dr. W. H. according to his brother's statement, had found both teills lying in the abdomen in a full-born child of seven or eight months, some years before the publication of Haller's "Opuscula Pathologica," and could not explain the matter to his satisfaction. Mr. J. Hunter published a very full and to his satisfaction of the origin of the hernial kind of its change in the testis. (See Medical Commentaries, p. 1. Lond. 1762, cap. ix.) About the same time the observations of Mr. Pott were made public. The vast practical opportunities enjoyed by this gentleman enabled him to explain all the pathological circumstances connected with the defect of the testis; his knowledge of the anatomy was probably derived from the sources already pointed out. (See account of a peculiar kind of rupture frequently attendant upon young born children, and sometimes met with in adults, London, 1765. Tentam on the Hydrocele, sect. 3. p. 12. Chirurgical observations and cases relative to ruptures, sect. 2.) Camper, who united so successfully anatomical and surgical pursuits, investigated this matter with considerable attention, and gave the results of his labours to the public in the Haarlem Transact, v. 6 and 7. The works of Neubarr and Lubitz are not to be omitted in this enumeration; that of the former is entitled, "De tumulis vaginibus testis et funiculi spermatici." Gieffel, 1750. The dissection of the latter, "De hernia congenita, inequa intestinum in contactu testis eff," Argenterat 1771, contains a very excellent and complete account of the whole matter, both in an anatomical

et and surgical point of view. In addition to these we have to notice, as containing good descriptions and useful information, the following more modern works. Girard's Appendix adjecta tabulis polliumias Santorini. Palletra nova gubernaculi testis Hunterianei et tumici vaginale anatomiae descriptio. Mediolani, 1777. Brugnione del testis in facti positio, &c. Wehrberg observationes anatomicae de testiculis, &c. in the Göttingen commentaries for 1778. Vizq d'Azy recherches sur la structure et la position des testicules, &c. in the Mémoires de l'Acad. des Sciences, année 1780. Martin commentarius de hernia congenitae ortus, &c. in the Nova Acta Reg. Scien. Upsal. v. 3. Sandifort icones herniae congenitae, Lugd. Bat. 1781, 4to.

Until the approach of birth, the testes of the fetus are lodged within the cavity of the abdomen; and may therefore be reckoned among the abdominal viscera. They are situated immediately below the kidneys, on the fore-part of the psoas muscles, and by the side of the rectum, where this intestine is passing down into the cavity of the pelvis; for in the fetus, the rectum, which is much larger in proportion to the capacity of the pelvis, than in the full-grown subject, lies before the lumbar vertebrae, as well as before the sacrum. Indeed the calf is nearly the same with regard to all the contents of the pelvis; that is, their situation is much higher in the fetus than in the adult; the tympanum of the colon, part of the rectum, the greatest part of the bladder, the fundus uteri, the Fallopian tubes, &c. being placed in the fetus above the hollow of the pelvis, in the common or great abdominal cavity. At this time the figure of the gland is much the same as in the adult, and its position is the same as when it is in the ferotum, that is, one end is placed upwards, the other downwards; one flat side is to the right, the other to the left; and one edge is turned backwards, the other forwards. But as the testis is less firmly connected to the surrounding parts, while it is in the joints, its position may vary a little. The most natural seems to be when the anterior edge is turned directly forwards; but the leat touch will throw that either to the right side, or to the left, and then the flat side will be turned forwards. It is attached to the psoas muscle along its posterior edge, except just at its upper extremity. This attachment is formed by the peritoneum, which covers the testis, and gives it a smooth surface, in the same manner as it envelopes the other loose abdominal viscera. The epididymis lies along the outer and posterior edge of the organ, in the same relative position, which it occupies at a more advanced age. This part is larger in proportion, and adheres behind to the psoas. When the fetus is very young, the adhesion of the testis and epididymis to the psoas is very narrow, the part is consequently more loose and prominent. As its age advances, the adhesion becomes broader and tighter. The blood-veeils, like those of molt parts of the body, commonly arise from the nearest large trunks; ven. from the aorta and cava, or from the emialgents. The nerves too come from the nearest source, that is, from the abdominal plexuses of the intercostal. In respect, therefore, to its supply of nerves and of veiiffs, this organ may be reckoned an abdominal viscera; and this circumstance of its peculiar situation before birth accounts for its being supplied afterwards from so remote a source.

The vas deferens, instead of running upwards from the lower end of the testis, as it does at a more advanced period of life, goes downwards and inwards in its whole course; it continues, indeed, in the direction of the epididymis. It turns iowards from the lower end of that organ, behind the upper extremity of the gubernaculum, which we shall de-
It will be plainly seen to be a continuation of the peritoneum; the testis and epididymis will be seen at the lower part of it; and the spermatic vessels and vas deferens may be observed, covered by the posterior part of the bag, in their whole course from the groin to the testis.

Before the testis has quitted the abdomen, the scrotum is small and corrugated, and contains nothing but cellular substance. This is loose, and yielding near the ring, but more dense and close below. Some have described a pouch of peritoneum passing through the ring, and therefore contained in the scrotum, previously to the descent of the testis; but this is not generally correct. There is no such pouch while the gland remains near the kidney. The parts about the ring are surrounded by such a loose and cellular texture, that, by drawing the gubernaculums downwards, the peritoneum is carried with it as to represent a small cul-de-sac.

The testis, too, after it has passed the ring, may be drawn up again into the abdominal cavity, in consequence of this laxity of the surrounding fibres.

In the human body then, when the testis has recently come down, it is contained in a membranous bag, formed of an elongation of the peritoneum, and communicating with the abdomen by means of a narrow process, advancing in front of the spermatic cord. The parts remain in this condition throughout life in the quadruped, but in man the communication between the membranous covering of the testis and the abdomen is soon cut off. The upper end of the canal is closed first, and the aperture is obliterated so speedily, that there is seldom any communication in a child born at its full time. The process of contraction is continued downwards, along the cord, to the upper end of the testis, at which it closes. Thus the tunica vaginalis testis, which was in the first instance a production of peritoneum, becomes entirely separated from that membrane; the peritoneal covering of the gland is the reflected tunica vaginalis.

"This contraction and obliteration of the passage seems," says Mr. Hunter, "to be a peculiar operation of nature, depending upon steady and uniform principles, and not the consequence of inflammation, or of anything that is accidental; and, therefore, if it is not accomplished at the proper time, the difficulty of bringing about a union of the parts is much greater: as in children who have had the face kept open by a turn of the intestine falling down into the scrotum immediately after birth. "The closing of the mouth and of the neck of the face, is peculiar to the human species; and we must suppose the first cause to be the prevention of ruptures, to which men are so much more liable than beasts, from their erect state of body." We feel some hesitation in admitting this reasoning as to the cause of obliteration: at all events, if we should acknowledge it, the frequent occurrence of ruptures must prove that nature accomplishes her end very imperfectly. "What!" says the same physiologist, "is the immediate cause of the descent of the testis from the loins to the scrotum? It is evident that it cannot be the compressed force of respiration, because commonly the testis is in the scrotum before the child has breathed; that is, the effect has been produced before the suppurative cancele has existed. Is the testis pulled down by the cremaster muscle? I can hardly suppose that it is. Because, if that were the case, I see no reason why it should not take place in the hedge-hog, as well as in other quadrupeds; and if the mammalian testis had this power, it could not bring it lower than the ring of the muscle."

The proceed which we have now described, is liable to some variations. In some individuals, the neck of the peritoneal elongation is not obliterated, so that the tunica vaginalis...
GENERATION.

radii communicates permanently with the abdomen, as in quadrupeds. Hence, we sometimes see hydromes particularly in children, when the fluid can be made to pass into the belly by puncture. If a rupture occurs in such individuals, it is contained, together with the testes, in the tunica vaginalis. Sometimes the testes do not descend before birth; when they pass down after this time, a part of the intestine or omentum is liable to descend with them, and is of course contained in the tunica vaginalis. One or both may be retained in the abdomen beyond the usual period. When the natural process has not begun, or has been interrupted before birth, it becomes afterwards very uncertain when the descent will be completed. It takes place most frequently between the years of two and ten, while the person is young and growing, being seldom delayed beyond the age of puberty. However, one or both of these glands may be retained in the abdomen through life. In this case, Mr. Hunter conceives that there is some imperfection in their formation. "I am inclined," says he, "to suspect that the fault originates in the testicles themselves." And again, "when both testicles remain in the belly, I believe that they are exceedingly imperfect, and incapable of performing the natural functions of those organs; and this imperfection prevents the disposition for their descent taking place." The writer of this article has seen two cases, where one testis had remained in the abdomen, and where the circumstances ascertained by anatomical examination corroborated the opinion of Mr. Hunter. In one, the body of the gland was not more than half its usual size: the epididymis, which was very imperfect, ran for about an inch behind the face of a horn, which had occurred in this individual, and did not join the body of the testis. The other case presented exactly the same appearances. A third instance has come to his knowledge, in which both of the testes remained in the abdomen, but were formed apparently perfect in their structure. In this case, it was underflood, that the ordinary functions of the glands had been executed in a healthy manner during the person's life.

The times, at which the changes in position already described take place, are most accurately noted by Viriiberg in the memoir above quoted. He gives a tabular arrangement of his observations on this subject, deduced from very numerous examinations, of which the following account contains the chief particulars. "At the age of one month and three weeks, the testes were close to the kidneys, with the smallkilf possible interval; the scrotum loose and edematous. At two months, the testes, exceedingly small, touched the kidneys; the gubernaculum very long, and the scrotum wrinkled and rather hard. Two months and one week, testicles very near the kidneys; spermatic vessels discernible through the peritoneum, like very fine threads; gubernaculum distinct. Three months, testes about the size of hemp-seeds, placed rather further from the kidneys, and at the edge of the pelvic. Three months one week and a half, the scrotum extremely small, and indeed fearfully deformable, so that the penis hung from a slight prominence of the skin. The small intestines coiled together in the upper part of the abdomen, far from the testes. The latter had descended further on the side of the pelvis; the gubernaculum very short. Three months and three weeks, the scrotum small and contracted: the testes more than three lines below the kidneys. Four months, the scrotum very small: the testes deeply placed, with their inferior ends touching the rings. A distinct canal of peritoneum on the left side, leading from the cavity of the abdomen into the scrotum, although the gubernaculum was not yet inverted. Four months and one week, the testes very high, nearly touching the kidneys; the gubernaculum long; no canal passing through the ring, which was perfectly closed. Eight months and two weeks, the testes near the ring, with a canal of peritoneum on each side, passing to the bottom of the scrotum. Five months and two weeks, both testes in the rings; so that they could not be seen until pressed towards the abdomen, when they appeared readily. Eight months, scrotum well formed, with its surface wrinkled, but empty. The testes had passed the ring, but remained in the neighbourhood of the groin; the right could be easily pushed back into the abdomen through the process of peritoneum, which was still open; but the left could not, as the communication was already closed. Nine months, testes in the bottom of the scrotum; the canal of communication perfectly closed on the left side; it was flat on the right by a soft cellular substance easily yielding to the probe. Nine months, both canals perfectly closed."

From the foregoing facts, the following conclusions may be drawn: 1st. Before the beginning of the fifth month the testes have not passed the ring on either side; but generally remains near the kidney: so that this situation may be depended on as a proof of the immaturity of a fetus. 2dly. Between the beginning of the fifth, and end of the sixth month, they are generally found about the ring; being in some instances above it, in some within the canal, and in others just below. 3dly. The scrotum in the first months, up to the fifth, is small in proportion to the body, sometimes less than in infants, but always empty; and containing cellular substance instead of the cavity, in which the testis is to be afterwards lodged. A broad and strong fasciculus of fibres (the gubernaculum) is contained in the midst of its cellular substance. 4thly. When the testes have first descended into the scrotum, the canal of peritoneum still opens to the abdomen, so that they can be easily drawn back into the belly, and sink down again. This is generally practicable, in fetuses, between the 7th and 9th months. The ordinary law of nature on this subject is, that the human subject, born at the expiration of the full term of utero-gestation, has both testicles in the scrotum. Haller's contrary statement, "ut rarissime fetus in lucem edamus, cum testiculis scroto inlatus," (Element. Physiol. vol. 7. p. 413.) has been completely disproved by the testimony of subsequent observers. Whether the canal of communication be generally closed before birth, is a point on which authors are not unanimous. According to Viriiberge, with whom Vicq d'Azur agrees, this is commonly the case. But the representation of Camper is somewhat different: this anatomist and Leflau-ó deceive, that the obliteration takes place earlier on the left than on the right side. Of 53 newly born children examined by Camper, 23 had the canal open on both sides, 11 on the right side only, and 5 on the left only. In six it was closed on both sides. In four both testes were contained in the abdomen; and in these only the right. In the excellent memoir of Viriiberge, already referred to, there is a table of 103 births observed by himself, in which the position of the testes was carefully ascertained. The proportion of premature to mature and perfect births was as 9 to 51, or in round numbers 1 to 6. All the children, whose weight did not exceed 5 lbs., came into the world at the beginning of the ninth month, or in the eighth, or even in the seventh month. Three of these had both testes in the scrotum, three in the groins, and three in the abdomen of the children born towards the end of the ninth month, 69 had both testes in the scrotum, 17 one or both in the groin, eight one in the abdomen, and three, whose weights were 5½, 6½, and 7½, both in the abdomen. In the 12 out of these 103 causes, where one or both testes remained in the abdomen, they were observed to descend on the days mentioned below.
GENERATION.

In one instance it passed down on the day of birth; the defect took place in three subjects on the second day, in an equal number on the third, in two on the fifth, and in one on the twenty-fifth. In the remaining individuals, they had not appeared on the fourth and fifth weeks from the time of birth; and as the children then left the hospital, the time of defect was not known. In three instances, the defect was observed to be accompanied with crying and convulsive motions of the limbs. Both testes had passed into the ferotum of one child, born at the end of seven months, and weighing only 34 lbs.; which must be deemed a rare occurrence. They have been seen in the ring in a fuscus of four months. Bichat, Anat. Defcr. t. 5. p. 234.

The colour of the organ, while in the abdomen, is greyish, and its form elongated. The epididymis is considerably larger in proportion than in the adult, and its head lies considerably above the testis: it is more loosely connected to the body of the gland. The circumference of the testis at this time is fuit and pulpy.

The penis, at the time of birth, although small, is well formed, and possesses an elongated prepucce, which completely covers the glans. The integuements of the penis, as well as those of the ferotum, are not distinguished in colour from those of the body in general. The rugae of the ferotum are not yet well marked. There is a small quantity of fat in the ferotum, and the fibrous covering, common to the cord and testis, cannot yet be distinguished. The vesicula feminales, in consequence of the position of the bladder, peculiar to this age, are nearly vertical in their direction, very small and collapsed, and not exhibiting the tubercles on their surface seen in the adult. Internally they contain a mucous fluid.

The corpus cavernosum penis is very short and small, and remarkable for the small proportion of its spongy subfiance, and the trifling quantity of blood which it contains. The latter circumstance is still more striking after a few years, in consequence of the increased thickness of the fibrous membrane: hence, as erection depends principally on the swelling of the spongy part of the corpus cavernosum, the penis of children, when erected in consequence of some sympathetic excitement, is hardly increased in size, and very little in length. The urethra, in the first years of life, is long; and its direction from the bladder to below the symphysis pubis is more oblique than in the adult. These two circumstances, in the formation of the urinary canal, arise from the bladder being situated higher in the abdomen, and from the superior aperture of the pelvis being more flattening. The prepucce is elongated, so as to give the penis a pointed termination. Its opening, always very narrow, may be so small as to prevent the discharge of the urine, or to render it impracticable to denude the glans. The latter circumstance constitutes congenital phimosis. The frenum is narrow and reaches to the opening of the urethra.

No great changes are observed in the organs of generation from the time of birth until puberty. Butted with the general organization of man, and particularly attentive to the bringing to perfection the agents by which he communicates with surrounding objects, to the putting in action the springs of his intellectual powers, nature seems, if we may use the expression, to forget the instruments of reproduction, which continue for a time stationary. If, during this long period, their organs undergo no important revolution, they partake slightly in the general growth. Each of them, considered singly, without increasing in any very marked degree, becomes more perfect in its organization, of which the principal traits may be more easily observed some years after birth. But these changes, which take place very gradually, are trifling when compared with those which happen at puberty.

Changes in the male Organs at the Time of Puberty.—In the two or three years immediately preceding this period, the testes are covered by a flight down, which appears generally before the beard. We may remark also, that its appearance is more constant, and its growth more rapid. In fact, the hair on the generative organs, although it is not completely developed for some years, has gained nearly its full length and thickness, while the beard is still thin and short. At this time, the hairs appear, the skin of the ferotum and penis loses its whiteness, and becomes more or less brown in conformity with the tint which it possesses in other parts of the body. The ferotum, hitherto contracted, becomes longer; the testis is removed to a greater distance from the ring, and the spermatic cord proportionally elongated. The penis becomes larger and longer; the frequent erections occasion the prepuce to appear shorter, and the glans to be a little uncovered. The various layers composing the ferotum are complete at this time. The testis is proportionally larger than the vesicula feminales and penis, as the exercise of the generative functions commences here. The vesicula feminales are still very small, even in a subject of 14 or 15 years. The canal of the urethra, as well as the other parts of the penis, is considerably increased, as may be seen by observing the stream of urine.

In old men the ferotum is generally soft and pendent, and external impressions are no longer able to bring it into the state of corrugation. The cellular subfiance which it contains is frequently the seat of watery effusion. The fibrous covering of the testis and cord is dense, thick, and easily demonstrable. The testis is small, soft, and waffed; but without any remarkable change in its organization: the volume of the epididymis, on the contrary, is equal to what it possesses in the adult. The spermatic cord is rather smaller, unless the veins should be in a dilated state. The vesicula feminales are collapsed, and the protrate becomes hard: the penis is constantly placid.

Physiology of the male Organs of Generation.—We shall describe, in the first place, the secreting fluid, as it appears when expelled from the body in the act of copulation; and shall then distinguish the various parts of this compound liquor. We shall exhibit the facts which have been ascertaincd concerning this interesting subject, just as we treat any other part of physiology: we shall either use such language as shall be intelligible, or pass over in entire silence every thing which relates to the production and development of the new beings, and the continuation of the species.

The fluid expelled from the urethra of a healthy man, under the influence of the venereal act, is white, inclining perhaps slightly to a blueish cast. But it is not homogeneous, as it contains thicker and more opaque mixed with a more thin and semipellucid matter. The latter is more abundant in proportion as the subject is weaker, and the act more frequently repeated. From this difference in the appearance of its component parts it has been sometimes compared to congealed milk. It is of a viscous or glutinous nature, and therefore readily entangles air; hence it becomes frothy if rubbed in a mortar. When first discharged, its consistence is about equal to that of a thick cream; but as it cools, the opaque mucilaginous part becomes transparent, and acquires greater consistence. In about twenty minutes after its emission the whole becomes liquid; at this time, too, it is transparent, having deposited a sediment of a whitish matter, resembling a mass of slender rags. The liquefaction is not owing to the absorption of moisture from the air, for it loses instead of acquiring weight during its exposure to the atmosphere; nor
GENERATION.

The feminal fluid, in its recent state, contains an immense number of animalcula, called sometimes vermiculi spermatici. They have a rounded head, with a gradually tapering tail, not straight, but alternately bent to either side. They are 1000 times smaller than a hair, and 10,000 times more slender than one of the tubuli testes: so that, according to Leeuwenhoek, 216,000 of them would go in a sphere, equal in diameter to the breadth of a hair. Their length has been estimated at 0.244, 4th of an inch. They are found in all quadrupeds, in reptiles, birds, fishes, insects, and even in tellacous animals. Some variations in figure are observed in different animals: but their size is nearly uniform in all. They are no larger in a whale than in a small fish. They are said not to exist in children, nor to be observable after frequent coition, nor in old subjects; but only in healthy and prolific females, so that their presence may perhaps be deemed a criterion of the maturity and perfection of that fluid. The feminal vermiculi were first observed by a German youth, Lewis Hamme. He showed living animals in the human female to Leeuwenhoek in the year 1677. This indefatigable observer immediately employed himself on the subject, and in the same year sent an account of the phenomenon, with drawings of the vermiculi in the dog and rabbit, to the Royal Society at London. (See Phil. Trans. n. 143.) The communication was received with great applause, the facts were flown to King Charles II., and admitted by all. At the same time they were examined and described in France, and, as far as the mere demonstration goes, they were universally admitted in the literary world. Nicolas Hartsoeker claimed the discovery, but not till the year 1678. (Essais de Dioptriques, p. 227.)

It has been alleged that these animalcula are not peculiar to the female, but that they are found in various other animal fluids. Accurate investigation has not substantiated this objection; but, on the contrary, shows that they are peculiar to the femal fluid. Others have denied that they possessed tails; and Buffon, in particular, represents the facts very differently from Leeuwenhoek. (Histoire Nat. Gener. & Partic. t. 2. p. 176 & seq.) His representations being supported by those of Torberville Needham. ( Nouvelles Observations Microscopiques, p. 213.) M. de Buffon observed the fluid from the femal vessels of a dead human body; yet warm. It was full of filaments moving about, and branching into many parts. The filaments swelling burst, and many ovular corpuscula escaped, which still remained attached to the filament, as by a thread: then they oscillated like a pendulum, and during those oscillations the thread extended. The corpuscula, at length detached from the filaments, traversed the most fluid part of the female, along with their filaments, the extreme length of which impressed their motions, and they seemed to him to endeavour to free themselves from it. Having diluted the female with rain water, he more than once observed that each ovular corpuscle had a double motion of oscillation, and of progression. In two or three hours the femal matter acquired greater fluidity, the filaments disappeared; the number of corpuscula increased; the thread contracted; the oscillations relaxed; and the progress motion increased. In five or six hours the ovular corpuscle, having lost the threads, resembled animals more than ever; not only because their quickness in swimming was greater, but because they directed their course to every quarter. In twelve hours the activity of the corpuscula was great; and some revolved upon their axis; others changed the ovular to the globular figure under the observer's eye; some divided atunder, so that one formed two.
At the end of one day the number diminished; and, upon the third, none were to be seen. In other fermen, which seemed to be entirely filamental, the ovular corpuscula did not proceed from the filaments; but these, dividing in two, were metamorphosed into corpuscula. They were embarrased by a thread. The longer it was, the more it impeded their motion; but it gradually contracted, and was at last completely destroyed. The figure of these ovular corpuscula resembled that of those of infections. They swam with a progressive motion, though, at first, the thread occasioned a simple oscillation. He observed similar phenomena in the feminal fluid of other animals. Sometimes the corpuscula altered their figure; sometimes they divided into two. Buffon conceives that they cannot properly be deemed animals, and he forms of them a particular class, under the term of *organic molecules*, which are particles diffe-
milated through all matter, original, incorruptible, animated, and always active. Nor does he hesitate to confide the formation of the animated universe to these molecules. Subsequent researches have not confirmed these opinions of the French naturalist. That the feminal vermiculi have tails is proved by numerous accurate observers, and is particularly supported by the testimony of Haller. (Elem. Physiol. t. 7. p. 521.) It seems questionable whether Buffon ever saw the real femoral vermiculi; for the latter live at most only for a few hours after the discharge of the fluid, while those observed by him remained for some days. And his remarks on the whole seem much more applicable to the microscopic animalcula observed in vegetable infections, as well as in all liquors exposed to the air. This point seems clearly proved by the labours of Spallanzani, who made a vast number of observations on the subject, and fet the whole history of the femoral animalcula in so clear a light, that no doubt can remain on the subject. The general result of his researches tends completely to correct the original remarks of Lecu-
vendoece. (See his Treats on the Nature of Animals and Vegetables. Edinb. 8vo. 1799.) He observes that his experiments on fresh human semen presented him with totally different results from those described by Buffon, but as he could not regard Buffon's statements as purely chimerical, he thought the contradiction might be reconciled by the sup-
position that the French naturalist had described animals of a different kind. "I had remarked," says he, "that there is no part of an animal which, when infusoried, does not give existence to a particular kind of animalcula. They are produced indifferently, by the muscles, brain, nerves, membranes, tendons, veins, and arteries. The same holds good of the blood, serum, milk, chyle, saliva, &c. mixed with water, or even by themselves. I had not yet made experiments upon the human semen for this purpose; but it was most probable, that the putrefaction of this liquid would give existence to particular beings. May not M. de Buffon have confounded this with the feminal vermiculi, and ascribed to the latter the properties and phenomena exhibited by the former? I determined to ascertain this fact by observing what happened successively to the semen, when long preserved in a water-
glass. I made my first experiments on the human feminal fluid. The vermiculi died in three hours and a half, and were precipitated to the bottom of the glass. Upon the fifth day, the feminal fluid began to exude a fætid and disagreeable odour; but I could perceive no animated being: only, upon taking some drops from the bottom of the glass, I observed the dead bodies of the vermiculi apparently very entire. The seventh and eighth days I saw no change, but the factor increased. On the ninth I discovered very minute animalcula, their size nearly equaling that of femoral ver-
iculi; but they had no tail, and greatly resembled most minute spherules. Like animalcula of infusions, they sometimes dropped at little segments of corrupted semen; sometimes their course was very rapid, retrograde, rising and sinking in the fluid; in a word, they poissified every property of infusion animalcula. They were seen in every stratum of the semen; and those at the bottom put in motion the dead bodies of the feminal vermiculi, which were still entire, and remained for some days longer." Two or three successive generations of these animals were observed, as in the case of other animalcula. When the semen was exposed to a greater degree of heat, they appeared at a more early period, even as long as twenty-three hours from the removal of the fluid in the dead body. In one instance they were observed to propagate by a spontaneous transverse division of the body. "These facts sufficiently satisfied me that Buffon had erroneously ascribed to the femoral vermiculi properties belonging only to the animalcula of infusions. Let us, in a few words, collect the circumstances. According to this author, after a certain time, the vermiculi were deprived of their tails. He should have said that the animalcula of infusion came in the place of the vermiculi, which were already dead, and precipitated to the bottom of the liquid. He was arrested by their first appearance; and took them for feminal vermiculi deprived of their tail, which in truth they often very much resemble. When diffigented from the tail, Mr. Buffon adds, they acquire greater activity. This was a necessary consequence of the first mistake. When the infusion animalcula had taken place of the vermi-
culi, their increased agility could not be unobserved, since the animalcula move with much greater quickness than the vermiculi. This erroneous supposition being admitted, Mr. Buffon had to relate, as he has done, the remainder of the phenomenon. He had to speak of the imaginary changes of the vermiculi, of their division, and their diminution, with the more confidence, as his opinions had to be confirmed by a repetition of his experiments, if not upon all, at least upon many species of infusion animalcula in the semen." p. 135—142. The following account of the femoral vermiculi is taken from the work of Spallanzani already quoted, which contains the most complete account of the subject.

When the semen begins to dissolve, if it be examined with a magnifier of small power, the irregular parts seem to be in an indistinct flow agitation, produced by globular cor-

puscula, of which each possesseth a sort of filament, or short appendage, about six times the length of the body. They have two motions; one oscillatory, from right to left, and vice versæ, in which the appendage is curved from one side to the other: the other is progressive, the vermiculæ transporting itself by oscillation. They strike against every obstacle, and when in considerable numbers, make a thousand contor-
tions to elude, at last taking that way where they feel the least resistance. Thus they are in continual motion. In twenty-three minutes the motions of oscillation and pro-
gecession diminished; and in an hour and a half it had lessened to much, that a very small number of corpuscula poissified any power of motion. In general, the progressive motion scales before the oscillatory; so that, at last, the corpusculæ merely bends from right to left, and reciprocally. They continue fixed to the same spot, until the oscillatory motion insensibly dies away. After all motion is gone, the corpusculæ remain entire in the fluid, and then they are bet-
ter few than even when the liquid is diluted with water. Each corpusculæ is not properly globular, but elliptic, and the appendage is not only longer than it appears, but the breadth is not equal throughout like a thread, but increases
as it approaches the body. Water or other fluids rendered them immediately motions. They may be sometimes offered, in the clots of the semen, before they have dissolved, attached by their appendages to the filamentous matter, they struggle to disengage themselves, and then swim about in the fluid. The motion continues much longer when the temperature of the atmosphere is increased: at 36 all motion had ceased in three quarters of an hour; at 49 in two hours; at 59 in three hours and a half; and at 81 they lived for seven or eight hours. The corpuscles were seen in the fluid obtained from the epididymis and testicles of various living and recently dead animals. That they are not formed, according to the sentiment of Buffon, from the filamentous part of the semen, is proved by this: that they are most abundant in the fluid part, and even do not exist at all in the clots, where they are examined in a very recent state, and freed as much as possible from the thinner part of the seminal fluid; while, the latter, at the same time, abounds with them. Nor are they generated, as Needham affirmed, by exposure to air. For Spallanzani saw them in the vaginal numbers, when the time employed in taking the fluid matter from the seminal vessels was warm, to present it to the microscope, did not exceed a second; and they were observed in the same numbers in seminal fluid carried without day by the epididymis of a living ram to the microscope.

Great care and attention are necessary in observing the appendages of these vermiculi, and hence they escaped the notice of Buffon. It is wonderfully slender, and at the same time transparent, so that too strong a light confounds it with the seminal fluid: the slider should be fine and thin, and the drop of fluid vary thin: and a microscope of a single lens is preferable to the compound one.

They live longer in close vessels, than when the semen is exposed to the air: and they also live longer in vacuo. The difference of time at which they die in these different situations amounts even to one, two, or three hours. "These facts prove that the air is noxious to the vermiculi, and the following prove that it is the cause of their being in continual agitation. With the blow-pipe I formed capillary tubes, one end of which Iimmered in recent semen; it ascended the cavity, filling the tube to a certain height. Breaking the tubes near to the part to which it ascended, I preferred this extremity to the blow-pipe, and immediately sealed it hermetically. I did the same to the other end, by which means the seminal fluid was deprived of all communication with the external air. I drew out the tubes, so that the thinnest of the tubes permitted me to see the vermiculi within. The peculiarities presented by the vermiculi in the tubes were very different from those of the rest. All, or at least most of them, had a singular mode of moving. Some had that fort of activity observed in those, which experience the influence of the open air. Others had a continued irregular motion; they changed from quickness to inactivity, and reciprocally. Others stopped entirely after reeling some minutes, resumed their former velocity; besides, they were not observed to run against the solid portions of the semen, but to avoid them by turning aside or retreating. Those peculiarities always succeeded better, and with more uniformity, when the tubes were kept warm. I have before said that the longest period of life, of the human spermatic vermiculi, was seven or eight hours, when exposed to the open air, but this period is greatly prolonged when they are included in tubes. In summer I have succeeded in preserving them two days or more; and in spring and autumn they have lived almost three." P. 156.

Cold, near to that of freezing, renders the vermiculi motionless; but they are recovered by the application of heat.

A temperature of 131° kills them; but the animalcula produced in the semen by putrefaction are destroyed by a temperature of 108°.

To this account of the seminal vermiculi we subjoin the following reflections on them by Boumet, oberving only that we are in a state of the most profound ignorance of all the points alluded to in his questions.

"The vermiculi are, of all the animalcula of liquids, those which have most excited my curiosity; the element in which they live, the place of their abode, their figure, motion, secret properties, all in a word, should interest us in so singular a kind of minute animated beings. How are they found there, how are they propagated, how are they developed, how are they fed, and what is their motion? What becomes of them when the liquid they inhabit is returned by the vehicle, and mixed with the blood? Why do they appear only at the age of puberty; where did they exist before this period? Do they serve no purpose but to people that fluid, where they are so largely scattered? How far are we from being able to answer any of these questions!" Spallanzani’s Facts, p. 179. The reader may also consult, on this subject, W. E. von Glucken über die Samen-nusk infusions-thierchen, Norim. 1778, 4to.

The opinions of Leeuwenhoek concerning these vermiculi; e.g. that they are of different sexes, that they copulate, become impregnated and produce young; and that they are the rudiments of the future beings, to be conveyed by copulation into the body of the mother, and there developed; are destitute of all proof, and completely chimerical.

We have no accurate accounts of the sensible properties, nor any chemical history of the fluid separated in the teftis. When observed in the vas deferens or epididymis of man, after death, it possesses a light-brown or yellowish colour, and approaches in fluidity to water. It may be seen in animals, on cutting into the teftis or epididymis, much thicker, viscous, and of a grey colour. At least it has this appearance in a dog. The whole gland, in a healthy animal, is turgid with this fluid. The contents of the vesiculae deferentis differ in their appearance from the secretion of the tefticles. It is a brownish or yellowish fluid of light colour, semi-transparent, and often containing flakes or corpuscles, so as to vary in consistence in different parts of the bag. Exposure to the air produces no change in its consistence, as it does in the semen. Sometimes the contents of these bags are a clear mucous fluid. Mr. Hunter took the trouble of observing them, in two healthy persons killed suddenly, immediately after death. In one the fluid in the vesicle was of a lighter colour than is usually found in men who have been dead a considerable time; but it was not by any means like the semen either in colour or smell. In the other the contents of the vesicle were of a lightish whey colour, having nothing of the sinell of semen; and in so fluid a state, as to run out on cutting into them." (Obl. on the Animal Economy, p. 28.) Thus it appears that the fluid of these bags differs both from that contained in the teftis, and from the semen emitted in coition; consequently, that they are not mere secretions for the matters separated in the tefticles, but that they add to the secretion of that gland some considerable bulk of fluid, separated by their own vessels. The peculiar organization of their internal surface would have led us to expect this, as it exhibits an arrangement of parts found only where some secretion is performed. The same argument will lead us to assign a similar function to the enlarged portion of the vas deferens lying by the side of the vesiculae semen. The exact nature of the fluid separated in the vesicle
it is not known; nor have we any chemical analysis of it. In many instances it looks like a simple mucus; and there can be very little doubt, that in all cases the contents of these bags conflict chiefly of their own secretions.

The opinion, that the vesiculae perform a particular secretion, was held by Heller: "I have," says he, "no experiments of my own to prove that any thing is separated in those organs, and mixed with the fluid formed in the testes; but, however, that a secretion takes place here as in the gall-bladder." (Tom. Phyol. 7. p. 540.) Galen conceived that the mucus was generated in these parts; and Kiolan, Raych, and Swammerdam, were of opinion that they added something to the seminal fluid. The point has been most clearly proved by Mr. Hunter in a paper contained in his Observations on the Animal Economy, and entitled "Observations on the Glands situated between the Rectum and Bladder, and called Vescicule seminales." His chief argument is derived from the examination of the organs in persons who have lost one of the testicles by accident, or in consequence of disease. It is well known that this loss does not affect the generative powers, and that such individuals retain their sexual appetites and the faculty of procreation. We may consequently presume that they have afterwards had connection with women, and consequently had the action of emission, which must have emptied the vesicula of the castrated side, if it had contained semen; and, as the removal of the testis must have cut off all source of supply from that quarter, it should be found empty after death, on the supposition of its contents being ordinarily derived from the testes. Such cases afford an opportunity of making comparative observations between the vesicula of the perfect and that of the imperfect side.

"A man," says Mr. H., "who was under my care in St. George's hospital for a venereal complaint, died there, and was discovered to have lost his right testicle. From the cicatrix being hardly observable, it must have been removed some considerable time before his death; and the complaint, for which he was received into the hospital, is a convincing proof that he had connection with woman after that period. I opened the body in the presence of Mr. Hodges, the house surgeon, and several of the pupils of the hospital. Upon dissecting out, and examining the contents of the pelvis, and the structures surrounding the duct on the right side, I found that the vesicula deferens of the right side was smaller and firmer in its texture than the other, especially at that end next to the abdominal ring, near to the part that had been cut through in the operation. The cellular membrane surrounding the duct on the right side was not so loose as on the left; neither were the vessels which ramified on the right vesicula so full of blood. But upon opening the vesiculae, both appeared to be filled with a kind of mucus similar to that which is found in other dead bodies; and the vesicula on the right side was rather larger than that on the left. Whatever, therefore, may be the real use of these vesiculae, we have a proof from this dissection, that in the human subject they do not contain the semen.

"In a man who died in St. George's hospital with a very large bubonoccele, the testicle of that side was discovered to have shrunk lost its natural texture from the preface of the seminal fluid; and upon examining the testicle, with attention, there was no appearance of vesicula deferens till we came near the bladder, where it was a mottled as large as a nail. The vesicula of that side was found to be full as the other, and to contain the same kind of mucus.

"I examined the left testicle of a Frenchman on account of its being dissected. He was a married man, and died about a year afterwards, having been extremely ill for several months before his death. On examining the body, the vesiculae were both found nearly full; more especially that of the left side, which I suppose might be accidental. But upon examining the vesiculae of the left side, where it has along the side of this bag, and where it has a similar structure with the vesicula, I found it filled with the same kind of mucus; and this, I believe, is always the case, whether the testicle has been removed or not.

"A young man, a coachman, who had a disease in his left testicle, had it removed, at St. George's hospital, by Mr. Walker, in August 1785; and in February 1786 he returned again to the hospital, on account of uncommon pains all over him, and for which he requested to be put into the warm bath. But as he was going from the ward to the bath, he dropped down, and died almost immediately. The body was dissected, with a view to discover the cause of his death, and upon an examination of the vesiculae, the bag of the left side was as full as that on the right, and the contents in both were exactly similar.

"In dissecting a male subject, in the year 1755, for a side view of the contents of the pelvis, I found a bag on the left side, lying contiguous to the peritoneum, just on the side of the pelvic, where the internal lute vessels divide above the angle of reflection of the peritoneum at the union of the bladder and rectum. The left vesiculae was seen passing on to the bag; and, what is very singular, that of the right or opposite side crossed the bladder near its union with the rectum to join it. I traced the left vesiculae down to the testicle; but on following the right through the ring of the external oblique muscle, I discovered that it terminated at once, about an inch from its passage out of the abdomen, in a blunt point, which was impervious. On examining the spermatic cord from this point to the testicle, I could discover no vesicula deferens, but by beginning at the testicle, and tracing the epididymis from its origin about half way along, where it lies upon the body of the testicle, I found that it at first became fritillary, and soon after seemed to terminate in a point. The canal at this part was so large as to allow of being filled with quicksilver, which however did not pass far, to that a portion of the epididymis was wanting; and the vesiculae for nearly the whole length of the spermatic cord of the right side. On the left side the vesiculae began where the epididymis commonly terminates; and there was a deficiency of nearly an inch of the extremity of the epididymis. I then dissected the bag above-mentioned, which proved to be the two vesiculae; for by blowing air from one vesiculae I could only inflate half of it; and from the other vesiculae, the other half. They contained the mucus commonly found in these bags; but upon the most accurate examination I could discover no duct leading from them to the prostatic gland, nor any remains of one. In this subject it was evident that there was no communication between the vesiculae and epididymis; nor between these bags and the urethra. The caput gallinoginis had the common appearance, but there were no orifices to be seen. The testicles were very found; and the ducts from them to the epididymis were very manifest, and full of semen." P. 32-33.

Mr. Hunter observes further, in support of his opinion, that these bags are as full of mucus in bodies much emaciated, where the periton has died from a lingering disease, as in strong robust bodies, where death has happened from violence or acute diseases; and they are nearly as full in the old as in the young; which might probably not be the case if they contained semen." Ibid. p. 33.

The evacuation of the prostatic is the last ingredient in the seminal fluid; and it contributes very largely to the bulk of what
what is expelled in copulation. Its opaque whiteness and viscidity completely obscure the properties of the fluid secreted in the testis, and below on the female liquor its most obvious characters. The opinion which supposes that the semen is formed, or that part of it is produced in the prolate, is not therefore far from the truth. A thick, white, and opaque liquor may be expelled in considerable abundance from the prostatic ducts on each side of the caput galliaginis after death. Physiologists ascribe to the prostatic fluid the office of increasing the bulk of the semen, and of thereby augmenting its impetus; so that it may arrive with greater force at the place of its definition.

It has been conjectured that a copious fluid is mixed with the semen, and hence the weakness of the male after copulation has been explained. We may be excused from discussing this opinion until we know what nervous fluid is. The contralateral exertion of the whole frame, which occurs in the vesical organs, will sufficiently account for the sense of fatigue that follows it.

It appears from what we have said, that the fluid expelled in copulation is furnished in a small proportion only by the testes; that a peculiar secretion of the vesicular feminales is added to this, and that the chief bulk is made up of the prostatic liquor. An important question arises here, which of these is the essential and immediate agent in impregnation? The general practice in the East, continued from ages of the most remote antiquity, of entrusting their females to the care of eunuchs, and the common operation of gelding, as performed on various domestic animals, lead us to affix this prerogative to the fluid secreted in the testis. In emasculating animals, or men, the testes are cut or torn out, or they are compressed so as to destroy their organization, or the cord is so squeezed or bruised as to annihilate the functions of the part. Yet, under the circumstances just enumerated, we read of numerous examples where vesical definies have been experienced, where eversion, copulation, and emission have taken place, and even where children have been begotten. These examples, however, are too repugnant to the general effect of castration, as observable in man and animals, to allow us to admit them. Ordinarily we observe not only that no desires are felt, but also that the lofs of the organs, in which the natural and leading stimulus resides, occasions the other parts concerned in the business of generation to be much diminished in size, and altered in appearance.

Where emasculation has been performed merely by compressing the cord or testis, the organization of the part may not have been destroyed sufficiently to interrupt its functions, and such an animal might be still capable of fecundating; but no well authenticated instance can be produced of impregnation being effected where the testes had been cut out in any male animal. Yet it cannot be doubted that eunuchs may have eversions, since the seats of the physical feeling is in the glands, and the whole apparatus concerned in erection remains entire after the loss of the testes. A man, after the latter occurrence, like one who has lost his powers through age, may at times be stimulated by the recollection of past joys. Hence, in the East they value those eunuchs most highly, in whom the penis as well as the testes have been removed; no cause for the slightest jealousy can then remain. The prostatic liquor, or that of the vesicular feminales, might be discharged in the eunuch. If an animal has impregnated another after castration, there may have been some semen remaining in the vesicular feminales. Before the facts now enumerated, we may observe that all animals which copulate have testes; but that several have either no prolate or no vesicular.

The secreted semen is either expelled from the body, fully filling the purp. of its formation; or it is retained in its receptacles, and taken up by the absorbers. The seminal vesicles are always full of their peculiar fluids, which are only discharged at considerable intervals, and often only at periods of some months or years. As the testis and vesicular feminales posse numerous absorbers, we cannot doubt that the contained fluids are conveyed by these vesicles into the general circulation. It has been a general opinion that this absorption produces many of the changes which are well-known to take place at puberty; and which obviously depend, as we have already shown, on the testes. We refer to a former part of the article on this subject. The males of the great animals, when the rutting season approaches, have their whole bodies penetrated by a singular fetor, so that they are unct for food. The flesh at this time partakes more rapidly than at other seasons in the ill. That absorbed semen is the cause of this fetor, is rendered probable by the fact, that the removal of the testes destroys it; and by its absence from castrated animals of the same species. The same cause has been assigned for the phenomena consequent on conception in the female; but this seems very doubtful. This absorbed semen has been supposed by physiologists to act as a stimulus on the heart, and the organs of motion, to increase the muscular strength, and to contribute thereby to health of body and strength of mind. Hence, too, they have explained the softness and suppleness of the flesh observed in some animals after the copulating season; as, for instance, in the boar. The flesh of the fallox is remarkably changed in colour and flavour at this time. Castration produces debilitating effects both on the body and mind of man and animals; the ferocious and powerful bull is changed into the mild and patient ox. The influence of the same process in mankind has been already noticed; and we have sufficiently proved that the remarkable development of the frame at the time of puberty arises entirely from the influence of the testicles.

And it is no less true that the rest of the sexual organs are particularly affected by the presence and activity of the testes. In this country, we have little or no opportunities of observing in eunuchs the effects of the ablation on the other organs of generation; but we can see the consequences in animals. Following Hunter's opinion, the penis, urethra, and all parts connected with them, are in subterflect to the testicles, that he conceives, that most of them would have existed if there had been no testicles in the original construction of the body; these parts would then have been so formed as to assist merely in the expulsion of the urine. To illustrate this opinion, let us observe what is the difference between these parts in the perfect male, and in a male that has been deprived of the testicles when very young, at an age when they have had no such influence on the animal economy as to affect the growth of the other parts. In the perfect male the penis is large; the corpora cavernosa being capable of dilatation. The corpus spongiosum is very vascular; and that part of the canal which is called the bulb is considerably enlarged, forming a cavity; the muscular accelerators urinæ, as they are called, are strong and healthy. In many animals which have long penes, they are continued forwards to the end of it, and in others they are not extended so far, but are very large. On the contrary, in the castrated animal, the penis is small and not capable of much dilatation; the corpus spongiosum is less vascular; the cavity at the bulb is a little larger than the canal of the urethra; and the muscles are white, small, and have a ligamentous appearance. The same observations are true, if applied to the erectors penis. The penis of the perfect male is of sufficient length, when erected, to reach to the full depth of the vagina of the female. In the castrated animal it
is much shorter; and erections having thus become unnecessary, the parts which should project often adhere to the inside of the prepuce. The prostate, Cowper's glands, and the glands along the urethra, of which the Lacunare are the secretory ducts, in the perfect male, are large and pulpy, exerting a considerable quantity of a fliny mucous, which is felt to the taste, is most probably for the purpose of lubricating the urethra, and is only thrown out when the animal is in vigour for copulation; while in the castrated animal they are small, flabby, tough, and ligneous, and have little secretion." Animal Economy, p. 39.

It must be acknowledged that we have no very direct proof that any actual absorption of semen takes place from the tubercles or vesicles, and some physiologists deny it altogether. "I very much doubt," says Blumenbach, "whether red tiles however absorbed from its vesicular secretions in a healthy man—still more of what has been occasionally affirmed, that it is immediately conveyed into the neighbouring veins, and most of all, that such absorption (supposing existence to be granted) should be considered as a positive snail premature venereal infuini. On the contrary, if we compare the phenomena observed in animals, the injurious insensible nature of their desires at particular seasons of the year, with the constitution of such as are castrated, we shall rather deem such absorption the cause of that ungen receptive and almost furis appetite. I conceive that a very d sincere means (peculiar, as far as I know, to the human subject) has been adopted to answer the purpose just alluded to; viz. nocturnal emissions, which I refer to the natural excretions of man, inasmuch as their more rare or frequent occurrence, according to varieties of temperament and constitution, serves to liberate him from the troublesome and inconvenient consequences of an abundant seminal secretion. It may be readily granted that barbarous nations, of a phlegmatic temperament, and practising irregular sexual intercourse, do not require such an excretion: yet, I think it must be deemed a very natural and suitable relief in a young unmarried man, of a sanguine temperament, plectoric habit, lively and warm imagination, particularly if he indulges in a luxurious mode of life and enjoys perfect health. See Chr. Rud. Jaenicch de pollutione nocturna. Götting. 1795, 4to. Institut. Phylol. sect. 36.

The length of course, and the small diameter of the spermatic artery, together with the impossibility of forcing any injected fluid from its branches into the secretory tubes of the vesicles, have led physiologists to conclude that the secretion of the seminal fluid is performed very slowly. But various circumstances are capable of accelerating this process.

"Princeps est amor," says Haller, Elém. Physiol. 7. 551.

"Nemo forte fuerit, quin in juventute fua feminam concupisci esset; quin si cana fuit, in eum familiaritate ignes conceperit accidit; quin feminarum cum dolore et incommodo fii tertices tumesceret, et venas feminarum; dolore certe tanto, ut vis tangeres potest, tu regioni, viv incidere. Manifesso in huius modo accelerata ejus secrecione, ejusque liquoris major pars testis tenere dilinere. Id mali genus ex re extensa tranquillitate animi, et abstinentia amitum femineo fudato; et ecehriae eum feminam fructus capite paullo, et si neutrum remedium accedisset in difficiles tumores abire poterit. Quare in mature, ut plurimum ad movendam venereum irritamenta fainam et aliarum feminarum non imaginis affici labores, aut alia quæ rerum, qua per legem allocationis idiomarum venarum renovant: sua abstinentia eummodo illiuni, et cagitationes perpetuo ad alia averse. Ipsaque religio, in ea minuent feminis generationem, ut multo minori copia gigantor, neque molimentum, et demum vasa feminina pene coelest, atq gentilium mox ipa Cumaanatur. A healthy and strong state of the animal, nutritious and perhaps rather generous food, and a certain warmth of the weather, promote the seminal secretion. All these circumstances dispose the organs for action, when the natural feelings are duly excited; and the opposite causes, as inhuman fatigue, insufficient or bad food, and considerable cold, prevent the feelings or dispositions necessary for the action of the generative organs from taking place. The reproductive functions are much influenced by the season in animals, that it is only carried on at a particular time of the year; and the leading organs (the testicles) are reduced in many instances to a very small size in the winter. But in man, and in such domesticated animals as are not in a state of nature, no such change takes place in the testicles; they are consequently always in a good condition, and in that state to which other animals that are left to themselves, can only attain in the warmer seasons.

That the semen, secreted in the serpentine tube of the testis, is conveyed from them to the epididymis, and thence into the vas deferens, is sufficiently obvious from the anatomical structure. De Graaf proved it still further, by tying the vas deferens of a dog before copulation; all the secreting tubes were dilated to the utmost, and the testis considerably swelled.

We cannot doubt that the secretory vessels of the testis propel their contents by some contractile power; although the precise manner in which this is effected escapes our observation. Does the elevation of the testis to the ring, by the action of the cremaster, constantly observed to accompany emission, promote the progress of the secreted fluid? The immense length and numerous turns of the seminal tubes must render the passage of this fluid from its first secretion very slow; hence, when the supply contained in the vesicles is entirely exhausted, an interruption of some time is necessary for the reproduction of a sufficient supply; hence too, in the dog, where there are no vesicles, the act of copulation is uninterruptedly prolonged.

It has been generally considered that the fluid produced in the testis is deposited and retained in the vesicular seminifer, as in reptiles, until occasion occurs for its discharge. Mr. Hunter has endeavoured to show that those bags are not to be regarded in the light of receptacles for the semen, but as destined to perform a peculiar function. The common opinion rests on the facts of the very free communication between the vasa deferentia and venas, on the course which injected fluids take in the dead body, and the extreme malleability, numerous convolutions, and great length of the vesicular tubes, which seem very unfavourable to the production of semen in the sudden way, and at the very short notice at which it must be formed, if we do not suppose it to come from the vesicles. We have already detailed the proofs by which it appears that these organs perform a secretion; but none of those facts shew that the contents of the vesicles may not consist, in part, of matter formed in the testis. We know that the gall-bladder produces a copious secretion of its own; but that it also receives bile from the hepatic duct through the ductus cysticus. Mr. H. endeavours to adduce a decisive argument from comparative anatomy: he states that in many animals, the parts corresponding to the human vesicular seminifer have no communication with the vasa deferentia, and moreover, that their structure, in several instances, seems little calculated to make them receptive. Where the obvious structure is so different, we are by no means warranted in concluding that the functions are exactly similar. To argue that the semen does not pass into the vesicle of man, where the vasa deferentia are so intimately connected to those bags, because the analogous parts are not connected in other animals, is not more reasonable, than it would be to affirm
GENERATION.

affirm that the fluid of the vasa deferentia passes into the vesicles in animals, when the two are not connected, because the structure leads us to infer that it does so in man.

Mr. Hunter continues, "we may likewise infer, from what has been said, that the semen is not retained in reservoirs after it is secreted, and kept there till it is used; but that it is secreted at the time, in consequence of certain affections of the mind stimulating the vesicles to this action: for we find, that if licentious ideas are excited in the mind, and the paroxysm is afterwards prevented from coming on, the vesicles become painful and fæculated from the quantity of semen secreted, and the increased action of the vesicles; which pain and swelling are removed immediately upon the paroxysm being brought on and the semen evacuated; but if that does not take place, the action of the vesicles is still kept up, and the pain in the vesicles will generally continue till the paroxysm and the evacuation of the semen are brought on, which renders the act complete; without which a stop cannot be put to the action of the vesicles that produce the erection, nor the parts be allowed to fall back to their natural state. There is at this time no sensibility felt in the situation of the vesicular females. The pain in the vesicles, in consequence of their being filled with semen; and the action being incomplete, is sometimes so considerable as to make it necessary to produce an evacuation of the semen to relieve the patient." Animal Economy, p. 53.

We certainly admit with Mr. H., that the vesicular females of the human subject perform a particular secretion; but we do not conceive him to have succeeded in proving that they are not also reservoirs for the semen.

The opinion, which denies the vesicular females to be reservoirs for the semen, is defended also by J. A. Chaptal, in the Journal de Physique, February 9, 1787, p. 101. Soemmerring has refuted it in the third vol. of Blumenbach's Medicinische Bibliothek, p. 87.

The transmision of the sexes, from its dugs or vesicular, into the urethra, takes place under the influence of a particular state of mind; and its expulsion from the body is effected, in all animals which have a penis, by means of what is called the erection of that organ. In the human subject, this is an increase of volume produced by the dilatation of the three corpora cavernosa. Among the exciting causes of this process, we may enumerate, in the first place, the presence of a sufficient supply of seminal fluid; when this is present, any additional stimulus easily produces the effect. Hence, we observe, that the seminal powers of animals are the greatest, when their testes are of the largest size; hence, too, we may perhaps explain the erection sometimes observed after a full meal. A second and more powerful excitement is derived from mental causes. "Aliter ex cauda," says Haller, "in famo homine ut imaginatio, lice cupidus venereus, quae ex quacunque causa orta, lectione, vita pictura, memoria volapi tis prilim, co fabricatione, tactu, et aliis causis, in fama homine continue in erectionem erumpit. Edem nocturnum illam et solitariam veneream sola abolit, qui se natura nimiis feminis ured liberat varis, pro varia feminis abundantis, et femina acutior aut obtusiior, intervalibus. Nam prius facilissima, semen ex eae ex rario est, aut nulla. Soli homini data est, forte quod homo potilium memoria et imaginatione valere. Imaginazione solam, non erectionem, sed pleanum veneream, etiam in vigilius tibi pulvisque aquis animum. Neque potest abique imaginatio excitata usque haec opus perfici; ut inter, neque hactenus admata in feminas venas vix exerciti potissimum. Invenit ille impatientem ex veracrit, ex imaginaria debilitate, quia elenchum revoce, aut ex odio, quia quidem species cum relativa poteclata conjuncta est. Hinc manifesta irituationes ejus legis, quae ex congrupto de virilitate mariti judicabat, queen in exsilia uxor, post summam injuriam paflam, in conspectu tot hominum, feraces aperatur opus, ut utum impietatis veneoe juris perfectum. Quoae in Galilia anno, 1677, die 18. mensis Junii, rididus lex absolta fuerit, cum Marcius de Langey, a judicis poæ congradatrum pro impotente damnato, diffulto matrimonio, cerni aal uxor, morto filios generaret." (Element. Phys. Phil. 5, 577.) The peculiar odour exhaled from the female organs, particularly at certain feasons, is a very powerful incentive of venereal feelings in the animal kingdom. Haller considers that this causö acts in the human race also. "Propius partes genitalia ipsa adiecti, et excretionem extortae, angust et perfecto, frictio glandis, et potissimum colliculorum, qui sunt sub ortis uretrarum, quocumque fere modo et frictio administratur. Sed ea cum voluptate peculiari, summa, pene nimia, conjunctu, agitque iterum manifesto in nervos, ut vel ex acuto frui glandis conjuncte licet." Elem. Phys. Phil. ibid.

Erection of the penis takes place from various causes, not enumerated under the foregoing heads; and then it has no concern with the expulsion of the female fluid. When a person wakes in the morning, with the bladder tolerably full of urine, the organ is commonly erect; but it subsides when the water is evacuated. Striking the nerves with a rod is well known to produce erection; and has sometimes been resorted to, to rouse dormant passions. Calculus, Strangury, and hemorrhoids are sometimes attended with this symp- toom; which has been occasionally observed also in other affections. It is often particularly troublesome in gonorrhoea; and has been observed many times after death, particularly in those who have been baged. (See Morlagni's D. et C. Ep. xix.) Mechanical obstruction to the return of blood from the part will produce erection, and even such a toiling as ends in gangrene, if the obstacle be considerablenb and long continued. Ligatures, thoughtlessly placed on the penis by children, and the stricture produced by the retracted glands in paraphymosis, come under this description. In the same way dangerous swelling has been produced by drawing a ring over the penis. The effect of intercepting the return of blood is clearly shown, in an experiment made by Mr. Hunter on the dog. "In April 1760, in the presence of Mr. Blount, I laid bare the penis of a dog, about three quarters of its length, traced the two veins that came from the glans (which in this animal makes the large part of the penis), and separated them from the arteries by division, that I might be able to compress them at pleasure, without affecting the arteries. I then compressed the two veins, and found that the glans and large bulb became full and extended; but when I irritated the veins, in order to see if there was any power of contraction in them, which might occasionally stop the return of the blood, no such appearance could be observed." Animal Economy, p. 45, note 2.

That erection is produced by blood being sent into the penis faster than it can be returned, and that the encroached view of the organ is entirely produced by this confluence of circulation, are points clearly ascertained. The obstruction to its return is so complete, that no mechanical pressure applied to the body of the penis can force the blood on into the veins. The exact mode, in which this object is accomplished, has not, we believe, been as yet ascertained. There certainly is no power capable of directly compressing the veins; and the erect penis in particular, by drawing the organ away from the lymphatics pubis, would rather free them from pressure. The accelerator urinæ, by squeezing the blood forwards from the bulb, may make the front of the corpus spongiosum and glans rather more firm when they are erect, but can produce no effect on the penis in general. Neither
Neither is the phenomenon at all like those produced by muscular contraction: it is a quiet and gradual increase, and it often lasts for hours. Muscular action is sudden, and not of such long duration. There are other examples of analogous effects, which are totally inexplicable by muscular action. The nipple, when left to itself, like the penis, is soft and flaccid, short, and retracted; when excited by gesticulation, it rises into a cylindrical form, swells, grows red and warm; yet there is nothing like a muscle in the part. The red flabby organs about the head and neck of some gallinaceous birds undergo a similar process.

It appears, therefore, that the change termed erection, may take place in animal structures, without the assistance of any muscular power; and it is by no means certain, that any muscle is concerned in the particular case now under consideration. All that we can ascertain on the subject is, that the blood is sent into the corpora cavernosa in much greater quantities than it can return. If a mechanical obstacle does not produce that rigid state of the organ, which is created by the immediate action of desire, we conclude, that a more sudden and complete congestion is produced by the latter than by the former cause. We cannot explain how the proportion of blood, which arrives, is thus altered in relation to that which returns, any more than we understand the analogous phenomenon in inflammation. It does not seem possible to ascertain the mechanism of the process by actual observation. The circumstances already mentioned render it probable that the nerves are materially concerned.

Erection varies considerably in its degree. The organ at first swells, but continues soft; it then grows considerably longer, thicker, more firm and warm; and the glands become redder. The corpora cavernosa penis are first distended, and the glands secondly. In the state of greatest rigidity, it is proved, by ridiculous experiments, that considerable weights can be supported by the organ. The mere act of erection is not attended with those remarkable effects on the frame which accompany emission; it may be repeated or continued for any length of time without any injurious operation on the animal economy: hence, it is much more frequent than the latter act. Under the influence of certain feelings of the most acute kind, excited in the act of copulation, the seminal fluid is expelled from the ejaculatory ducts into the urethra. The pleasurable sensation is raised to its highest pitch, and is attended with a convulsive agitation of the whole frame, before this effect follows. "Maxima certe est in venere convulsi, et late patens tremor, ut feminic, cui chloris titillatur. Neque facta, neque posita, neque genua coarcere, ne tremant, et in accius res in pleno ejusdem erumpit: nihil autem minus factum in venere sensibile. Sinat, qui animo in venere lispantat, etiam feminic; fine non rari, qui in grato animo opere praeclaro, et antem omnino major multis veluptatis, etiam pl. pl. pl. animalium; nam mares, crasser pati exempla, feminae furentarian, et nonnamque penes virum e sub grat: et in viris gravis, febri venereus simpliciter folet, multis quant literis major, et ector est venereus atior. Et si aliquis feminae, et in obtus ocludere interior, quando femen co potest, manifeste tamen mus in egerendo feminic hierarchia, quae feminae in tene venere, furiae agitur. Quae anima seu corporis confitatis in facta tum, ut vinum robore aqua, anormales id hic esse redderet aequorum. Demum et comites vires vehementer instantatur, et pulsus acceleratur, sicut palpator, et refrenatio labitur, et calidum, quae nixom, parasomnia oriantur." Elemen. Physiol. 7. 515.

The anus is closed by its sphincter, and it is said that the levatores ani, by their mechanical Pressure, squeeze out the contents of the prostrate and vesicula into the urethra. Probably the coats of the vesiculae and vasa deferentia polish some contractile power, by which their evacuation is assisted. The contents of the prostrate and vesiculae are collected in the bulb of the urethra, which is elongated so as to form a kind of reservoir for them; and are expelled with some force, by successive spasmodic contractions of the accelerator urinae. As soon as this is finished, the temporary agitation subsides, the blood returns from the cells of the penis, and that organ regains its original magnitude. A degree of languor follows, proportioned to the previous excitation; the palpitation of the heart goes off, the hurried respiration is quieted, and the strength slowly returns. The frequent weakness is greater, in proportion as the act has been more frequently repeated, and at shorter intervals. In many animals, where the sexual appetities are only exerted at a particular season, and where the powers are exhibited and exercised on a much grander scale than in man, the debilitating influence is very strongly marked. The venereal powers of the human subject certainly appear very limited, when compared to those of most animals; with a due regard to health, he cannot much exceed the limits assigned by Haller. "Homines adeo medicum font vires, ut non plus multa quam bis in septem diebus coire posset, et si forte acer amorer percussus, potius longam alitatem, femina concepuita potius, aliquoties posset fermen emittere. Sed ex neque multum repeti poennis, neque durare." An attention to the dictates of nature will certainly enjoin temperance in these enjoyments. The performance of a function, so necessary to the continuance of the species, has been ensured by the physical pleasure associated with it; but the effects of too frequent repetition produce those serious consequences which the universal and violent influence of the act on our bodies would naturally lead us to expect. Severe nervous affections, impaired mental faculties, and premature death, are the sure concomitants of excessive venereal enjoyments. Whether the convulsive agitation of the body, or the emission, be the most injurious under these circumstances, cannot, perhaps, be decidedly ascertained. "Omnia illa majora et celeriora, et minus medicea manu obtentura, eventum ab illa dictationalis juvenum circiter, a qua essent, et in qua femina, multo quam in nature opere difficillius, excipitur. Ab ea enim corruptela impotentia infamabilis superficiei, et feminis fluxerunt voluntarum perpetuum, obliqua rigidius, tabes intra triumnum funicula, amnalis judicii vit, et omne fere malorum genus, quod votis velis avertetur." Elem. Physiol. 7. 539.

These circumstances render it very plain that polygamy is not suited to the organization and powers of man; and afford a much stronger argument against the practice, than the alleged superior numbers of females in Eastern countries would be in favour of it, even if the fact were well proved; which we by no means admit. We may call and ask, from the foregoing account, that the sexual functions ought not to be exercised, until the growth and strength are complete; and that all attempts at exciting the venereal appetites, before the natural period of their development, must be prejudicial. On this subject we should bear in mind the observation of Tacitus concerning the ancient Germans; "Seu juvenum Venus, seque inmediatam pueratas." Man is capable of exercising the generative functions through a certain portion only of his life. We have explained that the organ are in a state of very imperfect development during the early periods of his existence. Boys have erections, but they are not produced by those stimuli which act at a more advanced age. In the middle of Europe, a scarce-
a secretion of seminal fluid generally takes place about the
twelfth or fourteenth year, insomuch that it is commonly
discharged from the effect of dreams. Soon after this time
there is a complete capacity of performing the sexual func-
tions; and there is a well-known instance of a prince who
begot twins in his 16th year. The approach of puberty is
regulated considerably by the climate, and also by manners;
in warm countries it comes on earlier than we have men-
tioned, and later in colder regions. In the higher ranks of
society, where the feelings are prematurely and artificially
excited, and encouraged by a copious and generous diet,
and loose morality, the generative functions may be called
into exercise more early, than under the opposite circum-
stances. As the individual approaches to the 20th year, the
venerial susceptibility is considerably diminished. Semen
is still secreted, but hardly ever emitted during sleep, even after
the longest abstinence. The venerial act is more slowly
performed, but is equally effectual in producing impreg-
nation. From this time the powers are gradually diminished;
but a man of 60 may still become a father, although some
legislators have chosen to determine otherwise. A longer
continued and more powerful irritation is required to pro-
duce erection and emission at this age. In rare examples
men have been known to retain their powers of propagation
even to the age of 100 years; and it is very well authenti-
cated that Thomas Parre married at 120, and performed
the duties of a husband until the age of 142. These latter
examples may, however, be regarded as deviations from the
ordinary course; and we have equal remarkably instances
of the generative functions being performed at an unusually
early age. Perhaps the most remarkable case of this kind
is a boy now living in London, of whom an account is given
in the Medical-Chirurgical Transactions, vol. i. p. 276, &c.
At the time of birth this child had much long hair
on the head, and the futures of the cranium were perfectly
closed. At the end of the first year those changes took
place which usually happen at puberty. The penis and
testicles increased in size, hairs appeared on the pubes, and the
tone of the voice was evidently altered. From this time
his body grew very rapidly, and the expression of his fea-
tures, as well as the general organization, had a completely
manly character. The prominence of the thyroid cartilage,
and the voice, resembled those of a youth of 16. "The pubes
and femur are covered with black curling hair. The penis
and testicles are as large as I have seen in some adults. The
latter are firm and perfect in their formation, and the cord
could be distinctly felt. The usual brown appearance of the
integuments of these parts is here to be observed." There has
been a secretion of semen from the end of the second year.
This account was drawn up when he was three years old.
In his "Anecdotes de Medicine," Borden mentions three boys
who had strong venereal defiles between 10 and 11
years of age: the generative organs were unusually large
in these individuals, and were fully capable of exercising
their ordinary functions at this time. "It is no question
quoniam phylicum de l'amour; ils ne semblbient avoir
autre sensation que celle de cette passion; ils fe fondent,
pour ainsi dire, en feérens; ils traînaient leur caractère indivi-
duel de l'orgasme femelle." The most suitable and natural state
after the age of puberty, is that of marriage. If the design
of nature are not fulfilled;
if, by relating to satisfy the insatiable curve of love, we prevent
the excess of vital energy, which soon animates the generative
organs, from being carried off in its natural channel,
the accumulated irritability of these organs will frequently
disturb the whole frame by its re-action. The physical
feeling of love, the impulse of reproduction, has generally a
remarkable character of violence and energy in animals.
The phenomena of the rutting season shew the effects of
this powerfull appetite in a much stronger point of view than
they are seen in the human subject; as the influence of the
passion is here heightened by its being reduced within a short
period of time. Great fierceenes, impetuous motions, and
often even convulsions, are the effects of the new want in
many animals. Parrots, canary-birds, and bull-finchels,
experience attacks apparently of an epileptic kind, when sepa-
rated from their females. The physical appetite is rarely
accompanied with such phenomena in man. With many in-
dividuals, the obversion of the laws of chastity hardly re-
quires an effort. However, if the influence of the generative
organs should predominate so far as to constitute a well-
characterized erotic temperament; it was ardently imagined
and a forced state of celibacy should strengthen this tempe-
rament, its influence on the constitution may be excessive, and
cause various kinds of general disorder. Under the influence
of such circumstances, a folder feizd and attempted to viol-
a girl in public at Montpeller. Neither the publicity of
the occasion, nor the cries of his victim, nor the exclama-
tions and blows of the surrounding persons, could prevail with him
to relinquish his attempt, for which he was hanged. (Borden,
Anecdotes de Medecine.) The unnatural influence observed
from amokkemotions of religion, has produced very remark-
able effects in some cases. A Macedonian lather mentioned by Buffen,
in whom the feelings were very strong, longed to be permitted to
break his vow, cut away the organs. The same
author relates the sufferings of another individual during a kind of erotic delirium, which lasted for six months, and
seems to have amounted nearly to mental derangement.

**Female Organs of Generation**—Woman contributes more
largely than man to the business of reproduction; and the apar-
ratus destined to this function includes the generative organs,
properly so called, and the breasts. The female organs are
appropriated to the execution of a common object, to which
each contributes in its own way, and their development is
regulated by a common law. They are called into activity at
the same epocha, and their respective functions cease, or
at least their capacity of fulfilling them ceases at the same
time. The close sympathy which connects them has been
remarked at all times. The breasts, however, are
manifestly dependent on the generative organs; while the former
exercise but a very slight influence on the latter. As the
female organs are calculated by their formation to convey the
prolific fluid, so the female are constructed with a view to
its reception; and the two differ completely from each other.
Yet there is a considerable resemblance in some parts of the
apparatus in both sexes. Thus the clitoris, which is concealed
under the pubis in the inferior commissure of the labia,
reminds the penis in many points; differing from it
by having no connection with the urethra, and consequently
being imperforate, also in being very small in well-formed
individuals. The most convenient arrangement of the subject,
for anatomical description, is that in which the organs are
divided into the external and internal. The latter include the
diffusible agents of the generative process in the female;
the uterus, the vagina, and its appendages. The
former consist of a longitudinal slit, placed between the
thighs, containing the termination of the urethra and vagina,
and certain prominent parts composed chiefly of folds of the
integuments.

The external organs, which can be seen without the aid of
reflection, are the mons veneris, the vulva or pudendum, the
labia, frenulum, fossa navicularis, clitoris, hymen, meatus
urinarius, and opening of the vagina.

A broad prominence, placed in front of the pubes, and
between
between the groins, is called the mons veneris. At the time of puberty, this part becomes more convex, and is covered with hairs, of which the number, length, and colour, vary in different individuals. These very seldom advance along the middle line of the abdomen, towards the navel, as in man. Their eminence is formed simply by the accumulation of an adipose cellular substance at this particular point, and it consequently varies in size, according to the embonpoint of the individual. A longitudinal furrow, or slit-like cavity, extends from the mons veneris, between the thighs, to within an inch of the anus; this is called the vulva, or pudendum, (which names sometimes include, in a more large application, the external organs,) or fucus pudoris. This excavation is larger in women who have had children, than in virgin. The space left between the posterior end of the vulva and the anus, which may be about one inch in length, is the perineum, in which the sphincter can hardly be traced. The labia, or alae majores, are two elongated cutaneous eminences, filled with adipose substance, descending from the mons veneris towards the anus, and forming the lateral boundaries of the cavity just mentioned. They have been named, as a comparison with the lips of the mouth; but the furrow between them is vertical, instead of being transverse, as in the other instance. Their length, which is nearly the same in all individuals, and may be somewhere between two and three inches, determines the extent of the vulva. Their size and prominence vary according to the general embonpoint of the individual. These folds are thicker above than below; their external surface, which corresponds to the upper and inner side of the thighs, is covered with hairs similar to those of the mons veneris, and pusses some febaceous glands. The internal surface, formed by a mucous membrane, is smooth, soft to the touch, is contiguous to that of the opposite side, and to the nymphæ. In virgins the colour of this surface is red; it acquires afterwards a pale and rather livid cast. The upper edge of the labia is adherent, and continues externally with the integuments, on the inside with the covering of the nymphæ: the inferior margin is unconnected, convex, rounded, and covered with hairs, and exhibits the continuity of the integuments with the mucous membrane. The anterior, or superior extremity, is confounded with the mons veneris: the posterior, growing gradually smaller, ends in a point, and is united with that of the opposite side behind the fumicarctis. From this union a fine prominent ridge results, called the commissura of the labia majora, and in French la fourchette. The following parts enter into the composition of the labia; 10th, a continuation of the skin forming their external surface and inferior or convex edge, provided with febaceous glands, in the secretion of which the distinguishing colour of these parts resides; 12dly, a mucous membrane covering their internal surface, continuous on one side with the integuments, and on the other with the mucous covering belonging to the whole vulva; 3dly, an adipous tulle filling the interval between these layers, and giving to the parts their various degrees of thickness and prominence. The latter texture resembles on the whole that of the mons veneris, with which it is continuous, but it presents, in addition, some membranous lamina descending from the fumicarctis and pubes to the external edge of the labia. It does not contain so much fat as the mons veneris, and hence, like the scrotum of the male, it is a part in which unctuous depositions are frequently observed. The labia cover all the other external organs of generation, which, by this means, are coarsely moulded with a mucous fluid, preventing the effects of friction, and preserving the acute sensibility of the parts. In the ordinary attitudes of the body, these organs are in a state of mutual contact, and therefore completely conceal the parts which we are proceeding to describe: they are separate only when the thighs are thrown widely apart; they receive an extraordinary development during parturition, and thereby increase the capacity of the vulva. When the labia are separated, the following parts may be observed in succession from above downwards: 1. The clitoris, which appears as a small tuft, more or less prominent, separated from the upper commissure of the labia by a small smooth surface; 2. The nymphæ, also minores, or petties leaves, arising from the inferior lateral parts of the clitoris, descending and diverging as they descend, and lost on the sides of the opening of the vagina; 3. A triangular surface slightly concave, bounded above by the clitoris, below by the nuchæ, and at the extremity by the nymphæ, and sometimes called velum; 4. The meatus urinarius, situated about one inch below the clitoris; 5. The orifice of the vagina, with the hymen, or cutaneous myrtiforme, placed immediately under the meatus; 6. The fumicarctis, a small transverse depression, separating the entrance of the vagina from the frenulum; 7. The frenulum, or posterior commissure of the labia; behind which is the perineum. The clitoris occupies the upper part of the vulva, and forms a reddish slightly elevated tuber, which ordinarily does not exceed the level of the labia. Its figure is ebulliously conical, something like that of the end of the penis; this is called the glans clitoridis, and is covered by a loose fold of the mucous membrane lining the vulva, and named preputium clitoridis. Besides, the difference of its size, the want of a perforation at the extremity, sufficiently distinguishes it from the penis. A small part only of the organ appears on external examination; the larger portion, which is concealed, and can be brought into view only by dilatation, lies over the vagina, and under the arch of the pubes, and bears a great analogy to the penis, as it consists of two crura or corpora cavernosa, with erector muscles. These arise from the inner, and even posterior surface of the ramus of the ossa innominata; ascends, approaching to each other, and unite into a small cylindrical body, terminating in an obtuse extremity, called the glans. These crura are made up of a firm fibrous membrane, confused with the periostum, forming a tube filled with a cellular or spongy substance, into which blood is exuded from the arteries, to be again taken up by the veins, as in the penis. There is a complete septum between the two crura, so that they are distinct throughout. The spongy fibulacrum of the crura is more dense than in the penis, and consequently admits of less dilatation; hence the size of the organ is not greatly increased in the erectile state. The erector clitoridis muscle is analogous in every respect to the erector penis of the male; its origin, termination, and probably use, are similar, but the size is smaller in proportion to that of the crura. It arises from the inner surface of the lamina, ascends and passes forwards, and is implanted in a tendinous form, in the inferior and posterior extremity of the crura clitoridis. The substance of the glans is not different from that of the body of the clitoris, as there is no urethra in this organ, and consequently no peculiar corpus cavernosum. It is rounded above and slightly bifid below. The loose and folded prepuce covers it above and at the sides, but not below, being attached to the two sides of the slit, by which the part is marked in this situation. A white, friable, febaceous, and concreting substance, similar to that formed by the glandulae osifereae of the penis, is deposited under the preputium clitoridis. This secretion, being liable to accumulate, and becoming irritating in warm countries, is, as the case with the analogous substance...
The clitoris corresponds above to the arch of the pubes, to which it is fixed by a kind of supfenory ligament; below to the urethra, to which it is united by a loose cellular tissue.

It resembles the penis in its acute sensibility: "...ejus minre vehemens eff, ut tota cura ab ejus particulie solicitatione contremicam, femineaque tota extra sepolantur, nihilque possint prope negare. Quae extra venerem, in cauta femina parva fuerat, led etiam modo arriget et intumecit, ut prepslere veneri inferirae posset, multoque nuf ejus turpidudinis dignus moles ejus augetur, ut omnim membra felet, quibus multum utinam. Quae caua videtur fully, cur orientales populi, accurati capilatibus mulcibus cutodes, hanc insuper natus puellis amputaverint, an certe ferro decurtaverint."—Element. Physiol. lib. 28. § 20. We have made some observations, concerning the occasional increase in size of this part, in the remarks on Hermaphroditism.

The nymphæ are two membraneous folds, united above to the prepuitum clitoridis, and depending about as far as to the middle of the aperture of the vagina. They are thin and flattened, broad in the middle, and narrower at the two extremities. Their external surface corresponds to the inside of the labia, while the internal, approximating above to that of the opposite side, corresponds below to the meatus urinarius and orifice of the vagina. Their adherent edge is tolerably thick; while the loose margin is thin and convex: the latter is sometimes wrinkled or notched, so as to have occasioned a comparison of the part to a cock's comb. The superior extremity arises from the prepuitum or glans clitoridis: the inferior ends at the side of the vagina. They are smooth and of a red colour in young women, and acquire a darker hue in older subjects, and particularly such as have had children. They are formed of duplicatures of the membrane lining the vulva, filled internally with a cellular substance, free from fat: and they contain sebaceous glands, the excretory ducts of which form very obvious pores: they differ very much in size. Ordinarily, they are completely covered by the labia, when approximated. Sometimes they form scarcely perceptible prominences, while at others they are very large, and hang down between the labia, so as to form an inconvenient obstruction to the sexual functions; in this case their surface is irregular, being grooved and tuberculated. Such formations are more frequent in the inhabitants of warm climates, where it is not unnatural to cut off some part of them; and the operation is even occasionally practised in European countries. Frequently one is larger than the other. They polledls considerable sensibility. The chief ufe assigned to them is that of affitting, by their development, the enlargement of the vulva during parturition: the dilatation of the parts by the passage of the child destroying the fold. The name of nymphæ was given to them from a supposition that they regulate the jet of urine; but as women evacuate this fluid with the thighs apart, and as the direction of the flow seems to depend on entirely on that of the urethra, we cannot adopt this supposition. And we are further confirmed in rejecting the opinion by the existence of these folds in many animals where they can have nothing to do with the stream of urine.

We have nothing further to say concerning the vestibulum, except that the surface is smooth, and that it is terminated below by the opening of the urethra, which is about three quarters of an inch, or an inch from the clitoris. The description of this canal, and its termination, will be found, together with that of the female bladder, under the article Kidney.

Immediately under the orifice of the urethra is the entrance of the vagina, called sometimes the os externum uteri; the diameter and appearance of which vary very considerably in different individuals. In virgins this opening is very narrow; it is broader after the sexual act has been performed, and most ample in women who have had many children. The narrowness in the first cafe arises from the presence of a duplicature of the mucous membrane, called the hymen, which contracts the opening so considerably, that marriage cannot be consummated without its being ruptured; hence, after this laceration, the entrance of the canal is more free. As the parts are vascular and sensible, more or less bleeding and pain generally attend this dilatation of the aperture; and these circumstances are expected in some countries as the necessary proofs of virginity in the bride. However, they do not always attend the first coition; and it should be noted, by the following quotation, that the existence of the hymen hangs by a very slender thread: "...L'hymen, pendant le premier âge, est très mince, il rompt facilement et il détruit, lorsque on efcape au trau de management les parties extérieures de la génération, soit lorsque l'enfant nait même, avec ou sans intention, contracte des habitudes Léthargiques, prepare et dépose ainsi aux pluies folatrices, des organes qui font à peine chouchouts."—Moreau Hift. de la Famme. tom. t. p. 53.

The hymen is a duplicature of the same membrane which lines the entrance of the vagina, and has the same texture and properties. It is soft, red, vascular, and sensible. The polserior surface is reticulated, as the columns of the vagina terminate on it. Its size and figure vary very considerably. Generally it has the shape of a crescent, with the concavity turned upwards or downwards. The convex edge is attached, the concave hole: the former is fixed to the inferior part and sides of the vagina: the latter is turned towards the urethra. The orifice of the vagina, in the virgin, is the space bounded in front or above by the meatus urinarius, below or behind, and at the sides, by the loose concave edge of the hymen. The dimensions of this opening must depend therefore on the breadth of the hymen, which differs much in different individuals: ordinarily, it will admit the little finger without any stretching. This crescented or faliform figure of the hymen is seen only when the labia are drawn apart, and the sides of the vagina gently stretched; for in the ordinary attitudes, the membrane is thrown into longitudinal folds, the sides of the vagina coming into contact with each other, so that the entrance of the canal is completely shut. However, the space left between the urethra and the edge of the membrane will always allow the escape of the menstrual discharges. The lower part of the hymen is the broadest, and the horns of the crescent, where they advance along the sides of the aperture, grow gradually narrower, until they are completely lost.

Sometimes the hymen is continued under the orifice of the urethra, so as to form a complete membranous circle, perforated in the middle, instead of a crescent. Indeed Haller, and many other very accurate anatomists, have found the fold, when the parts were carefully examined in water, generally continued under the urethra; but very narrow at that part. In more rare cases the hymen is an imperforate circular membrane, attached to the edge of the orifice of the vagina in every part, so as to close the canal completely. Such females have been termed atroce, by a word derived from the Greek, and signifying imperforate. As there is...
no aperture in such cases for the discharge of the menstrual fluid, it accumulates in the uterus and vagina, and must be evacuated by a surgical operation, consisting of a puncture of the hymen. For the various appearances which this part exhibits in different individuals, the reader may consult J. G. T. Tolberg, de varietate hymenum, Hal. 1791, 4to.

It has generally been ascertained, that the hymen does not exist in quadrupeds; but the statement of Cuvier, in his "Les Animaux comparés," vol. 3, ldp. 29, sect. 6, art. 2, clearly establishes this fact very doubtfully. The general opinion of its non-existence in the other invertebrata appears, and the circumstances of its being found in women only, at a particular period of life, and even then not universally, have led many anatomists to deny its existence in the human species. But the fact is so clearly proved by the concurrent testimonies of all modern anatomists, who have enjoyed favourable opportunities of dissection, that we need not find Bisson's opinion concerning the point; any of his anatomical friends might surely have convinced him by oculor proof. Though we are fully convinced, by repeated observation, that Buffon's opinion is incorrect in point of fact, we cannot help admiring the eloquence with which he inveighs against the different opinions and practices which have prevailed on this subject. "Les hommes," says he, "abolit des principes en tout genre, ont toujours fait grand cas de tout ce qu'ils ont cru pouvoir poiffer exclusivement et les premiers: c'est cette efièce de jolies, qui a fait un être réel de la virginité des filles. La virginité, qui est un être moral, une vertu que nous confîte que dans la puretě du cœur, est devenue un objet physique dont tous les hommes se font occuper; ils ont établi fur cela des opinions, des usages, des fémoves, des superstitions, et même des jugemens et des peines; les abus les plus illicites, les coutumes les plus déformées ont été autorisées; on a loufnis à l'examen de matrones igno- rantes, et expose aux yeux de médecins prévenus, les parties les plus sacrées de la nature, sans fonger qu'une parcelle indécence est un attentat contre la virginité: que c'est la violer que de chercher à la reconnoître: que toute situation honteuse, tout état indécenl, dont une fille est obligée de raconter intérimement, est une vraie déclaration. Je ne peur pas réciter les prejuges ridicules qu'on a formés sur ce sujet; les choses, qui font plaisir à croire, seront toujours crues, quelque vaines et quelque déraisonables qu'elles puissent être: cependant, comme dans une histoire on rapporte non seulement la suite des événements, et les cir- constances des faits, mais aussi l'origine des opinions et des erreurs dominantes, j'ai cru que dans l'histoire de l'homme je ne pourrois me dispenser de parler de l'idole favorite à laquelle il sacrifie, d'examiner quelles peuvent être les raisons de son culte, et de rechercher si la virginité est un être réel, ou si ce n'est qu'une divinité fabuleuse."

"It is not so easy to explain the use or purposes of this membrane, as to establish the fact of its existence. The partisans of final causes have been much puzzled in attempting to display the wisdom or goodness of the Creator, as evinced in this part of our anatomy, and have as yet assigned no rational explanation of it. We subjoin from Haller, a statement of the commonly received notions, which, however, appear to ourselves entirely unsatisfactory."

"Et elemos."

"Elem. Physiol. lib. 28, fept. 2, § 27."

After the hymen has torn, the entrance of the vagina presents some bulky prominent tubercles, called carunculae myrtiformes, and varying in number and form. These are generally considered to be the remains of the lacerated mem-brane; "et corrupte adeo pudicitia indicia." The carunculae are generally largest at the sides of the vagina, where the hymen is narrowed; so that all these prominences cannot well be referred to the origin just mentioned. Some are found behind the hymen, and exist previously to the laceration of that membrane: these are the prominent, obtuse, and callous apices of the columns of the vagina. Lastly, there are projections at the termination of the mucous ducts, which may be enumerated among those carunculae: and warts are sometimes formed in this situation. Whatever their origin may be, we find from two to five or six rounded and firm, or thin and loose prominences, of a red or livid colour, about the entrance of the vagina.

The frenulum, or fourchette, is a cutaneous field of a crescent shape, with the concavity upwards, placed behind and below the entrance of the vagina, visible in the virgin flat, when the sides of the vulva are drawn apart, but not well marked when the parts are collapsed. It lies between the two labia, not quite at the lower extremities, and is extended almost to the symphysis, protecting in some degree the entrance of the vagina. It is near to the hymen, which it resembles in some respects. The act of copulation does not injure it, but repeated parturitions entirely efface it. A very manifest transverse cavity, named the fossa navicularis, is intercepted between the frenulum, the hymen, and the Labia; and this cavity is lost of course when the frenulum disappears, so that it may not be recognizable in married women.

A mucous membrane, by which the genital and urinary organs are united in the female, is continued over all the parts contained in the vulva, and even forms many of them. It arises on the loose convex edges of the labia, and on their commissures; covers the internal surface of their folds, the space below their anterior commissure, and the fossa navicularis, then forms the nymphæ and preputium clitoridis, covers the vestibulum, is continuous with the lining of the urethra, and with that of the vagina, after forming the hymen or caruncula myrtiformes. It is connected to the subjacent parts by a copious and loose cellular texture, in which, generally speaking, there is very little fat. Its colour is of a tolerably bright red in young women; but it assumes darker shades in more advanced ages, particularly when the sexual functions have been much exercised. The texture of the integuments changes gradually into this mucous surface, so that there is no abrupt line of division, and an epididymus can be distinctly demonstrated at its origin. The colour proves that it is copiously fopplicated with blood. The membrane is soft on its surface, and plentifully bedewed with a mucous fluid, poured out from small tubes, which commence by open orifices, and run into the substance of the membrane, where they terminate by cul-de-sacs. These, which are called lacunæ, are similar to what we have described.
The internal Organs of Generation.—The vagina, or cul-de-sac
uteri, is a membranous canal, extending with a very slight oblique
to the pubis, between the urethra and bladder, which are in front of
the vulva, to the neck of the uterus. Its anterior portion
was, during parturition its is nearly tranverse; the posterior portion
the anterior is shorter than the posterior. We shall describe in it an
external and an internal surface, and two extremities.
The external surface may be divided into an anterior,
a posterior, and two lateral regions. The anterior, forming
upwards and slightly concave, corresponds to the bladder
and urethra, being connected to the former by a loose
and firm substance. The posterior region, forming from
above and behind downwards and forwards, is gently
convex, and corresponds to the rectum; its superior half,
being covered by the peritoneum, is simply contiguous to the intes-
tine; while the inferior part, polishing no such covering, is
connected to the intestine by cellular substance. This con-
necting medium is much looser above than below; and in
the latter situation it is difficult to separate the two organs
without cutting one or the other. The lateral regions are
narrower than the parts just described, and surrounded by
much cellular substance. They correspond to the ureters,
the blood-vessels of the uterus and vagina, and below to the levatores ani. The internal surface of
the organ presents a vast number of folds and prominences,
which make it irregular throughout. These cellous
rugosities exhibit a most elegant arrangement in the infant,
and in the virgin; they are conflated and partially obliterated
by parturition, but are very soon restored, and may often
be very distinctly observed even in old women. In some
subjects, however, the whole vagina is nearly smooth.
The half of the canal next to the uterus contains the fewest and
least remarkable irregularities; the folds here are soft, molly
transverse, but sometimes partly oblique. These promin-
ences are jagged laminae, ending in a thin edge, turned
towards the opening of the vagina, differing in size and
variably interwoven with each other. On the anterior half
of the canal are raised two prominent columns; an anterior
and a posterior one. These are becfit with hard and nearly
cartilaginous wart-like prominences, closely arranged, of a
roundish figure, and circumcised by grooves. The ante-
rior column is the largest, and corresponds to the orifice of the urethra. Frequently this is bised towards the front, and
its two portions, joined by transverse ridge, end in the hy-
men. The front end of this column sometimes projects like
a papilla at the orifice of the vagina. The posterior or
larger column is exactly opposed to the anterior, and corresponds
to the rectum; sometimes it is hardly distinguishable. This
ends also in the hymen, and in some instances projects an-
teriorly like the anterior column, but less considerably.
From each of these columns, hard, cartilaginous, transverse
or oblique folds are extended; they project downwards,

G e Ⓛ
have a jagged edge, and are mixed with variceae and other
lefs prominent liiniae in various directions. Between the
two columns is a reticulated surface, formed by the trans-
verse productions. The use of this structure does not seem
very obvious. It may possibly facilitate the dilatation of the
organ. "Voluptatem et arterium augere credites, nil in
uteri servici fimiles valvata rect credas. Arclant tamen emi-
nendo vaginam; et inferior columna partis glandis femino
vicine occurrit. Sedulium vaginam etiam facere credas,
quod ob has valvulas et pilis majis confractur. Insetam
hanc tamen subito," Haller, Elucid. Physiol. lib. 28.
All the generative apparatus abounds with mucous, and
this moisture is obviously convenient in many of the functions
of the part. In the female it appears as a whitish milky
kind of fluid; and it is a true mucus in the adult. The
floor absas and genitourae seem to be merely a differed ilate
of this secretion. Round livid spots are frequently observed
on the smooth part of the vagina, near the uterus; their
cause and nature are unknown. Numerous pores are ob-
served among the folds and rugae of the vagina. Enflata-
chius noticed osfucces in the membrane; i. e., tolerably large
flats, sometimes ramified, and containing mucac. No glands
can be discovered in the organ.

The superior extremity of the vagina is united to the in-
ferior part of the neck of the uterus. It embraces the lat-
ter organ obliquely, so that the anterior surface of the vagi-
na is nearer to the os uteri, and the posterior is more re-
move from it; and the vacancy between the vagina and the
neck of the uterus extends higher behind than before. The
inferior extremity occupies the lower and posterior portion
of the vulva, in front of the anus, and ends there by the
orifice which we have already described. The sides of the
vagina, poifces coniderable thickens and strength. The
upper half of its posterior surface is covered by peritoneum.
The chief subjacent of the canal is a thick, close, and firm
texture of a greyish colour, poififing large vessels, and
having fibres in various directions, so as to give it somewhat
of a muscular appearance. It appears to be continuous
above with the subjacent of the uterus. Below it is sur-
rounded by a kind of corpus cavernosum, of about an inch
in breadth, and two lines in thickness, composed apparently
of veins, and called the plexus reitiformis. A determination
takes place to this part at the time of copulation, and it
experiences a kind of swelling analogous to erection. On the
whole, the membrane of the vagina is not so thick, as the
dilatation which it experiences in parturition might lead us
to expect. Excepting where it is covered by the perito-
neum, and by the plexus reitiformis, the surface is surrounded
by a copious cellular subjacent, containing many vascular
ramifications.

The vital properties of the sides of the vagina are not well
understood. Some ascribe to it a contractile power, excrec-
as, as it is said, in cotton, and felt by the hand when introduced
in the prococies of midwifery. The phenomena of partur-
ition shew that it poifices in a high degree the powers of ex-
tension and subsequent contraction.

The internal surface of the canal is lined by a mucous
membrane, to which the peculiar hifue of the vagina already
mentioned adheres very closely. It is continuous with the
membrane of the vulva; and, after lining the vagina, is ex-
tended over that portion of the cervix uteri, which projects
into the canal, and communicates, at the os tunicae, with the
lining of the uterus. This mucous lining forms all the ine-
qualities already described; it is thicker near the vulva, and
grows manifestly thinner towards the uterus. At the en-
trance of the canal it has a red colour, which changes
farther into a grey or whitish cafe, diversified near the cervix
uteri by the livid spots already mentioned, which give it a
marbled appearance. The almoft carthaceous hardnefs of
the membrane in some parts is peculiar to the vagina, as well
as the permanent folds in its structure; in other mucous mem-
branes the inequalities are occasioned by some external caine,
and disappear by extenfion. Some anatomists affcribe an
epidrhmos to the vagina; but this point is doubtful. The
organs, by which its mucous fluid is secreted, have been already
mentioned.

The place of the accelerator urine of the male subject is
occupied in the female by the sphincter vaginae, which covers
the plexus reitiformis. It descends on each side from the
body of the clitoris, behind the erecter; surrounds the an-
erior extremity of the vagina, immediately behind the
labium, where it poifies considerabfe breadth, and terminates
below, on each side, in the lateral fibres of the sphincter ani.
It must have the power of contracting the front orifice of the
vagina.

The arteries of the vagina come from the internal iliac;
its veins join the venous plexus, which surrounds the canal.
The lymphatics are not well known; the nerves come from the
facial trunks.

The uterus is the organ in which the facts and its coverings
are contained until the time of parturition. It is almost
always single; in some rare cases there have been two uteri.
There is some variety in these inances; either there may be
two uteri and two vaginae; or a single vagina divided by a
feptum in its whole length, or in its upper half; or one of
the uteri may open into the rectum, and the other into
the vagina. In some cases the uterus is divided internally
by a longitudinal septum, either confined to the neck, or
prolonged to the orifice of the vagina. Sometimes the uterus
is altogether deficient. A vast number of references to au-
thors who have related examples of all the above-mentioned
unusual formations may be seen in Voiglet's Pathologifche
Anatomic, b. iii. p. 452-456.

This organ is situated in the pelvis, behind the urinary
bladder, before the rectum, below the convolutions of the
ilium, and above the vagina. Its situation is oblique, the
fundus being placed upwards and rather backwards, the
neck downwards, and slightly inclined forwards. Two
broad folds of peritoneum, named the ligaments lateral uteri,
fix it to the side of the pelvis. Other ligaments assist in
maintaining this viscus in its situation; viz. the round, the
anterior, and the posterior ligaments.

The broad ligaments extend from the sides of the uterus
to the sides of the containing cavity. Together with the
uterus they form a complete transverse partition, dividing
the pelvis into an anterior and a posterior cavity, of which
the former and smallest contains the urinary bladder, the
latter and largest, the rectum. These ligaments are flat-
tened from before backwards and quadrilateral. Their two
surfaces are smooth, and unattached; the anterior being
turned directly forwards, towards the bladder, the posterior
directly backwards, towards the rectum. The upper edge is
divided into two prominent lines; of which the anterior and
highest contains the Fallopian tube, the posterior, the ovary
and its ligament. The three other margins are adherent to
the inferior, to the lower part of the pelvis; the external,
to the side of the cavity; and the internal to the lateral margin
of the uterus. These ligaments are formed by two layers of
peritoneum, between which are placed the vessels and nerves
of the uterus, the ovaria and their ligaments, the Fallopian
tubes, and some cellular subjacent. They fix the uterus in
its situation, and give it a covering, in proportion as it in-
creases in size during pregnancy; they consequently become
much narrower at the time; in the latter months, indeed,
they,
they are almost entirely effaced, so that the tubes and ovaries, which they contained before the enlargement of the uterus, are now applied to the contiguity of the lateral and inferior parts of the uterus, in consequence of the manner in which this organ has separated the two layers of peritoneum.

The anterior ligaments are two small folds formed by the peritoneum, as it is reflected from the back of the bladder to the front of the uterus. They are visible only when the two viscera are separated from each other, and they appear under the form of creases, with the concavities directed upwards. The posterior ligaments are two other folds of the same membrane, where it is continued from the back of the uterus to the rectum. They resemble the former in every respect. The round ligaments are two whitish cords, extended from the upper angles of the uterus, in front and rather below the Fallopian tubes, to the groins. They pass first outwards and rather upwards, in the broad ligaments, on the front surface of which they form a remarkable prominence, they then pass on the inner surface of the iliac vessels, behind the peritoneum, to the upper opening of the abdominal ring. They traverse that canal in a direction obliquely downwards and inwards, just as the spermatic cord does in the male subject, and escape at the lower orifice. They then separate into several threads, which are lost in the cellular substance of the mons veneris and labia. These ligaments are slightly flattened in their whole extent, and broader at their two extremities, than in the middle. They are arched, so as to describe altogether a semicircle.

The round ligaments are composed of longitudinal fibres, confiding apparently only of a dense cellular tissue, very slightly susceptible of extension, of blood-vessels and lymphatics, and nerves. As they are swelled in pregnancy, and in some affections of the uterus, this circumstance has been employed to explain the pains in the groins experienced by females on such occasions. They contribute to fix the uterus in its position, and to limit its motions.

The ligaments, which we have just particularized, are so disposed, as to allow to the uterus, in its natural state, a certain degree of mobility. Hence its situation may be slightly changed in all the considerable motions of the abdominal viscera in general; coming to the ground on the feet with much force, a violent exertion in raising a considerable weight, a deep, forcible, and long continued inspiration, all tend to force the uterus downwards into the vagina, and thereby to produce the affection termed prolapso or defect of the uterus. Distention of the bladder, or of the rectum, occasions changes in the position of the uterus. But age and pregnancy produce the most signal effects in the position of this organ.

In an adult and unimpregnated female, its length is about 2½ inches, its thickness one inch, its breadth at the fundus ½ or 2 inches, and at the cervix about ½ lines. Although it returns after parturition to its original size, it never becomes again so small as it was in the virgin. Its figure on the whole is triangular, with the base upwards, and the apex downwards, and flattened from before backwards. It is divided into two parts, a superior and a broader, named the body; an inferior and narrower, called the neck. The body of the uterus is nearly oval externally, with the greatest diameter transverse. We observe in it an anterior and a posterior surface, a superior, an inferior, and two lateral sides. The anterior surface, slightly convex, slopes gently downwards and forwards, and corresponds to the bladder. The posterior, more convex, is inclined in the same direction, and is contiguous to the rectum. The superior edge, which is named the fundus, and which extends from one Fallopian tube to the other, is gently convex, and supports the convolutions of the small intestine. At the ends of this upper edge angles are formed between the fundus and the lateral sides of the viscera. To these angles of the uterus the round ligaments, the Fallopian tubes, and the ligaments of the ovaries are attached. The inferior edge, much shorter than the superior, is continuous with the neck of the organ; and indeed the line of separation is imaginary. The lateral sides are very short, slightly convex, and converging; they give attachment to the broad ligaments, and are concealed by them.

The neck of the uterus resembles a cylinder, slightly flattened from before backwards, and continued downwards from the body. Its long axis is perpendicular to the transverse diameter of the body. We describe in it an anterior and posterior surface, two lateral margins, and a superior and inferior extremity. The two surfaces are convex and smooth; the former corresponds to the bladder, and the latter to the rectum. To the sides, which are straight, the broad ligaments are attached. The superior extremity is continuous with the body of the organ; the inferior is obliquely embraced by the vagina, in which it projects, more considerably on the interior than on the posterior part. This extremity is perforated by an oval opening, with its long diameter placed transversely, named the os uteri, os internum, or os tenuis. The latter name has been given to it from a comparison to the mouth of the tenses; the end of the uterus is obtuse, and as the aperture is transverse, there is some resemblance to two thick lips. In a newly born child, the length of the opening is two lines; in a girl of twenty years, three lines; in women, who have had children, five to eight lines. The orifice is always naturally gaping, but it is more or less fo, in proportion as women have had many children, or none. Instead of being exactly in the middle it is rather behind; so that the anterior lip of the orifice is the thickest. That portion of the cervix uteri, which projects into the vagina, and forms the os tenuis, is about four or five lines long in front, and rather more behind; it measures about eight or nine lines transversely, and fix or eight from before backwards, being slightly flattened in that direction. This part of the uterus is sometimes much longer and thicker, without any displacement of the organ, or swelling of its neck. In women who have had many children, the neck of the uterus is generally thicker, and more rounded. Its orifice is almost always very gaping, and the lips more or less irregular, presenting generally one or more grooves or chaps, separated by a kind of tube recte. The os uteri may however be as regular in its figure in women who have had children, as in others; and, on the contrary, it may present in the latter those irregularities which are more usual in the former. Hence the differences drawn from the state of this part, in infancies where infanticide is suspected, or where parturition is supposed to have been concealed, are very liable to uncertainty.

The cavity of the uterus is proportionate to the bulk of the organ when it is empty; the parietes are contiguous, and leave between them no farther vacuity than suffices to hold a little mucous fluid. In this hollow the menstrual discharge flows, and the produce of conception is received. It is divided into two parts, one belonging to the body, the other to the neck of the organ. Of these, the former is the largest; its figure is nearly triangular, especially when the uterus has experienced no alteration in its bulk. We have to notice in it an anterior and a posterior surface, three edges and three angles. The two surfaces are smooth and contiguous to each other. On each of them a slightly prominent longitudinal line may be observed, dividing
disting them into equal right and left parts. Of the three margins one is superior, and two lateral: they are slightly concave, particularly in women, who have had many children. The superior, which makes the basis of the triangle, and is continued from one Fallopian tube to the other, is usually the thirtd: sometimes, however, it is the longest. Of the three angles, two are superior, and one inferior. The former may be considered as two slender appendages of the cavity, terminating at the Fallopian tubes. The inferior angle presents an opening of about four lines in extent, communicating with the cavity of the cervix. The cavity of the body of the uterus is lined by a mucous membrane, on which the vessels that furnish the menstrual blood terminate.

The cavity of the cervix uteri is a kind of canal, flattened from before backwards, and more capacious at the middle than at the two extremities; so that it has the figure of a cone, joined by its base. Such is the figure which it constantly exhibits in women who have never borne children; but, from the time of conception, that tractility of the canal, which opens into the vagina, is dilated; and after parturition has once taken place, it is always found much wider than before. It then represents a cone, with the base towards the vagina, and the apex towards the uterus. The cavity of the cervix uteri has an anterior and posterior surface, and a superior and inferior orifice. A great number of hard, and as it were cavernous, differently disposed in different subjects, may be observed on each of the surfaces. In order to see their arrangement to advantage, the uterus of a newly-born child, or of one not very old, should be selected. They will then be observed in an arborecent form (arbor Morgagni) on each surface. A hard ridge extends along the middle of each surface, and ends above in a flattened point, which is often continued with the line dividing the corresponding surface of the body of the uterus. The inferior end is prolonged to the os tinnce. From this kind of trunk laminae are extended laterally on each side; the superior ones forming nearly half right angles, and the inferior more open angles. The number of these plates may amount to about 15. They are continued outwards, describing a curve, of which the convexity is always towards the uterus, and the concavity towards the vagina. Their margin is grooved, except towards the outer end, which is smooth. The breadth of the laminae diminishes insensibly, and they disappear on the sides of the cavity, where the anterior and posterior ones are confluent with each other. The superior are broader than the inferior. These laminae are not simple, they produce other smaller ones. More or less deep grooves separate the plates from each other: in the bottom of these are observed small eminences, like the teeth of a comb, passing from one lamina to another.

The disposition of these wrinkles is regularly such as we have described in newly-born infants; but, when the cervix uteri is enlarged in pregnancy, the eminences are flattened, and the whole structure is confluent; this is still more remarkably the case just after parturition; the laminae are then nearly destroyed, and the arborecent appearance almost entirely effaced.

The superior opening of the cavity communicates with that of the bay, so that they form indeed but one. The inferior has been already described under the name of os tinnce.

In the cervix uteri we may notice the openings of numerous lacuna or short ducts ending in cul-de-sacs, concealed among the rugosities already described. Most of these are small; some are larger and long. There are fix or seven just above the os tinnce, the fundus of which is towards the inferior end of the uterus. These are large, and receive the terminations of several smaller ones. They are filled with a mucous fluid, which can be squeezed out, and they will often admit of a fine bristle for a certain length. They are best seen in a woman who has just been delivered, or who has died in the latter periods of utero-gestation; the prominences being flattened, the lacunae are more exposed. These organs secrete the mucous fluid, with which the cervix uteri is moistened.

We see also sometimes in this cavity a considerable number of round or oblong, larger or smaller follicles, formed of a thin membrane, filled with a clear mucous fluid, and not polluting any excreta duct. They adhere to the trunk or branches of the arborecent structure already described, and their number is not constant. Sometimes they are half buried in the substance of the uterus, sometimes they are completely isolated, and hold only by a pedicle. Their nature and use are not known. Probably they are one source of the mucous secretions of the part, although we cannot explain how the secreted fluid is evacuated.

The thickness of the sides of the uterus varies from four or six lines to fifteen ; but it is not uniform in all parts of the organ. It is much the same on the surfaces and edges. The fundus is generally the thickest; and this is thicker in the middle than towards the angles. The neck is rather thinner than the body. The substance of the organ is of a greyish colour, and a firm consistence, especially towards the neck, which is more compact than the rest of the organ. It consists of an external membrane, of a proper tissue, of an internal membrane, of arteries, veins, lymphatics, and nerves.

The external membraneous covering is contributed by the peritoneum, which is reflected from the posterior surface of the bladder over the uterus, of which it covers the anterior surface, the fundus, and the posterior surface, is continued to the upper half of the posterior surface of the vagina, and is reflected from that vertex to the rectum. It adheres every where to the proper tissie of the uterus by means of a very fine and close cellular texture, without any fat. It is very difficultly separable, particularly at the fundus.

The proper tissie forms nearly the whole thickness of the organ. It is a greyish, dense, and very compact substance, very refising to the scalpel or scissors, cutting almost like cartilage, and containing numerous small vessels. This substance, which appears cellular, spongy, and to contain fluids, is manifestly fibrous; but the order and arrangement of the component fibres cannot absolutely be determined in the unimpregnated state, on account of their being so inextricably interwoven. They are larger and more confidcd in the cervix than in other situations, where they are softer and more numerous. Although in the empty state of the organ these fibres have scared any of the characters of materiality, their nature seems to be sufficiently pointed out by the contractile powers which they exhibit in parturition.

The external membrane of the uterus is continuous on one side with the mucous lining of the vagina, and gives origin on the other to two prolongations, which enter into the Fallopian tubes. It is extremely thin, and so closely united to the proper tissie of the organ, that it seems to form one substance with it. It reddish in the body of the uterus, and whiter in the neck. It is perforated by an infinite number of pores, which are merely the extremities of exhaling vessels, and give issue to the menstrual discharge.

Appendages of the Uterus.—Under this name are included the
the round ligaments which have been already described, the ovaries, and the Fallopian tubes.

The Fallopian or uterine tubes are two (a right and left) conical, tortuous, and vermiform canals, arising from the inferior and lateral parts of the uterus. They float loosely in the cavity of the pelvis, being enveloped in the upper and anterior edge of the broad ligament, and fixed by their inner extremities. Their length is four or five inches; and the direction of their course very uncertain: it may be stated in general that they go transversely outwards, and that they bend backwards at their outer ends, so as to turn towards the ovaries. But, as they are in great measure loose, and as the edge of the broad ligament restrains them but slightly, the intestines, when diffused with air or aliments, may displac them in different directions. The calibre of the tube is so narrow towards the uterus, that the orifice by which it communicates with this viscus will only admit a hog's brittle. It enlarges gradually to the middle, where it is slightly contracted; and dilates again to terminate by an aperture which communicates with the cavity of the abdomen. The tube is considerably broader at its end than at the uterus, but rather narrower than in the portion immediately preceding. The internal membrane of the tube, together with the external, which is formed of peritoneum, is produced to some length beyond this orifice, and forms round it a fringed and radiated kind of ornament, called the fimbriae (pavilion de la trompe; morceau frangé). When this part is examined in water, it has a very beautiful appearance, and seems composed of small separate leaves, like hone flowers. The breadth of this membranous fringe is not equal at all parts; its circumference has somewhat of an oval figure. All the portions into which it is divided are not of the same length: the longest extends to the ovary, and is firmly fixed to its outer extremity, so that the fringed end of the tube is constantly retained near to that body. The fimbriae are conceived to poffefs a muscular structur.

The Fallopian tube is composed: 1st. Of an external membrane, furnished by the peritoneum, which covers it as it does the intestines; 2. Of an internal, soft and pulpy membrane, the surface of which presents everywhere where more or less prominent longitudinal lines, covered by some authors to be muscular fibres. Indeed the office of the tube seems to require the existence of contractile fibres in their composition; 3. Of a spongy tissue, compared to that of the urethra and corpus cavernosum, but the real nature of which is not understood. Very numerous blood-velsels are distributed in this substance, which appears to swell and experience a kind of elevation in the act of copulation: in consequence of this the fimbria are applied to the surface of the ovary; 4. Of blood-velsels, derived from the spermatic arteries and veins, of lymphatics, and nerves furnished by the renalplexuses. That the office of the tube is immediately connected with the functions of generation, and that they convey the germ from the ovary to the uterus, cannot be doubted: but we do not understand how they execute this function. We may observe that they form a communication between the uterine cavity and that of the abdomen: and, as the former communicates externally through the medium of the vagina, the serous membrane of the abdomen has thus a continuity with the surface of the body:—a circumstance that is observed in no other instance.

The ovaries, called by the ancients the female testicles, are two oblong, flattened, and whitish bodies, placed at the posterior surface of the broad ligaments, in which they are included. They nearly equal the size of small pigeons' eggs in the adult; but their flattened form gives them a different figure. Their long diameter is placed transversely. They present two surfaces, two edges, and two extremities. The surfaces and the upper edge are loose, and present nothing remarkable except slight tubercular ridings. The inferior margin adheres to the posterior edge of the broad ligament. The external extremity is connected to the longitudinal Fallopian fimbriae; and the ligament of the ovary is attached to the internal end. This ligament is a small fibrous cord, about ½ inch long, contained in the posterior part of the broad ligaments, and fixed to the angle of the uterus behind the Fallopian tube. Some old anatomists regarded it as a canal destined to convey into the uterus the leucos, which they supposed to be secreted by the ovaries; but it is in reality a solid fasciculus, similar in its nature to the round ligament, and having no other office than that of fixing the ovaria in its place. Yet the latter organ possesses considerable mobility; its situation in the broad ligament, which is itself moveable, gives it a power of motion. The intestines and the urinary bladder may make it change its position; and we know that it has sometimes been contained in a rupture.

The ovaries are composed: 1st. Of an external membrane, derived from the peritoneum forming the broad ligament; 2. Of a proper membrane, of a white colour, and firm fibrous texture, hardly separable from the proper tissuse of the organ; 3. Of a spongy substance, which is dense on the outside, more soft on the inside, where it is greyish, and in some degree cellular and spongy. In this substance are lodged some small, roundish vessels, amounting in number to between fifteen and twenty. Scarcely visible in infancy; these are very apparent in adult and fruitful women. Generally, in old women, these vessels are no longer visible, and their place is occupied by hardish tubercles. The vessels are not all of the same size; those which are near the surface of the organ are as large as hemp-seeds; while the others, being more deeply seated, are considerably finer. These bodies are placed in the cellular or spongy substance of the ovary, in which they may be said to be enchaufed; but they form for the most part small prominences under the external membrane. Others are completely elevated on the surface of the organ, and others again are concealed in the interior. They are not suspended by filaments, nor do they form any particular cells different from the cellular matter comprising the parenchyma of the ovary. They were very particularly described by De Graaf, and have often been called, after him, ova, or ovula Graafiana. They are generally regarded as so many germs, or rudiments of new beings. They are composed of a simple and very thin membrane, smooth externally, and containing a clear, sometimes yellow or reddish liquor, coagulable by heat and alcohol, and forming white threads, like the alubums of an egg.

The arteries of these parts are derived from two sources: viz. the spermatic branches of the aorta, and the uterine branches of the internal ilium. The former are more tortuous than the corresponding vessels in the male; they pass between the two layers of peritoneum, which form the broad ligaments, and are chiefly distributed to the ovaries. But they send numerous ramifications to the Fallopian tubes; others to the sides of the uterus, and form along the round ligaments, which communicate with small branches of the epigastric. The chief arteries of the uterus are the uterine branches of the internal ilium trunk. They partly fill the uterine arteries, ascending in the left and right. These arteries first runs downwards, then turns up at the neck of the uterus, and enters between the layers of the broad ligament. It gives large branches to the vagina, then runs along the side of the uterus, from the neck towards the fundus, producing numerous arteries, which ramify over the organ in every direction. These have a tortuous course, and communicate freely with each other, and with those of the opposite side.
Some ascend to the upper edge of the broad ligament, are distributed in the Fallopian tube and round ligament, and communicate with the peritoneum.

The veins, like the arteries, may be referred to two divisions: the peritoneal and uterine. Numerous branches come from the uterus, ovary, and Fallopian tube, and form a large venous plexus in the upper part of the broad ligament; under the name of corpus pampiniforme, this ascends towards the loins, and terminates in forming a single vein, which has the same termination in the male subject. A great number of venous ramifications accompany the arteries all over the viscera, but are in general less tortuous. They communicate freely with the peritoneum. They form a large plexus running along the side of the uterus, with the uterine artery, and end in one or more considerable venous trunks, which join the internal iliac.

The uterus possesses numerous lymphatic vell, which are divided into three orders: one of these ascends with the round ligaments, and goes to the inguinal glands; another joins those of the vagina, and passes to the pelvic glands; and the third, together with those of the ovary and tube, ascends with the peritoneal vell, to terminate at the glands in front of the aorta and vena cava near the kidneys.

The nerves come from the great sympathetic, of the hypogastric and peritoneal plexuses, and from the pelvic plexus.

Fetal Properties of the Uterus.—Until the period of impregnation, this organ seems to poffef only that modification of sensibility and contractility, which are necessary for the purposes of nutrition, and the menstrual evacuation. It seems doubtful whether or not it is endowed with animal sensibility in its healthy state. It has been imagined, and attempted, that the contact of the glans penis with the os tincæ, in copulation, is one source of the physical sensation experienced by the female on that occasion: this we conceive to be problematical. Hailer states, that a wound of this organ by a leaden bullet produced very violent symptoms; viz. repeated faintings, and speedy death. It must be doubtful how far this could be referred to the uterus merely, as much other injury must have been inflicted in such a case. Animal sensibility is certainly developed in the uterus by disease, whether it exit in the natural state or no. The same observations may be applied to the vital properties of the Fallopian tubes and the ovaries. However obscuring the vitality of these organs may be exhibited, when not immediately engaged in the exercise of their important functions, it is manifested in a much more striking point of view by the sympathies established between them and other parts of the body. We have already shown, that the removal of the ovaries at an early age entirely changes the subfquent characters of the animal; affecting even the organization of the bony and muscular parts of the frame. From the time of puberty, when the organs now under consideration acquire a fitness for exercising their particular functions, we shall find that their condition and various changes affect in the most striking manner all the other vital phenomena of the female constitution. The previous symptoms, the commencement and periodical returns of menstruation; the first impulses of love; the change to a new temperture; pregnancy and its various epochs; perturbation and its consequences; lastly, the cessation of the sexual life, and the symptoms of the critical age, are so many remarkable changes in the organization of the female, keeping up a constant alternation of suffering and disease, of lively impressions, nervous and spasmodic affections, the influence and general result of which must be carefully attended to in apprehting the nature of woman, and the part which she has to fill in society. When we con-
marked, is nearly white, and does not exhibit those successive shades which, at a more advanced age, distinguisn its erine, its middle, and its posterior extremity. In the newly born child, and during the first years of life, the uterus does not occupy the cavity of the pelvis; together with the ovaria and tubes, it is placed above the superior aperture. At this time it is very small, and has a very different figure from what it presents when perfectly developed. The neck is larger and thicker than the body, which narrows, and elongated, has not the triangular figure. The parietes of both are thin, and the cavity very small. The tubes are proportionate in length to their future flate.

From birth till puberty, the generative organs of women experience fewer changes than those of men: yet they grow in proportion as the body encreases; and to those, which at first were remarkable for their size, as the clitoris and mons veneris, gradually lose this distinction. The uterus appears less elevated above the pubes, in proportion as the pelvis changes its form and proportions, and as the superior aperture becomes less inclined. It encreases principally in breadth and thickness, but its growth is not very rapid. The changes which occur at the time of puberty, considered in an anatomical point of view, are not considerable; there is a remarkable revolution in the vital powers of the generative system, rather than any considerable increase of the organs. The internal parts, however, at this time, have acquired their complete size, and the external organs become covered, in the situations already particularized, with hairs.

In extreme old age, the generative organs of the female, already reduced for a considerable time to complete inaction, bear the marks of decrepitude common to the whole frame. The vulva presents the most remarkable changes; this is the part most affected by the performance of the sexual functions, and many parts of it partake the general encreasement. The prominence of the mons veneris is nearly effaced, and a great part of the hair, which covered it, is lost; the remainder becoming grey and straight. The labia and mons veneris are soft and flaccid; the latter sometimes can scarcely be laid to exst: the mucous membrane is whitish, or at least very pale in its colour. The blade of the vagina presents nothing very remarkable. The volume of the uterus is diminished, its parietes having become thinner. The tubes and round ligaments are also in some degree reduced. The ovaries do not exceed half the size which they had in the adult age; they are sometimes very denfe, and marked with deep grooves, so as to render the surface tuberculous; in other instances, their subsidence is removed, so that they are reduced to a very thin appearance. The vessels contained in their parenchyma are no longer discernible.

State of the Generative Organs during Pregnancy.—The uterus, intended to serve as a receptacle for the fetus, dilates after it has received the germ from the ovary, and enlarges in proportion as this is developed: its blood-vessels bring an additional quantity of fluid, from which the fetus draws its support: lastly, at a certain period, fixed by the laws of nature, it discharges the produce of conception by virtue of the vital properties, with which it has been endowed, during the remarkable change of its organization. Such are the threefold objects, to the attainment of which are directed the new dispositions acquired by this organ during gestation.

The anatomy of the gravid uterus has been most fully elucidated by Dr. William Hunter, whose splendid and beautiful plates form an engraving in the history of our knowledge of this subject. "The Anatomical Description of the human gravid Uterus and its Contents," London, 1794, drawn up by Dr. Ballie, from the papers of Dr. Hunter, contains Vol. XVI.

a very clear account of the subject; this, with the plates already mentioned, is the source from which the following description is principally derived. The observations, unless where it is otherwise expressed, apply to the state of the organ as it is found in the 9th month.

Considerable variety exists in the size of the organ. The child and placenta may be twice as large in one case as in another: there may be six or eight times more water in one case than in another; not to mention the differences arising from there being only one child or twins, &c.

The development of the uterus appears to be immediately produced by the general dilatation of the liquid surrounding the fetus, and not by the fetus itself, since the latter does not come in contact with the organ. The size of the part depends principally upon the quantity of the liquor amni. For, though woman who have twins, or a very large child, are commonly observed to be very big, yet the greatest number of those who are really very much swelled out, are so only from a vast quantity of water. In such cases there is frequently but one child, and that very often a small one.

The general figure of the uterus is oviform; the fundus answering to the largest extremity of the egg, and its inferior and uterine to the small end; but the fundus is larger and more flat, or less pointed, in proportion to the lower extremity of the uterus, than one end of an egg is to the other; and the whole uterus seems more or less compressed, so as to be broader from right to left, than it is from the forepart backwards. Besides these more constant deviations, the figure of the uterus differs from the regular oviform, from a variety of accidental causes, as it adapts itself to the neighbouring parts, to the attitude of the body, and to the position of the contained child. In order to conceive these varieties more easily, we must remember that in most cases the uterus is not so completely filled as to be upon the full stretch. Were it out of the body, and filled artificially, it would easily contain more than it actually does. Thus the uterus, like a bladder of water not quite full, is pliable, and moulds itself into various shapes from accidental circumstances.

The figure of the organ, in particular situations, is modified by the pressure of the surrounding parts: the brim of the bony pelvis has the effect of a belt girding the lower part of the organ, and the projections of the spine, and of the psoe muscles, and bone vessels, mould the outside of the uterus into corresponding cavities. The attitude of the body influences the figure of the uterus, as the parts against which it rests vary in different postures. The position of the child is another cause influencing the figure of the uterus. Not only in dead bodies do we see the parts of the child making various different projections on the outside of the uterus; but we can frequently observe the same variety in the living state, by examining the outside of the abdomen. The round projecting ball, made by the child's head or buttocks, is commonly very perceptible, and in many instances smaller parts, as the knees or elbows, can be distinctly felt. Dr. MacKenzie met with a case of twins, where the uterus, instead of making one compacted oval body, had stretched into two distinct bags, containing the respective fetuses; so that its outside was marked by a notch, dividing it into two apartments, as deep and distinct in proportion, as that in the heart represented on cards. The organ often stretches unequally in the corresponding opposite parts; so that either the right or the left half may be considerably larger than the other. It may swell unequally on the front or back part, so that the diameter between the insertions of the Fallopian tubes may be much smaller either before or behind them, in the opposite directions. In the unipregnated state, it has commonly one triangular cavity: but it is sometimes subdivided, at its upper part.
part, into two lateral cavities, so as to bear some analogy to the two horns of the uterus in a quadruped. This peculiar conformation may explain the unequal extension of the two sides in some cases of pregnancy; and may elucidate the above-mentioned cafe of Dr. Mackenzie.

The small or lower end of the organ is placed in the cavity of the pelvis. This generally contains the greater part of the child's head, and fills up the cavity so completely, as to press the bladder against the pubes, and the rectum against the facrum. Tho os uteri is directed against the coccyx, or the lower part of the facrum. The body and fundus, which contain the rest of the child and the placenta, are so placed in the front of the abdomen, from the brim of the pelvis upwards, to the epigastric region, as to be under and before all the other bowels, and in immediate contact with the parites abdominis, and to occupy the whole space from one hip-bone to the other, and a proportional extent from these bones upwards. As it rises up from the cavity of the pelvis into the hypogastric and unilobal regions of the abdomen, the loose connections of the intestines andomentum can take account for these parts being pushed up before it.

The axis of the uterus is oblique, its lower end being turned backwards, and the upper p. proportionally forwards. This obliquity is changed by the attitude of the body, and by many other causes. In the erect posture, the weight of the uterus presses the first part of the organ into a greater rotundity, and its axis then approaches the nearest to a transverse or horizontal line. In the recumbent posture, the contrary situation is exhibited. In a first pregnancy, the uterus stretches itself higher up in the epigastric region, and its axis comes nearer to the longitudinal or vertical direction, because the parites of the abdomen do not easily give way: but in a woman who has had many children, the abdomen, by repeated dilatation, is rendered more loose and pendulous, and the uterus extends forwards rather than upwards. This position is more remarkable in very short subjects; because in them the chest is so near the pelvis, that the uterus is flopped in affect. The same circumstance happens, and for a similar reason, when the pelvis is very narrow: as no part of the organ, in such a case, can be lodged in the pelvis, it must be placed proportionally higher. In a very short and crooked woman, on whom the csarcan sectio was performed, the fundus uteri was not only turned forwards, but even a little downwards. As the lay upon the table, the navel could not be seen, as it was placed on the posterior and inferior part of the abdominal tumour. In order to expose that part of the abdomen to the surgeon, it was necessary to lift up the fundus uteri, without which the hypogastric region would have been inaccessible. The deviation of the organ towards the right or left side cannot, in general, be very considerable; as it poises nearly the whole space between the hip-bone, and its lower extremity is fixed to the pelvis. A small lateral obliquity is very common; and we can easily suppose, that in a reclined posture, the projecting of the lumbus vertebra will throw rather more than one-half of the uterus into the lateral cavity between the spine and one hip-bone. We know, indeed, that in all the last months, the abdomen is often more full on one side than on the other. Women lay in such a cafe, that the child lies on one side, and they judge rightly. Where the child lies the bulk must be both more considerable and more permanent, but where there is only uterus, placenta, and water, the swelling will be softer, and project less. The pressure of the child, when it lies more in one side than in the other, makes the limb of that side weaker, more benumbed, and more liable to cramps, and oedematous swellings.

Of the Ligaments, Tubes, and Ovaria of the Pregnant Uterus.—It has been commonly observed that the ligaments and tubes of the pregnant uterus are attached lower upon the side of the organ than they were in the unimpregnated state; and the reason is very obvious. The peritoneal coat of the uterus makes the broad ligament on each side, much in the same manner as the analogous membrane of the intestines makes the mesentery. When the woman is not pregnant, the ligament is of considerable breadth, the spermatic vessels pass between its two lamina, the round ligament runs downwards and outwards, on its anterior surface, and the tube runs in loose peritoneum turns on its upper edge. But in proportion as the circumference of the uterus grows larger, the broad ligaments become narrower, their posterior lamella covering the posterior surface, and their anterior lamella the anterior surface of the uterus itself. We observe now, that the round ligaments do not run down on the foremost part of the broad ligaments, but upon the foremost part of the body of the uterus itself. In proportion as the fundus rises upwards, and increases in size, the upper part of the broad ligament is fo stretched, that it clings close to the side of the uterus, so that in reality the broad ligament disappears, no more of it remaining than its very root; namely, its upper and outer corner, where the group of spermatic vessels passes over the iliacs, to the side of the uterus. In this state, although the small end of the tube opens into the same part of the uterus, as before impregnation, yet the tube has a very different direction: instead of running horizontally outwards, it passes downwards, closely attached to the side of the uterus. Behind the fimbrice lies the ovarium, also connected to the uterus. The fimbrice and ovarium are commonly placed upon the fickle vessels, or fleshy brim of the pelvis, behind the group of spermatic vessels.

The round ligaments run almost perpendicularly downwards from the fundus uteri to their passage through the muscles; they are considerably enlarged in thickness, and are so vascular, that when injected they seem to be little more than a bundle of arterics and veins. Their arteries are all convoluted. Both their arteries and veins proceed principally from the spermatics, and anastomose evidently with the external vessels in the groin or upper part of the labia. Even in this enlarged state of the round ligaments, it is very difficult to say how they terminate in the groin: they appear to be infeinbly lost. The tubes are more fleshy, vascular, and soft in their subsurface, and are less convoluted than in the unimpregnated state. The fimbrice and internal rugae are larger and much more beautiful, especially when their vessels are well injected. The ovaries, excepting that which contains the corpus luteum, seem to have undergone no remarkable change. The latter body can be distinguished by a rounded fullness, and frequently a considerable prominence, sensible both to the sight and touch, upon the middle of which there is a small pointed cavity or indention, like a cecixir. Upon lfitting the ovarium at this part, the corpus luteum appears a round body, of a very distinct nature from the rest of the ovarium. Sometimes it is oblong or oval, but more generally round. Its centre is white, with some degree of transparence; the rest of its substance has a yellowish cast, is very vascular, tender and friable, like glandular flesh. The larger vessels appear round its circumference, and send smaller branches inwards. A few of the larger vessels are situated at the cecixir or indention on the outer surface of the ovarium; and are there so little covered, as to give that part the appearance of being bloody, when
when seen at a little distance. When there is only one child, there is only one corpus luteum, and two in case of twins. There may be, in the latter case, two distinct ones in one ovary, or one in each ovary. The sex of the foetus has no relation to the corpus luteum, being formed in the right or left ovary.

**Thickness of the Uterus.**—Those who say that the uterus grows thicker in proportion as its bulk is increased, have probably been deceived by examining the uterus of a woman who died some hours or days after delivery. In that contracted state the uterus is often found even two inches thick: but in the natural dilated state, though there may be some difference, the thicknefs, in general, is but little more considerable than before impregnation. When not injected, its ordinary thickness is from one to two-thirds of an inch; when its vesfdels, and particularly the veins, are pretty well filled with wax, its thicknefs is thereby considerably increafed, more especially where the placenta is fixed, on account of the number and size of the vesfdels at that part. For this reason only, perhaps, the uterus is thickest at that part, and for the fame reason it is thicker towards the fundus than near the cervix. Much variety may be observed with respect to thicknefs: and such inequalities in the fame individual, that even where the placenta did not adhere, the uterus may be almost twice as thick at one part as at another. On opening the organ, its thicknefs is generally found more considerable than external examination would have led us to expect. For its substance is soft, and a fluctuation, like that of water in a thin bladder, may be felt.

**Blood-vesfdels.**—There is no circumstance, in which the gravid uterus differs more from the unimpregnated, than in the size and termination of its vesfdels. The arteries, both spermary and hypogastric, are very much enlarged. There are infinite numbers of anaimolous arteries through the whole thicknefs of the part, fo that the whole uterum makes a general net-work, and the branches are convoluted or serpentine in their course. None of the larger ramifi- cations are seen for any length of way upon the outsife of the uterus. As they branch from the fides, they disappear by plunging deeper and deeper into the thicknefs. The arterial branches, which are much enlarged, are thofe which run towards the placenta; fo that, wherever it adheres, that part appears evidently to receive by far the greatefl quantity of blood; and the greatefl number, both of the large and fmall arteries at that part, pafs through to the placenta, and are necessarily torn through upon its separation. The branches of the uterus appear to be fill more enlarged, in proportion, than the arteries. From the fides of the uterus they ramify through its thicknefs, running deeper and deeper as they go on, and without following precisely the course of the arterial branches. They form a plexus of the largest and moft frequent communications which we know of among the vesfdels of the human body. And this they have in common with the arteries, that their larger branches go to, or rather come from that part of the uterus to which the placenta adheres; fo that, when the venous fystem of the uterus is well injected, that part is evidently the chief source of the returning blood. Here, too, both the large and fmall veins are continued from the placenta to the uterus, and are always necessarily broken upon the separation of these two parts. The veins are without valves, and are therefore easily injected. In injecting them, we observe that at first they become turgid, and project on the outer surface of the uterus; but in proportion as we throw a greater quantity of wax into those vesfdels, they grow more flat and obscure; because the uterus itself becomes more filled and tenfe, which has the effect of com-

The vesfdels are more numerous, and many of them larger than could have been imagined. They pervade the thicknefs of the organ uniformly. Its peritoneal coat appears, like that of a calf's fileen, to be interwoven with a crowded plexus of these vesfdels; and where they get to the fides of the uterus, when filled with mercury, some of them are even larger than a goose's quill. Some are remarkably variegated, or enlarged at particular places.

We do not know that any change takes place in the nerves of the uterus during pregnancy.

**Muscular Fibres of the Uterus.**—The substance of the organ is rendered remarkably soft and loose in its texture by pregnancy; fo that, when an incifion is made into it, the wound can be easily made to open wide; or if a narrow ilrip be cut out, it can readily be extended to at leaft twice its original breadth. This laxity appears to depend on two caufes; viz. the great quantity of large vesfdels in its composition; and the loose fibre connection between the falficuli of its fibres. When we speak of the muscular fibres, it is dif-

cult to treat the subject with precision. We neither know their external appearance, nor their internal composition. They only manifest themselves to our fenses, where numbers of them are collected into bundles, and make what we commonly call muscular falficuli. In the quadruped, as, for instance, the cat or rabbit, the muscular action of the uterus is seen as evidently as that of the intestines, when the animal is opened immedi-
ately after death. In many parts, particularly of the internal surface of the uterus, thefie fibres have the fame striking falficulated appearances as we observe in common muscles; yet they are of a paler colour and harder texture. Dr. Hunter exa-
mined the fibres very carefully in a woman who died seven days after delivery. He stretched it gradually in warm water, and then inverted it, to have a full view of the inner surface. The remains of the decidua had paifed off with the lochis, fo that the falficulated ftratum of muscular fibres appeared to be bare, and to make the internal surface of the uterus. In many places, but particularly where the placenta had been fixed, the falficuli left oval fpaces between them, for the paffage of arteries and veins, somewhat like those separa-
tions between the tenuous fibres of the abdomen and thighs, where veins pafs out to the cellular membrane and integuments. The cervix uteri, where the rufle are intimated, had not such regular nor fo large falficuli as the rest of the uterus. In the body of the organ the fibres were very regularly circular. The falfidus was made up of two planes of concentric fibres, at the very centre of which was the orifice of the Fallopian tube. When this internal ftratum was removed, the falfi-
culated appearance and regular direction of the fibres was lefs and lefs apparent, in proportion as the deflufion was continued outward; which seemed to be owing in great meafure to the infiniite number of branches and communications of the large veins. Afterwards, says the doctor, I had the most favourable occasion that could be defired, for examining the fibres on the intine of the uterus. It was in a woman who died at the end of the ninth month, without being in labour, and without having any loothing or discharge of waters. When I had examined, and taken out all the contents, I attended particularly to the internal surface of the uterus. I found it every where covered with a thin ftratum of the decidua through which the muscular fibres appeared, but with some degree of obscurity. Upon rubbing off this tender membrane with a cloth, it gave mee

pleasure
pleasure to see how exactly the above description agreed with the appearances.

The existence of muscular fibres in this organ has not, however, been universally acknowledged. "Reflexing the alleged muscular texture of the uterus," says Blumenbach, "I must observe that all the human uterus, which I have carefully examined both in the pregnant and unpregnant condition (and I have had opportunities of such investigations, not merely in preparations, but in the most recent flate after death) have not exhibited any thing that could be taken for genuine muscular fibres. The advocates for the muscularity of this organ must allow that the fibres differ moit remarkably from all others in the body. I am more and more convinced every day that the uterus possesses no true irritability; but that it poiffes, if any part of the body can be said to posses, a peculiar modification of vitality (vita propria) corresponding to its peculiar motions and functions, and not referrible to the common laws of irritability. These functions appeared vs irregular and peculiar to the old physicians and philosophers, that they called the uterus an animal contained in an animal." Institut. Physiolog. p. 222.

The mouth of the uterus differs considerably in the different times of utero-gestation. For the greatest part of the nine months, that is, till the cervix uteri be fully dilated, there is a projection of bone of the anterior and posterior part of the os uteri; and in some women this continues till the very time of labour. But in most women, when they are at their full time, or very near it, the os uteri is flat, and makes only a small ragous hole, often not readily discoverable by the touch on the lower or posterior part of the rounded lower end of the uterus. The border of the orifice, and the internal surface of the uterus, for an inch or more all around, is full of little irregular cavities. These contain a tough mucus, which shoots across, and plugs up the inner part of the orifice. This mucus is commonly squeezed out from all the lacunae, by the dilatation of the os uteri in the beginning and progress of the labour; and so loosing its hold, it falls out. In the dead body, when the part is kept some days in water, the glutton swells out more and more from all these cavities, and then separates entirely. Then the innumerable lacunae, which contained it, being empty, are very visible. And if the glutton be thus carefully taken away, and be floated in water, its external surface is seen beautifully ornamented with all the processes which were drawn out of the innumerable lacunae.

I have given the above account of the uterus in the earlier months of pregnancy. "In the third and fourth months, the substance of the uterus become more soft than before conception, and all its vessels being proportionally enlarged, it appears to be much more vascular. We may, therefore, reasonably believe, even if we knew nothing from diffections of quadsels, that the uterus changes its nature in that respect from the time of conception, and receives a greater quantity of blood. Its thickens is only a little increased in its natural state, but considerably when the veins and arteries are artificially dilated with any fluid. At this time the conception is lodged entirely in the fundus uteri, or in that part which in the unimpregnated state has a smooth internal surface; no portion of the conception touching that part, and being crowded between the two layers of the uterus, which is narrow and rugged within.

The cervix uteri remains contracted and hard in its substance, and contains a tough and firm jelly, which cement and fills up its cavity so completely, that, upon attempting to push a probe through it, the probe will as readily force its way through the hard substance of the uterus itself, as through the cementing jelly. When the uterus is kept a considerable time in water, six or eight days perhaps, the cementing jelly swells, grows in proportion, and at last comes away, or falls off in one mass. Then the internal surface of the cervix exhibits a most beautiful appearance; being variegated with projecting rugar, and innumerable intermediate narrow, but deep cavities, which lodged so many processes of the jelly. In separating the jelly, when previously macerated it had been hit for such an operation, I have seen those processes drawn out of the little cavities as distinctly as we can see a hand drawn out of a glove: and when the jelly is carefully separated and floated in clear water, it preserves its figure, and exhibits a most elegant appearance, produced by the processes that shoot out from its surface all around.

"The os uteri, or very extremity of the uterus, is in some women narrow or pointed, with a very small orifice, that will just admit the point of a very small finger; and in some it is large, soft, or spongy to the touch, granulated upon its surface, and the orifice so wide as to admit the end of the finger full half an inch up with great ease. There the passage becomes narrow, and is closed with the gelatinous cement. The os uteri, all around its passage, is crowded with small cavities, containing the fame fort of jelly, which by maceration swells, pushes out from the cavities, and comes away, leaving the cells void. This, no doubt, is part of the jelly which naturally comes away in labour. Some women have much more of it than others; and, in comparing different dissections, I have observed more of the jelly within the cervix uteri, and more likewise in the cells round the os uteri, in one subject than another.

"The uterus, at the time of three or four months, is by no means so tightly filled but that it would easily contain more. It is like a bladder therefore, so filled with water, that it would easily contain a third part more. Hence it is soft and swaggiong, and easily changing its shape, accommodates itself to the neighbouring parts.

"The situation of the uterus, which at first is in the cavity of the pelvis, but afterwards gradually rises up into the cavity of the abdomen, and the changes which its ligaments undergo, may be easily conenced by any person acquainted with the state of those parts before conception, and who has considered what has been already said about the same things in the ninth month of pregnancy.

"The peculiarities of the ovum are very different at the different periods of utero-gestation. In the earlier months the corpus luteum is considerably larger and more vascular; and within it there is a considerable and evident cavity containing a fluid. When the uterine vesicles have been injected, I have observed that the wax very easily extraveses into that cavity. On the outside of the ovum there is a little pit, which looks like a hole, leading into the cavity of the ovum. But in the cases which I have seen, no break in would pass; it appeared to be an oblitered duct, or passage grown together."

The ferox covering of the uterus, derived from the peritoneum, undergoes very considerable extension during the enlargment of the uterus in pregnancy. We have already shown that the broad ligaments nearly disappear at this time, but there is no accesion of the same kind either before or behind, as the bladder and rectum still continue to be covered to the usual extent by that membrane. The increased surface of the peritoneal coat must be considered therefore as an extension of the membrane.

"As the mucous surface of the organ is the medium of communication between the uterins and the bowels, its changes refer to the purposes accomplished by this connection. In the natural state, it exhibits merely the fine orifices of exul-
haling vessels, but after conception a large number of considerable arteries and veins pass from it to the surface of the ovum; and these are more numerous and large in the situation of the placenta than elsewhere. These communicating vessels have been described already in the article Embarvo. Towards the latter periods of gestation the vulva becomes swollen and relaxed, affording a lapse which favours its dilatation in the act of parturition.

The vital properties of the uterus, as well as its organization, are considerably altered after conception. The organ acquires animal sensibility; hence women feel the motions of the child, and even experience very considerable pain in particular positions of the fetus, hence too the sharp pains felt in parturition. We do not know whether much pain is experienced by the incision of the uterus in the cephalic section. But, supposing that it is not, the fact would not prove that the organ is not possessed of animal sensibility. Its powers may render it susceptible of some stimuli and not of others. When no circumstances interrupt the ordinary phenomena of pregnancy, we have no proof, until the natural period of this condition arrives, that the organ possesses so strong a contractile power as that which we see exerted in parturition. We might even believe that this property is not developed until the end of pregnancy; but there is no epocha of gestation, from the first presence of the germ in the uterus, at which this contraction may not be excited by the action of particular causes, which, under certain circumstances, are powerful enough to produce the expulsion of the child. Violent contusions of the abdomen, and penetrating wounds affecting the uterus, are frequently followed by abortion. Violent pallor may cause this premature expulsion of the fetus. The same effect is produced by the evacuation of the waters of the amnios, independently of any other cause; the uterus, when no longer dilated, contracts, and abortion ensues. This contractile power, with which the uterus becomes endowed on the change of its organization, partsake of the characters of animal contractility and of irritability. The inactivity of the uterine parietes, until the termination of utero-gestation, resembles, in some respects, the quiescent state of the voluntary muscles, when they are not excited by the influence of the brain; and the contraction, by means of which this organ expels its contents, can be compared only to the exertion of these muscles. On the other hand, the contractility of the uterus is independent of the cerebral influence, and its exercise is absolutely involuntary; this circumstance particularly characterizes irritability in those organs which possess it in the most remarkable degree, as the heart. Like the latter power, it may be lymphatically routed, when the action of the uterus is suspended during or after parturition; and it continues for some time after apparent general death.

The attention of physiologists has been much occupied in investigating the immediate cause of parturition; that is, the cause which calls into action the contractile power of the uterus at the end of utero-gestation. Many adopt the following explanation. They admit a species of opposition between the body and neck of the uterus, during gestation, the resistance of the latter overcoming the tendency of the former to contract. As the neck is gradually obliterated, its opposition is diminished, and it then gives way to the contractions of the body and fundus. Against this explanation we may urge that the supposed struggle between two opposing forces is purely hypothetical, that there is no evidence of any contraction or attempt at it during pregnancy, and that it comes on quite suddenly at the expiration of the term. It is this sudden exercise of the contractile power, at the end of the ninth month in the human species, that marks the term of gestation, and for which we can assign no other cause than the immutable laws by which the operations of nature are regulated. However this question may be decided, it is clear that the contraction of the uterus alone does not accomplish the expulsion of the fetus. The diaphragm and abdominal muscles assist in the operation; and hence parturition is in some degree voluntary, is accelerated in some cases by the courage of the individual, while in others it cannot be concluded without the assistance of art, in consequence of the strength being exhausted. Yet this action of the abdominal muscles is not so indispenisible, but that the uterus can get rid of its contents without their aid. We know the extraordinary facility with which parturition takes place in some women, who, in consequence of particular circumstances in their condition, exert themselves even to retard the process; and the expulsion of the child is sometimes completed at the approach of death, when the abdominal muscles can hardly be supposed to contribute.

After the expulsion of the child, and of the secundines, the action of the uterus still continues, and the organ is gradually reduced in its bulk. For a short time its parietes are in a state of increased thickness; the vessels, being compressed by this permanent state of contraction, pour out but a very small quantity of blood, notwithstanding the preceding dilatation of their orifices. This blood, effused very slowly, is soon succeeded by an abundant secretion of mucus from the surface of the uterus, constituting a species of discharge peculiar to women recently delivered, and known by the name of lochia. This evacuation lasts for a longer or shorter time, and probably does not cease altogether, until the uterus has regained its original state. The contraction of the organ is owing at first to the evacuation and contraction of its vessels; but soon nutrition is carried on in it with less activity, while absorption proceeds vigorously until the excess of matter deposited for its development has been removed.

Physiology of the Female Organs of Generation.

Puberty and Menstruation.—From the uterus of every healthy woman (at least with very rare exceptions) who is not pregnant, or who does not give suck, there is a discharge of blood at certain periods, from the time of puberty to the approach of old age (during a period in general of about 30 years); which, from the periods or returns of the discharge, is called the menstrues or catamenia, and, from the general regularity of its appearance, is termed in French les règles. The commencement of menstruation is coeval with that signal revolution in the female constitution, which indicates the power of executing the generative functions, and may be regarded as the development of the sexual life. It is therefore one of those circumstances which, taken altogether, mark the period of puberty in females. At the same time their complexion is improved, their countenance is more expressive and animated, their attitudes graceful, and their conversation more intelligent and agreeable; the tone of their voice becomes more harmonious, their whole frame, but particularly the breasts, are expanded and enlarged, and their minds are no longer engaged in childish pursuits and amusements. These phenomena have been described very elegantly by Harvey: "nece minus notam ell, quanta virgini alteratio contingit, inerecente primum et tepetatio utero; pubescit nempe, colorationem aedit. mammam protubent, pulchrior vulvus residet, splendent oculi, vox canora, inceleus, gruitus, femina, amma decora fluent."
recent and accurate inquiries. It is a general and essential phenomenon in the life of woman, and if different climates, or the varieties of savage and civilized states, are capable of modifying the phenomenon, their influence is not sufficient to annihilate it altogether, even in the frozen and inhospitable regions, where some writers have supposed that it does not occur in a constant and regular manner. It is hardly necessary to refute an opinion, which has prevailed very generally, that whole nations, particularly Americans, are not liable to this discharge. In their visits to those countries, Europeans saw numerous females in a state of nakedness, without observing any signs of the discharge, which may be accounted for by two circumstances. The women at that time are generally suppos’d to be in an impure state, and to communicate a malignant influence; they are consequently compelled to bow society while the discharge lasts, and to avoid the sight of man by hiding themselves in solitary huts. Travellers have also observed that their superficial attention to personal cleanliness, and to the modest attitude of the lower extremities, would prevent the spectator from discerning the phenomena of the catamenia. The discharge is peculiar to the female of the human species, which, in the language of Pliny, is the only “animal menstruall.” Many naturalists, says Blumenbach, and among others Buffon, have ascribed a periodical flux of this kind to some other animals, particularly of the monkey kind. But having had the opportunity of observing several individuals for many successive years, I discovered that these suppos’d catamenia did not exist at all in some, while in others there was a slight occasional uterine hemorrhage appearing at no regular intervals. (Inllust. Physiolog. sect. 37) There is a great determination of blood to the organs in animals when they are in heat; this is attended with a mucous secretion, and sometimes even blood has been discharged, so as to give rise to the erroneous notion of their being subject to the menstrual flux. Such a casual and infrequent occurrence can by no means be compared to the regular periodical discharge observed in women almost without an exception. On the other hand there are examples of women who have never menstruated, and of others, in whom this discharge has not appeared through long periods of their lives, without any ill consequence. Dr. Denman knew two instances in which the menes had never been discharged; the individuals married, but had no children. (Intro. to the Pract. of Midwifery, 4to. p. 115.) Some continue to menstruate during the time of suckling, and the circumstance is not very rare, although it is the general rule that the discharge should cease at this time. The vital powers are differently employed, and their exercitio has a different object and direction. Pregnancy almost invariably interrupts the procès. The important functions carried on in the uterus at this time require all the powers of the mother; and the adhesion of the ovum to the uterus seems to form an insuperable mechanical obstacle to the discharge. Hence Mr. Denman states that he has never known an instance of menstruation during pregnancy. The cessation of the discharge without the presence of any unhealthy cause, is the only sign by which women know that they have conceived. Authors relate many examples, however, where the catamenia have flowed during gestation; but very strong evidence would be necessary to prove a circumstance so unlikely in itself.

The menes may appear prematurely in some women, from peculiarity of organization, as the phenomena of puberty have occurred at unnaturally early periods in men; and the circumstance must be referred to original difference of constitution. Haller knew a girl of good family, nine years of age, well constituted both in mind and body, who had been subject to the regular periodical return of the catamenia for some years, without any other apparent disadvantage than that of being rather short and delicate in her make. He mentions another instance in Switzerland of a girl having a child by her uncle at nine years. Many of the accounts of menstruation in early infancy must be deemed morbid or symptomatic discharges, and cannot be referred to the catamenia. When the female constitution from any cause is disfigured to, or requires a fangious discharge, it is commonly made from the vessels of the uterus.

The early or late appearance of the menes may depend upon the climate, the constitution, the delicacy or hardiness of living, and upon the manners of those with whom young women converse. In general, the warmer the climate the sooner the menes appear. In Greece, and other warm countries, girls begin to menstruate at eight, nine, and ten years of age. According to Thevenot and Chardin they even marry and bear children at eight and nine years of age in some parts of Asia. The discharge does not appear in Europe until the female has nearly attained her full growth. Haller mentions the twelfth and thirteenth years as the usual periods in Switzerland; the discharge appears sooner in the more southern countries of Europe, and later as we approach to the north. According to Linneus, in his “Flora Lapponica,” the women of Lapland do not menstruate until a maturer age, and then in small quantities, at long intervals, and sometimes only in the summer. But if the procès does not go on according to the general prevailing rule in the country, they suffer equal inconveniences as in warmer climates, where the quantity discharged is much greater, and the periods shorter. In this country girls begin to menstruate from the fourteenth to the eighteenth year of their age, and sometimes at a later period, without any signs of disease; but if they are luxuriously educated, sleeping upon down beds, and sitting in hot rooms, menstruation usually commences at a more early period.

The variety in the time at which women arrive at puberty has given rise to some moral deductions. It has been assigned as the reason why women in hot climates are almost universally treated as slaves, and why their influence is so powerful and extensive in cold countries, where personal beauty is in least estimation. In hot climates, women are at the height of their beauty when they are full children in understanding; and, when their understanding is matured, they are no longer the objects of love. In temperate climates their perfections and their minds acquire perfection at the same time, and the united power of their beauty and faculties is irresistible.

At the approach of old age women cease to menstruate, but the time of the cessation is commonly regulated by the original early or late appearance of the menes. About the fortieth year, a little sooner or later, the regular periods of the catamenia are interrupted; and before the fiftieth year, profuse discharges occur followed by long intervals; about the time just mentioned, the catamenia generally cease, and the power of reproduction is lost. With those who began to menstruate at ten or twelve years of age, the discharge will sometimes cease before they arrive at forty; but if the first appearance was protracted to sixteen or eighteen years of age, independently of disease, such women may continue to menstruate until they have passed the fiftieth, or even approached the sixtieth year of their age. In this country, the most frequent time of the cessation is from the forty-fourth to the forty-eighth year, after which women never bear children.

By this constitutional regulation of the menes the propagation of the species is, in every country, confined to the most vigorous
vigorou part of life, and, had it been otherwise, children might have become parents, and old women might have had children, when they were unable to supply them with proper or sufficient nourishment. Yet the rules just mentioned are not free from all exceptions. The catamenia, with powers of fecundity, have continued in particular instances much beyond the age we have specified. Some of these have had regular catamenia; in others, after a long suppression, the discharge has returned. We must be careful, however, here, as in the case of premature appearance, not to confound with the menstical accidental and morbid hemorrhages. A relation of Halber's has had two sons after her fiftieth year, and in colder countries, where the access of puberty is late, children have been born when the mother was even above 60.

The proper menstrial blood is generally preceded, sometimes even for some months, by a whitish fermen fluid. Symptoms of more or less violence, indicating the accumulation of blood about the hypogastric vessels, such as pain in the loin and about the pelvis, latitude with painful affections of the lower extremities, and various nervous and hysterical feelings, are then observed. Pains in the head, shuffling of the cheeks, and even simply appearances in the face sometimes take place. In younger virgins these symptoms are milder, and in the female instances often go off spontaneously; but they return with greater intensity, attended with considerable colic pains, and quick and strong pulse, until a bloody fever, and then more genuine blood flows more or less rapidly from the vulva. The duration of the flux is uncertain; it may be accomplished in three or four days, or be protracted till the seventh or eighth. The quantity is subject to no settled law; it is greater in warmer countries, where it may amount to a pint or more; while in colder regions it does not exceed five, four, or three ounces. Yet, says Dr. Denman, lib. cit. p. 118, "there is a common quantity, to which, under similar circumstances, women approach, and it may be estimated in this manner. Supposing the quantity to be about eighteen ounces in Greece, and two ounces in Lapland, there will be a gradual alteration between the two extremes, and in this country it will amount to about six ounces." Manners and way of life make a considerable difference. Luxurious and lascivious women have a more copious discharge; while those who take much exercise, or are weak or insufficiently nourished, furnish a more sparing quantity. The pain subsides as the discharge proceeds; the inflammatory symptoms about the uterus go off as the determination to that organ ceases, the pulse is diminished, and the blood is followed by a serous fluid. Signs of debility succeed, with a hollowness about the eye, and a dark circle surrounding the organ. The first appearance in a young girl is generally followed by an interval of some months, and this period approaches gradually to a year; so that a healthy woman, in whom the discharge is established, will have it return on the same day of the month for many succeeding years. If seven or eight days are occupied by the flow of the catamenia, there is an interval of twenty-two to twenty-three, making up the menstrial period. Such is the course observed in healthy temperate subjects, whose bodily and mental powers are not abated or overtrained. Improper regimen and manners may precipitate or retard the discharge. Luxurious manners, with high living, may occasion returns after fifteen days; under various other circumstances there is a similar protraction of the period, which recurs however at regular intervals. Similar symptoms to those which attend the first menstruation, but in a milder form, accompany each return. In this respect considerable varieties are observed; the affection recurring with considerable violence, at every period, in some women, while others do not seem to suffer at all.

The nature of the discharged fluid has not been ascertained by any accurate investigations, but its obvious characters are so exactly like those of blood, that it has been generally considered and called blood. This remarkable difference, however, at least, seems to distinguish the two fluids; viz. that the catamenia do not coagulate. They are blood deprived of fibrine. Coagula are sometimes seen, but are considered to denote unhealthy menstria, as they occur when the procès is obviously disturbed, and attended with great pain, &c. Opinions have been very generally received that the menstrual discharge possesses those peculiar malignant properties. These notions seem to have originated in the East; they appear in all their force in the ordinances of the Jewish legislator, were adopted by the Arabian physicians, and have been credited in most countries. The severe regulations which have been made in some countries, for the conduct of women at the time of menstruation, the expressions used, the dispersal of the blood discharged, or of any thing contaminated with it, the complaints of women attributed to its retention, and the effects enumerated by grave writers, indicate the most dreadful apprehensions of its baneful influence. The following quotation exhibits these absurd notions in very elegant language. "Penis cum menstruato consubstantiis excoriatur; in nova vita eo tangatur, in perpetuum levitatur; flerides hunc tote fruges; moritur infanta; exuvatur扭矩torum genitum; in mulier preparata alternus menstrua supergregatur, aut illis circumstaret, aborvat factur; elautern, quod uterum gemet, conceipient ipsi admittur; purgatant spuitur, et vapurare speciosa aquo erit nitorum obtrahatur. Julians hic fanguis canes in rabiem agit, homines vero hirs cruciatus affligit, comitalem meruim, polum effuat,айте echantlosem vita inducit; idcirco a veteribus itiner venena relatis; pari malignitate exsanguatur, atque fanguis echantse petus." De Graaf.

Under peculiar circumstances of health, or states of the uterus, particularly in hot countries, if cleanliness be not observed, and the evacuation take place slowly, the discharge may easily become acrimonious and offensive. But there is nothing of this kind belonging to healthy menstruation in a cleanly woman, where the effused fluid differs from any other Blood only in the circumstances already mentioned. Nay, when the catamenia are chronicled in the body for many months, in cases of imperforate vagina, they produce no ill effect whatever, and are distinguished by no particular odour or offensive qualities when discharged by an operation. We have, therefore, no reason for thinking otherwise than that this discharge is of the most inoffensive nature.

That the catamenia come from the uterus is tolerably evident from the change in the lining of that organ during the period of their flow. It is purchased under softer and more vitious; and exhibits bloody spots, with hemorrhages, from which the fluid may be expressed. The appearance of the menstrual blood in its cavity during the period is a further proof; to which we may add the suppression of the discharge in various morbid conditions of the uterus, and in pregnancy, where its surface is occupied by the adhesion of the ovum. Direct evidence of the fact is furnished in cases of prolapsus, where the fluid may be actually seen distilling from the os uteri. To these arguments we may add the obvious connection of the menstrual flux with the functions of the uterus. Some have contended that the vagina is partly or wholly the source of the catamenia; but the opinion rests on no sufficient ground: the structure and functions
functions of the vagina, as well as the direct evidence of facts. Strongly oppose the opinion.

Whether the menstes come from the arteries or veins of the uterus has been a point of discussion with physiologists; and also whether it be a simple effusion of blood from the vessels or a secretion. The structure of the organ refiects that of glands, and the appearance of the blood, on many occasions, differs widely from mere blood; which indeed it never refiects entirely in the healthy state; so that we are disposed to consider it as a secretion performed by the uterus like fluids that are formed by other glands. A circimstance is sometimes observed in this process, which must be referred to the secreteory action of the uterine vessels. This is the discharge of a membrous fulblance, of the figure of the uterine cavity, smooth on one surface, and flocify on the other, and much refembling the decidua on the whole. The fact is mentioned by Dr. Denman, who first saw it in married women, and afterwards in unmarried ones under circumstances which proved undoubtedly that it was formed independently of cohabitation or communication. The menstruation has been painful in all these cases, and conception has never occurred while the habit remained.

The efficient cause of menstruation has afforded an ample field for those who delight in speculations and hypotheses. As the periods of the moon agree nearly with those of the discharge, the influence of this body has been referred to in explanation of the occurrence. If we admit the solution, the effect of lunar attraction ought to be very different in the various relative positions of the moon and earth; but the observation of several individuals will immediately shew that there is no day of the month in which feveral do not begin to menstruate, and that the moon's apace or perige has no influence at all in this respect. We shall see, too, that the discharge begins in some, is diminished or entirely ended in others, at the very same time; consequently that the moon can have nothing to do with the matter. Moreover, as the menstrual period rather follows full moon, the same woman menstruates at one time in the new moon, and at another in the full moon. The existence of some ferment, causing an interline motion in the vessels of the part, meets now with no advocate. Local or general plethora have been alligned as the reasons of the menstes, and many of the circumstances which accelerate or increase, or on the contrary retard and diminish the flow, favour these opinions. But we still cannot adopt the opinion; the loss of several times the quantity of blood previous to or in the very act of menstruation, from the arm, or any other part of the body, does not prevent or interrupt the flowing of the menstes; and in those complaints which arise from their obstruction, greater relief is afforded by a few drops of blood from the uterus itself, than by ten times the quantity from any other part. A curious circumstance must be noticed respecting the effects sometimes produced by obfructed menstes; viz. that their place is supplied by periodical emissions of blood from various other parts of the body, as the nose, lungs, ears, eyes, breasts, and almost every other part. These probably should be deemed in many cases rather as discharges belonging to some disease under which the patient may labour, than as connected with menstruation. Hemorrhages of every kind, in either sex, are frequently referred to be periodical.

That the catamenia are a secretion from the mucous lining of the uterus, of which we cannot understand the direct mechanism, any more than the method in which any other secretions are performed; and that we are ignorant of the causes which determine their appearance to the monthly period, seem to be nearly the limit of our knowledge on this subject. It is clear that the procexs, being a part of the healthy operations of the organ, and therefore indicating its general condition, is necessary to preserve the uterus in a state fit for conception. Observation has fully proved that women, who do not menstruate from the uterus, or who are not in a state disposed to menstruate, cannot conceive, even though they should have a periodical discharge of blood from any other part of the body. All animals, at the time of their being fruculous, or in a state fit for the propagation of the species, have a discharge, analogous and perhaps equivalent to menstruation, which is generally mucous, but in some instances, in any hot feasons and climates, becomes fanguineous.

That the menstrual blood contributes to the formation or nutriment of the fetus may be reasonably doubted. The time of the discharge is not the most favourable to conception, which occurs most readily just after the period. Since all animals, whether they menstruate or not, supply the offspring of conception with nourishment of a proper kind, and in a sufficient quantity to bring it to perfection, we may conclude: that the end is accomplished by some more common principle. The mucous discharge from the generative organs of animal proofs that they are in a state favourable to the propagation of their species; and the catamenia prove the same circumstance in woman.

From the time when the phenomenon of puberty announce the aptitude of the female for the exercise of her sexual functions, the generative organs exert an influence which modifies the whole organization, and beflows on woman the most ftriking traits of her physical and moral character. The various revolutions to which her constitution is subject, the nervous affections, the frequent returns of indisposition and suffering, the strange and unaccountable anxieties and caprices, and sometimes the increased acuteness of the imagination and judgment; all depend on this influence; and if it be true that man is made only at certain times, while woman is female during her whole life, it must be attributed chiefly to this cause. It is this that constantly receds woman to her sex, and marks her whole existence with so characteristic a physiognomy. We shall not be surprised to find, that a cause of such power and extensive influence is liable to irregularities which have very marked effects on the constitution. When the new powers with which the organs are endowed exceed the joint standard, and deviate into a kind of unnatural irritability, they affect sympathetically the whole frame, and particularly the nervous system. This, in an extreme degree, constitutes morbus uteri. Generally, however, this excessive vitality of the sexual organs, without going to such an extent, produces various inflammatory and nervous symptoms, constituting what are called hysteric disorders, and arising evidently from the artificial and forced state of celibacy. These affections are removed by marriage, which re-establishes the balance of the various functions by giving its natural employment to an organ, whose excessive sensibility deranges the whole system. Other and very various phenomena may be referred to the same cause; and those physicians who have collected, in particular works, observations on the diseases occasioned by celibacy, or by the imperfect and unnatural enjoyments of the coitator, present us with an alarming catalogue. "Ut reliqui hiimuli a natura dati nobisque foentrum, ita et veneris albitatem, ut natura immutabatur, ipse ipse defcitur. Ipsa anima ex defiderio venerei languent et perirent. Cyprini ex retinis ovis laborant. In faecis additus, de quibus fevera religio venerem arcert, multa, parum cognita, neque fama morborum generae vigore idoneus audior exaltat. Frequentem ex potentillii, quae veneris dulcedinem degustantur, quae nunc preventur, in chlorofin, in hyaterico male, in convulsiones,
fiones, in maniam, in furorum uterum incident; quam nec femel vidis inque carum femorum aperits cadaveribus fecini, et fractomata, & hydropes ovarii repetiturum. Quare, nihil mortuorum culludia vprove, ea mala pleuraque, et uterorum uteri, et vera mania, veneris fu fulvuntur. Haller, Elem. Physiol. t. 3. p. 14. We may affirm, in short, that from the time when the organs, which characterize these amiable and sensible beings, are fully endowed with all their vital powers, woman is constantly subject to their influence, until the period arrives when she is no longer capable of the life of the species, when she has passed through the revolution of her latter age, and enjoys quietly her individual life, during the remainder of which women suffer much less, in every respect, from the other sex.

A delineation of the effects, which the physical changes occurring at the time of puberty produce on the moral character and ideas of women, may be seen in the eloquent work of Cabanis, "Rapports du Physique et Moral de I’Homme." The various morbid derangements of the menstrual process will be considered in the medical department of this dictionary.

The generative process is subject to very different laws in animals and in the human species. In the former, particular feasons of the year are appropriated to these functions, and the organs undergo certain physical changes, by which they are rendered fit for the process. It is a peculiarity belonging to the human race, that they are confined to no season in exercising these functions. Moll animals, and particularly birds, copulate in spring; and that want of health which has much influence in the affair is evident from this, that animals of warmer countries seldom copulate or are fecundated in Europe. Perhaps women conceive rather more frequently in spring; at least, accoucheurs have observed that there are more labours in the months of December and January.

As the effect of sexual communication is so important, it cannot be indifferent to the design of nature to what part of the uterine system the semen should be conveyed. It admits of no doubt, that it either remains in the vagina, passes into the uterus, or else extends its course along the Fallopian tubes to be applied to the surface of the ovaries, which stimulate, and from which the new animal derives its existence; but the question whether it be one or other of these, has given birth to more physiological controversy than perhaps any other operation of a living animal. Those who have entered the lists have ranged themselves either on the side of application of the semen to the ovaries, by means of the tubes; or on that of the intality of this process. These latter contend for an absorption of this fluid by the vagina, and a peculiar excitement of the whole frame ana consequence, of which excitement the changes produced on the ovaries are to be regarded as the local effects. The advocates for the first opinion allege, that the semen has been found both in the uterus and tubes, and quote as their authority the observations of Morgagni for the former, and Ruyfch for the latter. When seen in this last situation, some have thought that it was conveyed thither by the muscular power of these parts, in the manner of a peristaltic motion, beginning at the uterus, and ending at the amnioned termination of the tube; and when at this level, it was supposed that the semen was applied to the surface of the ovaries, and impregnated them by actual contact. Various analogies, drawn from the animal and vegetable kingdoms, have been adduced for and against these different opinions; but such arguments must be received with caution. Where different instruments are employed to produce the same ultimate effect, we may reasonably conclude that the means used are essentially different. On this principle no direct conclusions can be drawn respecting

the human species, from observations either on vegetables, or even on frogs, toads, and newts. The impregnation of birds, being effected by semen conveyed into the body, resembles that of the human subject more than the former, but they differ so widely in the mode of perfecting the fetus from the ovum, that we cannot rest with much confidence on their general analogy.

To the observations of Morgagni and Ruyfch a numerous train of facts has been opposed, ascertained by the experimental labours of Harvey, Du Graaf, Haller, and others, in which no semen was ever seen beyond the vagina in animals, examined at various periods after coition. One experiment of Haller, on a sheep, constitutes a single exception to this observation: he once saw semen in the uterus forty-five minutes after coition. These facts bring the advocates for the necessity of a contact of semen with the ovaries into a dilemma, from which they attempt to extricate themselves by contending, that fecundation does not require the application of semen to the ovaries in a palpable form; but that there is exhaled from it a subtle fluid, in a vaporific state, called aura feminals, and that the contact of this vapour is sufficiently sufficient to impart to the ovaries their discretion of stimuli.

The opinion, that the presence of the semen in the vagina alone was sufficient to account for impregnation, was defended by the statement of caes, in which, from some anatomical peculiarities, it seemed almost impossible that the fecundating fluid could be conveyed into the uterus; yet in several of these cases impregnation really took place. Those who hold a contrary opinion either call at the accuracy of the statement, or draw a different conclusion. In order to throw some light on this subject by direct arguments, Dr. Haighton undertook a series of experiments, the results of which are detailed in the 8th vol. of the Philosophical Transactions. He divided the tubes which form the cornu uteri in rabbits, and admitted them to the male, when they had completely recovered from the experiment; but this operation seemed to destroy entirely not only the power of conception, but also the disposition to employ the means. After several ineffectual trials, he varied the experiment by dividing one tube only, and in many instances the animals conceived afterwards. Corpora lutea were found on both sides of the body, but fetuses only on the sound side. If the former bodies are produced only after conception, which the doctor assumes, then conception must have taken place here, although the direct access of semen to the ovarium was interrupted; for the operation in question completely obliterates the tube. It must be acknowledged that the proof is incomplete in these cases; we cannot justly assert that conception has taken place, when no fetus was formed. Dr. H. attempts to elude this objection, by showing that the division of the tube at any period after coition, but before the passage of the germs from the ovary, will equally prevent the appearance of fetuses; accordingly no fetuses were seen in the tube, when it was divided as late as forty-eight hours after coition. But if the operation be performed until the time at which the rudiments of the new animal have passed into the tube, the actions of the parts furnish no interruption, and fetuses are formed in the tube of the mutilated side. "If," adds the Dr. "the ovaries are susceptible of their proper excitement only from the contact of semen, how did it happen that the effects of that excitement were not more obvious where nothing had been done to intercept its course for 48 hours, than in those where all communication between the uterus and ovary had been cut off before the means of impregnation had been employed? I think it must appear, on tracing nature's

Vol. XVI.
G E N E R A T I O N .

... through the different stages of this work, that they are the product of that law in the constitution, which is called sympathy or consent of parts. That the semen first stimulates the vagina, uterus, cavity of the uterus, or all of them. By sympathy the ovarian vessels enlarge, project, and burst. By sympathy the tubes incline to the ovaries, and having embraced them, convey the rudiments of the fetus into the uterus. By sympathy the uterus makes the necessary preparation for perfecting formation and growth of the fetus. And, by sympathy the breasts furnish milk for its support after birth.

Physiologists have certainly not yet ascertained, by direct observation, whether or not the semen enters the uterus and tubes; and consequently all explanation of the mode in which it co-operates in conception must be, in a great measure, hypothetical. If we cannot speak from actual knowledge on a point, which must be so important as the present, in the generative process, and the determining of which must be so essential towards forming right notions of the nature of the business, how uncertain must our representation be of the more intricate and obscure parts of the subject!

The circumstances just described do not appear to be essential to the business of fecundation; they contribute to the important object of reproduction in a secondary manner. The strong desire implanted in all animals, and the physical gratification experienced in its indulgence, ensure the union of the sexes, and consequently the continuation of the species. The celebrated Spallanzani has given to the world a very interesting series of experiments, by which it is proved that impregnation in many cases may be effected by artificial means. He proved the first in the case of various amphibias, as the frog, newt, and tadpole, and afterwards in the bitch. He experimented on a spaniel bitch, which had before had whelps. He confined her very closely until she was in heat, and then proceeded in the following manner: "A young dog of the same breed, nourished by me, from a spontaneous emission, with 19 grains of feed, which were immediately injected into the matrix, by means of a small syringe introduced into the vagina. As the natural heat of the feed in animals of warm blood may be a condition necessary to render fecundation efficacious, I had taken care to give the syringe the degree of heat which man and dogs are found to possess, which is about 30°. Two days after the injection, the bitch went off her heat, and in twenty days her belly appeared swollen, which induced me to let her at liberty on the twenty-sixth. Meanwhile the swelling of the belly increased; and sixty-two days after the injection of the feed, the bitch brought forth three lively whelps, two males, and one female, resembling in colour and shape not the bitch only, but the dog also from which the feed had been taken." (Dissertationes, vol. ii. p. 256.) The experiment was repeated with success by Dr. Rossi, ibid. 476.

We have an account of a similar trial in the human subject, made at the suggestion of Mr. Hunter. It was in an instance of malformation, where the urethra opened in the perineum. "Under these circumstances the person married. When he had connection the emission was complete, which proved that the vesicles were perfect, but the semen always passed out at the perineum. The late Mr. Hunter was confused to remedy, if possible, this inconvenience, and to enable the person to begot children. He advised that the husband should be prepared with a syringe fitted for the purpose, previously warmed; and that, immediately after the emission had taken place, it should be taken up by the syringe, and injected into the vagina, while the female organs were still under the influence of the coitus, and in the proper state for receiving the semen. This experiment was actually made, and the wife proved with child. On a subject of this kind it is proper to speak with caution; but, from all the attending circumstances, no doubt was entertained by Mr. Hunter, or the husband, that the impregnation was entirely the effect of the experiment." Home on Hermaphrodites, in Philos. Transact. for 1799.

Various circumstances have been enumerated, as proofs that conception has taken place; as peculiar feelings during coition, horripilation, and even fluid dentium, &c. Haller's sensible remarks on this subject seem to us to be nearer the truth. "Hae omnis quidem nihil nisi videntur, et difficillimam expertum. Neque enim feminis, dum maritus admissit, otiose et ad experimentum anima; neque, nisi longo abhine tempore nonit ferrare fac concepisse, quando jam eujusmodi phemenon membra clapsa fiant. A feminis certe, qua quis verum poteram expectare, nihil de horripiliatione, neque de dolore potu diferire." Ibid.

The opinions concerning the effusion of a seminal fluid by the female, and its mixture with that of the male, are altogether imaginary. That a mucous fluid is sometimes poured out in coition, from the apparatus already described in the external organs and the vagina, is undoubted; but this happens only in infertile women, or such as live luxuriously; it consists merely of mucur, and is discharged externally, instead of passing into the uterus.

Circumstances do not admit of the internal changes which accompany and follow copulation and conception, being accurately ascertained in the human subject; and, consequently, these have been investigated in various animals. Mr. Cruikshank gives the following description of the parts in a rabbit at heat. "The orifice and internal surface of the vagina are as black as ink from the great determination of blood. The ovaries had, under their external surfaces, a great number of black, round, bloody spots, somewhat less than mulberry seeds. These black spots are the cervices or cups which secrete the ova; they are extremely vascular; the ova themselves are transparent, and carry no visible blood-vessels. These cervices, on the expulsion of the ova, enlargé and become yellow, projecting above the external surface of the ovaries, and form the corpora lutea: a certain mark of conception in all quadrupeds, and in women themselves, whether the embryo is visible or not. The use of the corpora lutea is not yet made out; but the orifice, through which the ovum bursts into the Fallopian tube, is often extremely manifest, and always has a ragged border, as lacerated parts.
G E N E R A T I O N .

usually have. The Fallopian tubes, independent of their black colour, were twisted like writhing worms, the peristaltic motion still remaining very vivid; the fimbriae were also black and embraced the ovaria (like fingers laying hold of an object), so closely and so firmly, as to require some force, and even laceration, to disengage them. Haller and other observers support this statement of the erection of the tube, and its close application to the surface of the ovarium. But Dr. Haighton seems not to have found it out until a later period. He examined a female rabbit in high season a few minutes after coition, and found the fimbriae in their natural situation. He found, moreover, from a regular series of observations made on different rabbits, at every hour between the first and the ninth, that the fimbriae remained nearly in their usual situation; and the only difference he noticed in the last hours was a greater turgescence of vessels, as if preparatory to some important action. That the prominent vessels or calyces of the ovaria, already mentioned, burst, and allow something to escape into the Fallopian tube, which conveys it to the uterus, is what all observers seem to agree in: and they concur, moreover, in representing the corpora lutea as produced by a particular process carried on in the empty ovarian calyces, and consequently, as exhibiting incontestible proofs of impregnation having been effected.

These circumstances have all been ascertained by the observations of animal bodies, and transferred by analogy to the human subject; in which, indeed, the formation of a corpus luteum is very evident, although the earlier stages of the processes have not been traced. Observers by no means agree as to the time at which these changes are effected. Mr. Cruikshank represents the bulging of the calyces as following a fruitful coition very speedily. "I opened," says he, "a female rabbit two hours after the last received the male; the black bloody spots just mentioned now projected much above the surfaces of the ovaria; none of the ruptured orifices were just visible; but in many of these spots there was not the least viscid of an orifice; whence I conclude that they heal very quickly in general." The narrative of Dr. Haighton's experiments would lead us to conclude that this escape of the germ from the ovarian calyces does not take place till a much later period. In twelve hours after coition "several of the vessels evidently projected; they had lost their transparency, and became opaque and red. When punctured a fluid of the same colour escaped. The corpora lutea, which are formed by the thickening of the parietes of the vessels, were not very evident." At 24 hours after coition the fluid in the vessels was similar to that of the last experiment. They projected more evidently, and their thickened parietes, manifesting the commencement of corpora lutea, were become more apparent. At 48 hours past coition, the vessels formed to be in the very act of bulging, and a semi-transparent substance of a mucous-like consistency was beginning to protrude from some of them; others, indeed, were less advanced. The imbricated extremities of the Fallopian tubes were preparing to receive their contents, as appeared by their having quitted their usual position, and embraced the ovaries in such a degree, that only a small portion could be seen until the tubes were taken away. Sections being made into the thickened vessels, the formation of corpora lutea appeared to have made further advances. From the appearance of an inipient rupture of the vessels in this experiment, it was but reasonable to expect that their contents would soon have escaped. In two days and twelve hours after coition the fatal rudiments had escaped; but the cavity of the ovarian vessels had suffered but little diminution. Brittle were easily introduced by the ruptured orifices. In this experiment the advances towards the formation of a perfect corpus luteum were such as the period of examination would naturally lead us to expect. The contents of the vessels having escaped, it was but reasonable now to look forwards to a speedy oblitera

...
voked per annum. Lastlv, the germ may be detained in the Fallopian tube, without arriving at the uterus. The structure of the part does not allow it to dilate sufficiently to contain a full-sized child, and it accordingly hurries, in general, long before that time, and the patient perishes from bleeding.

We must allow, that the escape of any thing from the ovarium in the human subject, or other mammalia, is rather inferred than directly proved; and that we cannot see the germs in the Fallopian tube, on their passage to the uterus; so to obscure a fact are the rudiments of the future animal at the time, and immediately after conception.

The appearance of the corpus luteum as the consequence of a fruitful copulation; but there is some doubt whether the latter circumstance be an essential condition of its production. It is well known that birds lay eggs without the concourse of the male, and such eggs are unproductive. Valeriani affirms, that he has seen corpora lutea in the ovaries of virgin unreared, and Blumenbach appears, in the following quotation, to agree with him in opinion on the subject.

Porro autem non minus verum et inapptas aves ejusmodi, ova subventanæa ex mecanica titillatione generatioe concipere poeif, quod quidem physiologicai comparati, adeoque omnis zoologiae vere scientifica pares Areoliteæ et pretentiæ fecundittimini. Specimen physiologicai comparati, Gotting, 1789, p. 42.

Physiologist has endeavored whether a second impregnation can take place after a fruitful copulation. Instances of twins, born with different degrees of development, have been considered as proofs of Superfetation. The reasoning does not seem very conclusive, the fact does not clearly prove that the two fetuses were conceived at different and distant periods, since the growth and development of one germ may have been prevented by various causes. The question is, whether a woman, having only a single uterus, can conceive two or more months after a fruitful copulation; and at present we have no facts to prove the affirmative, while presumption is strongly against it. The thing appears more easy, if we suppose the two conceptions to be separated by a very short interval. Thus we can conceive that the Americam lady mentioned by Buffon, who received the embraces of her husband, and of a negro slave, in the same morning, may have brought forth twins of different colours.

On the subjects of the preceding paragraphs, the reader may refer to the ample collection of facts, in the eighth volume of Haller's Elementa; to Spallanzini's dissertations relative to the natural history of animals and vegetables, vol 2d.; to Haighton's experimental inquiry concerning animal impregnation, in the Philosophical Transactions for 1797; to Cruikshank's experiments, in which, on the third day after impregnation, the ova of rabbits were found in the Fallopian tubes, and on the fourth day after impregnation in the uterus itself, with the first appearances of the fetus; ibid.

The various opinions concerning the source from which the new animal is derived, and the manner in which its formation is effected, form the last subject of the present article. In the science of life, as in all others, the speculations and hypotheses concerning any matter are in an inverse ratio to the number of ascertained facts; and perfons are disposed to talk more, in proportion, as they know less. Hence the vast abundance of theories of generation, which almost exhausted the patience even of Haller, and extorted from him the following very sensible observations. "Iterum ingratiatum mili impendit opus, feriher de ipsis, quia multae natura circumjectis tenebris velata, fenestrum hic inaccesse, hominem agitantur opinionibus; est deis non modic congresso, in quibus quidquid, ubique quidque, id autem parvis, in quo animus, in quere aliquid fundamentum, adequiteat. Erunt libranda cum phenomenis contrarioribus, cum argumentis contra argumenta, ut demum nihil docet certum, quam nihil me docere. Et eum tamen etiam in deprecatione de problemati solutione fund utilitas, proximumque eil vero, nihil docere, quod furtum fit." The first subject of our inquiry will be, from what quarter the materials of the new animal are derived; then, by what cause those materials are formed into an animal, such as we have shown to be produced in the female by conception. The opinions concerning the source of the offspring may be reduced to three; one gives to woman only the humble office of affording a proper nidus for the due evolution of the fact, which, according to this theory, already exists in the male semen, and requires only a fruitful habitation. Another directly reverses this position; it puts the female in possession of every requisite for the formation of a new animal, and considers the male a mere instrument of the operation of the fetus, which, according to this theory, already exists in the female semen, and requires only a fruitful habitation. The third gives no pre-eminence to either sex, but, with the mutual embrace, suppresses a mutual effect to be produced; it regards both the male and female, as concurring essentially in the work of reproduction, by each affording a something, which, when united under proper circumstances, becomes the proximate cause of impregnation.

The ancients admitted a seminal liquor in both sexes, and concluded, not unnaturally, that the fact was formed by the union of these. Hippocrates and Aristotle held this opinion, and conceived that the sex of the offspring depended on some predominance in quality of one or the other fluid. However obtuse the mode of this mixture may seem, specious arguments are not wanting in support of the opinion. The necessity of the co-operation of the two sexes, in producing a fetus, in almost every instance in the animal kingdom, may be alleged in favour of the doctrine. Also the existence of different sexes in almost all plants; the fecundating power of the male duct, and the perpetual presence of the seed before fecundation; which, however, remains unfruitful without the influence of the former. The resemblance...
blame of the fetus to both parents in the human race, in animals and even in plants, may be urged in support of the same doctrine.

The old opinion, which supposes that males are produced by the right testis and right ovary, and are contained in the right side of the uterus, while females are formed on the left, is delusory of all foundation. A male with one testis has produced children of both sexes; and male or female fetuses are seen indifferently in the right and left common uteri of animals.

The hypothesis of Hippocrates and Aristotle was adopted by Buffon, and is presented in his natural history with all the advantage it can derive from his warm imagination and eloquent diction. But figurative language recomposes us very imperfectly in scientific matters for want of observation, and hasty generalizations; and the theory of Buffon is so delusory of foundation, that we can hardly think it worthy of notice. He conceives that there is a matter in nature, composed of incorruptible molecules, always living and active, and defined to the nutrition and evolution of all organized beings. These particles are received in the food, and are applied to every part of a plant or animal. Every animal is an interior mould, by which these particles are fashioned to their particular shape. When there is more of this matter than is required for purposes of nutrition, the surplus is conveyed from all parts of the body to the teatles of each sex, which are its referrers. It exists here in a liquid form, and contains molecules analogous to all parts of the frame, sufficient to form a smaller being, exactly similar to the large one, from which it is produced. The molecules composing the new being are analogous to those of all parts of the body, from which they have been conveyed to the teatles, and may be deemed a kind of extract of the old body. This matter, having passed through the interior mould, and finding the uterus in a favourable state, generates a new animal. We shall not abuse our reader's patience by the further detail of such vague chimera: they more than justify the farce of Voltaire in his "Homme aux quarante cens." 

"Ah! monsieur le fantais, says the man aux quarante cens, could not you inform me how children are made? no, my friend! replies the fantais; but I will tell you what philosophers have imagined on this subject, or, in other words, how children are not made.

This defêit contains a lively ironical account of the various theories of generation, which the reader will find much more entertaining, and quite as instructive as the original accounts of these reveries.

Of these, who consider that the father has the principal share in producing the child, Leuwenhoek is the foremost. He considers the spermatic vermiculis as men in miniature; and conceives that one of these crawls in some way or other into the ovarian vehicle, and is there developed.

That the fetus is produced by the mother has been more generally supposing; and seems more probable on the first glance, since the child most certainly comes from the mother, although it is by no means clear that it ever went to her from the father. The analogy of almost all animals, and of plants, favours this opinion. The generation of the aphides has been adduced in its support; where a single fecundation suffices for several generations. In the frog and tad, and in the bird, it is very clear that the fetus pre-exists in the ovary; and that the contact of the female produces at first no perceptible change in its appearance. Indeed the wonderfully small portion of fecundating fluid necessary to produce the requisite effect in the frog or tad would lead us to conclude too i cannot excite any very great change at the first moments of its application; and this circumstance, together with the obvious existence of the something, which is afterwards evolved into a tadpole, in the ovary before copulation, clearly proves the pre-existence of the germ in the females of this species of animals. 

"A quantity of seed," says Spallanzani, "far more incomprehensible than we should ever have imagined, is sufficient to animate a tadpole. We have seen that it is not necessary to cover the fetus completely with this prolific fluid; a drop will suffice. Further, three grains mixed with twelve, and with eighteen ounces of water, communicate to every part of it the power of fecundation, since tadpoles placed in any part of the mixture are fecundated. The three grains of seed must therefore have been diffused through the whole mass of water. But, what an enormous division of its particles must such a division occasion! How small a share of prolific liquor must fall to the share of each tadpole! Yet there are facts which prove that the semen still retains its virtue after this excessive division; for I have found a globule 1.5-3ths of a line in diameter, taken out of a mixture of three grains of seed with eighteen ounces of water, was often capable of fecundating a tadpole. Deprived of knowing the proportion, which the tadpole (that of a frog is 2-3ds of a line in diameter) bears to the particles of seed diffused in a drop of this dimension, I have found, on calculation, that it is as 100 to 187,777,777 to 1. How infinitely small, therefore, is the quantity of seed in comparison with the bulk of the particles, which it fecundates! This deduction led me to calculate the weight of the particles of semen diffused in this drop of water: it is 10,714,714 of a grain. That I might view these particles under every possible aspect, I reduced their bulk to cubic lines, when it appeared to be about equal to the volume of a cubic line."

Dissertation, vol. iii. p. 212. The researches of Haller, and of others on the formation of the chick, have clearly proved the pre-existence of the fetus in the female of birds.

But, although this hypothesis appears to be supported by the most numerous and satisfactory proofs, there are difficulties opposed to its adoption. "It is very certain," says Haller, "that children often resemble the parents in the human race; so that you may distinguish one brother by his resemblance to another, or know a fun by his likeness to the father or mother, or even to his grandchild or grandson. All the individuals of some families are characterized by particular lines of countenance. My own family have now been distinguished for tallness of stature for three generations, without excepting one out of many grandsons descended from one grandfather. Families of red-haired persons are not uncommon: the disagreeable color being derived from the father or mother or grandmother. But this resemblance of children to parents is deriv'd most plainly when there is any defect or peculiar formation transmitted from one to the other. The traits of the face may perhaps not be deemed surprising, since nobody denies that the traits of fluids is derived from the mother; but the father contributes the smallest drop possible, if any. Yet we find various defects, or dispositions to disease, passing from either parent to the offspring. This is matter of common notoriity with respect to gout, rheumatism, infirmity, feebleness, consumption, &c. but there is more doubt of some others, as catalepsy, hemer, aneurism, squinting, hardihood, chub-foot, futility, &c. of which, however, authors relate many examples. We know a very remarkable influence of two noble females, who got husbands on account of their wealth, although they were nearly idiots, and from whom this mental defect
defect extended for a century into several families, so that some of all their descendants will continue ideas even in the fourth and fifth generations. Perhaps the resemblances of the mother are rather the most common. The ill-made Per- fians have improved themselves into a very beautiful nation by their repeated marriages with the celebrated Georgian females. The offspring of Negroes and Europeans partakes of the characters of both parents in form, colour, form of the lips, nose, &c.; and we may observe in general, of all such mixed breeds, that the children produced seem to constitute a mean between the father and mother. Peculiarities of formation are not uncommonly transmitted; as a very hollow palate, which I myself have seen, and many others. A man covered universally with hard, elasic, cylindrical, wartv excrescences, begot sons and daughters with the same deformity. An excess in the number of thumbs (four) passed from the father to the children: and there are curious examples of similar facts in individuals poHing five fingers on each hand. Play mentions that Q. Horatius, who had this structure, begot two daughters resembling him in this respect. A family mentioned by Regnemur is more remarkable: the grandfather had a supernumerary finger on each hand, and a toe on each foot. His first son produced three children with the same peculiarity: the second, who had the usual number of fingers, but in whom the thumb was very thick, and货车ed, as if composed of two united together, had three daughters with the supernumerary members: the third had the natural structure. A daughter, with a very thick thumb, brought forth a boy with the additional finger. That too much influence may not be attributed in this case to the influence of the male, it may be observed that another daughter, who had large thumbs, produced some sons with supernumerary members. Maupertius has also recorded a family of children disinguished by this character, produced by a mother with the same peculiarity. The thick lip in the Aulrian family was introduced by the marriage of Mary of Burgundy with Maximilian. It is asserted that caudal mutations, as blindnafs, &c. have been transmitted to the offspring, in horses; and some complain of the plan of employing Arabian stallions rather than mares for improving the breed. There is a peculiar breed of four-horned sheep, depending from the female; and another of pigs with undivided horns. The difficulty of the subject is increased by the circumstance that these defects and peculiarities do not in general pass to the offspring. Blind, lame, or mutilated parents have perfect children. In the family with the supernumerary fingers, already mentioned, several individuals had the ordinary formation. Fowls without the rump breed with the common kind of chicken, both with and without that particular formation; and the same mother has children like herself and the father, and others without such resemblance. 8. Elementa Physiologia, lib. 29, sect. 8.

The phenomena afforded by hybrid generations are curious. It is only in the case of animals very nearly allied in their general characters that any hybrid offspring is produced: and this has the mixed characters of both parents. The relations of women in Africa breeding with monkeys are not sufficiently authenticated. "The mule (produced from the mare by the asf) does not," says Haller, "seem to me to be an asf, which however it resembles in its tail, ears, and obliquity, since the form of the body, the strength and size, the hocks, the hair, and colour are those of the mother. The voice is more like that of the father, and there is a farther resemblance of the asf in the pec ill hair hollow of the larynx. As the mule seems to be stronger and more lively than the asf, so the hairy begotten by the ittalian on the fie-asf, seems rather to follow the mother: it is said to have the ears of the horse, the mane and tail of the asf; and to be smaller than the male. The offspring of the common fie-goat with the Angora he-goat has the long hair of the father; while that of the Angora female with the European male has not that character. The fine hair of the former breed was continued in Sweden to the third generation. This fact shows the prevalence of the male, which, being born in a warmer region, exceeds in stature the European animal. The pheasant breeds with the common hen: the offspring has the mother's colour, with the form of the father, whom on the whole it most resembles. If the animal produced from such a connection breeds again with the male pheasant, the young are complete pheasants. When these and various other analogous facts are compared, we remain in as much doubt as before. It appears that the offspring is affected by both parents, in some cases more by the father, and in others more by the mother. And I think, that where the father is greater in size, his characters prevail, and vice versa." Ibid.

Neither is it merely the form and external appearance that are changed in the cases of hybrid animals; we have already observed that the mule has the peculiar laryngeal cavity of the asf: and it is further known that this animal, and all other hybrids, are very rarely propagated: so that we may conclude that some general internal change is effected in these cases. A more accurate anatomical description of hybrid animals would probably contribute to illustrate the subject: the facts at present in our possession lead us to conclude that the fetus is not produced entirely by the mother or father, that both parents contribute something to the offspring, and that the new being is rather generated de novo than evolved.

In considering the powers by which the admirable structure of the animal frame is raised, we encounter a vast host of the most wild and visionary hypotheses: we descend, to use the expression of Haller, from twilight into regions of utter darkness. In the first place we reject entirely the operation of fortuitous causes: the notions concerning equivocal generation have been sufficiently refuted by modern naturalists, even in the lower orders of animals, where the phenomena, on a superficial view, tend to confirm the vulgar opinions, and there is not even the shadow of probability in favour of such explanations in any of the higher classes.

In these times, however, men of considerable reputation have not been wanting to defend opinions very much resembling the hypothesis of equivocal generation. Buffon has contended that all the parts of an animal are not formed at once, but successively, by epigenesis. His observations concerning the organic molecules of the fenn are believed by some to have been already noticed: he even admits the formation of new beings by putrefaction and by the fortuitous concourse of particles. His associate, Turriever, Needham, does not allow of equivocal generation, but supposes the existence of a power, which forms the body from the smallest germ by the assimilation of aliment. He thinks that the primitive germ alone are created at once, but that there are no compound germs at all resembling animals. He quotes the phenomena observable in vegetable infusions; and conceives that animal and vegetable substances are the same in their origin, and admit of being changed into each other. The first germ of an organized body is very simple, and not yet organized, nor poHing any lineaments of the animal. Hence the smallest animalcula, as consisting of the fewest germs, are formed the foonest; and those of a more compound structure, more slowly. The whole affair of vegetation consists of an expansive force refuting in matter, and a refilling power. The former is perfectly elastic, and exists
in every sensible point of matter; it is affiliated by heat.
There is a power, in every point of vegetable matter, to produce filaments, from which microscopic animula may be formed. A real generating caufe exists in nature. The expansive force is increased, and the resistance diminished, when matter is elevated to a state of vitality. This is effected by the development of the active principles; it returns again to a vegetable nature, when the contrary causes obtain. He does not, however, admit of equivocal generation, but conceives it necessary, that the feminine fluids, both of the male and female, characterized by their peculiar properties, should be present.

In this hypothesis the power of the femen is not neglected, nor is any attraction or fortuitous concourse of atoms admitted. But the experiments on infuscation animulae are employed to authorize conclusions, which cannot be very easily admitted. We find a great difficulty in admitting how any blind force, not regulated by design, can form animals designed for certain purposes, and fit to fill their place in the chain of beings. Hence we find that these animulae are not produced when the experiments are so conducted as to remove all possibility of the introduction of ova from without.
The experiments of Spallanzani clearly prove this point.
The fyllem of epigenesis met with an able defender in C. F. Wolf; see his Theoria Generationum, Halle, 1775, 4to. He explains the mode of growth, and the formation of parts in animals and vegetables, by the action of a power which he calls vir effentia, without any mould or model. This power, together with the fixation or coagulation (foli defectis) of juice, accomplishes the whole work of formation. The heat of the air in plants, and the heart in animals, are accessory causes of generation. The primordia of animals are globules, which cannot be reduced into smaller component parts; neither arteries, veins, nor heart exist in the egg at 2.4 hours. The vis effentias, different from the power of the heart, now begins to act, and, in the globular matter of the area umbilicalis, forms grooves, which gradually growed, and constitute vessels. These at first are large intervals of the globular matter, but gradually become smaller. Membranes are formed round these pellages. All parts are first fluid and inorganic, and then formed into vessels. Trunks are formed to the branches, and at last the great trunk of all, the heart. New parts are formed, from the juices of the first; and thus the organs appear in succussion, one after the other.
Haller refutes this theory from his accurate observations on the formation of the chick; he shews that in fact parts exist, distinguished by their form and other characters, when superficial observation would lead us to infer that there was only an inorganic homogenous matter. The transparency of the whole prevents the outlines and distinction from being visible, but coagulation by acids brings these differences into view. Because the original gelatinous mass, which forms the animal, seems to have no obvious structure or smaller distinguishable component parts, we are not therefore to conclude that it has none. Spirit of wine, poured on this jelly, hardens it so, that we can see fibres, vessels, and viscera, where there seemed at first to be a mere transparent concrete. There is no effential power in the alcohol to model rude matter into an organic structure; but the destruction of the transparency allowed the outlines of parts to be distinguished; similar explanations may be given of all his observations on this subject. Moreover, we can by no means understand how this single power can form such different parts always in the same place in one animal, and according to one archetype, if the materials be inorganic, mutable, and susceptible of any configuration. Why should this matter always produce, without any error, a chicken in the common fowl, a pea-chick in the pea-fowl? Nothing is assumed but a dilating force acting progressively; this might give origin to a vacuolar net-work, growing constantly larger as long as the expansive force exceeded the resistance; but how does it produce a heart, a head, brain, and kidneys? Why is a peculiar order of parts formed in each animal?

Some again have explained the formation of the body according to mechanical principles, by the power of fermentation, &c. We cannot, says Haller, conceive that any power, unless guided by intelligence, can act on matter in a manner constantly changing, and to directed, that inorganic materials are formed into bones, muscles, vessels, and viscera, arranged in a certain order with respect to each other. All spontaneous productions, as for instance the beautiful figures seen in snow, are arranged in an uniform and invariable manner. Let any person, in order to estimate the value of such hypotheses, reflect merely on the eye. How can this organ be moulded by any expansive force into such various succedaneous layers, all differently fabricated, where the light passes through transparent bodies, everywhere surrounded by others perfectly opaque, and so arranged, that in the millions of men and animals the rays of light constantly converge upon the retina? Yet this blind material caule knows nothing of light, nor of the laws by which it is refracted, although we must suppose it to have adapted all the parts so accurately, even to the hundredth part of a line, in order to the collection of the rays in the retina. Again, this unintelligent cause has furnished the eye with eye-lids and eye-brows, and has given to the iris a power of contraction and dilatation, by which the organ is accommodated to too great or too small a quantity of light.

Buffon supposes the nutritive matter to penetrate all parts of the body, and thus formed in them, as in an internal mould; and he conceives that the superfusorous particles are carried back to the femen, conveying into that fluid every thing necessary to the production of a new being, similar to the former. The feminal fluid of either sex contains the particles necessary for forming an individual of the same sex.
These must be mixed for the production of a new being. The generative organs are the baizes of the new animal, and these are first formed of themselves; the other organic particles of the body are arranged round them as a centre, according to the order, which they held in the body, from which they were produced. That sex prevails, of which the particles are the most numerous. The author of this hypothesis considers that it explains completely the resemblance of the offspring to either or both parents, the formation of twins, &c.
The illustrious name of Buffon can hardly induce us to animadvert seriously on such dreams. In the first place, what is an internal mould or model? The authors of the hypotheses are so far from satisfying us on this fundamental point, that they could not be understood; if, unless we had a seventh sense. How then came they to know it? So far from understanding what this model is, we have no hesitation in affenting that its existence is purely ideal. But if we should grant this, there are still insuperable difficulties remaining. Many children are unlike both parents, and they sometimes have parts which both the father and the mother wanted, and with which, therefore, neither parent could have supplied them; this is the case with the offspring of mutilated individuals, and particularly with the male children of fathers who had lost one testis; a case which was not uncommon when castration was an ordinary mode of treating ruptures. The mother cannot bellow on her daughter the hymen, which she has lost; nor can we fee the source from which the foramen ovale, the ductus arteriae, and venous, the
the umbilical vessels, the placenta, the cord, &c. are derived.  

The teeth too must puzzle us greatly. The various transformations, and every other phenomenon in the lower orders of animals, are altogether irreconcilable with the hypothesis.  

The adult frog has no branches, which are yet seen in the tadpoles. In the bee kind, the males, females, and working bees differ in structure. The offspring might resemble the father or mother, but whence do the working bees come, which resemble neither parent, and have no generative organs.  

How entirely does the catapher differ, in all points of its organization, from the butterfly? How can the particular parts unite, when the male and female are so entirely different, as in the case of many insects, where one is winged, and the other not, &c.  

The supposition of the face-to-face fixation of parts round the generative organs is quite indubitable; for those very parts cannot be recognized until a comparatively late period, and after others have been some time formed.  

This fact was confirmed, says Blumenbach, by an observation which I lately made on abortive twins of different sexes, about sixteen weeks old. Although these were remarkable for the beauty of their proportions, and were most perfectly formed according to the standard of their tender age, the difference of the sexual organs could be ascertained only by the most careful investigation; in every other respect, as in the figure, phylogeny, measurement of the limbs, &c. they resembled each other completely.  

P. 387.

In reply to some of these objections it has been affirmed, that those parts of the facts, which the parents have not, are formed by intelligent nature from the fopperity of the organic molecules; that the add a second tesser to the excess furnished by the single gland of the father; and that the placenta and fetal coverings are produced in the same way from the excess of nutritive molecules; but if nature can make wings, intestines, nerves, feet, tails, placenta, and membranes, &c. without any mold, why shouldn't the form the whole body in the same way? and, whence arises this abundance of particles, produced by the tessor of a man, who has only one gland, when the mould must be one half less than in a perfect individual? How came this intelligent nature to be so suddenly produced in a mere machine, when we had before heard nothing of her? Can any one understand how particles transmitted from so vast an extent as the father's whole body, can occupy so small a space, even when united to those of the mother, as to be invisible for several days after conception? In short, there is no female semen, no corpus luteum before copulation, and consequently no fluid from the mother to be mixed with that of the father, and convey to the fetus the female generative organs, the mamma and the other distinctions of the female sex.

A very different theory from that which we have just considered, and a very old one, affirms the formation of the fetus to a formative power of the mind or soul (anima fructrix, vs phylaxis); and some conceive that the object is effected by the mind of the fetus. The partisans of these opinions rely much on the effects said to be produced on the body of the fetus by causes operating on the mother's mind. They allege that the structure of the offspring is often materially changed and impaired by the longing of the mother, or by various violent emotions: that these effects are produced, not from any corporeal cause, but from the action of the mind on the anima fructrix of the fetus; that there is a harmony between the mind of the mother and her body, and between the bodies of the mother and child. Various attempts have been made to explain the manner and nature of this influence and connection. But it would have been better to have established the fact incontrovertibly in the first place. The records of medicine abound with instances of almost all imaginable effects produced on the fetus from the causes above-mentioned: —of the likeness of fruits or flowers, &c. on the body, of various animals, of bruises; —of parts being cut, destroyed, or otherwise injured, &c. &c. That credulity and ignorance have given birth to most of these narratives, cannot be doubted. Our faith in them must be most seriously shaken when we observe that there are no examples of the most violent mental disturbances, as terror, longing, passion, occurring repeatedly during pregnancy, particularly in delicate and hysterical women, without any thing unnatural appearing afterwards in the child, even when the mother has expressed her strong persuasion that her child would be mutilated. Nor can women forestell when the marks above alluded to (navi) will appear. Deformed and monstrous children, and others marked with navi, have been repeatedly observed by the most judicious and accurate observers, when the mother was not conscious of any such cause as those above alluded to. Children are born blind of healthy parents without the occurrence being considered as extraordinary or requiring any thing accidental to account for it. When women observe any deformity in their offspring, they recall to their memory every thing which has happened during their pregnancy; and if they can remember any fall or fright, or suddenly seeing any uncommon animal, the carcase of a bird opened, or a wound, &c. they immediately set it down as the cause of the phenomenon. And, from the various turns which superstitious and whimsical fancies take in different countries, the same appearances are ascribed to very different causes.

In weighing the testimonies of authors, we shall find that the most experienced and judicious indulge the common notions about navi much less than others. In the numerous collections, where monsters and extraordinary productions of all kinds are carefully collected and preferred, we see no example of a genuine navi, according to the common notions, that is, of the resemblance of a fausage, or a pig's foot, or a wound, &c. in any part of the body of a fetus. In further support of our opinions we may quote the numerous instances of monsters, vegetable productions, which cannot be ascribed to any power of imagination, or any mental affection whatever. We cannot doubt that the egg and the ovum contain the cause of the future structure, which is always preferred uniform in the same species. That various external circumstances, as a copious or deficient supply of nutrition, and many causes of a nature entirely unknown to us, may have an effect in altering or variously modifying the original fabric, within certain limits, we do not pretend to deny.

If the phenomenon of navi afford no proof of a plastic soul; if we acknowledge that the beautiful structure of an animal body cannot be reared by chance, nor by any blind force with which inorganic parts may attract each other, it remains for us to consider whether the fetus is formed before the time of conception, according to the hypothesis of evolution. This opinion has been chiefly held in modern times: it is ably defended by Haller, and has been supported by the experiments and writings of Spallanzani and Bonnet.

If, says Haller, the germ or original of the fetus be contained in the mother, if it be already formed in the ovum, and so far perfected as to require merely a supply of nourishment for its growth, the great difficulty of forming such an artificial and complicated structure from inorganic matter is overcome. In this hypothesis, the Creator,
with whom nothing is difficult, forms the machine: he has arranged dead matter, in conformity with his own designs, and according to the archetypa fixed by his wisdom, before the accession of the influence furnished by the male. In the same way you may have in plants a perfect flower, capsule, and well-formed seeds, differing from fruitful seeds only in the circumstance, that they would not grow into a new plant. The metamorphoses of insects have been adduced in support of this notion of evolution: the butterfly, so entirely different from the chrysalis, was entirely contained in the former, and needed only to be disengaged by the removal of the skin, and have its parts unfolded. The rudiments of the race, which are to contain air in the bee, exist in the fatty substance of the worm from which the perfect insect is formed, and numerous examples of a similar description might be adduced. The phenomenon of incubation, and the successive appearance of various parts until the whole animal is completed, afford a convincing argument for the hypothesis of evolution. After recounting the gradual and progressive unfolding of the body of the chicken, Haller observes, that the progress is nearly the same in quadrupeds. "In the human fetus, which at first seems a mere unorganized mass, Leeuwenhoek already discerned, by means of his microscopes, distinct organization. Thus it is clear, that an animal without any limbs, or discernible arrangement of parts, is gradually changed by various stages into a perfect being, nourished by food, and susceptible of voluntary motion. It may be inquired, whether the animalcules, before it can be recognized by the senses of the director, exist in the father or the mother; whether they were formed by epigenesis, or the successive union of particles: or whether we may call them组织. Epigenesis is altogether possible. Whoever has contemplated the structure of the body with a little attention, must be convinced that an animal could not exist without a heart, since the principle of life and motion exists in that organ. But the heart must be furnished with arteries to carry the vital fluid to all parts, and with veins to carry it back again.

It is easily proved that the fetus does not consist of a mere skeleton of blood-vessels. Viscera must accompany these, of which, with some cellular substance, they are entirely composed. But no one has seen the viscera composed by particles successively deposited: they are perfect, although small, as soon as they can be discerned. Mucules must have been present from the first: for the young animal, in the incubated egg, is capable of motion, and from its slightest state bends the body. It is moreover irritable, and must consequently have mucules, although they are concealed under the appearance of a mere gelatine. The head is large, and the eyes are visible among the first parts, together with the heart. The mucules require the presence of nerves, the brain must have been present with the head and heart." The hypothesis then, to which these arguments lead, is, that the perfect animal exists previously to conception, and that nothing new is generated, but that the parts, which were folded up, and contracted into a small space, are expanded, unfolded, enlarged, and rendered conspicuous. In this mode of explanation, we must, it seems, admit, that the germ of all the human race, as well those who have already lived, as those who may hereafter be born, were contained in the ovum of Eve: a proposition of so strange a nature, and so completely unanswerable, that we cannot value very highly the hypothesis, which renders it necessary.

The pre-organized germ would remain in a kind of torpid state in its ovum receptacle, were it not stimulated by the male semen. This fluid arouses it from its lethargy, and causes its growth and development. The stimulating properties of the semen are supposed by Haller to excite the motion of the heart; and he conceives that the subsequent development of the new being is easily understood.

The great reputation of Haller has not however gained his opinions on this subject universal assent. The accurate and well-informed Blumenbach of Gottingen has opposed the hypothesis of evolution with great effect, and has arrayed against it a number of objections, which its advocates will not easily elude. His opinion on this subject are, on the whole, the most rational that have hitherto promulgated: the following statement of them is derived from his manual of natural history, and his institutes of physiology. "The hypothesis of evolution has been employed, particularly in modern times, in order to explain the origin of organized bodies; it has been stated that no man, no other animal, and no plant is generated, but that they have all existed in their parent and ancestors, in the state of complete previously formed germ, since the first creation. The various generations have been continued, one within the other, like a series of pill-boxes, and have been only gradually unfolded and brought to light by fecundation, in their respective turns." Haller, who was the leader of the modern evolutionists, roundly asserted, "that the viscera, and all the bones of the future fetus, exist before conception in the maternal germ, but nearly in a fluid state, and therefore invisible." This opinion must be formed, on the first view of it, irreconcilable with reason, on account of the complication involved in it, of the utmost creation of innumerable germs, which are never to be evoked, and it is utterly at variance with all clade and found phyiological reasoning, on account of the great aid which it requires from preternatural agency, and the hopeless complication of natural powers which it supposes in opposition to all the laws of philosophical investigation. According to the unanimous representations of the most celebrated and zealous advocates of evolution, the pre-organized germs lie ready in the mother, are routed at the time of fecundation, and proceed to their development by this agency of the male seminal fluid. What we call conception is, therefore, nothing but the excitation of the torpid germ by the affusion of the male liquor. Here then, in the first place, we must suppose an exciting power. But children often resemble most strikingly their father only: hitches, after copulating with different dogs, often have puppies resembling their different fathers: two individuals of different races, as a Negro and an European, produce together offspring of a middle character, or a mulatto: and, where the species of animals or plants is different, mongrels are produced, having as many characters of the father's formation as of the mother's. All these facts cannot be overlooked; and, in order to account for them, the evolutionists suppose in the fermen, in addition to its exciting influence, a formative power, by which it can change the pre-organized germ contained in the mother into something of the form of the father. Thus we find two powers in the fermen, an exciting, and a formative one. But, by means of an artificial hybrid intermixture, repeated through several generations, we can, at last, change one species of organized bodies entirely into another. One species of plant, fecundated with the male pupule of another, produced seeds, from which hybrid fecundable plants were produced. These were again fecundated with seeds of the same male plant; and, after this had been repeated four times, a complete metamorphosis had taken place, by which the characters of the male were fully
fluted for those of the female plant. The same circumstances will occur in the human species if the offspring of an European woman by a negro be fecundated by a negro; and the produce of that conception again by a negro, &c. Thus, at last, the preformation of the maternal germ, which has been preferred since the creation of the world, avails nothing, but yields entirely to the formative power of the male fluid, which, according to the hypothesis of evolution, should merely excite it to action. We may affirm, in short, on the whole, that of all the phenomena adduced in support of this hypothesis, not one can be established sufficiently clear to be admitted as a proof; while there are numerous unexceptionable observations directly opposing it.

But, in proportion as this hypothesis of evolution is inconsistent with the phenomena, and with the rules of philosophy, so, on the contrary, the opinion, not that any fictitious germs are evolved by means of conception, but that the new being is in fact generated, and gradually and successively formed from the generative fluids, commends itself to our approbation by its simplicity, and its accordance with the other processes of nature.

Since this affair of a true generation by successive formation has been variously explained by physiologists, I conceive that we shall approach most nearly to the truth, by adopting the following propositions. 1d. The materials, of which organized bodies, and consequently the human frame is composed, differ from all other matter in being regulated simply and exclusively by vital powers. 2d. Of these the most remarkable, and that, whose existence and agency can be the least questioned, is the force which acts on organized matter, when prepared for its destination, but not yet moulded into shape, and betows on it, according to its various natures, various but determined and definite forms. In order to distinguish this vital power properly from all others, I give it the name of nius formativus. 3d. This nius formativus is imparted to the materials of generation, when they are contained in a mature flate, under the requisite conditions, in the urine cavity, builds up in it the rudiments of the embryo, and gradually forms its organs to correspond to their pre-ordained purposes; it preserves the same structure by the process of nutrition, as long as life continues; and it obviates the effects of casual mutation, as far as that can be accomplished, by means of reproduction.

This gradual formation of new organized bodies can be most manifestly discerned in thoé, which combine, with a considerable magnitude, a rapid growth, and such a kind of delicate semi-transparent texture, that they can be clearly seen through, particularly in a sufficient light, and with moderate magnifying powers. This is the cafe in the vegetable kingdom, with some simple aquatic productions, as the coniferae, in the marine class, which is propagated in the early part of spring; in the bloodless divisions of the animal kingdom, with the polypoys (lydra); in the animal kingdom, with the incubated egg, on the first appearance of the chicken, and its subsequent daily development.

It must be observed here, that the expression nius formativus is employed simply for the purpose of distinguishing this from the other kinds of vital powers, and by none means with any intention of explaining the cause of generation. I believe the latter to be concealed by no lefs impenetrable darkness than that which involves the causes of gravitation and attraction, which are only names for effects, recognized like the nius formativus, a posteriori. I have employed the word nius chiefly in order to denote that the nature of this force is truly vital, and to distinguish it as clearly as possible from the merely mechanical powers, by means of which

some philosophers formerly endeavoured to explain the business of generation. The very point on which the whole of this doctrine concerning the nius formativus hinges, and which alone sufficiently distinguishes it from the vis vitalis of the ancients, the vis essentiales of Wolf, and other hypotheses of the like nature, consists in the combination of the two principles, by which the nature of organized bodies is explained, viz. the phisico-mechanical and the teleological.

I hold it most probable, that in the first place, a definite time is required for the various fluids of each sex, which seem to be united in the cavity of the uterus after a fruitful copulation, to be more intimately mingled, and brought to maturity. When the period of this preparation is completed, the mature and intimately blended fluids become animated by the nius formativus, by which the hitherto unformed materials of generation are partly moulded into the elegant coverings of the ovum, partly into the figure of the contained embryo. Hence we can understand, why the smallest vestige of a formed fetus cannot be discerned, even with the aid of the excellent modern optical instruments, during the first week after conception, excepting the unformed fluids contained in the uterine cavity; while the embryo appears as it were on a sudden in the third week.

I should exceed the limits of these institutions, if I were to pursue at greater length those arguments drawn from nature herself, by which the influence of the nius formativus in generation seems to me to be rendered very highly probable. I shall advert very shortly to a few of these points, the force of which will be easily discovered by a more attentive consideration. On this principle I explain the memorable experiment in the history of hybrid productions, where prolific hybrids, fecundated during several generations, by the male seed of the same species, have produced an offspring gradually deviating from the original maternal form, and assuming the characters of the father, until at last the former has been completely changed into the latter by a kind of arbitrary metamorphosis.

The well-known fact of the great frequency of monstrous productions in some species of domesticated animals, particularly fowls, and their rarity in the wild condition of the same animals, can only be explained on the principles already stated. The evolutionists are compelled to assert that all these monstrosities must have existed in the germ from the first creation of things. The phenomena of reproduction, taken altogether, can be much more aptly explained by the agency of the nius formativus, than on the action of pre-existent germs; and some particular examples, as, for instance, of nails growing in the middle, after the loss of the first phalanx, cannot well be solved on any other principle.

After considering, and carefully weighing the arguments on both sides of the question, it appears, that even those who assume pre-existent germs, must allow to the male seminal fluid a considerable formative influence, in addition to the exciting power, which they recognize in it, and consequently that the doctrine which they defend requires, in fact, the assistance of the nius formativus; while the latter sufficiently explains the phenomena of generation, without the aid of pre-existing germs." Whatever theory of generation we adopt, w: must ultimately ascend to the agency of the Creator, the primary cause of all existence.

The circumstances belonging to the state of pregnancy; the period and phenomena of parturition and its consequences, are treated under those articles of the Cyclopedia which relate to the subject of midwifery.
GENERAL

Generation of Plants. See Foundation and Gemma.

Generation of Shells. See Shells.

Generation of Stones. See Stones, Spar, Trochites, and Crystals.

Generation, in Theology. The father is said, by some divines, to have produced his Word, or Son, from all eternity, by way of generation; on which occasion the word generation raised a peculiar idea: that procession which is really effected in the way of understanding, is called generation, because in virtue thereof the Word becomes like to him from whom he takes his original; or, as St. Paul expresses it, the figure or image of his substance, i.e. of his being and nature. See Trinity and Person. And hence it is, they say, that the second person in the Trinity is called the Son.

Generation is also used, though somewhat improperly, for genealogy, or the series of children inferred from the same stock. Thus the gospel of St. Matthew commences with “the book of the generation of Jesus Christ, &c.” The latter and more accurate translators, instead of generation, use the word genealogy.

Generation is also used to signify a people, race, or nation, in the literal translations of the scripture, where the word generally occurs wherever the Latin has generation, and the Greek γενεαί, γενεᾶς.

Thus, “A wicked and perverse generation seeketh a sign,” &c. “One generation passes away, and another cometh,” &c.

Generation is also used in the sense of an age, or the ordinary period of a man’s life.

Thus we say to the third and fourth generation. In this sense, historians usually reckon a generation the space of thirty-three years, or thereabouts. See Age.

Herodotus makes three generations in an hundred years; which computation appears, from the latter authors of political arithmetic, to be pretty just. See Chronology and Political Arithmetic.

GENERATOR, in Music, signifies the principal found or bounds by which others are produced. (See GENERATE.) Thus, the lowest C for the treble of the harpichord, besides its octave, will strike an attentive ear with its twelfth above or G in alt, and with its seventeenth above, or E in alt. The C, therefore, is called their “generator,” and the G and E its products or harmonics. But in the approximation of chords for G its octave below is substantiated, which constitutes a fifth from the generator, or lowest C; and for E is likewise substantiated its fifteenth below, which, with the above-mentioned C, forms a third major. To the lowest notes, therefore, the denominations of products or harmonics are likewise given, whilst the C retains the name of their “generator.” But still, according to the system of Tartini, two notes in concord, which, when produced, produce a third, may be termed the “concurring generators” of that third.

GENERAL NAME, in Natural History, the word used to signify all the species of natural bodies, which agree in certain essential and peculiar characters, and therefore all of the same family or kind; so that the word used as the general name equally expresses every one of them, and some other words expressive of the peculiar qualities or figures of each are added, in order to denote them singly, and make up what is called a specific name.

Thus the word rosa, or rose, is the general name of the whole series of flowers of that kind, which are distinguished by the specific names of the red rose, the white rose, the apple rose, &c. The ignorance of former ages, in the true principles of natural history, has occasioned the bodies, which are the objects of it, to be arranged into very unnatural series under the name of genera; and these have been called by names as improper as the characters they were distinguished by. Linnaeus has done a great deal in exploring the bad general names in botany, and Artedi has applied his rules about the formation of these names with very little difference to the subjects of ichthyology.

Many of the general names of fish, till the time of this author, were so barbarous and obscure, that it was not easy to trace them to their original, or to find whether they were truly Teutonic, English, Dutch, Swedish, French, Italian, Spanish, Portuguese, Latin, or Indian. The ignorance of the writers on these subjects, or their too frequent adherence to the customs of their predecessors, seem to have been principally the causes of this, and often an entire regurgitation. Artedi’s rules for general names for fish are these: whatever fish there are which agree in the same general characters, and are properly of the same genus, these ought all to be called by the same general name, their differences being only expressed by specific ones. This appears to plain, to just, and to necessary a rule, that it is also most a shame to lay it down; yet the writers on fish, till the time of this author, had very seldom observed it.

Another barbarism and impropriety in the general names of fish among the old authors, is the using of the same words to express them, which are also the names of other animals, quadrupeds, birds, and reptiles. These are subject to great objection; because when they are used, it is not easy to see, in some cases, whether the author is speaking of a bird, a beast, or a fish. It is therefore one of the general rules of Artedi, that all these names are to be abolished, as also all those which are common to fish, and to plants, minerals, and to the tools of husbandry, or other services.

Another rule of this excellent author is, that general names that are composed of two whole words, unnaturally tied together, are to be abolished, it being easy to contrive names that are barbarous, and as expressive: next to these are to be exploded those names which are formed of several words before in use, the one broken or cut short, the other preferred entire.

Another general rule in regard to these names is, that all such as are not of either Latin or Greek origin, are to be proscribed and wholly rejected. This rule cuts off a prodigious number of barbarous words, with which we find the books of authors of former ages on these subjects crowded.

A sixth rule for the regulating general names is, that all such are to be abolished as terminate in adus, as expressing a resemblance often imaginary, and often alluding to something unknown, or rendered difficult to trace from the changes which the names of other things have undergone since the time it was formed. These words convey no idea of the character of the genus expressed by them, except that they are like the other thing alluded to in some external, though perhaps not essential, character; of this kind are the rhomboids, lepidopods, &c.

A seventh rule in regard to these names is, that all such are to be rejected as are barely diminutives, and terminate in als or uth. These convey no other idea, but that of the fish being like some other fish, only less: now bignefs is no general character; therefore if this genus, and that referred
ferred to, differ only in five, they have no generical difference at all: if they do differ otherwise, they should be exprest. What makes many of these names also more inadmissible is, that they allude not to fish, but to other things so different in their nature, that there must needs be many other more essential varieties between them, besides fish.

Another general rule is, that such generical names as are pure Latin, but are mere adjectives, are to be exploded: there being no reason for using them as substantives.

A ninth general rule is, that such names as are formed of Latin words, unknown to the ancient Romans, and forced by the later writers, are to be exprest as barbarous, and others of better credit placed in their stead.

Finally, such generical names as have been given to fish from the places where they are caught, are to be rejected: of this kind are the tarda and tarnica from the land of Sardina, and the floria from Artilis, a province of Spain. These forms of names can convey no idea of the nature of the fish, and may belong as well to one genus as to another.

Artedi, Ichthyolog. p. 10. 69. 73. 79.

These rules of prostration handled so many of the received generical names of fish, that it might be supposed the whole number was exhausted, and all the fish in the world to be named anew. But this is not the case: the genera are, in reality much fewer in number than they have been usually supposed, and therefore fewer words will serve to express them, and there yet remain many truly Latin words used by the ancient Romans, by which the far greater part of the genera may be exprest, and the few remaining may be best denominated by compound Greek words, expressive of their real characters.

Among the true and genuine Latin, and Greco-Latin names of the genera of fish, there are: acipenser, anis, anisus, halecena, blemius, clupeus, eobates, cyprinus, delphinus, clupea, coccus, clupeus, gobius, labeus, lamia, liparis, mugil, mullos, marina, percus, phylather, pristis, rajus, salmo, salpa, saurus, sauber, talus, iphas, xelopus, xiphias, zeus. These will go a great way toward the naming of the true genera.

Artedi has enriched greatly of the world, in this reforming the names of fishes and the rules he has laid down, thus given at large, may, with little variation, be made to serve for any other author, in whatever branch of knowledge he has occasion to write.

GENEROSIS SECOND. See SECOND.

GENEROSA, a Gentlewoman. See GENTLEWOMAN and SPINSTER.

GENEROSITY, Order of, an order of knighthood, established in 1649, by Frederick Ill., elector of Brandenburg and king of Prussia, whilst he was electoral prince. The badge was a gold cross of eight points enamelled azure, bearing in the centre this inscription "La Generosit" and under to a blue ribbon.

GEOGRAPHIA, a town in the Arabian Iraq; 90 miles S. of Bagdad.

GENSAB, or GENSABER, called also Gensabo, and afterwards Jibrut, a town of Isbline on the lake of the same name, called also seer of Gilead, which see.

GENESEE, a township of America, in the state of New York, and county of Ontario, having 211 electors.

GENESEE Country, a large tract of land in the state of New York, deriving its name from Genevise, one of its rivers, and bounded N. and S. by lake Ontario, S. by Pennsylvanias, E. by the western part of the military townships in Vermont county, and W. by lake Erie and Niagara river. This is a rich tract of country, and well watered by lakes and rivers, it is flatish, its rivers are sluggish, the soil is moist, and its lakes are numerous.

GENESEVER, or Geneve River, rises in Pennsylvania, near the most elevated spot of this state, where also the cañon of the Allegheny river, and Pine creek, a water of Susquehanna, and Tioga river rise. It has several falls, which furnish excellent mills, etc., that are improved by the inhabitants. After a course of about 100 miles, chiefly N., it discharges itself into lake Ontario, 43 miles E. of Greatwater, or Edmunds bay, and 2 miles E. from the fall of Niagara. The settlements on this river, from its mouth upwards, are: Northfield, Northampton, Hartford, Genevee, and Williamshurgh. When the western canals and locks are completed, there will be a traveling place between the city of New York and Williamshurgh. The Geneve River lies on the borders of this river, about 20 miles in length and about four in breadth. These are mostly the property of the Indians.

GENEVER, or Geneve County, is bounded N. by lake Ontario, W. by Niagara river and lake Erie, S. by Pennsylvania, and E. by the counties of Tioga and Orandago. It comprehends the counties of Ontario, Steuben, and Genevee, and contained, in the year 1828, upwards of 17,000 persons. This county is finely watered by the Geneve River and its tributary streams, several creeks, and also lakes, which are from 20 to 40 miles in length. The southern part is watered by several branches of the Susquehanna. This country is large, and comprehends the western part of the state of New York.

GENESIS, in Biblical History, the first book of the Old Testament, containing the history of the creation, and the lives of the first patriarchs.

The book of Genesis stands at the head of the Pentateuch, which see. Its author is held to be Moses; it contains the revelation of 2360 years, viz., from the beginning of the world to the death of Joseph. The Jews are forbid to read the beginning of Genesis, and the beginning of Ezekiel, before thirty years of age.

The Hebrews called this book B. yei forbidden, because it begins with that word, which in their language signifies in principle, or in the beginning. The Greeks gave it the name Genesis, from g. o., production, generation, because it begins with the history of the production or generation of all beings.

This book, besides the history of the creation, contains an account of the original innocence and fall of man; the propagation of mankind; the rise of religion; the general defection and corruption of the world; the deluge; the restoration of the world; the division and peopling of the earth; and the history of the first patriarchs to the death of Joseph. It was easy for Moses to be satisfied of the truth of what he delivereth in this book, because it came down to him through a few hands: for from Adam to Noah, there was one man, viz., Methuselah, who lived so long as to see them both; in like manner Shem conversed with Noah and Abraham; Isaac with Abraham and Joseph, from whom the records of this book might easily be conveyed to Moses by Amram, who was contemporary with Joseph.—Patrick.

GENESIS, in Geology, denotes the formation of a line, plane, or solid, by the motion or flux of a point, line, or surface. See each respectively; also Elevation and Curve, and Generation.

The geoin, or formation, e. g., of a globe or sphere, is conceived by supposing a semi-circle to revolve upon a right line, drawn from one extremity thereof to the other, called its axis, or axis of circumvolution: the motion or revolution
of that semi-circle is the genesis of the sphere, &c. See \underline{Globe} and \underline{Sphere}.

In the genesis of figures, &c. the line or surface that moves, is called the deferent; and the line round which, or according to which, the revolution or motion is made, the dirigent.

\textbf{GENEST, Charles-Claude}, in \textit{Biography}, was born at Paris in 1630. Being of an unpretented disposition, he resolved to go to the Indies to seek his fortune, but the vessel in which he sailed having been captured by the English, he was brought to London, where he subsisted for some time by teaching the French language. On his return to his own country, he obtained the post of preceptor to Madame de Blois, afterwards duchess of Orleans, and other considerable offices among the great. He became a member of the French academy in 1698, and died at Paris in 1739. Though a courtier, he was sincere and simple in his manners, and estimable in his character. He derived a taste for natural philosophy from the lectures of Rohault, the disciple of Descartes, and for metaphysics from the instructions and conversation of Buffet. He was an elegant scholar, and greatly devoted to poetry and polite literature. His works are numerous, of which the principal are \textquoteright{Principes de Philosophie,} in which the author adduces many arguments in defence of a God, and of the immortality of the soul. \"Occasional Pieces of Poetry.\" Several tragedies, and \"A dissertation upon Passoral.\" Mercier.

\textbf{GENEST-DAMBRIERRE, St. in Geography, a town of France, in the department of the Vienne; seven miles W. of Châtellerault.}

\textbf{GENEST-MALLISAUT, St. a town of France, in the department of the Loire, and chief place of a canton in the district of St. Etienne; four miles S. of St. Etienne. The place contains 1587, and the canton 5648 inhabitants, on a territory of 150 kilometres, in five communes.}

\textbf{GENET, Francis, in Biography, was born at Avignon in the year 1640; here he received his grammatical learning, and having acquired a considerable knowledge in the Latin and Greek, he entered upon philosophy, and was for a time a disciple of Scottus, but he afterwards relinquished his studies, and became zealously attached to the philosophy and theology of Aquinas. In 1670, he was admitted to the degree of doctor in civil and canon law at Avignon, and acquired much reputation by the theses, which he delivered on that occasion, against infancy. His talents recommended him to the notice of the archbishop of Aix, who for some time made use of him in the management of the ecclesiastical concerns of his metropolitan district. He was afterwards employed and patronized by M. Le Camus, bishop of Grenoble, who engaged him in the composition of a syllabary of moral theology, which was afterwards published in five volumes 1720, under the title of \"Moral de Grenoble.\" This work was well received, has gone through many editions, and has been translated into the Latin language. Soon after its publication, the pope, Innocent XI. created M. Genet canon and prebend of the cathedral church at Avignon, and in 1685 appointed him bishop of Vaison. He discharged all the duties of his episcopal functions with exemplary watchfulness and zeal, till the year 1688, when he was prosecuted for having admitted into his diocese the religious belonging to a new convent at Touloanche, which Louis XIV. had suppressed. By the arbitrary mandate of the king, the good bishop was arrested, and imprisoned for fifteen months in the isle of Rhe, whence he was released by the intervention of the pope. He was accidentally drowned in 1702. Moreiri.

\textbf{GENET, or Jennis, said to be derived from \textit{verpes}, some notus, in the \textit{Manege}, &c. a small-sized, well-proportioned Spanish horse.}

Some also give the name geneta to well-made Italian horses.

\textbf{GENET, Order of, an order of knighthood, instituted in France by Charles Martel in the year 726, for commemorating a signal victory, which he obtained in that year over the Arabian army, commanded by Abdarrah. The badge of the order was a genet sable, enamelled azure, spotted or flecked gules, and collared or, on a mount vert, enamelled with flowers proper. This badge was worn pendant to a collar composed of three chains of gold interlaced with red enamelled rosettes. This order was instituted for sixteen knights, and continued in great repute till the reign of king Robert, when it was abolished on his deviation the order of the star, in honour of the holy virgin.}

\textbf{GENETHLIA. \textit{Teuthis}, in Antiquity, a solemnity kept in memory of some person deceased.}

\textbf{GENETHLIAE, in Biology, formed of the Greek \textit{genethlai}, signifying generation, \textit{natal}, nativity, in \textit{Veterinary}, persons who erect horsecap, or pretend to forestall what shall befall a man, by means of the stars which preceded at his nativity.

The ancients called them \textit{Chaldai}, and by the general name \textit{magi}, according to the several civil and cabinet laws, which we find made against the mathematicians, only respect the genethlai, or astrologers.

They were expelled Rome by a formal decree of the senate; and yet found so much protection from the credibility of the people, that they remained therein unmolested. Hence an ancient author speaks of them as \"homine genus, quod in civitate nostrae temper & vetabitur, \& retribui.\"}

\textbf{Antipater and Archiæpolis have shown, that genethiology should rather be founded on the time of the conception than on that of the birth. Vitruvius.}

\textbf{GENETHLIAECUM, GENETHLLACUM, Poem, is a composition in verse, on the birth of some prince, or other illustrious person; wherein the poet promises him great honours, advantages, success, victories, &c. by a kind of prophecy or prediction: such is the eulogy of Virgil to Bollo, beginning,}

\textbf{\"Sicelides Mufa, paulo majora canamus."}

There are also genethlial speeches or orations, made to celebrate a person's birth-day.

\textbf{GENETIDES, in Natural History, a name given by the ancients to the stone more generally known under the name enammonites. This was the first inculcated on the tops and sides of subterranean caverns, which they supposed daily to bring forth more, and therefore gave the power of it to women at the time of their lying-in, to promote their speedy delivery.}

\textbf{GENETTA. \textit{To ride a}, is to ride in the Spanish fashion, \&c. with the stirrups so short, that the spurs bear upon the flanks of the horse. This is deemed a piece of gallantry in Spain, but not among us.}

\textbf{GENETTA, in Zoology, a species of \textit{Viteria}, which see.}

\textbf{GENETTE, in the \textit{Manege}, a Turkish bit, the curb of which is all of one piece, and made like a large ring, and placed above the liberty of the tongue. When they bridle a horse, they make his chin pass through this curb, which surrounds his head. This sort of bit was much used at the court of France when Guillet wrote.}

\textbf{GENETYLLIS, \textit{Februalis}, in Antiquity, a solemnity celebrated by women, in honour of Genetyllis, the goddess of that sex.}

\textbf{GENEVA, or \textit{Gin}, a popular name for a compound water,}
GENEVA.

water, which is, or ought to be, procured from the berries of the juniper-tree, distilled with brandy or malt-spirits. See JUNIPER.

The word is formed from *genevre*, the French name of the juniper-berry.

The best geneva we now have, is made from an ordinary spirit, distilled a second time with an addition of some juniper berries; but the original liquor of this kind was prepared in a very different manner. It was a custom in the distilling of spirits from wort, or other fermented liquors, to add in the working some aromatic ingredient, such as ginger, cortex Winteranum, or grains of paradise, to take off the bad flavour, and to give a pungent taste to the spirit. Among other things used with this intent, some tried the juniper-berries, and finding that they gave not only an agreeable flavour, but a very valuable virtues also to the spirit, they brought it to a general custom, and the liquor fold under the name. The method of adding the berries was in the malt in the grinding; a proper proportion was allowed, and the whole was reduced to meal together, and worked in the common way. The spirit thus obtained was flavoured *abo exigas* with the berries, and exceeded all that could be made by any other method. Our common distillers leave out the juniper-berries entirely from the liquor they now make and sell under that name. Our chemists have let them into the secret, that the oil of juniper-berries, and that of turpentine, are very much alike in flavour, though not in price; and the common method of making what is called geneva in London, is with common malt spirit, and a proper quantity of oil of turpentine distilled together. Shaw's Essay on Distill. p. 7. See DISTILLER.

GENEVA, in Geog., a city of France (since the revolution), principal place of a district, and capital of the department Levan, but formerly capital of a republic, in alliance with the Swiss; situated on the confines of Savoy, France, and Switzerland, at the southern extremity of the Lake of Geneva, 6. of Leman lake, upon the narrowest part of it; where the Rhone divides in two large and rapid streams, which join afterwards unite, and, passing through the city, divides it into two unequal parts. The adjacent country is uncommonly picturesque, and abounds in magnificent views, formed by the town, the lake, the numerous hills and mountains, particularly the Salève and the Môle, rising suddenly from the plain in a variety of fantastic forms, backed by the glaciers of Savoy, with their frozen tops glittering in the sun, and the majestic Mont Blanc rearing its head far above the rest. Geneva, which stands partly in the plain, upon the borders of the lake, and partly upon a gently ascent, is irregularly built: the houses are high, and many in the trading part of the city have arcades of wood, which are raised even to the upper storeys. These arcades, supported by pillars, give a gloomy appearance to the street, but are useful to the inhabitants in protecting them from the sun and rain. This is the most populous town in Switzerland; and the inhabitants are estimated to be from 23,000 to 25,000. This population is owing to the industry and activity that prevail in this place, to its extensive commerce, to the facility of purchasing the burghership, and to the privileges which the government allows to all foreigners. The members of this city are distinguished into citizens and burgesses, inhabitants of native birth, and foreigners, who are divided into five classes, established after the revolution in 1782, and called "dominics," who receive from the magistrates an annual permission to reside in the city. The citizens and burgesses were, under the old police, admitted to a share in the government; the inhabitants are strangers allowed to settle in the town with certain privileges, and the natives are the sons of these inha-

The liberal policy of this government, in receiving strangers, and conferring the burghership, is the more remarkable, as it is contrary to the spirit and usage of the Swiss. Here it is peculiarly necessary; as the territory of this state is so very small, that its very existence depends upon the number and industry of the people; for, exclusively of the city, there are scarcely 16,000 persons in the whole district of the Genevois.

Geneva boasts, and not without reason, of its antiquity. The precise time of its commencement is not known; but it existed before the Christian era, and is particularly mentioned by Caesar. (De Bell. Gall. l. i. c. 1.) It belonged to the Allobroges (see this article), and flourished under the successors of Caesar. The Christian religion was introduced among the Genevans in the third century, and about the middle of the 4th century Geneva appears to have been the seat of a bishop. It suffered, however, in a considerable degree, and in common with other parts of the western empire, from the incursions and ravages of the northern barbarians. About the middle of the fifth century the Vandals, who had settled in the country of Vaud, and built several strongholds, assumed the name of Burgundians, or, according to modern orthography, Burgundians, had possession of it; and in the year 520, it was transferred to the Franks. Towards the end of the 8th century, Charlemagne convened an assembly of his vassals at Geneva, to consult about a war with the Lombards, and confirmed both the civil and religious privileges of this city. In the year 1032, it was annexed to the German empire; but the authority of the emperor was little regarded in distant provinces, and they found it expedient to protect associations of the common people, and to enlarge their liberty, in order to counteract the tyranny of the lords and clergy. In process of time, the clergy acquired a great degree of secular power and jurisdiction in connection with their spiritual authority: and thus the bishops of Geneva had obtained of the emperor the title of princes and sovereigns over the town and the adjacent country. On the other hand, the counts of the Genevois, or of the district in the vicinity of Geneva, who were originally officers of the empire, though afterwards they became vassals of the bishops, aspired to an exclusive administration of justice both in the town and the country. The people availed themselves of the contest between their superiors in rank and power to confirm and extend their own privileges. In the mean time, the liberty of the city was menaced by a third power, no less formidable than either of the other two. The counts of Savoy became powerful by the successive possession of feudal provinces; and among the rest the Genevois favoured the pretensions of the ancient counts, and aspired to the sovereignty of a flourishing town, which was also a convenient and strong frontier.

It would not be very interesting to relate, in minute details, the contests that were from time to time renewed between the Genevese and the counts of Savoy. We shall content ourselves with observing that in the year 1415, the emperor Sigismund visited Geneva, and that two years afterwards he erected Savoy into a dukedom in favour of Amadeus, the 8th count, who, in the year 1420, petitioned the pope for the sovereignty of the city. The duke's suit was referred by the pope to the bishop, who summoned a general assembly of the people, to deliberate upon the duke's request, which had obtained the approbation of the pope. The inhabitants unanimously rejected it, and at the same time required the bishop to be true to his charge, affurming him of their con-

G. 4.

A. 5.
currence in maintaining his just rights, and those of the city. This noble spirit encouraged the bishop, and produced a most excellent act in favour of liberty: for he entered into a formal agreement with the people and the syndics, never to alter the constitution without their consent. This act, having been engrossed in Latin, and the observance of it sworn to by the bishop, the syndics, and the council, was subscribed by all the magistrates, commonalty, and clergy of Geneva; and in the following year was confirmed by the emperor Sigismund, who declared Geneva to be an imperial city, under the title of “Nobile Imperii Membrum,” and took it into his immediate protection against all powers, the duke of Savoy in particular. The Genevese, however, maintained their liberties against the repeated attacks made upon them by the dukes of Savoy under very great disadvantages. Nevertheless, they persevered till about the beginning of the 16th century, when an alliance was entered into between Geneva and Friburg, the content continued, and was the occasion of many acts of oppression and persecution. When the treaty was concluded, in consequence of the active interference of a young citizen of Geneva, named Berthelier, two parties arose in Geneva, one of which retained an attachment to the interests of the duke of Savoy, and the other declared itself on the side of liberty. Thence of the latter description were called “Eignots,” which in Swiss, or High German, signifies “confederates by oath,” and from which the term “Huguenots” is probably derived; whilst those of the former were denominated “Mamalukes,” in reference to the Egyptian soldiery, who being originally Christians, renounced both their religion and liberty, to become slaves to the sultan. The duke, irritated by this conduct, entered Geneva with an armed force, and compelled the people to renounce their new alliance, whilst he perjured Friburg to withdraw from the treaty, promising not to injure the liberties of the Genevese. Berthelier, the Genevan patriot, was however sacrificed to his vengeance, and the magistrates of the city were deposed by the bishop. In the year 1526, a new alliance was formed between the towns of Bern, Friburg, and Geneva, which the duke of Savoy was not able to prevent, and occasioned wars of long continuance between the republic and Savoy. This alliance was confirmed by the bishop; and may be considered as the true era of the independence of Geneva. Soon after this period, viz. in 1533, the doctrines of the reformation were preached at Geneva by William Farel, a native of Gap in Dauphiné, and Peter Viret, of Orbe; and the people, animated by the enthusiasm of liberty, determined to emancipate themselves from the yoke of bondage, both ecclesiastical and civil. The bishop, who had always acted a weak and deceitful part, became despicable both to the Genevese and to the duke; and by his impudent menaces and precipitate retreat, served to strengthen the cause of the reformation. In 1535, the doctrines of the reformation were adopted in full council; and in consequence of this decision, the canton of Friburg renounced the alliance. In the following year, the famous John Calvin, driven from France by persecution, arrived at Geneva, and completed the reformation, that had been already begun by Farel and others. So great was the ascendency which Calvin, though a foreigner, acquired over the citizens, that he possessed considerable influence even in civil matters; and was eminently instrumental in settling the political constitution. To this end, as well as to encourage theological rudiments, he prevailed upon government to establish a public academy, the presidency of which he obtained for his friend and fellow labourer, Theodore Beza. In this new seminary, Calvin, Beza, and others, eminently for their superior knowledge, read lectures with such uncommon reputation and fascets, as attracted students from all quarters. It had also a public library, which owed its origin about this period to the liberality of Lionard, prior of St. Victor, who was twice imprisoned for having suffered, against the dukes of Savoy, the independence of Geneva. He was a principal promoter of the reformation by gentle means and gradual instruction. He closed his benefactions to his beloved city, by the gift of his valuable manuscripts and books, and by bequeathing his fortune towards the establishment and support of the seminary. Geneva was now regarded as the asylum of the reformed religion; and by the accension of persecuted protestants from other cities and countries, its arts and commerce flourished, and its population increased.

In 1584, Geneva concluded a treaty of perpetual alliance with Zürick and Bern, by which it formed a part of the Helvetic confederacy. The last attempt of the house of Savoy against Geneva took place in 1602, when Charles Emanuel attacked the town during a profound peace. The inhabitants, however, nobly defended themselves, repulsed the enemy, and obliged him to abandon his treacherous design. This perilous attack was followed by a war, which was terminated in the following year by a solemn treaty. Since that period, uninterrupted peace has been maintained between Geneva and the duke of Savoy; although the king of Sardinia did not, till the year 1734, formally acknowledge the independence of the republic. From that period, the history of Geneva contains little more than a narrative of contentions between the arithetocratic and popular parties. The constitution of Geneva, which had then been established, and which continued for several years, under a certain modification and improvement of the year 1768, was a kind of mean between those of the arithetocratic and popular cantons; more democratical than any of the former, as the sovereign and legislative authority were vested in the general assembly of the citizens; but more arithetocratic than the other, because the powers entrusted with the great and little councils were very considerable. The fabrics of the magistrates were so inconsiderable, as not to offer any temptation to pecuniary emolument; and the revenues of government, at the highest calculation, generally amounted to 36,000 pounds a year. Their constitution, indeed, was defective, as they had no precise code of penal law; but that of civil law was the most perfect part of their government. In Geneva, as well as in all the other principal towns of Switzerland, a public granary was established, and they had always in reserve a sufficient quantity of com to supply the inhabitants during a year and a half. Geneva was the only republic in Switzerland which had no regular companies of soldiers in any foreign service. Geneva was always more or less irritated by internal dissensions and tumults. In 1782, these had prevailed to such a degree, that the kings of France and Sardinia, together with the canton of Bern, interfered, and threatened to besiege the city. The peasants of the territory joined the Genevese, and offered to serve in their cause without pay, to mount guard, and work at the fortifications. M. de Jaucourt, the commander of the French troops, threatened, in case of resistance, to enter the town by force, and forbidden that no person should appear in the streets, that all arms should be delivered up, and that the chief of the “representants,” as the popular party was called, should retire from Geneva, and that the deposed magistrates should be reinstated. Resistance in these circumstances must have been altogether unwieldy, and unfit, indeed, have terminated in the destruction of the city. The representatives, therefore, restored the confined magistrates to liberty, and left the city in a body. The Sardinians, who first entered the gates, found the city almost deserted; and soon after the two other commanders
the commanders made their entry at the head of their respective troops, with drums beating and colours flying. The aristocratical party celebrated their triumph with balls, feasts and every species of public diversion. A committee, appointed by the great and little councils, prepared, in concert with the three generals, an edict for new modelling the constitution, which, being approved at the courts of Verfailles and Turin, and by the canton of Bern, was confirmed by the great and little councils. Much as the Genevans feared to deplore the consequences of this revolution, the change that was made in their constitution, and the diminution of that liberty to which they had been accustomed, and to which they ascribed the increase of their population and riches, the ferment was multiplied; and excepting the principal leaders, those of the popular party who were banished, and some few others who renounced their country under the influence of their political principles, the greater number of the emigrants returned, and again settled in the place of their nativity. According to Mr. Cooke, this revolution caused fearfully 600 persons to leave Geneva. The emigrants principally established themselves at Bruiss and Conflan; where they introduced manufactures of linen and of watches. A plan was also formed for giving an asylum to the Genevan emigrants in Ireland. (See New Geneva.) The form of government established in 1782 underwent another very considerable change in consequence of the revolution in 1789. The aristocratical party was obliged to yield, on this occasion, to the accumulative demands of the people; and when the solicitor-general, in the name of the citizens and burghers, requested the recovery of their ancient liberties, the permission of bearing arms, the re-establishment of the militia, and of their circles or political clubs, the removal of the garrison from the barracks, and the recall of the representatives banished in 1782; such moderate demands were received with satisfaction; and the new edict of pacification, under the title of "Modifications à l'Edit de 1782," was approved by the Senate, Great Council, and General Council. In this latter council, the "Modifications" were carried by 1321 suffrages against 52. The publication of the new edict was followed by loud acclamations and general rejoicings. This new constitution was judiciously modelled into a mean between the too popular form established in 1768, and the too aristocratical form established in 1782. It is natural to imagine that the widely extended influence of the French revolution would very soon reach the Genevan republic. Many, seduced by the principles of infidelity with by sedimented by Voltaire, and fascinated by the sifon of "Social Contract" of Rousseau, whom they proudly riled the philosopher of Geneva, became the apostles of licentious and democracy. Accordingly, a large party was predisposed to admit the French doctrines; and in the beginning of 1791, a club, called the "Circle of Light," gave energy and direction to the advocates of general equality. Their efforts were opposed by all the friends of the constitution, and two parties were again formed, which threatened the renewal of past commotions. In this crisis, emissaries from France exerted an inclination amongst the peasants of the Genevois, and a large body of them marched towards Geneva, to demand the extinction of the bourgeois. Although this first hostile attempt proved unavailing, the government, apprehensive of another insurrection, and anxious to remove every cause of complaint, granted additional privileges to the nation, and particularly general admission to the burgesses for the small sum of 6 sous guineas. (March 1791.) Soon after the abolition of monarchy, the Brissotins party, in conformity with their plan of surrounding France with a chain of petty republics, proposed to separate Geneva from the Helvetic confederacy, and either form it into a small dependent commonwealth, or incorporate it with the French republic. Although this attempt failed, the independence of Geneva was at length terminated, and it was incorporated, together with its territory, with the French republic in 1798; and now forms part of the department of Leman, (which fes.) Geneva, according to this new division, comprehends three cantons, 22 communes, on a territory of 125 kilometres. N. lat. 46° 12' 17"; E. long. 6° 5' 30". Mod. Uni. Hist. vol. xxx. Cooke's Travels in Switzerland, vol. ii.

Geneva, a populous town of America, in the county of Ontario, and state of New York, in the great road from Albany to Niagara, situated on the bank of the N.W. corner of Seneca lake, about 74 miles W. of Onondaga, and 52 W. of White Plains. It has nearly 100 houses. N. lat. 42° 52'. W. long. 74° 5.'

Geneva, Lake of, or Lake of Leman, a large lake of Switzerland, which stretches from Geneva to Villeneuve, being in length 54 miles, in the shape of a crescent; the hollow is formed by Switzerland, and the convex part by Savoy; the greatest breadth, from St. Sulpice to Grande Rive, is 12 miles. Savoy affords a rude and awful boundary of aspiring Alps, craggy and covered with ice of long standing. From Geneva to the environs of Lausanne the country, expects for, a considerable distance to the margin of the lake, is enriched with all the varieties which nature can bestow: the long ridge of the Jura, fertile in pasturage, and varied with woods, backs this beautiful tract. Near Lausanne the banks rise very considerably, and form a most charming terrace. A few miles beyond is a rapid descent. Near Vevey begins a plain, which is continued far beyond the end of the lake, but contracting, by the approach of the mountains, towards the lake. The colour of the water is extremely beautiful, clear, and at a distance seems of a most lovely blue.

Near Geneva the coast abounds in small pebbles covered with a brown incrustation; from thence, as far as Lausanne, the shores are sandy; between that town and Chillon appear ledges of rocks, hard and calcareous; and the extremity of the lake is a marsh formed by the collected mud of the Rhone. The depth is various; M. De Luc affirms, that on finding it, he had found the greatest depth to be 162 fathoms. The surface of the lake is said to be 1250 feet, and its deepest part 837 feet above the Mediterranean; like all inland lakes enclosed within high mountains, it is subject to sudden storms. The peaks of the tippet grebes, which appear in December and retire in February, because this lake is almost totally defiluite of reeds and rushes, in which they form their floating nest, are an elegant article of luxury, and fell for about 12 or 14 shilling each. This lake abounds in fish, remarkable both for their quality and size.

Geneva is also a lake in Upper Canada, which forms the western extremity of lake Ontario, to which it is joined by a short and narrow istnt.

Geneva, New, a thriving pop-town of America, on the bank of the Monongahela river, juft below George's creek, about 18 miles N. of Morgantown; this town is rendered famous as a place of much bustle, partly by the foundries, works in its vicinity, which not only supply the neighbourhood with window-glass, but also furnish large quantities down for the New England market. Here is also a paper-mill, and a manufactury for muskets. Small boats are also built in this place.

Geneva, New, a village of the county of Waterford, Ireland, nearly opposite to Duncannon fort, where many good houses were erected several years ago by government for the reception of the expatriated citizens of Geneva, but
they having relinquished the design of settling in Ireland, the place remains uninhabited.

Soon after the revolution of 1782, a memorial, signed by more than 1000 Genevans of both sexes, who were either persons of some property, or versed in trade or manufactures, expressing a desire of settling in Ireland, was presented to earl Temple (marquis of Buckingham) then the lord-lieutenant of Ireland. His Excellency, apprized of the advantage which would redound to Ireland from the reception of so many industrious artificers, many of whom possessed property in the English, Irish, and French funds, communicated, in September 1782, the proposal to the privy-council of Ireland for giving an asylum to the Genevan emigrants. This proposal, patronized by the lord-lieutenant, and unanimously consented to by the privy-council, was approved by the king. The Irish parliament voted 50,000l. towards defraying the expenses of their journey, and building a town for their reception; lands were purchased for 8000l. and part of the town was actually completed at the expense of 10,000l.; a charter was granted, with very considerable privileges; the island of gold was altered for the accommodation of the new manufacturers; the foundation of an academy; approved, upon a useful, extensive, and economical plan; in July 1783, several Genevans landed in Ireland; and when the nation had expended near 30,000l., the project was suddenly relinquished, and the settlement finally abandoned. The failure has been attributed to delays in the arrangement of fo court, from circumstances, occasioned by the high demands of the Genevan commissioners, who, in preparing the charter, required many privileges, that were contradictory to the laws of the land, and by the building of New Geneva. In consequence of these delays, and the remittance of the Genevans, many returned and took the oaths of allegiance to the new government. The project became gradually less popular; the few Genevans, who prematurely landed in Ireland, were discontented, at not finding the new town ready for their immediate reception; and the emigrants who possessed most property, having withdrawn their names, the rest wanted sufficient capital to settle in a foreign country, and to establish an extensive manufacture without still further assistance. In consequence of this deficiency, the Genevan commissioners petitioned to appropriate 10,000l. of the 50,000l. for the purpose of forming a capital. But, as that sum had been voted by parliament for other purposes, the petition was rejected; and the Genevans, in an address to the duke of Rutland, who succeeded Lord Temple as lord-lieutenant, relinquished the settlement, and soon afterwards quitted Ireland.

GENEVEVE, Str., a town of France, in the department of Paris; 6 miles W. of Paris.—Also, a town of France, in the department of the Aveyron, and chief place of a canton, in the district of Epinal; 27 miles N. of Rhodex. The town contains 1241, and the canton 6877 inhabitants, on a territory of 175 kilometres, in 17 communes.—Also, a town, or village, of America, in Louisiana, on the western bank of the Mississippi, 12 miles southerly of the city of New Orleans. It contained, some years ago, more than 100 houses, and 460 inhabitants, besides negroes. N. lat. 37° 35'. W. long. 90° 44.'—Also, a town of Canada, on the St. Lawrence. N. lat. 46° 38'. W. long. 72° 14.'

GENEVEVE, St. Genevieve, or St. Genevieve, fathers or religious of St. Genevieve, the name of a congregation of regular canons of the order of St. Augustine, established in France.

The congregation of St. Genevieve is a reform of the Augustinian canons. It was begun by St. Charles Faure, in Vol. XVI.

the abbey of St. Vincent de Senlis, whereof he was a mem- ber, in the year 1618.

In the year 1624, the abbey was made elective; and a general chapter, composed of the superiors of fifteen houses who had now received the reform, chose F. Faure, canon of the abbey of St. Genevieve, and general of the whole congregation. Such was its beginning.

It has since increased very much, and has consisted of above a hundred monasteries; some of which the religious are employed in the administration of the parishes and hospitals; and, in others, in the celebration of divine service, and the instruction of ecclesiastics in seminaries for the purpose.

The congregation takes its name from the abbey of St. Genevieve, which is the chief of the ordre, and whole abbot is the general of it. The abbey itself took its name from St. Genevieve, the patroness of the city of Paris, who died in the year 512. Five years after her death, Clovis erected the church of St. Genevieve, under the name and invocation of St. Peter, where her relics have been preserved, her shrines venerated, and her image carried with great processions and ceremonies, upon extraordinary occasions, as when some great favour is to be intreated of heaven.

GENEVEVE, in Geography, a bay on the W. coast of Newfoundland, in the fruits of Belleisle; 20 miles N. of St. John's bay.

GENEVOIS, or DUCHY of GENEVA, a province of Savoy-Bourbon, bounded on the N. by the Swiss territories, on the E. by Fauconay, on the S. by Savoy Proper, and on the W. by France, from which it is separated by the Rhône. Geneva and its territory formerly made a part of it. it is now annexed to France.

GENEVRAY, a town of France, in the department of the Ille; 10 miles S. of Grenoble.

GENEURO, a mountain which divides Piedmont from the ancient Dauphiny, in the road from Briançon to Sufs.

GENCA, Girolamo, in Biography, a painter of very considerable celebrity in his day. He flourished at the early period of the revival of the art, being born at Urbino in 1476. At the age of 15 he studied under Luca Signorelli of Cortona, then in great esteem, and acquired a master in most of his undertakings in different parts of Italy, but particularly at Orvieto, being acknowledged the best disciple of that school. He afterwards spent three years with Pietro Perugino, at the same time that Raphael was under the tuition of that artist; and that intercourse laid the foundation of a most cordial friendship between Raphael and Genga, which never was impaired.

He was highly encouraged by Guido-Baldo II., and his successor, Francesco Maria III., dukes of Urbino, in their palaces and theatres, and in designing triumphal arches. In Rome, Siena, Forli, Pisa, and many other places, he left behind him an incalculable number of works, both in painting and architecture, which were held in great esteem, and which procured him honour and riches. He died of a fever in 1551, aged 75, leaving two sons, one of whom, Bartolomeo, followed the profession of his father in the same style, and was moreover an eminent statistician and architect.

GENOA, Bernard, a doctor in philosophy and medicine, was born in the duchy of Urbino. He was a teacher of anatomy and surgery at Rome about the middle of the 17th century; and, according to Mangetus, surgeon to the hospital of the Holy Ghost in that city. He was a man of firm understanding, and maintained the doctrine of the circulation of the blood, which was not generally admitted in Italy; but he attributed the discovery of it to Paul Sarpi.

He
He also ventured to accuse Hippocrates of committing such errors, in the cure of several surgical diseases, as would not be pardonable in a student. His works are, 1. "Anastomia Chirurgica," or "Italia dell' offa e muscoli del corpo umano, con la descrizione de' vali," Rome, 1675, 1687. 2. "Anastomia per ufo ed intelligenza del disegno," Rome, 1691. This work contains some good figures of the ancient statues. Genga prepared the bodies, by disposing the bones and muscles in the forced attitudes of the gladiators in their combats, and Lanceti added explanations of the figures. 3. "Commentaria Latina et Italica ad Hippocratis Aphorismos, ad Chirurgiam pertinentia," Rome, 1694, 8vo. Bonon, 1697, 8vo. Elov.

GENGENBACH, in Geography, an imperial town of Germany, in the circle of Swabia, situated on the Kinzig, in the Ortenau: in this town is an abbey, whose prelate was a prince of the empire. Among the indemnities agreed on at Ratisbon in 1822, this town and abbey were given to the margrave of Baden: 15 miles S.E. of Strauburg. N. lat. 48° 27', E. long. 8° 1'.

GENGOU-LE-ROYAL, St., a town of France, in the department of the Saône and Loire; celebrated for its wine; 11 miles N. of Chuy.

GENIAL, GENIALIS, an epithet applied by the ancients to certain deities, whom they supposed to preide over generation. They were thus called a genus, from bearing; or, according to the correction of Scaliger and Vossius, a genus, to bear, produce: yet Feussel says, that they also were called geruli, which seems to require the former reading. M. Dacier, in a note, thinks that genera has the sense of gerula. Among the ancient gods, di geniades, says Feussel, were water, earth, fire, and air, which the Greeks called elementa. The twelve signs were sometimes also ranked in the numbers; as also the sun and moon.

GENICULATUS, CULMUS, in Botany, a straw bent like the knee, as in Alpecurus geniculatus; see CULMUS; and CAULIS, n. 19.

GENICULI, the joints or knees which appear in the shoots of plants; whence botanists call those marked there with geniculate plants.

GENIE. See Genius.

GENIES, St., in Geography, a town of France, in the department of the Aveyron, and chief place of a canton, in the district of Epeanon; 18 miles E.N.E. of Rodez. N. lat. 44° 28'. E. long. 3° 5'. The place contains 3335, and the canton 7988 inhabitants, on a territory of 2025 square kilometres, in 8 communes.—Allo, a town of France, in the department of the Gard; 9 miles N.W. of Nîmes.—Allo, a town of France, in the department of the Lower Alps; 6 miles N.E. of Sisteron.

GENII, in Mythology. See Genes.

GENILLE, in Geography, a town of France, in the department of the Indre and Loire; 3 miles N. of Loches.

GENIO-GLOSSUS, in Anatomy, (from γένιος, the chia, and γγλωσσα, the tongue,) a large muscle belonging to the tongue. See DEGLUTITION.

GENIO-HYOIDAEUS, from γένιος, the chia, and υιοιδας, an epithet given to the bone of the tongue, is a muscle belonging to the hyoides. See DEGLUTITION.

GENIO-PHYANGUS, from γένιος and φυναγας, a name given by Winckle to a particular leaf of the concomitant pharyngeus superior.

Gen. Ch. Col. Perianth inferior, turbinate, permanent, with five acute segments. Cor. of one petal, funnel-shaped; tube dilated upwards, longer than the calyx, its orifice becket; linth spreading, in fine deep, ovate, rather pointed segments, as long as the tube. Stam. Filaments five, short, in the tube of the corolla; anthers oblong, prominent. Pist. Germen superior, ovate, lyre thread-shaped, longer than the tube; stigma cylindrical, obtuse, furrowed. Peric. Capsule oblong, of two cells. Seeds numerous, somewhat angular, ranged along a thread-shaped receptacle.

Eff. Ch. Corolla funnel-shaped, bearded at the mouth. Calyx inferior, with five segments. Stigma cylindrical, abrupt, furrowed. Pericarp of two cells, with many seeds.

1. G. supfllilis. Forst. Prod. 17. Native of rocky places in the island of Tanna. Stem shrubby, climbing without tendrils, branched in an opposite manner, round, with a smooth grey bark. Leaves opposite, about three inches long, elliptic-lanceolate, pointed, entire, slightly wavy, smooth, opaque, with one rib, and a few remote, curved, interbranching veins. Fossilatak tender, smooth, channelled, half an inch long. Stipules infratransverse, united, short, acute, rather membranous. Flowers small, in foliary, few or opposite, somewhat downy, axillary panicules, rather longer than the flowers. Bracteas short, acute, united at their base, in pairs under each fork of the panicle. Calyx minutely fringed. Corolla apparently reddish.—From one of Forster's own dried speciments. Jullien probably never saw the plant, or we think he would have referred it to his Apincus. No figure has been published, except of the fructification.

GENIPA. (See GENIOPA.) The name is barbarous, of Well Indian origin, and appears to be sometimes called Genipat. See Tournefort, 658.

GENIPABU, in Geography, a river of Brazil, which runs into the Atlantic, S. lat. 5° 35'. W. long. 34° 46'.

GENIS, St. a town of France, in the department of the Lower Charente, and chief place of a canton, in the district of Jonzac; 24 miles S. of Saintes. The place contains 852, and the canton 12,600 inhabitants, on a territory of 2125 square kilometres, in 17 communes.—Allo, a town of France, in the department of Mont Blanc, and chief place of a canton, in the district of Chamley, near the confluence of the Rhône and Saône; 15 miles W. of Chambéry. The place contains 1550, and the canton 7962 inhabitants, on a territory of 1126 square kilometres, in 12 communes.

GENIS la Val, St. a town of France, in the department of the Rhône, and chief place of a canton, in the district of Lyons; 4 miles S. of Lyons. The place contains 2400, and the canton 15,522 inhabitants, on a territory of 973 square kilometres, in 10 communes.

GENISTA, in Botany, Green-weed, or Dwarf Broom. The etymology seems not very clear, either from genis, a knece, in allusion to the bending of the twigs, or from gens, to produce, because it grows wild in abundance; yet such are proposed by the learned, and we have no better to offer. Linna. Gen. 368. Schreb. 488. Willd. Sp. Pl. v. 3. 976. Sm. Pl. Brit. 754. Mart. Mill. Dict. v. 2. Jull. 303. Lamarck Illutr. t. 619. Garret. t. 131 Chas and order, Diandepha Decandria. Nat. Ord. Papilionaceae. Linna. Leguminosae, Jull.

Gen. Ch. Cal. Perianth inferior, of one leaf, small, tubular, two-tipped; the upper lip with two teeth, more deeply divided;
GEN

divided; lower with three nearly equal teeth. Cer. papilionaceous: standard oblong, remote from the keel, entirely reflexed; wings oblong, lax, shorter than the other petals; keel straight, emarginate, longer than the standard. Stam. filaments ten, all united, emerging from the keel; anthers simple. P.)' Germen oblong, envelope by the common filament; style simple, directed upwards; stigma acute, involute. Peric. Legume roundish or oblong, turgid, of one cell and two valves. Seeds several, mottly kidney-shaped, with a smooth elevated border round the scar.

Eff. Ch. Calyx two-lipped, the upper lip with two teeth, lower with three. Standard oblong, bent backwards from the rest of the flower.

A genus of shrubs, almost entirely European, with tough angular stems and branches, either ternate or simple leaves, and yellow flowers. Willdenow has twenty-five species, eighteen of which are unarmed, the other seven furnished with spines, in many instances remarkably compound. The spiny ones have all simple leaves. Three Genus are native of Britain.

G. tinctoria. Engl. Bot. t. 44. Dyer's Green-weed. So called from its use in dyeing yellow, and, with the addition of wood, green. Ray says it gives a better flavour to the milk of cows that feed upon it.

G. pilosa. Engl. Bot. t. 208. Hairy Green-weed, or Petty Whin. This is our only spiny species, and its spines are very conspicuous, long, simple, and spreading. Stem of humble growth, but nearly erect. Flowers not inlegant, turning green when dried. It is frequent on moor turfy or finely heaths, blooming in May and June.

G. candida, G. flava, and G. virgata, are hardy garden plants, worthy of cultivation for their beauty or singularity. The first especially has a flowery appearance when trained against a wall. G. canariensis, and Cynfolia. Curt. Mag. t. 442, are rather greenhouse shrubs, and the latter is very elegant on account of its silky filery leaves. It grows in Switzerland as well as in Spain, but like many other alpine plants, does not well bear our winters.

GENISTA, in Gardening, comprehends plants of the low shrubby evergreen and deciduous kinds, of which the species chiefly cultivated are, the common dyer's broom (G. tinctoria); the painted broom (G. fasciculata); the Spanish dyer's broom (G. florids); the hairy broom (G. pilosa); the English genista petty-white, or needle furze (G. Anglica); the hoary genista, or Montpelier Cyrus (G. candidans); and the Canary genista or Cyfocso (G. cumaranica).

Method of Cultus.—The six first sorts are all of the hardy kind, and capable of being increased by sowing the seeds in beds of common mould, and, which is better, in the borders or clumps where they are to remain, but which should be done in the early autumnal or spring season, though the former is by much the better, as a great deal of time will be saved. In cases where they are raised in beds, the plants should be carefully taken up and renewed, as soon as they have attained about twelve months' growth, into the situations in which they are to continue. In the latter mode of cultivation, they however require no other management than that of properly thinning them out, and keeping them free from all sorts of weeds.

The leaf, or Canary furf, may likewise be raised by sowing the seeds in pots of good garden mould in the spring season, but the aid of a moderate hot-bed is necessary to bring them forward. As soon as the plants have acquired a little growth they should be removed into separate small pots, and be immediately replanted in the hot-bed. In their after-management they demand the same sort of attention as other kinds of tender kinds of green-house plants.

Each of the first six sorts is proper for the more forward parts of the clumps and borders in ornamented grounds, and have a good effect from the fine appearance of their flowers.

The last kind produces a variety among other evergreen plants in the green-house collection.

GENITA BRIDGE, in Geography, a town of America, in Powhatan county, Virginia, 166 miles from Washington.

GENITA-mand, in Mythology, a goddess who presided over child-birth, to whom the Romans sacrificed a dog.

GENITAL, in Anatomy, formulating that relates to generation; which see.

GENITAE, are sometimes used in the ancient Roman poets for those we otherwise call indicia.

Anson is, in the argument of the fourth book of the Aeneid, takes the word in a different manner: the di genitai, he observes, were such as were not born of human parents, and were not thus called quasi genitae ex hominibus, but rather because they themselves had begot human children.

GENITALIA, or GENITORES, in Anatomy, a name sometimes given to the testicles or testicles of a man, on account of their office in generation, which see.

GENITE, in Geography, a town of France, in the department of the Corrèze; 18 miles W. of Brive.

GENITID, in Geomeby. See GENITAE.

GENITAE, in Mythology, called Gentils, among the Hebrews, those that descended from Abraham, without any mixture of foreign blood.

The Greeks distinguished by the name of genitea fuch of the Jews as were hid from parents who, during the Babylonish captivity, had not allied with any gentile family.

GENITIVE, in Grammar, the second case of the declensions of nouns.

When one thing is represented as belonging to another, in the relation of cause, origin, or author, its name has a termination given to it, called the genitive case; and as the author is properly the owner of a thing, the genitive is also called the possessive case.

In English, the genitive case is made by prefixing the particle of; or it is expressed by an apostrophe, with the letter s coming after it, as "thy father's house;" when the plural ends in s, the other s is omitted, but the apostrophe is retained, as "on eagles' wings," sometimes also, when the singular terminates in s, the apostrophe is not added; as "for righteousness' sake." In French the genitive is expressed by de, or du, &c. though, in italics, there are no cases at all, or at most only one, in either the French languages, insomuch as they do not express the different relation of things by different terminations, but only by additional prepositions. (See CASE.)

An ingenious grammarian observes, that though the termination called the genitive case be rendered by of, it means invariably from, beginnings, motion: and this, he says, seems to be the true signification of of, if we regard its etymology, it being taken from, ad, e in, from; and though custom seems to have allotted it some different undetermined meaning, it is in all cases resolvable into
the sense of from. Thus, a table of wood is a table from wood, wood being the origin or beginning of it. Again, he is sick of love, i.e. sick from love, love being the cause of his sickness; and so in other alliterations. And this is the reason why some prepositions which signify origin or beginning in Greek, Latin, and French, are rendered in our tongue by of. Jones's Greek Grammar, p. 194.

In the Latin, this relation is expressed in divers manners, thus we say, ceput hominis, the head of a man; color rofæ, the colour of a rose; opus Dei, the work of God, &c.

As the genitive case serves to express very different; and even opposite relations, there sometimes arises an ambiguity from this circumstance; thus, in the phrase, vulbus Arcebis, the wound of Achilles, the genitive, Arcebis, may either signify passively the wound Achilles has received, or actively the wound Achilles has given: thus in this passage of St. Paul, Certus sum quod neque moris, neque vitæ, &c. non potest separare a caritate Dii in Christo, &c. the genitive Dii has been taken by interpreters in two different senses; some, giving it the relation of object, understand the passage of the love which the elect bear to God in Jesus Christ; whereas others give it the relation of subject, and explain it from the love which God bears the elect in Jesus Christ.

In the Hebrew tongue, the genitive case is marked after a manner very different from that of the Greek and Latin: for whereas in those languages the noun governed is varied, in the Hebrew the noun governing undergoes the alteration.

GENITO, Sr. in Geography, a town of Naples, in Calabria Citera: 21 miles N. W. of Bifignano.

GENIUS, in Mythology, a good or evil spirit, or daemon, whom the ancients supposed set over each person, to direct his birth, accompany him in life, and be his guard until death. Tho' that attended women were females, and called Junones, but those that attended men were males, and called Genii. They seem, in their original, to be nothing else but the particular bent and temper of each person defined; and as every one's own temper is in a great measure the cause of his happiness or misery, each of these was supposed to have, and have an equal feeling in all the enjoyments and sufferings of the persons they attended. (See Horace, lib. ii. ep. ii. ver. 189.) The ancients had their Genii of nations, of cities, of provinces, &c. Nothing is more common than the following inscription on medals: GENIUS POPULI ROM. "the Genius of the Roman people:" or, GENIO POP. ROM. "to the Genius of the Roman people." The ancient Gauls acknowledged Genii, who took care of each particular province and canton: but the foundation of the worship, which they paid to their deified cities, or rather to the genius who protected them, and became their tutelar divinity, was to engage them to take care of them, to defend them against enemies, and to remove from them all evils, with which they might be distressed; such as epidemic distempers, and other calamities. The names of these tutelar Genii were kept secret, lest, if they should be known, they should be conjured away, and forced to abandon the cities that were committed to their charge, and pass into others, where they were promised a more solemn worship.

In this sense, genius and lar were the same thing; as, in effect, Centorinius and Apulian affirm they were.

Of these genii or demons, Plato supposes that every man has his own, who is his guardian, and the witness, not only of his actions, but of his very thoughts; but that, at death, the genius delivers up to judgment the person who had been committed to his charge; and if, when the person is interrogated by the judge, his answer be found not agreeable to truth, the genius condones and reprimands him very severely, as, on the other hand, he pronounces an excomium upon him when what he says is true; and it is upon the approbation of the genius, that the doom is pronounced; for this daemon knows whatever passes in the man, even his most secret thoughts.

Although Plato and Jamblichus were of opinion that every individual had but one of these genii to conduct him, and to preside over all his actions, other philosophers of the same school were perfused, that he had two, the one good, the other bad. To this purpose Servius upon Virgil (Æn. i. vi. c. 743.) says, "Volunt unicumque genus oppositum, Damo- nem bonus et malum: hoc est, rationem quae ad meliora feren tur hastatur, et libidinem quae ad peorja; hic est Larva et genius malus; ille bonus genius et Lar. "They will have that every one has two genii, the one good, and the other bad; that is, reason, which always excites men to good, and lust, which prompts them to ill: the latter is what they call "Larva," or evil genius: the other good Genius, or "Lar."

The Platonists, and other eastern philosophers, supposed the Genii to inhabit the vall region, or extent of air, between earth and heaven. They were a sort of intermediate powers, who did the office of mediators between gods and men. They were the interpreters and agents of the gods; communicated the will of the deities to men; and the prayers and vows of men to the gods. As it was unbecoming the majesty of the gods to enter into such trifling concerns, this became the lot of the genii, whose nature was of a middle kind between the two; who derived immortality from the one, and passions from the other; and who had a body framed of an aerial matter. Most of the philosophers, however, held that the genii of particular men were born with them, and died. Thus Plutarch attributes the ceasing of oracles partly to the death of the Genii.

The heathens, who considered the Genii as the guardian spirits of particular persons, believed that they rejoiced and were afflicted at all the good and ill fortune that befell their wards. They never or very rarely appeared to them; and then only in favour of some person of extraordinary virtue or dignity. They likewise held a great difference between the Genii of different men; and that some were much more powerful than others; on which principle it was, that a wizard in Appian bids Antony keep at a distance from Octavius, because Antony's Genius was inferior to, and stood in awe of, that of Octavius.

There were also evil Genii, who took a pleasure in perverting men, and bringing them evil tidings; such was that in Paterculus, &c. which appeared to Brutus the night before the battle of Philippi. These were also called larves, and lemures.

According to the theogony of Hesiod, the men of the golden age became demons, or good genii; tho' according to him, are the guardians of men, the earth having fallen to their lot. Tho' of the silver age there were changed into men, or subterraneous genii, happy though mortal. Tho' of the brazen age went down to the infernal regions. Tho' of the heroic age took possession of the Fortunate Islands, of the Elyian fields, atuate at the extremities of the world. See DIONYX, and DIONYSUS OF SORATES.

The Mahometans also admit the existence of Genii, supposed by them to be a class of intermediate beings, between angels and men; of a groffer fabric than the former, and more active and powerful than the latter. Some of them are good, and others bad; and they are, like men, capable of future salvation or condemnation.

Genius is more frequently used for the force or faculty of the soul considered as it thinks or judges.

Thus, we say, a happy genius, a superior genius, an elevated genius, a narrow confined genius, &c. in like sense we also say, a work of genius, a want of genius, &c.
Genius is also used, in a more refined sense, for a natural talent, or disposition to one thing more than another. In which sense we say, a genius for verse, for the sciences, &c. Dr. Blair, in his "Lectures on Rhetoric, &c." (vol. i.) distinguishes between Taste and Genius. Taste, he says, confines in the power of judging: Genius, in the power of executing. One may have a considerable degree of taste in poetry, eloquence, or any of the fine arts, who has little or hardly any genius for composition or execution in any of those arts. But genius cannot be found without including taste also. Genius, therefore, deserves to be considered as a higher-power of the mind than taste. Genius always imports something inventive or creative; which does not reit in mere facility to beauty, where it is perceived, but which can, moreover, produce new beauties, and exhibit them in such a manner, as strongly to impress the minds of others. Refined taste forms a good critic: but genius is further necessary to form the poet, or the orator. Besides, genius is a word, which, in common parlance, extends much farther than to the object of taste. It is used to signify that talent, or aptitude, which we receive from nature, for excelling in any one thing whatever. Accordingly, we speak of a genius for mathematics, as well as a genius for poetry: or a genius for war, for politics, or for any mechanical employment. This talent or aptitude, for excelling in any one particular, is received from nature; and though it may be greatly improved by art and study, it cannot be thereby alone acquired. As genius is a higher faculty than taste, it is more limited in the sphere of its operations. Whilfl we find many persons, who have an excellent taste in several of the polite arts, such as music, poetry, painting, and eloquence, all together; it is much more rare to meet with one who is an excellent performer in all these arts. Indeed, an universal genius, or one who is equally and indifferently turned towards several different professions and arts, is not likely to excel in any. The rays must converge to a point, in order to glow intensely. A genius for any of the fine arts always supposes taste; and the improvement of taste will serve to forward and correct the operations of genius. But genius, a poet or orator, may sometimes excel in a higher degree than taste; that is, genius may be bold and free, when taste is neither very delicate, nor very correct. This is often the case in the infancy of arts; a period when genius frequently exerts itself with great vigour, and executes with much warmth; while taste, which requires experience, and improves by flower degrees, hath not yet attained its full growth. Homer and Shakspere may be referred to as examples in proof of this assertion. (See Taste.) Longinus, in his "Treatise on the Sublime," remarks, that liberty is the nurse of true genius: it animates the spirit, and invigorates the hopes of man; excites honourable emulation, and a desire of excelling in every art. It is observable, that writers and artists most distinguished for genius have generally appeared in considerable numbers at the same period. Besides the moral causes which have been alleged to account for this phenomenon, such as favourable circumstances of government and manners, encouragement from great men, and emulation among men of genius, the Abbé du Bos, in his "Reflections on Poetry and Painting," has collected a great many observations on the influence which the air, the climate, and other natural causes, may be supposed to have upon genius. The opinion of the Abbé du Bos, that genius chiefly depended on soil, food, air, and climate, has been favoured by Montesioue in his "Spirit of Laws?" and it occasionally occurs in other writers. Mr. Hume, however, has attacked this hypothesis with great ingenuity and strength of reasoning in his "Essay on National Cha-

racters." In that Essay he has clearly proved, that the differences we observe in nations, with regard to genius, science, and manners, arise from moral, and not from physical causes. (See Climate.) The fact, however, is unquestionable, that some periods or ages of the world have been much more distinguished than others for the extraordinary productions of genius. (See Age, in the History of Literature, &c.) If we institute a comparison between the ancients and moderns in this respect, we must allow, that while the advancing age of the world brings along with it more science and more refinement, its earlier periods may lay claim to more vigour, more fire, more enthusiasm of genius. Among the ancients, we find higher conceptions, greater simplicity, more original fancy; among the moderns, sometimes more art and correctness, but feckless exertions of genius. Admitting this to be in general a mark of distinction between the ancients and moderns, it cannot be admitted without exceptions; for, in point of poetical fire and original genius, Milton and Shakspere are not inferior to any poets in any age.

Genius, is not a musical term, nor does it appertain to one of the polite arts more than another; but Roufeau (Dict. de Mus.) has volunteered an article for it among musical terms, and has written it with peculiar eloquence and enthusiasm.

Roufeau, paradoxical on almost all other subjects, is sometimes not only capricious, but mitchievous; yet his bitterest enemies admit, that music is his bright side: and though he is not allowed by the present French musical critics to be a profound contrapuntist, yet his taste in music and poetry was refined, and of the highest class; and his views concerning dramatic music were enlarged, rational, ingenious, and free from all caprice and paradox.

Genlis, in Geography, a town of France, in the department of the Côte d'Or, and chief place of a canton, in the district of Dijon. The place contains 707; and the canton 8590 inhabitants, on a territory of 1871 square miles, in 27 communes.

Gennala, a town of Peru, in Farflian, in the Persian Gulf; 15 miles N.W. of Bender Riga.

Gennadius I., in Biography, patriarch of Constantinople, was elected to that dignity, having been some years an ordained prebendar of the church, in the year 458, on the death of Anatolinus. In the following year, in a council of 73 bishops, he procured the passing of a canon against monochasical ordinations, and established the equitable regulation, that the oblations made in the churches, which it had been customary to claim for the patriarch's treasury, should thenceforward belong to the officiating clergy. He died in 471, leaving behind him a high character for great zeal and disinterestedness in correcting the relaxed state of discipline which prevailed in his time. He is placed by those who lived about the same period among the ecclesiastical writers of the day, and is applauded for the extent of his learning and the elegance of his style. The proofs of this have not come to us, excepting in "A synedrit Epitaph" against anodyne, inserted in the fourth volume of the Collect. Concil.; and fragments against the anathemas of Cyril of Alexandria, quoted by Facundus, bishop of Harnia: and another from a treatise addressed to Parthenius, and quoted by Ioan. Moretii.

Gennadius II., another patriarch of Constantinople, in the fifteenth century, assumed the name upon embracing the ecclesiastical life, having, prior to this, the name of George Scholarius. He was a native of Constantinople, where he was educated, and attracted much notice by his talents and remarkable progress in the different branches of learning. He became secretary to the emperor John Paleologus,
and afterwards chief judge of the Greeks. In 1438 he accompanied the emperor to the council at Florence for the purpose of bringing about an union between the Greek and Latin churches: it is, however, a matter of much doubt whether Scholarios was in favour of the measure which his duty to his master required him to function and support. After his return to Constantinople he united with Mark of Ephesus, in opposing the reception of those terms of union to which the emperor had acceded, as well by his influence as by his writings, which brought on him for a time the displeasure of the emperor. After the death of Palaeologus in 1448, Scholarios was as violent as ever against the proposed union, and finding that his opposition must subject him to danger with the new emperor, Constatine, he resolved to relinquish his civil employments, and to embrace the ecclesiastical life. He accordingly, in 1450, after finding a valid动力 of oration to the emperor, entered into a monastery adjoining Constantinople, and lived a secluded life for two years, which is supposed to have been the result of the emperor's orders, to prevent him from taking part against the proposed union. During his retreat from the world he composed several homilies, which could offend no one; but he did not engage in any controversy until the union was completed. This called forth his zeal in behalf of the Greek church: he wrote letters to all the ecclesiastics of Constantinople, and to the different monastic orders, exhorting them to adhere to the faith of their ancestors, and not to submit to the Florentine union: he also renounced with the emperor on the subject, but the monarch was not to be turned from his plan, and made every effort, by persuasion and by threats, to bring over Gennadius. The attempt was fruitless; he had gone too far to retract, and had obtained a multitude of adherents whom he had converted by his writings and exhortations, which represented the union to be a defection of the cause of God and his truth. The emperor subordinated the act of union at Constantinople, as it had been ratified in the council of Florence. On the 12th of December 1452, the two nations, in the church of St. Sophia, joined in the communion of sacrifice and prayer. But the dregs and language of the Latin priest who officiated at the altar were objects of scandal; and it was observed, with a feeling of horror, that he consecrated a wafer of unleavened bread, and poured cold water into the sacramental cup. From the dome of St. Sophia, the inhabitants of either sex, and of every degree, rushed in crowds to the cell of Gennadius to confound him, as the oracle of the church. He was invincible, and entranced, as it should seem, in deep meditation, or divine rapture; but he had expiated on the door of his cell a tablet, on which were written these words: “O miserable Romans, why will ye abandon the truth; and why, instead of confiding in God, will ye put your trust in the Italian? In abandoning your faith, you will lose your city. Have mercy on me, O Lord! I protest, in thy presence, that I am innocent of the crime. O miserable Romans, confider, pause, and repent! At the same moment that you renounce the religion of your fathers by embracing impiety, you submit to a foreign servitude.” This was the signal for insurrection, (see Constantinople); and, after the capture of the city, the sultan Mahomet, deeming of concluding those inhabitants who had suffered the immense slaughter made by his army, and of recalling the Greeks, who had escaped, to their deserted houses, ordered Gennadius to be sought for, and offered him to the choice of the clergy and people, by whom he was immediately elected their patriarch. In the election and investiture of Gennadius, the ceremonial of the Byzantine court was revived and initiated. With a mixture of satisfaction and indignation, they beheld the sultan on his throne, who delivered into the hands of Gennadius the pastoral staff, the symbol of his ecclesiastical office, who conducted the patriarch to the gate of the ferglio, preferred him with an horde richly caparisoned, and directed the vizirs and bashaws to lead him to the palace which had been allotted for his residence. The churches of Constantinople were shared between the two religions: their limits were marked, and till it was infringed by Selim, the grandson of Mahomet, the Greeks enjoyed above forty years the benefit of this equal partition. Gennadius presided over the see of Constantinople between five and six years, when he resigned his dignity, and retired into a monastery. He died about the year 1450. He was the author of “An Explanation of the Christian Faith, delivered before the Turkish emperor Mahomet.” This work was the result of a long conversation which he had with the emperor, soon after his installation, when Mahomet suffered him to produce all the arguments he was able in support of the truth of Christianity. It is to be found in Cudinus’s Tucur-Gracian; and is also in David Chytraeus’s “De Gratia Ecclesiastica in Gracian.” Gennadius wrote likewise a treatise concerning predestination, and another on the trinity. He composed many homilies in the early part of life, which were delivered before the emperor, as orations, which laymen were, in that age, accustomed to pronounce in the imperial dining-room. Moreri. Gibbon’s Hist.

**Gennadius,** an ecclesiastical writer, flourished towards the close of the sixth century, and became priest of Mesphiles. He was a great writer, and is said to have composed eight books against all heresies, five against Nestorius, three against Pelagius, and a treatise concerning the millennium and the book of Revelation. The most notable of this author was entitled “De viris illustribus,” which is a continuation of St. Jerome’s catalogue of Ecclesiastical Writers; and a treatise “De Fide, de dogmatibus Ecclesiasticis Liber ad Gelasium Papam missus.” This last was for a considerable time attributed to St. Augustine, and was generally inserted in the editions of his works. The time of Gennadius’s death is not known, but it did not take place before the year 395.

**Gennari, Cesare and Benedetto,** two brothers who both made painting their profession. They were nephews, heirs, conspirators, and imitators of Guercino; they frequently repeated his pictures, but not with adequate sweetness or force. At first they worked together at several places in Italy; but separating, Cesare remained at Bologna, and Benedetto went to England, where there are many of his works, particularly at Windsor Castle, discoverable by a labourer, dry imitation of Guercino; with a mixture of the flutter and parade exhibited by the French painters of that period. He was made painter to James II. and executed a picture of that prince and his family. At their expulsion he returned to Italy; and as his manner, by the mixture of French art he had introduced, was novel, he obtained applause and employment. He died in 1715, aged 82.

**Gennes, in Geography,** a town of France, in the department of the Maine and Loire, near the Loire; 9 miles N.W. of Saumur.

**Gennes,** a town of France, in the department of the Ruer, situated on the Niers, near the Meuse. It contains two churches, one for Roman Catholics, and another for Protestants; 9 miles S.S.W. of Cleves. N. lat. 51° 47′. E. long. 5° 50′.

**Genelles,** a town of France, in the department of the Maine and Loire, and chief place of a canton, in the district
GENOA.

trick of Saumur; 5 miles N.E. of La Guerche. The place contains 14,550, and the canton 8,248 inhabitants, on a territory of 190 kilometres, in 15 communes. 

GENOA, and since the French revolution the “Ligurian republic,” is a small, mountainous territory, in the northern part of Italy, forming a kind of crescent along the Mediterranean sea on the south, and covered on the land side by the Apennines, which separate it from the countries of Milan, Piedmont, the Montferrat, the Milanese, and Parmisan. Its length from the town of Vintimiglia on the west, almost to the territory of the republic of Lucca on the north, measured every where on the sea to the interior of the country, is not more than 20 miles. The mountains that enclose it are, in some places, covered with forest, in others they are barren rocks, and in some few parts they yield excellent pasture. There is but a small quantity of arable land in this country, so that it is under a necessity of seeking a supply of corn from Naples, Sicily, and other places; but the inhabitants avail themselves of every spot which is capable of cultivation. They are furnished throughout the year with excellent legumes and vegetables for the table; they also make a considerable quantity of wines, and are amply provided with various kinds of fruit, especially citrons, oranges, pomegranates, almonds, and figs. They raise a great number of mulberry trees for feeding silk-worms, and olives grow in great plenty, particularly round the gulf of Spezzia. Salt is produced for exportation. The Apennines, and some other hills, supply them with excellent marble, while Polzera, in the Boscutta, yields the beautiful stone so called, being serpentine of various colours veined with marble, which is so closely covered by a magnificent traffic formed, in 1798, from the Boscutta, or mountains to the north of Genoa, through the Polvera, by three years' labour of from five to eight hundred men, at the expense of one patriotic and noble family, the Camiati. The inhabitants of this country, amounting to about 400,000, are Roman Catholics, though the papal power is not much venerated; the people being devoted to commerce, and disposed to receive money heretics, without any religious scruples. The manufactures were formerly very considerable, but they have of late declined; the principal are velvet, plush, damask, different kinds of silk, for which they are supplied with the raw material from Messina and other places; gold and silver fillets, lace, gloves, stockings, ribbons, soap, paper, &c. Other articles of commerce are, oil, fruit, macaroni, confectionary, Parmesan cheeses, anchovies, &c. Although Genoa is a free port, Leghorn, which is likewise free and indulged with greater liberty, interferes with its trade, and diminishes it. This country is part of the ancient Liguria (see Liguria; which, in the second Punic war, espoused the interest of the Carthaginians; but the city of Genoa, which was then a celebrated emporium, taking part with the Romans, was plundered and burnt by Mago the Carthaginian. It was afterwards rebuilt by the Romans, and continued under their dominion, together with the rest of Italy, till the conclusion of the fifth century, about A.D. 498, when Theodoric, king of the Goths, having defeated the usurper Odoacer, was proclaimed by the army king of Italy, even with the consent of the emperor Zeno. Genoa was afterwards recovered by Belisarius, when he entirely subdued the Goths; and when the Lombards invaded Italy, this city remained for some time unoccupied, deriving an ascension of wealth and inhabitants by the refugees who fled from the vicinity of the Po, in order to escape the fury of the invaders. At length, in the seventh century, Genoa was plundered and burnt by the Lombards, and remained under their power till Italy was conquered by Charlemagne, when the territory of Genoa, distinguished by its wealth and populousness, was erected into a marquisate. It soon afterwards became so powerful, under the Genoese empire, and after it had obtained a kind of independence, that, in 805, it reduced the island of Corfica, and in 935 defeated the Saracens, who had plundered and burnt the city, in their return to Africa, on the coast of Sardinia. About the year 950, when the Franks having lost all authority in Italy, the Genoese began to form themselves into a kind of aristocratic republic, under a chief called doge, (see Doges,) and in two years, and to be governed by their own magistrates, who were freely elected, and took the name of consuls. In order to maintain their independence, they applied, with great address, to navigation and commerce, and thus became rich and powerful. Their commerce extended from Spain to Syria, and from Egypt to Constantinople, and was carried on in vessels, that were fitted for war as well as traffic. In the year 1017 they united with the Pisans in an expedition against Sardinia; and about 33 years after this expedition, the Genoese and Pisans were engaged in a destructive war, which lasted nearly 18 years; but when a treaty of peace and alliance was concluded between them, they continued in a successful expedition against the Moors, in Africa. What contributed more than any other circumstance to the opulence and grandeur of the Genoese, was the part they took in the crusades, and the important services they rendered to the religious warriors, towards the close of the eleventh and commencement of the twelfth centuries. During the latter century, they subjected the half of Sardinia, and the city of Savona: they also made themselves masters of the Black sea, formed establishments in the Crimea and in the suburbs of Pera, at Constantinople, where they remained till the Turks took that city. In the thirteenth century, they added to their conquests the towns of Albenga, Savona, Vintimiglia, and others in their neighbourhood; and for the superiority of the sea, they engaged in a long and obstinate contest with the Venetians, which did not terminate till the year 1381. In their various conflicts with neighbouring powers, their strength was enfeebled, so that, in 1471, they were expelled from the Crimea; though their maritime power still continued respectable. Exposed by the Venetian war, in particular, Genoa offered voluntary subjection to France and to Milan; but after many revolts and conflicts, with a view of recovering their independence, they were at length, in 1528, reduced from the dominion of foreign princes, by the vigorous exertions of Andrew Doria. Doria, having driven out the French, and gained possession of Genoa, restored the nobility, and restored the government into their hands, declaring that he pretended to no greater share in it than became him as a nobleman. He re-established the ancient form of the republic, and received from his country all those testimonies of gratitude, which a conduct so disinterested seemed to deserve. (See Doria.) Towards the end of the sixteenth century, Genoa was distracted by a civil war; but after a reconciliation had been effected between the two contending parties, distinguished by the appellations of the old and new nobility, the republic enjoyed peace and felicity for an interval of 48 years, during which period scarcely an incident, domestic or foreign, occurred, that is worth recording. In the year 1624, a dispute arose between the republic and Charles Emanuel, duke of Savoy, in which Lewis XIII. bore a share; and a treaty was concluded between France and Savoy, that was hostile to the Genoese. On this occasion the Spaniards declared in favour of Genoa and a
peace with France and Savoy restored the republic to its former situation, at the commencement of the war. In 1646, the Spaniards attempted to surprize the city; but their enterprise was frustrated; and from this time till the year 1659, Genoa enjoyed all the blessings of peace and commerce. In the following year, Hippolito Centurion, the Genoese admiral, gained several advantages over the corsairs of Barbary, which paved the way for a treaty of commerce that was concluded with the piratical states, and the grand signor. The treaty with the Porte was considerably extended by the marquis Durazzo, who went in quality of ambassador to Constantinople in the year 1666. The refit of this treaty renewed the vigour of the Genoese trade, to a pitch beyond what any of the maritime towns had experienced since the Dutch founded their commercial republic, and extended their trade not only to the Levant, but to every quarter of the globe. For some years Genoa lived in peace with all the neighbouring powers, enjoyed domestic harmony, and advantageously cultivated commerce, and whatever should render the republic powerful and happy. Some little jealousies and differences arose between her and Venice, theiffer and rival republic; but they were such as terminated amicably, and never caused any disturbance to the repose of Italy.

In the year 1683, the Genoese unfortunately incurred the resentment of Lewis XIV., who looked with jealousy on their attachment to Spain; and could not bear to see the republic under the protection of that crown. His attempts for humbling them proved too successful; but in consequence of their submission, and the interposition of the pope, peace was obtained. The terms stipulated by the French were peculiarly severe and oppressive; among others, they required that the doge and four councilors should appear in person at Versailles, in order to sue for pardon; and that the state should disarm all their galleys, fix excepted, with a promise not to fit out more, without the knowledge and consent of the king. During the ensuing war, kindled by the ambition of Lewis, which embroiled the greatest part of Europe, the republic of Genoa adhered wisely to a neutrality, and enjoyed the advantages of peace and commerce, while the dominions of their neighbour, Victor Amadeus, king of Savoy, were wasted by all the calamities of war. In 1713, Charles VI. fold the marquisate of Finale to the republic for a considerable sum of money. In 1725, the queen of Hungary, having at the treaty of Worms ceded to the king of Sardinia all her rights to the town and marquisate of Finale, and demanding that the Genoese should deliver up the marquisate, they entered into an alliance with France, Spain, and Naples; and, in 1745, declared war against the king of Sardinia who had made himself master of a great part of the state; several Genoese ports were bombarded by an English fleet; and the Imperialists seized upon the city of Genoa; but after a dreadful slaughter on both sides, they were again driven out by the inhabitants; and, in 1747, miscarried in their attempt to recover it. The treaty of Aix-la-Chapelle, in 1748, restored its tranquillity. The ancient nobility consisted of 28 families, whom Andrew Doria, in 1528, reparted from all the rest, and declared to be only capable of holding the chief offices and dignity of doge; all the other inhabitants being reduced by him to the class of contributors. Since that time it has been found necessary to create other nobility. The nobility of Genoa were allowed to keep manufacturies of velvet, silk, and cloth; to farm the duties, and to have ships in merchant vessels; but all other business and handicrafts were forbidden. The form of government in this republic was aristocratical; the chief being called doge. This government continued till the year 1798, when the French form was chosen, and the new style assumed of the Ligurian republic, confirmed by the more recent treaty of February 1801. The troops of this state, including the militia, may amount to about 30,000; and the fleet, annually to celebrate for its victories over the Saracens, the Pisans, the Venetians, Spaniards, and Turks, and for maintaining during a long period a considerable dominion over Sardinia, Corfica, Malta, Majorca, Minorca, Cadi, Cyprus, and many other places in and near the Mediterranean and Archipelago, and even the Black sea, the Crimea and other parts, is now reduced to a few galleys.

Genoa, or Jovia, frequently, though corruptly, called by the Latin writers Jonia, is the capital of the country described in the preceding article. It is situated partly on a level strand near the sea, and in part rises gradually to the top of the hill. It is about 10 miles in circumference, and is defended towards the land by a double wall. Several bastions are erected along the sea-shore, on rocks which appear above the water. The streets are in general narrow, but clean and well paved; two of which, called the *Strada Nuova*, and *Strada Belpoli,* are filled with magnificent palaces, fronted with marble. It is the seat of an archbishop. The cathedral is built in the Gothic style, and paved with black and white marble; in the treasury is preferred a curious hexagonal dish, said to be of a single emerald, found at Calvare in the time of the Crusades, which the Genoese received as their share of the plunder. Besides the cathedral, it contains 32 parish churches, some of which are magnificent, and adorned with sculptures and pictures by the best masters. The doge's palace is large, without decoration, except two statues of John Andrew Doria, and Andrew Doria, larger than life, at the entrance. The arsenal contains arms for 33,000 men, models for bridges, the armours worn by a number of the Genoese women in the crusades, a shield containing 120 piths, made by Julius Caesar Vezzo, for the purpose of affronting the doge and senate at one time. Other public buildings are the Albergo, which serves as a poor-house, and house of correction, where is a beautiful relique, the Virgin supporting a dead Christ, by Michael Angelo, and the assumption of the Virgin, which merits, by Puget, an inimitable piece of sculpture; a large hospital for the sick of all nations and religions; the conservatory, for educating and protecting 300 poor girls; and a great number of palaces belonging to the nobility; and the number of convents for men and women is reckoned to be 69. Such was the state of Genoa before the late revolution; what devastation it has suffered by its new masters, we are not able to say. It is certain, that the siege in 1799 was very destructive. The harbour is large and deep, but exposed to the south-west wind; but it has a mole for the security of gallies and small vessels; nevertheless the city is much exposed to a bombardment. The number of inhabitants is estimated at 80,000. N. lat. 44° 25'. E. long. 8° 58'.

Genoa Bar, a reef of rocks, extending some miles from the north coast of the island of Bahama. N. lat. 26° 20'. W. long. 79° 26'.

Genoa Balloon, in Medicine, the name of a famous composition, called also the baloon of Aquirapendente. Its great virtues are the curing pains in the extremities of the body, and allaying the violent pains in the bowels, to which many women are subject after delivery. The prescription is given at large in Velzecus, but the medicine is now out of use.

Genola, in Geography, a town of France, in the department of the Stura; three miles N. E. of Savigliano.

GenolHac, a town of France, in the department of
the Gard, and chief place of a canton, in the district of Alais; 15 miles N. W. of Alais. The place contains 1,502, and the canton 95,9 inhabitants, on a territory of 95 kilometres, in 14 communes.

GENOPLESIMUM, in Botany, from γένος, a genus, and πλῆςμα, a carly aitn, indicating its great affinity to Phylyphyllum, another new orchidean genus of Mr. Brown's. The name is but too expressive of many genera recently established, that it is wonderful no writer has hit upon it before. Brown Prod. Nov. Holl. v. 1. 319. Clafs and order, Cyandria Menardiana. Nat. Ord. Orchidae. Gen. Ch. Col. Perianth ringent, helmet-like in front, its two inner petals more longer and spreading. Cor. Petals, (inner calyx leaves of Mr. Brown,) attached below to the column. Necary, or lip, affembling, undivided, hooded at the base, without a spur. Style or column, cloven half way down, without any lateral membranous segments, in which last particular aline it differs from Phylyphyllum. Ammer parallel to the stigma, permanent, its cells close together. Malles of pollen not observed. The only species is

G. Baueri, seen by Mr. Brown growing near Port Jackson, New South Wales, but the above character was drawn up by him from Mr. Ferdinand Bauer's coloured figure.

GENOSA, in Geography, a town of Naples, in the province of Otranto; 10 miles S. E. of Otranto.

GENOVIUS, Anthony, in Biography, a man of letters, and philosopher, was born of parents of very moderate circumstances, at Castiglione, a small town in the district of Salerno, in the year 1712. He was intended for the church, and received an education suitable to the purpose. An early attachment to the daughter of a neighboring peasant induced his father to place him, at a distance from home, under the care of a lay ecclesiastic, who was an able classical scholar, as well as deeply skilled in theology and jurisprudence. Here the young man made such progress in learning as astonished all about him. His resolution to marry the object of his love created in him a zeal and diligence that surmounted all difficulties; but, however, he was in a situation to maintain a wife, and, at the instigation of his father, married. This disaffection made him resolve to devote himself to the church, and he was in due time consecrated a priest, and obtained the patronage of the archbishop of Conza. Unfortunately for Genoveli the prelate died, which made him repair to Naples to follow the practice of the law, an employment highly lucrative in that city. He was soon dissatisfied with his business, and after diligently studying the elements of modern and ancient philosophy, he obtained the office of extraordinary professor of metaphysics. He began his lectures in November 1741, and his school was crowded with pupils; the boldness of his manner, and the novelty of many parts of his system, excited his enemies, who accused him not only of impiety, but of opening the door of free-thinking in Italy; merely, it is said, because he recommended the works of Galileo, Grotius, and Newton.

His friends, however, powerfully supported him, and by the influence of Galvani, the director of the Neapolitan universities, he was appointed to the office of professor of ethics, which afforded him ample field for combating the ignorance and prejudices of the schools. The principle of his system was, that the happiness of man is the only object of the philosophical doctrine of morals, and he deduced his duties from analytical considerations. He interwove in his lectures the history of the human passions, and enlivened them by a boldness and spirit peculiarly his own. He composed a new system of logic, which he dictated in his lectures, and which was afterwards published in 1745, under the title of "Elementorum Arts Logico-criticae, Libri quinque." This might be considered as an introduction to his metaphysics, the first part of which had been published before this period, but the second and third parts made their appearance in the years 1747—1751. In 1748, he put up for the vacant chair of theology, but, as this was always connected with the episcopal dignity, he was immediately regarded as unfit for so high an office in the church, on account of his heretical notions. His enemies now discovered the most serious and alarming doctrines, in the published and unpublished pieces of which he had been the author. He was obliged therefore to renounce the science of theology, and to suppress some works on this subject. He now turned his attention to political economy, and in a few years he not only made himself master of every thing differing of notice on this science, but struck out some new lights. He published, in 1753, the first fruits of his researches, entitled "Essays on Agriculture, with considerations on the true Object of the Sciences." He was now, at the instance of his friend Intieri, made professor of political economy, with a considerable salary. The office had been conferred solely for him, and it was agreed that the lectures should always be delivered in the Italian language, a circumstance, at that time, which was unknown at Naples. His lecture room was crowded, and in a short space of time he was obliged to take a still larger place for the display of his talents, which also was insufficient to contain all who came to be benefited by his instructions. His chief and avowed object was, while he taught the principles of political economy, to inspire the Neapolitan youth with the social and civil virtues, and above all with a public spirit of patriotism, which was then almost unknown in Italy, and which he hoped to create in that nation, by which the prosperity of which it was susceptible. He caused to be translated Carey's History of the English Trade into the Italian, and then published it with useful notes. After this he pointed out in a short treatise the cause of the decline and neglect of agriculture in the kingdom of Naples. In 1765 he published another work, in which he examined the question, "Why countries, the most fruitful by nature, are often exposed to the miseries of scarcity." He was also author of many other works, but his master-piece was the "Italian System of Morality," of which the first part was published in the year 1767, under the title of "Discourses." His health now gave way, and he was unable to prosecute his studies, and, in 1768, he was obliged to discontinue his lectures, and in the following year he expired, in the fifty-seventh year of his age. He had attained, as a man of science, a very high reputation, and his moral character was in every respect worthy of a true philosopher. He possessed a most adorable love of truth, and a desire to extend its dominion, in which he was aware the happiness of his fellow-creatures was deeply concerned. "He was," says his biographer, "an irreconcilable enemy to injustice and deception; his countenance displayed cheerfulness, tranquillity, and invincible courage. He was too proud to flatter in order to become rich, and was contented with a very moderate income." He died poor, and would have been in dittered circumstances in the latter years of his life, had not the sovereign supported him unfailingly. He was held in high estimation by pope Benedict XIV. and many of the cardinals; and by infusing in the breasts of his pupils an ardent love of their country, with a well regulated zeal for
its chief interests, he was the means of introducing them to offices of distinction, which they filled with honour to themselves, and high advantage to the chief interests of the state.

GENOUILLAT, in Geography, a town of France, in the department of the Creuse; nine miles W. of Boufiaç.

GENOUILLE, a town of France, in the department of the Charente; 10 miles W. of Jean d'Angely.

GENOWI, a town of Africa; six miles N. of Sennaar.

GENASC, a town of France, in the department of the Gironde; nine miles S. E. of Libourne.

GENS D'ARMES. See Gendarmes.

GENERIC, in Biography, a famous king of the Vandals, succeeded his brother Gonderic in his Spanish dominions in the year 428. He had already signallized his courage and skill in war, and was entered to toil and hardships of every kind. Soon after his succession he invaded Africa, at the head of 50,000 men, and made himself master of the greater part of the country on the sea-coast. The persecution of the Donatists was an event highly favourable to the designs of Generic. Seventeen years before he had landed in Africa, a public conference was held at Carthage by order of the magistrates, which ended in a most severe persecution. Under these circumstances, Generic, himself a Christian, but an enemy of the orthodox faith, avowed himself the vindicator of the rights of the Donatists, who, in their turn, looked up to him as their deliverer, from whom they might reasonably expect the repeal of the odious and oppressive edicts of the Roman emperors. Generic obtained the most signal victories over his enemies, but notwithstanding his success, he agreed to a treaty with the emperor Valentinian, whom he consented to leave in possession of the three Mauritanias. He delivered to the Romans his own son Huneric, as a hostage for the observance of his treaty; but they, trusting to his good faith, sent back the youth. Generic abated this indulgence by feizing upon the city of Carthage in 439, at a time when the empire was engaged in a war with the Goths. From Carthage he sailed with a large fleet, and landed in Sicily. He ravaged almost the whole of that island, and made a valet bootty, but was unable to effect the conquest of Palermo. The object of this prince was to render himself formidable by sea; and he succeeded so completely, that the eastern and western emperors, Theodosius and Valentinian, thought it necessary to join against him. They fitted out a powerful fleet, with a large army, destined for the recovery of Africa, but Generic deluded them by proposals of accommodation, and the irruption of the Huns obliged Theodosius to recall his forces. When Maximus ascended the western throne, he compelled Eudoxia, the widow of Valentinian III., to marry him; she in a short time secretly applied for the dangerous aid of Generic to free her from his tyranny. He, feizing the occasion, appeared at the mouth of the Tiber with a numerous fleet; and in the conflict Maximus was slain, which afforded Generic an opportunity of marching to the gates of Rome, where he was admitted almost without opposition. For fourteen days the city was abandoned to all the licentiousness of a barbarian multitude; and on his return he carried away an immense quantity of treasure, besides multitudes of captivest, chiefly of the female sex, among whom were the empress and her two daughters, one of whom he married to his son Huneric; and after the lapse of several years, he restored the other and her mother to their native place. Generic continued to annex to his dominion the remaining Roman provinces in Africa; and then sent a fleet, consisting of sixty galleys, into the Italian sea, which was destroyed. But the loss of his ships did not prevent him from renewing his ravages on the coast of Italy, till his power received a severe check from the emperor Majorian, who now began to act on the offensive, and formed the spirited resolution of attacking the Vandals, in Africa. He fitted out a formidable fleet with the purpose, which obliged Generic to sue for peace. His suit being rejected, he sent out a squadron, which coming unawares upon the Roman navy, in the bay of Carthage, almost destroyed it. Peace was now made between the two warriors, the terms of which were observed till the death of Majorian, in 461. After this, Generic prepared to repeat his aggressions, and he again ravaged the coasts of Italy and Sicily, and even took possession of Sardinia. He extended his hostilities to all parts of the Mediterranean, and frequently indulged in acts of the most brutal atrocity. At one time he is reported to have massacred five hundred noble citizens of Zaccynthius, and to have thrown their dead bodies into the sea. Leo, the eastern emperor, resolved to make an effort to free his dominions from this terrible scourge, and made vain preparations for the invasion of Africa. The conduct of the expedition was given to Basiliscus, who might have exhorted for ever the kingdom of the Vandals, had he freed the moment of confirmation, and boldly advanced to the capital. Generic beheld the danger with firmness, and engaged it with his veteran dexterity. He professed himself ready to submit his person and dominions to the will of the emperor; but requested a truce of five days to regulate the terms of his submission. Basiliscus conferred to the fatal truce; and during the short interval, the wind became favourable to the designs of Generic. He manned his largest ships of war with the bravest of the Vandals and Moors; and they towed after them many large barges filled with combustible materials. In the obscurity of the night these destructive vessels were impelled against the unguarded and unsuspecting fleet of the Romans, who were soon awakened to a sense of their infant danger. "Their close and crowded order," says the historian, "afflicted the progress of the fire, which was communicated with rapid and irresistible violence; and the noise of the wind, the crackling of the flames, the dilluent cries of the soldiers and mariners, who could neither command, nor obey, increased the horror of the nocturnal tumult." Basiliscus returned ignominiously to Constantinople with the remainder of his shattered fleet; and thus the fruits of all this mighty effort were lost. Generic put to sea, recovered Sardinia, which had been taken from him, reduced Sicily and all the islands between Italy and Africa, and became a greater terror to the empire than ever. In 476, he made a peace with Odoacer, king of Italy, to whom he restored Sicily, but on condition of receiving tribute. The emperor Zeno likewise relinquished to him and his successors all claims to the African provinces. Generic died in the year 477. In his early youth he had renounced the orthodox communion; and as an apostate he could neither grant nor expect a sincere forgiveness. He was exasperated to find that the Africans, who had fled before him in the field, still presumed to dispute his will in synods and churches; and his ferocious mind was incapable of fear, or of compassion. His catholick subjects he oppressed with intolerant laws and arbitrary punishments. The language of Generic was various and formidable; the knowledge of his intentions might justify the most unfavourable interpretation of his actions; and the
the Arians were reproached with the frequent turbidities which stained the palace, and the dominions of the tyrant, Gibbon. Univer. Hist.

GENTIANA, in Geography, a town of Aicia, in the country of Alans; 370 miles E. of Patna. N. lat. 25° 10'. E. long. 92° 10'.

GENTIANA, in Gardening, the common name of a large hardy perennial herbaceous plant, which has a root that affords an extremely strong bitter. See GENTIANA.

GENTIANA, in Botany, varietum of the Greeks, named after Gentius, a king of Illyria, who is said to have discovered it, or at least to have first experienced its virtues as a cure for the plague, which infected his army. Gentian, or Fellwort. The latter name, we presume, is derived from fel, gall, alluding to its extreme bitterness, and not from fell, the north-country appellation of a mountain. It therefore ought to be, as Gerarde writes it, Fell-wort.—Linn. Gen. 126. Schreb. 175. Willd. Sp. Pl. v. t. 1331. Mart. Mill. Dict. v. 2. Sm. Fl. Brit. 284. Juss. 141. Larmor. Illutr. t. 199. Gertr. t. 114. Clas. and order, Pentandria Digynia. (Monogynia; Larmor.) Nat. Ord. Rosaceae. Linn. Gentiana, Juss.

Gen. Ch. Cal. Perianth inferior, in five deep, oblong, acute, permanent segments. Cor. of one petal, tubular in the lower part, without pores; in the upper five-cleft, regular, various in form and direction, withering. Stamina five, awl-shaped, shorter than the corolla, connected with its tube; anthers oblong, simple, sometimes united into a cylinder. P. G. Germanus inferior, ovate or oblong-cylindrical, as long as the flaments; styles none; filaments two, ovate, recurved. Peric. Capsule oblong, rounded, pointed, slightly cloven at the summit, of one cell and two concave inclosed valves. Seeds numerous, small, flatish. Receptacles two, affixed longitudinally to each valve.

Eff. Ch. Corolla tubaral at the base, delilute of neeta-

riberous pores. Capsule superior, of one cell and two valves, with many seeds.

Obf. The figure of the fruit is conical, but the corolla is very different in various species, being either wheel-shaped, bell-shaped, or funnel-shaped. In some there are small intermediate segments, in others a fringe to the corolla is given. It is plaited, in others plain. A few species have a four-cleft tetradalous flower; but the remark in Linn. Gen. 176, that there is a species with three additional parts of the flower, alludes to Clhora, once reckoned a Gentiana. Linnaeus has erased the line from his own copy, and his editors might easily have made the fame correction. G. lutea, and some others, however, have frequently a superabundance of divitions and flaments in a few of their blossoms.—The upper part of the germin so much resembles a style, that Larmor has perhaps offered no great violence to nature, or the Linnean fylinem, in considering it such.

This very noble and beautiful genus of herbaceous plants is chiefly of alpine origin, where the lovely blue flowers of many species enamel the turf in a most splendid manner. Most are perennial, some few annual. All are intensely bitter in flavor, especially the roots of the larger perennial kinds, G. lutea, Woodv. Med. Bot. t. 156, which is the official Gentian; purpurca, Fl. Dan. t. 50, which is the Curfita of the Edinburgh Pharmacopoeia; pannonica, Jacq. Aurtr. t. 136; pumilata, ibid. app. t. 28; and campurpula, t. 29. These are scarcely ever seen in gardens, except the first, which is not easily established; but few plants are more flately and ornamental. The North American G. sepa-

nica, Curt. Mag. t. 1039; and the alpine aqebidenta, t. 1578, are both very handsome, and we have found the latter thrive for many years in a bed of peat, earth and loam, as well as on its native mountains. See Curt. Mag.—G. acutula, Curt. Mag. t. 52. Eng. Bot. t. 1504, is one of the most common in gardens, but requires rather a pure air. G. ferru-

na, closely allied to it in habit and beauty, see Eng. Bot. t. 453, though wild in the mountainous parts of Durham, and abundant on the Swiss and Italian Alps, will scarcely live in a garden at all. G. Pseudomaranta, ibid. t. 20, found on turfy heaths in many places, is likewise very handsome, and rather impatient of culture. We have never seen the culture of the annual kinds attempted; such are niveas, Eng. Bot. t. 896; Amarella, t. 236; and campurpula, t. 237.

Linmeus was by no means well acquainted with the different species of this genus, having never visited the more southern Alps of Europe, where alone they are to be studied to advantage. Hence his varia and noronica are one species, and he confounded with lutec, which he seems never to have seen, or at least to have afterwards forgotten, the G. florib-

bus terminatus diaphanus, Gmel. Sib. v. 4. 160; G. alpige, Pallas. Rof. t. 95. Hence the erroneous remark under lutec, "petala puncta farpa cereberrima, flava." There is some doubt whether G. sepurnida, Sims in Curt. Mag. t. 1229, be the same as Pallas's t. 92. f. 3. In the former the flower appears to us very rarely, if ever, with more than five divisions, nor do the habits of the two figures accord. Willdenow has fifty-fix species of Gentiana, some of which among the annual kinds we are not able to determine to our satisfaction. He quotes a monograph by Froelich, which appears to have great merit, but which has not come to our hands.—Six species only of this genus are wild in Britain, the Clhora and Chiroria being now, with the greatest possible propriety, separated from it.

GENTIANA, in Gardening, comprises plants of the hardy, herbaceous, perennial, flowery kind; of which the species cultivated are the yellow gentian (G. lutec); spotted flower-

ed gentian (G. punctata); swallow-wort-leaved gentian (G. nuladiata); and the dwarf gentian, or gentianella.

Method of Culture.—In the three first sorts it is easily es-

saced by laying the seeds in pots soon after it is ripe, as when kept till spring it will not succeed; the pots should be placed in a shady situation, and kept clean from weeds. Some advise their being kept in a greenhouse, which is not bad; but the best is probably the last method. In the springing the plants appear, when they must be duly watered in dry weather, and kept clean from weeds till the following autumn; then be carefully shaken out of the pots, so as not to break or injure their roots; and a shady border of loamy earth should be well dug and prepared to receive them, into which they should be put at about six inches distance each way, the tops of the roots being kept a little below the surface of the ground, and the earth profiled close to the roots. If the fol-

lowing spring prove dry, they should be duly watered to forward their growth. The plants may remain here two years, by which time they will be fit to transplant where they are designed to grow, removing them in the autumn as soon as their leaves decay; great care being taken in digging them up not to cut or break their roots, as that greatly weakens them. They require afterwards another culture but to dig the ground about them early in the spring before they begin to flower, and in the summer to keep them clean from weeds. The roots continue many years, but the Falks decay every autumn;
the same roots not flowering two years together, or seldom oftener than every third. When they flower strongly, they have, however, a fine appearance among other similar plants.

In respect to the last it is mostly propagated by offsets or parting the roots, and planting them where they are to remain in the early autumn; but in order to have the plants flower well, they should not be often transplanted or parted. And they are also capable of being raised from seeds managed in the same way as in the first kinds.

All these plants succeed the most perfectly in moist loamy soils, where there is a degree of shade afforded. They are useful as ornamental plants, for the clumps, borders, and quarters of pleasure-grounds; those of low growth being planted towards the fronts, and the latter kinds more backward in them.

GENTIAN, Gentiana, in the Materia Medica. The root, which is the only medicinal part of the plant, has little or no balsam, but to the taste it manifests great bitterness; a quality which is extracted by aquae, spirituous, and vinous menstrua, though not in so great a degree by water as by spirit; and the extract of this root, prepared from the watery infusion, is left bitter than that made from the spirituous tincture. Gentian is the principal bitter now employed by physicians; and as the intense bitters are generally admitted to be not only tonic and homoeopathic, but also antiseptic, antispasmodic, antihypertensive, and diuretic, this root has a better claim to the possession of these powers than most of this kind. Many dyspeptic complaints, though arising from acidity of the stomach, are more effectually relieved by bitters than by Peruvian bark; and hence may be inferred their superior tonic power on the organs of digestion; but we are told by Dr. Cullen (Mat. Med. vol. ii.) that the gentian, joined with equal parts of tormentil or galls, considerably succeeded in curing intermittent fevers, if given in sufficient quantity. As a simple bitter the gentian is rendered more grateful to the stomach by the addition of an aromatic; and for this purpose orange-peel is commonly employed. The official preparations of this root are, the "infusum gentianae compostitum," and "tinctura gentianae compostis," (Ph. Lond.) and the "infusum amarum," "vinum amarum," "tinctura amara," five "elixir flammacum" (Ph. Ed.) which latter is made by Dr. Cullen to be the same as Stoughton's elixir, (see Stoughton's Elixir) and by both Pharmacopoeia the extract is directed. The "compound infusion" is prepared by taking gentian root sliced and orange-peel dried, of each a dram, of fresh lemon-peel two grains, and boiling water twelve ounces; and macerating for an hour in a covered vessel, and then straining the liquor. For the "tincture," take of gentian root dried, two ounces, orange-peel dried, an ounce, cardamom seeds bruised, half an ounce, and proof spirit two drachms; macerate for fourteen days, and strain. For the "extract," take of gentian-root sliced, a pound, and boiling water, a gallon; macerate for twenty-four hours, then boil down to four pints; strain the hot liquor, and evaporate it to a proper consistence. The extracts are made into pills, with or without aromatic additions. Wines and mulled liquors are likewise prepared with the virtues of this root in different proportions. An ounce of the gentian root, the same quantity of fresh lemon-peel, and two drams of long pepper, communicate by maceration, without heat, a grateful warmth and bitterness to a quart of mountain. There is an Indian gentian brought from America by the Portuguese, of a pale yellowish colour, jointed and marked with knots and circles like ipomea, and more intensely bitter than any of the officinal bitter drugs. This root is greatly commended in obstinate intermitents, and other disorders; a scruple is said to be more effectual than repeated half doses of bark.

There was a mixture of henbane root brought over some years ago with the common gentian, which occasioned violent disorders, and in some instances proved fatal.

This root is of a paler colour than gentian, and its longitudinal wrinkles finer and closer; the poisonous root, when cut, appears white, without any degree of the yellow hue, which is deep in gentian; and its taste is not bitter, but mucilaginous. Phil. Trans. vol. xlvi. p. 250. Lewis's Med. Cold. Woodville's Mat. Med.

GENTIAN Water. See Water.

GENTIANAE, the forty-fifth natural order of plants in Jullien's family, or the thirteenth of his eighth clads, so named from the principal genus contained in it. The characters of this eighth clads is Cotyledons two. Flowers of one petal, inferted below the germen, regular or irregular. Ca- tyleon of one leaf. Stamen of a definite number, inserted into the corolla, and usually alternate with its divisions, when they agree in number. Gernn superior, simple; style one, (sometimes none in the Apices, with a double germen); stigma simple or divided. Fruits one, or two, containing either one or two seeds, or for the most part enclosed, either in a pulpy or a capsular feed-veil, of one or many cells.

The characters of the Gentiana are these. Calyx divided, permanent. Corolla regular, often withering before it falls, with a limb equally divided, whose segments agree in number with those of the calyx and are mostly commonly five, sometimes oblique. Stamens as many, inserted into the middle or upper part of the corolla; anthers incumbent. Style one, or rarely, by splitting, double; stigma simple or lobed. Capsules simple or of two parts, of two valves, and one or two cells, the valves inflexed at the margin, involute where there is but one cell, flat and confining the portion where there are two. Seeds numerous, small, inferted into a marginal receptacle connected with the valves. Stem herbaeous, rarely somewhat thorny. Leaves opposite, mostly undivided and sessile; floral ones occasionally smaller, resembling bracteas, the flowers in such case becoming, as it were, doubly bracteate. — The first section has a simple capsule, of one cell, and contains Gentiana, Lili of Schreber (Vatleia of A. Sol.) Pedatum of Schreber (Gentiana of Aublet), Scardata and Chlora; the second, with a simple capsule of two cells, contains Exacum, Lithanthus, Myrrzia of Schreber (Tackia of Aublet), Gloriosa and Nigrina; the third with a didymous or two-lobed capsule of two cells, contains only Spigelia and Ophiophriza. In a fourth section stands as the kind to this order, by itself, Nicaudae of Schreber (Petalis of Aublet.) The plants of this natural order are chiefly remarkable for their intense bitternesses, and consequent florimachic virtues. Their flowers are usually beautiful, either blue, yellow or red, rarely white, except by occasional variation of the blue or red.

GENTIANELLA, in Gardening, the common name of the dwarf gentian, and which properly signifies the little gentian, which has a broad leaf and large flower. See Gentia- na.

GENTILE, Gentile, a pagan, or person who adores false gods. The Hebrews applied the name [נוכי], geres, nations, to all the people of the earth who were not Israelites or Hebrews.

Some will have it that the gentiles were thus called in contradiction to the Jews, because the latter had a positive law
The law to observe in matters of religion, whereas the gentiles had only the natural law: hence they are called "gentiles, quin sunt uti gentii fuerunt," because they remain as in a state of nature.

The Jews apply the denomination gentiles much as the Christians do that of infidels. St. Paul is called the δικαιος, or απολυμανος of the gentiles, which appellation he first gave himself; Rom. xi. 13. "As I am the apostle of the gentiles, I magnify mine office."

The calling of the gentiles to Christianity had been predicted in the Old Testament, as it was accomplished in the New. See Psa. ii. 8. lxi. ii. Joel ii. 29. Matt. viii. 12. xii. 18. Acts. xi. 18. xiii. 47. 48. xxviii. 28. Rom. i. 5. iii. 29. xii. 13. 25. Eph. ii. 11. Rev. xi. 2. xiiii. 2.

Some account may not be improperly given in this place of the state of Christianity both before and after the time of Constantine's conversion. The opposition of the Jews to its reception and prevalence appears in the Acts of the Apostles, and the epistles of the New Testament. Our present object is to consider, first, the state of its progress in gentile countries, and under heathen emperors, from about the middle of the first century, when it began to be preached among the gentiles, and to make some progress among them, to the period when Constantine embraced the Christian religion; and, secondly, its state under the Christian emperors, and their treatment by the gentiles. In the former period, we find from St. Luke's account in the Acts of the Apostles (ch. xiv. 19, 20. ch. xvi. 19-24.) that St. Paul met with some difficulties in preaching the gospel in gentile cities: but no imperial edicts were issued against the Christians, before that of Nero in the year of Christ 64 or 65, at which time the two apostles, Peter and John, were put to death. For an account of the ten persecutions, as they have been usually reckoned, which the Christians suffered under heathen emperors, we refer to the article Persecution. These persecutions were ordered by edicts of emperors, beginning with Nero's and ending with Diocletian's. During the whole of this period Christianity had been in a state of persecution. At the commencement of the second period, in 313, Constantine and Licinius issued a law or edict, giving liberty to all men, Christians and others, to follow that way of worship which should be most agreeable to them. However, it appears that Constantine did not strictly observe his own edict; for, according to the utmost of his power, by various methods, by laws, institutions, rewards and encouragements, he endeavoured to root out the ancient religion, and to promote the Christian doctrine. Conceiving that neither he nor the Roman empire could be safe, as long as the ancient superstition subsisted, he openly opposed the gods of the gentiles, and their worship, as dangerous to the public welfare. After the death of Constantine in the year 337, the whole empire was divided between his sons, Constan- tius, with whom his brother Constantine remained, was put under suspicion of perjury to cease, and the madness of sacrificing to be abolished; under the menace of a proper and convenient punishment. This law was followed by another law of Constantius in the next year, 332, forbidding the demolition of temples, which flourished without the walls of the city of Rome. Another law, which was the first of Constantius, and passed, as it has been supposed, in the year 335, ordained that in all places, and in all cities, temples should be immediately shut up, and that the people should abstain from sacrifices, under the penalty of death and the confiscation of their estates to the treasury. The second law of Constan- tius, in the same year, prohibited nocturnal sacrifices; and a law, published by the same emperor in the year 336, appointed capital punishment to such as were convicted of per- forming sacrifices or worshipping images. Three other laws of Constantius were also published in the year 356 or 357, with the penalty of death against all who consulted any of the ministers of divination, who are enumerated under their several titles of haruspices, mathematicians, Chaldeans, la- rioloi, augurs, vates, and magicians. The emperor Julian is well known for his zeal in favour of gentilism, and for his injurious treatment of the Christians. At his accession we may reasonably suppose, that all the laws of preceding Christian emperors against gentilism and its rites, were abrogated, and that it was actually established by imperial edicts; whilst the Christians were deprived of magistracy, and all honours and dignities as well as all of equal rights of citizenship. The emperors Jovian, Valentinian, and Valens were Christians; and they encouraged their subjects in the profusion of Chri- stianity, and protected them in the enjoyment of the privi- leges conferred upon them by Constantine: but it does not appear that during this period any new laws were issued against gentiles and their sacrifices. Jovian, indeed, pub- lished a law of universal toleration; and Valentinian was remarkable for the moderation of his government. In the year 381 was issued a law of Theodosius, with the joint authority of Gratian, and the younger Valentinian, enacting, that apostates from Chritianity to paganism should lose the power of making a will. This law was afterwards ratified, and followed by other laws of Theodosius the Great, Valen- tian the Younger, Arcadius, Honorius, and Theodosius II., with the addition of other clauses. In the same year, 381, and by the same authority, was enacted a law, for- bidding all sacrifices in the way of divination, either by day or by night, in the temples or elsewhere, upon the pain of proscription. By another law of Theodosius, in the following year, the magnificent temple in the province of Ofrhoenc, or Edesia, was allowed to be frequented, provided no sacrifices were performed there. In 385 Theodosius published another law, forbidding sacrifices, especially such as were made in the way of divination, and for discovering futurities, upon pain of death. In 391 was pub- lished a law of Theodosius, in which all sacrifices of inno- cent victims, and access to the temples, and the worship of false gods, were prohibited. This law was particularly designed for Rome and Italy; and in the same year a simi- lar law was published for Egypt, forbidding sacrifices and access to temples. In 392 was published a severe law of Theodosius, forbidding to men of all ranks every kind of heathenish worship; and in 399 Arcadius published a law for destroying temples in country places. Several other laws were published by Theodosius the younger against all Pagan obligations and sacrifices, and ordering the destruction of chapels, temples, and consecrated places. Nevertheless gentilism still subsisted. Upon the whole it may be observed, that the period of 20 or 25 years, from the death of Con- stantine to the accession of Theodosius, or thereabout, is remarkable for the mildness of law, which the gentiles were treated, and the few laws that were issued against them; and these laws against gentilism were not rigorously executed; but many gentiles were admitted into civil offices of great trust and profit; and many influences occur, which enshrine the mons- tration of Christian magistrates under Christian emperors; and, indeed, it is true both with respect to Christians and gentiles, that all wise and understanding men, of every sect and religion, recommended moderation, and concurred in condemning force and compulsion in religious matters. See more on this subject in Lardner's Works, vol. ix. 98-218.

Gentile, Gentilis, in the Roman Law and History, a name which sometimes expresses those whom the Romans otherwise call Barbarians; whether they were aliens of Rome,
GEN

or not. In which sense the word occurs in Ammianus, Antonius, and the Notitia Imperii.

Gentilis was also used, in a more peculiar sense, for all strangers, or foreigners, not subject to the Roman empire; as we see in the Theodosian Code, in the title of "De Nuptiis Gentilium;" where the word gentiles stands opposed to provinciales, or the inhabitants of the provinces of the empire.

The word is likewise used, in this sense, in the Greek; but it was not introduced either into that, or the Latin tongue, till after Christianity was established; it being taken from scripture. See Esquire and Gentleman.

Gentileschi, Orazio, in Biography, a painter, born at Pisa in 1563. His parental name was Lomi; but he chose to adopt that of his maternal uncle. He first learnt the art under his half brother Aurelio Lomi, but afterwards studied at Rome. After distinguishing himself at Florence, Turin, and Genoa, he passed to Savoy and France, and thence was invited into England by Charles I. who gave him lodgings, and a considerable salary; and employed him in painting ceilings, &c. at Greenwich. He was also employed by Villiers, duke of Buckingham, at York House, on a picture of himself and his family. After residing here about twelve years, he died at the age of 84 in 1647. The cleverness and brilliancy of the style in which he painted may be seen to the greatest perfection in a picture at Hampton Court of Joseph and Potiphar's wife. He made king Charles a present of a large book of drawings, and was deservedly respected and admired for his abilities.

Gentileschi, Artemisia, daughter of Orazio, and his pupil, who obtained almost as much skill and credit as her father. She followed him to England, where she practised in portraits with great success. She also exercised her talents in historical painting, and has left many highly creditable works behind her.

Her picture of Judith with the head of Holofernes at St. James's palace, is in the same style of design as her father's, but though very skilful, is not so bright, or so finely wrought as his pictures usually are. After the death of Orazio, she retired to Naples, where Graham says she became as famous for her amours as for her skill in painting. She died in 1642.

Gentilis, Alberico, was born in 1550, at Castel S. Giovanni, in the marche of Ancona. He studied the law, and took his degrees at the university of Perugia, and was priest at Ascoli, when his father, becoming a convert to the reformed religion, determined to quit Italy, and take with him his son Alberico and Scipio. The former, the subject of this article, came to England, and in 1582 was chosen professor of jurisprudence in the university of Oxford, which he held with much reputation till his death in 1608. He was a man of great learning, and published various works. One, entitled "Six Dialogues on the Interpreters of Law," he dedicated to his patron the earl of Leicester. He is author of three books "De Jure belli," which are highly applauded by Grotius; of three others "De Legationibus," and several tracts relative to antiquities. His "Lectiones Virgiliana" prove that he had cultivated polite literature very successfully.

Gentilis, Scipio, brother of the preceding, was born in 1563, and, while a child, was sent to Tübingen for his education. He here distinguished himself in the study of the classics and jurisprudence, which he afterwards pursued with inebriating success at the universities of Wittemberg and Leyden. In 1589 he took his degree of doctor at Bafl, and then went to Wittemberg as a public expounder of the law. Shortly after he removed to Aldorf, and became principal professor of law. His fame extended very far, and he received invitations to settle at several universities, and one from pope Clement VIII. to settle at Bologna, which he declined. He died at Aldorf in 1616, leaving behind him many works as monuments of his deep erudition. These were afterwards collected and printed in 8 vols. 4to.; they are chiefly on subjects connected with jurisprudence. As a teacher, his manner was clear and interesting. He was a good Latin poet, and translated several of the Psalms, and the first two cantos of Tasso's Jerusalem. Bayle.

Gentilis, Gentiles, was born at Foligni, in Italy, about the year 1530. He studied medicine under the tuition of Thiaddeus of Florence, with great diligence and reputation, so that on his return to his native place he was regarded by his fellow-citizens as the first physician of the time; and his fame soon extended through Italy. He was also esteemed one of the best commentators upon Avicenna, whose writings were then held in high veneration in most of the universities of Europe. Gentilis died at Bologna about the year 1590. He published several treatises, which were collected and published at Venice, in four volumes folio, in 1584, 1586, and 1592. The following works were likewise printed separately: 1. "Expositio in De Avcicenna."—2. "De Fideibus," Venice, 1482—5. "Expositio cum Commento Avidgi Monachi Benediclini Libri de Judiciis Unrinarum, et Libri de Pulpibus." Ibid. 1494—6. "Confusis peregrinatu quies morborum totius corporis generis," with some other tracts, Venice, 1593—5. "Quaestiones et Traetatus extravagantes." Ibid. 1520—9. "De Lepra Traetatus." Ibid. 1536, with the surgery of Dinos de Garbo. 7. "De proportionibus Medicinorum," with different dissertations upon the subject of doses of medicines by the most celebrated physicians, Padua 1556, &c. See Elyot. Dict. His.-Several other individuals of the family of Gentilis were distinguished for their knowledge of medicine and the sciences.

Gentilis, John-Valentine, was born at Cofenza in Calabria. Educated in the principles of the Roman Catholic religion, and becoming a convert to the principles of the Reformation, he was obliged to quit his native country, and take refuge in Geneva, where several Italian families had already formed a congregation. His enquiries did not stop by the open renunciation of papal errors; he became diffusified with the orthodox doctrine of the Trinity. He was required to subscribe to the articles of faith which the persecutor John Calvin had established against here, to which a promise was annexed, never to do any thing, directly or indirectly, that should controvert the doctrine of the Trinity. At first Gentilis refused the test, but was afterwards prevailed on to comply, dreading probably, in case of his resistance, a similar treatment to that which Servetus had experienced. What his hand had signed, and his tongue confessed, his heart abhorred, and in private he did not scruple to avow the truth, which coming to the ears of the magistrates, they committed him to prison. From the dungeon he attempted to escape, and fled with his persecutor, showing the insufficiency of his opinions, but their hearts were filled against the supplications of a heretic, till he offered to abjure his errors, consented to throw his writings into the fire, and take an oath not to quit Geneva without leave of the magistrates. Being thus, in a measure, freed from suspicion, and feeling conscious that he would be justified in breaking an oath which had been purged by terror, he withdrew from the city, but finding no place of safety he returned, was again imprisoned, but in a short time liberated. From this period he seems to have wandered from place to place, and we find him at Lyons, in various parts of Poland and Germany, in Savoy, and at laf
GEN

at Bern, where he was accursed of hereby. He underwent a long and tedious trial, and being convicted of obliquely oppugning the mystery of the Trinity, he was sentenced to lose his head. This sentence was carried into execution, but death, which, at a greater distance, seemed so formidable to him, was now deferred of his terrors, and by a manly fortitude he was enabled to triumph over his enemies, who expected that his mind was ill-adapted to so trying a scene; his last moments were probably the happiest of his life. He died exulting that he was thought worthy of suffering for the cause of truth, and that he was admitted to seal, with his blood, the doctrine of the supremacy and unrivaled glory of the Father. Merer. Bayle.

GENTILITIA, SACRA, among the Romans. See SACRA.

GENTILITIUS, an epithet used by some authors to express different propagated from father to son, and running through whole families; such were more usually called hereditary disorders. Such are the gout very frequently, and often many others.

GENTILLET, VALENTINE, in Biographia, a native of Dauphiné, who flourished in the sixteenth century. He had in early life studied jurisprudence, and was a civilian by profession. He was an advocate in the parliament of Toulouf, and afterwards a syndic of the republic of Geneva, and at one period of his life he was president of the parliament of Grenoble. He became distinguished by his writings against popery, but by the edicts published in France against those of the reformed religion, he was driven into exile. His principal work is, "An Apology for the Protestants," which went through several editions in the French, and was afterwards translated into Latin and enlarged, under the title of "Apologia pro Christianis Gallis Religionis. Evangelicae feud Reformatae, qua doctur hujus Religionis fundamenta in Sacra Scriptura jacta effe:;" and "Le Bureau du Concile de Trente, &c." This was printed in French in 1586, and in the same year a Latin translation of it was published, which was frequently reprinted at different places. Its design is to show that many of the decrees of that council were contrary to the ancient councils and canons. He was author also of "Anti-machavel," and the "Anti-focioin." Bayle.

GENTIMANETOUR, in Geography, a town of Hindooftan, in the Carnatic; 30 miles W. of Cuddalore.

GENTILOUX et PALLIER, a town of France, in the department of the Creufe, and chief place of a canton in the district of Aubution; 9 miles S.W. of Tulle. The place contains 907, and the canton 6,527 inhabitants, on a territory of 3273' kilometres, in 8 communes.

GENTLE PET OR, in Mineralogy, a name given by our miners in Suffolk, to a kind of iron ore found in considerable plenty in that county, and very readily running in the fire, though not very rich in metal. It is a strong subfiance, and lies in several parts of that county in form of a moderately thick stratum. It is of a dully brown colour, and in some places much paler than in others. It has always a great number of glittering splangles in it, and very often contains foillie shells, and other extraneous subfances.

GENTLEMAN, a person of good family, or descended of a family which has long borne arms, the grant of which adds gentility to a man's family.

The word is formed of the French gentilhomme, or rather of gentil, fine, fashionable, or becoming; and the Saxon mon, q. d. beneplus, or honfio loco natur. The same signification has the Italian gentilhomme, and the Spanish heredez, or hijo-
dez, that is, the son of somebody, or of a person of note. If we go farther back, we shall find gentilhomme originally derived from the Latin gentilis homo, which was used among the Romans for a race of noble persons, of the same name, born of free or ingenuous parents, and whose ancestors had never been slaves, or put to death by law. Thus Cicero, in his Topics, "gentiles sunt, qui inter se eodem futinem non minu" ingenii oriund, quorum majorum nemo furt detriment furtivit, qui capitae non futinem, &c." Some hold that it was formed from gentile, i.e. person, and that the ancient Franks, who conquered Gaul, which was then converted to Chriftianity, were called gentiles by the natives, as being yet heathens. Others relate that towards the declension of the Roman empire, as recorded by Arnimianus Marcellinus, there were two companies of brave forders; the one called gentilium, and the other futoriarum; and that it was hence we derived the names gentleman and esquire. This sentiment is confirmed by Palquier, who supposes the appellation gentiles and esquires to have been transmitted to us from the Roman forders; it being to the gentiles and futori, who were the bravest of the forders, that the principal benefices and portions of lands were assigned. (See BENEFICE.)

The Gauls observing, that during the empire of the Romans, the futori and gentiles had the best tenements, or appointments of all the forders on the frontiers of the provinces, became insensibly accustomed to apply the fame names, gentilhommes, and esquire, to such as found their kings gave the best provisions or appointments to. Palef. Rech. lib. ii., cap. 15.

In strictness, Chamberlayne observes, a gentleman is one whose ancestors have been freemen, and have owed obedience to none but their prince; on which footing, no man can be a gentleman who is not born fo.

Among us, the term gentleman is applicable to all above yeomen; so that noblemen may be properly called gentlemen.

In our statutes, gentilis homo was adjudged a good addition for a gentleman, 27 Edw. III. The addition of knight is very ancient; but that of esquire, or gentleman, was rare. Before.

We read that J. Kingdon was made a gentleman by king: Richard II.

As it may justly be asked what constitutes a gentleman with us? the reply is easy; being a gentleman, is being entitled to bear arms. And Mr. Camden observes, that the distinction of a gentleman of coat-armour, or an uplar, and a gentleman of blood, is the bearing of arms from the grandfather; and that he who bears arms from his grandfather is to all intents and purposes a gentleman of blood; for which cause it is requisite by the statutes of the Bath that every knight, before his admission, proves himself to be so qualified, which done, it carries with it, if its merit be equal, a passport into the order of the Garter. Notitia Anglicana, p. 24. See also Dodridge's Honour's Pedigree, p. 147.

Smith, De Re Libr. Angl. & Fortefcue, fol. 82.

Guillum, in his chapter of gentlemen, says, that they have their beginning either of blood, as being born of worshipful parents; or that they have done something, either in peace or war, whereby they deserve to bear arms, and be acknowledged gentlemen. He further says, chap. xxiv., that a gentleman be bound apprenrice to a merchant or other trader, he hath not thereby lost his gentility; and he devises it may be remembered, for the honour of trade, that king Henry VIII. thought it no dishonour to him, when he quitted his queen, to take to his wife Anne, the daughter of Thomas Bolen, some time mayor of London. To which he may be added the thought, that the first William, who founded our royal race, was the grandson of a tanner.

Sir Edward Coke says, that esquires and gentlemen are only:
only names of worship, and not of dignity. And before thee the heralds rank all colonels, serjeants at law, and doctors in the three learned professions. See PRECEDENCE.

Sir Thomas Smith (ubi supra) says, that whatsoever studieth the laws of the realm, or studieth in the university, or professeth the liberal sciences; and (in short) who can live idly, and without manual labour, and will bear the port, charge, and countenance of a gentleman, shall be called master, and shall be taken for a gentleman.

GENTLEMAN Ulster of the Black Rod, is the chief gentleman usher to the king, called in the black book "Lator virgis nigris, et haitianus," and elsewhere "Virga bajuclus." His duty is to bear the rod before the king at the feast of St. George at Windsor; he has also the keeping of the chamber-house door, when a chapter of the order of the garter is sitting; and in time of parliament attends the house of peers. His badge is a "black rod," with a lion in gold at top. This rod has the authority of a mace; and to his custody all peers questioned for any crime are first committed.

GENTLEMAN of the Bed-chamber. See BED-CHAMBER.

GENTLEMEN of the Chapel, are officers whose duty and attendance are in the royal chapel, being in number thirty; ten whereof are priests, and the other twenty called clerks of the chapel, who assist in the performance of divine service. One of the first ten is chosen for confessors of the household, whose office it is to read prayers every morning to the household servants; to visit the sick, examine and prepare communicants, and administer the sacrament.

Another, well versed in music, is chosen first organist; who is master of the children, to instruct them in music, and what is necessary for the service of the chapel: a second is likewise an organist; a third a lutenist; and a fourth a violist.

There are likewise three vergers, so called from the silver rods they usually carry in their hands; being a serjeant, yeoman, and groom of the vestry: the first attends the dean and shuttle-dean; finds surplices and other necessaries for the chapel: the second has the whole care of the chapel; keeps the pews, and seats the nobility and gentry; the groom has his attendance within the chapel-door, and looks after it.

GENTLEMEN Pensioners. See PENSIONERS.

GENTLE, in Geography, a town of Germany, in the duchy of Magdeburg; 30 miles N.E. of Magdeburg.

GENTLEWOMAN, GENTLOGA, is a good addition for the estate and degree of a woman, as gentilicus is for that of a man; and if a gentlewoman be named spinster in any original writ, appeal, &c. it hath been held that she may abide, and quash the same. (2 Inst. 668.) But it seems that spinster is in general a good addition for an unmarried woman, as single woman is for one who, being unmarried, hath had a bastard.

GENTOOS, in Modern History, according to the common acceptance of the term, denote the professors of the religion of the Brahmins (see BRAMANS), who inhabit the country called Hindoostan, in the East Indies, from the word sian, a region, and hind or hindu; which Periplus, as we learn from colonel Dow's translation of his History, supposes to have been a son of Ham, the son of Noah. It is observed, however, that Hindoo is not the name by which the inhabitants originally dyed themselves, but according to the idiom of the Sanscrit, which they use, jambudvip, from jambu, a juckale, an animal common in their country, and dep, a large portion of land surrounded by the sea, or herakhain, from bhaut, i. e. a continent, and herai, the name of one of the first Indian kings. It is also observed, that they have assumed the name of Hindoos only since the era of the Tartar government, to distinguish themselves from their conquerors, the Mussulmen. The term Gentoos, or Gentoo, in the Sanscrit dialect, denotes animal in general, and in its more confined sense mankind, and is never appropriated particularly to such as follow the doctrines of Brahms. These are divided into four great tribes, each of which has its own separate appellation; but they have no common or collective term that comprehends the whole nation under the idea affixed by the Europeans to the word Gentoo. Mr. Halhead, in the preface to his translation of the "Code of Gentoo Laws," conjectures that the Portuguese on their first arrival in India, hearing the word frequently in the mouths of the natives, as applied to mankind in general, might adopt it for the domestic appellation of the Indians themselves, or, perhaps, their bigotry might force from the word Gentoo a fanciful allusion to gentle or pagan. The Hindoos, or Gentooos, vie with the Chinese as to the antiquity of their nation. They reckon the duration of the world by four ages, or distinct periods; for the first is the Sutter, or age of purity, which is said to have lasted about 3,250,000 years, during which the life of man was 100,000 years, and his stature twenty-one cubits; the second, the Thirtah jogue, or the age in which one-third of mankind were reprobrate, which continued 2,400,000 years, when men lived to the age of 10,000 years; the third, the Dwapar jogue, in which half the human race became depraved, which endured to 60,000 years, when men's lives were reduced to 1,000 years; and fourthly, the Collee jogue, in which all mankind were corrupted, or rather diminished, which word colle imports. This is the present era, which they suppose will subdue for 40,000 years, of which near 5,000 are already past, and man's life in this period is limited to 100 years. It is supported by many authors, that most of the Gentoo jesters or scripturites, were composed about the beginning of the collee jogue or cal jug, of which, according to Mr. Dow, the year of Christ 1769 was the 488th; but an objection occurs against this supposition, viz. that the flavers take no notice of the deluge; to which the Bramins reply, that all the scripturites were written before the deluge, and the deluge never extended to Hindoostan. Nevertheless, it appears from the flasters themselves, that they claim a much higher antiquity than this; instances of which are cited by Mr. Halhead.

After all, it must be allowed, that persons of sagacity and good judgment have made it appear with sufficient evidence, that the oldest accounts of the Hindoo nation do not, in reality, go further back than to the deluge mentioned in the books of Moses, and that their religious institutions were consequentially posterior to that event. Sir William Jones says, (Discourses relating to Asia, vol. i. p. 195,) that the first corruption of the purest and oldest religion, which consisted in the worship of one God, the maker and governor of all things, was the fyllem of the Indian theology, invented by the Brahms, and prevailing in those territories, where the book of Mahabob, or Menu, is at this time the Standard of all religious and moral duties. In his preface to the "Institutions of Menu," (see Menu) he says, they are supposed by the Brahms to have been originated by Menu, the son of standard of Brahms, or the first of created beings. This work he supposes to have been written about 2500 years after the Vedas, or about 1280 years B. C. Sir W. Jones is of opinion, that the origin of the Hindoo nation and government is to be looked for in Iran, or Persia, where a great monarchy was established before the Aryanian, called by the oriental historians the "Pithodian dynasty;" and they say, that
that the first of these ancient monarchs, whom they call Mahabad, or Menu, received from the creator a sacred book, in a heavenly language, meaning the "Vedas." (Diff. relating to Aia, vol. ii. p. 111.) This first monarch, they also say, divided the people into four orders, the religious, the military, the commercial, and the servile. (Diff. &c. vol. i. p. 197. 206.) In the reign of Hulhang, the third of the Phidadiad race, a reformation, he says, was made in the religious system, when the complex polytheism of the preceding times was rejected, and religion was reduced to what is called "Sabaiwm," which consisted chiefly in the worship of the sun, moon, and stars; but it is probable, that fabâim, being a more simple form of religion than that of the Hindoos, must have preceded it. The laws of Mahabad, however, were retained, and their superstitious veneration for fire. Upon this change, the favourers of the old religion retired to Hindoostan, and their oldest existing laws forbade them ever to return, or to leave the country they now inhabit.

Another reformation, or change in the system, was made, he says, under Guhaftap, in the next, or (2) "Hindoo," dynasty, thought to have been the same with Durias Hyfalsn. This was effected by Zeratthu, or Zoroaster; he introduced genii, or angels, predestined over months and days, new ceremonies in the veneration shown to fire, and gave out a new work, which he said came from heaven, but at the same time established the adoration of the Supreme Being. This work was loft at the conquest of Persia by the Mahometans; but the priests of that religion have composed another from what they were able to recollect of their institution. It is called "Zendbrijia," which fee. The followers of Zeratthu, now called "Gehres," or Parâis, perverted those of the religion immediately preceding; and this also took refuge in India, where they wrote a number of books, which are now very scarce. They resemble, according to the account of Sir William Jones, the Hindoo sects of "Sauras," and "Sagunias," of which the latter is very numerous at Benares.

Another innovator in the religion of the Ealr, before the Christian era, was "Buddha," (see Boopri), generally supposed to have been the same with Po or (3) "Buddha," the "Sonomocomor of Shitam, the "Xena," of Japan, and the "Odia" of the north of Europe. According to Sir W. Jones, he disapproved of the Vedas, because they enjoined the sacrifice of cattle; and made his appearance in the year 1057 B.C. His disciples are thought to have been the same with the "Sammânes," who were opposed to the Brahmanes of the Greek historians. But thes Sammanes were, it is probable, of much greater antiquity, as was also Somonocomor. The followers of Buddha gave great umbrage to the Brahminks, who never ceased to persecute them till they had effected their expatriation from Hindoostan by fire and sword, about 500 years ago. There is, however, a great resemblance between the system of the Hindoos and that of Buddha; and perhaps with a view to conciliate these people, the Brahmins of Càfô make Buddha the 9th avatar or transformation of Vishvow. This religion is that which prevails in India beyond the Ganges; it was received in China A. D. 65, and in established in Japan. A religion, very similar to this, is also that of the Lamas of Thibet. Indeed, all deviations from the original Hindoo system, retained the same general principles. The advocates of these all held the doctrine of the pre-existence of souls, their sublimating and acting independently of bodies, and their transformation into other bodies after death. They had the same low opinion of matter, and the same veneration for the elements of fire and water, as purifiers of the soul. They had similar restrictions with respect to food, the same additional edenics to divination, and the same idea of the use of corporeal austerities for the expiation of sin.

There can be no doubt of the very high antiquity of the religion of the Hindos, and it is not improbable that the commencement of all those systems which deviated from the religion of the patriarchs, preferred in the writings of Moses, was prior to the general dispersion of mankind. A system so ancient as that of the Hindoos must have been formed about the same time with that of the Egyptians, from which that of the Greeks, and other western nations, was in some measure derived; and accordingly many points of resemblance have been observed between them; too many, and too striking, to have been altogether fortuitous. Even some of the inhabitants of Ethiopia appear to have been of the same origin with those of Hindoostan (see Diff. relating to Aia, vol. i. p. 112.); and both the Egyptians and Ethiopians seem to have had some connection or intercourse with the Hindoos; but of what kind it was, or when it subsisted, we have no certain account; and they have been so long separated, that it is very difficult to trace in what their connexion was. According to Eufubius and Synceus, some people from the river Indus settled in the vicinity of Egypt in the reign of Amenophis, the father of Setoefiris, and many Egyptians, banished by their princes, settled in other countries, and some went so far as India. It is also supposed, that many of the priests of Egypt left the country on the invasion of it by Cambyses. But such circumstances as these are not of themselves sufficient to account for the great resemblance between the two systems. The Hindoos themselves say, that their sacred books came from the west, (see Ezoutredam, p. 15-17.) But the Hindoos, as well as their books, most probably came from that quarter, and their sacred books were composed while the seat of the empire was in Persia. The affinity of the Egyptians and Hindoos may be inferred from the similarity that subsists between some Egyptian words and those that occur in the ancient language of Hindoostan. The names and figures of the 12 signs of the zodiac, among the Hindoos, are nearly the same with ours, which came from Egypt through Greece, and each of these races preserved their proper weights, and the peculiarities of their own systems, so that the Egyptians and Hindoos had also the same division of time into years, months, and days, and they denominated each day by the names of the stars and planets. The resemblance between the oriental and occidental systems extends much farther than Egypt. The office and power of the Druids in the northern parts of Europe did not differ much from those of the Bramins; and the Etruscans, from whom the Romans derived the greatest part of their learning and religion, had a system very much resembling that of the Perfians and Indians, and they wrote alternately to the right hand and left. (See ETRUSCA.) Several remarkable "general principles" were held alike by the ancient Egyptians and the modern Hindoos. They both believed that the souls of men existed in a prior state, and that they go into other bodies after death. They had the same ideas of the body being a prison to the soul, and imagined that they could purify and exalt the soul by the mortification of the body; and from the idea of the great superiority of spiritual to corporeal substances, they held all matter in great contempt. They also both believed that plants had a principle of animality. Several religious ideas, and customs were common to both countries. The Egyptians of Thebes represented the world under the figure of an egg, which proceeded from the mouth of Cneus; and this resembled the first production according to the Hindoo system. Several of the Egyptian deities were both male and female, which corresponds to the figure of the "lingam" with the Hindoos. This obscene figure, or at least the "phallos," was...
was much used in the Egyptian worship, and from Egypt it was carried into Greece, where it was used in the mysteries of Bacchus. Beliefs, the licentious pollutions of the Egyptian women before their god Apis, were the same with those of the Hindoo women, before their idols, (see Brachmans); and, moreover, the Hindoos chuse their sacred bells by the same marks that were used by the Egyptians. The Egyptians worshipped the Nile, as the Hindoos do the Ganges; the pyramidal or conical form of the Egyptian temples resembled that of the pagodas: and the onion, which was held in veneration by the Egyptians, is not eaten by the Hindoos. Besides this resemblance of general principles, and religious customs, it is observable, that the Hindoos, Egyptians, and Greeks adopted the same gods, and paid homage to them under similar representations or images. The Egyptians held cows in much greater veneration than any other animal: they were sacred to Isis, and never sacrificed. That the cow was respected by the Hindoos is well known. Upon the whole, it is undeniable that a system, very similar to that of the present Hindoos, must have been of very great antiquity, and prior to the general dispersion of mankind. For the similar situations may lead to similar fictions, and corresponding practices, the above-mentioned similarity, which might be traced in a much greater number of instances, extends to too many particulars, to admit our accounting for it in this way: nevertheless, it is impossible that a system, so extensive and complex, and implying such abstruse metaphysics, as that of the Hindoos, should have been completed at a very early period. This must have been subsequent to the rudest age of mankind; and, therefore, we may well imagine, that it could not have had its origin long before the time of Moses. Whether the Jewish law-giver was acquainted with it or not, it will appear to any candid as well as accurate examiner of the one or the other, that he was far from deriving any advantage from it; nor is there in his writings any allusion to books pretended to be sacred, such as the Vedas, but only to such practices as were common to the Hindoos and other heathen nations.

The Hindoos seem to have preserved the knowledge of the Supreme Being, when the Greeks, and other more polished nations in the western parts of the world, had lost sight of him; and their civilization being brougth by inferior objects of worship, Some of their depositions of the deity are juf[t, and truly sublime. In the "Institutes of Menu" he is said to be "one whom the mind alone can comprehend, whose essence eludes the external organs, who has no visible parts, who exists from eternity, the soul of all beings, whom no being can comprehend." They also say, that "goodness is the very essence of God." (See Brachmans.) Nevertheless, the most sublime conceptions of Deity entertained by the Hindoos fall far below those that were formed of him by the Hebrews, and which are recorded in the sacred writings. In the Hindoo system the first production of the Supreme Being was something similar to the chaos of Mofes, an earth covered with water; and they speak of the "spirit of God" as moving upon it. One of the Hindoo fables, related by Father Bouquet (Ceremonies of Religion, p. 48.) bears some resemblance to the mofiac history of Paradise. The Hindoos say that the first man was called "Adam," and the first woman "Eve." The Hindoos have also a peculiar day of the week, which they appropriate to acts of religion, as prayer and fasting; and in agreement, at least in part, with the account of Moses, the Hindoos say that in the first ages of the world men were generally superior to the present race both in the length of their lives, and in the powers both of body and mind; but that, in consequence of vice, they gradually declined. The Hindoos have also preserved an unequivocal tradition of an universal deluge; and according to the "Puranas," books which are said to contain a faithful account of their doctrines, eight persons escaped the general deluge. A curious account of the intoxication of Noah, and of the behaviour of his three sons on the occasion, is given us from the Hindoo writings in the third volume of "Asiatic Researches." The 4th and 5th "avatar" of the Hindoos, as Sir W. Jones says (Diff. &c. v. i. p. 110,) relate to the punishment of impurity, and the humiliation of the proud; and refer, as he thinks, to the delusion from Babel. In the "Bagavadam" there are, besides the mofiac account of the deluge, the principal circumstances of the history of Ishmael, and the facrifice of Isaac. Several things occur in the Hindoo traditions, which greatly resemble some in the history of Abraham; and Brahma, the Hindoo law-giver, very much resembles this ancient patriarch.

The several inuences contained in the collection of the Hindoo laws, which we shall presently notice, are interwoven with the religion of the Gentoo, and revered as of the highest authority. The curious reader will discover an astonishing similitude between the institutes of this code and many of the ordinances of the Jewish law, between the character of the Bramins or priests, and the Levites; and between the ceremony of the scape-goat, under the Mofiac dispensation, and a Gentoo ceremony, called the "hummed jug," in which a horse answers the purpose of a goat. In this code we find some of the more extraordinary laws and customs of the Hebrew nation, such as were never received in the western part of the world; as that of a man taking the widow of his brother, in order to keep up his family. Polygamy appears also to have been allowed to the Hindoos, as it was to the Hebrews. Many obfolute customs and usages, alluded to in many parts of the Old Testament, may also receive illustration from the institutes of this code. It appears from the code, that the Bramins, who are the priests and legislators of the country, have relinquished all the secular and executive power into the hands of another cast or tribe; and no Bramin has been properly capable of the magistracy since the time of the fatte judge; the only privilege of importance which they have appropriated to themselves is an exemption from all capital punishment; they may be degraded, branded, imprisoned for life, or sent into perpetual exile; but it is every where expressly ordained, that a Bramin should not be put to death on any account whatsoever.

Among the Hindoos there is a considerable difference of opinion on the subject of creation; but in the following general outline they seem to be all agreed. They say, that after the Supreme Being had existed alone from all eternity, he resolved to produce other beings. But this production was wholly "from his own substance;" and after a certain period, they believe that every thing will be absorbed into him again, when he will exist alone as before. There will, however, be a succession of these creations and absorptions without end. At what time the first creation took place they do not say; but according to them, every thing that now exists has existed before, and will hereafter exist again. The great superiority of the spiritus to the corporeal part of man is the fundamental doctrine of the Hindoo system; and hence springs the satisfaction which the Hindoos always express on the separation of them. From the Indian philosophy it is probable that the Manichasians had their idea of an original difference in souls, some being necessarily good, and others bad. That all nature is animated, and that the souls which animate the lowest forms of things are capable of rising to the highest state, is inferred in the "Institutes of Menu."
GENTOOS.

Menu."' Thus it is said, "the souls that animate worms and insects, serpents, moths, bees, birds and vegetables, attain heaven by the power of devotion.

The doctrine of transmigration is one of the distinguishing tenets of the Gentoos. With regard to this subject it is their opinion, according to Mr. Holwell, that those souls which have attained to a certain degree of purity, either by the innocence of their manners, or the severity of their mortifications, are removed to regions of happiness, proportioned to their respective merits; but that those who cannot so far surmount the prevalence of bad example, and the powerful degeneracy of the times, as to deserve such a promotion, are condemned to undergo continual punishment in the animation of successive animal forms, until, at the flated period, another renovation of the four jouples shall commence, upon the dissolution of the present. They imagine five different spheres above this earth. The highest of which, called futter, is the reidence of Behi, and his particular favorites. This sphere is also the habitation of those men who never uttered a falsehood, and of those women who have voluntarily burned themselves with their husbands; the propriety of which practice is expressly enjoined in the code of the Gentoos law.

This is confirmed by the testimony of a very curious collection of Hindoo jurisprudence, which was selected by the most experienced pundits, or lawyers, from curious originals in the Shauri-Shahri language, who were employed for this purpose from May 1773 to February 1775; afterwards translated into the Persian idiom, and then into the English language, by Mr. Halhed.

We have already observed, that the Hindoos are divided into four great and original tribes, which, according to the Gentoo theology, proceeded from the four different members of Behi, the supposed immediate agent of the creation under the spirit of the Almighty. These tribes are the Brahmins, which proceeded from his mouth, and whose office is to pray, read, instruct, and conduct the sacrifices; the Chehterees, which proceeded from his arms, whose office is to draw the bow, to fight, and to govern; the Bce, proceeding from the belly or thighs, who are to provide the necessities of life by agriculture and traffick; and the Sooder from the feet, which are ordained to labour, serve, and travel.

Few Christians, says the translator of the Gentoo Code, have expressed themselves with a more becoming reverence of the grand and impartial design of Providence in all its works, or with a more extensive charity towards all their fellow-creatures of every profession, than the Gentoos. It is, indeed, an article of faith among the Brahmins, that God's all-merciful power would not have permitted such a number of different religions, if he had not found a pleasure in holding their varieties.

Mr. Holwell, and also Mr. Dow, attempt to extricate the Hindoos from the charge of polytheism and idolatry. "Let us rest assured," says the latter, "that whatever the external ceremonies of religion may be, the same infinite being is the object of universal adoration." But though the Hindoos acknowledge one Supreme Being, from whom all power is derived, they suppose that the immediate government of the world is placed by him in other hands. To these inferior deities their prayers and religious services are externally addressed; and this worship is encouraged and enjoined in their sacred books. According to their system, there sprung from the Supreme Being, as emanations of his divinity, an infinite number of futuriem deities and genii, of which every part of the visible world was the seat and temple. These intelligences did not rarely reside in each part of nature; but they directed its operations, each element being

under the guidance of some being peculiar to it. These inferior gods, being of various and opposite disposition and character, their worshippers adopted different methods of depreciating their anger, and soliciting their favour. Hence proceeded a great variety of whimsical and absurd, and also of cruel and dreadful, as well as impure, rites. The veneration of the Hindoos for the images of their gods subjects them justly to the charge of idolatry and polytheism; although the learned Brahmins pretend, that they do not worship the visible idol, but the invisible being represented by it. Mr. Sommert says, that besides those whom the Hindoo place in the rank of gods, they have also "saints," whose pictures they place in their temples, and that they address prayers to them as well as to their gods. Nor let it be said, that these are the accounts of travellers. In the sacred books of the Hindoos mention is made of various divinities besides the Supreme Being. The worship of the fun, says Mr. W. Jones (Diff. &c. v. l. p. 481) is principally recommended in the Vedas. The "Institutes of Menu," say, that the Supreme Being created an abominable interior deities, and divine attributes, and pure souls, and a number of gods equally delicate. The word mention is also made of demi-gods, and inferior genii, the despotic genera of the figures and lunar deities, &c. The worship paid to thrones, or ancestors, is a great article in the syllogism; and is mentioned almost in every page of the "Institutes." All the neighbouring nations, whose religions have some affinity to that of the Hindoos are polytheists. The ancient religion of the northern Europeans nations was, in several respects, similar to that of the East; and we find among them the acknowledgment of one Supreme God, with the worship of several inferior deities. Thus, their deities, Odin the God of war, Freo his wife, and Thor the god of thunder, were the principal objects of worship to all the Scandinavians.

It has been said that the polytheism of the Hindoos, and others, was mild and tolerant in its nature; but the fact is, that like the ancient Egyptians, they quarrelled with one another on account of their attachment to different deities, especially in Malabar; and mild as the religion of the Hindoos appears to be, and gentle as are their general manners, they can assume a very different character when their religion is concerned. The Danes, for instance, exterminated the Samaritans, and the followers of Buddha, with fierce and ferocious rage; none of them on the west side of the Ganges, under a pretence of their being atheists; and when any Hindoo is converted to Christianity, he is not only banished from his tribe, but abandoned to the insults of the whole nation. Such was the treatment of those who were excommunicated by the Druids. The Hindoos regard all Christians with the utmost abhorrence and detestation, as much below the lowest of their own sects. The Brahmins themselves can be cruel and malignant, where their religion is concerned. Nevertheless, when the Hindoos converse with Christians on the subject of religion, they profess to believe, as we have already observed, that the Supreme Being is equally pleased with all religions, and intended that all the different modes of it should be adopted by different nations.

Although there are many points of resemblance between the religion of the ancient Egyptians and that of the Hindoos, yet in many respects they are exceedingly different; for this, though they may have gone together at the fall, they must have branched at a very early period. The Hindoos never worshipping living animals, which is a principal feature in the religion of the Egyptians; and the names, the characters, and the images of their deities have very little resemblance to each other. But between the religion and mythological tables of the Greeks and those of the Hindoos, there
there is a very remarkable resemblance; though we are unable to trace any connection that ever subsisted between them.

The religion of the Hindoos seems to be much too complex to have been, as Sir W. Jones supposes, the oldest of all polytheistic and idolatry. It is evidently a refinement on something much more simple, and this seems to have been the system of the "Sammanes," whom the Greek writers mention as a sect of philosophers in India, opposed to the "Brachmanes," and to be the same with those who are now called "Schamans" in Siberia. See SAMANCANS.

Nothing can be more humiliating than the situation to which the Hindoo institutions reduce the female sex. According to the Vedas, the souls of women, as well as those of all individuals of the inferior orders, are condemned to continual transmigrations, till they are regenerated in the bodies of men. The female unfavourable character is amply justified by the representations that occur in the "Institutes of Menu," and the "Code of Gentoo laws." Such being, in the opinion of the Hindoo law-givers, the natural character of women, it is no wonder that little regard is paid to their evidence in courts of justice; nor can we be surprised that the birth of a female is no cause of rejoicing in a Hindoo family. In perfect agreement with such degrading ideas of the female character, the women must always be under the absolute control of men; nor has the subjection of the wife to her husband any bounds. As women are treated in this disrespectful manner, and considered as unqualified to read their sacred books, they are in general very ignorant, so that few of them can either read or write.

The devotion of the Hindoos is supposed to comprise all other duties; but their devotion consists in the frequent repetition of the names and attributes of God. The first thing in their prayer is to pronounce the word om, then excluding all sensible objects, even forbearing to breathe, and to think only on God. This kind of prayer serves for the pardon of sin and purification. This word om, on the pronunciation of which so much is supposed to depend, signifies, according to Sir W. Jones, Brahme, Vishnum, and Siva, or the three powers of creation, preservation, and destruction. This mystical word, he conjectures, may be the Egyptian ai, commonly supposed to mean the sun, and by the ancient idolaters the solar fire. The religion of the Hindoos confunds principally in obligations to the gods, i. e. to the inferior deities, and to the names of their ancestors; and these obligations are accompanied with many frivoulous ceremonies. Moreover, a great part of their religion consists in the austerities to which they subject themselves. Among other things, all fermented or spirituous liquors are forbidden, and they submit to various restrictions with regard to their food. To a genuine Hindoo nothing appears more heinous than the killing, and much more the eating of any thing that had life. The Hindoos are much devoted to pilgrimages for the purpose of bathing in dilant rivers; and they generally prefer the Ganges. In these pilgrimages, they practise singular austerities. Their fasts in honour of different deities are of long duration, and are very strictly observed; and they are thought to have singular efficacy in effecting all fins. See FAIRIES.

It is not uncommon with the Hindoos to devote themselves to certain and very painful death, under the influence of their wretched superstition. They throw themselves on the large iron hooks that are fastened to the wheels of the carriages, which carry the images of their deities in procession. Others lie sprawling on the ground for the wheels to pass over them, and thus bring death. But the most affecting instances of involuntary death are those of the Hindoo women, who learn themselves alive with the bodies of their deceased husbands. In this way of terminating life they indulge the hope of attaining the fame and bliss of happiness with them after death. This is deemed a kind of religious duty, though it is not regarded as of universal obligation. On the deaths of perfons of high rank and celebrity, these victims of superstitious, voluntary, or involuntary, are sometimes very numerous. At the death of a king of Tanjore, no less than 300 of his concubines leaped into the flames, and 400 burned themselves at the funeral of a minque, of Madura. (Maurice's Ind. Antiq. vol. ii. p. 165.) The Hindoo religion, which has been extolled as the mildest of all religions, formerly enjoined and constainted human sacrifice; and Sir William Jones says, that the ancient solemn sacrifice of the Hindoos was that of a man, a bull, and a horse. Among other superstitious notions and practices prevalent among the Hindoos, we may mention their execrable veneration for the cow, and also for the elements of fire and water. Peace of a singular and severe nature were enjoined for killing cows without malice; and if this crime was maliciously committed, it amounted to an expiation of whatever sort. Mr. Wilkins informs us, (Sketches relating to the history and op. of the Hindoos, vol. i. p. 234.) that the Brahmins are enjoined to light a fire at certain times, and that it must be produced by the friction of two pieces of wood of a particular kind; that with a fire thus procured their sacrifices are burned, the nuptial altar flames, and the funeral pile kindled. Their veneration for water, especially that of the Ganges, has already been mentioned; and perfons chuse to die in rivers from an idea, that the foul passing through the water, as it leaves the body, is purified from its impurities.

The Hindoo religion is little, if at all, more exceptionable than the ancient Egyptian, with regard to the extraordinariness and indecency of many of its ceremonies. Instances occur at their pagodas, which we have already noticed under the article BRACHMANS, and which it is needless here to repeat. (See also PAGODA.) Charms are also held in estimation among the Hindoos; a regard to them is authorized by their sacred books, and the practice of incantation is professed by their learned Brahmins. From a veneration for the elements of fire and water, and an opinion of their presiding somewhat of divinity, they have been deemed proper teuls of guilt, or of innocence. Hence has proceeded the trial by Ordeal; which see. With regard to the Hindoo doctrine of a future state, Mr. Dow says, that men first stone for their crimes in hell, where they remain for a space of time proportioned to the degree of their iniquities; then they rise to heaven, to be rewarded for their virtues, and thence they will return to the world to re-animate other bodies. The more learned Brahmins, he says, affirms, that the hell which is mentioned in the "Besang" is only intended as a bag-bearing to the vulgar; agreeably to the doctrine of the Greek philosophers. On the other hand, Mr. Holowell, contrary to all other accounts, which represent future punishment as in all cases finite, says, that whoever shall free himself by violence from this mortal body, shall be plunged in "Ordeles," for ever. According to another account of the religion of Malabar, they who destroy themselves go neither to heaven nor hell, but stroll about, and become what are called "Spirtis," under the power of the chief of the devils. Sometimes they enter into men, and then they become demons, and go about naked and mad, to disturb the neighbourhood, eating grubs and raw flesh. According to the Indians, says Mr. Della Valle, some very wicked men become devils. To conclude our account of the Hindoos, or Gentooos, we observe, that notwithstanding the
the unreasonable griefs which they lay on mere external observances of various kinds, there are not wanting in their writings some excellent moral maxims, similar to many in the books of the Old Testament, which represent every thing of this kind as insignificant, without moral virtue. A peculiar griefs, we find, even too great, is laid on the duties to parents; so as to supercede the obligation, and to depreciate the importance of other duties. Upon comparing the Hindoo sytem with that of Moses, the authority of the former is as apparent as the superior wisdom of the latter. With the Hindoos we perceive the rudiments, and more than the rudiments, of most of the arts and sciences, especially that of astronomy, of which most other nations are wholly ignorant. Yet while the Hebrews made no discoveries in science, they had a religion perfectly rational; and that of the Hindoos was absurd in the extreme. This, surely, is an argument of the internal kind in favour of the divine origin of the Hebrew religion, almost as irresistible as any argument from miracles. From the preceding sketch of the Hindoo religion, we must be led to acknowledge the necessity and utility of a divine revelation.

Those who are desirous of being farther acquainted with the principles, manners, and various institutions of the Gentoo, may consult Holwell's Interesting historical Events, &c. 1765. Dow's History of Hindoosan, 4to. 1768. and the Code of Gentoo Laws. Priestley's Comparison of the Institutions of Moses with those of the Hindoos and other Ancient Nations, 8vo. Northumberland, in America, 1799. For a further account of the religious tenets and practices of the Gentoo, see Brachmann. See also Shastan and Viedman.

GEN-TSING, in Geography. a town of China, in Setalcan, 87 miles N.W. of Hocheii.

GENUFLEXION, of genu, knee, and flexus, I bend, the act of bowing, or bending the knee; or rather of kneeling down.

The Jesuit Rosweyde, in his Onomacular, shews, that genuflexion, or kneeling, has been a very ancient custom in the church, and even under the Old Testament dispensation; and that this practice was observed throughout all the year, excepting on Sundays, and during the time from Easter to Whitsun tide, when kneeling was forbidden by the council of Nice.

Others have shewn, that the custom of not kneeling on Sundays had obtained from the time of the apostles; as appears from St. Irenæus and Tertullian; and the Ethiopic church, ferupulously attached to the ancient ceremonies, still retains that of not kneeling at divine service. The Russiuns esteem it an indenit poffure to worship God on their knees. Add, that the Jews usually prayed kneeling. Rosweyde gives the reasons of the prohibition of genuflexion on Sundays, &c. from St. Basil, Anatillius, St. Julian, &c.

Baronius is of opinion, that genuflexion was not established in the year of Christ 56, from that passage in Acts xx. 36 where St. Paul is expressly mentioned to kneel down at prayer; but Saurin shews, that nothing can be thence concluded. The same author remarks, also, that the primitive Christians carried the practice of genuflexion so far, that some of them had worn caviory in the floor where they prayed: and St. Jerome relates of St. James, that he had contracied a hardnec on his knees equal to that of a camel.

GENUS, in Algebra. The ancient algebraists distributed the art into two genera, or kinds; the logarithmic, and geometric; which see.

GENUS, in Systematic Botany, from genus, a family, implies one or more species of plants, differing essentially in their parts of fruitification from all others, and agreeing together in the general structure of those parts, as well as in one or more peculiar marks or characters. If a genus be perfectly natural and distinct, such characters in the fruitification are accompanied with more or less decided distinctions in the other parts of the plant, as well as in its general habit or aspect. On this principle it is contended by Linneaus and his school, that all genera are, or ought to be, natural, and that the genus ought to give the character, not the character the genus. The same principle is extended to the animal kingdom. Botanically, in the French school, on the contrary, maintain that all such affinities and distinctions are merely arbitrary, tending to facilitate the study of plants, but not at all founded in nature. It is singular that, with such ideas, these philosophers should not only strenuously contend for a natural sytem of arrangement, but object to the Linnean method, whose facility cannot be disputed, merely because it is not natural, terming it in their language esse natura. If genera are not natural, certainly the more comprehensive assemblages, of such genera into orders and classes, can, in no sense, be so. We nevertheless do not scruple to allow, that the principles of all such distinctions are founded in nature, though we readily admit that no system has as yet applied them correctly to practice, even with regard to generic, and far less to classical, distinctions. The latter indeed have been scarcely found capable of definition, or in fo vague a manner as to leave us most in doubt where precision is most wanted: and were it not for that intuitive, or at least practical, perception of affinities and differences, which is, by the French, contended to be inscrutable in judging of genera, we could certainly find at no knowledge of most of the natural orders of these leaves, not worse.

Examples of natural genera, each characterized by an essential character of its own, which distinguishes it, not only from every other genus in its natural order, but from every one hitherto discovered, are found in Quercus the Oak, whose acorn affords such a character; in Upefa, whose quadrangular nut is armed with spines that once conifhit the calyx-leaves; in Paraga, so well marked by the fringes and lucid bards that bore its pecufes; in Solancium with its many-clfted monocotetal corolla, and Eleacarpos, whose polypetalous one is similarly cut; in Geoflas, the only known instance of a papilionaceous flower with a drupa; not to mention a great number besides. Instances of good natural genera, distinguished by some one essential character from all others in their natural order, are found in Echium, whose irregular corulla keeps it distinct from all others of the Ajp ripolfa; Canonadica, known from other genera by its remarkable involucrum; Pimpinella distinguished from its allies by the g1obofe fymbes; Rumanca by the nectariferous pore in the claw of each petal; Pella by the prominent dilated partition of its pouch, extending twice as far as the valves; to which may be added many genera of the clafs Didymiua Gymnapfomia; see Smith's Introd. to Botany, 434. The Linnean leguminos Polypogon affords one of the most perfect examples of a natural class and order, of which all the genera are natural, and so well distinguished in habit, that any person at all observant of plants may know them by their foliage, inflorence, or general appearance, while their fruit affords clear essential generic characters. The natural family of Orchidacea, as arranged by Swartz and Brown, come very near the same point of perfection, but their differences of habit are less obvious. Such inipexes ought to riformulate the philosophical botanist te "go on from one degree of perfection to another."
another," though, like the Christian moralist, he cannot hope to reach the summit.

Lamarck has very well traced the indistinguishable origin, and gradual improvement of generic knowledge among botanists. In an early state of the science, some general associations were formed, though founded on vague and unphilosophical principles. The idea and name of a rose soon embraced many different species, and hence the dog-rose, the white-rose, the damask-rose, &c. were distinguished from one another, and a sort of generic and specific nomenclature arose, finally extended systematically to every plant by Linnaeus. Caspar Bauhin in his Pinax, anno 1623, first distinguished plants under a kind of generic sections, with some mention of the peculiar characters of each; but he did not profit, as he ought to have done, of the great principle first inculcated by Conrad Gersmay, that the parts of the flower and fruit afford the only clue to a scientific distribution of vegetables; a principle to which "the very existence of botany, as a science, is owing." Tournefort at length, adopting this maxim, undertook the arrangement of all known plants into genera, illustrating each by a figure of the parts of fructification, so as to display their distinguishing characters; but it was reserved for Linnaeus to define these characters in words, and thus to perfect the plan of Tournefort, as well as to reform it in many points, and correct some fundamental defects. He extended moreover his improvements to the clear definition and nomenclature of the species, which Tournefort had, without discrimination, merely collected, by their old appellations, under each of his genera, except indeed that he preferred an uniformity in his generic names.

Linnaeus did not at once hit upon the belt manner of defining his genera. His first aim was to describe all the seven parts of fructification in each, so that their differences might appear, which is the plan of all the editions of his Genera Plantaum. At length, in the fifth edition of his Systma Naturarum, published in 1753, he undertook a synoptical table of the short essential characters of the genera, and in the tenth he carried this plan nearly to the perfection in which he left it at his death. It has been adopted, not only by his pupils, but by the followers of his system of classification, and even by the celebrated Jussieu and his scholars, who have widely differed from the learned Swedish; as to other principles of arrangement, and who have certainly not improved upon his style of definition, terminology, or nomenclature. Jussieu indeed has, like Gouan, subjoined to the generic characters taken from the fructification, very useful indications of the habit, which invention of the latter botanist was highly applauded by Linnaeus.

Linnaeus termed the full descriptions in his Genera Plantaum, the natural character of each genus. They ought to accord with every species of each, but in large genera, many species of which have been discovered subsequently to their establishment, this is scarcely possible. Such characters as serve merely to distinguish each genus from every other in its artificial order, in the Linnaean, or any other artificial, ylem, are called specific; these are much better extended to as to include sufficient marks of discrimination between the genera under consideration and every other, and they then become the essential characters thus-named, which ought in every putative botanical work to stand at the head of each genus, or at least to be indicated by a reference. Lamarck, though much disposed to criticize the great Swedish Botanist, and differing totally from him respecting his opinion of natural genera, very candidly allows that "these essential characters are the result of one of Linnaeus's most happy ideas, and cannot but contribute greatly to the perfection of Botany." The same able writer affords entirely to the Linnaean maxim, founded on the good sense and penetration of Conrad Gersmay, that "generic characters ought always to be taken from the parts of fructification alone;" "at least," says Lamarck, "if that be always practicable." When it is not, he would borrow characters from any thing very decided in the habit; nor does he perceive that any inconvenience would result from it. To this we object the uncertainty of such characters, even when taken from what is least exceptable, the inflorescence. Of this no more striking example can be found than the Umbellata, as distributed by Linnaeus after the principles of his friend Artedi, in which, however it may be disfigured by sophistry, the inflorescence makes a leading part. Those who justify, like Lamarck, complain of the errors, unjustly termed by him arbitrary and voluntary errors, which are found in this part of Linnaeus's system, cannot but allow that they all originate from his having had respect to the inflorescence, that is, to the umbels and involucres, instead of the flowers and seeds, which if truly observed are fully sufficient in this, as, we believe, in every other natural order. Indeed the more we consider the subject, the more we are convinced that the inflorescence ought, like every part of a plant, to enter into our general contemplation before we decide upon a genus, it ought never to form a part of the technical or essential character. It is tempting enough to botanists who are not endowed with clear mathematical powers of discrimination and definition, to amplify their generic characters with any thing that, as they suppose, may give them additional strength. But characters, when too long, rather indicate feebleness in themsehves and in their authors, and endanger a return towards barbarism in a science, which has been raised to its present pitch of perfection by the didactic precision and decisive brevity of Linnaeus. S.

Genus, Kind, in Logic and Metaphysics, is that which has several species under it; or it is the origin and radix of divers species, joined together by some affinity, or common relation between them. See Classification.

Genus is a nature, or idea, so common and universal, that it extends to other general ideas, and includes them under itself, the more so as it is founded on a genus, in respect of man and brute; because man and brute agree in the common nature and character of animal; so a right-lined figure of four sides is a genus in respect of a parallelogram, and a rectangle; and so, likewise, is substance in respect of substance extended, which is body; and thinking substance, which is mind.

A good definition, say the schoolmen, consists of genus and difference.

In the general, genus may be said to be a class of a greater extent than species; and which is not convertible therewith: for though we may say, that all body is substance; yet it cannot be said all substance is body.

Add, that whatever may be said of the genus may likewise be said of the species under it, e. g. whatever is said of nari, being, will equally hold of the body.

The schoolmen define the genus logica to be, an universal which is predicatable of several things of different species; and divide it into two kinds: the one, the summum, which is the highest, or most general; and has nothing above it to respect as a genus: the other, the sublateral, which they likewise call m. d. m. a

Genus summum is that which holds the uppermost place in its class, or predicament: or that which may be divided into several species, each whereof is a genus in respect of other species placed below it.

Thus,
Thus, in the predicament of things subsiding of themselves, subsidence has the place and effect of genus sumnum, and is predicated of all the things contained in that class: for Plato, and man, and animal, and even spirit, are properly called subsidence. 

Accordingly there are as many sumnum genera, as there are classes of predicaments, or categories. 

Genus, fulvulum, is that which, being a medium between the highest genus and the lowest species, is sometimes considered as a genus, and sometimes as a species. Thus, bird, when compared with animal, is a species; when to a crow, an eagle, or the like, it is a genus. 

Genus, again, is divided into rerum, remote, where between it and its species there is another genus; and proximum, or next, where the species is immediately under it; as man under animal. 

Genus is also used for a character, or manner applicable to every thing of a certain nature or condition. In which sense it serves to make capital divisions in divers sciences; as music, rhetoric, botany, anatomy, &c. &c. 

Genus, in Magie. See Genera. 

Genus, in Natural History, we understand a certain analogy of a number of species making them agree together in the number, figure, and situation of their parts in such a manner, that they are easily distinguished from the species of any other genus, at least by some one article. This is the proper and determinate sense of the word genus, whereby it forms a subdivision of any class or order of natural beings, whether of the animal, vegetable, or mineral kingdoms, all agreeing in certain common and distinctive characters. See General name, and Classification of Animals. 

Genus, in Rhetoric, is one of the common places or topics, and contains under it two or more sorts of things differing in nature. From this head logicians reason thus: Because every animal is mortal, and man is an animal, therefore man is mortal. (See Genus, in Logic.) But orators make a further use of this argument, which they call ascending from the hypothesis to the thesis, that is, from a particular to a general. As if a person, speaking in praise of justice, should take occasion from thence to commend and dwell the excellence of virtue in general, with a view to render that virtue more eminent. For since every species contains in it the whole nature of the genus to which it relates, besides what is peculiar to itself, whereby it is distinguished from it; what is affirmed of the genus must, of necessity, be applicable to the species. 

Besides, authors distinguish the art of rhetoric, as also orations, or discourses, produced thereby, into three genera, or kinds; demonstrative, deliberative, and judicial. See each term. 

Genus, in Ancient Geography, a town of Italy, in that part of Magna Graecia called Messapia. It was situated a little S. of the road that led to Tarentum. 

Genzano, in Geography, a town of Naples, in Basilicata; 12 miles E. S. E. of Venosa — Alto, a town of Campagna di Roma, in Italy; 3 miles W. of Velcerti. 

Genzingen, a town of France, in the department of the Rhine and Moselle; 5 miles N. E. of Crefzentnach. 

Geocentric, of gea, earth, and centrum, centre, in Astronomy, is applied to a planet, or its orbit, to denote it concentric with the earth; or, having the earth for its centre, or the same centre with the earth. All the planets are not geocentric: the moon, alone, is properly geocentric.

Geocentric latitude of a planet, is its latitude seen from the earth; or the inclination of a line connecting the planet and the earth, to the plane of the earth's (or true) ecliptic. 

Or it is the angle which the subfixed line (connecting the planet and the earth) makes with a line drawn to meet a perpendicular let fall from the planet to the plane of the ecliptic. See Latitude. 

Thus in Plate XIII Afternoon, fig. 116, the angle $\angle T \pi$ is the measure of that planet's geocentric latitude when the earth is in $T$; and the angle $\epsilon \pi$ the measure of it when the earth is in $t$. 

Geocentric place of a planet, is the place wherein it appears to us, from the earth, supposing the eye there fixed: or, it is a point in the ecliptic, to which a planet, seen from the earth, is referred. 

Geocentric longitude of a planet, is the distance measured on the ecliptic, in the order of the signs between the geocentric place and the first point of Aries. 

Geodesia, that part of practical geometry which teaches how to divide, or lay out, lands, or fields, between several owners. 

The word is Greek, γεωδεσια, formed of γεος, earth, and δεσια, divide. 

Geodesia is also applied, by some, to all the operations of geometry which are performed in the field. 

This is more usually called surveying, (which see,) when employed in measuring of lands, roads, countries, provinces, &c. 

Vitalis defines geodesia the art of measuring surfaces and solids not by imaginary right lines, as is done in geometry, but by sensible and visible things: as by the sun's rays, &c. 

Geodes, in Natural History, a genus of crufulated bodies formed into large, and in great part, empty cases, including a small quantity of earthy or arenaceous matter. See Siderochita. 

Of this genus are five known species. 

Geoff, in Rural Economy, a term provincially applied to a mow of hay, corn, &c. See Stack. 

Gen. Ch. Cal. Perianth of one leaf, inferior, bell-shaped, five-cleft half way down; its two upper segments diverging, spreading. Cor. papilionaceous; standard roundish, emarginate, flat, reflexed; wings equal to it in length. obtuse, con-cave; keel compressed, the length and shape of the wings. Stam. Filaments in two fests (single and nine-cleft), the length of the keel; authors roundish. Pyl. German superior; roundish; style awl-shaped; stigma obflute. Peris. Drupa nearly ovate; large, with a longitudinal furrow at each edge. Seed. Nut nearly ovate. Somewhat woody, a little compressed, with a furrow along each edge, acute, of two valves. 

GEO

(Umar; Margr. Bras. 121.)—“Spinous. Leaflets oblong, obtuse.”—Native of Brazil, and the country about Carthagena, in woods on a sandy soil near the sea. Jacquin describes it as an inelegant tree, twelve feet high, with a few spikes on the trunk and larger branches, which are awl-shaped, and generally an inch long. Leaves pinnate, about seven pair, with an odd one, of oblong, obtuse, broad, entire leaflets, on a stalk four inches in length. Flowers nearly as long, white, in long, large, lateral spikes; Flowers a dirty orange, and their scent extremely powerful and offensive. Fruit like that of an almond in its coat, slightly greenish-yellow; the pulp soft, sweet, but of a nauseous smell, yellowish, flaming the hands with a rusty hue, very difficult to wash off. This fruit adheres firmly to the nut, whose kernel is white, mealy and astringent. Jacquin was justly surprised at meeting, for the first time, with a drupa to a papilionaceous flower, but he justly named it, in spite of any preconceived theory.

GEO

3. G. inermis. Swartz. Prod. 106. Woody. Med. Bot. t. 112. (Cabbage-bark tree of Jamaica; Wright in Phil. Trans. v. 67. 507. t. 10—Without spines. Leaflets lanceolate.”—Native of Jamaica and Martinico. A tall tree, whose whole wood is white, and so tough as to be preferred beyond all others for the shafts of carriages. The bark is celebrated remedy for worms in the intestines, administered in a decoction, syrup, powder, or extract, and given in gradually increased doses, till a nausea is produced. The leaves consist of five or six pair, with an odd one, of elliptic lanceolate, pointed leaflets, about three inches long. Flowers light-red, in very large muscule-branched, terminal, downy panicles. Fruit the size of a small plum.

GEOPHREA, OR GEOPROVA, inermis, cabbage-bark tree, or worm-bark tree, in the Materia Medica, is a native of Jamaica. (See the preceding article.) The bark of this tree, which has a mucilaginous and sweetish taste, and a disagreeable smell, was first noticed as a vermifuge by Mr. Peter Duguid (Eff. and Obs. Physic. and Liter. vol. 2. page 264.) But the fullest information concerning this tree, in respect to both its medical and botanical characters, has been communicated by Dr. Wright, who resided a long time in Jamaica. According to his account, the bark of this tree is powerfully medicinal, and its anthelmintic effects have been established in Jamaica by long experience. It may be given in different forms, as in decoction, syrup, powder, or extract; and the manner of preparing, and exhibiting these, are particularly stated by Dr. Wright. For the decoction, take fresh dried or well-preheated cabbage-bark, one ounce: boil it in a quart of water, over a slow fire, till the water is of an amber colour, or rather of a deep-coloured Madeira wine; strain it off, sweeten it with sugar, and let it be used immediately; as it does not keep many days. In order to obtain the syrup, add a double portion of sugar to any quantity of the above decoction. This syrup will retain its virtues for years. The extract is made by evaporating the strong decoction in bulino maris; to the proper confidence; it must be continually stirred, as otherwise the resinous part rises to the top, and on this, probably, its efficacy depends. The powder of well-dried bark is finely made, and looks like sap, though not of equal specific gravity. As this anthelmintic has also a narcotic effect, it is proper to begin with small doses, which may be gradually increased till a nausea is excited, when the dose for that patient is ascertained. A strong healthy grown person may at first take four table-spoonfuls of the decoction or syrup, three grains of the extract, or thirty grains of the powder for a dose. The dose must be diminished for younger persons; and children two or three years of age, may take a table-spoonful of the decoction or syrup, one grain of extract, or ten grains of the powder; and children of a year old, half the quantity. Cold water must not be drawn during the operation of the medicine, as it is apt to occasion sickness, vomiting, fever, and delirium. In this case, the stomach must be washed with warm water, after oil must be administered, and lime juice beverage used plentifully for common drink. The bark purges pretty briskly, especially in powder; thirty or forty grains working as well as 1/2 of a cup of coffee. In this mode of administering it, it does not seem to kill worms so well as in decoction. The cabbage-bark is a valuable remedy when used with proper caution; but some fatal accidents have attended the imprudent use of it, chiefly from overdosing the medicine. Phil. Trans. vol lvii. p. 597.

GEOFFREY OF Monmouth, in Biography, an early historian of our own country, who flourished about the middle of the 12th century, was first archdeacon of Monmouth, and then bishop of St. Asaph. On account of tumults in Wales he quitted his diocese, and obtained the abbacy of Abingdon in commendam. His clergy applied to him to return, which he refused, thinking he might still keep his abbacy; in this he was disappointed, and was left without any preference. As an historian he is known by his "Chronicon Historiae Britanniae." This work has been cenured for its fabulous narrations; the author is, however, entitled to much applause as a polite scholar. His Latin style rises greatly above mediocrity. He was author of many other pieces, among which is a poem on Merlin, which is much commended by Leland. The Chronicon is supposed to be translated from an ancient history in the Welsh language, and it contains a pretended genealogy of the kings of Britain, from the time of Brutus the Trojan, and enumerates upwards of seventy illustrious monarchs before the invasion of Julius Cæsar. This work has been frequently reprinted. Byde. Moreri. New Annual Register, vol. iv.

GEFFROY, ETIENNE FRANCOIS, a physician, was born at Paris on the 13th of February, 1672. His father was an apothecary, and had held the offices of sheriff and confid. While the young Geoffroy was pursuing his studies under his paternal roof, his father held regular scientific meetings, at which Cassini attended with his planisphere, Sébañen with his machines, and Joblot with his magnets, and at which Du Verney performed his experiments, and Homberg his chemical experiments. After an excellent foundation of general science was thus laid, his father sent him, in 1692, to Montpellier, to study his own profession of pharmacy under an experienced apothecary. Here he attended the courses of the most celebrated professors of the university, and afterwards travelled through the southern provinces before he returned to Paris. Already he had acquired considerable reputation; and, although not yet a physician, he was appointed to accompany the duke de Tallard, as his medical attendant, on his embassy to England, in 1698. In London he was much esteemed by Sir Hans Sloane, and other men of science, and was elected a member of the Royal Society. From England he went to Holland; and afterwards to Italy in 1700, with the abbé de Louvain. Natural history and the materia medica were among the principal objects of his inquiries; for his father intended him for his successor in his establishment at Paris, but he aimed at the higher walk of the profession, and with the consent of his father at length took the degree of bachelor in 1702, and that of doctor in 1704. His dissertation was mild
rild and kind to his patients, who, on his outlet in practice, were alarmed by the holens air which his sympath for their sufferings occasioned him to assume; but his reputation soon increased, and he was called in consultation even by the most distinguished members of the profession. In 1709, he was appointed by Louis XIV. to the professorship of medicine, which he filled by the death of Tournefort. In his new office he undertook to deliver to his pupils a complete history of the materia medica, upon which subject he had been for a long time collecting information. He completed his account of the mineral substances employed in medicine, of which he gave a most correct and ample history: and was employed on the vegetable kingdom, which he treated alphabetically, and carried no farther than the article Melia; on the animal kingdom he had not touched; but the whole of what he had delivered in his lectures was found among his papers in good order, and afterwards published. In 1712, he succeeded Fagou as professor of chemistry in the king's garden. In 1726, he was elected dean of the faculty, in the exercise of the functions of which he was led into some active and anxious disputes, which, together with the duties of his professorship, and of his other offices, destroyed his health, which was naturally very delicate. He lingered from the beginning of the year 1730 till the 6th of January, 1731, when he died. Notwithstanding his malady, however, he had the resolution to complete a work, which had been deemed necessary by preceding doctors, but never accomplished; namely, a pharmacopoeia, containing a collection of the compound medicines requisite to be kept by apothecaries, "Le Code Medicamenteux de la Faculte de Paris," of which two editions, enlarged and corrected, were afterwards published. His papers on the materia medica were published under the following title: "Traite de Materia Medica, five, de Medicamentorum simplicium historia, virtute, delectu, et usu," Paris 1741, 3 vols. 8vo, under the inspection of Antoine de Jullien. Several editions have been subsequently published. It was translated into French by Ant. Bergier, who published 7 vols. 12mo. in 1743, and the remainder in 3 vols. in 1750. Arnaud de Nobleville, and Salmor, physicians of Orleans, published a continuation of this work, under the title of "Histoire Naturelle des Animaux," Paris 1756, 1757, 6 vols. 12mo, which is deemed not unworthy to be ranked with the production of Geoffroy, Eloy, Dict. Nat. Hill.

Eff. Ch. Receptacle club-shaped, fleshy, generally compressed, short, with a prominent margin next to the stalk.

This genus of Fungi is founded by Perseon on the Clavaria ophioglosside of other authors, with some different species which resemble it, and which have the appearance of a little tongue, growing out of the earth upon a stalk. He enumerates and defines seven species. His G. kirsium is Clavaria ophioglosside of Sowerby's Fungi, t. 83; his G. glabrum is a smaller and smooth fungus, very like the fruiting spake of the lora. Ophioglossum, except in being nearly black.

GEOGNOSY. See GEOLOGY and MINERALOGY.

GEOGRAPHICAL. Mile is a minute, or the sixtieth part of a degree of a great circle. See DEGREE and MILE.

GEOGRAPHICAL Table. See MAP.

GEOGRAPHY, formed of geo, terra, earth, and graphie, to write; the doctrine or knowledge of the earth, both as in itself, and as to its affections; or a description of the terrestrial globe, and particularly of the known habitable part thereof, with all its subordinate divisions. Geography constitutes a branch of mathematics, of a mixed kind; because it considers the earth, and its affections, as depending on quantity; and consequently, as measurable: viz. its figure, place, magnitude, motion, celestial appearances, &c. with the several circles imagined on its surface.

Geography is distinguished from cosmography, as a part from the whole; this latter considering the whole visible world, both heaven and earth.

From topography and chorography, it is distinguished, as the whole from a part.

Gollitz considers geography as either exterior or interior: but Varenius more justly divides it into general and special: or universal and particular.

Geography, general or universal, is that which considers the earth in general, without any regard to particular countries, or the affections common to the whole globe; as its figure, magnitude, motion, heat, &c. This may be subdivided into absolute geography, which respects the body of the earth itself, its parts and peculiar properties, &c. relative, which accounts for the appearance and accidents owing to celestial causes; and comparative, which explains those properties that arise from comparing different parts of the earth together.

Geography, special or particular, is that which considers the constitution of the several particular regions, or countries, their bounds, figure, &c. with the mountains, forests, mines, waters, plants, and animals, &c. therein; as also their climates, feaons, heat, weather, distance from the equator, &c. and their inhabitants, arts, foods, commodities, customs, language, religion, policy, cities, &c.

Special geography may be subdivided, with regard to the several periods of its progress, into ancient, including a description of the earth, conformably to the knowledge which the ancients had till the decline of the Roman empire; of this kind Cellarius's Ancient Geography is an excellent summary; the geography of the mean age, which extended from the fall of the Roman empire to the restoration of learning; and modern geography, comprehending the actual description of the earth since that time. With regard to its objects and uses, special geography may be divided into naturall, which treats of the divisions and distinctions which nature has made in the surface of the globe, and the complexion, language, &c. of its inhabitants; historical, comprehending the different revolutions which any country or town has undergone; civil, or political, including the government of any country; historical, describing those countries and places that are mentioned in scripture and ecclesiastical history; ecclesiastical, giving an account of the ecclesiastical jurisdiction established and exercised in various countries; and physical, which considers not only the surface of the globe, but also its intrinsic nature and suffrance. Geography is very ancient, at least the special part thereof; for the ancient writers fearfully went beyond the description of countries. Of this kind is the geography which we find in the books of Moses, written about the year 1452 B. C. and that of Homer, in his Iliad and Odyssey, who flourished, according to the Arundelian marbles, 907 years B. C. The geographical knowledge we derive from Herodotus, who flourished about 445 years B. C., is very partial and imperfect. It chiefly relates to certain parts of Asia, and divers others unknown, as well as the northern and western parts of Europe; and also Africa, Egypt, and Libya excepted.

It appears (see Phil. Geog. i. c. 9.) that the early geographers, being destitute of mathematical in-
GEOGRAPHY.

...ments and of astronomical observations, began first to determine the situation of places according to climates; and they were led to fix upon these climates from the form and colour of certain animals which were to be found in those different countries. The appearance of asp, or of those called by them Ethiopians, and of animals of the larger size, such as the rhinoceros and elephant, suggested to them the line of division, where the limits of the Torrid Zone began towards the north, and terminated towards the south. This groover manner of dividing their climates must be considered as the first rude outline of geography in the more iliterate ages of the world. However this be, the Chaldseans and Egyptians, who were distinguished by their skill in geometry and astronomy, were of course the first persons that paid any particular attention to geography; and it is said that the first map was made by order of Scophires I., who conquered Egypt.

This Egyptian king, says Euthathius in his epistle, prefixed to his commentary on Dionysius's περιγραφή, having traversed great part of the earth, recorded his march in maps, and gave copies of his maps not only to the Egyptians, but to the Scythians, to their great advantage, also to have well surveyors among them; and hence some have imagined that they had a map of the Holy Land, when they gave the different portions to the nine tribes at Shiloh. (Joth. xviii. 4. 9.) And Josephus tells us (I. v. c. 1.), that when Joshua sent out people from the different tribes to measure the land, he gave them as companions persons well instructed in geometry, whose skill would prevent their deviating from the truth. We may therefore reasonably premise that a geometrical survey was then made of the Holy Land; though we cannot absolutely determine whether their measuring was only taken down in numbers, or regularly projected and digested into a map.

Besides the method of dividing countries by climates, already mentioned, the Egyptians and Babylonians adopted another, which was that of determining the situation of places, or their distance from the equator, by observing the length of their long and short days. This they performed by means of a gnomon, erected upon a horizontal plane, by which they were enabled to measure the length or shortness of the shadow cast by the gnomon in proportion to the height of the gnomon. For an account of this invention, and of the method of applying it, see Gvozyov.

From the days of Thales, and his immediate successors, who flourished in the sixth century before Christ, geography seems to have received little improvement for 200 years, till the establishment of the famous school of Alexandria; although Pythagoras and his disciples were rightly informed with regard to the true syllem of the world, as they placed the fun in the centre, and ascribed to the earth both its diurnal and annual revolutions. During this period we have an astronomical observation of considerable importance to geography, and the first Greek observation upon record; which is that of Meton and Euctemon, who observed the summer solstice at Athens on a day corresponding to the 27th of June, 432 years B.C. This solar observation would have given them an opportunity of determining the latitude of Athens at the same time, if they had known the simple manner of deducing the conclusion: for the length of the shadow of the gnomon was attentively watched at the moment of the solstice, the proportion of that to the gnomon's height was easily known, by which the angle of the sun's altitude would be given; and though the sun's greatest declination was not then accurately known, yet still the latitude of Athens might have been determined within the limitations of the error respecting the declination. We have reason to believe that Timocharis and Arisillus, who began to observe 295 years B.C., were the first who introduced the manner of determining the position of the sun, according to their longitudes and latitudes, which were taken with respect to the equator. This we know from Ptolemy, who has preferred many of their observations in his "Almagest," and particularly one, which gave rise to the famous discovery of the Precession of the Equinoxes: which see. It was after the precission of the equinoxes was fully established by Ptolemy, that the longitudes and latitudes of the stars were uniformly referred to the ecliptic instead of the equator. It was, therefore, by an easy translation, that Hipparchus would be led to adopt and displace the different parts of the earth according to latitude or longitude: this being only a new application or transposition of that artifice, which had been already so happily introduced in the arrangement of the constellations, and therefore equally proper to be adopted in tracing the meridians and parallels of the earth. Hipparchus must be universally allowed to have first fixed the solid foundation of geography by uniting it to astronomy, and thus rendering its principles self-evident and invariable.

Pliny N. H. i. c. 12., confirms this, when, after mentioning Thales and Sulpicius Gallus, who had both predicted eclipses, he adds, "that Hipparchus had foretold the revolution (of the eclipses) of the sun and moon for 600 years, comprehending the months, days, and hours of different nations, and the situation of places," by which it would seem that the latitudes and longitudes of these places were particularly given. But the fullest and strongest authority for appropriating this invention to Hipparchus, is that of Ptolemy in his "Geography," (i. i. c. 4.) who says, "that Hipparchus was the only author who had given the elevations of the north pole of a few cities, in proportion to the great number that were to be delineated, and such too as lay under the same parallels. &c. &c." And yet it is somewhat remarkable that though latitudes and longitudes were in this manner introduced and pointed out by Hipparchus, yet they were so little attended to till the days of Ptolemy, that none of the intermediate authors, such as Strabo, Vitruvius and Pliny, all of whom minutely described the geographical situation of places according to the length and breadth of the gnomon, have ever given us the least hint of the latitude or longitude of any one place whatever in the language of degrees and minutes.

When the true principles of geography were thus pointed out by this new invention of latitude and longitude, it was no wonder that maps were from thence made to assume a new form of projection essentially different from those in use prior to this period. For the history of the construction of maps, see MAP.

It was a constant custom among the Romans, after they had conquered and subdued any province, to have a map, or painted representation thereof, carried in triumph, and exposed to the view of the spectators. Thus the Romans, as they were the conquerors, became the Surveyors of the world. Every new war produced a new survey and itinerary of the countries where the scenes of action occurred, so that the materials of geography were accumulated by every additional conquest. Polybius, (l. 3. p. 123. ed. Caes.,) when he tells us, that at the beginning of the second Punic war, Hannibal was preparing his expedition against Rome, by crossing from Africa into Spain, and so through Gaul into Italy, says, "that all these places were
were measured or surveyed with the utmost care by the Romans."

Vegetius De Re Mil. (l. iii. c. 6.) has well described the surveys of particular provinces, with which certain Roman generals were regularly furnished before his march. In the preface to his "Cosmographia," further informs us, that Julius Ceasar ordered a general survey to be made of the whole Roman empire by a decree of the senate: selecting for this purpose persons well instructed in every branch of philosophy. The three surveyors were Zenodorus, Theodorus, and Polycletus, each of whom was appointed to survey a different division of the empire. This survey commenced in the consulship of Julius Ceasar and Marc Antony, in the year 44 B. C., and continued for twenty-five years one month and ten days, to the consulship of Quintus Saturninus and Lucius Cina, in the year 19 B. C. The Roman itineraries that are still extant, evidently flew with what accuracy their surveys were made in every province; and Pliny has filled the 3d, 4th, and 5th books of his Natural History with the geographical diliances that were thus measured.

Before the Romans engaged in this business, Necho, king of Egypt, ordered the Phenicians to make a survey of the triumphal arch of Africa, which was accomplished in three years: Darius procured the Egyptian ships, and the mouth of the Indus, to be surveyed. Thales of Miletus, Anaximander his disciple, who is said to have contructed the first map; Democritus, Eudoxus, &c., who made the use of maps common in Greece; Ariffagoras of Miletus, who prefuced to Cleomenes, king of Sparta, a table of brafs, on which he had described the known earth, with its seas and rivers; and other Greeks, availing themselves of the assistance derived from the Chaldeans and Egyptians, proficuated the study and enlarged the extent of this science. It appears that in the time of Socrates geographical maps were used at Athens; for this philosopher admired the pride and boast of Alcibiades, by defining him to point out his territories in Attica in a map: and Pliny relates, (l. vi. c. 17.) that Alexander, in his expidition into Asia, took two geographers, Diancetus and Buton, to measure and defcribe the roads, and that from their itineraries the writers of the following ages took many particulars. Indeed, this may be observed, that whereas most other arts had been fullers by war, the fifth book of the Natural History has been improved thereby. We also learn from Strabo, that a copy of Alexander's survey was given by Xenocles, his treasurer, to Ptolemy the geographer, who, as Pliny informs us, was admiral of the fleets of Seleucus and Antiochus. Hisbook on geography is often quoted both by Strabo and Pliny; and it appears that this author furnished Eratosthenes with the principal materials and authorities for constructing the oriental part of his map of the then known world. For the voyages of Ptolemy's under Seleucus, upon the Cepfan sea, and elsewhere, were a kind of supplement to those measurements given by Buton and Diancetus already mentioned, and by Nearchus and Oceanicetus, the two admirals who were employed under Alexander, and therefore Pliny quotes them immediately after. It appears likewise from the same passage, that Mégat-thenes and Dionysius were two surveyors sent into India by Ptolemy Philadelphus, for the purpose of geography: and their authority was sometimes set in opposition to Patroclus by Hipparchus in his criticism upon Eratosthenes. Later, Strabo, lib. ii. § 1. From the memorable era of Alexander's expedition and conquests and those of his immediate successors, geography began to assume a new face and form. For Eratosthenes, who is de-
time, and which he had actually in his possession. These
confident of various particulars, some of greater and others
of a less degree of authenticity. The principal were the
proportions of the gnomon to its shadow, taken by dif-
erent astronomers at the times of the equinoxes and
solstices; the calculations founded upon the length of the longest
days; the measures or computed distances of the principal
roads contained in their surveys and itineraries, and the various
reports of travellers and navigators, who often
determined the intervals of places by hear-fay and guess-
work. All of these were to be compared together, and
digested into one uniform body or system, and after this, were
converted and translated by him into a new mathematical lan-
guage, expressing their different degrees and minutes of
latitude and longitude, according to the invention of Hippar-
chus, but which Ptolemy had the merit of carrying into
full practice and execution, after it had been neglected for
upwards of 250 years. We have no reason to suppose, that
Ptolemy had in his possession real astronomical observations
sufficient to determine all the longitudes and latitudes which
he has given; in which case we ought always to remember, that
their degrees of accuracy depended upon the veracity of the
fact or suggestion communicated to him, from which they
were afterwards deduced. We have therefore no reason to
be astonished at the multitude of errors that are to be found
in it, when his original materials were so imperfect for ex-
cuting so large a work, as that of fixing the longitudes and
latitudes of all the places, coasts, bays, and rivers of the then
known world; an undertaking, which, even in our days, has
not hitherto been brought to any sufficient degree of ac-
curacy. The mistakes of Ptolemy ought to be regarded
with candour, as they arose from the ignorance of the age
in which he lived, which could give him no better informa-
tion, and not from ignorance or imputation on his own part.
Nevertheless, Ricciolus, Cellarius, Paul Meruh, and Sal-
manius have been too severe in their criticism and censure;
as if they were disappointed in not seeing this science in its
full maturity in the writings of Ptolemy; at a time when it
was evidently but just beginning to advance beyond the verge
of its earliest infancy. They might with equal justice con-
demn the modern geographers for giving no better account
of Nova Zembla, or New Holland, or of those continents
and islands that lie on the northern or southern extremities of
the great South sea towards the two Poles; of which the
knowledge which they could obtain was very imperfect.
The principal mistakes in Ptolemy took their rise from cer-
tain astronomical observations and surveys, which were sup-
pposed to have been made with accuracy in a prior age, and
which were adopted by this great geographer as genuine;
and they have been, for want of better information, copied
by succeeding geographers and inserted in their maps, as
being, in their opinion, of acknowledged and undoubted
authority. These mistakes, thus introduced, maintained
their places in all maps, by a kind of unquestioned prescription,
even to the commencement of the last century, and it
unfortunately happened that these errors related to that part
of the world which was least known to the ancient Greeks and
Romans. Thus, Ptolemy states the latitude of Byzantium to
be 45° 5' instead of 44° 17', the latitude according to mo-
dern observations. In this particular Ptolemy was misled
by Hipparchus, who is mentioned by Strabo (1. i.) as
having visited Byzantium, and made this observation in
person. The latitude of Marcellis, which was supposed to
be under the same parallel with Byzantium, was not, however,
so much mistaken, as by modern observations it has been
found to be 43° 17½ 45'; and allowance being made for the
now acknowledged diminution of the obliquity of the
ecliptic, (see ECLIPSTIC.) the result will be nearer the truth.
Another error of Ptolemy relates to the latitude of ancient
Carthage, which he has placed in 32° 20' instead of 36° 52',
the true latitude according to the best observations. This
error seems to have been copied or translated from a paf sage in Strabo (1. i.), in which it is stated that
at Carthage the gnomon has the same proportion to the
equinoctial shadow, which 11 has to 17, whence by plain
trigonometry we shall have the latitude of 32° 28', very
near that of Ptolemy. The third capital mistake of Ptolemy
relates to the length of the Mediterranean, which is generally
measured from the Straits of Gibraltar to the bottom of the
bay of Ifus, where Alexandria, Scanderoon, now
stands, whose ancient name was Alexandria ad Ilum. The
difference of longitude of Alexandria ad Ilum and Gibraltars,
according to Ptolemy, is 62° 0'; whereas the difference of
longitude between these two places, according to the latest
observations, is 41° 28', and Ptolemy's error is 20° 32'.
This error, which continued in all our maps, more or less,
till the beginning of the last century, took its rise from the
supposed surveys of persons of reputation, recorded by
Strabo. (See DEGREE, EARTH, AND LONGITUDE.) But
to return from this digression:—many valuable geographical
works appeared under Diosclian, Constentinus, and
Maximian, &c. Under the emperor Theodosius the pro-
vincial and itinerary chart or table, since known under the
name of Peutinger, was digested and formed; and the last
work, that ought to be classed with those of the ancients,
was the Notitia Imperii, attributed to Athéus, who lived
between the years 400 and 450 of the Christian era. The
ages of barbarism succeeded the fall of the Roman empire;
and the arts and sciences were obliged to seek refuge and pro-
tection from the Arabians and Orientalists in Asia; the
principal of whom, distinguished by their attention to geo-
ography, were Almamom, caliph of Babylon, and Abuleda,
a Syrian prince. (See DEGREE.) After the revival of
learning in Europe, and particularly during the two last cen-
turies, geography has derived very considerable accretions
from travels, voyages, and a variety of nautical and astro-
nomical observations.

The great misfortune of ancient geography, and which
indeed confined it to such a lingering state of infancy, was,
that the true method of determining with accuracy the dif-
ference of longitudes was a matter of such difficulty, and
remained so long unknown. One of the first attempts to
rectify the length of the Mediterranean was made under the
auces of M. de Périgre in 1635; and he also, with a
direct view of correcting the errors in the longitudes of dif-
ferent places, took particular pains to get observations made
at Marcellis, Aleppso, and Grand Câiro, of an eclipse of
the moon, which happened August the 27th 1635. Before
that time the difference of longitude between Marcellis and
Alessano had been supposed to be 45', but by these obser-
vations it was found only to amount to 30° (the real dif-
fERENCE has been since found to be 51° 58'); so that by this a
very considerable correction was made in the length of the
Mediterranean, by taking off the difference of one whole
hour, or 15'; at once. About this time eclipses of the sun
and moon were thought sufficient to determine the longitudes
of all places with a tolerable accuracy. But, in the event,
the abode astronomers soon found that from these eclipses,
however carefully observed, no clear deduction could be
made of the longitude of any one place to any sufficient de-
gree of exactness. Hence several eminent astronomers,
such as Fourniers, Kircher, and even Ricciolus, who had
collected the observations of no less than 56 eclipses of the
sun and moon, between the years 1560 and 1658, gave up
the
the correction of geography by the application of eclipses of the sun and moon alone, as a fruitful and desperate undertaking. At length recourse was had to the eclipses of the satellites of Jupiter, and they were found essential for the purpose. It was some time, however, before the theory of the secondary planets was regularly reduced to tables; and though Simon Marius first, and after him Baptista Hodierna, composed ephemerides of their motions, yet nothing of that sort was found to be sufficiently accurate for the purposes of longitude, till M. Caffini published his tables of the revolutions and eclipses of the satellites in 1663. The first opportunity of effectually applying this theory to the rectifying of geography was nugatified by M. Caffini, and taken by M. Picard in 1671 and 1672, who, at the observatory of Tycho Brahe at Uraniborg, observed two immersions and three eclipses of the first satellite of Jupiter, which were afterwards compared with the fame observed by M. Caffini at the observatory at Paris. This first experiment gave at once the difference of longitude in the clearest manner beyond the possibility of a doubt; and it likewise afforded the certain prospect of rectifying the whole extent of geography as to longitude, upon principles that were self-evident, and not liable to any mistake whatever. In consequence of this success, M. Picard and M. De la Hire, were immediately employed in correcting the map of France in doing which they were obliged to contract it every where within less boundaries than it was supposed, according to their former maps, to have occupied; inasmuch that Lewis XIV. jealously said, that he found by their journey he had suffered a loss of part of his kingdom. Other academicians determined by the fame method the longitude of the isle of Goree, near cape Verd, on the coast of Africa, and of Guadaloupe and Martinico in the West Indies. And when M. Caffini had corrected his tables of the satellites of Jupiter, and published a new edition of them in 1693, M. Chazelles was sent up the Levant to observe the longitudes and latitudes of Scanderoon, Alexandria, and Constantinople, in order to determine the length and breadth of the Mediterranean, which he executed with great ability.

Since the correction of longitudes has been introduced by means of the satellites of Jupiter, other methods have been also adopted and devised, which are proper and effectual for that purpose; such as the transits of Mercury and Venus over the body of the sun; occultations of the fixed stars by the moon; and since the lunar tables have been improved by M. Mayer and others, another mode equally applicable to this important object, has occurred, by measuring from time to time the exact "differences of the moon from the sun," and "from a fixed star" of the first and second magnitude. In this mode there is a limitation of error, which so far gives a degree of satisfaction, and prepares the way for bringing the point that it thus unsettles to a more speedy and certain determination. Instruments of observation have also been improved; and time-pieces have been contrived, free in a great degree from the error and uncertainty of those that were formerly in use. See Chronometer and Clock. See also Ephemerides and Longitude.

For a fuller account of the history of ancient geography, see the preface to Bertius's edition of Ptolemy's Theatrum Geographicum Veteris, fol. For a brief history of the rise and progress of geography, see Varenius's Geog. and the Introduction to Blair's Tables of Chronology.

The art, however, until now, has been exceedingly defective; as a great part of the globe was then unknown; particularly all America, the northern parts of Europe and Asia, with the Terra Australis, and Magellanic; and as they were ignorant of the earth's being capable of being divided round, and of the torrid zones being habitable, &c.

The principal writings on this art, among the ancients, are Ptolemy's eight books; among the moderns are, Johannes De Sacrobosco De Sphere, with Clavius's comment; Riccioli's Geographia and Hydrographia Reformata; Weigelius's Speculum Terra; Dechales's Geography, in his Mundus Mathematicus; and above all, Varenius's Geography, with Jurin's additions; to which may be added, Lohnecht's Elements and Geographie generally; Sturmiius's Compendium Geographicum; Weigelius's Geography, in his Elementa Mathematica; the preface to M. Robert's Atlas; the introduction to Buchinger's Geography; the works of Duval, Briet, Delisle, D'Anville, Banne, Briache, Mentelle, the Sanfons, Hovann Morvilliers, Martiener; Pinkerton's Geography, Gordon's, Salmon's, and Guthrie's Grammars, &c. Hornii Orb. ant. delineatio, Cluerius, Cellerius, Pomp. Mela, &c. &c.

The reader will find under the appropriate terms in this Cyclopaedia, such information concerning the subjects which they expect, as is consistent with the nature and limits of the work; and it would be, therefore, altogether superfluous to detail them in this place, and, in to doing, to transcribe articles that will be found in their proper places. See Altitude, Amphith, Astrol. Stars, Circles, Climate, Columns, Degree, Earth, Ecliptic, Equator, Equinoctial, Globe, Heptarchy, Horizon, Latitude, Longitude, Map, Meridian, Mountain, Ocean, Parallels, Peripheries, Pole, Sphere, Sphere Oblique, Parallel, and Right, Tropics, Zones, &c. &c. &c.

GEOLOGY, in a strict sense of the word, or Geography, is the science which illustrates the structure, relative position, and mode of formation of the different mineral substances that compose the crust of the earth. This interesting part of mineralogy principally owes its distinguished rank it now holds among the sciences to the celebrated professor of Freyberg, who has however separated geology, or the science to which the above-given definition applies, from geology in the sense in which the word is taken by him; considering the latter as merely a speculative branch of knowledge, and as having nearly the same relation to the former as botany has to natural history. Geology, however, finds its basis in its attempt upon enquiring into the primordial state of the globe, is connected with the art of observing, of collecting, and arranging simple facts in order to ascertain what can be known respecting the relative situation and ages of mineral substances.

Geology (in the sense in which the word is taken by Werner) applies to the higher merit of recording the events of periods, when the planetary system of which the earth forms a part was yet uncreated, and of ascribing causes to effects, and explaining phenomena, before it is ascertained whether they really have existence, or are merely the offspring of fancy and ignorance. The framers of the most of the theories of extravagant notions, known by the appellation of theories of the earths (see Earth and Theories of the Earth,) have been satisfied with a very moderate share of materials for their structures, not to mention that most of them were utterly unacquainted with the nature of the fulminations, the origin of which they undertook to elucidate. Nothing is better calculated to flatter fell-lover than to be mentioned as the creator of a theory of the earth; nothing easier, with a moderate share of imagination and a knowledge of facts, than to frame a new theory sufficiently distinct from all its predecessors to be noticed; and nothing safer than to branch opinions which, though they cannot be proved true by their authors,
are certain to be left unruffled by others. And who would be defruous to waffe his time in refuting, or even remembering, all the theories of the earth now extant? Their number, amounting already to above half a hundred, appears to be daily increasing, and fands in need of clarification to afflit the memory; which, it must be allowed, might be more profitably employed in retaining those general observations which, unconnected with any theory of the earth, or with the Moabie account, have in latter times been presented to the world by a few unprejudiced geognosians. Indeed of premature endeavours of the kind, if the literature of the world is considered, we find the events hinted at in the field of geology, which was by no means intended for a system of geology; we should commence our researches in this field of knowledge with subverting to a careful examination what nature produces as it were under our eyes, such as the manifold alterations that have taken place in the physiognomy of tracts of country almost within the memory of man. How little are we acquainted with the means which nature employs to form the very soil on which we tread, by converting into mould the various animal and vegetable exuviae! How scanty are the genuine observations we possess on the processes of alluvial deposition! on the detritus accumulated at the foot of mountains by means of the decomposition of the various rocks! How little do we know of the processes employed to produce petrifications! and how little of the circumstances under which the latter occur! And yet many of these, and other phenomena within the sphere of human observation, will admit of considerable elucidation, and may lead to very interesting results, by applying to them the found principles of logic and induction. But researches of this nature require we few are inclined to follow upon them, the latent of development, and, what falls to the lot of few observers, a facility of combining and generalizing isolated facts. As an instance both of the difficulty and utility of such researches, if properly conducted, and of the little attention that has hitherto been paid to considerations that should precede any attempt at framing a system of geology, we advert only to the highly interesting discoveries made within the last twelve years, by Cuvier in the neighbourhood of Paris. It is in the confined space of the well known gysps-formation of that part of France that this incomparable naturalist has found the offside remains of no less than fifteen quadrupeds, unlike any species now known to exist. Have these beings, it may be asked, lived in the places where their remains are found, or have they been carried thither? and are they still to be met with living, or to be considered totally or partly destroyed? It is obvious that the cauks to be aligned for the occurrence of these petrifications must be diametrically opposite according as these two simple questions are answered in the affirmative or negative; and yet somebody has thought it worth while to satisfy himself respecting this circumstance; nor have any of the authors of the ten or twelve hypotheses that profits to explain the formation of the basin of Paris, been aware that in a solitary small corner of that basin, namely, at Grignon, there have been discovered by Lamarck, in the course of several years, about six hundred unknown species of shells, besides forty or fifty, of which the prototypes are supposed to be still existing.

We shall not attempt in this article to give a history of geology, which would be nothing more than a chronological exposition of the different theories of the earth (see Earth, and Theories of the Earth), nor is it to naturalists of earlier periods than the latter end of the last century, that we are indebted for genuine observations in this department of science. But much as we owe to the exertions of a Lehman, Deluc, Dolomieu, and particularly Saussure, who, in his celebrated agenda, has proved how well he knew the defiderata of geology, and what remained to be done to give this branch of knowledge all the perfection it is susceptible of; yet the merit of arranging, into a harmonious whole, a multiplicity of materials furnished by an intimate acquaintance with the internal structure of a considerable and highly interlacing tract of country, is entirely due to Werner; who, being afflicted by the most profound knowledge of the various mineral substances, and gifted with a happy faculty of generalizing facts, has produced a system of geology, at once simple and practical, and much more free from gratuitous assumption than all the rest. Professor Jameson is the first in this country who has given an exposition of the Wernerian geology, constituting the third volume of his "Mineralogy." The following is intended only as a brief sketch of that system, fuller details of which will be found under the various articles referred to.

The surface of the globe, considered relative to its inequalities, is divided into highland, lowland, and the bottom of the sea. The highland comprises, 1. Alpine land, composed of mountain groups or series of mountain chains; 2. Mountain chains, formed by a series of those still more simple inequalities, called 3. Mountains: in the former we consider their length, height, form, and connection; the parts of the latter are the foot, the acclivity, and the summit. See Mountains, and Mountain Groups.

Lowland we call those extensive flat tracts which are almost entirely defilite of small mountain groups, which latter, if they occur in them, generally occupy the middle part of the lowland. The principal lowland in Europe is the eastern part of Great Britain, the north of France, the adjacent Netherlands, the northern part of Germany and Sileia, the whole of Poland, the N. W. part of Russia, towards the Ural mountains, a very small part of Sweden, namely, Gothland. The second extensive lowland plain is in the centre of Asia; it is known by the name of the Steppes, and includes almost the whole N. E. part of Russia; some smaller ones are in Arabia. The extent of the lowland of Africa is not known. America has two considerable lowland plains: the one, in its northern half, is traversed by the Mississippi and Missouri, and borders towards the east by the Appalachian mountains, and the West India islands; the second, in South America, borders on the Andes. With these plains of the lowland are connected the river-courses, or river valleys, in which we have to consider the bed of the river and the holm or haugh land, the high and low bank of the river. (See River-courses.) The inconvenient rising ground with which the lowland plains are frequently marked, is, by German geognosians, called Landtucke when they are nearly of equal length and breadth, and Landrücker when they have an elongated form.

The bottom of the sea, or that part of the globe which is still covered by water, may equally be considered with a view to its depressions and elevations; to the latter belong the flat, the rocky bottom, the fossils, reefs, and islands. See Sea and Island.

It is only after a diligent study of the inequalities just pointed out, that we can with advantage undertake to explore the means employed by nature to produce them; and the first step is to proceed to the examination of the physical causes of the flow, but unceasing changes of the globe. Observation teaches us, that most of the elevations and hollows we meet with on the surface of the earth owe their origin to the action of the atmosphere, to that of the ocean, and to volcanic fire. These powerful agents may be considered
confured with regard to their deifying, and, in consequence of this deification, with regard to their forming effects. The waters of the ocean possess the form of the oceanic powers in a superior degree: whole marine districts are known to have been overwhelmed by their irregular action upon the land; but also the regular motion of the sea, ebb and flood tide, currents, &c., considerably contribute to gradually changing the face of the bottom of the sea, and of the shores on which they act. The destroying effects of the atmospheric waters are both mechanical and chemical; the former are produced by long continued rain, water-spouts, ice, snow, thaws, and consequent floods, by which considerable portions of rocks are detached and carried, together with other loose materials they meet, to more or less distant places, according as the bulk of these materials or the nature of the country, either favour or impedes their progress. The chemically destroying effects of water are less rapid, and depend on the solubility of the different rocks over which they flow. The forming effects of water, both mechanical and chemical, are the natural consequence of its destructive effects; examples of the former are sandbanks, changes of coasts, &c. Of the latter, beds of salt, calcareous, and other depositions, &c. See WATERS, ATMOSPHERIC, and OCEAN.

The effects of volcanic fire are destroying by means of the consumption of the inflammable materials, by denudation and fusion; and forming by sublimation, and by the production of lavas and other volcanic ejections, by sublimation, &c. See VOLCANO.

From the detection of the inequalities of the surface of the earth, and of the means employed in forming them, the Wernerian school proceeds to the consideration of the internal structure of the earth, the knowledge of which we derive from a careful examination of the order which nature has followed in the deposition of the mountain masses, and which is principally laid open to view in the clays and sediments produced by floods, &c. in natural caverns and in the interior of mines. By these means we may be acquainted with four different structures, besides that of the simple soil, which is the object of Oryctology: 1. The structure of rocks or mountain rocks; these are either simple (such as limestone, clay-flate, ferpenite), or aggregated, in which case the principal kinds of texture of the component parts are granular, flaty, porphyritic, and amygdaloidal. (See ROCKS.) 2. A more general structure is that of mountain masses; these have either a simply stratified structure, or, when a mountain, or mountain masses are composed of one species of rock divided into parallel tabular masses or strata; or they consist of alternating strata of different rocks, which in this case are called beds. Mountain masses also display what is termed folded structure, in which distinct concordances on a large scale are observable, such as the columnar, the large-globular, and the club-shaped structure, several modifications of which are observed in basalt. Another variety of this structure is called tabular folded structure, which is not unlike stratification. (See MOUNTAIN MASSES, and STRATA.) A still more general structure is 3. The structure of formations, which term Werner applies to a determinate assemblage of several similar and dissimilar rock masses which constitute an independent whole. If the mafs is uniform throughout; if, for instance, it consists entirely of sandstone, granite, &c. it is termed simple, whereas it is a compound formation, if it exhibits dissimilar masses, such as black coal with fletz-trap, &c. Some formations constitute the principal mass of a mountain in which they occur, (gneifs, clay-flate, porphyry, &c.) while others occur only imbedded (porphyry, limestone, &c.); and these beds, if they occur in different principal formations, and always under the same circumstances, notwithstanding the difference of the rocks in which they are found, and if, moreover, they form members of a series of formations, are considered as, and designated independent formations. If the reverse of all this is observed in single beds, they are called subordinate to the formation in which they are imbedded, as is the case with the beds of rock-flate, in the second sand-flate, &c. For forms further distinctions, see RESTORATION, MINERAL.

The most general of the structures we know is 4. That of the crust of the earth, composed of rock formations which cover each other in certain directions, and in a regular manner. As to the original extent of formations in general, Werner terms universal formations those which, without great interruptions, surrounded the whole globe, and thus constitute the greater part of its crust; to it belong almost the whole of the primitive, transition, and flate-formation. Partial formations, on the other hand, are those that appear only in detached spots, and exhibit characters distinct from those of the universal formation; thus the deposition at Wehran in Lusatia (which Werner supposes to be the residuum of a small and partial flood) is composed of sand-flate, limestone, bituminous flake and iron-flate, which all rest on loose flate. The present extent and continuity of formations are so far different from the original, that those called universal often appear broken into small detached portions, frequently resembling partial formations, and they receive different names according to their different shapes, and the situations in which they are found. Other considerations relative to the structure of the crust of the globe are derived from the position and direction of the strata in regard to the fundamental or subjacent rock, from the direction of the strata without reference to the fundamental rock, and from the relation of the outgoings (i.e. the upper extremities of the different strata as they appear at the surface of the earth), to the exterior of the mountain; for which see STRATA.

A comparison of the different classes of rocks, and their succession and stratification, points out the following distinctions. The clays of rocks on which all others rest, and which, on that account, is considered as the oldest, is the class of the primitive rocks, whose texture is often more or less crytalline, a quality denoting previous chemical solution. They comprehend granite, gneifs, micaceous, talc-flake, hornblende-flate, fynite, porphyry, ferpenite, and limestone. These rocks are mostly disposed in conformable and unbroken stratification, each younger stratum with lower level, as is the case with gneifs, mica-flake, and clay-flake, while the granite beneath will sometimes appear to rise up through them, encompased, in various manners, by the other rocks. (See ROCKS, PRIMITIVE.) The rocks next in succession are such as are likewise principally composed of chemical productions, but in which mechanical deposition is observed more abundantly the nearer they approach the following clays; the rocks constituting the intermediate classes are called transition-rocks. Limestone occurs more frequently in this than in the preceding clays; the other rocks it contains are principally green-wacke, grey-wacke flake, and clay-flake. (See TRANSITION-ROCKS.) To this succeeds, as of flatter origin, the clays of flett-rocks, in which the mechanical deposits occur in greater abundance, at the same time that the chemical precipitation disappears. (See FLEET-ROCKS.) The next clays which bear the character of flate more recent formation, is entirely composed of mechanical deposits, such as sand, clay, &c. (See ROCKS, ALLUVIAL.) But, besides these formations, the outgoings of which shoal gradually diminishing levels from the older to the newer, there are two others, the flate...
of which, instead of having parallels with, are superincumbent on, the outgoings of the other strata: they are called the newet flate-trap, and the newer porphyry formation, and are seen to rest both on flate-strata of very recent formation, and on elevated primitive mountains. The former of these formations is particularly interesting, as including rocks, whose origin has been, and continues to be, a subject of controversy between the Neptunists and Volcanists, such as basalt, wacke, &c. all of which, according to Werner, are the results of a deluge, or sudden rise of the water at a more recent period than that within which the flate-strata at first were formed. (See Flate-Rocks and Tra[p-Formation.)

The latter of these great formations, occurring in the same unconformable stratification, consists of porphyry, fymite, and pitch-flone, and is supposed of much older origin than the newest flate-trap formation, with which, however, it agrees in many respects. See Porphyr.

No geologist before Werner has pointed out the succession in which the different suites of formations have been deposited from the water at different periods; a succession which shows the alterations that fluid has undergone with regard to the substances it held, at different times, either chemically dissolved, or mechanically floating. Thus the oldest of the primitive rocks contain metals almost peculiar to them, and which, therefore, were not again deposited in succeeding periods, such as tin, molybdenum, and tungsten; and in several cases, one and the same substance, (such as lime-flone,) though it be repeated at considerable intervals, still adopts in each of them a peculiar character. These suites are, 1. That of the fymite-flone formation, beginning with the primitive crystalline granular limestone, and passing, by indefinite gradations, through the transition, and flate-line flones, into the lowermost links of the series, viz. chalcedony, and calcareous flane. 2. That of the flate formation: its central point is flate-flone (from which this formation derives its name), passing, on one hand, through mica-flone into gneiss, when the flane structure gradually disappars, and a paifage is formed into the oldest member, namely granite; and, on the other hand, through transition-flate, grey-wacke flane, and grey-wacke, into the series of flate-flone, and from thence into the alluvial series, confilling of flane clay, bamm. flane, and gravel. 3. The trap-formation flane passes from the primitive hornblende-flone, characterized by its crystalline nature, and from the primitive green-flone, and green-flone flane, through the transition green-flone, into the flate-flone, formed chiefly of augitoid, and from thence into the newest flate-trap formation, confilling principally of basalt and wacke, unconformably superincumbent on rocks of various antiquity. 4. The porphyry formation flane is equally characteristic in its different members, from old primitive porphyry down to that mentioned above, as of familiar origin with the newest flate-trap formation; the nature of the different members of this formation demand, however, in need of further examination. (See Porphyr.) 5. The gypsum-flone comprises three principal members, the oldest of which, or the primitive gypsum, occurs in mica-flane and clay-flone; the second and third are flate-gypseum, the former of them accompanying the following, or 6. Salt-flone, which comprises two series, one of which occurs only with flate-gypseum, (see Flate-Rocks,) while the other is still forming on the bottom of lakes, &c. (See Rock-Salt.) 7. The coal-flone flane, comprising, besides the independent coal formation, various varieties of coal belonging to the flate-trap formation, and to alluvial depositions; the members of this suite require farther investigation. (See Flate-Rocks, and Coal.) 8. The fpeclai-flone flane is composed, as far as we know, of two members, the first or older occurring with primitive rocks, especially primitive lime-flone, in conformable stratification; and the second or newer, found in an unconformable and overlying position on the older rocks. See Serpentine.

For further particulars relating to the Wernerian systenm of geology, we refer to the articles Strata, Vein, and Waters, Division of.

GEOMANCY, Geomancy, a kind of divination, performed by means of a number of little points, or dots, made on paper at random; and considering the various lines and figures which these points present; and thence forming a pretended judgment of futurity, and deciding any question proposed.

The word is formed of the Greek γη, terra, earth; and μαγία, divination; it being the ancient custom to cast little pebbles on the ground, and thence to form their conjectures; instead of the points afterwards made use of.

Polydore Virgil defines geomancy a kind of divination performed by means of clefts, or grotts made in the ground; and takes the Persian Magi to have been the inventors thereof.

GEOMETRICAL, something that has a relation to geometry.

Thus we say, a geometrical method, a geometrical genius, geometrical likeness, geometrical conduction, geometrical demonstration.

Geometry itself seems to lead us into errors; after once reducing a thing to geometrical consideration, and finding that it answers pretty exactly, we pursue the view, are pleased with the certainty and agreeableness of the demonstrations, and apply the geometry farther and farther, till we often outrun nature.

Hence it is, that all machines do not succeed; that all compositions of music, wherein the concords are the most rigidly observed, are not agreeable; that the most exact astronomical computations do not always foretell the precise time and quality of an eclipse, &c.

The reason is, that nature is not a mere abstruse; mechanical levers and wheels are not geometrical lines and circles; as they are often supposed to be: the taste for tunes is not the same in all men; nor at all times in the same man: and as to astronomy, as there is no perfect regularity in the motions of the planets, their orbits hardly seem reducible to any fixed, known figure.

The errors, therefore, we fall into in astronomy, music, mechanicks, and the other sciences to which geometry is applied, do not properly arise from geometry, which is an infallible science, but from the false use, or the misapplication of it.

GEOMETRICAL Construction of an equation, is the contriving and drawing of lines and figures, whereby to demonstrate the equation, theorem, or canon, to be geometrically true. See Construction of Equations.

GEOMETRICAL Line or Curve, called also algebraic line or curve, is that wherein the relations of the abscissas to the semi-ordinates may be expressed by an algebraic equation. See Curve.

Geometrical lines are distinguished into classes, orders, or genres, according to the number of the dimensions of the equation that expresses the relation between the ordinates and the abscissas: or, which amounts to the same, according to the number of points in which they may be cut by a right line.

Thus a line of the first order will be only a right line: those of the second, or quadratic order, will be the circle, and
GEO

and the conic sections; and those of the third, or cubic order, will be the cubical and Neapolitan parabolæ, the eudoid of the ancients, &c.

But the curve of the first gender (because a right line cannot be reckoned among the curves) is the same with a line of the second order; and a curve of the second gender, the same with a line of the third order; and a line of an infinitesimal order is that which a right line may cut in infinite points; as the spiral, cycloid, the quadratrix, and every line generated by the infinite revolutions of a radius.

However, it is not the equation, but the description, that makes the curve a geometrical one; the circle is a geometrical line, not because it may be expressed by an equation, but because its description is a postulate; and it is not the simplicity of the equation, but the cælein of the description, which is to determine the choice of the lines for the construction of a problem. The equation that expresses a parabola is more simple than that which expresses a circle; and yet the circle, by reason of its more simple construction, is admitted before it.

The circle and the conic sections, if you regard the dimensions of the equations, are of the same order; and yet the circle is not numbered with them in the construction of problems; but by reason of its simple description is preferred to a lower order, viz., that of a right line; so that it is not improper to express that by a circle, which may be expressed by a right line, but it is a fault to construct that by the conic sections, which may be constructed by a circle.

Either, therefore, the law must be taken from the dimensions of equations, as observed in a circle, and so the distinction be taken away between plane and solid problems; or the law must be allowed not to be strictly observed in lines of superior kinds; but that one, by reason of their more simple description may be preferred to others of the same order, and be numbered with lines of inferior orders.

In constructions that are equally geometrical, the most simple are always to be preferred; this law is so universal as to be without exception. But algebraic expressions add nothing to the simplicity of the construction; the bare descriptions of the lines are, where only to be considered; and they alone were considered by the ancients, who joined a circle with a right line. And as there are easy or hard, the construction becomes easy or hard; and therefore it is foreign to the nature of the thing, from any thing else to establish laws about constructions.

Either, therefore, with the ancients, we must exclude all lines beside the circle, and perhaps the conic sections, out of geometry; or admit all according to the simplicity of the description: if the trochoid were admitted into geometry, we might, by its means, divide an angle in any given ratio; would you therefore blame those who would make use of this line to divide an angle in the ratio of one number to another; and contend, that this line was not defined by an equation, but that you must make use of such lines as are defined by equations?

If, when an angle were to be divided, for instance, into 1001 parts, we should be obliged to bring a curve defined by an equation of above a hundred dimensions to do the business; which nobody could describe, much less understand; and should prefer this to the trochoid, which is a line well known, and described easily by the motion of a wheel, or circle: who would not see the absurdity?

Either, therefore, the trochoid is not to be admitted at all in geometry; or else, in the construction of problems, it is to be preferred to all lines of a more difficult description, and the reason is the same for other curves. Hence, the section of an angle by a conchoid, which Archimedes, in his Lemmas, and Pappus, in his Collections, have preferred to the invention of all others in this case, must be allowed to be good; since we must either exclude all lines, besides the circle and right line, out of geometry, or admit them according to the simplicity of their descriptions; in which case the conchoid yields to none except the circle.

Equations are expressions of arithmetical computation, and properly have no place in geometry, except fo far as quantities truly geometrical (that is, lines, surfaces, solids, and proportions) may be said to be equal to others; multiplications, divisions, and such sort of computations, are newly received into geometry, and that apparently contrary to the first design of this science: for whoever considers the construction of problems by a right line and a circle, found by the first geometers, will easily perceive that geometry was introduced that we might expeditiously avoid, by drawing lines, the tediousness of computation.

It should seem, therefore, that the two sciences ought not to be confounded together: the ancients indifferently distinguished them, that they never introduced arithmetical terms into geometry; and the moderns, by confounding both, have lost a great deal of that simplicity, in which the elegance of geometry principally consists. Upon the whole, that is arithmetically more simple, which is determined by more simple equations; but that is geometrically more simple, which is determined by the more simple drawing of lines; and in geometry, that ought to be reckoned best, which is geometrically most simple.

Geometrical Locus, or Place, called also simply locus. See Locus.

Geometrical Medium. See Medium.

Geometrical Method of the Ancients. It is to be observed that the ancients established the higher parts of their geometry on the same principles as the elements of that science, by demonstrations of the same kind; and that they seem to have been careful not to feepose any thing done, till by a previous problem they had shewn how it was to be performed. Far less did they suppose any thing to be done that cannot be conceived, as a line or series to be actually continued to infinity, or a magnitude to be diminished till it becomes infinitely less than what it was. The elements into which they resolved magnitudes were finite, and such as might be conceived to be real. Unbounded liberties have been introduced of late, by which geometry, which ought to be perfectly clear, is filled with mysteries. See Maclaurin's Fluxions, Int. p. 39, sec.

Geometrical Solution. See Curve, Evolvent, and Osculum.

Geometrical Pace, is a measure consisting of five feet. See Pace, and Foot.

Geometrical Plan, in Architecture. See Plan.

Geometrical Plane. See Plane.

Geometrical Proportion. See Geometrical Progression.

Geometrical Proportion, called also absolutely, and simply, proportion, is a humidity or identity of ratios. See Ratio.

Thus, if A be to B, as C to D, they are in geometrical proportion: fo 8, 4, 36, and 15, are geometrical proportions. See Proportion.

Geometrical Solution of a problem, is when the problem is directly solved according to the first principles and rules of geometry, and by lines that are truly geometrical.
The same term is likewise ufed in opposition to all indirect and inadequate kinds of solutions, as by infinite series, &c.

We have no geometrical way of finding the quadrature of the circle, the duplicature of the cube, or two mean proportionals; but mechanical ways, and others, by infinite series, we have.

The ancients, Pappus informs us, in vain endeavoured at the trifecting an angle, and the finding out of two mean proportionals by a right line, and a circle. Afterwards they began to consider the properties of several other lines; as the conchoid, the cissoid, and the conic sections; and by some of these endeavoured to solve those problems. At length, having more thoroughly examined the matter, and the conic sections being received into geometry, they distinguished geometrical problems into three kinds:

1. Plane ones, which, deriving their original from lines on a plane, may be regularly solved by a right line, and a circle.
2. Solid ones, which are solved by lines deriving their original from the consideration of a solid; that is, of a cone.
3. Linear ones, to the solution of which are required lines more compounded.

According to this distinction we are not to solve solid problems by other lines than the conic sections; especially if no other lines but right ones, a circle, and the conic sections, must be received into geometry.

But the moderns, advancing much farther, have received into geometry all lines that can be expressed by equations; and have distinguished, according to the dimensions of the equations, those lines into kinds; and have made it a law, not to construct a problem by a line of superior kind, that may be constructed by one of an inferior kind.

**GEOMETRICAL SQUARE.** See SQUARE.

**GEOMETRICAL TABLE.** See PLAN TABLE.

**GEOMETRICALLY PROPORTIONALS.** See quantities in continual proportion; or which proceed in the same constant ratio; as 6, 12, 24, 48, 96, 192, &c.

They are thus called, in contradistinction to equi-different quantities, which are called, though somewhat improperly, arithmetically proportionals.

**GEOMETRY,** the science, or doctrine of extension, or extended things; that is, of lines, surfaces, or solids.

The word is Greek γεωμετρία, formed of γῆ, γε, earth, and μέτρον, measure; it being the necessity of measuring the earth, and the parts and places thereof, that gave the first occasion to the invention of the principles and rules of this art; which has since been extended and applied to numerous other things; insomuch that geometry, with arithmetic, is now the general foundation of all mathematics.

Herodotus, lib. ii. p. 102, edit. Wicliefmgii, Diodorus, lib. i. § 81, or vol.i. p. 91, edit. Amst. 1746; and Strabo, lib. viii. vol. ii. p. 1130, edit. Amst. 1707, affir. that the Egyptians were the first inventors of geometry; and that the annual inundations of the Nile were the occasion of it; for that river bearing away all the boundary landmarks of men's allotments, and covering the whole face of the country, the people, say they, were obliged to distinguish their lands by the consideration of their figure and quantity; and thus, by experience and habit, formed themselves a method, or art, which was the origin of geometry. A farther contemplation of the draughts of figures, of fields thus laid down, and plotted in proportion, might naturally enough lead them to the discovery of some of their excellent and wonderful properties; which speculation continually improving, the art became gradually improved, as it continues to do to this day. Josephus, however, seems to attribute the invention to the Hebrews: and others, among the ancients, make Mercury the inventor. Polyb. Virgil, De Invent. Lib. i. cap. 18.

From Egypt geometry passed into Greece, being carried thither, as some say, by Cleans; where it was much cultivated and improved by himself. Pythagoras, Anaxagoras, of Clazomene, Hippocrates of Chios, and Plato, who made his acquaintance with the necessity of geometry in order to the successful study of philosophy by the following inscription on the door of his academy, "μαθητήν τοῦ διδάσκαλος μου, θεᾶ, let no one ignorant of geometry enter here." Plato, conceiving that geometry was too mean and restricted an appellation for this science, substituted for it the more extensive name of "Menfuration;" and others have denominated it "Pantometry." Other more general and comprehensive appellations are more suitable to its extent, more especially in the present advanced state of the science; and accordingly some have defined it as the science of inquiring, inventing, and demonstrating all the affections of magnitude. Proclus calls it the knowledge of magnitudes and figures, with their limitations; as also of their ratios, affections, positions, and motions of every kind. About fifty years after Plato, lived Euclid, who collected together all those theorems which had been invented by his predecessors in Egypt and Greece, and digested them into fifteen books, entitled the Elements of Geometry; and those propositions which were not satisfactorily proved, he more accurately demonstrated. (See Euclid.) The importance of these ancient writers, whose works are extant, is Apollonius Pergeus, who flourished in the time of Ptolemy Euergetes, about two hundred and thirty years before Christ, and about a hundred years after Euclid. (See his biographical article.) The third ancient geometer, whose writings remain, is Archimedes of Syracuse, who was famous about the same time with Apollonius. (See Archimedes.) We can only mention Eudoxus of Cnidus, Archytas of Tarentum, Philolaus, Eratosthenes, Aristarchus of Samos, Dinostratus, the inventor of the quadratrix, Menechmus, his brother and the disciple of Plato, the two Arifteus, Conon, Thradeus, Nicoteles, Leon, Theudins, Hermodius, and Nicomedes, the inventor of the conchoid; besides whom, there are many other ancient geometers, to whom this science is indebted.

The Greeks continued their attention to geometry even after they were subdued by the Romans. Whereas the Romans themselves were so little acquainted with this science, even in the most flourishing time of their republic, that they gave the name of mathematicians to their politicians, and formed us, to those who pursued the chimeras of divination and juridical astrology. Nor were they more disposed to cultivate geometry, as we may reasonably imagine, during the decline, and after the fall of the Roman empire. The case was different with the Greeks; among whom we find many excellent geometers since the commencement of the Christian era, and after the translation of the Roman empire. Ptolemy lived under Marcus Aurelius; and we have extant the works of Pappus of Alexandria, who lived in the time of Theodosius; the commentary of Euclides, the Aetabonite, who lived about the year of Christ 530, on Archimedes's
GEOMETRY.

Archimedes's menurbation of a circle; and the commentary on Euclid, by Proclus, who lived under the empire of Amphilochus.

The consequent inundation of ignorance and barbarism was unavailing to geometry as well as to the other sciences; and those few who applied themselves to this science, &c., were calumniated as magicians. However, in those times of European darkness, the Arabians were distinguished as the guardians and promoters of science; and from the ninth to the fourteenth century they produced many astronomers, geometers, geographers, &c. from whom the mathematical sciences were again received into Spain, Italy, and other parts of Europe, somewhat before the beginning of the 15th century. Some of the earliest writers after this period are Leonardus Pifenus, Lucas Paciolius or de Burgo, and others between 1400 and 1500. After this period appeared many editions of Euclid, or commentaries upon his Elements; e.g. Oronautus Fineus, in 1530, published a commentary on the first five books; as did James Peletarius in 1537; and about the same time Nicholas Tartaglia published a commentary on the whole 15 books. We might here mention other editions or commentaries; such as those of Commandine, Clavius, Dillingly, Schebelinus, Harlins, Dalpambris, Ramus, Herigon, Stevinus, Saville, Barrow, Taucet, Dechales, Figan, Scarabrough, Keill, Cansy, Wills, Mercator, &c. (See Elements.)

At the revival of letters, there were few Europeans capable of translating and commenting on the works of the ancient geometers; and geometry made little progress till the time of Des Cartes, who published his Geometry in 1637. However, not to mention all those who extended geometry beyond its elementary parts, such as Theodorus in his Spheres, Sermius in his sections of the cone and cylinder, Kepler in his Nova Stereometria, &c.; and in 1635, Bonaventure Cavalierius, an Italian of the order of Jesuits, published his "Geometry of Indivisibles." Torricelli his "Opera Geometrica." Viviani, his "Divinationes Geometricae," "Exercitatio Mathematica," "De Locis Solidis," "De Maximis et Minimis," &c.; Viete, his "Effectio Geometrica," &c.; Gregory St. Vincent, in 1647, published his treatise, entitled "Quadratura Circuli & Hyperbolae," a work abounding with excellent theorems and paradoxisms; and Pafcal, about the same time, published his treatise of the cycloids. Geometry, as far as it was capable of deriving aid and improvement from the arithmetic of infinites, was indebted to the labours of Fothermat, Barrow, Newton, Cavalierius, Bruncker, J. Gregory, Huygens, and others, to whom we may add Newton and Leibnitz. (See Planets.) But for Isaac Newton contributed to the progress of pure geometry by his two treatises, "De Quadratura Curvarum," and "Enumeratio Linearum Tertii Ordinis" (see Curve); and still farther by his incomparable and immortal work, entitled "Philosophiae Naturalis Principia Mathematica," which will always be considered as the most extensive and successful application of geometry to physics. We cannot forbear transcribing in this place the compliment paid to this author by the editors of the Encyclopædia, who, considering the various monuments of the author's genius, and that he had made his principal discovery before the age of twenty-four, are tempted, they say, to suberect to the words of Pope, that the sagacity of Newton alloweth even celestial intelligences, and that they contemplate him as a being occupying a kind of middle station between man and themselves; or at least they cannot forbear exclaiming, hanc hominem quidem praedit? what a distance does there subsist between one man and another? The modern geometers are innumerable; and the names of Cotes, Macfarlin, R. Simson, T. Stewart, T. Simpson, &c., not to mention living writers, will always be held in esteem and veneration by those that are devoted to the study of geometry and mathematics. See Elements.

The province of geometry is almost infinite; few of our ideas but may be represented to the imagination by lines, upon which they become of geometrical consideration: it being geometry alone that makes comparisons, and finds the relations of lines.

Astronomy, music, mechanics, and, in a word, all the sciences which consider things susceptible of more and less, i.e. all the precise and accurate sciences, may be referred to geometry; for all speculative truths consisting only in the relations of things, and in the relations between those relations, they may be all referred to lines. Consequences may be drawn from them; and these consequences, again, being rendered tenable by lines, they become permanent objects, which may be constantly exposed to a rigorous attention and examination: and thus we have infinite opportunities both of enquiring into their certainty, and pursuing them farther.

The reason, for instance, why we know to distinctly, and mark so precisely, the concords called octave, fifth, fourth, &c., is that we have learnt to express sounds by lines, i.e. by chords accurately divided; and that we know, that the chord, which sounds octave, is double of that with which it makes a key; that the fifth is the fequalalterate ratio, or as three to two; and fourth, the half. The ear itself cannot judge of sounds with such a nice precision; its judgments are too faint, vague, and variable, to form a science. The finetest-tuned ear cannot distinguish many of the differences of sounds; whence many musicians deny any such differences; as making this sense their judge. Some, for instance, admit no difference between an octave and three dittones; and others, none between the greater and lesser tone; the comma, which is the real difference, is inestimable to them; and much more the schisma, which is only half the comma.

It is only by reason, then, that we learn, that the length of the chord which makes the difference between certain sounds being divisible into several parts, there may be a great number of different sounds contained therein, useful in music, which yet the ear cannot distinguish. Whence it follows, that had it not been for arithmetic and geometry, we should have had no such things as regular fixed music; and that we could only have succeeded in that art by good luck, or force of imagination; i.e. music would not have been any science founded on incontrovertible demonstrations: though we allow, that the times composed by force of genius and imagination, are usually more agreeable to the ear than those composed by rule. So, in mechanics, the heaviness of a weight, and the distance of the centre of that weight from the fulcrum, or point by which it is sustained, being susceptible of plus and minus, they may both be expressed by lines: whence geometry becomes applicable to this science; in virtue of which, infinite discoveries have been made, of the utmost use in life.

Geometrical lines and figures are not only proper to represent to the imagination the relations between magnitudes, or between things susceptible of more and less; as spaces, times, weights, motions, &c. but they may even represent things which the mind can no otherwise conceive, e.g. the relations of incommeasurable magnitudes.

It must be observed, that this use of geometry among the ancients was not strictly scientifical, as among us; but rather symbolical: they did not argue, or deduce things and properties unknown, from lines; but represented or delineated by them things that were known. In effect, they were not united as means or instruments of discovering, but as images or characters, to prefer, or communicate, the discoveries that were already made.
GEOMETRY.

"The Egyptians," Gale observes, "used geometrical figures, not only to express the generations, mutations, and destructions of bodies; but the manner, attributes, &c. of the spirit of the universe, who, diffusing himself from the centre of his unity, through infinite concentric circles, pervades all bodies, and fills all space. But of all other figures they most affected the circle and triangle; the first, as being the most perfect, simple, and capacious, &c. of all figures: whence Hermes borrowed it to represent the divine nature; defining God to be an intellectual circle or sphere, whose centre is everywhere, and circumference nowhere." See Kirch. Ædip. Egyptiac. and Gale Phil. General lib. ii. cap. 2.

The ancient geometry was confined to very narrow bounds, in comparison of the modern. It only extended to right lines and curves of the first order, or conic sections; whereas in the modern geometry new lines of infinite and higher orders are introduced.

Geometry is commonly divided into four parts, or branches: planimetry, altimetry, longimetry, and stereometry; which see respectively.

Geometry, again, is distinguished into theoretical or speculative, and practical.

The first contemplates the properties of continuity; and demonstrates the truth of general propositions, called theorems.

The second applies those speculations and theorems to particular uses in the solution of problems.

Geometry, speculative, again may be distinguished into elementary and sublime.

Geometry, elementary or common, is that employed in the consideration of right lines, and plane surfaces, and solids generated from them.

Geometry, higher, or sublime, is that employed in the consideration of curve lines, conic sections, and bodies formed of them.

The writers who have cultivated and improved geometry may be distinguished into elementary, practical, and those of the sublimer geometry.

The principal writers of elements, see enumerated under Elements.

Theorems of the higher geometry are Archimedes, in his books De Sphaera, Cylindro, and Cerculi Dimenfione; as also De Spiralibus, Conoidibus, Spharimidibus, De Quadratura Parabolae, and Ararenus: Kepler, in his Geometria Nova; Cavalieri, in his Geometria Indivisibilibus; and Torricellus, De Solidis Spharicis; Pappus Alexandr. in Collectionibus Mathematicis: Paulus Galenus, in his Mechanica and Statices; Barrow, in his Lechiones Geometricae; Huygens, De Cerculi Magnitudine; Bullialdus, De Lineis Spiralibus; Schooten, in his Exercitationes Mathematicae; De Billy, De Proporcionis Harmonicis; Lalo- vera, De Cycloide, For. Er. Com. a P. Habenfein, in Diatome Circulorum; Viviani, in Exerc. Mathematic. de Formatione & Mensura Figurem; Bap. Palmi, in Geomet. Exercitation. and Apoll. Pergamus, De Sectione Rectiorum.

For practical geometry, the fullest and completest treatises are those of Mallet, written in French, but without the demonstrations; and those of Schwenter and Cantzlerus, both in High Dutch. In this class are likewise to be ranked Chavias's: Tresquet's, and Oszan's Practical Geometries; De la Hire's École des Arpenteurs; Reinhold's Geometria; Hartman Beyer's Stereometria; Vogt's Geometria Subterranea; all in High Dutch: Hallius, Galileus, Goldmannus, Schefelt, and Oszan, on the Sector, &c.

The science of geometry is founded on certain axioms, or self-evident truths (see Axiom); it is introduced by definitions of the various objects which it contemplates, and the properties of which it investigates and demonstrates, such as points, lines, angles, figures, surfaces, and solids,—lines again are considered as straight or curved; and in their relation to one another, either as inclined or parallel, or as perpendicular:—angles as right, obtuse, acute, obtuse, external, vertical, &c..—figures, with regard to their various boundaries, as triangles, which are, in respect of their sides, equilateral, isosceles, and scalene, and in reference to their angles, right-angled, obtuse-angled, and acute-angled; as quadrilaterals, which comprehend the parallelogram, including the rectangle and square, the rhombus and rhomboid, and the trapezium and trapezoid; as multilaterals or polygons, comprehending the pentagon, hexagon, heptagon, &c.; and as circles:—and as solids, including a prism, parallelopipedon, cube, pyramid, cylinder, cone, sphere, and the frustum of either of the latter. We shall not here attempt to compile a complete system of geometry, as it would occupy too many of our pages, in a work from its nature protracted and enlarged to a very great extent; and this is the less necessary, because the reader will find under the titles above enumerated, and others naturally connected with and derived from them, the most essential and important principles of geometry, together with the operations that are founded upon them; and because any person who is desirous of acquainting himself with the science of geometry, in its whole extent and application, will have recourse to one or other of those numerous treatises, in a more enlarged or more comprehensive form, which may be easily procured. The Elements of Euclid by Dr. R. Simpfon occur first to our recollection, and deserve particular recommendation; but the object of the geometrical student may be satisfactorily attained by T. Simpson's Geometry, or by the treatises of Emerson, Hutton, Bonycastle, Leslie, &c. &c.

But as the analytic method of treating geometrical questions is less generally known, and as complete treatises on this subject are only to be found in foreign works, we have been induced to devote a considerate space to this part of the science; the following treatise is chiefly compiled from the "Feuilles d'Analyle" by Monge, which were published in separate portions for the use of the polytechnic school, and afterwards collected in a quarto volume. A more elementary work has lately been published by Garnier in octavo, to which the reader is referred.

GEOMETRY, ANALYTIC.—Method of defining the position of a point in a plane.

A point M (Analysis, Plate VIII., fig. 1) is defined by referring its position to two lines, as A Y, A X, generally at right angles to each other, but they may be inclined at any given angle.

If M Q is drawn perpendicular to A Y, and M P perpendicular to A X, then Q M, M P, are called the co-ordinates of the point M; the distance of the point from A Y is usually denoted by x, and its distance from A X by y.

The point of intersection of the two lines A Y, A X is called the origin of the co-ordinates, and the lines A Y, A X, produced each way to Y' and X' are called axes.

If the distance of the point M from these axes is given, viz. M Q = a, M P = b, then x = a, y = b is the equation to the point M.

But if the point M be situated in any other of the angles, the sign of a and b will vary, and these variations are governed by the same rules, as the lines and coines in trigonometry.

For instance, if the point M is situated in the angle Y X A,
The equation of $M'$ is $x = -a$, $y = +b$

$M''$ is $x = +a$, $y = -b$

If the point M is situated on the line $AX$, then $y = c$,

If it is situated on $AY$, then $y = c$; $y = l$, and at the point $A$, $x = a$, $y = 0$.

The point M may likewise be defined by the length of the line $AX$, and by the angle $\varphi$, which it makes with the axis $X$. If this length be expressed by $x$, and the angle by $\varphi$, $x = \cos \varphi$, $\varphi = \lambda$.

$A^2$ being the number of degrees contained in the angle $\varphi$, and $c$ the value of $x$.

The position of a straight line is determined in a plane by the co-ordinates of two of its points, or by the co-ordinates of a single point, and the angle which it makes with one of its axes: the latter is the method most usually employed.

If the line passes through the origin of the axes, its position is determined by the angle which it makes with the axis $X$.

We shall first consider the case as being the most simple. Let it be proposed to determine the relation between the co-ordinates of any point in such a straight line.

Let us take, for example, a point $M'$ (fig. 2) whose abscissa is $A' = x'$, $P'M' = y'$; the co-ordinates, like those of the other points, making an angle $\alpha$ with each other, which is that of the axes, we shall have this equation:

$$y' = \frac{\sin \alpha}{\sin (\alpha - \beta)} x'$$

and for the points $M'$, $M''$, &c. whose co-ordinates would be $x'$, $y'$, $x''$, $y''$, &c. we have

$$y'' = \frac{\sin \alpha}{\sin (\alpha - \beta)} x'' = \frac{\sin \alpha}{\sin (\alpha - \beta)} y''$$

If $x, y$ represent the co-ordinates of any point in $AX$, the general equation will be

$$y = \frac{\sin \alpha}{\sin (\alpha - \beta)} x$$

thus $x$ becoming successively $x'$, $x''$, &c. $y$ changes to the corresponding ordinates $y'$, $y''$, &c. The formula (1) is called the equation of a straight line; it is the algebraic enunciation of a property common to all its points, and is thus written;

$$y = \frac{\sin \alpha}{\sin (\alpha - \beta)} x$$

The abscissa $x$ being given, the ordinate $y$ may be deduced.

When the angle $\alpha$ varies, the line changes its position, turning round the point $A$; thus another ordinate $y$ corresponds to the same abscissa $x$, which also happens if $\alpha$ varies, but it is essential to observe that for all the values both of $\alpha$ and $x$, the equation (2) retains the same form.

If it should be required to find the relation between the co-ordinates of the point of a straight line $P'LI'$, situated in any manner whatever, then if $AL$ be drawn parallel to $R'LI'$, passing through the point $A$, we shall observe that for the same abscissa $x$ every ordinate of $AX$, for example; $P'M$ will be augmented by the same quantity $AR = b$; let $y + b$ be represented by $y$, equation of $R'LI'$ will be according to (2):

$$y = \frac{\sin \alpha}{\sin (\alpha - \beta)} x + b$$

Here $a$ and $b$ give the position of the straight line $R'LI'$; when these quantities are known it may be constructed, but if the line is subject to any particular conditions, as to pass through a given point; or to either parallel or perpendicular to a given line; or to pass through two points, &c. $x$ and $b$ become unknown quantities, as we shall see immediately.

Let us suppose the quantities $a$, $\beta$, and $b$ given, and that it is required to construct the straight line $y = \frac{\sin \alpha}{\sin (\alpha - \beta)} x + b$; the problem is reduced to finding two of these points; we endeavor to find the points in which the line cuts the two axes $AX$, $AY$, (fig. 3,) the intersection $R$ being the only point of the line in which $x = 0$, and $A'$ the only point of the same line in which $y = 0$; we suppose, successively, $x = 0$, $y = 0$, and we shall find $y = b = AR$, $x = \frac{\sin (\alpha - \beta)}{\sin \alpha} b = AR'$; taking, then, $A'R'$ on the other side of the point $A$, if it is negative, and $A R$ on $A Y$ if it is positive, the line drawn through these two points will be that belonging to the equation.

If the equation to a straight line $y = x + 1$ be supposed to refer to two axes, making an angle of $45^\circ$ with each other, and the inclination, $\alpha$, which the line makes with the axis $X$ be required; since $\frac{\sin \alpha}{\sin 45^\circ} = 1$, $\frac{\sin \alpha}{\sin 45^\circ} = \frac{1}{\sqrt{2}}$; hence, $\tan \alpha = \frac{1}{\sqrt{2}}$.

The value of $b$ remaining constant, the line takes every possible position round the point $R$ (fig. 2), for every possible angle from $0$ to $360^\circ$; for every angular value of $\alpha$, taken with every ordinate $b$, positive and negative, the line will pass through every point of the axis $Y$. There exists, therefore, no line in the same plane that cannot be defined by equation (3), provided $b$ and $\alpha$ are taken of a proper value.

The angle $\beta$ has no influence on the position of the line; the variations of this angle only affect the inclination of the ordinate upon the axis of the abscissa; so that for the same abscissa, the ordinate corresponds with another point in the line.

But, in general, the co-ordinates are supposed rectangular; in which case, $\sin \beta = \sin 90^\circ = 1$, and $\sin (\alpha - \beta) = \cos \beta$; and equation (3) becomes $y = x \tan \alpha + b = \alpha x - b$, $a$ being supposed the angle $\alpha$.

When the straight line passes through the origin of the co-ordinates, its equations becomes $y = 0$.

This equation is constructed by taking $AP = 1$ = radius, and then setting off from a scale of equal parts the value of $a$ on the perpendicular $PM$ (fig. 4); $PM$ being equal to $a$, $M$ will be a point in the required line.

We may now construct the equation $y = x + 1$, $y = -x - 1$.

These two lines cut the axis $AX$ in the same point, and are situated similarly to it, one above, the other below; they are moreover perpendicular to each other.

The straight lines $y = -x - 1$, $y = -x + 1$, are parallel, because they make the same angle with the axis, having the same tangent, $-1$.

The straight line expressed by the equation $y = x \sqrt{-1} - 1$ is reduced to a point on the axis $Y$ below the origin, and distant from it by a quantity equal to unity, since, for every other value than zero, the ordinate is imaginary.
GEOMETRY.

The problems relating to a straight line, in general, require the unknown quantities \(a\) and \(b\) to be determined, so that the required line \(y = ax + b\) (1) may have the required position.

Problem I.

To make a straight line pass through two given points. Let the co-ordinates of one point be \(x', y'\), and of the other \(x'', y''\); which signifies that when the ordinate generally expressed by \(y\) becomes \(y'\), the ordinate becomes \(x'\); and when \(x = x''\), \(y = y''\), we have therefore two equations of condition:

\[ (2) \quad y' = ax' + b, \ y'' = ax'' + b \]  

from whence we obtain

\[ a = \frac{y'' - y'}{x'' - x'}, \quad b = \frac{y' - y''}{x'' - x'} \]

and by substituting for \(a\) its value,

\[ b = \frac{y'' - y'}{x'' - x'} \]

or equation (2) may be subtracted from equation (1), then \(y - y' = a (x - x')\); and substituting for \(a\) in this equation its value, as found above, the equation of the line required is

\[ y - y' = \frac{y'' - y'}{x'' - x'} (x - x') \]  

in which equation we may observe that when \(x\) becomes \(x'\), the second term becomes equal to zero, and \(y = y'\).

If \(y' = y''\), then \(y = y'\), or \(y = y''\), which denotes that the line is parallel to the axis \(AX\).

If \(x' = x''\), \(a = \frac{y'' - y'}{x'' - x'} = \infty\), the angle which the line makes with the axis is in this case a right one.

Problem II.

To determine the distance between two given points in a plane.

The distance \(M' M''\) (fig. 5) is the hypotenuse of the right-angled triangle \(M'M'' m'\); if it be represented by \(D\), then

\[ D = \sqrt{M'M''^2 + M''m'^2} = \sqrt{(y'' - y')^2 + (x'' - x')^2}. \]

If the point \(M\) is at the origin, the co-ordinates \(x', y'\) become nothing, and the preceding expression is reduced to \(D = \sqrt{(y'' - y')^2 + (x'' - x')^2}\) = \(x'' - x'\), because then the equation to the straight line is \(y = ax\); and as this also takes place when \(x = x'', y = y'', \) it gives \(y' = ax''\).

Problem III.

To determine the equation of a straight line that shall pass through a given point, and be parallel to a given straight line.

These two conditions are sufficient to determine the two elements of position for the required straight line.

Let the equation of the given straight line be \(y = ax + b\) (1), and that of the line required \(y = a x + b'\) (2); \(a\) and \(b\) are, in this case, given, and \(a'\) and \(b'\) required. Let \(x', y'\) denote the co-ordinates of the given point; and since this point is in the required line, we have \(y' = a x' + b'\) (3). From equation (1) take equation (3), and \(y - y' = a' (x - x')\) (4).

The same result may be obtained by taking the value of \(b'\) in equation (3), and substituting it in equation (2). Moreover, the two straight lines being parallel, their trigonometric tangents are the same, that is, \(a = a'\); introducing this condition in equation (4), that of the line required will be

\[ y - y' = a (x - x') \]  

Substituting this value of \(y'\) in equation (5), we obtain

\[ y = ax + b \]

which shows that the required line and the given line are identical, which is, indeed, self-evident.

Problem IV.

The equation of two straight lines being given to determine the angle which they make with each other, (fig. 6.) The angles \(\angle A, \angle B\), are given, the angle to be found is \(\angle C\). Put \(C = \alpha, \angle B = \alpha'; \angle C = \beta, \angle A = \beta'; \angle A = \alpha = \beta\); then \(x' = x + V, \) and \(V = a' = \infty, \) or \(\frac{1}{\tan V} = 0; \) therefore \(x' = a' = \infty, \) and \(a' = a\).

Problem V.

To determine the equation of a straight line that shall pass through a given point, and make a given angle with a given straight line. Let the equation of the given line be

\[ y = ax + b \]  

and that required \(y = a' x + b' \) (2); \(a\) and \(b\) are given; whence \(a'\) and \(b'\) are to be determined by the conditions of the problem. Since the required line is to pass through a point whose co-ordinates are \(x', y'\), its equation must satisfy the conditions, that \(x = x', \) and \(y = y', \) hence

\[ y' = a x + b \]  

and consequently

\[ y - y' = a (x - x') \]

\(b'\) being determined from one of the conditions, it remains to determine \(a'\) from the other. Now, \(m\) being the trigonometric tangent of the angle which the two lines make with each other (by Problem IV.), \(m = \frac{a' - a}{1 + a' a}; \) hence \(a' = \frac{a + m}{1 - m a}. \)

Substituting this value of \(a'\) in equation (4), we have the equation required,

\[ y - y' = \frac{a + m}{1 - m a} (x - x') \]  

Problem VI.

To determine the condition under which three lines, drawn from the angles of a triangle, will meet in a single point. Let \(x', y'\) ; \(x'', y''\) be the co-ordinates of the angles \(D, B, C\) (fig. 7.); the equations to the three straight lines drawn from these angles will be \(y - y' = a' (x - x')\); \(y - y'' = a'' (x - x'')\); \(y = y'' = a'' (x - x''); \) \(a', a'', a''\) being the trigonometrical tangents of the angles which they make with the axis \(AX\). For these lines to meet in a point, it is requisite that the same system of values of \(x, y\) should satisfy for the three equations, which is equivalent to the finding the value of \(x\) and \(y\) by means of any two of them, and making the result of their substitution in the third
third equal to zero; we thus find the equation of condition
\[a'(y' - y'') + a''(y'' - y') + a'''(y' - y') + a''''(x' - x'') = 0 (1)\]
and of extremity and \(x''\) which will satisfy this equation (1) suffices.

Let us suppose the required straight lines to be perpendicular
to the sides of the triangle, and then examine if, upon this
supposition, the equation (1) suffices.

The equation to \(B C\) is \(y - y'' = \frac{x'' - x'''}{x'' - x'} (x - x')\); and that of the straight line drawn through \(D\) is \(y - y' = a' (x - x'')\).

Now as this latter straight line should be perpendicular to
the other, the equation \(a' + r = c\), from whence \(a' = - \frac{r}{a}\)
ought to exist between the trigonometrical tangents; but
here \(a = \frac{y'' - y'''}{x'' - x'}\); therefore \(a' = \frac{x'' - x'''}{y'' - y'}\).

The straight line drawn through \(B\) being perpendicular to
\(D C\), we conclude
\[y - y'' = \frac{y - y'''}{x - x'} (x - x'), y - y''' = a'' (x - x'');\]
and the straight line drawn through \(C\) being perpendicular
to \(D B\), we have likewise
\[y - y'' = \frac{y - y'}{x - x'} (x - x'), y - y' = a''' (x - x''');\]
and likewise
\[a'' (x' - x'') = \frac{(x' - x'')(x' - x''')(x' - x''')}{(x' - x') (x' - x'') (x' - x''')} \cdot \frac{y' - y''}{y' - y''} = \frac{N}{D} (y' - y'' + y'' - y' + y''' - y'') = 0 (2).
\]
If the sides \(B C\) be placed on the axes of the
abscissae, which does not alter the general nature of the results,
and also the point \(B\) be placed at \(A\), then \(y'' = c\), \(x'' = c\),
\(y''' = c\), and the equation of condition is simplified, and becomes
\[a'' (x' - x'') + a''' (x' - x''') + a''' (x' - x''') = 0 \Rightarrow (3).\]
In this position of the triangle, \(a' = - \frac{x'' - x'''}{x'' - x'}\) \(y'' - y''' = c \), and in fact the line \(D\) is perpendicular to
\(A X\). If in equation (3) the terms which do not include \(a'\)
be suppressed, to express that the tangent is infinite, the
equation (3) will be simplified, and expressed, thus,
\[a'' (x' - x'') + a''' (x' - x''') = c; \text{ and dividing by } a', a'' (x' - x'') = c; \text{ but in this position of the triangle, we have } a'' = \frac{y'''}{y''} \text{ and } a''' = - \frac{x'''}{y''} \text{ and by these values the preceding equation is satisfied.}\]

If from the points \(A\) and \(C\) lines be drawn to the middle
of the opposite sides, the trigonometrical tangent will be
\[a'' = \frac{y''}{x'' - x'}, a''' = \frac{y'''}{x'' - x'} \text{ The substitution of these values in equation (3) will give, after dividing by } y,\]
\[a' \left\{ \frac{x'}{y'' + y'} + \frac{x''}{y''' + y''} \right\} = \frac{y'' + y'}{y''' + y''} \text{ from which we deduce } a'' = - \frac{2 y''}{y''' + y''} \text{ and as this is found to be the value of } a', \text{ that is, of the trigonometrical tangent of the angle which the line } D \text{ makes with } A X, \text{ it may be concluded that this third line is parallel through the point of intersection of the two first.}\]

Let us consider the perpendiculars drawn from the centres
of the sides of the triangle \(A D C\) (fig. 9), the equation
of \(A D\) is \(y = \frac{y''}{x''} x\); of \(D C, y - y'' = \frac{y''}{x''} (x - x')\);
of \(A C, y = c\).

The equations of the perpendiculars to these sides are:
\[y - \frac{1}{2} y' = - \frac{x'}{y'} (x - \frac{1}{2} x'),\]
\[y - \frac{1}{2} y' = - \frac{x'' - x'''}{y''} \left( \frac{x - x' + x''}{2} \right),\]
\[x = \frac{x''}{2}.\]

The equation of condition may be immediately formed by
determining \(x\) from the two first equations, and employing
this value in the third; which ought to be satisfied by this
substitution if there exits a point of intersection; now \(x\) is
found \(= \frac{x''}{2}\); therefore these three lines intersect in a
point.

Method of determining the Position of a Point in Space.—
Let \(A X, A Y, A Z\), be three straight lines reciprocally
perpendicular to each other (fig. 10) at the point \(A\); each
of them will be perpendicular to the two others, because it
is perpendicular to two straight lines which intersect at its
extremity in this plane. Therefore each of these planes will
be at the same time perpendicular to the two others. These
three planes form then the three faces of a rectangular parallelepiped, and the solid trihedral angle \(A\). Let us suppose
the planes \(Z A X, Z A Y, Y A X\) in real position, for example, before the first plane, to the right
of the second, and above the third; and let us suppose perpendiculars \(M M', M M'', M M''\), from the point \(M\) to
to these three planes; these perpendiculars will measure the
shortest distances from the point to each of these planes.
The planes drawn through the perpendicular \(M M', M M''\),
\(M M''\) and \(M M''\), and the point \(M\) will be the summit of the solid
trihedral angle \(M\) opposite to the angle \(A\).

The distance \(M M'\) from the point \(M\) to the plane \(Z A X\)
is in real length equal to \(M M'\) or \(A M'\); the distance \(M M''\)
from the same point to the plane \(Z A Y\) is \(M M''\) or \(A M''\).
and the distance from this point to the horizontal plane  
Y A X is M M" or M' M or A M'. Thus these distances  
may be found on the fixed lines A Y, A X, A Z.

The points M', M", M'" of the perpendiculars let fall  
from the point M on the planes to which we refer the  
position of this point, are called the vertical and horizontal  
projections of the point M, vertical in considering M' and M",  
and horizontal when considering M'".

Two of these projections are sufficient to determine the  
point; for if from each of them perpendiculars be drawn to  
the plane which contains it, they will intersect in the point  
M.

The third projection evidently results from each of the  
two others, as may be seen in the figure.

Since the position of a point is completely defined by  
its distance from three rectangular planes of projection, if we  
denote the distance of the point from the plane Y A Z by x,  
the distance of the same point from the plane Z A X by y,  
and its distance from the plane Y A X by z, and the linear  
values of these distances be denoted by a, b, c, its position  
will be indicated by x = a, y = b, z = c; the formula  
x = a, y = b, z = c denote the position of the projection M;  
the formula y = b, z = c, denote the projection M' ;  
and the other two projections are sufficient, as we have seen,  
to find the position of the point; and these two syllables  
of formulae comprise the data of the three distances.  
When the point is in the horizontal plane, z = 0, and its position  
is fixed by x = a, y = b; when it is in the plane Z A X,  
y = 0, and its position is determined by x = a, z = c; and  
if in the plane Y A Z we have x = 0, and it is defined  
y = b, z = c.

For a point situated on the axis A X, we have z = 0,  
y = 0, x = a.

If on the axis A Y, z = 0, x = a, y = b; and if on  
A Z, x = 0, y = 0, z = c.

At A, the origin of these distances, we have x = 0,  
y = 0, z = 0.

Every point in the plane, M M', m M'" and consequently  
the plane itself, is denoted by x = a, because a is the common  
distance of each of its points from the plane Y A Z.

The plane M M' m M'" is denoted by y = b, and the  
plane M M" m M'" is described by z = c.

The position of these three planes gives that of the point M,  
and consequently this position will be defined, as we have  
already said, by the formula x = a, y = b, z = c.

Of the Equations of a Straight Line.—The equations of  
a straight line, situated in space, express the relation which  
exists between the co-ordinates x, y, z, of any point whatever  
of the straight line: let us suppose it projected on the  
planes x = 0, and y = 0; these projections will be other  
straight lines, which have for their equations

\[ x = a + \alpha , \quad y = b + \beta ; \]

eliminating z from these equations, the resulting equation  
is \[ b x - a y = \alpha b - \beta a , \]
which belongs to the plane x y.

The equations of these three projections, of which any  
two imply the third, are the equations of the straight line,  
whose position in space depends on the constant quantities  
\( \alpha \), \( \beta \).  

To obtain the co-ordinates of the points in which this  
straight line cuts the three planes, we must make successively  
the three values \( x = 0 \), \( y = 0 \), \( z = 0 \), which gives \( x = \alpha \),  
y = \beta , for the point where the straight line intersects the plane  
x y; \( z = \frac{-\beta}{b} x = \frac{-\alpha}{b} + \alpha \) for the point where it  
intersects x z; \( z = \frac{-\beta}{b} x = \frac{-\alpha}{b} + \beta \) for the point  
where it meets the plane y z.

The straight line, whose equation is \( x = a + \alpha , y = b + \beta \),  
has, with the axes \( x \), \( y \), an angle, whose tangent is \( \theta \): it cuts the  
axis x in a point, whose distance from the origin of the co-  
ordinates is equal \( x \), since, if in this equation \( z = 0 \), \( x = a \).

If two straight lines are situated in the same plane;  
suppose that \( x = a \), \( y = b \); and to the second \( x = a + \alpha , y = b + \beta \);  
for these straight lines to be parallel, \( a \) must = \( a \), and, if perpendicular,  
\[ 1 + a a' = 0 \text{ or } a a' = \frac{1}{a}. \]

The equation of two straight lines, situated in space,  
being, for the first,

\[ x = a + \alpha , \quad y = b + \beta ; \]

\[ x = a + \alpha , \quad y = b + \beta ; \]

the equation, which expresses that these lines meet each other,  
is \( (x - \alpha) (y - b) = (b - b) \), which results  
from the elimination of \( x, y, z \), from the four equations  
of the two straight lines.

Problems relating to a Straight Line.—Prob. I. To draw  
a straight line through a point given in space parallel to  
a given straight line. Let the three rectangular co-ordinates  
be \( x, y, z \); \( z \) being first supposed vertical; and let the  
equations of the projections of the straight line on the  
vertical planes be \( x = a + b, y = a + b + \beta \); then the equation  
of the horizontal projection will be \( y = y' = a (y - y') \)

\[ (\text{of any two imply the third}). \]

Prob. II.

To determine the equation of a straight line drawn  
through two points given in space. Let \( x', y', z' \), be the  
co-ordinates of the first point; \( x'', y'', z'' \), the co-ordinates of the second,  
the straight line passing through the first point, its equations  
will be of the form

\[ x = a' = a (z - z') \quad y = y' = b (z - z') \]

(See Prob. I. of the plane.)

And since it must pass through the second, its equations  
must also be

\[ x = a'' = a (z - z'') \quad y = y'' = b (z - z'') \]

\( a \) and \( b \) being eliminated from their equations, the four equations  
of the required straight line will be

\[ x (x' - z') + (x' - y') (z' - z'') \]

\[ y (z - z') = z (z' - y') + y'' z'' \]

The co-ordinates of the two extremities of a right line  
being \( x', y', z' \), for the first, and \( x'', y'', z'' \), for the second,  
the distance between the extremities, or length of the line  
joining them, will be

\[ \sqrt{(x' - x'')^2 + (y' - y'')^2 + (z' - z'')} \]

Prob. III.

To determine the conditions requisite for two straight  
lines to meet in space. Let the equations of one straight  
line be

\[ x = a + \alpha \]

\[ y = b + \beta \]

and of the other

\[ x = a + \alpha' \]

\[ y = b + \beta' \]

T. 

GEOMETRY.
GEOMETRY.

To determine the relation between the elements of position $x, y, z$ of a point, $x', y', z'$ of the same point, and the co-ordinates $a, b, c$ of the plane on which it lies, we eliminate $x, y, z$ from the four equations, and $(a' - a) (b' - b) - (b' - b) (c' - c) = 0$.

The condition for parallelism is expressed by the equations $a = a', b = b'$.

**Problem I.**

Problems relating to a straight line and a plane.—To draw a plane parallel to a given plane, let the equation to the given plane be

$$z = a x + b y + c$$

and that of the plane required

$$z = a' x + b' y + c'$$

then the condition of parallelism will be

$$a = a', b = b'.$$

**Problem II.**

To determine the equation of a plane which shall pass through three given points, let the co-ordinates of the given points be $1, 2, 3$, the three following conditions are obtained:

$$A x + B y + C z + D = 0$$

from which are deduced the following equations:

$$A = (y' - y'') (z'' - z') + (z' - z'') (x' - x'),$$

$$B = (x' - x'') (z'' - z') + (z' - z'') (y' - y'),$$

$$C = (x' - x'') (y'' - y') + (y' - y'') (x' - x').$$

The three co-efficients to determine are $A, B, C, D$ from the three equations.

If the triangle formed by the straight lines joining the given points be projected on the three planes $x, y, z$, the areas of these respective projections will be $A, B, C$, and it will be shown that $D$ is the area of the solid of a pyramid whose base is the triangle in space, and whose vertex is the origin of the co-ordinates.

Let a triangle, as $x'y'z'$, represent the projections of the above three points on the plane $x, y, z$, the area of the trapezium $x'' x' y'' z''$ will be $\frac{1}{2} (x'' - x') (y'' - y')$.

The area of the trapezium $x'' y'' x' z''$ will be $\frac{1}{2} (y'' - y') (z'' - z')$.

and that of the trapezium $x' y' x'' z''$ will be $\frac{1}{2} (z'' - z') (x'' - x')$.

From the sum of the two first surfaces, take the left, the difference will be the area of the triangle projected on the plane $x, y, z$, which will be $t = \frac{1}{2} A + B + C$.

In the same manner, $t$ and $t''$ representing the projections of the same triangle on the planes $y, z, x$, we have

$$t = \frac{1}{2} A, t'' = \frac{1}{2} C.$$

**Problem III.**

Given the co-ordinates of a point, and the equation of a straight line, to find the equation of the plane which passes through the straight line and the given point, let $x', y', z'$ be the co-ordinates of the point:

$$\begin{cases} x = a x' + b y' + c \\ y = b z' + \beta \\ z = (x - \alpha) = \gamma (y - \beta) \end{cases}$$

be the equations of the line.
GEOMETRY.

Then since the plane, whose equation is required, passes through the given point, and likewise through the point where the given line intersects the plane \(xy\), the co-ordinates to which points are \(z = c\), \(x = a\), \(y = b\). If the equation to the plane be supposed

\[ z = Ax + By + D, \]

in which \(A, B, D\), are co-efficients to be determined, then

\[ z' = A'x' + B'y' + D'. \]

Now the right lines being in the plane, suppose them both moved parallel to themselves till the plane passes through the origin of the co-ordinates, the equations there will be, for the straight line,

\[ x = ax, \quad y = bz, \quad ay = bx \]

and for the plane \(x = A'x + B'y\).

In this position the line is still in the plane, so that their co-ordinates are still the same; therefore,

\[ z = Ax + Bz, \quad 1 = A + B. \]

The equations 1, 2, 3, will give \(A, B, D\) in terms of \(x, y, z\), and the equation of the plane will be

\[ (x - a)x' - b)z' - \beta) = (y - b)(y' - \beta) \]

\[ + (z - z) = (a + c) \]

PROBLEME IV.

Given the equations of a straight line, and of a plane to determine the conditions; 1st, that the plane and straight line may be rectangular; 2d. The co-ordinates of the points where they meet; 3d. The distance of this point from a given point, either in the given line or given plane.

When a plane is perpendicular to a straight line, the intersection of the plane with the co-ordinates planes and the projection of the line with these same planes are perpendicular to each other.

Let \(x = ax + a_1, y = bz + b_1\) be the equations to the line; \(z = Ax + A_1, y = C_1\) to the plane; the equations to the intersections of this plane with the rectangular planes of \(ax, y\), are \(z = Ax + A_1, y = C_1\); but the plane being perpendicular to the line is \(A = -a, B = -b\); therefore the equation of a plane perpendicular to the line, is \(x + by + z = C\); combining this equation with those of the straight line \(x = ax + a_1, y = bz + b_1\) we may deduce the values of \(a, b, z\) the co-ordinates of the point in which the straight line intersects the plane. If the plane is given by the equation \(ax + by + z = C\), and the perpendicular to it be required to be drawn through a point whose co-ordinates are \(x, y, z\), the equation to this perpendicular will be \(x - x' = a(z - z)\), etc., \(y - y' = b(z - z)\); and the equation to the plane may be expressed in this form

\[ a(x - x') + b(y - y') + c(z - z) = C - a'x' - b'y' - z'. \]

Let \(x, y, z\) be the co-ordinates of the point of intersection of the plane and perpendicular, then

\[ z = z' + \frac{C - a'x' - b'y' - z'}{1 + a + b} \]

\[ Z = y' + \frac{b(C - a'x' - b'y' - z')}{1 + a + b} \]

\[ X = a(C - a'x' - b'y' - z') \]

The length of the perpendicular comprised between the points \(X, Y, Z\) and the points \(x', y', z'\) is

\[ \sqrt{(X - x')^2 + (Y - y')^2 + (Z - z')^2} \]

\[ = \frac{C - a'x' - b'y' - z'}{\sqrt{1 + a + b}^2}. \]

Hence it follows that the perpendicular drawn from the origin of the co-ordinates upon a plane whose equation is

\[ ax + by + z = C \]

is expressed by

\[ \frac{C}{\sqrt{1 + a^2 + b^2}} \]

Having the equations of a straight line \(\begin{cases} x = a + a' + \beta \frac{a}{\sqrt{1 + a^2 + b^2}} \\
y = b + b' + \beta \frac{b}{\sqrt{1 + a^2 + b^2}} \end{cases} \)

the equation of a plane perpendicular to this line drawn through the point \(x', y', z'\) is

\[ a(x - x') + b(y - y') + c(z - z') = 0. \]

To find the co-ordinates of the point of intersection of the plane, the equations of the straight line may be put under the following form:

\[ x - x' = a + x - x' \]

\[ y - y' = b + y - y' \]

Let \(X', Y', Z'\) be the co-ordinates of the points of intersection; then

\[ Z = a(x = a) + b(y - y') + c(z = c) \]

\[ Y = b(x - x') + b(y - y') + c(z - z') \]

\[ X = a(x - x') + b(y - y') + c(z - z') \]

Substituting for \(X', Y', Z'\) their values in the radical

\[ \sqrt{(X - x')^2 + (Y - y')^2 + (Z - z')^2} \]

an expression is obtained for the perpendicular contained between the given point of the straight line, of which the co-ordinates are \(X, Y, Z\). When the straight line passes through the origin of the co-ordinates, its equations become \(x = a, y = b, z = c\), and the radical

\[ \sqrt{X'^2 + Y'^2 + Z'^2} \]

expresses the length of the straight line, drawn from the origin of its coordinates to its intersection with the perpendicular let fall from the point \(x', y', z'\), upon it; then upon this supposition \(x = a, y = b, z = c\) and

\[ Z' = a(x + b(y + c) + z) \]

\[ Y' = b(z') \]

\[ X' = a(z') \]

therefore

\[ \sqrt{X'^2 + Y'^2 + Z'^2} = \sqrt{a + b + c} \]

This expression is used in finding the angle which two straight lines make with each other.

4. The equation of two straight lines being given to find the angle which they make with each other, and if they do not intersect each other to determine the angle which their projections form on a plane that is parallel to them; let the equations of the given lines be

1st. \(\begin{cases} x = a + a' \\
y = b + b' \end{cases} \)

2d. \(\begin{cases} x = a + a' \\
y = b + b' \end{cases} \)

If they intersect, the angle which they make is equal to the angle formed by their parallels which pass through the origin of the co-ordinates; the equations to their parallels being \(\begin{cases} x = ax, y = by \end{cases} \). If a point be taken on the second parallel, whose co-ordinates are \(x', y', z'\), and a perpendicular be let fall from this point to the first parallel; then in the right-angled triangle formed by this perpendicular, and by the straight lines drawn from the origin of the co-ordinates to the two extremities of this perpendicular, there are given the two sides which contain the required angle; the expression for one of these sides is

\[ \sqrt{a^2 + b^2} \]
\[ \sqrt{x'' + y'' + z''}, \] the other, as found in the preceding problem, is \[ \frac{a x' + b y' + z'}{\sqrt{1 + a^2 + b^2}}. \]

Therefore the cosine of the required angle is equal to
\[ \frac{a x' + b y' + z'}{\sqrt{1 + a^2 + b^2}} \times \frac{v = a z', y = b z'}{\sqrt{1 + a^2 + b^2} \times \sqrt{v^2 + y^2 + z^2}}. \]

But \( v = a z', y = b z' \); therefore the cosine of the angle formed by the two given straight lines
\[ \frac{1 + a d' + b b'}{\sqrt{1 + a^2 + b^2} \times \sqrt{1 + a^2 + b^2}}. \]

It appears from this expression, that when two straight lines have for their equations
\[
\begin{align*}
1 & \quad x = a z, y = b z, \\
2 & \quad x = a' z, y = b z,
\end{align*}
\]

if they are perpendicular to each other, the following equation of condition will be obtained, \( 1 + a d' + b b' = 0 \), which equation may be likewise obtained directly as follows: the plane perpendicular to the first line drawn through the origin of the co-ordinates, has for its equation \( a x + b y + z = 0 \). But the perpendicular to the first straight line must be contained in the plane perpendicular to it; therefore the equations to the perpendicular \( x = a z', y = b z' \), and the equation of the plane must fulfills at the same time; therefore \( 1 + a d' + b b' = 0 \). The angle of the two planes may be thus determined. Let \( a x + b y + z = C \), \( a' x + b' y + z = C' \) be the equations of the planes; these make with each other the same angle as the straight lines which are perpendicular to them, and which are drawn from the origin of the co-ordinates; therefore the cosine of the angle formed by the given planes, is
\[ \frac{1 + a d' + b b'}{\sqrt{1 + a^2 + b^2} \times \sqrt{1 + a^2 + b^2}}. \]

If the angle be required between one straight line and one plane, then suppose a parallel drawn to the given lines through the origin of the ordinates, and a perpendicular to the plane, the angle contained between these two straight lines will be the complement of the required angle; and consequently, the cosine of the angle of the two lines is the sine of the angle required.

The straight line, whose equations are \( x = a z, y = b z \), makes with the axes \( x, y, z \), angles whose cosines are
\[
\begin{align*}
\sqrt{\frac{x^2 + y^2 + z^2}{a^2 + b^2}} & \quad \sqrt{\frac{a^2 + b^2}{1}} & \quad \sqrt{\frac{a^2 + b^2}{1}} & \quad \sqrt{\frac{x^2 + y^2 + z^2}{a^2 + b^2}}.
\end{align*}
\]

\( a x + b y + z = 0 \) be the equation of the plane; \( a x + b y + z = C \), \( a' x + b' y + z = C' \) be the equations of the planes; these make with each other the same angle as the straight lines which are perpendicular to them, and which are drawn from the origin of the co-ordinates; therefore the cosine of the angle formed by the given co-ordinates, planes, then \( t = \frac{1}{2} A, t' = \frac{1}{2} B, t'' = \frac{1}{2} C \); \( D \)

being the solidity of a pyramid which has for its base the triangle \( T \), and whose vertex is the origin of the co-ordinates. Now the solidity of this pyramid is the product of the base

\( T \), by one third of its height \( \frac{\sqrt{A^2 + B^2 + C^2}}{6} \); therefore
\[ \frac{D}{6} = \frac{T}{3} \times \frac{\sqrt{A^2 + B^2 + C^2}}{6}, \]

or substituting for \( A, B, C \) their values \( 2 t, 2 t', 2 t'' \), \( T' = t' + t + t'' \).

If \( s \) be the area of another triangle whose projections are \( x', y', z' \), and situated in the same plane as the triangle \( T \); then
\[ \frac{s}{2} = \frac{s'}{2} + s'' \]

Since \( T = \frac{1}{2} \sqrt{A^2 + B^2 + C^2} \), \( T = \frac{1}{2} \sqrt{A^2 + B^2 + C^2} \), \( T'' = \frac{1}{2} \sqrt{A^2 + B^2 + C^2} \), which signifies that any triangle is

to its projection on one of the co-ordinate planes, as radius is to the cosine of the angle which the plane of the triangle makes with the plane on which it is projected.

But the triangle \( S \) being in the same plane with the triangle \( T \),
\[ \frac{t}{s} = \frac{t'}{s''} = \frac{t''}{s''}, \]

therefore if the equation \( T' = t' + t'' + t''' \), be put under this form, \( T = \frac{t}{s} \times t + \frac{t'}{s'} t' + \frac{t''}{s''} t'' \); it will become
\[ T = t + t' + t'' \]

T' \( s + s' + s'' \); but \( T' = T + T' s + T'' s'' \). If \( T' = t'' + t'' t' t'' t'' \); therefore \( (T' + S)^2 = (t + t' + t'')^2 \); hence if any plane figure whatever be projected on three rectangular planes, the square of the area of this figure will be equal to the sum of the squares of the areas of its three projections.

\section*{Problem V.}

Two straight lines being given, to determine the equations to a straight line perpendicular to each of them on which their shortest distance is measured; \( z \); to find an expression for this shortest distance.

The direction of a plane parallel to two straight lines given in position may be determined: this plane being drawn through any point in space, we may conceive a plane to pass through each of the straight lines perpendicular to it: the intersection of these two planes is evident the line required, therefore the equations to these planes will be those of the line required.

Let \( x = a z + z, y = b z + z, \) be the equations to the first line, it will meet the plane \( x y \) in a point \( P \), of which the co-ordinates are \( z = \alpha, y = \beta, x = \alpha \).

The second straight line having for its equations \( x = a' z + a', y = b' z + b', \) it meets the plane \( x y \) in a point \( P' \), whose co-ordinates are \( z = \alpha, y = \beta, x = \alpha \).

The equations of the planes drawn through the points \( P \) and \( P' \) parallel to the two given straight lines are of the form
\[ \frac{1}{2} \Lambda (x - \alpha), \]
\[ A (x - a) + B (y - b) + z = 0 \quad \text{(a)} \]
\[ A (x - a') + B (y - b') + z = 0 \quad \text{(c')} \]

A and B being two constant quantities determinable by the following equations

1. \[ a + A a + B b = 0 \]
2. \[ b - b' = 0 \]
3. \[ A = \frac{a - a'}{a b - a' b'} \]
4. \[ B = \frac{a - a'}{a b - a' b'} \]

The perpendiculars to these parallel planes drawn through the points \( P_1, P_2 \) have their equations

1. \[ x - a = z + \alpha \quad y = B z + \beta \]
2. \[ x - a' = z + \alpha' \quad y = B z + \beta' \]

The plane drawn through the first of these perpendiculars, and the first given line, has for its equation

\[ L (x - a) + M (y - b) + z = 0 \quad \text{(E)} \]

L and M being given by the two equations

1. \[ i + L A + M B = 0 \quad \text{(3)} \]
2. \[ i + L a + M b = 0 \quad \text{(4)} \]

The equation of the plane drawn through the second perpendicular, and the second straight line is

\[ L' (x - a') + M' (y - b') + z = 0 \quad \text{(E')} \]

\[ L' \text{ and } M' \text{ being determinable by these equations} \]

1. \[ i + L' A + M' B = 0 \]
2. \[ i + L' a' + M' b' = 0 \]

Now each of these last planes contains the required line, therefore the equations of their line of intersection will be those required.

The equations (1) (2) give the values of A and B, and combining them with equations (3) (4) the following values are obtained for \( L, L', M, M' \):

\[ L = \frac{a - a'}{a b - a' b'} + \frac{b (a b - a' b')}{a (a - a') + b (b' - b)} \]
\[ L' = \frac{a - a'}{a b - a' b'} + \frac{b (a b - a' b')}{a (a - a') + b (b' - b)} \]
\[ M = \frac{a - a'}{a b - a' b'} + \frac{b (a b - a' b')}{a (a - a') + b (b' - b)} \]
\[ M' = \frac{a - a'}{a b - a' b'} + \frac{b (a b - a' b')}{a (a - a') + b (b' - b)} \]

Substituting these values in equations (E) (E') we have

\[ (\alpha - \alpha) \left\{ \frac{a - a'}{a b - a' b'} + \frac{b (a b - a' b')}{a (a - a') + b (b' - b)} \right\} + (y - \beta) \left\{ \frac{a - a'}{a b - a' b'} + \frac{b (a b - a' b')}{a (a - a') + b (b' - b)} \right\} = 0 \]
\[ (x - a') \left\{ \frac{a - a'}{a b - a' b'} + \frac{b (a b - a' b')}{a (a - a') + b (b' - b)} \right\} = 0 \]

\[ b - b' = \left\{ \frac{a - a'}{a b - a' b'} + \frac{b (a b - a' b')}{a (a - a') + b (b' - b)} \right\} + \left\{ \frac{a - a'}{a b - a' b'} + \frac{b (a b - a' b')}{a (a - a') + b (b' - b)} \right\} \]
\[ (b - b') = 0 \]

Substituting these values in the equations of the line (E) (E') we have

\[ \frac{a - a'}{a b - a' b'} + \frac{b (a b - a' b')}{a (a - a') + b (b' - b)} \]
\[ A = \frac{a - a'}{a b - a' b'} + \frac{b (a b - a' b')}{a (a - a') + b (b' - b)} \]
\[ B = \frac{a - a'}{a b - a' b'} + \frac{b (a b - a' b')}{a (a - a') + b (b' - b)} \]

The values of the new co-ordinates will be

\[ \alpha = A x + B y + C z + D \]
\[ \beta = A' x + B' y + C' z + D' \]

The three planes intercept each other two by two in three straight lines which are the new axes. The new co-ordinates of the point are measured on the lines drawn through this point parallel to the new axes. The length of any one of these co-ordinates is the part of one of these lines contained between the point, and the plane of the co-ordinates to which this line is parallel.

Let \( x_1, y_1, z_1 \) be the co-ordinates of the point in relation to the primitive planes, and \( a, b, c \) its co-ordinates in relation to the three new planes.

For conciseness let

\[ L' = \frac{(C'B' - C'B') + (A'C' - A'C') + (B'A' - B'A')}{(B'A' - B'A')^2} \]
\[ L'' = \frac{(C'B' - C'B') + (A'C' - A'C') + (B'A' - B'A')}{(B'A' - B'A')^2} \]
\[ L''' = \frac{(C'B' - C'B') + (A'C' - A'C') + (B'A' - B'A')}{(B'A' - B'A')^2} \]

The values of these new co-ordinates will be

\[ u = \frac{A x + B y + C z + D}{L} \]
\[ v = \frac{A' x + B' y + C' z + D'}{L'} \]
\[ w = \frac{A'' x + B'' y + C'' z + D''}{L''} \]

If the three new planes be supposed perpendicular to each other, then \( A A' + B B' + C C' = 0 \), \( A A'' + B B'' + C C'' = 0 \), which is the case of each point in the plane of the new co-ordinates.

Multiplying the first of these three equations by \( B' \), the second by \( B'' \), and subtracting, we have

\[ C (B'B'' - B''B') = 0 \]

and

\[ A (A'A'' - A''A') = 0 \]

Multiplying the first by \( A' \), the second by \( A'' \), and subtracting, we have

\[ B (B'B'' - B''B') = 0 \]

and

\[ A (A'A'' - A''A') = 0 \]

The values of the new co-ordinates will be

\[ u = \frac{A x + B y + C z + D}{L} \]
\[ v = \frac{A' x + B' y + C' z + D'}{L'} \]
\[ w = \frac{A'' x + B'' y + C'' z + D''}{L''} \]
GEOMETRY.

A (A'C'' - A'' C) - B (C'B'' - C'' B') = o.

By means of the three equations the expression for L is reduced to \( \sqrt{A^2 + B + C^2} \).

By a similar calculation,

\[ L' = \sqrt{A'v^2 + B'^2 + C'^2}; \quad L'' = \sqrt{A''v^2 + B''^2 + C''^2}; \]

which gives for the new co-ordinates \( u, v, w \),

\[ u = A x + B y + C z + D \div \sqrt{A^2 + B + C^2}; \]
\[ v = A' x + B' y + C' z + D' \div \sqrt{A'^2 + B'^2 + C'^2}; \]
\[ w = A'' v + B'' y + C'' z + D'' \div \sqrt{A''^2 + B''^2 + C''^2}. \]

The values of \( u, v, w \), might have been determined directly, since they are the perpendiculars drawn from the points \( x, y, z \), upon three planes, whose equations are known.

If it be required to transform one system of rectangular co-ordinates into another system likewise rectangular, and having the same origin as the first, the three new axes may be given by the equations of the three new rectangular planes. Of the six constant quantities which enter these equations, three are determined by the condition that the planes are perpendicular to each other, and their values are to be calculated from that which is afforded to the other three; but this calculation may be avoided by determining the position of the new axes by means of any three angles, \( x, y, z \). This transformation is useful in the application of analysis to mechanics. The following method is that used by La Place in the "Mechanique celeste."

Let the primitive planes be designated by two of the three co-ordinates \( x, y, z \), which they contain, and the new planes by two of the co-ordinates \( x', y', z' \).

Let \( x \) be the angle of the two planes \( x, y \) and \( x, y' \).

\( \theta \) the angle which the axis \( x \) makes with the line of intersection of the plane \( x = y' \) with the plane \( x = y \).

\( \gamma \) the angle which this line makes with the axis \( x' \).

It is now required to find the values of \( x', y', z' \), in terms of \( x, y, z \), and of the three angles \( x, y, z \).

Let \( x', y', z' \), be the co-ordinates of a point referred to the rectangular axes, reckoned upon the three following lines.

1. The line of intersection of the plane \( x = y' \) with the plane \( x = y \).

2. The projection of the axis \( z' \) on the plane \( x, y \).

3. The axis \( z' \); then

\[ x = x' \text{ cof. } \downarrow + y' \text{ fin. } \downarrow \]
\[ y = y' \text{ cof. } \downarrow = x' \text{ fin. } \downarrow \]
\[ z = z'. \]

Let \( x', y', z' \), be the co-ordinates of a point referred to the rectangular axes, reckoned upon the three following lines; 1. The line of intersection of the plane \( x' = y' \) with that of \( x = y \). 2. The perpendicular to this line on the plane \( x' = y' \). 3. The angle \( x' \), then

\[ x' = x'' \]
\[ y' = y'' \text{ cof. } \downarrow + y'' \text{ fin. } \downarrow \]
\[ z' = z'' \text{ cof. } \downarrow = y'' \text{ fin. } \downarrow \]

\[ z'', y'', z'' \] being the co-ordinates of the point relative to the three axes \( x'', y'', z'' \), we have

\[ x'' = x'' \text{ cof. } \downarrow + y'' \text{ fin. } \downarrow \]
\[ y'' = y'' \text{ cof. } \downarrow + z'' \text{ fin. } \downarrow \]
\[ z'' = z'' \text{ cof. } \downarrow + y'' \text{ fin. } \downarrow \]

Hence \( x = x'' \) \text{ cof. } \downarrow + y'' \text{ fin. } \downarrow + \text{ cof. } \downarrow + \text{ cof. } \downarrow \)
\[ y = y'' \text{ cof. } \downarrow + z'' \text{ fin. } \downarrow + z'' \text{ fin. } \downarrow + \text{ cof. } \downarrow + \text{ cof. } \downarrow \]
\[ z = z'' \text{ cof. } \downarrow + y'' \text{ fin. } \downarrow + \text{ cof. } \downarrow - x'' \text{ fin. } \downarrow \]

Multiplying these values of \( x', y', z' \), respectively by the coefficients of \( x'', y'', z'' \) in these values, we have

\[ x'' = \left\{ x (\text{ cof. } \downarrow \text{ fin. } \downarrow + \text{ cof. } \downarrow \text{ cof. } \downarrow) + y (\text{ cof. } \downarrow \text{ fin. } \downarrow + \text{ cof. } \downarrow \text{ cof. } \downarrow) + z (\text{ fin. } \downarrow \text{ cof. } \downarrow + \text{ cof. } \downarrow \text{ cof. } \downarrow) \right\} \]

And by multiplying these values of \( x, y, z \) respectively by the coefficients of \( x'', y'', z'' \), and afterwards by the coefficients of \( x', y', z' \), we have

\[ z'' = x (\text{ cof. } \downarrow \text{ fin. } \downarrow + \text{ cof. } \downarrow \text{ cof. } \downarrow) + y (\text{ cof. } \downarrow \text{ fin. } \downarrow + \text{ cof. } \downarrow \text{ cof. } \downarrow) + z (\text{ fin. } \downarrow \text{ cof. } \downarrow + \text{ cof. } \downarrow \text{ cof. } \downarrow) \]

Another transformation is sometimes used; a point being referred to three rectangular planes by the co-ordinates \( x, y, z \), a straight line is drawn from this point to the origin of the co-ordinates; the length of this line is given, as likewise the angles which it makes with the three rectangular axes. If \( r \) represent this line, and \( x, y, z \), the three angles, then \( r = r \text{ cof. } x + r \text{ cof. } y + r \text{ cof. } z = r \text{ cof. } \gamma \).

Of these three angles two only are necessary; because

\[ \text{cof. } x^2 + \text{cof. } y^2 + \text{cof. } z^2 = 1. \]

When the position of a point is thus determined by a line \( r \) and two angles, \( r \) is called the radius vector, and the origin of the co-ordinates becomes a pole, from which proceeds the radius vector of different points in space.

Sometimes the radius vector is projected upon one of the rectangular planes, suppose on \( x \); the angle of the radius, with its projection, is given, as likewise the angle of the projection with the axis of \( x, y, z \); if \( \gamma \) represent the first, and \( \delta \) the second of these angles,

\[ z = r \text{ fin. } \downarrow + y = r \text{ fin. } \downarrow \text{ fin. } \downarrow + x = r \text{ fin. } \gamma \text{ cof. } \downarrow. \]

If the point, referred to three rectangular planes by the co-ordinates \( x, y, z \), belongs to a surface, we have between these three co-ordinates an equation, \( F (x, y, z) = 0 \). If the co-ordinates are transformed, and the new ones become \( u, v, w \), we must substitute in \( F = o \) for \( x, y, z \); their values in terms of \( u, v, w \), and the resulting equation will belong to the new surface referred to the new planes.

If in the equation \( F = o \), for \( x, y, z \), we substitute the values given in equations \((1)\) and \((2)\), it will become what is termed the polar equation to this surface.

When a curve is given by two equations \( f (x, y, z) = o \), \( f (x, y, z) = o \), substituting in these equations the values given by equation \( F (x, y, z) = o \), we obtain an equation to the curve, relating either to three new planes by the co-ordinates \( u, v, w \); or to a pole, by the radii vectors, and their angles.

Of the centres of surfaces, and of their diametral planes. 

The centre of a surface is defined to be a point, in which all the chords passing through this point are divided into two equal parts.

A diametral plane is that which divides a system of parallel chords, each into equal parts.

Hence, if a surface has a centre, all the diametral planes which it can have, necessarily pass through this centre.

Having given the algebraic equation of a surface, to determine 1st, if it has a centre; 2d, if it has a diametral plane.

If the proposed surface has a centre, let it be referred to three planes, the origin of whose co-ordinates is the centre itself.

Any straight line drawn through the origin of these co-ordinates will be a diameter, and will cut the surface in two points, the co-ordinates of the first being \( x, y, z \), and of the second \( -x, -y, -z \). Therefore, the equation to the surface must fulfill in taking \( x, y, z \), positive or negative; to satisfy this condition, the sum of the exponents of the three co-ordinates in every form must be the same in every party as the number which expresses the degree of the equation proposed, that is, if even, even, if odd, odd.
GEOMETRY.

if \( \zeta \) be the equation to the surface referred to, any three planes, then, in this equation make

\[ r = x + a_1 x = y + b_1 x = z + c_1 x; \]

and an equation of the surface will be obtained in terms of \( x, y, z \) referred to three new planes parallel to the first, and passing through the point suppoled to be the centre of the surface: if, by the three particular values assigned to \( a_1, b_1, c_1 \), the terms may be made to disappear, in which the sum of the exponents of the three co-ordinates are of a different denomination as to even or odd, then the degree or dimension of the equation \( \zeta, r, s, \) the proposed surface will have a centre.

Of Diametral Planes.—When, in all the terms of an equation of a surface, the exponent of one of the co-ordinates is an even number, the plane of each of the other co-ordinates divides the surface into two equal and similar parts.

The equation being \( \zeta = z, x, y, z \) if in all its terms the exponent of \( z \) is an even number, the plane of \( x \) and \( y \) will be a diametral, for it will give for \( z \) a value \( \infty \), function of \( x, y \), and constant quantities, and \( z = \infty \) will satisfy this equation; therefore, to the same values of \( x, y \), two values of \( z \) will correspond, differing only in the sign; therefore the plane of \( x, y \) will be diametral, and for the reason the two other planes of the co-ordinates will be diametral; when in each term the exponents of \( x, y \) are even numbers.

Let \( \zeta \) be the equation of the proposed surface; by the transformation of the ordinate, the surface may be referred to three new planes, then \( A r + B x + C z + D = \infty; A' r + B' x + C' z + D' = \infty; A'' r + B'' x + C'' z + D'' = \infty \); in which equation there are nine constant quantities.

The surface proposed has diametral planes, when, by affiging real and particular values to these constant quantities, the terms in which the exponents of the co-ordinates which are odd numbers, may be made to disappear. The real root of the equation, obtained by making the co-efficients of these terms equal zero, determines the number of diametral planes.

In considering surfaces of the second degree, great use may be made of these principles, in determining the centres and diametral planes of these surfaces.

Of Surfaces of the Second Degree.—Let the general equation of the second degree, between three variables \( x, y, z \), be \( a x^2 + b y^2 + c z^2 + d x y + e x z + f y z + g x + h y + k z + l = \infty \). To determine if the surface to which this equation belongs has a centre.

Making \( x = \beta + x, y = \gamma + y, z = \delta + z, \) \( x, y, z \) being suppoled the co-ordinates of the center, the equation becomes \( a' x^2 + b' y^2 + c' z^2 + d' x y + e' x z + f' y z + g' x + h' y + k' z + l' = 0 \).

In this equation, which is likewise the equation of the second degree, there are only three terms in which the sum of the exponents of the co-ordinates is an odd number; these terms may be made to disappear, by making their co-efficients equal to zero, which gives \( g' = 0; b' = 0; \delta = 0; \) making this substitution and taking only the terms multiplied by \( x, y, z \), the equation becomes \( x + y + z + g = 0; b + d + e + \gamma + b = 0; \delta + e + f + \gamma + k = 0 \).

These equations being linear in \( \beta, \gamma, \delta \), these quantities have real values; therefore, surfaces of the second degree have a centre.

If a certain relation be established between the constant quantities \( a, b, c, d, e, \) etc, this centre may be placed at an infinite distance from the origin of the co-ordinates. In effect, the value of \( x, y, z \) are fractions whose common denominator \( a x^2 + b f^2 + c d + \delta a b c + d e f \); therefore, when the following equation sublates between the constant quantities of the general equation of a surface of the second degree, \( a x^2 + b f^2 + c d + \delta a b c + d e f \); the co-ordinates of the centre of this surface are infinite. The surface of the second degree has likewise diametral planes, for by transposing the ordinates it may be referred to three new planes, containing nine constant quantities; taking \( a, b, c \) for the new ordinates, the general equation becomes \( A u^2 + B v^2 + C w^2 + D x + E y + F z + G z + H w + K w + 1 = \infty \); exminating the terms in which the exponent of any one of the co-ordinates is odd, the following equations are obtained: \( D = 0, E = 0, F = 0, G = 0, H = 0, K = 0, (A) \). Of nine constant quantities, fix only are determined by these equations; hence it follows, that three planes may cut a surface of the second degree in four equal and similar parts in an infinite number of ways; it has therefore an infinity of diametral and conjugate planes, and of the three perpendicular ones, which intersect each other on the three direct lines on which are reckoned the axes of the surface. This property is analogous to that of curves of the second degree, which have an infinity of conjugate diameters, and in these curves there are two conjugate diameters perpendicular to each other, called axes. The three equations which express that the new planes of the co-ordinates are rectangular joined to the fixed equations \( (A) \), determine the nine constant quantities which enter into the equations of these planes.

Taking for granted what however may be demonstrated, that these constant quantities have always real values, we may suppose, that referring the surface of the second degree to its rectangular co-ordinates, its general equation will always be of this form, \( L x^2 + M y^2 + N z^2 + 1 = \infty \). We shall consider the surfaces comprehended under the general equation, and next the case where the centre is removed to an infinite distance from the origin of the co-ordinates.

Every surface of the second degree intersected by a plane, has for its section a curve of the second degree; for whatever be the planes, it may become, by the transformation of its co-ordinates, one of the planes to which the surface is referred, so that after this transformation, the equation to the surface is a term of the second degree; moreover, the equations of the sections made on a plane by the planes of the co-ordinates cannot be of a higher dimension than the equation of the surface, therefore every surface of the second degree cut by a plane has for its section a curve of the second degree likewise.

If the intersecting plane moves parallel to itself, the section remains always similar to itself; its axes remain always parallel, and its centre is on the same diameter of the surface, which may be thus demonstrated.

The equation of a curve of the second degree may always be reduced to this form,

\[ I x^2 + M y^2 + N z^2 + P = 0. \]

If in this equation \( f \) and \( g \) be substituted for \( x \) and \( y \), \( f \) being a constant quantity, the new equation which results from this substitution belongs evidently to a curve similar to the first, and similarly situated; it only differs from the first in the constant term, for after having divided all the terms by \( f \), it becomes

\[ L x^2 + M y^2 + N z^2 + \frac{P}{f} = 0. \]

Therefore all curves of the second degree, whole equations are of this form, differing only in the constant term, will be similar and similarly situated.

The general equation to a surface of the second degree being

\[ L x^2 + M y^2 + N z^2 - 1 = \infty. \]

Let
GEO

Let the equation of any intersecting plane be
\[ z = Ax + By + C. \]

The projection of the intersection of the curve with the
surface on the plane \( x = 0 \) will have this equation,
\[
x^2 + (A + N AB) + B' = \frac{A^2 + 2 N x + 2 B C N y + C^2 - 1}{x} = 0 \]

If the intersecting plane be supposed to change its posi-
tion by moving parallel to itself, \( A \) and \( B \) will remain con-
stant, and \( C \) only will change its value; hence it follows that the
equations of \( x, y, z \) in the equation of projection,
will remain the same, whatever be the value of \( C \). But by the transforma-
tion of the co-ordinates this equation may be reduced to this form;
\[ l^2 + m^2 + n^2 + \mu^2 = 0; \]
in which the equation of the co-ordinates \( l^2 + m^2 \) only contain \( A \) and
\( B \); \( \mu^2 \) alone being some function of \( C \). If \( \mu \) be made to vary,
the value of \( \mu^2 \) may be supposed to become \( \mu^2 \), and the
preceding equation to become
\[ l^2 + m^2 + n^2 + \mu^2 = 0 \]

which as it only differs from the former in the con-
stant quantity, evidently belongs to a similar curve; hence it may be
demonstrated that all parallel sections are similar, and
similarly situated. Moreover, the locus of the centres of these
sections is in a diameter of the surface.

If in the equation \( Lx^2 + My^2 + N = 1 \) we sub-
stitute for the co-ordinates \( L, M, N \), the constant quanti-
ties \( \frac{1}{a^2}, \frac{1}{b^2}, \frac{1}{c^2} \), \( a \) being greater than \( b \), and \( b \) greater than \( c \); it be-
comes
\[ b^2 + a^2 + \epsilon \frac{a}{b} = a^2 b^2 + \epsilon \frac{a}{b} = \frac{a^2}{b^2} + \epsilon \frac{a}{b} \]

The advantage of this substitution is to render the sign of each
term of the equation independent of the particular values of
the co-ordinates, and to introduce as constant quantities
(in the equations of the sections of the surface by the planes of
the co-ordinates) only the principal axes of these sections.

From the different combinations of the signs three distinct
cases arise from equation \( E \); for a full investigation of which
we must refer our reader to the original work from which this
article was principally extracted. (Vide Analyse de
l'Analyse et de la Geometrie, par M. Monge.)

The three equations are
\[ \begin{align*}
b \epsilon x^2 + \epsilon a \frac{a}{b} = a^2 b^2, & \quad \text{or} \quad Lx^2 + M y^2 - N = 1 \\
b \epsilon y^2 + \epsilon a \frac{a}{b} = a b^2, & \quad \text{or} \quad Lx + M y - N = 1 \\
b \epsilon z^2 + \epsilon a \frac{a}{b} = a^2 b^2 & \quad \text{or} \quad Lx + M y + N = 1 \\
\end{align*} \]

The former belongs to the ellipsoid and the two others to
different species of hyperboloids.

—Widey. Sp. Pl. v. 4. 593.—Cliffs and order, Monocot Mo-
naepli, Nat. Ord. Plantae.

Gen. Ch. . . . .

Eff. Ch. General Spatha double; of two valves. Male,
Calyx in three deep segments. Petals three. Filaments
fix, united into a cylinder. Female, Calyx and Corolla like the male. Style one,
locus, Stigmas of two lobes. Drupa dry, with one seed.

I. C. family. "Froonds pinnate; the pinne abruptly
jagged."—The taste of the Caracas, in shady woods on
the lofty mountain of Baenovita. Bredeneyer.—The trunk
is simple and slender, an inch in diameter, smooth, rising to
the height of fifteen feet, when, by the power of the wind
on its ample foliage, it is blown down, but soon produces
new shoots and roots from the top, whence a new trunk
springs up to the fame height of about fifteen feet, and in
its turn is quickly laid prostrate like the former. The
froonds (rather leaves) are pinnate, their pinne irregular,
the leaves folded, jagged abruptly at the summit. Spatha
double, of two valves, wedge-shaped, somewhat compressed,
acute, three inches long. Spadix fifteen inches in length,
branching at the top, the branches round, bearing each from
seven to nine alternate, cylindrical spikes, of the length
of three inches each. Flowers conically, three, in a flower
bowl of the spike, two of which are male, one female.

Dropra dry and fibrous, the size of a pea. Nut globose, black.

2. G. bimphlicifrons. "Froonds simple, wedge-shaped,
clown."—Found at the Caracas with the former. Bred-
neeyer.—The trunk of this is permanently upright, ten feet
high, an inch thick. Froonds (or leaves) a foot long, simple,
shape-shaped, taper at the base, cloven, and divergatated
at the summit, supported on very long stalks. Spatha
double, of two valves. Spadix bearing at its extremity three or
four cylindrical spikes. Flowers immersed in little cavities,
like the former. Willdower.

GEOPONIC, something describing or relating to agri-
culture. Cato, Varro, Columella, Palladius, and Pliny,
are sometimes called geoponic writers.

GEORG, St., in Geography, a town of Germany, at the
confluence of the rivers Teya and March, formerly a roval
city, but now much reduced; 24 miles N. N. E. of Preb-
burg.—Also, a town of Hungary; 7 miles N. N. E. of
Presburg.

GEORGE, in Geography, surnamed the Cappadociam,
was made bishop of Alexandria when Athanasius was driven
from that see by the perfecutions of the emperor Con-
stantius, about the year 355. (See ATHANAS.) He was a
native of Epiphania, in Cilicia, where his father purfied the
business of a fuller. From this obscure situation the fou
ruined himself, it is laid, not by the most honourable means,
to the itation of a prelate in the church. At first he obtained
a lucrative appointment as purveyor of bacon to the
army: not contented with the regular profits of his office,
he made use of every art, however base and corrupt, in the
accumulation of wealth; so as to render a mean employment
honourable. His depredations on the public purse became
so notorious, that he felt it extremely dangerous to wait the
issue of a suit commenced against him. He fled
from the pursuit of justice, and contrived to take with him
his ill-gotten wealth. The place of his retreat was Alex-
andria, where he professed great zeal for the Arian fystem
of theology, and being a man of superior talents, he acquired
considerable influence with his disciples in that city. Here
he collected a large and very valuable collection of books,
which the emperor Julian afterwards made the foundation
of the noble library established by him in the temple erectd
in honour of the emperor Trajan, but which was burnt by
the connivance of the emperor Julian. When Athanasius
was driven from Alexandria, George was elected bishop by
the prevailing party. In this itation his conduct was in the
highest degree cruel and oppressive. He persecuted the Cath-
olics with an unrelenting hand, and the other inhabitants
of this vall diecefe were objects of his tyranny and avarice.
The merchants he impoverished by unjust monopolies and
cruel taxes; the Pagans, who had been excited with the
hopes of freedom and toleration, did not escape his rapacity,
and the rich temples of Alexandria were either pillagrd or
influted by him, who exclaimed, in a haughty and threaten-
ing tone of voice, "How long will these impudente be per-
mitted..."
GEORGE.

wished to fland." The people endured all these acts of oppression till their patience was exhausted; they then rose in stone man, and expelled him the city. With much difficulty he regained his authority, which he held till the year 362, when the accession of Julian to the empire was the signal for the downfall of the bishop. He, and two other persons, who had been ministers of his atrocities, were ignominiously dragged in chains to the public prison. Here, after a confinement of a few days only, they were attacked by the pagan populace, who forced open the doors of the dungeons, and with cruel insults maffacred the vile wretches. Their lifeless bodies were carried in triumph through the streets on the back of a camel, and after having suffered every indignity, they were thrown into the sea, with the avowed intention of disappointing the devotion of Christians, who, they foresaw, would gladly canonize the tyrant as a martyr and saint. The fears of the Pagans were justified, but their precautions were ineffectual. The meritorious death, as it was denominated, of the prelate, obliterated the memory of his life, and the infamous George of Cappadocia has been transformed into the renowned St. George of England, the patron of arms, of chivalry, and was the patron saint of Crete, Bari, and the Gregories; did not acknowledge his companion, and Pope Gelius, about the year 494, is the first Catholic who acknowledges St. George, and who placed him among the martyrs of the churches. He rejects his acts as spurious, and as the composition of heretics. His fame and popularity in Europe, and especially in England, proceeded from the crusades Gibbon, vol. iii. and iv. Moreri.

GEORGE OF TREBISOND, a learned modern Greek, was born, in 1395, in the isle of Crete, of a family originally from Trebizon, from which he derives his name. He came to Italy about 1420, and obtained the patronage of Francis Barbaro, a noble of Venice, through whose means he was invited to a professorship of Greek at Vicenza. Thence he removed to Venice, where he acquired great reputation as a grammarian and instructor in Greek eloquence. After this he obtained an invitation from pope Eugenius IV. to settle at Rome, and, during the life of the pontiff, he was occupied in teaching rhetoric and philosophy, and in translating several practical Greek works into Latin. He acquainted himself with the pope, Nicholas V., at whose instance George might have lived happily, had not his own temper involved him in many disputes with the learned men about the papal court. With Poggio he came to blows, and it was necessary to refer to the authority of the apostolic secretaries to part them. His own conduct at length forced him from Rome, and he took refuge, in 1452, at Naples, where he was graciously received by king Alphonso, but he did not partake of his liberality, and had great difficulty, at this period, in maintaining his family. It is supposed, that by the interference of his friend Filippo, he was reconciled to the pope, and that he returned to the papal city; but in 1459 he was at Venice, where he presented to the doge his version of Plato's book on laws, and was then engaged as a professor of helles lettres. In 1464 he went to Crete, and passed thence to Constantinople. On his return he found his own scholar Paul II. on the papal throne, which led him to visit Rome, but his treatment there did not probably correspond with his expectations; he was, for some offence not known, cast into prison, where he was kept during a space of four months. He died about the year 1465. He lived to a good old age, and was author of many works on rhetoric and subjects connected with polite literature; and he translated many others, particularly of the fathers, from the Greek into the Latin. He is esteemed very highly for the share which he had in introducing Greek literature into the West. His Latin style was far from poetical; and in controversy he dealt much in invective. The comparison which he indulged between Aristotle and Plato gave great offence to the adherents of the latter, particularly to cardinal Bellarion, who wrote an answer to him. Gen. Biog.

GEORGE, called also Athon, flourished about the close of the 16th century, and was at Rome under the pontificate of Clement VIII. He published "A Syriac and Chaldean Grammar" in 4to, in 1596. He was, after this, elected patriarch of the Maronites, among whom he introduced the use, and explained the principles, of the Gregorian calendar. He died about the year 1641. Moreri.

GEORGE LEWIS I., king of Great Britain, and elector of Hanover, the son of the elector Ernest-Augustus, by Sophia, daughter of Frederick elector-palatine, and granddaughter of James I., king of England, was born in 1660, and trained to the profession of arms under his father. When he had arrived to the estate of manhood, he engaged in the service of the emperor against the Turks, and became illustrious as a warrior in three campaigns in Hungary. He next distinguished himself in the war between the empire and France, and in the year 1700 he succeeded, on the death of his father, to the electorate. In the following year he marched to the assistance of the duke of Holstein, who was attacked by the king of Denmark, and obliged the Danes to raise the siege of Tonningen. He joined the alliance against France in the succession war, and forced the princes of the house of Wolfenstein to quit their alliance with the French. The command of the army of the empire was conferred upon him in 1707, but after the duties of three campaigns, in which he had been able to act only on the defensive, he resigned his command, and left his own troops in the service of the allies. At the peace of Ratisbon, Lewis XIV. recognized the electoral dignity in the house of Lunenburg, as he had before, at the peace of Utrecht, the succession of the same house to the crown of Great Britain. This event happened on the death of queen Anne in 1714, when the prince, now George I., was in the fiftieth year of his age. He was already celebrated for the wisdom and justice of his government, and his personal qualities, though limited in his views by the interests of a German prince, and but little acquainted with the character of the nation he was about to rule. "It is evident," says an historian, "that the title of this prince was founded solely on the choice of the parliament, that is, of the people, and that the usual order of succession was entirely superceded. For, admitting the male line of the house of Stuart to have been extinguished in the person of James II., the right of blood rested in the house of Savoy, descendend from Henrietta, duchess of Orleans, daughter of Charles I." Thus the rights of the people were fully exercised, and the family on the throne is in truth an elected family, though the general law of succession remains unaltered. The king threw himself into the arms of the Whig party, who, indeed, alone openly maintained those principles upon which the right of his crown was founded. Of thee the fundamental one was the superiority of the national will, in appointing a chief governor, to any claim derived from hereditary right. Such a principle had been already assumed, and was the only one that could justify the nation in setting aside the immediate heirs to the crown, on the plea of difference of religion. (See Whigs.) As soon as this prince was seated on his throne, the late Tory ministry were called to account for their conduct, particularly with respect to the treaty of Utrecht, and several of the heads of it were impeached, and either im-
prisoned, or driven into exile. These measures were the cause of great dissatisfaction; tumults were excited in various parts of the kingdom, and at length, in September 1715, the earl of Mar set up the standard of rebellion, and proclaimed, with due honours, the pretender. The plan was ill concerted, and very weakly supported, and early in the following year it was entirely quelled, but several of the leaders lost their lives on the scaffold. Still a large body of the people were disaffected to the new family, and the power of the Tory party was so formidable, that the ministry, to establish their authority, had recourse to septennial parliaments, instead of triennial ones, according to the law of the land. It was agreed by men of all parties, who were not personally interested in the change, that this innovation was a most gross violation of the principles of the constitution, which no temporary necessity could justify. The king had, about this period, acquired by purchase the duchies of Bremen and Verden, in order to extend his power as elector of Hanover. By the acquisition he was involved in a quarrel with Charles XII. of Sweden, who threatened to invade Scotland in favour of the claims of the pretender. The earl Peter also concurred in the scheme. To obviate the danger, the king entered into a triple alliance with Holland and France, a fleet was sent up the Baltic to awe the Swedes, and all commercial intercourse with that nation was suspended; but the death of Charles XII. in 1717, and the subsequent changes in the politics of Sweden, put an end to the alarm in that quarter, and secured George in the quiet possession of his newly acquired continental acquisitions. The ambition of the court of Spain, governed by cardinal Alberoni, disturbed the peace of Europe, and occasioned a quadruple alliance between the three powers above-mentioned, with the accession of the emperor. The seizure of Sardinia, and invasion of Sicily by the Spaniards, gave a pretext for sending a powerful English fleet into the Mediterranean under sir George Byng, who fell in with, and almost totally destroyed the Spanish fleet. This succedee was followed by the recovery of Sicily and Sardinia, and Spain was under the necessity of acceding to a peace dictated by the allied powers. A pacification of the north of Europe was also effected by the mediation of England. The national delusion and calamity in the year 1720, (see BUBBLE) recalled the king from a visit to his German dominions, and the prudent measures of parliament produced the reformation of public credit. In 1722 a new conspiracy against the government was discovered, and several persons were apprehended in consequence of it, among whom was Dr. Atterbury, bishop of Rochester, who was punished with perpetual banishment. The ministers of France and England, Fleury and Walpole, being friendly to peace, preferred a good understanding between the two countries for many years. Several treaties were negociated under the pretence of maintaining the balance of power, but usually other private ends were to be answered by them. The leading principle of George I. was the safety and prosperity of his German dominions, to the interests of which, those of Great Britain were, on various occasions, laid to be sacrificed. In 1725, a treaty between the emperor and the king of Spain excited the jealousy of king George so much, that he counteracted it by another at Hanover, compelling most of the other European powers, and he sent a fleet to the West Indies under admiral Hoffer, in order to block up the Spanish galleons at Porto Bello. The death of the admiral and most of his crew from disease, was considered as one of the most inglorious disasters of the reign. The Spaniards then besieged Gibraltar, but all differences were finally settled by a negociation. The king of England seemed at length to have surmounted all his political difficulties, and a prospect of permanent peace and tranquility appeared to open upon him. The toils, and dangers, and anxieties which he had felt during his whole reign seemed at last to be rewarded with glory, happiness, and repose. He thought every circumstance was favourable to his visiting his electoral dominions, and embarked for that purpose at Greenwich, June 3, 1727. He landed in Holland on the 7th, but in his journey from thence to Hanover he suffered a paralytic seizure, and feeling that he was near the end of his long journey, he exclaimed to his attendant, "C'est fait donc, yot." He reached the palace of his brother, the bishop of Osnaburg, but could not advance farther. He died June 11, 1727, in the sixty-eighth year of his age, and the 13th of his reign. He has been characterized as plain and simple in his appearance, grave and sedate in his manner, but easy and familiar among his intimates, in whole society he was fond of relaxing from the cares of the state. He possessed much natural prudence and good sense, and well understood his interests, at least so far as the objects nearest his heart were concerned. According to the crown of Great Britain when far advanced in life, he seemed ever to consider himself rather as elector than as king, and the influence and power of Great Britain were of little estimation in his eyes when directed to any other end than the aggrandizement of his native country. In the view of Europe at large, he fulfilled the character of a prudent, able, and fortunate prince. His government was not without defects in the administration, but he was unquestionably a zealous friend to civil and religious liberty. He had female favourites, but was not governed by them. He had little or no taste for literature and science, and was unable to appreciate their value, yet he founded in each university a professorship of modern history. He was, however, a lover of music; and soon after his accession established regulations for the conduct of this part of the service in the royal chapel. He had married in 1681, his cousin Sophia Dorothaea, daughter of the duke of Zell, a match that was attended with little domestic happiness. He left behind him one son, who succeeded him in his crown.

GEORGE AUGUSTUS II. king of Great Britain, son of the preceding, was born in 1683, and came to England with his father in 1714, where he received the rank and title of Prince of Wales. In 1716, he was appointed regent during the king's absence. After this, on account of some private difference with his father and fam., the latter lived for some time in a state of imprisonment from the court. He succeeded to the throne in 1727, and adopted the same ministers and measures which had governed the nation during the life of George I. He inherited also, in full force, the attachment which his father bestowed on his German interests, which swayed the councils of his cabinet, though it was frequently obliged to give way to other considerations. Europe, for some time, was in a state of peace, through the influence of the treaties of Seville and Vienna, the latter of which guaranteed the Pragmatic sanction, or the law by which the female heirs of the emperor Charles VI. were to succeed to the hereditary dominions of Austria. In 1732 Walpole introduced into parliament the financial scheme of a great extent of the excise; but the violent opposition it met with from the nation obliged him to relinquish the object. What the people refused to submit to at that period has been since adopted almost without a murmur. In the year 1737, complaints were made against the government for abridging liberty, by a bill for limiting the number of playhouses, and submitting dramatic writings to the inspection of the lord chamberlain. Difputes had long pre-
voiled between Spain and England, on account of the trade carried on in the West Indies by their respective subjects. In 1739, the matters in debate were compromised by a convention settled by the respective courts, but its terms were so little satisfactory to the traders, that Walpole found himself obliged by their clamours to prepare for hostilities. War was declared, and Portobello taken by admiral Vernon. The war, however, did not turn out so successful as the people expected, so that a clamour was raised against the minister, and Sir R. Walpole was obliged to resign in the year 1742.

At the same period France, and the other powers in league with her, seemed determined, on the death of the emperor Charles VI, to stir her daughter Maria Theresa of her inheritance, which had been guaranteed to her by the Pragmatic sanction. In defence of her just right, George sent an English army to the continent, and also a large body of forces from his electorate, who were taken into British pay.

The king himself joined the army, which was under the command of the earl of Stair, and displayed great bravery. Victory declared itself in favour of the British, but they were forced to leave their wounded to the care of the enemy. Soon after, the command of the allied army devolved on the king's second son, the duke of Cumberland, who was reckoned very deficient in talents as general of a great army. Under him was lost the bloody battle of Fontenoy in 1744, and the French maintained an undoubted superiority in Flanders during the remainder of the war. In the following year the adherents of the pretender encouraged him to try his fortune by a descent, in the northern part of the kingdom, where he might expect an immediate and decisive declaration to be made in his favour. His son, accordingly, under the protection of the court of France, landed on the coast of Scotland, in the month of July. He was received with much respect and affection, and was immediately joined by several of the clans, with whom he proceeded to the north, enlarging his small army with all those who would join in his cause. At Perth he proclaimed his father king, and immediately after took possession of Edinburgh, defeated a body of the royal troops at Preston Pans, and marched into England, where he had the strongest assurances of being powerfully reinforced. He proceeded to Derby, but found the people no where zealously inclined to support his cause; at length the duke of Cumberland arrived from Flanders, with several English regiments, engaged and defeated the rebels, and thus put an end to the hopes of the pretender, who could no longer be considered as an object of terror or alarm. The government of the house of Brunswick was from this period more firmly established; and it appeared that the greater part of the nation had indubitably connected the interests of religion and liberty with the support of those principles which called the family of the reigning prince to the throne. In 1748, peace was negotiated, and established by the treaty of Aix-la-Chapelle; this treaty did not correspond with the expectations of the people, but it was welcomed as a relief from the burthens needlessly imposed by a state of warfare. In 1751, the king lost his eldest son, Frederick, who had lived a considerable time at variance with his father, but who had made his peace with the court after the dissipation of Walpole. This prince, the father of our present sovereign, was amiable and well disposed, and the fondest hopes had been entertained of the patronage which he would have exhibited on the throne to which he was heir, and of which he was deprived by an early death. In 1755, a war broke out between Great Britain and France, the events of which, though truly important to the kingdom, are in no great degree connected with the character of the king. To his apprehensions for the safety of his German dominions, was imputed the alliance formed with the king of Prussia, and the employment of a large force in continental warfare. This was the least glorious part of the public transactions, and during the early years of the contest events were very unfavourable to England; but when, at the demand of the people, the king summoned to his councils the great William Pitt, afterwards earl of Chatham, the tide of successes set full in upon the measures of government. The French power in the East Indies was annihilated; and in America the reduction of Louisburg was followed by that of Canada. The island of Guadalupe, and the British settlement of Senegal, fell under the British dominion, and the famous battle of Minden exalted the reputation of the British soldiery. The navy of England reigned triumphant over the seas, while that of France was reduced to insignificance, from which it never after completely recovered. Notwithstanding all this success the German war was unpopular, and ministers were reprehended for the sacrifices which they had made, or were supposed to have made, to the personal wishes of the king.

In this state of affairs George II. suddenly died from a rupture of the right ventricle of the heart, which, without any previous illness or suffering, terminated his life on the 29th of October 1760, in his seventy-third year, and in the thirty-third of his reign. During this long period he had experienced many vicissitudes of fortune, but he lived to see himself the most successful of all the English monarchs. He was endowed by nature with an understanding by no means comprehensive, and he had taken little pains to improve and expand his original powers by intellectual cultivation.

Equally a stranger to learning and the arts, he saw the rapid increase of both under his reign, without contributing in the remotest degree to accelerate the progress by any mode of encouragement. He was hafty and obdurate in his temper, yet a natural goodness of heart, a love of justice, and an honest openness of disposition, conciliated the affection of his people, and have inspired respect and veneration for his memory. He was a firm friend to the establishe laws and liberties of the kingdom, and it must be admitted, highly to his honour, that the general principles of his administration, both civil and religious, were liberal and just. Many of the penal statutes, which still remain unrepealed, were in the reign of this prince reiterated, and virtually suspended, by the mildness and equity of the executive government. And he will long be remembered for his declaration, 'that during his reign there should be no persecution or confinement for conscience sake.' On various occasions he had given sigual demonstrations of personal bravery, nor did the general tenour of his conduct afford proofs less striking of his rectitude and integrity. If he cannot be ranked among the greatest, he is certainly entitled to be ranked among the most respectable princes of the age in which he lived.

George, St. a name whereby several orders, both military and religious, are denominated. It took its rise from a saint famous throughout all the East, called by the Greeks ΑΓΙΟΣ ΓΕΩΡΓΙΟΣ, O Holy George. He is generally represented on horseback, as being supposed to have frequently engaged in combats in that manner.

He is highly venerated throughout Armani, Muffcovy, and
GEORGE.

and all the countries which adhere to the Greek rite; from the Greek, his worship has long ago been received into the Latin church; and England and Portugal have both chosen him for their patron saint. See George of Cappadocia.

George, St. is particularly used for an English order of knights, more commonly now called the order of the Garter. See Garter.

George, knights of. There have been various orders under this denomination, most of which are now extinct.

The order of St. George, at first called the order of the "Golden Angel," is said to have been instituted by Constantine the Great, in the year 312. The collar is composed of fifteen oval plates of gold, richly chafed on their edges, and enamelled blue. On 14 of these plates is the cypher of the name of Christ, composed of the Greek capital letters X and P between the two capitals A and T, signifying that Jesus Christ is the beginning and end; but on the centre oval, which is edged with laurel leaves, the cypher XP is placed on a cross patence gules, edged or, and having on its points the letters I. H. S. V.; and from the bottom of the figure was the figure of St. George killing the dragon. The habit of the knights was a long cloak of sky blue velvet, lined with white silk, tied at the neck with a cord of crimson silk and gold intermixed, terminating at each extremity in a large tassel; on the left breast of the cloak was embroidered the cross of the order.

The order of St. George in Austria and Carinthia was instituted, as some say, by Rudolph, count of Habsburg, the first emperor of the house of Austria, about the year 1273 or 1290; or, as others say, by the emperor Frederic III., in order to guard the frontiers of Germany, Hungary, Austria, Carinthia, and Styria, from the inroads of the Turks.

The badge of the order was a plain purple cross edged with green.

The order of St. George in Burgundy was founded, in the year 1400, by Philip de Miojard, a gentleman of Burgundy, on account of his having brought from the East some relics of St. George, which he deposited in a chapel erected for the purpose, near to the parish church of Rougamaon. The badge of the order is a St. George on horseback, overthrowing a dragon, similar to that on the collar of the order of the garter. It was worn pendent to a blue ribbon tied to a button-hole. Women were admitted into this order.

The order of St. George in Austria was refounded by the last emperor Maximilian, who directed that the badge of the order should be a crof croset botonnee gules, encircled on the upper part with a ducal coronet or, and worn pendent from three chains of gold.

The order of St. George at Genoa was instituted in 1472. The doge of Venice is perpetual grand master of the order. The enlignt of the order is a plain red cross, worn round the neck, pendent to a ribbon.

The order of St. George in Rome was founded by pope Alexander VI., in the year 1492. The collar of the order was a gold chain, to which was pendent an enamelled figure of St. George on horseback, throwing down a dragon, and piercing it with a lance. The badge was a gold cross within a circle of gold, like an open crown.

The order of St. George at Ravenna is supposed to have been instituted by pope Paul III. in 1534. It was abolished by pope Gregory in 1752.

The order of St. George, defender of the immaculate conception of the blessed Virgin Mary, was instituted at Munich by Albert, elector of Bavaria, in the year 1729, and confirmed by the pope. The person admitted into this order must prove his gentility for five generations both on his mother's and father's side. The badge of the order is a star of eight points; on the centre is enamelled the image of St. George on horseback, flying a dragon; the cross is enamelled blue, and edged with white, and cantoned with smaller crofses, enamelled blue and white; which, pendant to a sky-blue watered ribbon, edged with white, is worn by the knights. On the left breast of the knights also wear the same star embroidered, having on the centre a red cross. On festivals they wear a collar composed of oblong plates with crowns at each end, and columns surmounted with globes; each column supported by two lions, holding in their anterior paws fleur-de-lis, joined together with lozenge-chains enamelled blue and white; on the oblong plates is the following motto: "In fide, justitia, et fortitudine."

The military order of St. George in Russia, called also the order of "Merit," was instituted by the empress Catherine II. in 1769, has the precedence over that of St. Anne of Holstein, and was divided into four classes. — The badge is a crose of gold, enamelled white, on the centre of which is a medallion, with the figure of St. George slaying a dragon. This is worn pendent to a black ribbon edged with orange colour, and two stripes of orange on the black. Those of the first class wear it under their coat, passing from right to left; and on the left breast of their coat is a star wrought in gold, in the shape of a lozenge; on the centre of the star are embroidered the figure of St. George and the dragon. Those of the second class wear the badge pendent to a ribbon passing round their neck, and a star on their left breast. Those of the third class wear the badge pendent to a narrow ribbon which passes round their neck; but they have no star. Those of the fourth class wear the badge pendent at the button-hole of their coats.

Each knight of the first class receives an annual fabric of 700 roubles = 140/. each of the second class 400 roubles = 80/. per annum; all of the third class 200 roubles = 40/. per annum; and each of the fourth class 100 roubles = 20/. per annum. The fund of this order, assigned by the empress for the payment of their salaries, and other expenses, is 40,000 roubles = 8000/. per annum. Of this 1680 is deeded for the first class, and 2000 for each of the remaining three. The number of knights is unlimited. In 1778, the first class, which is confined to commanders in chief, contained only four; the second class comprised only eight knights; the third, forty-eight; and the fourth two hundred and thirty-four. No person can obtain this order without having performed some gallant exploit, or having served in the ranks of an officer 25 years by land, or 18 by sea.

The order of St. George of Alcasa, or the order of Montesa, is an order of knighthood in Spain. When the order of knights-templars became extinct in Spain, an order was instituted, about the year 1317, to supply their places, in consequence of a permission for that purpose obtained from pope John XXI., at which time Montesa in Valencia was selected as a proper place for the residence of the knights. In the following year, James, king of Aragon and Valencia, built at Montesa a noble college for their habitation, and dedicated it to St. George: and hence the order assumed its appellation of the order of St. George of Montesa. The habit of this order is a white mantle, on the left breast of which is embroidered a plain red cross. The badge of the order is a plain red cross, enamelled on gold, which is worn in samewise, pendant to a broad red watered riband. The order of St. George of Alcasa, was instituted about the year 1201, at a town of that name in the diocese of Tortosa. In 1399 the order was united to that of Montesa, by pope Benedict XIII., and that union was confirmed in the council of Constance.

George, Religious of the order of St. Of these there are divers orders and congregations; particularly canons regular of St. George in Alga, at Venice, established by authority of
GEORGE.

of pope Boniface IX. in the year 1404. The foundation of this order was laid by Bartholomew Colonno, who preached, in 1396, at Padua, and some other villages in the state of Venice. Pope Pius V. in 1570, gave these canons precedence of all other religious. Another congregation of the same institute in Sicily, &c.

St. George's Cross. See Cross.

George noble, a piece of gold, current at six shillings and eight-pence in the reign of King Henry VIII.

George Bank, in Geography, a rocky shoal, near the west coast of Sumatra. N. lat. 34° 38'. E. long. 96° 12'.

George Cape, a cape on the S. coast of Kerguelen's Land. N. lat. 48° 33'. E. long. 151° 15'.—Alfo, a cape on the W. coast of Newfoundland. N. lat. 48° 28'. W. long. 59° 17'.—Alfo, a cape on the N. coast of the island of South Georgia. S. lat. 54° 17'. W. long. 36° 34'.—Alfo, a cape on the coast of Peru. S. lat. 23° 56'.—Alfo, a cape on the coast of New Holland, discovered on St. George's day by lieutenant Cook, and so called by him. S. lat. 35° 10'. W. long. 208° 51'.

George St., Cape, a cape on the W. coast of Newfoundland. N. lat. 49° 30'. W. long. 59'.—Alfo, the southern extremity of New Ireland. S. lat. 5°. E. long. 152° 15'.

George Creek, a town of America, in Allegony county, Maryland; 152 miles from Washington.—Alfo, a river of America, which runs into the Potomack; 12 miles S.W. of Fort Cumberland.

George Island, an island of America, lying between lake Superior and lake Huron. N. lat. 46° 15'. W. long. 84° 20'.

George's Islands, two islands in the South Pacific ocean, discovered by Commodore Byron in 1765, and so called by him in honour of his majesty. They were again observed by captain Cook in 1777, in the passage from the Marquesas to Otaheite. One of these islands, called by the inhabitants "Tiooka" was of an oval shape, and about 10 leagues in circuit, lying in the direction of E.S.E. and W.N.W., and situated in S. lat. 14° 27' 30", and W. long. 144° 56'.

The inhabitants of this, and probably of the other low islands, are of a much darker colour than those of the higher islands, and seem to be of a much more ferine disposition; which captain Cook attributes to their situation. Nature not having bestowed her favours on these low islands with that profusion the has done to some others, the inhabitants are chiefly indebted to the sea for their subsistence; consequently they are much exposed to the sun and weather, and thus become more dark in colour, and more hardy and robust; for without doubt they are of the same nation. They were observed to be stout, well-made men, and on their bodies was marked the figure of a fish;—a very good emblem of their profession. The other island was similar to the former, extending N.E. and S.W. near four leagues, and from five to three miles broad. It lies S.W. by W., again observed on the west end of Tiooka; and the middle is situated in S. lat. 14° 27'. W. long. 145° 10'. The natives of these islands appeared to be armed with long spears and clubs; their aspect and movements were hostile; some of them, however, appeared to captain Cook to manifest a friendly disposition; but they seemed to have no inclination to maintain any intercourse with him. They supplied him with dogs, which were plentiful, and cocoa-nuts, which were the only fruit they saw. These furnished them with almost all the necessaries of life, particularly food, fuel, cordage, timber, and vessels to hold water; and with a view to this use of them, their habitations, which were mean low hovels, thatched with cocoa-nut branches, were selected near groves of these trees. Scurvy-graffs was obtained in great abundance. Their canoes, which they are cextrous in navigating, are large and curiously constructed. Commodore Byron observed the shore to be covered with coral, and the shells of very large pearl-oysters; and he conceived that a very profitable pearl-fishery might be established on these islands. The women had a piece of cloth, appearing to be fabricated of the same stuff with their fins, which hung from the waist as low as the knee; but the men were flark naked. Near the huts of these people were buildings, that appeared to be burying-places, from the structure of which it was inferred that they had great veneration for the dead. In this water is feerves. Each of these islands has in it a lagoon, or large salt-water lake. The people are much addicted to theft.

George Lake, a lake of East Florida, which is an enlargement of the river St. Juan, or St. John. It is also called "Great Lake," being about 15 miles wide, and generally about 15 or 20 feet deep, except at the entrance, which has a bar with 8 or 9 feet of water. This lake is beautified with two or three fertile islands, the largest of which is about two miles broad, commanding an extensive prospect, bearing evident marks of a large town of the Aborigines, and appearing to have been the chosen residence of an Indian prince.—Alfo, a lake that lies to the southward of lake Champlain. The portage between the two lakes is one mile and a half. The water of this lake is very clear, and was formerly used by the French in Canada for sacramental purposes, whence the lake was denominated lake "Sacra-
ment." This lake is about 30 miles long, and from one to seven wide. It embosoms more than two hundred islands, or, as some say, three hundred and sixty-five; most of which are barren rocks, covered only with heath and a few cedars, spruces, and hemlock trees. There is a large lake, with rattle-raftes. The remains of Fort George stand at the south end of the lake, about 14 miles N. by W. of Fort Edward, on Hudson river. The famous fort of Ticonderoga, which stood on the north side of the outlet of the lake, where it discharges its water into lake Champlain, is now in ruins.—Alfo, a lake in Upper Canada, situated below the Falls of St. Mary, and N. of Muddy lake; it is about 25 miles long, with very shallow water.

George's Sound. See NOOTKA.

George, St., the largest of the Bermudas islands, about 15 miles in length and three in breadth, containing about 500 houses, surrounded and defended by a chain of rocks, which extend some way into the sea, so that ships can approach it only in two places, and not without the assistance of an experienced pilot. It is divided into nine parishes or districts. It has a town of the same name, containing a town-house, where the governor, council, and magistrates assembled, a handsome church, and a library. N. lat. 32° 40'. W. long. 64° 32'. (See BERMUDAS.)—Alfo, a town, or village, near the centre of the island, containing 30 families, with the seat of Delaware, N. America; situated on a creek of the same name, which falls into the Delaware river four miles below it, and a little above Reedy island; 45 miles S.W. of Philadelphia.—Alfo, a town and capital of the island of Grenada, and also one of its six parishes, formerly called by the French "Fort Royal." It is situated in a spacious bay, on the west side of the island, not far from the south end, and poffefieds one of the finest and most commodious harbours in the English West Indies, which has been lately fortified for a great expense, and being one of the ports of entry belonging to the island was made a port by 27 Geo. III. c. 27. The town of St. George is built chiefly of brick, and makes a handsome appearance. It is divided by a ridge, which, running into the sea, forms...
on one side the carenage, and on the other the bay. Accordingly here is the "Bay-town," which has a handsome square and market-place, and the "Carenage-town," in which the principal merchants reside; the ships lying land-locked, and in deep water close to the wharfs. On the ridge between the two towns stands the church, and on the promontory above it is a large old fort, which was probably constructed by the first French inhabitants. It is built of field-stone, and large enough to accommodate an entire regiment. N. lat. 12° 45'. W. long. 61° 31'.

Edwards's West Indies, vol. ii.—Alfo, one of the Azores islands, about 10 leagues in length, and two in breadth. The soil is generally level, except towards the north, where it is rocky and barren; it is elsewhere fertile in corn, and the other necessaries of life. It is chiefly remarkable for a great number of lofty and full-grown cedars, with which the natives carry on a considerable trade. N. lat. 38° 39'. W. long. 28°.—Alfo, a town of Hindustan, on the coast of Malabar; eight miles S. of Cochin.—Alfo, a sea-port on the island of Sciro. N. lat. 38° 58'. E. long. 24° 37'. —Alfo, a small island in the Grecian Archipelago, three miles E. of Milo.—Alfo, a small island in the Grecian Archipelago, at the entrance of the gulf of Sandarick. N. lat. 38° 48'. E. long. 26° 42'.—Alfo, a small island in the East Indian sea, near the coast of Hindustan; four miles from Goa.—Alfo, a town of France, in the department of the Mayne and Loire; 20 miles S.S.W. of Angers. —Alfo, a large and deep bay on the W. side of Newfoundland. N. lat. 48° 12'.—Alfo, a river of America, or rather an arm of the sea in Lincoln county and state of Maine, lying about two leagues S.W. of Penobscot bay. This river is navigable for brigs and ships of a large burden up to the narrows; and from thence about four miles higher, to nearly the head of the tide, for sloops and schooners of 80 or 90 tons. It is about half a league wide up to the narrows. The navigation is in winter. This river abounds with all kinds of fish.—Alfo, a river of St. Mary's county, in Maryland, which is a broad but short creek, having its mouth between Pusey point and St. Mary's river on the north bank of the Potomack; opposite to the island of the same name.

St. George's Bank, a fishing bank in the Atlantic ocean, in the Maffachusetts, E. of cape Cod. It extends from north to south between 41° 15' and 42° 22' N. lat., and between 67° 50' and 68° 40' W. long.

St. George's Bay, a bay of the Pacific ocean, on the S.E. coast of New Ireland, between cape St. George and cape Orford.

St. George's Channel, that part of the Atlantic ocean which is situated between Ireland and Wales.—Alfo, a strait of the Pacific ocean between New Britain and New Ireland, 300 miles in length.—Alfo, a strait between the little Nicobar and Sambelong islands, in the East Indian sea.

St. George's Island, a small island in the mouth of the river Potomack. N. lat. 38° 15'. W. long. 76° 24'.

St. George's Islands, a cluster of small islands near the coast of East Florida, opposite to the mouth of the Apalachicola.—Alfo, small islands in the Atlantic, near the coast of Maine in America. N. lat. 43° 50'. W. long. 68° 10'.

St. George's Key, was one of the principal British settlements in the bay of Honduras, taken by the Spaniards during the American war, but retaken by the British soon after. The British settlements on the Mosquito shore, and in the bay of Honduras, were surrendered to the crown of Spain at the Spanish convention, signed at London on the 14th of July, 1786. N. lat. 17° 35'. W. long. 88° 43'.

St. George d'Alboros, an island in the Grecian Archipelago, about seven miles in circumference. N. lat. 37° 28'. E. long. 23° 20'.

St. George de Comiers, a town of France, in the department of the Aisne; nine miles S. of Grenoble.

St. George d'Elmina, See Elmina.

St. Georges-en-Conflans, a town of France, in the department of the Loire, and chief place of a canton in the district of Montoiron, 9 miles N.W. of Montbrison. The place contains 1020, and the canton 7271 inhabitants, on a territory of 2071 square kilometres, in 8 communes.

St. George d'Esperance, a town of France, in the department of the Ile; 18 miles S.E. of Lyons.

St. Georges de Lévéjac, a town of France, in the department of the Lozere, and chief place of a canton in the district of Florac, 18 miles S.W. of Mende. The place contains 1000, and the canton 2600 inhabitants, on a territory of 127 square kilometres, in 5 communes.

St. Georges fur Loire, a town of France, in the department of the Mayne and Loire, and chief place of a canton in the district of Angers; 9 miles S.W. of Angers. The place contains 2420, and the canton 9951 inhabitants, on a territory of 205 square kilometres, in 9 communes.

St. Georges-des-Bailloingeaux, a town of France, in the department of the Vienne, and chief place of a canton in the district of Poitiers. The place contains 1119, and the canton 6027 inhabitants, on a territory of 190 square kilometres, in 14 communes.

St. Georges d'Ognes, a town of France, in the department of the Herault; 4 miles W. of Montpellier.

St. George de Renteubaut, a town of France, in the department of the Ille and Vilaine; 9 miles N. of Fougeres.

St. George in Reib, a town of Austria, 6 miles S.E. of Waidhoven.

St. George am See, a town of Germany, in the principality of Culmbach, seated on a lake, called the pond of Brandenburg; 24 miles N.E. of Bayreuth.

St. Georges des Sept Voies, a town of France, in the department of the Maine and Loire; 12 miles N.W. of Saumur.

St. Georges-du-Flecre, a town of France, in the department of the Eure, and chief place of a canton in the district of Pontaudemer; 25 miles N.W. of Evreux. The place contains 830, and the canton 11733 inhabitants, on a territory of 95 square kilometres, in 14 communes.

GEORGENBERG, a town of Silesia, in the principality of Oppeln; 40 miles E. of Oppeln. N. lat. 50° 30'. E. long. 18° 32'.

GEORGENFELD, St., a town of Saxony, in the circle of Erzgebirg; 18 miles S. of Hohn. N. lat. 50° 40'. E. long. 13° 44'.

GEORGENTHAL, a town of Saxony, in the principality of Gotha; 6 miles S. of Gotha.

GEORGENZELLS, a town of Germany, in the county of Heineberg; 5 miles S.S.E. of Salzungen.

GEORGE-TOWN, a town of America, being the chief and post-town of Suffolk county, in the state of Delaware, situated 103 miles S. of Philadelphia, containing about 30 houses, and lately made the seat of the county-courts.—Alfo, a post-town in Maryland, in Kent county, on the east side of Chesapeake bay, containing about 30 houses; 9 miles from the mouth of the river Susquehanna, 65 miles S.W. of Philadelphia.—Alfo, a post-town of Beaver county, Pennsylvania, on the S. E. side of Monongahela river, at the mouth of George's creek; 16 miles S.W. of Union. In this place are annually built many boats, for the trade and emigration to
to the western country.—Also, a post-town and port of entry in Montgomery county, Maryland, and in the territory of Columbia, pleasantly situated on a number of small hills, on the northern bank of Potowmac river, separated eastward by Rock creek from Washington city, and distant 4 miles from the capital, and 8 N. from Alexandria. The houses, which are about 390, are elegant and commodious. The Roman Catholics have established a college in this place, which is in a flourishing state. The town carries on a small trade with Europe and the West Indies; 64 miles S.W. by W. from Baltimore, and 148 S.W. from Philadelphia. N. lat. 38° 55'—Also, a town and township of Lincoln county, in the state of Maine, situated on both sides of Kennebee river; incorporated in 1716, and containing 1,534 inhabitants. It is entirely surrounded by navigable waters, excelling about two miles of land, which divides the waters of Winnagage creek, a part of the Kennebee, from an arm or influx of Cape bay, called Stephen’s river. This township contains about 28,000 acres of land, and salt-marsh. Upon this spot the European first attempted in 1606 to colonize New England. It is a part of what was called “Sagadahock;” and the patentes of the Plymouth company began here to lay the foundation of a great state. They sent over for this purpose a number of civil and military officers, and about 100 people. Several misfortunes obliged them to give up the settlement, and in 1668 the whole number who survived the winter returned to England. 

George-town is 15 miles S. of Powraborow, and 170 N. by E. from Bolton.—Also, a post-town of Georgia, in the county of Oglethorpe, 50 miles S.W. of Augusta, in the midst of a poor country, but indicating prosperity.—Also, a large maritime district in the lower country of South Carolina, situated in the N.E. corner of the State. Harvy and Marion districts have lately been taken from this territory, leaving 20,532 inhabitants, of whom 16,860 are slaves.—Also, a post-town, and port of entry, and capital of the last-mentioned district, situated on an isthmus over which several streams unite their waters, and form a broad water called “Winyawa” bay, 13 miles from the sea. It contains 3,040 dwelling-houses, built chiefly of wood. The public buildings are a court-house, gaol, and academy; four churches for Episcopalians, Baptists, Presbyterians, and Methodists respectively. The place carries on a small trade with the West Indies; 60 miles N.E. by N. from Charleston, and 681 from Philadelphia. N. lat. 33° 24'. W. long. 79° 35'.—Also, a town of Kentucky, on the Elk horn; 20 miles E. of Frankfort. N. lat. 38° 7'. W. long. 84° 50'.—Also, a town of New Brunswick, on the river St. John. N. lat. 45° 48'. W. long. 66° 12'.—Also, a town on the coast of the island of St. John, on the gulf of St. Lawrence.—Also, a town of the state of Georgia; 20 miles N. of Waynesboro.—Also, a town of Scotland, in Perthshire, with some barracks, at the end of Loch Rannock; 31 miles N.W. of Perth. N. lat. 56° 41'. W. long. 4° 25'.

GEOGIA, in Botany, Ehrhart Beitr. v. 1. 176, so named by that author after his majesty George III. king of Great Britain, when he embellished, as a new genus, the mols called by Linnaeus Arumum pellucidum. All botanists, nevertheless, have preferred the name Tetraphis, given by Hedwig. See FRIESE OF MUSES, n. 1. It seems, however, that there ought to be a Georgia after Georgi the Russian traveller and botanist. See GEOGNA.

GEORGIA, in Geography, a country of Asia, between the Cispijan and Black seas, and particularly appropriated to the territory that lies between the Cispijan sea and Mingrelia, anciently known by the name of “Iberia.” The ancient Iberia, which lies to the west, is now chiefly the “Immeretia” of European Turkey, on the other side of a branch of the Caucasus. Georgia, or more properly “Gurgtia,” including Daghestan and Schirvan, may be considered as constituting the Albania of the ancients; a name, however, that has been applied in different quarters to mountainous regions.

The whole country, which is known by the name of Georgia or Grumelii, is divided into two considerable Christian states. One of these, bounded by the Black sea, consists of the kingdom of “Immeretia,” and the principalties of “ Mingrelia” and “Guriel.” (which respectively) and is now governed by a common prince, who bears the title of czar or caesar. Each of these countries had formerly its own ruler, all acknowledging the supremacy of the Grand Sultan, till czar Solomon united them under his authority, and freed them from the paramount Ottoman. Solomon, having upon his accession forbidden the fraudulent traffic practised by the nobles of selling their peasants, greatly offended the Turks, who gained by that species of commerce. Being by their intrigues driven from his throne, and compelled to find an asylum in the woods and mountains, he lived like a wild man for sixteen years, in caverns and holes, and frequently, by his personal courage, escaped assassination, until he was re-instated in his dominions by the Russians. This prince, on ordinary occasions, was distinguished from his subjects by riding on an ass, perhaps the only one in Immeretia, and by wearing boots. He had no regular troops, but collected a defunct army of 6000 men, without artillery. These troops were drawn together by the sound of the trumpet; in other respects the prince’s orders were issued at the markets, which are held every Friday. One of his servants attended a tree near the place of meeting, and proclaimed the edict with a loud voice. His subjects were of the Greek religion. Solomon died of the plague in 1784, and was succeeded by his nephew David, who threw himself under the protection of Russia. In 1784 his emissaries were introduced to the empress at Petersburg, and, in the eastern style of homage, threw themselves on the ground at her feet.

The second Georgian state consists of the principalities of “Karduelia” or “Carduelia,” (Kartalnian) and “Kakhetty,” which have been long governed by Christian princes, in submission to the Perian empire, but, since the body snuffed out by the throne of the Sophs, have rendered themselves independent. Each of these two provinces formerly composed a distinct state; but they have both lately been reduced under the sole sovereignty of prince Heraclius of the Kakhetian dynasty. The state of Karduelia and Kakhetty borders northwards on the Kabastra, eastwards on Daghestan and Schirvan, (which respectively) southwards on the Perian Armenia, and westwards on Immeretia. The capital is Tiflis (which feat). The czar, or prince Herachus, who is celebrated for his bravery and other great qualities, as well as by the important part he acted during the disturbances that agitated Persia after the death of Tamas Kulf-Khan, submitted in the year 1783 to the Russian empire, thus voluntarily sacrificing an independence which he seemed to have secured by his exploits; but the advantages of which were richly compensated in the protection he procured by this submission. However, notwithstanding this close alliance with Russia, he was compelled in 1787 to renounce his connection with it, and to acknowledge himself tributary to the Porte; but he died soon afterwards. Within a few years past the Russian interest revived, and prevailed; and in February 1801, Georgia was by a public ukase united to that empire. The Georgians or Grumelians, as they are some-
times called, avoided all connivance with the Tartars, and have distinguished themselves as the most numerous and powerful body of the mountaineers of Caucasus, now for the greater part subject to the protecting authority of Russia. The inhabitants of Georgia, when it was one kingdom, were Christians, but since the year 1639, they were blended with Mahometans; the king of Persia having conquered and divided the country into two provinces or kingdoms, and having obliged the people to embrace the Mahometan religion. But since they have been under the protection of Russia, they have again avowed themselves Christians, following in part the rights of the Armenian, and in part those of the Greek church. They are represented as the most tractable Christians of the East. The Georgians excel in the use of the bow, and are reputed to be the best archers in Asia. The women are celebrated for their beauty, but though they are very handomely they love to adorn themselves with paint, and are not in high estimation for their modesty. As the country produces strong wine, the Georgians are addicted to intoxication, and the women, as well as the men, indulge freely in the use of brandy. The men, it is said, have no virtue but courage; father kill their children, and sometimes their wives. According to the laws of war in Turkey, any province which revolts is given up to pillage, and the inhabitants are reduced to slavery. In consequence of this custom, which prevails throughout Asia, Georgia and Circassia supply the market of Constantinople with slaves; though it is said, that the Circassians alone have the honour of being admitted into the bed of the sultan. This supply of female slaves is continually furnished by the Lutghe Tartars, who, situated between the Caffian and Black seas, between Georgia and Circassia, are perpetually at war with these two provinces. They carry over to the eastern coast of the Black sea the slaves they have taken, and sell them to the Turkish merchants, who come thither at stated times for this traffic. The inhabitants of this famine coast, likewise, seize on their countrymen in the neighbouring villages, and sell them; and children have been sometimes sold by their parents. See Circassia.

The air of Georgia is dry, very warm in summer, and very cold in winter. Fine weather commences in the month of May, and continues till the end of November. The soil is extremely fertile, provided the ground be watered. The bread and fruits are excellent; and the pastures feed a great number of cattle, fat and lean. The wine is of excellent flavour, and the wild hogs are delicate. The inhabitants make wine, which they fell into Armenia and Persia, especially to Iphalan, for the king’s table. Silk forms a considerable branch of trade to Erzeroum; though the inhabitants are unacquainted with the best method of winding it. In this province there are only four considerable towns; viz. Tiflis, Gori, Suren and Ali. See Persia.

Georgia, one of the United States of America, situated between 31° and 35° N. lat. and between 5° and 16° W. long.; extending in length about 600 miles, and in breadth 250; and bounded on the east by the Atlantic ocean; S. by East and West Floridas; W. by the river Mississipi; N.E. and N. by South Carolina, the Tennessee State, or by lands ceded to the United States by South Carolina. Its population is estimated, by the census of 1791, at 82,548 persons; of whom 29,264 were slaves; but the number has since been much augmented. The settlement of a colony between the rivers Savannah and Altamaha became the subject of contemplation in England in the year 1732, with a view to the accommodation of poor people in Great Britain and Ireland, and for the further security of Carolina. The benevolent and humane proposal to raise a fund for conveying indigent emigrants to this part of America, free of expense. Their generous project was encouraged by letters patent obtained from his majesty George II. in June 1732; and, in honour of the King, the new province was called “Georgia.” A corporation was established for settling the colony, which was to be separated from Carolina by the Savannah; and a large sum of money was raised for the purpose of carrying the liberal and humane design into execution. General Oglethorpe was selected for conducting the emigrants, about 116 in number, to their new abode; and soon after their arrival, in the commencement of the year 1733, they marked the spot, on which Savannah now stands, as the most proper for the foundation of their settlement. Accordingly they proceeded to erect a fort, and a number of small huts, for their defence and accommodation. A treaty of friendship was concluded between the settlers and their neighbours, the Creek Indians; and various regulations were framed, for their future government. The number of new settlers from the Highlands of Scotland and from Germany gradually increased; so that in the course of three years, Georgia received above 500 British subjects, and about 170 foreigners. Afterwards several adventurers from Scotland, Germany, and Switzerland followed their countrymen, and contributed to encourage the hopes of the trullers as to the permanence and prosperity of the colony. Several towns were built, and, in 1739, more than 300 people were employed in trading with the Indians for furs. Nevertheless, in 1741, the English government received information that scarcely a sixth part remained of the number of persons who had migrated to Georgia; and those that continued were so much discouraged, that they seemed to be defrains of fixing in a more favourable situation. It was thus found that the fylum of government, which had been formed for this colony, was highly injudicious and altogether inconsistent with its prosperity. The first use which the proprietors of Georgia made of the unlimited powers with which they were invested, was to establish a system of legislation that made them absolute masters, not only of the police, justice, and finances of the country, but even of the lives and estates of the inhabitants. As great inconveniences had been found to arise in other colonies from large polieishes, it was thought proper in Georgia to allow each family only 50 acres of land; which they were not permitted to mortgage, or to dispose of by will to their female issue. This half regulation, however, was such, as it made the males only capable of inheritance, was soon abolished; but other restrictions of a discouraging nature still remained. No man was permitted to leave the province without a licence. If any of the land granted by the trullers were not cultivated, cleared, and fenced round with a wooden fence, or MIile fix feet high, within 18 years from the date of the grant, such part was to revert to the trullers for the benefit of the colony. It was forbidden to use negroes, to import rum, and to trade with the Indians without a special licence obtained for this purpose. Under these restrictions the province languished, and the people complained; till at length the trullers, in the year 1752, surrendered their charter to the king, and it was made a royal government. From this time, till the peace of Paris in 1763, the province struggled under many difficulties, arising from the want of credit with friends, and from the frequent molestation of enemies. The good effects of this peace were feebly felt, and its annual exports, which in 1752 amounted to no more than about 10,000. florins, were very much augmented; and its population and agriculture proportionably increased; though under some checks and interruptions from disputes and wars with the Creek Indians. But since a treaty of peace and friendship with the Creek nation was concluded in 1750, the state of Georgia has been rapidly advancing in every kind of improvement.

Since.
G E O R G I A.

Since the revolution, Georgia has been divided into counties, comprehended under two districts, viz. the Upper and the Lower; the former includes 15 counties, viz. Montgomery, Washington, Hancock, Greene, Franklin, Oglethorpe, Elbert, Wilkes, Lincoln, Warren, Jefferson, Jackson, Bulloch, Columbia, and Richmond; the latter contains nine counties, viz. Beaufort, Glynn, Liberty, Chatam, Bryan, M'Intosh, Effingham, Screven, and Burke. The principal towns are Augusta, formerly the seat of government, Savannah, the former capital of the state. Sunbury, Brunswick, Frederica, Washington, and Louisville, which is the metropolis of the state, and where its records are deposited. The principal rivers which water Georgia, are Savannah, which separates it from South Carolina, Ogeechee, which runs parallel with the former, and Alatamaha, which runs parallel with the others. Besides these and their numerous branches, we might mention Tlice river, Little Stilla, Great Stilla, Crooked river, and St. Mary's, which forms a part of the southern boundary of the United States. The rivers in the middle and western parts, belonging to the "Georgia Western territory," will be noticed in another place. All these rivers contain a plentiful supply of various sorts of fish, as rock, mullet, whiting, flad, trout, dace, cat fish, whiting, brim and butter-fish; and the bays and lagoons afford oysters, and other shell fish. The chief lakes or marshes in this state, is Eufaula, called Lake Noseeumphenogaw, which is nearly circular. The eastern part of the state is bounded by the mountains and the ocean, and the rivers Savannah and St. Mary's, comprehending a tract of country more than 120 miles from N. to S., and from 50 to 80 E., and W., is level without a hill or slope. At the distance of about 40 or 50 miles from the sea-board, or salt-marsh, the land gradually rises to mountains. The chief chain of the Alleghanian or Appalachian mountains terminates in Georgia, 60 miles S. of its northern boundary. From the base of this mountain spreads a widely extended plain, of the richest soil, and in a latitude and climate well adapted to the culture of most productions either of the south of Europe or of the East Indies. In the low country, near the rice swamps, bilious complaints and fevers are very general during the months of July, August, and September; and at the approach of this sickly season, the rich planters, with their families, remove either to the sea-islands or to a more elevated situation, for the benefit of the air. In the winter and spring, pleurisy, peripneumonia, and other inflammatory disorders, produced by colds, which are frequent in Florida and the Carolinas, in Georgia, however, are mild and pleasant; snow is seldom seen, nor is vegetation interrupted by severe frosts. In the hilly country, commencing about 50 miles in some parts, and in others about 100 miles from the sea, the air is pure and fabulous, and the water good and abundant. From June to September the mercury in Fahrenheit's thermometer fluctuates from 76° to 90°; and in winter from 40° to 60°. The most prevailing winds are S.W. and E.; and in winter N.W. The E. wind, is warmest in winter and coolest in summer; the S. wind, in summer and autumn is damp, sultry, and infalubrious. In the S.E. parts of the state, the trade winds impart their agitation to the atmosphere, and serve to purify and melliorate it. In the lowlands rice is cultivated; and in the interior and hilly parts, wheat and Indian corn, and the other productions common to the northern states, are the objects of agricultural attention. Rice is at present the staple commodity of this state; and the other chief articles of produce are tobacco, wheat and indigo. Georgia also yields cotton, flax, corn, potatoes, oranges, figs, olives, peaches, &c. The forest consists of oak, hickory, blackberry, pine, cedar, &c. The whole coast is bordered with islands, of which the principal is Skidaway, Waiaaw, Offalaw, St. Catherines, Sapelo, Frederica, Jekyll, Cumberland, &c. These islands are surrounded by navigable creeks, between which and the main land is a large extent of salt-marsh at a medium four or five miles broad, fronting the whole state, and interfected with creeks, which admit a general inland navigation, between the islands and the main land, from the N.E. to the S.E. corners of the state. The entrances of rivers flowing between these islands, form capacious harbours from three to eight miles broad; communicating with each other by parallel salt creeks. The islands in their natural state are covered with pine, oak, hickory, live oak, and red cedar. The soil is grey, formed by a mixture of sand and black mould; and a considerable part of it is very rich, and yields, by cultivation, good crops of indigo, corn, cotton, and potatoes. The soil of the main land, adjoining the marshes and creeks, remarbles that of the islands; except that, which borders on the creeks and river that penetrate far into the interior of the country, and which furnishes the valuable rice swamps. The soil between the rivers, at a greater distance, changes from a grey to red colour; and still more remotely, into the mulatto kind, consisting of a black and red earth. This sort of land is generally strong, and yields large crops of wheat, tobacco, corn, &c. This soil is succeeded by sandy, black, and very rich. This mixture of different soils is uniform, and regular, intermixed with occasional veins of different sorts; and stretches, in the order above-mentioned, across this state nearly parallel with the sea-coast, and extends through the several states, nearly in the same direction, to the banks of Hudson river. The culture of cotton is now so much an object of attention in this state, as to afford a reasonable expectation, that the states of South Carolina and Georgia may, in a few years, be able to raise more than 10 millions of pounds annually for exportation. With proper attention, most of the tropical fruits would flourish in this state. The south-western part of this state, and the adjoining parts of E. and W. Florida, will, it is conjectured, at some future period, become the vineyard of America. The chief articles of export are rice, tobacco, indigo, fago, lumber, naval stores, leather, deer skins, snake root, myrtle and bees wax, corn, and live stock. The value, in sterling money, of the exports of Georgia in the year 1753, was 15,974; in 1772, 121,674; in 1791, value in dollars, 491,472; in 1792, 459,973; in 1793, 561,833; in 1794, 676,154; in 1795, 956,158; and in 1796, 1,804,952. In 1819, the total produce of this state was 28,546, and the number of American seamen was 11,237. In return for her exports, Georgia receives West India goods, teas, wines, clothing, and dry goods of all kinds, from the northern states, cheese, fish, potatoes, apples, cyder, and shoes. The imports and exports are principally to and from Savannah, which has a fine harbour, and is the chief emporium of the state. The disposition and character of the inhabitants, collected from various parts of the world, are very much diversified; they are charged with indolence, which is attributed partly to the relaxing heat of the climate, and partly to the want of motives, necessary for exerting industry; they are praised for their friendliness and hospitality to strangers. Their diversions are dancing, horse-racing, cock-fighting, and chiefly hunting. They are reproached with an addictedness to gaming.

The different religious sects of this state are Baptists, Methodists, Presbyterians, Episcopalian, Roman Catholics, Quakers, and Jews. The former are the two chief sects, and inhabit the upper part of the state. The Episcopalians and Presbyterians are about equal in number; and the Catholics and Jews have each of them one church. The civil con-
The constitution of Georgia was adopted and ratified by a convention of delegates from the people, on the 6th of May, 1798, and is founded upon a plan similar to the federal constitution of the United States. All legislative power is vested in two distinct branches, a Senate and House of representatives, both chosen by the people at large, and styled the General Assembly. The members of the Senate are chosen for the term of three years, and those of the House of representatives are chosen annually. The Senate consists of one member from each county, and the House of representatives of thirty-four members. The executive power is vested in the hands of a governor, who holds his office during two years. Freedom of the press and trial by jury shall remain inviolate, and all persons shall be entitled to the writ of "habeas corpus." All persons shall have the free exercise of their religion, without being obliged to contribute to the support of any religious profession but their own. In each county a superior court is held twice in every year, in which all causes, civil and criminal, shall be tried, those excepted, which may be subject to the federal court, or such as may by law be referred to inferior jurisdictions. The judges of the supreme court, and the attorney-general, shall have a salary established by law; and hold their commission for three years. In the administration of justice, this state is divided into two districts, called the upper and lower circuit; and there are only two judges appointed to sit in the superior court; each of these judges being appointed to try causes in each circuit. Besides the superior court, there is an inferior court, a court of common pleas established in each county, which sits twice in a year, with five judges, appointed by the legislature. The county courts have a jurisdiction of criminal causes, which can be tried only in the superior court. Besides these there are the sheriff's court, and courts held by the justices of the peace, in every part of the state. The literature of this state, which is yet in its infancy, is gradually advancing towards higher degrees of improvement. For this purpose a college is instituted at Augusta, with liberal endowments; and in subordination to this it is proposed to found academies in every county of the state. This institution is denominated the "University of Georgia." The funds for its support consist of land, consisting of valuable land, together with nearly 6000 acres in bonds, houses, and town lots in Augusta. Other property also, to the amount of 10000 lbs., has been set apart in each county for erecting and furnishing their respective academies. The fund originally designed to support the literary orphan school, founded by the Rev. George Whitfield, a few miles S. of Savannah, consists chiefly of rice plantations and negroes. On the death of the countess of Huntington, to whom Mr. Whitfield bequeathed this property as trustee, the legislature, in the year 1792, passed a law, vesting it in thirteen commissioners, with power to carry Mr. Whitfield's original design into execution; and in compliment to the countess, the feminary is denominated "Huntingdon college." The middle parts of this state are inhabited by the Muskogee or Creek Indians, the most numerous tribe of Indians within the United States. See Creeks.

The "Georgia Western Territory" consists of an extensive tract of land, a principal part of which belongs to, and is inhabited by the Creek, Checotah, Chickasaw, and Cherokee nations of Indians. It is washed by the Mississippi river on the west, and may be considered as extending eastward as far as the Appalachian and Flint rivers. It is intersected by a great number of streams, which run in every direction; the principal are the Yazoo, and Loofa Chitto, which discharge themselves into the Mississippi, Pearl, Pascagoula, Mobile, Alabama, Tombecokoe, Eficcambin, and Chatta Hatches, which fall into the gulf of Mexico; and the Tennessee Bend, with Chucarana river, which falls into it from the fork of it, water its northern part. Twenty millions of acres of this territory was sold in consequence of an act of the legislature, passed in 1755, to certain companies; and the purchase money, amounting to 500,000 dollars, was paid into the state treasury. This land was afterwards sold at an advanced price, by the original purchasers, to various persons, principally of the middle and eastern states. This transference produced a great degree of discontent; but the ferment has since subsided; and the termination of the dispute has been a general satisfaction on the part of the purchasers, that the discordant proceedings of the legislature cannot affect their title, which they conceive to be good against all claims on the part of Georgia. Morde.

Georgia, New, or South Georgia, an island in the South Atlantic ocean, discovered by La Roche in 1675, seen by Mr. Guyot, in the ship Lion, in 1756, and more particularly described by Captain Cook, who explored it with attention in 1775, described its extent and true position, and named it Georgia, in honour of his majesty. It is situated between 33° 57' and 34° 54' S. lat., and between 88° 45' and 85° 34' W. long. It extends S. E. by E. and N. W. by W., in that direction is 31 leagues long, and its greatest breadth is about 15 leagues. It seems to abound with bays and harbours, especially on the N. E. coast; but they are rendered inaccessible for the greatest part of the year by the vall quantity of ice; or, at least, it must be dangerous lying in them, on account of the breaking up of the ice-cliffs, by which the coast is bounded, and which rise up perpendicularly in malleys of very considerable elevation. When these fall they float about in the seas like detached islands, and in falling make a noise like that of a discharged cannon. The inner parts of the country exhibit an appearance no less savage and horrible than the coast. The rocks raised their lofty summits, till they were lost in the clouds, and the valleys lay covered with everlasting snow. The lands, or rather rocks, bordering on the sea coast, were not covered with snow like the inland parts. The rocks seemed to contain iron. They are of blackish horizontal slate, probably approaching to hornblende. Not a tree was to be seen, nor a shrub even big enough to make a toothpick. The only vegetation that could be seen was that of a low stinging-bladed grass growing in tufts, wild burnet, and a plant like moss, which springs from the rocks. Seals or sea-lions were numerous, but smaller than those at Staten Land. Several flocks of penguins of a large size were observed, and besides the albatrosses, common gulls, and that fort called by Cook Port Egmont hens, terns, flags, divers, the new white bird, and a small bird like the pheas of the Cape of Good Hope, called yellow birds, which were found to be most delicious food. All the land birds that were seen consisted of a few small larks; but our navigators found no quadrupeds. The dung of one was seen, supposed to have belonged to a fox or an animal of that kind. On the whole coast our voyagers observed neither a river nor a stream of fresh water. They thought it highly probable, that the country has no perennial springs; and that the interior parts, as being much elevated, never enjoy heat enough to melt the snow in such quantities as to produce a river or stream of water. The coast alone receives warmth sufficient to melt the snow, and this only on the N. E. side; for the other, besides being exposed to the cold southerly winds, is in a great degree deprived of the sun's rays by the uncommon height of the mountains. On the approach of our navigators to Georgia, they first discovered an island in S. lat. 54° and W. long. 35° 23', which was called "Willis's island," which was a high rock of no great extent: East of this, between it and the main, they obser-
ed another island, to which, on account of the number of birds they saw upon it, they gave the name of "Bird Island." This island is of larger extent than the former, lies close to the N. E. point of the main land, which was called "Cape North." After having cleared the passage between these two islands, they pursuèd their coasting voyage to "Cape Buller," and at length arrived at a bay, which they denominated "Polefield bay," situated in S. lat. 54° 5', W. long. 37° 18', 11 leagues E. of Cape North. The land in which this bay lies, was at first judged to be part of a great continent; but upon coasting round the whole country, it was found to be an island, about 70 leagues in circuit. Between this bay and Cape Buller lies the "Bay of Isles," so called on account of several islands lying in and before it. The next projecting point was called "Cape Saunders," and beyond this is a large bay, which was named "Cumberland Bay." The next projecting land, which was an island appearing to be the extremity of the coast to the east, was called "Cape Charlotte," and on the west side of it lay a bay, which was named the "Royal Bay," the W. point of it being called "Cape George." These two capes are distant from each other six leagues. The island above mentioned, distant in the direction of S. by E. eight leagues from Cape Charlotte, was denominated "Cooper's Isle," which is a rock of considerable height, about five miles in circuit, and one mile from the main. The coast between them forms a large bay, named "Sandwich Bay." At Cooper's Isle the main coast takes a S. W. direction for the space of four or five leagues to a point which Capt. Cook called Cape Disappointment. Off this are three small islands, the southernmost of which is green, low, and flat, and lying one league from the Cape. Advancing towards the S. W., land opened beyond the Cape, which proved to be an island, and was called "Pickerel Fall island." In failing round this island, our navigators were almost continually involved in a thick mist, which led them to apprehend that they might be surrounded with dangerous rocks.—Cook's Second Voyage, vol. ii.

GEORGIA, a township of America, in the state of Vermont and county of Franklin, containing 8668 inhabitants. It is situated on Lake Champlain, opposite to the north end of South Hero island, and joins Milton on the south and St. Albans on the north. The river La Moille traverses the S. E. corner of this township.

GEORGIA, Gulf of, a large gulf of the North Pacific ocean, between the continent of North America and Quadra and Vancouver's island; about 120 miles in length from north to south; the breadth varying from 6 to 20 miles. It contains several clusters of islands, and branches off into a great number of canals, most or all which were examined by Capt. Vancouver and his officers.

GEORGIAN PLANET, or GEORGIAN SOLAR, in Astronomy, the name given by Dr. Herchel, the discoverer, to the seventh primary planet of the solar system. It is now generally known, particularly on the continent, by the name of Uranus.

This planet was discovered by Dr. Herchel on the 13th March, 1781. It is supposed that other astronomers have observed it, and inserted it in their catalogues as a fixed star. But Dr. Herchel, when he first saw it, was struck with its appearance, which seemed to differ from that of the neighbouring small stars. He happened to be accidentally engaged in examining the small stars near the feet of Gemini, and he observed one considerably larger than the rest, but it being quite so brilliant, he suspected that it might be a comet; in consequence of which he observed it with different magnifying powers, from 277, with which he discovered it, to 2010, and found that its apparent magnitude increased in proportion, contrary to what takes place in the fixed stars. He therefore measured its distance from some of the neighbouring fixed stars, and comparing its distance for several nights he found that it moved at the rate of about 213 in an hour. Dr. Herchel wrote immediately to the Royal Society, that other astronomers might join in observing it; upon which it was found and observed by Dr. Maskelyne, who almost immediately declared that he suspected it to be a planet; and on April 1, he wrote an account of this discovery to the astronomers at Paris, so that it was soon observed by all the astronomers in Europe. Mr. Lexell was then in England, and applied himself to compute the orbit upon the supposition that it was a comet; he therefore, according to the usual manner in such a case, supposed the orbit to be a parabola, and ascertained several perihelion distances, 6, 8, 10, 11, 12, 14, 16, and 18 times the earth's distance from the sun, and found that any perihelion distance between 14 and 18, would answer very well to the observations. Boscovich printed a memoir on the subject, in which he shewed that there were four different parabolas in which a body might move, and yet the computed places would agree with the observations which had then been made. Other astronomers, however, found that a circular orbit, whose radius was about 18 times the distance of the sun from the earth, would agree better with the observations; and confirmed Dr. Maskelyne's opinion that it was a planet. Upon the supposition, therefore, of a circular orbit, M. de la Lande proceeded to investigate its magnitude from the following observations. Mem. de l'Acad. Roy. des ScL 1779.

From these data, M. de la Lande calculated the elements of a circular orbit; but it having been found that the motion did not agree with any possible circle, it became necessary to calculate the elements of an elliptic orbit. When a sufficient number of oppositions had been observed for this purpose, professor Robison of Edinburgh undertook this investigation, a full account of which is given in Edinb. Trans. vol. I. 1788. The observations on which this investigation is founded are as follows:

From which the following elements were obtained:

Mean distance 19,082.47
Eccentricity 0.0006
Periodic time 83,359 years
Mean anomaly at the 7th opposition 4° 0' 32" 51"
Long. of aphelion | | 11 23 9 51 |
Long. of the node 31, 1783. 2 12 40 14
Inclination of the orbit 0 40 25
Equation of the centre 5 26 56 6

The elements, as given by La Place, are as follows:

| Sidereal revol. | | 84 29 0 0 0 |
| Scl. maj. axis or mean distance | | 19,183,620 |
| Proportion of eccentricity of semi maj. | | 0.046683 |
| Axis for beginning of 1750 | | |
| Secular variation (—indicates diminution) | | ——0.000026228 |
| | | Deg. Min. Sec. |

Mean longitude at beginning of 1750 228 33 53 6
Long. of perihelion 1750 2 166 36 48 8
Sidereal and secular motion of perihelion | | 0 4 6 1 |
Inclination of orbit to ecliptic 1750 0 46 26.0
Secular variation of inclination of orbit to true ecliptic 0 0 3.0
Long. of ascending node on ecliptic 1750 72 37 52.8
Sidereal and secular motion of node on true ecliptic 0 57 16.2

The diameter of this planet is about 44 times that of the earth, or 35,112 English miles nearly. When seen from the earth, its apparent diameter, or the angle which it subtends at the eye, is 3° 5; and its mean diameter, as seen from the sun, is 4°. As the distance of the Georgian from the sun is twice as great as that of Saturn, it can scarcely be distinguished by the naked eye. When the sky however is clear, it appears like a fixed star of the sixth magnitude with a blue-white light, and a brilliancy between that of Venus and the Moon; but with a power of 200 or 300, its disc is visible and well defined. Its arc of retrogradation is 3° 36', and the duration of its retrograde motion 151 days.

This planet is accompanied by fix satellites, all of them discovered likewise by Dr. Herschel. The two first, which he saw for the first time in the month of Jan. 1787, proved afterwards to be the second and fourth, the others were discovered some few years later.

The most remarkable circumstance attending these satellites is, that they move in a retrograde direction, and revolve in orbits nearly perpendicular to the ecliptic, contrary to the analogy of the other satellites, which phenomenon is extremely discouraging when we attempt to form any hypotheses relative to the original cause of the planetary motions.

According to La Place, if we take for unity the semidiameter of the planet, equal to 1° 49, supposing it at the mean distance of the planet from the sun, the distance of its satellites will be as follows:

| I. | 13.120 |
| II. | 17.022 |
| III. | 19.845 |
| IV. | 22.752 |
| V. | 45.507 |
| VI. | 91.608 |

And the duration of their sidereal revolutions

La Place conceives that the first five satellites of the Georgian may be retained in their orbits by the action of its equator, and the sixth by the action of the interior satellites; hence he concludes that the planet revolves about an axis very little inclined to the ecliptic, and that the time of its diurnal rotation cannot be much less than that of Jupiter and Saturn.

Use of the Tables.—The general construction of this kind of tables will be explained under Planet. The manner of calculating the mean longitude of the planet is as follows. Vince's Astronomy, vol. iii.

From Table I. take out the mean longitude, the aphelion, and node, together with the arguments I., III., IV., V., VI., VII., VIII., and place them in an horizontal line. But if the given year be not found in that table, take the nearest year preceding the given year as an epoch, and take out as before.

Under which, from Table II., place the mean motion in longitude of the aphelion and node, with the arguments answering to the number of years elapsed since the epoch, to the given year.

Under these write down (Table III.) the mean motions of the same, for the given month.

Under these write down (Table IV.) the mean motions of the same, for the given day of the month.

Under these write down (Table V.) the mean motions of the same, for hours and minutes.

Add together the numbers in the several columns, rejecting twelve signs, or any multiples thereof, if they occur; and in the arguments, rejecting 10,000 in the arguments IV., VI., and 1000 in the arguments I., III., V., VII., VIII., or any multiples thereof, and you get the mean longitude, the aphelion, and node, and the arguments for the given time.

From the mean longitude of the Georgian subtract the longitude of the aphelion, and you have argument I., or mean anomaly.

With argument I. take out the equation of the orbit in Table VI., together with the secular variation, with their proper signs, except the time be before 1780, in which case the secular variation is to be taken out with a contrary sign, making a proportion for the minutes and seconds of the argument, and you first get the equation; and doing the same for the secular variation, you get the secular variation; then, say, 100: the number of years from 1780 to the given time
GEORGium Sidus.

:secular variation above found: secular variation required.

Before 1780 the secular variation must be taken with a sign contrary to that found in the table. With argument II. take out the equation in Table VII., making a proportion in this and in the following equations, for the intermediate numbers of the arguments. With argument III., take out the equation in Table VIII. With argument IV. take out the equation in Table IX. With argument V. take out the equation in Table X. With argument VI. take out the equation in Table XI. With argument VII. take out the equation in Table XII. Take the sum of all these equations, regard being had to the signs of the first equation, and of the secular variation, the signs of the others being positive; and from it subtract 7'20", and you get the value of these eight equations; and this applied with its proper sign to the mean longitude already found gives the longitude of the Georgian in his orbit.

Example.—To find the heliocentric Latitude and Longitude of the Georgian, on Nov. 26, 1789, at 16° 14', mean Time at Greenwich.

This is the true heliocentric longitude from the mean equinox; and if we want it from the true equinox, we must apply the equation of the equinoxes.

In this operation the first five lines are taken out immediately from the tables, and the sums of all the columns give the mean longitude of the aphelion, the node, and the arguments for the given time. Argument I. is immediately found, according to the rule, the equation to which is thus found. The equation (Table VI.) for 4 22° is -3 26 59°.6, and the variation or 60° is 4'31".3; hence 60°: 54°: 15°: 31°: 4°: 5°: 7° 45°: 9°; which (as the equation is decreasing) subtracted from -3'26'59°.6 gives -3'22'54°.5, the equation required. And to find the secular variation, that variation is +7°.44 for 4 22°, and it decreases c°.16 for 60°; hence 60°: 54°: 15°: 31°: 4°: 5°: 7° 45°: 9°. With argument II, 638, take the equation from Table VII. Now the equation for 630 is 4°.7, and it changes c°.7 for 10; hence 10: 8: c°.7: c°.6, which as the equation
GEORGIIUM SIDUS.

GEORGIAN Bible. See Bible.

GEORGIAN Monks and Nuns, are religious of Georgia, in Aria, who follow the rule of St. Basil.

GEORGIANA, in Geography, a name originally given to a tract of country in the province of Maine, in North America.

GEORGIC, something that relates to the culture or tilling of the ground.

The word is borrowed from the Latin geucricus; and that of the Greek γεωργικός, of γῆ, terra, earth; and γεωργίαν, ope, I work, labour, of γῆς, opis, work.

The Georgics of Virgil are four books composed by that poet on the subject of agriculture.

GEORGIEV, in Geography, a town of Ruffia, in the government of Caucasus; 32 miles W.N.W. of Ekaterinograd.

GEORGINA, in Botany, so named by Willdenow in honour of Professor Georgi; see GEORGIA and DAHLIA.

We have retained the latter name, given by Cavanilles, for this fine genus, because it has been universally adopted in this country, where the various species seem likely to come into general cultivation. A change in such a cafe not only shocks vulgar prejudices and il!iterate indolence, but is materially inconvenient.

GEORGIUS, in Geography, a town of Walachia; 18 miles N.N.E. of Bucharest.

GEOGRAPHY, a kind of knowledge of the nature and qualities of the ground or soil, gained by viewing and considering it.

The word is formed of the Greek γη, earth, and γνωρίς, 1 see, view.

Geography is only conjectural; but its conjectures are very well grounded.

GEOSTATICS. See Statics.

GEPHRUS, in Ancient Geography, a town of Syria, according to Polybius, which surrendered to Antiochus.

GEPHYRA, a town of Syria, in the Seleucid territory, according to Ptolemy; 22 miles from Antioch.

Allo, a town of Africa, according to Polybius, in the vicinity of Carthage, situated on the bank of the river Macaras.

GEPHYRÆI, a people mentioned by Herodotus, who were probably natives of Gephyra in Syria; they migrated with Cadmus into Boeotia, where they occupied the territory of Tanagra; but on being driven from thence by the Boeotians, they took refuge in Attica.

GEPIDE, a people of Scandinavian origin, of whose Gothic extraction Jornandes gives the following account: the Goths, leaving Scandinavia under the conduct of king Barith, put to sea with only three ships. One of these, falling lower than the other two, was thence called "Gepants," signifying in the Gothic tongue flow: and hence the name of Gepantae and Gepide, which was at first given them as an appellation of reproach. Procopius likewise expressly affirms, that the Goths, the Vandals, the Visigoths, and the Gepide, were originally the same nation; that they had the same customs, manners, religion, and language; and that they only differed in names, borrowed, perhaps, he says, from their different leaders. They entered Scythia with the other Goths, and settled in the neighbourhood of the Tanais and Palus Marotis. There they continued till the reign of Arcadius and Honorius, when, their number being greatly increased, they approached the Danube, and having afterwards crossed that river, dwelt in the neighborhood of Singidunum and Sirmium, about the year 400, where they still were when Procopius wrote his history. They had kings of their own, and formed a distinct nation, separate from both the Ostrgoths and Visigoths; but perhaps not one from the Lombards, who were afterwards masters of Italy. Under their king Faﬁlida, they gained a complete victory over the Burgundians about the year 245; and Faﬁlida, dated with this victory, laid waste the territories of the Goths, whose sovereign Ottagothus refused to grant them land for their accommodation. Being defeated by the Goths, they afterwards joined them, and other northern nations, in the irruption which they made with their united forces into the empire in the second year of the reign of Claudius; but they were defeated by that prince with great slaughter. In the year 279 Probus granted them lands in Thrace, upon promise of their quiet submission; but whilst the emperor was engaged in war in the East, they seized the neighbouring provinces, and were cut off in great numbers by Probus after his return. St. Jerom mentions the Gepide among the other nations of Barbarians, who, in 407, invaded Gaul, and overran its provinces. Attila afterwards subdue them, and in 451 they served under him in his famous expedition into Gaul. Upon the death of Attila, the Gepidæ shook off the yoke under the conduct of their king Ardicæ, who obtained a complete victory over the Hunns; in consequence of which the Gepide not only recovered their ancient liberty, but gained possession of ancient Dacia, N. of the Danube, which they had been driven by Attila. They then entered into an alliance with the Romans, who agreed to pay them an annual pension. Having obtained possession of part of Illyricum, with the city of Sirmium, they continued quiet till the year 537, when, on account of their joining the Heruli, and plundering the neighbouring provinces, they were compelled by Julianus, after several encounters, to abandon Illyricum, and to content themselves with Dacia beyond the Danube. In the year 552, a quarrel arose between the Gepide and the Lombards; but the latter, having obtained a reinforcement from Julianus, attacked the former, and gave them a total overthrow. This defeat was followed by a peace between the two nations, which was brought about by the mediation of Julianus.

The peace, however, was of short duration. Under their respective sovereigns, viz. Cunimandus, king of the Gepidæ, and Alboinus, king of the Lombards, they commenced mutual hostilities; and determined to abide by the issue of a single battle. The contest was very severe, and remained for some time very doubtful; but at last, the Gepide were put to flight, and pursued by the victorious Lombards with such slaughter, that few only were left alive of the numerous multitude that had engaged. After this victory, the Lombards fixed the whole of Dacia, and obliged the Gepide either to submit, or to retire. Henceforth they had no king of their own, but lived in subjection either to the Lombards, who were masters of their country, or to the princes of the neighbouring nations, especially the Huns, settled in Pannonia. Thus their kingdom terminated in the year 572, Julianus, the successor of Julianus, being then emperor.

GEPE, in Geography, a river of Germany, which rises near Neublat in the county of Mark, and runs into the Bigger, two miles N. of Olpe, in Westphalia.

GER, Cape. See AGUER.

GERA, a town of Saxony, in the Vogtland, on the Elbe; 30 miles S.S.W. of Laepice. N. lat. 50° 49'. E. long. 13° 6'.—Allo, a town of Italy, in the department of the Upper Pa.—Allo, a river of Germany, which runs into the Unstrull, six miles N. of Erfurt.

GERA, in Ancient Geography, a town of Arabia. Ptolemy.

GERÆA, a town of Lyctania. Ptolemy.
GERÆSTIUM, a country of the Peloponnesus, in Arcadia.

GERÆSTUS, a town and port of the island of Euboea, upon the S.W. coast, about 15 miles from Carytis; now Gerefto.

GERALTINGEN, in Geography, a town of Switzerland, four miles S.E. of Soleure.

GERANDRUM, in Ancient Geography, a town of the island of Cyprus.

GERANGER, in Geography, a town of Norway, in the diocese of Drothem; 22 miles S.S.W. of Romdal.

GERANIA, in Botany, the 73d natural order in Jussieu's system, or the 13th of his 13th class. The following is his definition of this, one of his most important and extensive classes. Cotyledons two. Petals many, Stamens inserted below the germin.——The Calyx is of one or many leaves, very rarely deficient. Petals hypogynous, or inserted below the petal, definite in number, very rarely indefinite, for the most part distinct, but sometimes connected at the base, into a fort of false monopetalous corolla; they are rarely wanting. Stamens inserted below the petal, definite or indefinite, the filaments often distinct, sometimes united all or some of them into one tube, more rarely collected into several bundles; authors distinct, or united only in Valsa and Impatiens (called Balsamina by Jussieu). Germin superior, in many simple, in some multiplied; style single, or multiplied, or deficient; stigma one, or several. Fruit superior, sometimes simple, of one or many cells; sometimes, but more rarely, multiplied, each pericarp of one cell.

The order of Geranium is thus defined by Jussieu. Calyx simple, either of five leaves, or of one deeply five-cleft, permanent. Petals five. Stamens definite, their filaments united at the base, sometimes all fertile, sometimes part of them abortive. Germin simple; style one; stigma five, oblong. Fruit either of five cells, or of five capsules, each cell or capsule containing one or two seeds. Corollum without a perianth, or (allbum). Stem either somewhat fleshy, or herbaceous. Leaves with stipules, opposite or alternate. Flowers, in the former case, opposite to each leaf; in the latter, axillary.

Jussieu enumerates only two genera as properly belonging to this order, Geranium, which includes Erodium and Pelargonium, justly separated from that genus by the late M. L'Héritier; see Erodium: and Monanthes, which is but too nearly akin to Geranium. He subjoins three genera as related to this order; Tragopogon, whose affinity is very obscure; Impatiens (his Balsamina), which is perhaps still less akin to it; and Oxalis, which last we would rather refer to the Rutaceae, an order which Jussieu feems but imperfectly to have studied. He indeed, like Linnaeus, hints some relation between Oxalis and Tribulus or Zygophyllum, both which left hefixons in the first fection of his Rutaceae; but we presume to think they are there misplaced, and that Oxalis is not so much allied to them as to the real Rutaceae, so many of which are found in New Holland. In all such doubtful cases however, which form the difficulty and the pedantry of the study of natural orders, and in which our chief guide being conchylice, humidity and candour are most becoming, we merely aim at collecting observations. The unnatural combinations complained of in a fytem professedly artificial, cannot be half so hurtful as error marked in authority in the details of a pretend-ed natural one. The doubts and hints of the excellent Jussieu are in themselves instructive, but how few are content like him to confess their doubts! He has at length acquired a pupil worthy of himself in this country, Mr. R. Brown, whose opportunities of observation, among the paradoxical novelties of New Holland, have given ample scope to his intelligence and affability.

GERANIA, in Ancient Geography, a town of Thrace.——Alfo, a town of Phrygia.——Alfo, an ancient town of the Peloponnesus, in Laconia, on the confines of Melitenia.——Alfo, a mountain of Greece, in the territory of Megaris, towards the illims of the Peloponnesus.

GERANIS, or Geranium, in Surgery, a bandage formerly applied to fractured collar-bones, and dislocated shoulders. The word is derived from ρέγανη, a crane, because the shape of the bandage was thought to resemble an extended crane.

GERANITES, γερανος, a crane, in Natural History, a name given by some authors to such pieces of agate, or any other of the femail-pellucid gems, as have round spots in them, resembling in colour the eye of a crane.

Gen. Ch. Col. Perianth inferior, of five ovate, acute, concave, permanent leaves. Cor. regular, of five large, obovate or obcordate, equal, spreading petals. Nectary five glands at the base of the germin, alternate with the petals. Stam. Filaments 10, awl-shaped, recurved, united at the base into a small cup, five alternate ones longest, all shorter than the petals; anthers oblong, veratlic, five of them occasionally abortive. Pil. Germin superior, with five furrows, beaked; style central, awl-shaped, longer than the stamens; permanent; stigmas five, oblong, reflexed. Peric. Capsules five, aggregate, membranous, globose, lateral, separating at their minde, each attached upwards to a long, linear, flat, pointed, rigid, smooth awn, at length ephiathically recurved, adhering by its point to the summit of the style. Seeds solitary, lateral, roundish, their surface smooth or dotted.

Obf. This genus, as above defined, contains only the Gerania columna of Linneus, or what are commonly called European Geranioms, or Crane's-bills, bearing but one or two flowers on a stalk. (See Erodium.) Thus it is adopted by Willdenow, who has 39 species, 13 of which are natives of Britain. They are tolerably naturally distributed into three sections.

* Flower-stalks single-flowered; 4 species.

G. sanguineum, Engl. Bot. t. 272, a handflake inhabitant of rocky woods and abrupt gravelly ground, is an example of this section, though the late Mr. Davall once found in Switzerland an occasionally two-flowered variety. See Fl. Brit. 759. A variety found on the Lancashire coasts, of humble depressed growth, with white red-veined petals, is frequent in gardens.

G. fivirium, Jacq. Hort. Vind. v. t. 19, an inconspicuous species, is, we believe, contantly single-flowered.

** Flower-stalks two-flowered. Root perennial, 24 species. Most of the Crane's-bills usually cultivated for ornament are of this division, as

G. amoenifolium of L'Héritier. Curt. Mag. t. 266. This flowery species, discovered by Mr. Maffon in Madeira, was, as Mr. Curtis records, long known in our gardens by the name levigatum, admirably expressive of its smoothness, and the French botanist changed it for the worfe. We could have...
GER

no redress, as the original name had not been printed. It is a hardy greenhouse plant, throwing out, from its short knotty stam., a profusion of spreading, long-stalked, thinning, palmate, primitively leafy, and many spreading, leafy branches, forked upwards. The flowers are large, of a fine crimson, broader than a half-crowned.

G. macrophyllum, Linn. Sp. Pl. 953. Jacq. Rar. t. 134; native of Italy, is a very common hardy perennial in our gardens, remarkable for the roundness of its red petals, and the strong, but aromatic, cedar-like, scent of its herbage. The plant is of humble growth, with a short knotty stem, like the last. Locates soft and downy.

G. phaeum, Linn. Sp. Pl. 953. Engl. Bot. t. 322; and G. suffumum, Linn. Mant. 97; two species very nearly akin, are remarkable for the dark brown colour of their flowers; as G. reflexum, ibid. 257. Cavan. Diff. St. f. 1, is for its reflexed petals, and G. phaeum, L'Hert. Geran. t. 39, first well determined by Haller at his No. 935, though he was not for some time attended to, for its flat, round, ferrated petals, of a pale livid dove-colour. These four last are often seen in gardens about London.

G. nodosum, Linn. Sp. Pl. 953. Engl. Bot. t. 909, is the most rare British species, and scarcely found elsewhere but on the mountains of Provence and Dauphiny, in flaky places.

G. floriatum, Linn. Sp. Pl. 953. Curt. Mag. t. 55, a native of Italy, very hardy with us, is generally admired for its delicately pencilled blossoms.

G. austriacum, Curt. Mag. t. 203, now frequent in gardens about London, but from what country imported is not known, was first ascertained as a distinct species by the late Mr. Curtis. Its flowers are prettily veined with reddish purple on a pale ground.

G. pratensis, Linn. Sp. Pl. 954. Engl. Bot. t. 404, a very handsome blue-flowered species, common in purlines in the north, is extremely remarkable, and almost singular in this natural order, for having sometimes double flowers, in which flat it was found near Athol house, Scotland, by Lady Charlotte Murray in 1793. It is often seen with white petals.

G. argentatum, Linn. Sp. Pl. 954. Curt. Mag. t. 504, a native of Mount Balbus, was introduced into England by the indefatigable and intelligent Mr. Lod lugs, whole zeal and liberality as a cultivator are above all praise. Its leaves are beautifully silver, the plant dwarf, but the flowers peculiarly large, bluish-coloured, veined with red.

G. germanicum, Linn. Mant. 97. Sm. Pl. Brit. 735. Engl. Bot. t. 305. Curt. Lond. falc. 3. t. 424, common about London and Edinburgh, has not been well understood, even by Mr. Curtis, who undertook to illustrate it. Linnaeus originally confounded it with molle hereafter mentioned, from which its even capsules, perennial root, and greater magnitude, keep it very distinct.

** Flower-stalks two-flowered. Root annual; 11 species.

G. bokheianum, Linn. Sp. Pl. 955; placed first in this section, well drawn in Dillenius's Hort. Eth. t. 153. f. 165, is remarkable for its very black hairy feed-veffels, and vivid herbage.

G. molle, Engl. Bot. t. 778, ought to follow immediately; with dictum, t. 753; rapidulphiun, t. 157; and pyllium, t. 585. These four, long confounded, and scarcely understood by any botanist, are beautifully distinguished, in every degree of luxuriance, by their capsides, which are corrugated and twisted in the form, more slightly corrugated, but hairy, with reticulated seeds, in the second, curtained, even and hairy, with reticulated seeds in the third, with much more entire leaves; even and hairy, with smooth seeds, in the half, whose hairs in the part in question are, moreover, close-pressed, not spreading as in the preceding. We were obliged to the late Mr. Davall for first calling our attention to this part, and thus leading to one of the most satisfactory discoveries in European botany.

G. carolinianum, Linn. Sp. Pl. 956. Jacq. Hort. Schonbr. v. t. t. 140, where it is mistaken for a new plant, and called hanginum; follows these; with caldonius, Engl. Bot. t. 259. To which should succeed lucidum, t. 753; then, if it be a distinct species, which we much doubt, purpureum of Willdenow, n. 39, and Villars Dauph. t. 425; and finally rebitum, Engl. Bot. t. 1436. Curt. Lond. falc. t. t. 52. This purpureum has been a weed in Chelsea garden ever since the time of Miller, but though Ray mentions it as a native, see Pl. Brit. 732. G. rebitum, we never gathered it elsewhere.

GERANUM, in Gardening, comprehends plants of the herbaceous perennial kind, of which the species cultivated are, the dark flowered crane's-bill (G. phaeum); the knotty crane's-bill (G. nodosum); the streaked crane's-bill (G. ariatum); the Siberian crane's-bill (G. fibricum); the bloody crane's-bill (G. fanginum); and the long-rooted crane's-bill (G. macrophyllum); but there are other sorts that may be cultivated with propriety.

The fifth species has several varieties, as with short spreading limbs and small leaves and flowers; with large leaves deeply divided, and with variegated or striped flowers.

Method of Culture.—Each of these species of plants is capable of being increased in two ways, either by sowing the seeds or cutting the roots. Where the first method is adopted, the seeds should be sown in the autumn as soon as they have become perfectly ripened, either in pots or in a flaky border in the garden ground where the mould is light and fine. As soon as the plants have acquired a few inches in growth, they should be pricked out into other pots, or beds of fine light earth, at the distance of five or six inches in the latter case; but where this cannot be done, they may be permitted to remain until the following autumn or spring, and be then put out into other pots or borders, where they are to continue, being occasionally watered in a moderate manner.

In cases where the natural roots is practised, care should be taken not to divide them too much; planting them out in the early part of the autumn, either in pots or where they are to continue.

Most of these sorts of plants are of rather hardy growth, and succeed in most kinds of ground, demanding but little attention in their cultivation, beside that of which they are kept clear from all sorts of weeds and rubbish.

All of them are capable of affording variety in the borders, clumps, and other parts of pleasure gardens, and the potted kinds produce a fine effect in situations about the house in mixture with those of other sorts.

GERANOS, Phænix, in Antiquity, a remarkable dance performed in the festival called Delta.

GERANZAGO, in Geography, a town of Italy; nine miles E.N.E. of Pavia.

GERAR, or Gerasar, or Gezarah, in Scripture Geography, a city of the Philistines, S. of Judah. The Philistines were kings of this city in the time of Abraham and Isaac. At this time it was the boundary of the Canaanites, situated on the river Bezer, about seven miles S.W. of Debar, and fixed East of the Jordan. It afterwards belonged to the tribe of Simeon. Gerar extended far into Arabia Petraea, being 25 miles from Elnu, or Petrae, beyond Doroma, the south of Gudah. Mof's says, that it lay between Kadesh and Shur, and he mentions the brook or valley of Gerar. (Gen. xxvi. 26.) Suzon speaks of a little town, called Gera, 50 furlongs from Pelusium.

Gerar
Gerard is confounded with Beerheba, Anthelion, Allulph, and Arad.

GERARD, Herb. in Botany. See ANTHELION.

GERARD, in Biography. See ANTHELION.

Gerard, a native of the island of Martignies, on the coast of Provence. While Jerusalem was the seat of the Saracens, some Nepauaens merchants obtained permission from the sultan of Egypt and Syria, in the year 1250, to erect a Benedictine monastery, near the holy sepulchre, for the convenience of the pilgrims who came to visit it. Among others Gerard came to pay his devotions at the holy city, where he obtained a high character for piety and prudence. The monastery soon became rich, and in conformity with the spirit of the times the abbots built, with the wealth poured in by the rich devotees, an hospice for the reception of the poorer classes, and with proper accommodation for the aged and the sick. The management of this he gave to Gerard. A part of the building was appropriated for a chapel dedicated to St. John, in which the learned and military character should be blended. He began, about the year 1200, to carry his design into execution, when numbers of perfons associated with him under the denomination of the "Hospitales of St. John of Jerusalem," who, besides the three usual vows of chastity, poverty, and obedience, took a particular vow to devote themselves to the relief of all Christians in distress. The order was recognized, and privileges granted to it by pope Paeel II. Gerard was the first grand-master, and such was the commencement of that order which has been so frequently and so long celebrated in history: the members of it were first denominated knights of Rhodes, and afterwards knights of Malta.

GERARD, John, a learned German Lutheran divine, was born at Jena in the year 1621, where he was educated, but at the age of nineteen he went to Altdorf for the sake of greater progress in the oriental languages, and in 1643 the university conferred on him the degree of M.A. He was appointed professor of philosophy at Wittenberg in 1646, and in 1652 he was nominated professor of history at Jena. After this he was created doctor of divinity, and made professor in that faculty, having devoted much of his time to biblical and theological learning. He was likewise appointed rector of the university of Jena. He died in the year 1688, and left behind him, as memorials of his great learning, many works of very deep erudition: among these were: "Harmonia Linguarum Orientalium;" "Disputationum theologicae Practicae;" "De Ecclesiae Copticae Ortu, Progreflis, et Doctrina."

GERARD, Alexander, was born at Garisch, in the county of Aberdeen, in the year 1728; he was educated at the grammar-school at Aberdeen, and so great was his progress, that he was entered a student in Marischal college when he was but twelve years of age. Here he devoted his first four years to the study of Greek, Latin, the mathematics, and philosophy, and was, at the close of the course, admitted to the degree of M.A. He now commenced his theological studies, which he prosecuted at the universities of Aberdeen and Edinburgh. Immediately, on the completion of his twentieth year, he was licenced to preach in the church of Scotland, and in the year 1750 was chosen aitent to Mr. David Fordyce, professor of philosophy in the Marischal college at Aberdeen, and in two years afterwards, upon the death of the professor, Gerard was appointed to succeed him. Here, after a short time, the department assigned to Mr. Gerard was confined to moral philosophy and logic, the duties of which he discharged with conscientious and un Wearied diligence, and with equal success and reputation. He was a member of a literary society at Aberdeen, which met very regularly every fortnight during the winter, when the members communicated their sentiments with the utmost freedom, and received mutual improvement from their literary discussions. In 1759 Mr. Gerard was ordained minister of the church of Scotland, and in the following year he was appointed professor of divinity in the Marischal college, and about the same period he took his degree of doctor of divinity. He continued to perform the several duties attached to his offices till 1771, when he resigned the professorship, together with the church living, and was preferred to the theological chair in the university of King's college, a situation which he held till his death in 1795. Dr. Gerard's attainments were so great that it is not possible to enumerate all his disquisitions of his services, for which a learned and diligent discharge of his ministerial duties: his sermons were simple and plain, adapted to the common classes of hearers, but so accurate as to secure the approbation of the ablest judges. As a professor of divinity, his great aim was not to impose by his authority upon his pupils any favourite system of opinions; but to impress them with a sense of the importance of the ministerial office; to teach them the proper manner of discharging all its duties; and to enable them, by the knowledge of the scriptures, to form a just and impartial judgment on controverted subjects. Possessing large stores of theological knowledge, he was judicious in selecting his subjects, happy and successful in his manner of communicating instruction. He had the merit of introducing a new, and in many respects a better, plan of theological education, than those on which it had formerly been conducted. Having a constant regard to whatever was really useful, rather than to endless speculations, he enjoyed no duty which he was unwilling to exemplify in his own conduct. In domestic life he was amiable and exemplary; in his friendships steady and disinterested, and in his intercourse with society hospitable, benevolent, and unassuming; uniting to the decorum of the Christian pastor, the good breeding of a gentleman, and the cheerfulness, affability, and ease of an agreeable companion.

GERARD, John, a surgeon and famous herbalist of the time of Queen Elizabeth, was born at Nantwich, Cheshire, in 1545. He practised surgery in London, and rose to eminence in that profession. Mr. Granger says he was many years retained as chief gardener to Lord Burleigh, who was himself a great lover of plants, and had the best collection...

Gen. Ch. Cal. Perianth inferior, of one leaf, permanent, with five upright, sharp segments. Cor. of one petal, ringent, tube round, longer than the calyx; upper lip erebus, obtuse, flat, broadened, emarginate; lower reflexed, deeply three-cleft, its lateral segments emarginate, the middle one shorter, deeply divided. Stam. Filaments four, scarcely so long as the tube, two of them rather shorter than the rest; anthers small. Pfl. Germin superior, ovate, small; style simple, short; stigma obtuse. Peric. Capsule ovate, of two cells and two valves, opening at the base, the partition contrary to the valves. Seeds ovate; according to Linnæus solitary, which does not appear from Plummer's works.

Eff. Ch. Calyx five-cleft. Corolla two-lipped; the lower lip in three deep emarginate lobes, the middled smallest deeply divided. Capsule of two cells, opening at the base.

This
This genus, as founded by Plummer and adopted by Linnaeus, entirely depends on the first species.

1. G. tuberosa. Linnae. Sp. Pl. 848. (G. humilis, bugula folia, aphiodi radice; Plum. Ec. 64. t. 75. f. 2.) found by Plummer in South America, and never seen by Linnaeus. We have a very bad specimen from that country, which agrees with Plummer's figure, as to the leaves and habit, but nothing can be made out of the fructification. The above characters are taken from Plummer's works. Willdenow, by mistake, we presume, fixes the capite of is cells. Dr. Swartz appears not to have found this, or any other Lapso of Gerardia, in the West Indies. Linnaeus, well aware that the various plants he subsequently referred to this might probably not well accord with the above, has given a hint that "the fructification requires examination." Whatever might be the result of such examination, this plant must be the true, though it were the only Gerardia, and the rest in that cafe must have a new generic appellation and character.

2. G. dolynsifolia. Linnae. Sp. Pl. 846. Roxb. Coronam. v. 1. t. 42. is totally distint in habit and character. Its authors have a remarkable cres, indicated but misplaced in Roxburgh's figure, for what there appears the anther is the crest, and the apparent point of the filament is the true anther, at least in our specimen.

3. G. purpurea. A North American species, closely agreeing with the last in habit, but has no such crest or appendage; but their flowers are otherwise very similar. G. flava and polkalearia are undoubtedly of the same genus with this; but glatimina, figured in Lamarck's t. 529. f. 1, has a very different appearance. It was gathered in China by Osbeck, who likewise has given a plate of this species in his Travels, t. 9. Lamarck's f. 2 is G. polkalearia.

Willdenow has 12 species in all. None of them seem now to be known in the English gardens, though highly differing of culture for the beauty and size of their flowers. G. purpurea indeed is mentioned in the Hortus Kewensis, as a hardy annual, introduced in 1772, by Samuel Martin, M. D., but it probably did not long remain, or at least has not been dispersed among collectors in general.

GERARDMER, in Geography, a town of France, in the department of the Vosges, and chief place of a canton, in the district of St. Die, 10 miles E. of Remiremont. The place contains 4,285, and the canton 4,285 inhabitants, on a territory of 1224. kilometres, in one commune.

GERARDS, Mark, in Geography, a painter, born at Bruges in 1501, who came to England not long after the year 1506, and remained till his death in 1645. He was made painter to queen Elizabeth, as he was also to Anne of Denmark. His works are very numerous here, though, as he used no mark, they are not easily known. He painted very thin and neat; ornamenting the dresses of his figures with jewels and pearls in a, profile manner. The sitters he generally painted of a greyish taint, and these are the best tokens of his hands by which his pictures may be discovered.

He painted a procession of queen Elizabeth to Hunford house, which is engraved by Vertue; and he drew the queen and the knights of the garter in procession; from which design Ainsloe's print is engraved in his history of that order. He also wrote an introduction to the art of drawing, which was translated and published in English in 1677.

GERARDSTOWN, in Geography, a small town of America, in Berkeley county, Virginia, containing about 30 or 40 houses; 10 miles from Martinsburg.

GERASA, or Gerisa, in Scripture Geography, a city beyond and east of the Dead sea, included by some in Cellephoria, by others in Arabia; placed among the cities of the Decapolis, Matt. vii. 28. The Greek editions of Matthew, for Gereophenes, read Gerefenes, and some, Gadarens. Luke and Mark have the same reading. Origen thinks that the true reading is neither Gera nor Gadara; but that the city of Gergesa is meant, which lies on the lake of Tiberias, where, in his time, the people shewed the rocks and precipices from which the swine ran down. It is also called Gira and Girgeles, and was one of the cities that belonged to the half-tribe of Manasseh.

GERAS, ORF, in Geography, a town of Austria; 7 miles E. of Korn Neuburg.

GERAU, a small country of Germany, situated near the confluence of the Maine and the Rhine, in the circle of the Upper Rhine: its capital is Darmstadt.

GERAL, Grofa, a town of Germany, in the principality of Hesse-Darmstadt; 8 miles W. N. W. of Darmstadt.

GERBA, or Jerba, a small island in the Mediterranean, near the coast of Tripoli. Its principal product is barley and fruit. Its ancient name was "Lotophagitis." N. lat. 33° 56'. E. long. 14° 20'.

GERBEL, NICHOLAS, in Biography, a native of Pfortzheim, was known and highly celebrated in the fifteenth century as a most learned jurist. He was professor of the law at Vienna, and afterwards at Strasbourg. He attained like- wise to a high reputation for his knowledge in history and antiquities. He is characterized by De Thou as one equally estimable for his erudition and humanity. His works are "Itinera in Tabulam Graeciae Nicolai Sophiani;" "De Anabaptistarum ortu et progressu;" "Vita Joannis Capciniani." This first of these was published in 1545, and afterwards augmented into seven books, comprehending a complete description of all Greece, and printed at Basl in 1550. Gerbel corrected Capcinian's "Chronicle of the Cawars," and Arrian's "Hift. of Alexander."" GERBERA, in Botany. See ARNICA.

GERBERAY, in Geography, a town of France, in the department of the Oise, fortified in the 9th century, to fill the incursion of the Normans; 12 miles N. W. of Beauvais. N. lat. 49° 32'. E. long. 1° 57'.

GERBERT, or GIBERT, Pope, in Biography, was a native of Auvergne, and born of obscure parents in the neighbourhod of Aurillac, where he was a monk; and may be justly considered as one of the principal ornaments of the tenth century. His talents were so various, and his affinity in acquiring knowledge so great, that it is difficult to say what were those branches of literature and science in which he chiefly excelled. He was a divine, a mathematician, and a philosopher, and he wrote upon geometry, particularly the quadrature of the circle, astronomy, logic and rhetoric. He was eminently distinguished by his knowledge of music, on which he composed, in Latin monikih rhyme, a didactic poem, entitled "Ars Musica," preferred in the Rawlinson collection of MSS. at Oxford; and in this little work is a separate treatise, under the title of "Rythmomachia," or the battle of numbers or figures, which Gerbert composed as a kind of game, soon after the arrival of the Arabian figures or cyphers in Europe, for which the author gives rules refembling those for chefs. Having cultivated music very assiduously, regarding it as the second in rank, among the liberal arts, he must have acquired a considerable reputation in it, as the authors of the twelfth century gave him the title of Gerbert the Musician." He is said to have been as well skilled in the construction of musical instruments as in the use of them, particularly the hydraulic organ. William
of Malmsbury speaks with wonder of the perfection to
which he had brought this instrument by means of blowing
it with warm water. His extraordinary talents and attain-
ments established his claim on those high ecclesiastical pre-
ferments to which he was advanced. Before his exaltation
to the papal chair as the successor of Gregory V., in the
year 999, he was, first, archbishop of Rheims, and afterwards
of Ravenna. As pope, he assumed the name of Silvester II; but he died in 1003, having filled the papal throne
four years. The day of his death is marked in his epitaph,
which was written by pope Sergius IV., who succeeded
him in 1003, and is still to be seen in the Lateran church.
This pope contributed very much to the reformation of
letters in Europe. His genius, says Motheim, (E.H. vol. ii.)
was extensive and sublime, embracing all the different
branches of literature; but its more particular bent was
towards mathematical studies. Mechanics, geometry, al-
chemy, arithmetic, and every kind of knowledge that had
the least affinity to these important sciences, were cultivated
by Gerbert with the most ardent zeal, as his various writings
testify; and he had the merit of employing every method
that was proper to animate others in the culture of the liberal
arts and sciences. The effects of this noble zeal were visible
in Germany, France, and Italy, both in the tenth and fol-
lowing century. Gerbert was, in a great measure, indebted
for his extraordinary acquirements, more especially in physics,
mathematics and philosophy, to the writings and instruc-
tions of the Arabians, who were settled in Spain. It was in
this century that the plan of the holy war was formed; and
through the conclusion of it, the bloody signal was given by
our learned pontiff, in the first year of his pontificate. This
signal was an epistle, written in the name of the church of
Jerusalem, to the church universal throughout the world, in
which the European powers are solemnly exhorted and in-
terceded its succours and deliver the Christians in Palestine.
The pontiff’s exhortations, however, were only regarded by
the inhabitants of Pisa. We shall here add that Gerbert’s great
learning induced the vulgar to suspect that he was addicted
to magic, and Platina has adopted this absurd notion; for he
says that he obtained the papacy by ill arts, and that he left
his monastery to follow the devil. He allows him, indeed,
the merit of a sincere repentance; but mentions some pro-
digies at his death, which will claim little regard on the testi-
mony of such a writer. The most complete collection of
Gerbert’s letters is that of Duchesne.

GERBERT, Fader Martin, a German musical writer, who
belonged to the congregation of Benedictines, at the abbey
of St. Blaise, in the Black Forest, near Friburg, in Durlb,
about 50 miles from Strasbourg, and has been elevated
to the head of his society under the denomination of “Prince-
Abbot” of St. Blaise. In 1754, he learned abbots published
the plan of a “History of Church Music,” from the first
century to the present time, under the title of “De Cantu
et Musica Ecclesiastica à prima ecclesiae Ætate, usque ad praecipsum tempus.” After this publication he travelled through
Germany, and a great part of France and Italy, in order to
collect materials in the several convents and public libraries
of those countries, and in 1765 he published his “Itinerary,”
informing the public of the success of his researches. A great
part of the author’s materials for the history of sacred music were unfortunately destroyed by fire; but availing
himself of his remaining flock, he refixed the work.

Though the indefatigable and pious abbot was in search of the music used in the Roman masses and liturgy, he cau-
didly mentions the music of the Protestant churches. He
had procured from England Dr. Boyce’s magnificent publica-
tion of our cathedral music from the time of the reforma-
tion till the middle of the last century, and allows the com-
position to be excellent; but wishes for more plains and
simplicity in favour of the words; and thinks that fugues
and learned counterpoint, though ingenious productions,
render the words unintelligible. The author has intimated
at the end of the second vol. the whole mass, “In cetera Domini,”
in eight parts, in score, to be sung antiphonally as in our
choirs, from side to side.

The harmony is very pure; but we have been so long ac-
quainted to more varied, express, and elaborate composi-
tions in our cathedral service, that such music would be thought very timid and uninteresting, if adopted in our
choirs. After this, the “Gloria in excelsis” is given
in the same simple counterpoint; where nothing is varied.
These two choirs are accompanied by two organs on a ground.
Then the gradual, the credo, the offertorium, the sanctus, and
the benedictus, all in plain counterpoint.

The communion service is in figurative harmony, but very
dry, ancient, and common.

The plates given of the primitive notation of the chants
and hymns, before the invention of lines and spaces, or a
time-table; and indeed, even before counterpoint was
attempted, in dots over the words are innumerable, from the
Lexicon Diplomaticum of Walther, and from ancient
milliafs. But these ever remain more curious than useful.
For to acquire a clear conception of their import would lead
to no useful or amusing knowledge; as the chant or plain-
fong is generally rude, uncouth, and unmeaning, that it
would furnish a very inadequate reward for the labour of
deciphering it.

GERBEVILLER, in Geography, a town of France, in
the department of the Meurthe, and chief place of a canton,
in the district of Luneville; 5 miles S. of Luneville. The
place contains 2,070, and the canton, 9,169 inhabitants; on
a territory of 324 square kilometres, in 23 communes.

GERBER, Sir Balthazar, in Biography, a painter in
miniature, born at Antwerp in 1592. He was employed
by Charles I. but is far more conspicuous as having
been engaged, in conjunction with Rubens, to negotiate a
treaty with Spain; and for having been for a time British re-
sident at Brussels. His being in the suite of Buckingham
in Spain was the means of this elevation; for which he does
not appear to have been duly qualified. He was somewhat
acquainted with architecture, and was employed by lord
Craven to give designs for Hempsted-hall, which has since
been burnt.

Being neglected by the court, he, in 1648, appears as an
author, and founder of an academy at Bethlem Green; and,
in 1649, published his first lecture on geography. He af-
terwards went to Cayenne, and settled with his family at
Surtain; where, by order of the Dutch, he was fished and
sent back to Holland, from the jealousy of that govern-
ment, which regarded him since his naturalization in England
as an agent of the king. On the restoration of Charles II.
he returned to England, and prepared triumphal arches for
his honour. Here he practised various kinds of living for
several years, with no great respect or profit, and at last died in 1667, having passed his latter days in all the expeditions
of quackery.

GERBILLO, John Francis, a distinguished Jesuit
missionary, was born at Verdun in 1654. He entered into
the Society of Jesus when he was fourteen years of age,
and having constantly the million to China in view, he qualified
himself for it by the study of the mathematics, and those
sciences that might be most useful to him in his great work.
He had the good fortune to see his wishes accomplished in
1685, when he was allowed to embark for China, in com-

party with six other persons, members of the same society. On his arrival he remained at Pekin, studying the language, and during this period, being admitted frequently into the presence of the emperor, he so ingratiated himself with him, as to obtain an appointment to join an embassy sent to regulate the boundaries with the court of Muscovy. He contributed much to the succees of this business, and on his return to China was treated with great honour by the emperor, who chose him his instructor in mathematics and philosophy. Gerillon is supposed to have enjoyed more advantages than almost any other person, for studying the manners of the Chinese court, and for making observations on the neighbouring country. He obtained permission to preach the Christian religion in China, and had the direction of the French college in Pekin, and was in the end made superior of all the missionaries sent from France. He died at Pekin in the year 1707, leaving behind him curious accounts of his eight journeys into Tartary, which have been printed in Duc Halle's Description de la Chine. He was the author of the "Elements of Geometry," and of a work on Perspective, both printed in a very handsome manner at Pekin.

GERBOA, in Zoology. See Dirus.

GERBSTADT, in Geography, a town of Germany; in the county of Mansfeld; 30 miles S.W. of Dessau. N. lat. 51° 40'. E. long. 11° 47'.

GERDAU, a river of Lueneberg, which runs into the Ilmenau, at Oldenstadt.

GERDAVEN, a town of Prussia, in the province of Westphalia, situated on the Omet, near a considerable lake, which is called the "Calendar of Gerda ven," from its prophesying the weather; 30 miles S.E. of Konigberg. N. lat. 54° 16'. E. long. 21° 27'.

GERDEN, a town of Germany, in the bishopric of Paderborn; 16 miles E. of Paderborn.

GERDES, DANIEL, in Biography, was born at Bremen in 1698, where his father was engaged in a commercial life. Great care was taken of the education of Daniel, who made rapid progress in the classics. At first it was intended he should pursue the law as a profession, but the plan was changed, and he devoted himself to the study of theology. In 1722 he was admitted into holy orders, and immediately afterwards made a tour on the continent, and formed an acquaintance with the most learned men of that period. In 1726 he was admitted to the degree of doctor, and in 1735 he was chosen professor of theology at Groningen, and upon his entrance on the office he delivered an oration "De mutations que Fideles omnia docet." The same year he was elected a member of the royal academy of sciences at Berlin. He died in the year 1765, leaving behind him many works that bear ample testimony to his learning and zeal in the cause of literature. His writings are mostly theological, and tend to the elucidation of the difficult parts of the Old and New Testament. Gen. Bioq.

GERDIK, in Geography, a town of Russia, in the government of Perm, situated on the Volga; 152 miles N. of Perm. N. lat. 59° 40'. E. long. 56° 13'.

GERDOBA, a mountain of Africa; 80 miles E. of Angola.

GEREELK, a town of Hindoostan, in Bahar; 12 miles S. of Bahar.

GEREM, a town of Grand Ducharie; 15 miles S.S.W. of Badakhan.

GEREMSHANGEAIA, a town of Russia, in the government of Upha; 36 miles W.N.W. of Bagulma.

GEREN, a town of Prussia, in Pommerania, on the Vistula; 9 miles W.S.W. of Marienburg.

GERENI, or GERESTI, in Ancient Geography, a town of Italy. - Also, a town of the Peloponnesus, in Laconia, Prokon - y; also, a town of Megglen, on an eminence, S.W. of Alba - gonia. Paunian says that this town was the fame with the "Regio" of Homer. It was consecrated to Mars, an ingenious physician, slain by Eryphantes, whole bones were collected by Neller, and deposited at Rhodon, near this town. It had a temple dedicated to Mars. East of it was a mountain called "Calathous," on which was a temple consecrated to Calathus, with a grotto, having a strait entrance, and containing in its interior many curiosities.

GERENNA, or GERENA, in Geography, a town of Spain, in the province of Seville, surrounded by large stones, supposed to have been the effect of an earthquake; 12 miles N.W. of Seville.

GERENSKOAI, a fortres of Russian Siberia, in the government of Kolomna; 240 miles S.W. of Kolom - na. N. lat. 52° 53'. E. long. 59° 14'.

GERESHEIM, a town of the duchy of Berg; 5 miles E. of Duffeldorlo.

GEREK, in Myth, one of the clefs.

GERESPA, in Ancient Geography, a town of Asia, in the interior of Media, sometimes called Gerusa, and Ger - sa.

GERESTADT, in Geography, a town of Norway, in the bishopric of Agderhus; 32 miles S.W. of Tonberg.

GERESTO, a town of the island of Negropont; 15 miles S. of Carnito.

GEREUTH, a town of the principality of Wurzburg; 5 miles N. of Bern.

GERFALCON, GYRFALCON, or JERFALCON, (see Falcon). This is naturally a very bold, wild and fierce bird, and is therefore very difficult to be restrained; but when that is done it proves one of the very best kinds, and will fly at almost anything. The beak of the geyralcon is always blue, and the claws are remarkably long and strong.

In going up to the gate, the sportmen exports it, these birds do not hold the same fort of courage that others do, but immediately climb up upon the train on sight of the bird, and as soon as they have reached her, they immediately make the attack, and generally pull her down at the first encounter; but if not, always at the second or third.

This sort of hawk is to be fed and rewarded like the others. It is of a very fly and crafty nature, and is so slyish, that it loves to keep the calling a long time; therefore, Instead of cotton, it is proper to give them sometimes a calling of tow, and to keep them sharp. As to the reclaiming, this sort of hawk, it is only to be done by gentlemens and kindred; and when she has been taught to be turned loose, she is not to be taught to come to the pelts of hens or other fowl. But the muff never be suffered to taste any living flesh, for that will be apt to draw away her love from the hand and voice. Whenever the cats, the falconer must be close to her, and must make her eat the choicest pieces out of his hand. There is great care to be taken in the making of these birds, for as they are made at first, so they are for ever; and it is a necessary caution, with birds of this bold and fierce nature, not to curry over the business, but to repeat the same thing very often till it is perfectly fixed. See Falconry.

GERGAR, in Geography, a town of Spain, in the province of Grenada; 10 miles S.W. of Purchena.

GEREFALVA, a town of Transylvania; 16 miles W. of N. W. of Hermelstadi.

GEROCAS, See GERASA.
GER

GERGeszetes, or Gerghashites, in Ancient Geography, an ancient people, who inhabited the land of Canaan, before the Israelites took possession of it. Their territory lay next above that of the Amorites, on the east side of the sea of Tiberias; and it was afterwards possessed by the half-tribe of Manasseh. See Geresa.

Gergetha, or Gergesa, a town situated in the Tragade, E. of Rhethum, Ophrynnion, and Dardanus, in the vicinity of the site of Troy or Ilissus, near mount Ida. This town appears to have been inland from some distance from the sea.

Gergina, a town of Asia, in Phrygia, at the foot of mount Ida; being the same with Gergetha.

Gergis, the name given by Steph. Byz. to the Gergash of Strabo.

Gerets, in Geography, a town of Africa; 80 miles W. of Tripoli.

Gerovia, in Ancient Geography, a strongly fortified place of Gaul, belonging to the Arverni. According to Cesar (L. viii. 36), it was five miles in circumference, and every access to it was extremely difficult. At length it was obliged to submit to the victorious arms of Rome, and it was probably so completely destroyed, that no trace remains from which we may ascertain its situation. It has been conjectured, however, that its situation was in the vicinity of Clermont.

Gerhardston, in Geography, a town of Germany, in the principality of Anspach; 28 miles W. of Anspach. N. lat. 49°. 17'. E. long. 10°. — Alto, a town of Wurttemberg; 28 miles E. of Hallbrun.

Gerines, a sea-port of the island of Cyprus, anciently called “Ceriny.” The walls, which are about half a mile in circumference, appear to be erected on the foundation of the ancient walls. This place has one entire church, and two or three in ruins. Its chief trade is with Carmania, whither it exports rice and coffee brought from Egypt, and whence it brings back flax and a great number of packages. Gerines is the residence of an Aga and Cadi: 16 miles N.N.W. of Nicophorion.

Geringswald, a town of Saxony, in the circle of Leipzig; 20 miles S. E. of Leipzig. N. lat. 51°. 5'. E. long. 12°. 46'.

Geris, a town of Egypt, on the left bank of the Nile; 8 miles N. of Abydus.

Gerisa, in Ancient Geography, a town of Africa Proper, situated between the two Syrtides. Ptolemy.

Gerisau. See Gerisa.

Gerikow, Jorkow, or Barah, a town of Bohemia, in the circle of Saatz; 32 miles N. E. of Saatz.

Gerlach, Stephen, in Biography, was born at a village in Swabia in the year 1546. He laid the foundation of a learned education at Stuttgart, and became famous for his diligence at Tubingen, where, in 1566, he took his degree of B. A. with great applause. Shortly after this he withdrew from the university on account of the plague. He was admitted to the degree of doctor in philosophy in 1567 at Ellingen, and in 1573 he accompanied an embassy from the emperor Maximilian II. to the Turkish court. He continued at Constantinople about five years, acquainting himself with the manners and religion of the Turks and Greeks, and cultivating acquaintance with the most eminent men in the latter communion. Upon his return to Tubingen he obtained other preference, and engaged in the duties of his profussion with so much zeal and industry, as to injure his health. He died in 1612 in the 66th year of his age. He was author of “An Epistome of Ecclesiastical History,” of “A Journal of the embassy sent to the Porte by the emperors Maximilian II. and Rudolph II.” abounding in curious and interesting particulars, historical, ecclesiastical, and theological; and numerous theological "Dissertations," &c. Morei.

Geratzko, in Geography, a fortress of Ruffia, on the E. side of the Irtisich, in the government of Kolyvan; 212 miles W. of Kolyvan. N. lat. 55°. 20'. E. long. 75°. 24'.

Germ, in Vegetable Philosophy. See Embryo.

Germ, in Navigation and Commerce, the name given in Egypt to small vessels which serve to carry European merchandise from Alexandria to Rosetta, and to bring back to Alexandria the commodities of Egypt and Arabia. These vessels are a kind of strong bark, tolerably constructed; without decks, drawing little water; and, according to their size, having two or three mats with very large lateen sails, the yards of which are fixed to the heads of the mats, and cannot be lowered, so that, however bad the weather may be, the sailors are obliged to climb up the whole length of them, in order to furth the sails. They are, in general, of about five or six tons burden. Goods are often damaged in these uncovered vessels, and the navigation of them is dangerous in a rough sea. Although the distance which they have to sail is scarcely more than 12 leagues, and though the bay of Aboukir, which is in the middle of their passage, affords them safe shelter, this coasting trade is not free from danger, especially at the mouth of the western branch of the Nile, formerly called the "Bolbitis," now "the branch of Rosetta," where it is forced by the wind from the offing, and opposed by the stream of the river, breaks with great fury. A small island, dividing the entrance of this branch, leaves on each hand a narrow passage, called the "language of the country" "Boghais," a canal or strait. But there is only a narrow channel of this passage which is securely navigable; for it is continually shifting, on account of the shallowness of the bottom and stightening of the sea. A pilot, "Reis," or master of the "Boghais," incessantly employed in finding this changeable passage, and indicating it to the "germs." Inspite of all these precautions, they often go to shore; and, being foul overcharged with water and sand, perish with their crews and cargoes.

Germa, or Gers. in Ancient Geography, a town or Asia, on the Euphrates; which, according to Ptolemy, was a colony founded by the Gauls, named "Belisboanos," in Galatia.

Germain, Count St., in Biography, a conspicuous person of a mysterious character, who resided in England a considerable time, and of whom nothing was certainly known, but that he was a fine performer on the violin, and an elegant, though not a learned or original, composer. Being here at the same time as Prince Lobkowitz, they were inseparable. He printed a book of violin solos to present to his friends and admirers, which he called, "La Musique RAISONNEE," in which there were elegant pages, singular movements, and amusing "SUCCESSIONS." In his songs, the melody was Italian, and in good taste; but the accompaniments were thin, and without carrying on any ingenious design. It was reported, that when examined before the privy council, during the rebellion, he was obliged to divulge, "feu figlau cellamiones," that he was originally a musician by profession; but that by play, and his "bonnes fortunes," he had realized an independent fortune; but this, like newspaper reports, merits confirmation.

Germain, St. in Geography. See St. Germans.

Germain, St., a town of France, in the department of the Creuse, 15 miles S. W. of Gueret.—Alto, a town of France, in the department of the Aube; three miles S. W. of Troyes.

Alto,
GERMANY.

GERMAN, in Matters of Genealogy, signifies whole, entire, or own.

"Germani, quasi cadem filipe gereri."

Fell. Hence,

GERMAN, Brother, denotes a brother both by the father's and mother's side, in contradistinction to uterine brothers, &c. who are only so by the mother's side.

GERMAN, Cousins, are those in the first or nearest degree, being the children of brothers or sisters.

Among the Romans we have no instance of marriage between cousins german before the time of the emperor Claudius, when they were allowed by the usages of the law.

Theodosius prohibited them under very severe penalties, even fine and proscription. See Consanguinity.

GERMAN accacia, bezant, bible, black, color, compasst, emperor, empire, flute, language, meaures, monies. See the several substantives.

GERMAN School of Engraving. Germany was probably the birth-place, and Italy the cradle, of that art of engraving which is performed with a view to its being afterward printed on paper. Engraving itself, as performed on metals, and with the instrument which is still in use for that purpose, which in the English language is termed a graver, and in French la burin, is of very remote antiquity; the Greeks of the early ages having employed it in the decorations of their shields, pateras, and other implements of war and sacrifice; and the Hebrews, and perhaps the Chaldeans and Egyptians, at a still earlier period; but medals we suppose (which is by no means improbable) that the art of engraving and printing from tablets of wood travelled from China to Europe; it was referred for the artifts of Germany or Italy; and most probably the former, first to perceive that ink might be delivered, and impressions thus multiplied to an indescribable amount, both from the incisors and surfaces, of engraved plates of metal, and blocks of wood.

The precise time of the discovery has not been ascertained. The baron Heinschein, who had excellent opportunities of acquiring information, and pursued his enquiries with zeal and accuracy, has clearly shewn that the fabrication of cards for games of chance was first practised in Germany, by means of the art of engraving, and was in use so early as the year 1576. Not long afterward, the same art that had been sublervient to amusement, was employed to gratify and disseminate superflution, and extremely rude outlines of fants and legendary tales, which were cut on tablets of wood, and were printed in the cities of Mentz, Strafburg, and Haerlem, toward the close of the fourteenth, and beginning of the fifteenth, centuries, are not uncommon in the portfolios and bibliographical collections of the curios.

Of these engravings, the earliest that is known, whose inscription contains a date, and which may therefore be esteemed a great curiosity, is now in the library of Earl Spencer. It was discovered by Hein schem in the library of a convent in Buxheim, near Memmingen; it subject is the legendary tale of St. Christopher carrying the infant Jesus across the sea; it bears the date of 1423, and is intitled "Christo-feri faciens, die quacunque tueris. Illa nempe die morte mala non morieris." This rude but curious engraving is of the folio size, and was found carefully pasted within the cover of an old book, with a view, no doubt, to its preservation.

The same magnificent collection of Earl Spencer contains also one of the original engraved blocks which were used in the very infancy of printing, before movable types were invented. It appears to be of the wood of the pear tree, and in the course of the three centuries and a half since
GERMAN SCHOOL OF ENGRAVING.

It was engraved, is here and there perforated by worms. It may be necessary to observe, that the earliest printed books were imprefled from engraved blocks or tablets of this kind. To the rude representations of saints and miracles, their names and legends, cut in the Gothic character, or German text, on a scroll or label, were added, for the better information of the unlearned spectator, and in aid of the labours of the artist, if such he might be termed; and from these explanatory scrolls, the idea was first caught of printing books, to which the works of imitative art became in their turn merely illustrative. Some of these prints are finely outlined, and in others, which were produced from wood blocks, with shading, with a single course of lines, is feebly attempted. The tablet in the collection of earl Spencer, is of the former kind; and originally constituted the second leaf of the second edition (of which there is a complete copy in his majesty's Library) of the history and visions of St. John the Divine. It is, probably, therefore, one of the earliest engravings on wood that was ever performed, excepting the prototypes for the playing cards, which have been before-mentioned, and perhaps the oldest of which the original tablet itself is still extant. Hence it appears that the art of engraving is the parent of that of printing, and that at least that branch of printing which delivers the ink from the surface of the engraving, and which is now termed letter-press printing, originated in Germany.

The present writer conceives that a great deal too much of spurious importance has been attached to the invention, as it has been termed, of printing that the traffickers in its productions, by diverting the attention of those who might else have become men of taste, from its true mark, have filched or intercepted much of the pleasure which the engravers' art is capable of imparting; and that the philosophy of engraving has buried alive under a heap of rarity and early rubbish, which has been piled, and is still piling, on it without mercy, from the shovels of dealers, collectors, and those who have, unfortunately for society, nothing better to do than to labour under them.

A knowledge of the era, and of the author of a great work, or an useful invention, is certainly desirable. Bedefe that it is necessary to the truth of history, it seems to affict us in indulging the amiable sentiment of gratitude. It would call forth our sincere regret, if the name of the author of Paradise Lost, or the Cartoons, or Principia, had sunk in oblivion. But at the time which we are considering, paper and ink were in constant and daily use; and impressions from dies and from feals had for ages been taken; and were under hourly observation; it therefore required no protracted train of thought; no long connected chain of causes and effects; no mighty genius, like that of Homer, Michael Angelo, or Newton, to perceive that invention its might also be taken either from the surfaces or incisions of engraved blocks or plates. The art of printing, as I conceive, originated in a concurrence of circumstances entirely independent of the minds or studies of its reputed inventors. We have seen that at first, when it was coarsely performed, and (like the tops of ballads, and the dying speeches of criminals at press) grossly addrest itself to the lower classes of the community, it was regarded as of very little consequence; and though Kolker, Guttemburg, and Faul, cannot be ranked in the class of inventors, the inferior merit of perceiving that the arts of engraving and printing might be applied to purposes of greater magnitude and importance; than had hitherto been observed, may be justly claimed for them. It is the important confquences gradually resulting from the discovery, that have made us attach a degree of credit to the name; and entertain an unremitting respect for the supposed researches, of the discoverers, to which, in point of real ingenuity, the maker of the first pair of spectacles or stockings, or the first sheet of paper, would be far more justly entitled.

In tracing effects to their true causes, it ought not to be forgotten that the great benefits we have derived, and continue to derive, from engraving and printing, ought, in fairness, to be partly ascribed to the discovery of the means of converting rags into paper; this probably helped to suggest the idea of printing, and perhaps two centuries and a half had scarcely more than brought this invention to the degree of perfection necessary for the production of impressions from printing types and engravings. Had the modern art of making paper been known to the ancients, we had probably never heard the names of Faul and Finiguerra, for with the same kind of flamps which the Roman tradesmen used for their pottery and packages, books might also have been printed; and the same engraving which adorned the shields and pateras of the remote ages, with the addition of paper, might have spread the rays of Greek and Etruscan intelligence over the world of antiquity. The procaces of printing is indeed so simple in itself, and was so nearly obvious in the flate of things we have just attended to, that a child at play, who wanted to multiply a given form, might almost be ashamed not to have perceived it; and we ought rather to wonder it was not discovered sooner, than that it was discovered so soon.

The art of engraving and printing from tablets of wood, then, may be said to have been rather discovered than invented in Germany, and rather seen than discovered. That it was little thought of at the time, may be inferred from the number of wood cuts; the production of this period, which appear without either dates or the names of their authors, who were at once the designers, engravers, and publishers of their own works, but who deemed those works of too little importance to claim for themselves distinction on account of having performed them.

For the accommodation of those persons who could not afford to purchase manuscript copies of the Old and New Testaments, befide the apocryphal visions of St. John the Divine, which has been already mentioned, a small folio volume, entitled "Hiloriae Veteris et Novi Testamenti," (commonly known by the name of "The Poor Man's Bible," ) was published about this time, or soon after. In the same manner as the former, each leaf printed from a single engraved block of wood, confisted of a mixture of reading with pictorial representation, such as it was; to which colour was in some instances afterwards added with the hair pencil, or some such implement. The printing was performed only on one side the paper, and two of these leaves being pasted together have the appearance of a single leaf printed on both sides. Copies of these early wood cuts, sufficiently faithful, may be seen in Strutt's Biographical Dictionary of Engravers. As the title of this anonymous and undated book (the Poor Man's Bible) imports, its publication was regarded merely as a cheap contrivance for disseminating the knowledge of holy scripture. Other books of engravings, printed in the same manner, were soon afterward produced, among which are "Hiloriae beatae Mariae Virginis," "Ars Memorandi," "Ars Moriendi," and "Speculum Humanae Salvationis;" but we pass over, as of minor importance, all particular mention of these and various other engravings on wood by unknown workmen, which were apparently executed in Germany, about the time now under our observation. The next work which bears a date after the print of St. Christopher and the infant Jesus, and the first engraved book which bears date at all, is called "The Chirography of Doctor Hartleb." It consists of twenty-four small folio leaves, printed on both sides.
GERMAN SCHOOL OF ENGRAVING.

sides. "At the beginning of this curious book," says Strutt, "is a large vignette, representing Dr. Hartkib kneeling and presenting it to the princess Anne, who is seated upon her throne; and the names of these two personages are engraved at the bottom of their portraits. The prints in this book are exceedingly rude; but have not, as far as one can judge from the copy of one of them, given in the "Idee generale d'une Collection complete d'estampes," the appearance of being so ancient as those in the Apocalypse, or Poor Man's Bible. This curious compilation is dated 1458, and the name of Jorg Schafte, the artist, who is supposed to have performed the engravings, appears upon the fourth page."

Of Hans Sporer and Johann von Paderborn, who are mentioned among the earliest German engravers on wood, we know nothing more than their names. They may perhaps be the authors of some of the works we have enumerated.

Johan Schmitz executed the geographical charts for the edition of Ptolemy, printed at Ulm in 1496. His map of the world is ornamented with ten rude heads, which are intended to represent the winds, and is inscribed, "Inculptum eff Johanni Schmitz de Arnheim."

Sandrart indeed mentions and copies a print, which he believes to bear the date of 1455, and which is marked with a cipher, such as the reader will find in our first plate of the monograms, &c. of the German school of engravers. As this cipher is composed of the initials of Hans Sporer, it may possibly be from his graver; yet neither Sandrart, nor the author of "The little chronological Series of Engravers," which was printed at Cambridge, ascribes it to him; the latter allots it in his preface, that the two fires in the date, or what Sandrart supposes to be such, are intended for sevens; which makes a difference of twenty-two years in the age of the print, and brings it down to the time when the elder Schauflein is believed to have flourished.

The subject of the above print is a young woman carding an elderly man while she feeds his furies; a subject which has been often repeated by other masters, both on copper and on wood.

In what part of Germany, Hans or John Schauflein was born does not appear. Strutt says, "his prints are executed in a bold spirited style, and the compositions shew him to have been a man of genius, though the style manner which characterized the early German masters obscures much of their merit. Besides which they are incorrectly drawn; the extremities of the figures, in particular, are very defective. Schauflein usually marks his prints with an H and an S; or an L and an S joined together in various ways. To these he sometimes added a Baker’s peel, which formed a pun upon his name, a peel, in the German language, being called Schaufel, and the word Schauflein signifying a little peel. At other times we find prints of this early period, marked with two little peels crossing each other, which perhaps may mean the two Schaufleins, if they ever worked in conjunction.

The works of the elder Schauflein are chiefly very small, and he is therefore chaffed among "the little masters." The most remarkable of them are, "A Crucifixion, with St. John, the Virgin, and two Soldiers;" "The Virgin and Child;" "St. Christopher;" and "St. Laurence in Converstion with St. Angolfin." These are all of the circular form, and each about two inches and a quarter in diameter.

The principal wood cuts by the younger Schauflein are as follow, "Adam and Eve," a small upright; "Lot and his Daughters," a middling-sized, print, length-ways; "Christ preaching to the Multitude from the Ship;" a middling-sized print, length-ways, marked with an I and an S joined together, without the peel; "The Life of Christ;" a set of middle-sized upright prints, in quarto; another set of "The Life of Christ," in an octavo volume, consisting of 27 prints, entitled "Vite et passà del Christ," &c. published at Francfort by Christian Egonolphus, A.D. 1537. To these are added, "Historia Evangelica," containing the miracles, parables, &c. of Christ, in thirty-six prints, the same size as the above, and printed on both sides. These are marked with the I and S joined together upon the peel.

This artist is presumed by Strutt to have also engraved on copper; but perhaps "the very free etching of a landscape," if not the plate executed with the graver, of "Soldiers converging," of which this author treats, may be the work of a third engraver of the same firm. The date of the latter is 1551, and Strutt has previously recorded of the third Schauflein, that he has seen by him a print of two men lighting, cut on wood, in a coarse but spirited manner, and a very fine masterly etching in the style of a painter, representing a large company at an entertainment in a garden, which prints prove him to have been a man of great abilities. He was probably of the same family with the former two.

In the year 1493, appeared the celebrated Chronicle of Nuremberg, which was compiled by Hermann Schedel, a folio work, ornamented with a considerable number of engravings on wood by Wilhelm Pleydenwerff and Michael Wolgemut. These engravings are greatly superior to all that had previously appeared in Europe, and confit, for the most part, of figures of various kinds, and landscapes which, though professedly views of certain cities, towns, &c. bear to little resemblance to those places respectively, that they are probably altogether the work of fancy. They are, however, cut in a bold and spirited style, and the characters of the heads are in some instances far from being bodily delineated, though that meagre Riffines is everywhere prevalent, which so strongly marks the early art of Germany.

Pleydenwerff was a native of Germany, and perhaps of Nuremberg, but it does not appear that he ever engraved on copper, or used any monogram or other mark by which to distinguish his engravings from those of his associate.

Michael Wolgemut, or Wolgemuth, was born at Nuremberg in the year 1434. He is said to have been instructed in engraving by a certain Jacob Walch, but both Strutt and Huber doubt this fact, grounding their doubt on the want of resemblance between the styles of design and engraving of these two masters. Walch does not appear to have engraved at all upon wood, whereas Wolgemut did little else. The engravings on copper attributed to Wolgemut do not bear even a distant resemblance to those of Walch. The latter was a tame artist, or rather workman, and his work characterized by labour and care, which is generally ill bestowed; whereas Wolgemut may even be termed an artist of genius, a word, by the bye, which seems to betray down the argument of Strutt and Huber, since if a man of genius could work under a mere manual workman, as by chance he may, he will certainly emerge from the style, or want of style of his master.

Wolgemut did occasionally engrave on copper, but his works on wood are far more numerous, and more generally known. In Strutt's account of this artist, he says, "we have some few excellent engravings on copper, executed about this time: these have much of that spirited style in them which appears in the wooden cuts of Wolgemut; they are marked with a W surrounded by a small circle, and these prints, I verily believe, are the production of his graver."
GERMAN SCHOOL OF ENGRAVING.

He proceeds to describe one of the rarest and best of these prints which he found in the collection of the late Dr. Monroe. It is ten inches and a half high, by seven and a half in width, and represents an old man seated in a praying posture. He has a standard reeling upon his left shoulder, and a book before him. Behind him is an armorial shield, with three different bearings; and, at the bottom, a cave with a gate before it. Above the figure is a scroll, upon which is written, "See Wilhelmine Dux Aquitaine et Cornes Della-viensi." The head of this figure is well drawn; the hands are marked in a spirited manner, the folds of the drapery are broad, and boldly expressed, and the whole is composed in a style which does much honour to the artist. With respect to the mechanical part, it is executed with the graver only, in a dark, clear style, yet without formality, so as to have the effect of a neat etching.

It is no small addition to the honour of Wolgemut, that he was the tutor of Albert Durer, a name to greatly celebrated in the annals of engraving.

Arrived at the period when engraving both on wood and on copper began to shine forth with superior lustre in Germany, it is necessary to look back a few years in order to note the introduction of the latter branch of the art, into that part of Europe.

The reader will find under the article Italian school of Engraving, the popular and perhaps the true account of the discovery of the mode of printing from the incisions of the graver, which, soon after the middle of the fifteenth century, was introduced into Germany. As the first engravers on wood were the manufacturers of playing-cards, (called Formelsniders and Briefsniders in Germany and in France,) so the earliest modern engravers on metal, both in Germany and Italy, were goldsmiths, and the first artist who eminently distinguished himself in the former country was Martin Schöen.

Yet having already mentioned Jacob Walch of doubtful chronology, it may not be improper in this place to add, that this engraver was particularly fond of introducing Gothic architecture into his prints, in the delineation of which he took no small pains; but, from a want of knowledge in perspective, his designs of this kind are sadly confused. He drew very incorrectly, and his compositions are in the extreme of that stiff and meagre taste which characterizes the early productions of the German school. His mark, consisting of the initials of his name and a kind of lozenge crosses, may be found in our first plate of monograms, &c. of the German school of engravers; but it is to be observed, that there are some few prints marked with the crosses only, which have the appearance of being more ancient than those which are marked with the W and crosses.

Of the former kind are, "a hairy, wild, Man fighting with a Bear," and "a Woman seated, carressing a Unicorn," both small, and of the upright form.

Of the latter kind (marked with the W and crosses,) a Gothic ornament for a crosier, a large upright; "The Inside of a Gothic Edifice," a middle-sized circular plate, "A Ship striking against a Rock," with the inscription, "Haezdre" in German text, a small plate; a set of military subjects, small, and another of saints standing in Gothic niches, small uprights; "Three Skulls in an Arch," ornamented with Gothic work; and "The Genealogy of Jesus Christ," wherein saint Elizabeth appears on a throne, reading, with the Virgin Mary and infant Christ below. On the right hand is David with his harp, and on the left Aaron. Behind the throne arises a genealogical tree of the lineage of Christ from David to Joseph, represented (as usual) by half figures. This is a large upright print.

Martin Schöen, or Schön, or Schöengauer, called by the foreign writers on art, Le Beau Martin, or Hubert Martin, and misleadingly called by Vafari Martin of Antwerp, was born at Colmbach, a small city in the circle of Franchecon, in the year 1430. He was educated a goldsmith, and a certain Lutrecht Rush, and Frens Van Stofis, or Stolzhirt, have been mentioned as his tutors. At the age of forty, and probably before, he distinguished himself by extraordinary powers in the arts of painting and engraving, particularly the latter, and died at Colmar in 1486. His prints are without dates, but he, rather than any other man, may claim the honour of having been the first to practice the art of engraving on plates of metal, with a view to their being afterward printed on paper.

Schöen engraved from his own compositions; his plates are numerous, and shew that his mind was fertile and vigorous. If it was not sufficiently vigorous to burst the Gothic fetters which at that time manacled the taste of Germany, his admirers may impose themselves by doubting whether the unassisted powers of any individual whatever would have been found adequate to do difficult an occasion. The tyranny of established custom is probably not less firm and unrelenting in the arts of design than in those of education.

How the stiff and meagre manner,—the angular draperies and concealed forms which characterize the early productions of the German school, came to prevail among the Gothic and Celtic nations, for whom they derived them, is a curious, and perhaps not an unimportant question. By comparing the early efforts of art in all nations of which we have any memorials, we may be led to infer, that man has gradually learned to see objects as they really exist in nature; the images pictured on the retina of the eye appear to be refracted in their transmission to the intellectual retina, and in every country continue he so refracted, until, as the sun of science slowly ascends, the morning density of the mental medium is gradually rared; it is not left observable, nor a less curious fact, that a similar haggardunk is in the attempts of man in an uncivilized state, to imitate the human form, has almost universally prevailed, even in ages and climates the most distant from each other.

The early art of Egypt, Peru, and Hindoostan, agrees in meagreness with the rude efforts of the Mexicans and South-sea islanders; and with the German art, derived from the Gothic and Celtic nations, which is now under our observation.

In the time of Martin Schöen, and Albert Durer, German art was much in the same state with European ethics; theory was separated from practice; and both art and philosophy remained perplexed with false analogies, metaphysical jargon, and occult nonsense; till Bacon, and the resurrection of the antique, referred them to the results of experience, as a criterion of principle.

Neither lord Orford then, nor any other man, should have displeased either Schöen or Durer, for not having done, what no artist of any other school has of himself been able to perform: for, not only neither of these founders of the German school, but none of the early Italian masters, has shown that he possessed the penetration to see beyond this giddy exaltation from the barbaric ages, till the great examples of classic art began to re-appear, and reflect back on Nature the light they had received from her.

The works of Schöen evince a strong mind operating on the co-existing state of things, brooding over the abyss from whence the future elements of his art were to be created; and ming with considerable success the materials by which it was surrounded; and it may be regarded as fortunate for
his claims, that in the instance of his St. Anthony he has adopted a subject that in its nature is free, or nearly so, from the Gothic bondage with which, on other subjects, his genius was shackled; but he has boldly ventured into the regions of Chimeras, and by the potency of his art has compelled thence the demons that Calmet and Teniers were afterward solicitous to induce and provoke to employ; while the expression of undisturbed faith and pious resignation is the commonplace of the holy man whom they are hurrying into the air, shews that he saw and copied that portion of Nature which did vouchsafe to unveil to him, with a clear vision, and delicate, though determined, hand. If his demons are more fantastic and less terrible than modern art would deem it proper to introduce, we should recollect that the age of Schoen was that of Ariosto, and that two centuries elapsed between the grotesque monsters of Ariosto, and the sublime demonology of Milton.

It is consonant to the progressive improvement of critical observation, that more should be known of the human countenance at an early period, (or indeed at any period,) than of the rest of the figure, because it is the kind of study and observation in which men are most interested. Accordingly, Schoen's heads are in general by far the best parts of his performances. Those of his single figures of St. Martin and St. John have considerable merit; the divine character and expression of that of his Christ bearing his cross, as it appears in the good impressions, have rarely been surpassed; and several other heads in this extensive composition possess a proportional share of excellence.

In this, as well as in several other of Schoen's prints, may be traced a latent feeling exuding in the mind of his author, that the engraver's art might be rendered subservient to the expression of the various textures of substances. Nay more; this elementary principle strongly discovers itself in the manner in which he has treated the grain of the wooden cross; in the various modes he has invented of describing the different materials of drefs in which the figures are habited, and in the fertility of the ground; perhaps the latter is as much the result of the necessary operation of the uneducated graver, as of study. Yet, is it in such full concord with the barrenness of the scene, and the barbarism of the subjeet, as to be not unworthy of favourable notice; while, the whole together seems to shew that a sentiment has descended from the commencement of engraving, that it was susceptible of this particular merit, and which may therefore be fairly presumed to have not fallen in the fallacious refinements of modern fashion, (though perhaps sometimes run after with too much of fashionable avidity,) but one of the primary elements of the art.

The mark which Martin Schoen affixed to his works may be seen in our first plate of the monograms, &c. of the German school of engravers. Heineken has enumerated an hundred and sixty of his engravings, most of which are much admired and desiredly sought after by connoisseurs. We shall begin our select hit with the mention of those of which the subjeets are taken from facred history.

A Nativity, where the Virgin Mary is in the act of adorning the infant Saviour, who is lying on a straw pallet; behind the Virgin appears a bull and an ass; and in the distance St. Joseph. Three angels appear in the air, holding a torch.

Another Nativity, where Joseph is seen in profile, holding a lantern. The bull and ass are here looking at the infant Christ; the scene in a vaulted stable, where, through an opening, are seen three shepherds in conversation, and three angels hymning hallelujahs above.

On the same plate of copper, which is still kept as a curious curiosity, and may be seen in the chapel of the hospital at Cologne, is likewise engraved "The Adoration of the eastern Kings." The scene here is also in a stable, where the kings are kneeling and offering presents to the infant Saviour, who is held by the Virgin Mary. This plate is very skilfully executed, and is of a small folio size.

"The Flight into Egypt," in which angels are represented afflicting St. Joseph to gather dates, and lizards are introduced with both local and allegorical propriety, one on the ground, and two others climbing up a tree. This also is in small folio.

A set of ten plates of "The wife Virgins," and "The foolish Virgins," small uprights. The former bear their lighted lamps in their hands, and are crowned with garlands of flowers; the latter are trampling on their garlands, while their lamps also are on the ground.

A set of twelve small squares from the life of Christ. In the first he is represented in prayer on the mount of Olives; in the second, arrested by the government; in the third, before the high priest; in the fourth, solders are scourging him; in the fifth, he is crowned with thorns; in the sixth, Plate 7, is his crucifixion; in the seventh, he is exhibited to the multitude, in the eighth, bearing the cross; the ninth is the crucifixion; the tenth the holy sepulchre; the eleventh the descent into hell, and the twelfth the Resurrection.

A large folio of "Christ bearing his Crosses," one of the most celebrated of the engravings of Schoen, and on which we have commented above.

A Crucifixion, also in folio, and which has been copied by Israel von Mecheln. The Virgin Mary and St. John are in this print represented at the foot of the cross, and angels in great affliction; "The last Judgment;" a set of twelve middle-sized uprights, of which the subjeets are taken from the life of the Virgin; "The Death of the Virgin," ditto, which has also been copied by Von Mecheln and other contemporary artists, and is a composition of confiderable merit, and one of the most carefully finished engravings of the maker; "St. Anthony hurrying into the Air by Daemons," a very capital work, of which we have already spoken, an upright folio, but not very large. A set of the apollies, very small, in folio, of the Nativity, Schoen has engraved "The Alchemists fighting," "A Bishop's Crozier," in folio, in the spiral volute of which is the Virgin Mary with the infant Christ, and an angel playing on a lute; an incense-cup or center with a chain, ditto. Twelve small plates of goldsmiths' ornaments, consisting of armorial bearings with their appropriate supporters, &c. cloathing an eftecheon, bearing the cypher of the artist himself, supported by a female; and "The Battle against the Saracens," in which St. James appears on the part of the Christians; a large folio plate, presumed to have been the last of Schoen's engravings, from the circumstance of certain distant figures toward the left hand corner being left in an unfinished state.

Bartholomew Schoen is said, by professor Chrift, to have been the brother of Martin, but of the dates of his birth and death we find no account. His apparently very ancient engravings are known by his initials, having between them a mark of separation exactly resembling that which precedes the initials of Martin Schoen, which confirms the probability of their having been brothers.

The engravings of Bartholomew bear that sort of resemblance to those of Martin, that a bad copy does to a good original, and in neatness and feeling are exceedingly defective. They are partly original, but the greater number are copies from the very superior prints of his brother.
GERMAN SCHOOL OF ENGRAVING.

His original works consist chiefly of grotesque figures, of which some are by no means deficient of humour. It may be necessary to mention the few following, which are all engraved on small plates.

A beggar man, with an old woman in a wheelbarrow; a man playing on a lute, with an old woman holding a ladle and jar; two grotesque heads of an old man and woman, marked in a better style than the former; and a lover and his mistress, a small circle.

He copied the life of Christ, the large folio of the Gospels bearing the crosses, various other plates of the prints of Martin, but the copies may be known from the originals, by their inferiority as well as by the difference between the two signatures.

When a man of original genius, or one who may claim that noblest of human distinctions, the title of inventor, flourishes forth on the world, a swarm of busy flatterers round his glory are kindled into existence; buzz in his rays, and think to share his fame. Such was Bartholomew Schön, when confided with reference to his brother; such probably were Paul and Georg Schön, who have been mentioned as goldsmiths and engravers of this early period, and such were those other contemporary imitators and immediate successors of Martin, who now claim some portion of our notice.

Of talents far inferior to those of Martin Schön, yet engravers to whose works the virtuous and not by means intelligent, were the Israel von Mechels, father and son, whom Strutt had mistakenly inclined to identify; as having been one and the same individual. Both were natives of Mechel or Mekenin, a village near Boholt, in the bishopric of Mindel, in Westphalia.

The elder Israel von Mechel (or Mekenin) was born in the year 1424, and, like Schön, he was by trade a goldsmith.

The year of the nativity of the younger Israel has not been mentioned. The latest of his engravings is dated in the year 1522, and he died in 1532. It has been conjectured, that he studied under Martin Schön, from the number he has copied of that master's works, but this seems very insufficient evidence of the fact. It rather seems to prove that the barometer of his invention corresponded with the dryness and fulness of his style as an engraver.

The works of the von Mechels (if the father engraved) are numerous. That he did engrave, is inferred by the baron Heinrich in the following circumstance.

"An attentive examination (he says) will make it appear that all these prints are not by the same hand. I am almost certain that Israel, the father, engraved several, those especially which have the greatest marks of antiquity, and are executed in a rude style, approaching nearest to the work of the goldsmith. Nor do I deny, that the son may have commenced originally as a goldsmith, by engraving armorial bearings, flowers, foliage, crosses, and other ornaments; but he was a painter as well as an engraver, and a man of tolerable ability, considering the time in which he lived."

Strutt, on the other hand, can find no reason for dividing the works which pass under this name, nor can he find any other difference in the prints than might reasonably be expected in the works of an individual artist, who performed to many of his most early productions being of course the rudest, but all equally defective where he has attempted to express the naked parts of the human figure.

The difficulty, and the importance also, of the question, ceases, when we reflect that it was part of the professional business of the goldsmiths of that day, in which every apprentice was instructed, to ornament their productions with engraving.

Of these engravings, so little worthy of learned controversy, the principal are: the portrait of the senior Mecken, an elderly man with a long beard, his head dressed with a turban. The plate is in quarto, and bears the inscription "Israel von Mecken, Goldschmit." Ditto of Mecken, junior, and his wife, inscribed "Figuracio facerium Ifrahelis et Ida Uxoris, I. V. M." in 8vo.

These are among the prints which Heinrich supposes to be the work of Mecken the father, and Strutt, the early productions of the son. They bear the evident marks of being the attempt of a novice, being wretchedly engraved and quite ill drawn.

"Judith and Holofernes," of the folio size. In the back ground is an army, where cannon and other modern implements of war are ignorantly introduced. "The Banquet of Herodias." This is a folio plate, twelve inches in length, by J. Schoen, V. M. At one end is the decalogue of St. John the baptist, and at the other, Herodias and her father appear seated at table. "Herod's Cruelty," is a middle-sized upright.

Of holy families, the Israels engraved several, the chief of which may be known from each other by the following peculiarities. In one, the Virgin Mary, habited in a long robe, is fitting with the infant Christ, while beyond an enclosure appears St. Joseph reposing. Toward the bottom, at the right hand corner, is a small grashopper, from which it has obtained the name of the Virgin of the Grasshopper. It is in quarto, and inscribed Israel V. M. (This plate has been copied, with improvements, both by Albert Durer and Mark Antonus.) In another, the Virgin Mary, seated in a landscape, is about to bless the infant Saviour; the Deity appears in the clouds above; and St. Joseph kneeling. (This is a middling-sized upright, and is partly finished by means of frets, which are apparently made with the point of the graver, somwhat in the manner of Rembrandt.) In another, which is dated 1490, the Virgin and Child are surrounded by four angels. This is also a middling-sized upright.

Of other sacred subjects, we shall mention "The Annunciation," in 8vo, where an angel appears holding a cornet, on which is the motto "Arc. Gra," and the Virgin is kneeling before a praying desk, on which is inscribed I. V. M. "The Death of the Virgin Mary," copied from Schoen. "The Virgin crowned by Angels, and standing on a Cenocent, while the fall of Satan is represented below," an upright folio. "The Scourging of Christ," ditto. "The Bearing of the Cross," a large folio, copied from Schoen, and two large folios of the "Crucifixion of our Saviour," which are distinguishable from each other by the following peculiarities: in the one, angels are receiving the blood from the wounds of the dying Saviour, while the Madonna and St. John appear below; in the other, which is esteemed the superior work, St. John holds a book in one hand, while the other is lashed, and the hands of the Madonna are clasped; and the ground in the latter is almost left white, whereas in the former it is nearly covered with engraving.

From the legends of the Roman Catholic rubrics, the younger Israel has engraved, "St. George and the Dragon," in 4to, inscribed I. V. M. Schon's "St. Anthony tormentcd by Demons," and "St. Jerome," in which the saint appears seated in a room and pointing to a skull.
GERMAN SCHOOL OF ENGRAVING.

Full. On the right hand corner is the lion's head. The latter has been copied by Lucas von Leyden, and in the opinion of Strutt is Holbein's master-piece, though perhaps that distinction ought rather to be granted to his moral print of "A Cavalier and Lady, walking in amorous talk, while Death from behind a Tree is shaking an Hour-glass," a design which, whoever it is, original author, had previously been engraved by Strutt or Schauflink, and has been subsequently copied by Albert Duran and several others.

Of the angular design consisting of three naked women, with a globe hanging above, which is inscribed 8vo. there is also an engraving by Holbein.

A folio plate of "The Death of Lucretia," a pair in quarto, of "A Woman dancing, while a Man accompanies her on the Lute," and "A Man playing the Organ while a Woman blows the Bellows," both marked T. M.; Schön's richly ornamented incuse cup; and several plates of grotesque foliage and other goldsmith's ornaments, are all that we shall mention of the two hundred and fifty engravings by the Holbeins which are enumerated by Heinmck. Neither of them appears to have had any letted monogram, but marked his engravings variously, as we have stated in the course of our ill, sometimes adding to his name and reference the word "Goldschmit," and at others "Zan Beckholdt," in the German character. The best of their works, as has been hinted before, are copies from the superior productions of Martin Schöen.

Matthew, or Martin Zelger, Zafinger, or Zinck, goldsmith and engraver, was born in the year 1420, but in what part of Germany is not known, though from the subjects of two of his engravings, it may be guessed that he was of Munich: neither is the year of his death certain, though, that he lived to the beginning of the sixteenth century, and engraved till the age of seventy-five, may be inferred from the circumstance of one of his prints being dated in the year 1505.

The extreme of Gothic stiffness appears in his works. His composition is bad, and his drawing ill-wrks: the mechanical part of his engraving, indeed, possesses a certain degree of neatness, but it is without the faintest ray of taste. It is proper, however, to observe, that from the delicacy, or rather fancifulness of Zelger's manner of engraving, his plates would not stand many good impressions; that many of the retouched prints, which are exceedingly bad, are abroad in the world, and that therefore, to do justice to the slender sense of merit which he possessed, it is necessary to see the early impressions of his plates, nor should be left unmentioned, that in his latter engravings he displays a more intimate knowledge of perspective than we find among his predecessors in Germany. Zelger marked some of his prints simply with the initials M. Z. and others, as will be found in our first plate of the monograms, &c. of the engravers of Germany. Among his best engravings may be reckoned "Solomon's Idolatry, a middling-sized upright, dated 1501," "A Holy Family," in which the Virgin Mary is receiving water from a fountain, in a cup of the same date with the preceding," "The Legendary Story of St. Christoph, in which the Infant Jesus is given to the arms of the Virgin, a small upright," "A Lover seated in a Landscape, entertaining his Miltrefs," and "Two Lovers Embracing," ditto.

Two large and very rare folio engravings of "The Grand Ball and Tournament at Munich," in the former of which is represented a dance and card party, in which the duke of Bavaria is engaged at play, and in the latter a tournament, at which the duke is present. "The Martyrs St. Catherine and St. Ursula," both in 8vo. "The Martyrdom of St. Sebastian," in 4to. "The March to War," ditto, and "Aristotle the Philosopher," a subject often repeated, and called by some Socrates and Xantippe. The last is a very rare print, in 4to.

Albert Glockenton was a native of Nuremburg, born in the year 1452, and who flourished as an engraver at the commencement of the sixteenth century; but the time and place of his death are uncertain. Strutt says of him, that if he did learn his art from Schöen, he not only imitated his manner, but copied a great number of his prints; which copies constitute the greater part of the works of Glockenton. He executed his plates with the graver in a neat but fervile manner, by no means improving the drawing of his originals. He marked his engravings with a sort of half Gothic initials of his name, as may be seen in our first plate of the monograms of the German engravers, and sometimes added the date.

The principal works of Glockenton, after the originals of Martin Schöen, are "Chrift bearing his Crofs," and "Chrift crucified," both rare and of the folio size; "The Death of the Virgin." The feast of the wife and foolish virgins, ten plates; the Passion of our Saviour, a set of ten others, both of which are more particularly mentioned in our account of Schöen, and the "Virgin and Child at an Altar," in 4to. The latter is superior, in point of composition, to the German art of that period, is marked with only a Gothic G, and bears the very early date of 1506; which is perhaps the most ancient that is to be found on any copper-plate print whatever. Of this engraving particular mention is made under the article Glockenton, in the "Catalogue Raisonné of the Cabinet d'Estampes de Brandes."

Contemporary and co-equal with Zelger and Glockenton, was an engraver for whom Strutt claims a sort of doubtful existence, by the name of Wenzellaus of Olnutz, in Bohemia. He found a copy of Martin Schöen's "Death of the Virgin" in the Monro collection, which had not only the name of this artist inscribed upon it, but the date of the year in which it was engraved, namely 1501. He adds, "there is no doubt of its being a copy from Schöen, because it bears the evident marks of a fervile imitation. It is highly probable that Wenzellaus was the disciple of Schöen,"—"another observation arises from a strict examination of this print, upon comparing it with the ancient German engravings marked with the W only: which is, that they are evidently the work of the same artist as the preceding, though they have usually been attributed to Michael Wolgemut, the master of Durcr. The name is perfectly plain, but the words that follow are far less legible, and in the opinion of the present writer are much more like Olomuc ibidem than Olnutz in Bohemia."

Of these prints marked with the letter W only, Strutt mentions the following:

The "Annunciation," where the Deity appears above and a pot of flowers is introduced on the fore-ground; a small upright; "The Cavalier and Lady headless of Death;" "The Last Supper;" "The Crucifixion of St. Anthony," small and nearly square; and the set of small uprights from the "Life and Passion of Christ." 

The above are all from Schöen; those which follow are from the Izraels of Mckenin.

"An old Man leading a little Boy, with a Woman following carrying a Girl at her back;" and "A Lover entertaining his Miltrefs;" two small uprights; and "The naked Women with a Globe suspended from above."

We are now again arrived at the time when the Nuremberg Chronicle was published, and those extraordinary works both on copper and on wood began to appear, which are known to the world under the highly respected name of Albert Durcr.
GERMAN SCHOOL OF ENGRAVING.

Of the various powers of Albert; his reputation as the father of the German school of painting; and his general merits as an artist, we have already treated pretty much at large; (see Durer, Albert.) It remains to add our lift of his principal engravings, and to comment more particularly on some of those which are, and deferre to be, most conspicuous. Though the defects of the artist are pointed out in the critical remarks which follow, and which are chiefly extracted from lectures delivered at the Royal Institution in the years 1850 and 1856, yet are they calculated to lead the attentive observer to a more intimate acquaintance with the merits of this extraordinary engraver, and to confirm the general and justly merited praise which has now, for three centuries, been bestowed on Albert Durer.

The resemblances between the several objects which this master has introduced into his engravings, and their archetypal nature, proceed, for the most part, too much upon facsimile principles for the generalized dignity of his subjects; and his powers of imitation are too prodigiously lavished upon subordinate and unessential parts.

The expression of his figure of "Melancholy," which would else have approached sublimity, is considerably injured by the introduction of a multitude of objects, most of which the mind does not readily assimilate with the sentiment of melancholy. It must first be perceived or discovered, that these objects are allusions to astrology, alchemy, and the occult sciences, as they are called. The performance addresses itself, therefore, to the curious and inquisitive part of mankind, and not to man: and as neither the eye nor the mind can at once dilate with grandness and descend to littleness, it is evident that the research it requires must be the destruction of sublimity.

Though there is nothing of the "holy calm," with which Collins has surrounded his figure of melancholy, this composition may still be thought interesting on another account, namely, as a true picture of the times in which it was engraved; for precisely thus was attention perplexed and deflected on most philosophical subjects in the age of Albert Durer; and as he is author of seven treatises, most of which are on the metaphysics of art, he had probably experienced much of that species of melancholy which proceeds from the mental exhaustion and dissatisfaction in which such studies often terminate. Regarded in this view, it is no inapt verification of the old adage, "The painter paints himself." It might have aspired to reconcile us to the defects of this performance, if Albert Durer had named it Study; or, if we could fancy the figure out of the picture, we might be content to let our attention dwell awhile on the skill with which he has represented most of the other objects, when abstractedly and severally considered. This talent, however, of representing the characters and textures of individual objects, is still more conspicuous, and somewhat less objectionable, in the print of "St. Jerome in the Room," wherein all the objects are rendered with a fidelity little short of the camera obliqua. Regarding the art as in its infancy, we may look at this engraving with the fame kind of pleasure, and we should at all the works of art in this period, with the same candid indulgence, in which we look on his contemporaneously "The Virgin and Child" by Van Eyck, in the cathedral church of Bruges — "the artist," says Jollens, "having accomplished the purpose he had in view."

Another of the most celebrated, though not the best, of Durer's engravings, is his "Adam and Eve." He has, in this instance, had recourse to nature for his models, but his Eve is not "the fairest of her daughters," nor his "Adam the goodliest of men since born;" yet we may perceive that he selected from the nature with which he was acquainted; and though we do not behold the symmetry and superlative grace of Greek beauty, we probably see the refined and acknowledged beauty of Nuremberg. It will also be allowed, that the Paradise they stand shortly quit, does not seem very desirable to inhabit; here is no genial light, no luxuriance of vegetation, and no abundance of animal life. To use more of the words of Milton, nature is far from wanting as in her prime; — to very far from playing at will, or fancies, which the appears, in those of Shakespeare, "hail with dry antiquity;" yet if Raphael has violated this cardinal principle of propriety, by erecting a church, and houfes two stories high in his Paradise, who shall throw the first stone at Albert Durer? The holes of his trees, though among the first, if not the very finest that were ever engraven, have much of the truth of individual nature, and their foliage, and the fur of the cat, are expressed with a degree of freedom that must surprise those who reflect that no etching has been attempted, and how comparatively ill calculated are the fleck and shiff lines of the unaided graver to the expression of such objects. The introduction of the cat and mouse in Paradise could not fail to be understood, from its familiarity; but though ingenious, this very familiarity rendered it unfit for the occasion. The prophet Isaiah has far more nobly expressed the primordial harmony and happiness of the brute creation.

The Eve of Albert Durer is apparently of the same family that Otho Venius, and Rubens, afterwards adopted for their models; and in the engraving which collectors call "The Death's Head," is a female figure, which still more evidently shews the esteem in which Rubens must have held the works, or at least the women, of Albert Durer. It is not easy to conceive the occasion that could have given birth to this mysterious print of Death's head. It presents us either the ordinary routine of human life in allegory, or perhaps a fort of poetic armorial bearing. The head is a winged helmet, richly ornamented, and beautifully designed; and though a skull, which one should think could not fail to be an avuncular looker, is highly embossed on the shield, the female supporter, heedles of her charge, heedless of the moral lesson, and of the moral character the shield sustains, is obviously listening to the very suspicious suggestions of a fort of savage man. It appears to be one of the night thoughts of Albert Durer, and perhaps, like those of Dr. Young, may be intended to mark the lamentable influence of the grosser passions. Whatever its author may have intended to inculcate by this print, its execution as an engraving is admirable. The helmet, with all its pomp of heraldic appendage, and the actual and reflex lights on its polished surface, are characteristically, though minutely, expressed; the skull is accurately drawn, and its bony substance is described with a masterly hand; the author has even sedulously attended to the finer enamel of its two remaining teeth. The head of the savage, with its beard and wild redundantness of shaggy tangle hair, has considerable and well-managed breadth of light and shade, though its character is far less savage than should seem to belong to the soul of the figure: its expression is, doubtless, meant to be alarming and infatuating. The countenance of the female has seldom been rendered for so successful a mixture of character and expression that lends a willing ear to a delusive promise; and the hands of both figures are far better drawn than we have hitherto seen among the productions of the German school: the drapery also, which we have accustomed to see stiff, flarced, and complicated, is here relaxed into freedom and simplicity, and is so remarkable for flaky texture; approaches so near to what is now termed picturesque composition of forms and light and shade; and
GERMAN SCHOOL OF ENGRAVING:

is, on the whole, so superior to that of his Melancholy, and some other of his subsequent works, as leaves us either to wonder that Albert Durer, having once attained, should ever lose sight of the excellence of its principles; or to infer that he did not perceive their excellence, or that the science he deduced from his own observation of nature prevailed but occasionally over the prejudices of his education.

In his small prints of the life of Christ, of which Marc Antonio is said to have pirated the copy-right, other instances occur of this style of superior simplicity in the draperies, and some of broad and captivating effects of light and shade. His Jesus Christ suffers greatly; or benings with God-like benevolence; his Magdalens and Madonnas are sometimes divinely pathetic; and many other heads in these interesting and often grand compositions, are exquisitely finished miniatures, remarkable for that sort of accordance and confidence of parts which we deem the internal evidence of truth and nature. The principal portraits of Durer, engraved on copper, are those of the elector Frederick of Saxony, dated MDXXIII. Albert, elector of Mayence, dated 1523. Birkhald Pirckheimer, dated 1524. Melanchton, dated 1525. These are of all the quarto size.

In folio he has engraved his friend Erasmus, good impressions of which are now become very rare, dated 1526, and two figures of himself, on the same plate, one being his portrait in the year 1509, and the other in 1517. They stand on either side of a piece of architecture.

Of the portraits of Durer, it may with truth be said, that, in point of drawing, they possess the same internal evidence of correctness which distinguishes the best of his historical heads: in style they are laboured; but the labour is not ill-begotten; and the chiaroscuro is frequently comprehensive and clear. His compositions from holy writ, and these legends which in his day were thought to be nearly of equal authority, are numerous. The principal of those on copper are "The Adam and Eve in Paradise, or Sin of our First Parents," which has already been the subject of detailed comment, a very elaborate work in folio, dated 1504. Another "Adam and Eve," which represents them after their expulsion from Paradise. "Adam crawling, and Eve sitting with an Infant at the Entrance of a Cavern," in quarto. "A Man with a Beard, seated on the Ground (his Horse fastened to a Tree) caressing a Young Woman," a small quarto plate, known by the name of "Judah and Tamar," and believed to be the earliest of Albert Durer's engravings. "The Nativity," where the Virgin Mary is adoring the Infant Christ, while St. Joseph is drawing water from a well. "A Holy Family," known, among connoisseurs, by the title of "The Virgin of the Butterfly," where the Magdonna is seated in a landscape, with the infant in her arms, and St. Joseph asleep near her. Another, known by the title of "The Virgin of the Ape," where the Infant Christ, kneeling, is playing with a bird, and an ape is tied near the group. Another, known by the title of "The Virgin of the Pear," which is dated 1514, where the Infant Christ, holding a pear, is sitting with his mother at the foot of a tree. Another, known by the name of "The Virgin of the Apple," which is dated 1514. All of them are of the 4to, dimensions. An etching of the "Holy Family," in folio, wherein the Virgin Mary is standing and holding the Infant Christ in her arms, and a girl is introduced at prayers, dated in the year 1519. A set of fifteen, including the frontispiece, entitled "The Small Passion," very rare, and dated from 1507 to 1512. "Christ Crucified, with the Holy Woman at the Foot of the Cross," a small circle, without the artist's mark, and said to have been done for the sword-belt of Charles V. "The Saviour prostrate in the Garden of Olives," very rare, and dated 1515. "A Group of Angels bearing the Inframents of Crucifixion, &c," engraved on tin, or iron tinned over, and dated 1516. "The grand Ecce Homo," in large 4to, with a Latin inscription, and dated in 1512, a very rare print, much sought after by connoisseurs. "The Entombing of Christ by the Holy Women," in small folio, a print dated 1507, and in which several cats are strangely introduced, but which some think is not by Albert Durer. "The Infant Prodigy," a kneeling figure, in folio, some pretend that this is a portrait of Durer himself. "St. Hubert at the Clafy," a folio print, in which the saint is represented kneeling before a crucifix, which appears upon the head of a stag; the scene is a wood, with a cottle at some distance.

Albert Durer has been analogically compared with our poet Spenser, and it has been remarked, that "if any one of his performances were to be pointed out as more particularly resembling Spenser, it should be that of the Legendary Tale of St. Hubert. They are characterized by the romantic heights of extravagance; the fame abundance of ideas; the fame unremitting and serviceful attention to minute excellence; the fame general air of incomodity rendered credible, and, as we should say now, if the works of the poet and engraver were now produced for the first time; the fame want of concentration, brevity, and general effect; but a temporary adoption of the sympathies of the sixteenth century, as far as art is concerned, reconciles us to thee."

Of the subject of St. Jerome, Durer has engraved two plates in small folio, on one of which, where the saint is sitting in a chamber, we have already commented; in the other he is kneeling before a crucifix, in a rocky desert, and the engraving is far less elaborately finished than the former.

"A naked winged Woman flanding on a small Globe suspended in the Clouds, holding in one Hand an elaborate wrought Cup, and in the other a Bridge," a folio print, known among dealers by the name of the Larger Fortune. According to Vafari, it should be called Temperance, according to others. Prudence; but, perhaps, Albert Durer meant it for the Guardian Genius of Nuremberg, of which city a bird's eye view appears beneath.

Another "Naked Woman on a Globe," in 12mo., called the Lefier Fortune. She holds a long stick and a thistle. The figure of "Melancholy," on which we have already commented. She is sitting, her head reposing on her hand, surrounded by various emblems, a folio plate, of exquisite workmanship, dated 1514. "The Dream of M. Wolgemut," where he is represented asleep near a frying pan: the devil is behind with a large pair of bellows, and on the side Venus, with Cupid walking on flints. "The great Satyr," who is attacked by a fawn whilst reposing with a nymph, a small folio, the work of the graver, and performed with admirable skill. "The Sorceresses," four naked women in a room: a globe, with the letters O. G. H. is suspended from above, and in an adjoining chamber appears the devil surrounded by flames: it is dated 1597. Baldi-mucci thinks it is the earliest of Durer's engravings. It is copied from Wolgemut, and is a rare print. "A Chevalier on Horseback, and in complete Armor, purified by Death on Horseback, (who is holding forth an Hour-Glafis,) and another Spectre:" this is a very highly finished and exquisite engraving, in small folio, of which good impressions are rare. It is by some termed "Death's Horfs," and by others, with more propriety, "The Worldly Man:" it is
GERMAN SCHOOL OF ENGRAVING.

Dated 1513, and the impressions which were taken before this date was incribed, are much valued. “The Death’s Head,” of which we have already given a particular description, in small folio, dated 1523. Another heraldic subject of the same dimensions, depicting a lion rampant on a shield, and a helmet surmounted by a cock spreading its wings. “A large Horse,” behind which marches an armed man with boots, bearing a halberd, and another horse of more beautiful form, behind which marches another armed man with a halberd, having a griffin on his helmet: both in 4to., and dated 1505. “A dishevelled Sorceef, mounted on a Goat, and flying through the Air, with a Ditafl in her Right-Hand.” “The Predial Son,” a small upright folio, of which the impressions, before the date 1513 was added, are held in mild esteem.

Under the article Engraving we have ascribed the invention of this mode of art to Albert Durer. The earliest of his etchings, which bears a date, is called “The Rape of Proserpine,” a folio print, dated 1516, and in two years after this work he more celebrated etching of the march of an army, which has been called “The Cannon,” from a large piece of ordnance forming the principal object on the fore-ground: the scene represented is the entrance of a village, with a bird’s-eye view over an extensive country, and three Turks are introduced near the fore-ground. Both these etchings are reported to have been performed on plates of iron or steel; and the latter, which is now become rare, is among the largest of the works of Albert Durer.

The principal of those works of our artist which are commonly supposed to have been engraved on wood, are as follow:—The portraits, in folio, of Albert Durer, inscribed “Albrecht Durer counterfeft in facem alter des LVI.” without the engraver’s cipher; another with his cipher; the emperor Maximilian I.; a bull with numerous ornaments, inscribed “Imperator Cesar Divus Maximilianus Pius Felix Augustus 1519;” Ulrichus Varnbucle, a rare print, with the following inscription on a piæf, “Albertus Durerus Noricus reddere que conatur 1522.”

From the numerous historical works which Durer performed, we select the following: A set of thirteen folio prints, including the frontispiece, from the life and paflion of Jesus Chrifti, inscribed “Paffio Domini, &c.” dated 1510, 1511. A set of twenty-seven small uprights, known by the name of the Smaller Passion, and inscribed “Figurae Paffionis Domini Noftri Iefu Chrifti 1519, 1520.” An “Ecce Homo,” in folio, engraved in a bold and broad style, and with great freedom. “The Holy Trinity, surrounded by the Angelic Host,” and dated 1511. Another “Ecce Homo,” known by the title of “The Mystery of the Mafs.” A set of sixteen folio pieces, inclusive of the frontispiece, of which the subjects are taken from the Apocalypse, and the text printed on the reverse of every leaf. A set of twenty-two small folio prints from the life of the Virgin Mary, dated 1509, 1511: seventeen of this beautifal set of engravings were copied by Marc Antonio at Venice, to all of which copies, except one, the Italian artist added the cypher of Albert Durer. “The Holy Family,” of the folio dimensions, where St. Anne holds the infant Saviour, and the Virgin Mary in the act of adoration. “The Rhinoeserous,” a rare print, in folio, with a German inscription, dated 1515.

In chiaroscuro (or chiaro-fecuro) printed from a succession of blocks, the following are ascribed to Albert Durer: “A Holy Family in a Landscape;” two angels are crowning the Virgin Mary, and on the fore-ground are three rabbits; in large folio. Two, of legendary stories from the lives of St. Augustin and St. Christopher, in large folio, the latter of which is scarce. A sort of apotheosis of the emperor Maximilian, where, accompanied by the Virgin Mary and numerous saints, he is adorning the Saviour (Of this piece Huber possefls an impression on vellum very richly coloured.) A pair, which are scarce, of “A Fortrel in a Plate of Sieges,” generally called the Siege of Vienna, dated 1527. A set of fix ornamental designs for tapestry, of astronomical subjects. The whole number of engravings by Albert Durer, and after his deigns, are flated to amount to 1274; but Marliette’s collection amounted to no more than 420, which were sold at his death for 1850 livres. See the article Durer in the Catalogue Raifonne of the Brandes cabinet.

The triumphs of the emperor Maximilian, which, when pasted together, form two very large and long prints of the frieze form, have been generally ascribed to Albert Durer, but the refarches of Mr. Duce of the British Museum, and Mr. Edwards of Pall-Mall, have determined that they are the performances of various other artists, though perhaps executed under the general superintendence of Albert Durer.

Lucas Cranach, or Cranach, was born at Cranach, in Welfphalia, in the year 1472 or 1474, and died at Weymar in 1553. He was educated a painter; yet whether he studied under any other master than his father has not been recorded. He pasted several years in the service of the elector of Saxony as an artist, distinguishing himself by his engravings on copper and wood, and in that manner which is technically called claire-féce. His fertility of invention far outran his judgment: led away by the liveliness of his fancy and talent for composition, he took such forms as were before him, following the old Gothic taste which prevailed in his country at the time, without attempting to improve it. His manner of drawing is rather dry and tasteless, than absolutely incorrect, but his heads have a moderate portion both of character and expression, though they are not marked with precision or in a pleasing style: his hands and feet are very defective, and a total ignorance of the art of distributing light and shade confuses his effects. The dragon is the crest of the elector of Saxony, to which, on some occasions, Cranach added the electoral shield.

The following will probably be found amongst the best of his engravings, beginning with those which are executed on copper: Portraits of Jean Frederic elector of Saxony, where an angel appears on high with a crown of laurel, in large 4to. and very rare. The two electors of Saxony, Frederic and Jean, the former of whom is holding a chaplet, in 4to, dated 1510, and almost figure, Christianus II. king of Denmark and Norway, surrounded by ornamental architecture, armarial bearings, &c. in larges 4to. Profile of Martin Luther in the habit of a monk of St. Augustin, inscribed “Des Lutertgenfalt,” in 4to, and dated 1523. The chief of his historical works are: “Adam and Eve after their Fall,” (called by some the Penitent of St. Chryfom) the scene is a desert, where a naked woman and child appear on the fore-ground, and in the back-ground a man is crawling, a folio plate, dated 1529, marked with the cypher and little dragon of Cranach, and executed quite in his Gothic manner. “The Temptation of our Saviour in the Desert,” where the Chrift is somewhat better pretentions to merit, than generally belongs to the figures of Cranach, but the tempter is as grotesque and entertaining a devil as you would wish to see; the print is in small folio, and marked L. C. W. the last letter devoting Wittenbourg: it
is very rare and bad. A whimsical composition, of "Je
fus Christ in the Clouds," surrounded by angels, and inspir
ing the electors of Saxony, a half length of whom appears be
d, a small print, almost square.

In chiaroscuro, that is, on two blocks of wood, the one
for the outline and darker shadows, and the other for the
dimmed lines and lights, Cranach has engraved "St. Christop
er carrying the Infant Christ over an Arm of the Sea," a foli
print, dated 1527. "St. George and the Dragon," a large
4to. "St. John preaching in the Desert," in folio, dated
1576. And, "A Naked Venus" (of ludicrous beauty) ac
 companied by Cupid, who is trying his bow, in folio.

The letter-press engravings of Cranach, commonly sup
posed to have been performed on wood, are as follows: Buil
of Jean Frederic, elector of Saxony; dittie of Martin Lu
ther in the costume of a monk of the order of St. Augus
tin, dated 1520; both in 4to.

Whole length portraits of Martin Luther; Philip Me
lanchthon; the emperor Charles V; the emperor Ferdinand
; Jean Frederic, elector of Saxony; and Jean Guillaume, duke
of Saxony, all of the folio size.

A half length of the elector of Saxony, holding a book
open before a crucifix, a rare print, marked with the little
dragon, dated 1552, and inscribed with a Latin sentence.

Of his historical works, the following are held in most
request among collectors. "Adam and Eve in Paradise, or
the Sin of our First Parents," dated 1569. "The Annun
ciation." "St. John preaching in the Desert," which has
been called a grand composition, and is dated 1516, and
the "Decollation of St. John;" all of the folio size.

A set of twelve in small folio from the life and passion of
Jefus Christ, inscribed on the title page "Paffo D N Jef
Chrifti ventillum imaginibus," &c. and dated 1569; this
set is highly esteemed among connoisseurs. Another set of
twelve, of the Martyrdoms of the Apostles, in 4to. and which
are held in high more request for rich composition and
expression of the heads, and are on the whole superior to the
preceding: they are dated in the year 1549.

It is curious to reflect on how frequent infrequency, the
Gothenberg artists of the age of Cranach selected subjects
that called for the introduction of beauty even of the highest
degree, and deftly out their virgin Maries and Venuses in all the fluff
magnificence of their age and country. "Paris visited by the
three Goddeses on mount Ida," a rare piece in large folio,
dated 1508. "Curtius leaping into the fiery Gulph" is also
in folio, and dated 1508. Three plates of tournaments, of
which two are called the great, and the other the little tour
ament, dated 1569; and a pair of park scenes with flags in
the rutting time, and which are very rare, conclude our
list of the engravings of Lucas Cranach.

Hans or John Burgkmair painter, and engraver on wood,
was born at Augsburg in the year 1474. He resided under
Albert Durer and some of his engravings are dated fo early as
1516, but the time and place of his death are unknown.
He engraved chiefly, if not entirely on wood, and his prints
possess much of the fire and spirit which distinguishes those of his
master. Professor Chriilt attributes to him some small spirited
woodcuts which were made for the ancient edition of the works
of Geyler de Keiferberg, which bear the above date (of 1510),
and are marked I. B. Many of the works of this artist bear
his name at length, the rest are marked with one or other of
the two cyphers which will be found in our plate of the
monograms, &c. of the German school.

The following are the engravings by Burgkmair, which
are most sought after by collectors: "The Emperor Maxi
milian I. on Horseback;" of which design there is a dupli
cate engraving in clare obscure, which bears the name of
Joel de Negker, but which is partly the work of Burgkmair.
It is a very rare print, dated in the year 1508, both of the
folio size. "St. George on Horseback," also bears the
name of Negker, and is of the folio size, and in clare obscure.
"Joseph and the wife of Potiphar," is of a figure form,
Sebastian," dated 1515, are all in folio. A young
Woman mourning the loss of a Hero that Death has over
come," is a rare print in folio; by Burgkmair and Negker.

The remainder of the letter press cuts of this artist are,
for the most part, hundred and thirty-five blocks or plates,
which were engraved on wood, and which were brought to Eng
and; within these few years have been removed to the Imperial
library at Vienna; its title is "Der weifs Konig" (the
wife king), and it consists of the distinguished acts of the
emperor Maximilian.

"The triumphal Entry of Maximilian," consisting of one
hundred and thirty-five blocks or plates, have remained for
a long period of time unknown at the castle of Ambra,
but within these few years have been removed to the Imperial
library at Vienna, since which impressions have been taken,
and several sets have been brought to England. Many of
these engravings are the work of Burgkmair, and are
marked at the back with his name or initials, though the
whole generally passes under the name of Albert Durer, and
were probably executed under his direction. Another work,
executed by these artists conjointly with Hans Schaufelb,
was called the Tewerdans; but the greater number of the prints
contained in it are from the graver of Burgkmair.

Johannes, or Hans Baldung, named Grun or Grum,
painted and engraved for the letter press and in clare obscure.
He was a native of Gemund in Suabia, and was born in the
year 1476. He flourished as an engraver through the
earlier part of the sixteenth century, and the latest of
his works is dated in the year 1534, but the time of his death
is uncertain.

His engravings are executed in a bold style, and with con
 siderable power over the instruments of his art. Strutt says
of him, that "his figures are rather expressive than correct;
the naked parts of them are poorly drawn; and the extre
mites, though free and spirited, are often heavy, and not
well marked," but considering the period and place at
which Balding lived, he may be regarded as a meritorious
artist. His engravings are sometimes marked with his name
at length, and at others with the cyphers which we have
given in our plate of German monograms. His principal
works are, "Adam and Eve in Paradise." "The Fall of
Adam:" in the latter, a tablet is inscribed from a tree, bear
ning the motto "Lapidus humanus generis," and the date 1511.
Both of the folio size, and the Fall of Adam is a per
formance of merit in clare obscure.

A set of thirteen figures in small folio of the Saviour and
twelve apostles, dated in 1514, and marked with the artist's
cypher. "The Crucifixion," with the holy women and St.
John at the foot of the Crosses, in clare obscure. A set of
four small uprights representing the Effects of Love, or
Influence of Women, exemplified in the stories of Sam
on and Dalilah, Solomon's Idolatry, David and Bathsheba,
and Xantippa and Socrates, (called by some Arbitotle and
Phrynus,) dated 1515. "A drunken Bacchus lying at
the mouth of a Calk," in 4to. "The Sorcerefs," who is
mounted on a lie-goat, holding a cauldron. A pair, cut in a manly
style, of wild horses in a forest, with the name of Balding at
length, and the date 1534. Another pair of small land
scapes, which are said to be etched on plates of iron, and are
very rare.
Of Hans Bréfag, a designer and engraver for the letter presses, very little more is known than that he was contemporary with Baldung, and has sometimes been mistaken for him from the similarity of their cyphers, and their taste in designing and engraving. Mitating the numeral 5, in the dates of his engravings, for a 6, Strutt has placed him a century too late.

Thole of his works which are best known, are "Adam and Eve in Paradise," of the folio size; bearing the cypher of Bréfag, and the date 1519. A set of three of the 4to. dimensions, dated 1504; viz. "Christ on the Cross;" "Christ lamented by the holy Women," and "A dead Christ," with angels bearing him away. Another set of thirteen of the Sixteen and Twelve Apostles, also in small 4to. and the three Dillins in a landscape, dated 1513, a very rare print in 4to.

Lucas or Louis Krug, or Krugen, painter, goldsmith, and engraver, was born at Nuremberg in the year 1489, and died in the same city in 1535. He formed his taste, in designing and engraving, from studying the works of Lucas of Leyden, and drew the human figure better than many of his contemporaries, though his attitudes are ill chosen, and his draperies ill. His mark was a small pot or jug placed between his initials on a tablet, as represented in our first plate of the monograms, &c. of the German engravers, to which the date was in some instances added. His principal engravings are as follow:

2. "St. John the Divine, writing," while the holy Virgin is dictating to him from the clouds, and below is the ludicrous incident of the devil emptying the ink-horn of the faint. "Two naked Women contemplating a Skull and Hour glases," and "A naked Woman sitting with her Back towards the Spectator," with a city and mountain appearing in the distance; all small uprights.

Hans S. Handslein, the third engraver of that name, was born at Nuremberg some time about the year 1487, and died at Nureligen, a town in Suabia, in 1550. He studied under Albert Durer, and imitated his style with considerable success.

But few libraries have the honour of possessing a complete copy of this celebrated work, of which Melchior Pfingsting says, in the dedication to Charles king of Spain, that he had been most of the actions that are therein engraved and described, which in fact are those of the emperor Maximilian I. under the fictitious name of Tewerdanks.

Albert Altdorfer, whom some have mistakenly supposing to have been of Altdorf in Switzerland, was a native of Altdorf in Bavaria, born in the year 1488. His name is found in the regifter of the citizens of Ratibou in the year 1517, where, having passed the routine of preparatory civil offices, he was made a member of the interior Senate, and architect of the city of Ratibou, and where, in 1538, he died without issue.

Some of his pictures may yet be seen at Ratibou, and at the town house is preserved a complete collection of his engravings. The French call him "le petit Albert," pre- Sumptuously in contradistinction to the great Albert Durer, and because his engravings are small, for which reason also he is usually ranked with the "little masters." His merit was however not inconsiderable. He engraved both for the rolling-presses and letter-presses; but those which he did for the latter are his best performances. He polished a lively fancy, a free hand, and great facility of invention. Yet his style is German, and his drawing, though spirited, is incorrect. He marked his plates and blocks with the two forts of monograms which appear in our plate of the cyphers, &c. of the German school. One of these marks has been attributed to Aldegrover; but the evident superiority of the latter letter is of itself sufficient (independent of the cypher) to correct the mistake.

From the spirited wooden cuts of Altdorfer, Holbein, of whom we shall presently speak, is said, and probably with truth, to have derived great assistance in the progress of his studies.

Altdorfer's principal engravings on copper are the portrait of himself; and that of Martin Luther, in an oval, surrounded by foliage; the head of an infant, one of his earliest works, dated in 1527; "Adam and Eve in Paradise;" "Solomon's Idolatry;" "Dallah and Sampfon;" "Judith and Holofernes;" several small prints of the Madonna and infant Christ; a Crucifixion, with numerous figures; another with the Virgin Mary and St. John, both small uprights; "St. Jerome standing in a Cavern," where is an altar, book, crucifix, and a tablet, with the monogram of the artist; another St. Jerome among buildings, accompanied by a lion; "St. George combating the Dragon," two etchings of the death of Dido, and that of Lucretia; a pair copied from More Antonio, of "Venus accompanied by Cupid entering the Bath," and "Venus leaving the Bath:" these are small uprights and in a neat style. "Cupid Sporting with Sea-horses," "Amplion faved by Dolphins," dated 1572. A pair of "Lusciunae," and prefumptively, "Chastity," represented by a female sitting on an altar, and holding a sceptre, with numerous attendants bearing lanterns. "A Warrior precipitating himself into the Sea." A pair of small landscapes lengthways, one with rocks and the other with trees, which are touched with considerable freedom. The "Synagogue," with a Latin inscription; and two plates of ornamented vases in 4to.

The number of engravings by this master, which are supposed to have been performed on wood, is considerable, probably exceeding a hundred, of which the following are most valued:—A set of forty of "The Fall and Redemption of Man," small uprights, executed in Altdorfer's best manner, and much valued; but collectors should be careful not to admit into their portfolios, instead of these, a set of all but two are copied from Altdorfer, and which were published at Zuric A. D. 1661, under the firm name of Albert Durer. "The Sacrifice of Abraham," and "Joshua and Caleb," both small. "The Annunciation," ditto, dated 1513.

The four following are in 4to. "The Purification;" "The Muffle of the Innocents," dated 1511; "The Decolation of St. John the Baptist," and "The Refurrection of Christ," both dated 1512, and the latter esteemed one of the most spirited works of the master.
The beautiful virgin of Ratibon, engraved from her picture in Ratibon cathedral, is engraved in chiaroscuro, though some few impressions were printed without the half tint: this is a rare print.

Of the often repeated subject of St. Jerome, Altdorfer has engraved two blocks, in one of which the holy man is kneeling before a crucifix in a cavern, and the other may be discerned, guilted by its very romantic background, both are small, but fairly held in edition. "St. George and the Dragon," and "The Judgment of Paris," both dated in 1511, and "St. Christopher and the infant Christ," are all in toto. A mountainous landscape with buildings, and a large tree on the right hand, another of a gateway, and a grand baptismal procession, a sort of allegory, where, inside of a church, the virgin and child, some angels, and a pilgrim appear in the procession, are all of the folio size.

Hans Holbein the elder flourished towards the close of the sixteenth century, and was of Augsburg; but afterwards removed to Basel in Switzerland. According to professor Chirill, he engraved on wood, and certain prints marked with an H., or the cypher H.B., the B being joined to the first perpendicular stroke of the H., are attributed to him; but Straut doubts whether they ought not rather to be ascribed to Burgkmair or Baldung.

The great celebrity of his son has reflected a steadier light upon his name. Hans, or John Holbein the younger, was born at Augsburg in the year 1495 or 1496, and died of the plague in London A.D. 1543. He was the pupil of his father, and gave earnest of his very extraordinary powers, at a very early age.

About the time of his father's removal to Basel, the genius of Holbein began to dawn on the arts of Europe. At this time, besides engraving, as has been said by various authors, for the letter-press in a very superior style, he painted portraits, and occasionally historical subjects in disinterest and in oil, and Erasmus, who was then superintending the printing of his works at Basel, came to fit for his likeness to young Holbein.

Being charmed with his portrait, Erasmus soon formed a friendship for the artist, and at his persuasion Holbein soon after travelled to England. He brought with him the portrait of his friend, and letters of warm recommendation to the great Sir Thomas More, who was at that time lord chancellor, and high in the favour of Henry VIII.

Holbein was received by the chancellor in the most friendly and flattering manner, and the family of the Mores, besides several other pupils of distinction, and finally the king himself, honoured our artist by fitting him for three portraits. Patronized by Sir Thomas, and possessed of such talent in the arts as had not appeared in England before, he was readily received into the royal service upon very liberal terms, and so proud was Henry of the abilities of his proteges, or so just to the claims of his genius, that he frequently sat to him for his portrait, and the glory which we have related of the condescension of the emperor Maximilian to Albert Durer has been often repeated of king Henry and our artist.

After the death of Henry, Holbein still continued to enjoy the royal favour, and several portraits of Edward VI. from his hand are still extant.

The career of Holbein was short; but as the poet on a less interesting occasion has beautifully said, "the sands of his hour-glass were diamond-sparks," which, as they fell, glittered in the radiance of his reputation. He died, as we have before mentioned, of the plague, in his apartments at Whitehall.

For an account of his merits as a painter the reader is referred to the article Holbein. He began engraving when he was about sixteen years of age, and very numerous and of extraordinary merit are the letter-press cuts which are laid to his hand, and after his own designs, which adorn the books that were printed about this time at Basle, Zurich, Lyons, Leyden, and London.

Holbein appears to have formed his style, probably under the direction of his father, from studying the works of his contemporary Altdorfer, who was now rising in reputation, though not more than ten years older than our artist, and it seems highly probable that the whole of whatever letter-press engravings are from the hand of Holbein himself, are the production of those fifteen years of his life which elapsed between the years 1511 and 1526, when he came to England, for it is not very likely that he would be led aside from the advantages of the royal and noble patronage which he enjoyed in England as a painter, by any inducements which the printers and booksellers of the continent might offer. Engaged in superior pursuits, the present writer is inclined to think that he did no more than design the little wood-cuts which are ascribed to him during his residence in our island.

The foreign writers on art, however, call him "the glory of wood engraving," and "the phenomenon of his age," adding that in order duly to appreciate his merit as an engraver, the connoisseur should not look at the hastily printed and worn impressions which are common, but should have before him, early proofs, printed only on one side the paper, such as were lately in the collection of M. Otto, an amateur of Leipzig, which, in point of delicacy, exceed all that had previously been exhibited.

His most esteemed production in this way bears the Latin inscription

"Cernere vis Hopfes simulacra simillima vivis?  
Hoc opus Holbiane nobile cernens manus,"

and consists of a series of ninety small letter-press cuts, of unequal merit, of which the subjects are taken from the Old Testament. The engravings that have been repeatedly praised on the whole, namely, that "holdness, spirit, and delicacy are united in their execution," are only applicable to the bolt of these cuts: the rest are scarcely, if at all, superior to the common place of the day.

The first edition of this work, which is commonly termed Holbein's Bible, is said to have been printed (at Lyons, by the brothers Melchior and Gaspard Trefchel) in the year 1539, and as this was thirteen years after the death of the artist, it is not easy to believe that these cuts are really engraved by Holbein, notwithstanding what is ascribed in the inscription: and they are on the whole inferior both in design and engraving to the "Dance of Death," of which we shall presently speak.

That the craft of publishers on such an occasion should have outlived the strictness of truth, and that a name which had revolutionised through Europe should be used as the trumpet of popularity and the means of profit, would be no very extraordinary occurrence. The work was for the multitude, and the multitude, on such a point, were easily deceived; nor could Holbein, if he were really the author of the designs, easily contradict the complimentary inscription:

"The Dance of Peasants," engraved from a picture which he painted in the fifth-market at Basle, and evidently before his departure for England, of which fine impressions are now become rare and valuable.

The cuts for "The Death of Folly," of his friend Erasmus, have also been ascribed to Holbein, besides several detached frontispieces, jewellery ornaments, and vignettes, and, lastly, we shall mention the "Imagines Mortis," or "Dance of Death."
GERMAN SCHOOL OF ENGRAVING.

Death," over Holbein’s claims to which the accurate research of M. Douce of the British Museum has thrown a shade of doubt that may not easily be dispelled. It consists of forty-six small upright prints, each surrounded by a double-line border, wherein Death, in the skeleton form, is poetically represented as leading off an individual from every station and condition of life, from the emperor in his imperial state, down to the meanest peasant; and the general moral which combines the whole is, that Death pays no regard to age, sex, or condition.

It seems proper here to be observed that these engravings are not taken, as Papillon, Strutt, and others have mistakenly supposes, from an ancient painting on the walls of a cemetery at Basil, and that this painting is not from the hand of Holbein, but is of much older date. The originals are drawings or small pictures which have been suppsosed to be by Holbein, between which and the large picture in the cemetery there is this material difference, that the former forms one long and connected procession of single figures, each led by a skeleton, whereas the latter is composed of separate groups, in which one or more living figures or skeletons are occasionally introduced, as hinted the views of the article, and altogether forming a series, the idea of which was doubtless suggested by the walls of the cemetery, and by the dances of death that were sometimes found painted in the crypts of ancient cathedrals, and of which there was one at Lubeck, another in the church of the Innocents at Paris, and another in our old cathedral of St. Paul.

Of Sigismund Holbein we shall say but little, for much could not be said to his credit. He was uncle to our Hans, and painted, and engraved on wood; but his powers were very inferior to those of his nephew, and even to those of his brother. The prints marked with the monogram, which will be found in our first plate of those of the German school of engraving, are ascribed to him, but Strutt doubts the fact of his having engraved them, nor does it much matter.

The cypher formed of an H and an L, which appears to that cut in the Imagines Mortis, of which the subject is called "The Duchess," is certainly not that of either of the Holbeins, and is very likely to have belonged to some German wood engraver, whose initials might be thus conjoined, who was the real engraver of the whole set of the Dance of Death, and who might perhaps be Hans Lederer, as is conjectured by Mr. Douce.

Bartolomeo Beham was born at Nuremberg some time about the year 1500, and, according to Sandrart, ended his days in Italy, a short time before the middle of the succeeding century. He travelled with Duke William of Bavaria, and became the disciple of Marc Antonio, under whose instruction he advanced rapidly in his profession, and whose style he imitated without implicitly following. He remained several years at Rome and Bologna, working chiefly in the excellent school of Marc Antonio, and incorporating with the careful and patient manual execution of German, the accurate drawing of his master, and the fine talents of Italy and Raphael. Strutt accordingly says of him, that “his drawing is correct and masterly; his heads characteristic, and the other extremities of his figures well marked.”

Sandrart states of this master, that in his time a great many of his engravings (presumptively engraved plates, and not impressions from them) might be seen in the gallery of the elector of Bavaria at Munich, and in the cabinet of the prince of Neubourg. The collection of the works of Bartolomeo Beham is however attended with considerable uncertainty, from the circumstance of many of them having been published with

out his name, monogram, or other mark. Strutt attributes to him the engravings that are marked with a small s, on which sometimes appears the letter B, whilst the abbe Marrois, Huber and Roff, contend that these prints are the production of Beatrici.

Of the works generally attributed to this master the following are the principal:—the portraits of William, duke of Bavaria; Erasmus Baldschuyn, at the age of 33, and Leonard van Eck, a counsellor of Bavaria, all in octavo. The emperor Charles V., at the age of 31, with the Latin inscription “Progenies divum quintus fice Carolus ille imperii Caesar et ora tulit;” and the emperor Ferdinand I., with the inscription “Proximus a fungo Ferdinandus Caesar Rex Romanorum fte turb oras genas,” both in quarto, and marked B.B. These are a finely engraved pair of portraits, and so much in the style of Marc Antonio, that Valfari thinks the portrait of Charles V. is really engraved by that master.

The best historical works of Beham are "Adam and Eve, with the figure of Death introduced into Paradise," "Judith beheading Holophernes," dated 1525, and in the style of Marc Antonio. "The Madama fucking the Infant Christ at a Window," (without the mark of the artist.) "A Sybil reading, and having before her a Boy holding a Flammbeau," (marked B. B. in four lines, and apparently after Raphael.) "Sufamah and the Elder," after Julius Romano. "The deaths of Lucretia and Cleopatra, both without the engraver’s mark. "The Judgment of Paris," with a dark back ground, a small frieze, representing a combat, and marked “Titus Querreus,” and another small plate of a combat, wherein soldiers are fighting with clubs, companion to the above. "An Infant carding a Dog," a small circle, dated 1525. Another Child, with a skull near him, marked B. B. and dated 1524. An emblematical piece, inscribed "Der Weif Laut," in which appears a half naked woman fettered, and asleep under a tree, an infant at her side, and a lamb at her feet; and an indelicate subject from Ecclesiastes.

Hans Schabd Beham, the cousin or nephew of Bartholomew, was born at Nuremberg in the year 1500, and died at Frankfort on the Maine in 1550. He is said by Sandrart to have studied under his relative, but Bartholomew went early to Rome, and, it must be remembered, was but four years older than Schabd; perhaps he merely learned of him what he knew, and afterwards studied with Aldegrever, of whom he shall presently speak, the works of Albert Durer.

He was obliged to quit Nuremberg on account of his libertinism, but settled afterwards at Frankfort; where, however, he relapsed into his former courses, and after engraving for some years, in the course of which the number of plates and tablets which he produced is surprising, he became the landlord of a tavern.

The German biographers of Schabd maintain, that when he established himself at Frankfort, he altered his monogram, by substituting the letter B for the P which he used at Nuremberg; they do not say he did it for the fake of concealment, and it may in some degree account for this variation, when we recollect that these letters are often orally confounded among the people of that nation. The Abbe Marrois, Le Conte, and the French writers, on the other hand, often call him Hifsens, and Schabd de Bohemis, for which we cannot so readily account.

Schabd Beham ranks defiderately high among the first masters; he engraved chiefly from his own compositions, which show a lively and vigorous invention, though sometimes impaired by the Gothic-german taste, which was then prevalent, and which chiefly appears in the crowded and inelegant folds with which he loaded his draperies. His drawing of the naked, on which he seems to have jullly prided himself, though not free from manner, is often
correct, and sometimes masterly; his heads are expressive, and his other extremities carefully determined. The manu-
part of his engraving on copper, executed with the graver
only, is clear and delicate. The prints which he first cut on wood are slight, but spirited and free, as wood engraving
ought to be; for wood engraving ought not to emulate the
delicacies and difficulties of the art of engraving on copper.

His two monograms will be found among those of the first
plate of the German school. From those which he engraved be-
tween the years 1519 and 1530, with the Nuremberg cypher,
we select the following: viz. the portraits of Sebald Beham
and his wife Anne, where his cypher appears encircled by
ranel. Two small plates of "Adam and Eve in the terrestrial
Paradise," dated 1519. "St. Jerome with his Lion holding the
"The Virgin of Ratibon," where he is represented standing
on a cresent, and surrounded by radiance, and "The
Death of Dido," all dated in 1520. "St. Anthony writing in
the Desert," and "St. Sebald, (the patron saint of Nure-
mburg), sitting among trunks of Trees, and holding in his
right hand the Model of his Church," both dated 1521.
"Two Phenomena," one of them playing on the violin, and
the other, a male and female Peafow Dancing," dated 1521.
"A Triton supporting a Nereid," dated 1523. "Force, allegorized
by a Woman sitting on a Lion," dated 1524. "A Young Man
fitting under an Ashbr unembracing a young Woman," dated
1526. "The Death of Cleopatra," dated 1529. An orna-
mented vase with an inscription. "A combat between the
Greeks and Trojans," inscribed "Kricken und Dronierun,,
and another combat, inscribed "Achilles und Hector,"
both small friezes.

Of those which S. Beham engraved at Frankfurt, between
the years 1531 and 1549, and which are marked with his
second cypher, the following are held in mould effem.
A vase enriched with sculptured ornaments, at the base
of which are two lyres, dated 1531. "Adam and Eve
carefully engaging," "Adam and Eve in Paradise," between
whom is Death, with a serpent wound round him, presenting
the fatal apple; a high finished plate, dated 1535. "The
emperor Trajan arrelled at the head of his Army." "Mar-
chiolo and Patience," two female figures, the former copied
from the celebrated engraving of the same subject by Albert
Durer, dated 1536. "The Virgin and Child," inscribed "Pa-
-"tiens," and dated 1540. Another pair, a Good-fortune and Evil-fortune, the former figure flanking and holding a wheel, the latter arrelled in her course by an evil genius, who is presenting her with a lobfiller or claw-fish.
An etching of a buffoon presenting flowers to a young
woman. A set of the four evangelists, dated 1541. Anoth-
er set of twelve of the labious of Hercules, dated from
1542 to 1548. "An Ensign beating a Drum," inscribed "Im
Baeren Kreig," small, and dated 1525. "A Roman Charity," very finely engraved, dated 1544. The arms of
Beham, as granted to the family by the emperor Maximil-
ian, a hexagonal print, inscribed "Sebalt Beham, von
Nurnberg, mähler, ject wohnhafte Bürger in Frank-
furt," dated 1544. Bust of Dominian in the manner of an
antique medal. A set of six, and a title-page of the months
represented by male and female peafows dancing, the last
feigned from behind by a naked Female," a beautifully finished
plate, dated 1547, with the following words inscribed on a
frame: "Ospexit homine venenum mortis alioque," "A Man
endeavouring to root up a Tree," dated 1549, and inscribed
"Impotibile, &c," and a virgin and child copied from
Bartholomew Beham, dated 1549.

The letter-precedents of S. Beham have not been thus carefully
arranged and separated. We select from them the following:

His own portrait in a bonnet and without a beard. A set
of eight from the Psalms of our Lord, two of which are
marked with his cypher, and two with his latter cypher.
An "Holy Family," in which St. Joseph is plucking straw.
"The Virgin and Child," "A Penitent," "St. Jerome with a
Billet and Crucifix," "Immortality," represented by a female
crowned with stars, and trampling on a skeleton, dated 1548.
A public bath of Anabaptists, of both sexes and all ages, of
the circular form. Another public bath, a large print on four
leaves. "A Village Fair" of the frieze form, and "A March
of Soldiers," also of the frieze form, and large; the four illu-
mentioned engravings are very rare; a set of three hundred
and forty-eight, engraved for "Biblica Historia Artifi-
ciofima depicta," printed at Frankfurt in 1537. But it is
to be observed that there are two editions of this bible,
of which the former is in Latin, and the latter, dated 1559,
is in the German language.

Gregory Peins, or George Penta, was also a native of Nu-
remberg, born in the year 1526. He first studied in the
school of Albert Durer, and profited much by the instruc-
tions of that distinguished master, but it was in Italy, and
under the direction of the great Frieri, Penta, that he formed
his style of engraving, and acquired that correctness of draw-
ing which we regard with so much admiration in his best
works. His plates are executed entirely with the graver,
which he handled with much skill, uniting with great pre-
cision a degree of freedom which was unexampled. He
appears to have worked on some of the best plates that pass un-
der the name of Marc Antonio.

The far greater number of the engravings of Peins are of
small dimensions; whereas he is usually classed among
the little masters but he has produced some few large
pieces; one especially of great merit, of "An Army passing a
Ditch, and scaling the Walls of a fortified City," after Julio
Romano; which, as Strutt has said, is "an admirable speci-
men of the artist's superior abilities."

Peins died at the age of fifty-six, but where, his biogra-
phers have not mentioned: his monogram will be found in
our plate of those of the German School; and the most
eclat of his numerous works are those which follow: Portraits of Gregory Peins and his wife on the same plate;
with the inscription, "Imago Gregori Peins Imagini Dux
German." From this engraving it should appear, that the
name it bears was the true name of our artist, and that the
name Georgius Penta, which appears under his large
plate after Julio Romano, is probably an error of the pub-
lisher Van Aelst. Portrait of Jean Frederic, elector of
Saxony, a rare print, dated 1543.

The belt of the historical works of Peins are, a pair of
"Ehther before Alahuzerus," and "The Temptation of
Job," another small pair of "Judith in the Tent of Hol-
onneus, and Judith appearing afterwards with his Head," anoth-
er pair, finely executed, of "Solomon's Idolatry," and
"The Judgment of Solomon."

Peins appears to have placed some judgment, at least some
humour, in pairing his prints; the next companions which we
have to notice, are "Sufanah solicited by the Two old
Men," and "Lot intoxicated by the Two young Women,
his Daughters."

From the history of the patriarch Joseph, we find a set
collating of four plates; another set from the history of
Abraham, seven, including the title-page, A pair of "The
Good Samaritan, and the Conversion of St. Paul." A set of
the Four Evangelists after Aldegrever, which bear the
cyphers of both artists. Another set of the Seven Works
of Mercy, of the circular form, and with German inscrip-
tions. Another set, very highly finished, collating of
twenty-five, from the Life of Christ. "Heredias receiving
the
the Head of John the Baptist." A pair of "The Rape, and Death, of Lucretia." A pair of "King Portmanns" pulling the Tiger, and Horatius Coclcs singly defending the Bridge." Another pair is a set of two plates, one illustrating the Life of Virgil, the other, "The Death of Cato," and "The Death of the Virgin." A set of three of "Two Musicians: Thrashing his Hand into the Fire;" "Marcus Curtius precipitating himself into the fiery Gulf;" and "The Punishment of Titus Manlius;" in the latter of which the artist has introduced the beheading machine, which is since known in France, the dreadful guillotine. A pair of "Sophonisba" and "Artemisia;" "The Supplication of Regulus;" "The Centaur Chiron instructing Achilles;" "The Triumph of Bacchus," a frieze in the antique style. A set of six emblematical triumphs of human nature, viz., Valour, Chastity, Love, Time, Death, and Religion. A set of five of the fences performed, with Latin inscriptions; another set of the seven liberal arts; and another of the seven mortal sins.

But his principal and largest work, of which we have already spoken, is "The Taking of Carthage by the Romans," after Titus Livius. Among that class of the ancient engravers of the continent who are called the "Little Masters," from the small dimensions of their works, Henry Aldegrever stands in the very first rank. He was born at Zoult in Westphalia, A. D. 1502, but of his ancestors we find no account. Both his baptismal and family names have been mistaken, for, by some authors, he is called Aldergrafi; while others, perhaps, mistaking some of the smaller works of Albert Altdorfer for his, lay that his Christian name was Albert; but professor Christ affirms his renders that the name of this artist was Henry, and not Albert; and upon his own portrait his surname is written, at full length, "Aldegrever."

Nuremberg was at that time the head-quarters of German art; and thither young Aldegrever was sent to study under Albert Durer. He imitated the style of his master with great success, and gradually learned to blend with it a certain small portion of the elegance and simplicity which Italy first caught from the resurrection of Greek art, and Germany from the engravings which were brought thither from Italy. Aldegrever's object, which receives the first family, is a set of a riting form, and it is generally allowed by his critics, that had he resided in Italy, "the genius and ability which displayed itself so conspicuously in his own country, would have shone with double lustre." The manual part of his engraving, executed entirely with the graver, is extremely neat, and in a style evidently founded upon that of Durer. He is among the first who gave texture to the light parts of flesh by the admixture of small long dots, which has since been carried to such admirable perfection by Nanteuil and others. His drawing of the naked, which he seems fond of introducing, is more correct than is found among his predecessors of Germany; and his men more correct than his women. His heads are, in general, expressive, and his other extremities well marked, though occasionally somewhat heavy.

The time of the decease of Aldegrever is not accurately known, but the latest of his prints is dated in the year 1558. The Abbé Marolles has seen at least three hundred and fifty different prints from his graver, of which the following list contains the name of the principal; but the great demand for his works has occasioned his plates to be much worn, and often re-touched; and Strutt, with becoming fidelity for his fame, advises the collector to be circumspect as to the impressions he admits into his port-folios. His monograms may be seen in our plates of those of the German school.

The principal portraits of Aldegrever, are those of himself, without a beard, aged 28, and dated 1530. Another of himself, aged 35, in which he appears with a long beard; Martin Luther, dated 1540; Philip Melancthon, of the same age; and Albert Vander Helle, aged 28, and dated 1538; all in quarto.

His folio portraits are those of William dux de Julius; John of Leyden, king of the Anabaptists, and Bernard Knipperdolling, another fanatic.

Of his historical engravings, the most celebrated are, A set of six, from the History of Adam and Eve, dated 1540. A set of four, from the History of Lot, dated 1555. A set of four, from the History of the patriarch Joseph, dated 1528 and 1532; all in 12mo.

The only etching from the hand of Aldegrever is now become very scarce; its subject is Orpheus and Euridice, dated in 1528, and in 12mo.

James, or Jacob Bineck, was also of Nuremberg, or, according to some authors, was born at Cologne, in the year 1506, and died at Rome in 1560. His style of engraving greatly resembles that of Aldegrever, under whom, or Albert Durer, he probably learned the rudiments of his art, and improved himself afterward in the school of Marc Antonio; yet his style is not always the same; it often pollides more feeling facility than that of Aldegrever, and when, at the best, more of Italian taste. He appears generally full, and imitated, that of Marc de Ravenna.

His cypher, composed of the initial letters of his name, is of the same kind as that of many other artists who lived about the same period; but he sometimes added a little bird, and at others used the monogram, which will be found on our second plate.

The chief works of Jacob Bineck are, "A Young Man drest in a Broome, holding a Skull under his Cloke, and a Cup in his Right-Hand." This, according to Sandrart, is his own portrait; but, though the face may possibly resemble him, the rest of the composition is copied from an engraving of the same size by Israel von Mechenin.

The portraits of Francis I., Christiannus II., surrounded by ornamental architecture; a young prince, dated 1526; Luke Gaftos, dated 1529; the archdukes of Elizabeth of Denmark; and of Martin Luther, inscribed "In filentio Veifra, and Philip Melancthon, inscribed "Si Deus pro nobis quis contra nos."

His principal historical engravings are a small plate of St. Jerome. "Marcus Curtius precipitating himself into the Fiery Gulf," marked 15 I. b. 29. A pair, of the frieze proportions, of "Infant Bacchanales gathering grapes, &c." and "The Triumph of Bacchus," wherein his car is drawn by satyrs, and attendant nymphs are playing an musical
Seven engraving a the Nurember," which is deduced from Bihlaid Pirkheimer's emblems, are Experience, Envy, Tribulation, and Intolerance, marked 15 L. B. 29. "History," a female figure with wings, writing. A pair of "Peafants marketing with People of Superior Condition." A set of twenty, of Divinities standing in Niches, copied from Curaticus, who copied them from Rosso.

The above are marked with the initials of the artist: the following are with his monogram. A pair, very small, of "Eve with Two Apples, and Adam holding the Branch of a Tree." "Lot and his Daughters," a small circle. "David with the Head of Goliah;" and "Judith with that of Holofernes," both small. "The Millennium, or Archangel Michael, chaining the Devil." "The Holy Family," "The Slaughter of the Innocents," a very rare print, after Raphael, but perhaps copied from the engraving by Marc Antonio. The Defeat of the Crofs," St. John asleep with the Lamb," dated 1526. "St. George and the Dragon." "Mercury travelling in a Defart," a small circle. "A Soldier defending himself against Death, who has overthrown him." "A Woman beating the Devil with a Distaff." "A Woman advancing with Surplice towards a Man who is seated near a Pedestal, on which is a Child," after Raphael, and engraved under the direction of Marc Antonio. "A Male and Female Peafant Dancing." "The Blind Child." A vignette, with Cupids mounted on dolphins.

Strutt begs leave to add, a figure of "Saturn flanding in a Niche devouring One of his Children," a small upright, which differs in the Ryle of engraving from the foregoing, being more bold, spirited, and correct. The real meaning of this allegory must be, that Time is swallowed up by Eternity. On a tablet which is introduced is "Jacobus Bisck Colomicis, fecit 1530.

Another of "the little makers" of Germany was Hans or John Brofamer, born at Fulda, in the circle of the Upper Rhine, in the year 1566. His manner of engraving offers peculiar refinement, but the school on which he studied is not known; sometimes, however, he differs from that distinguished master by interworking the lines of his draperies and backgrounds with rippling. His drawing of the naked is however very deficient, and in manual execution he by no means equalled the Behams. He died at the age of fifty-four, and his cypher, composed of the letters B and S, will be found in our first plate of those of the German school.

His principal engravings are, the portraits of Martin Luther, and the abbot of Fulda, dated in 1531.

And in history, "Samson and Dalilah;" "David and Bathsheba;" and "Solomon's Idolatry," dated 1543, all small uprights. "Xantippe and Sostratus;" "Laococon and his Sons;" dated 1535; "The Rape of Helen;" of the frieze form, dated 1540; "Marcus Curtius leaping into the Gulf;" a small circular plate; "The Judgment of Paris;" "A Crucifixion, with Angels, the Virgin Mary, and St. John;" "The grand procession of ChristiaW Heroes;" a rare print, engraved on wood, and sometimes attributed to Bargmair; and "Biblia a Vos Testamentis artificialn picta allegorica," printed at Frankfort in the year 1552, and consisting of a set of engravings on wood, chiefly, but not entirely, copied from those of Holbein, which were published at Leyden in 1547; but by no means equal to the originals, either in spirit, neatness, or trut

Augustin Hirchfogel was born at Nuremberg A.D. 1506, and died in the fame city in 1560. He was probably educated a painter, but produced several etchings, of which the landscapes possess considerable merit, being etched with some taste and the touch of a master, but when he introduced the human figure it is very ineptly drawn. The singular monogram of Hirchfogel, surmounted by a little cross, will be found in our first plate of those of the German school, and his principal productions are as follow: Part of "Raphael's slaughter of the Innocents," from a sketch by that master, which differs from the print by Marc Antonio, dated 1535. A set of four, and another set of six landscapes, from his own compositions of cattle and mountain scenery, in 4to., dated 1546. A folio landscape, in which is introduced an ill-drawn female intended for Cleopatra, dated 1547. An ornamented vase in 4to. dated the same year, and two small views of sea-ports, with flippings, &c. dated 1539.

Henry, whom Strutt has mistakenly confounded with Hans or John Lautenfack, was also of Nuremberg, or, according to some authors, was of Doppelmayr, and born in the same year with the preceding artist. He was the son of a painter, and learned the principles of design in his father's house, which he probably continued to inhabit, for we find that he died in his native city in the year 1529.

The elder Lautenfack employed much of his time in engraving on the precious metals for the sideboards and personal ornaments of the opulent and the great, but in the year 1567 he published at Frankfort on the Main the "Geometrical proportions and perspective of the Man and Horse," in small folio; "The Martyrdom of St. Catherine;" two ornamental plates of boys, &c.; "The decollation of St. John the Baptist;" "Christ expiring on the Cross," and a boy standing on a globe with a bow in his hand, and below whom is a deluge, with many small figures, are also engraved by Henry Lautenfack, whose marks will be found in our second plate of German monograms.

Of the fame place and family with the preceding, was Hans Sebald Lautenfack, who was born in the year 1568, but of the principal events of whose life, and the time of his death, we are ignorant.

His portraits are held in esteem among connoisseurs for their truth of resemblance; and his landscapes, which are characterized for their wild, or beautiful, or grand effects; but the figures which he has introduced are generally disproportionate.

His landscapes are of an historical character, and are commonly denominated after the figures they contain. Of these the following will probably be found most worthy of the collector's attention: "The little David battling the Great Goliah," dated 1551. "The Blind Man of Jericho, referred by our Saviour," and another miracle of "The Devil cast out from the Camaanite," both dated 1559. "Balaam and his Afs," in a very mountainous landscape, and a very rich scene of "The Labours of the Vintage," are also dated in 1559, all of the folio size. An upright landscape with a large farm, dated 1551. A pair of interesting and extensive scenes in 4to. dated 1553 and 1555. A grand tournament, of large folio dimensions, entitled "Equefris pedestrifric pugnaeicon," 1560; and another grand joust, entitled "Secundum Ciricenuim Ladorum, equidem certamen continens," 1560, both of which are now become very rare. A pair of views of the imperial city of Nuremberg, in large folio, each engraved on three plates, and dated 1572 and 1555.

The principal portraits by Hans Sebald, are those of his father Paul Lautenfack, painter of Nuremberg, in folio. Himself, in small folio, dated 1552. Hieronymus Swerflab. Georgius
GERMAN SCHOOL OF ENGRAVING.

Georgius Roggenbach, and two other half-lengths, all in folio.

The brothers David, Jerome, and Lambert Hopfer appear to have been the sons of a goldsmith, and flourished at Nuremberg within the first fifty years of the sixteenth century. They produced a great many spirited etchings, which Hollart afterwards made the foundation of his style. David was the most industrious of the three, but defaced in the vicious taste of his age and country: yet his freedom of handling is very pleasing, and displays itself to advantage in buildings and ornaments. He usually marked his plates with the initials of his name, between which he introduced what the Abbé Marolles appears to have mistaken for a candlestick; for he emphatically calls the Hopfers "les Maîtres du Chandelier," but what is really intended for a hop-plant, in allusion to their name, which in the German language signifies hop-plant. These letters, with the plant, sometimes appear on a tablet, for which see our plate of German monograms.

Jerome Hopfer etched much in the same style with his brother, but was somewhat inferior in merit. He made several copies from celebrated works of Albert Durer, and sometimes engraved from his own compositions, marking his prints as did his brother.

His best works after Durer are, "St. Hubert," "St. Jerome," and "The Grand Cannon." "Hercules Battling the Hydra," is from Andrea Mantegna; and the belt from his own design are "Lucina holding a Moon in her right Hand, and a Palm branch in her left." "Minerva holding a small Figure of Victory." A rare print of "The English and French drawn up in battle array, previous to the Fight at Agincourt." And a battle, after Julio Romano.

Of all his merit than his brethren, was Lambert Hopfer, who copied in etching a great number of the works of Durer, but his works display little talent and lees correctness. Among them are a set of fifteen of "The Life and Passion of Christ," "The Conversion of St. Paul," "The Fall of our First Parents." Several plates of arabesque ornaments, and four beautiful candelabra, with an arabesque band which is esteemed the best of his engravings.

Strutt has added to these another Hopfer, for whom he claims equal merit with the poet. The initial letter of his christen name was an N. He worked with the graver, but imparted to his lines somewhat of the roughness of etching, and drew more correctly than David or any other of the family. To this artist he affixes "The Call of Jeremiah," a small upright, dated 1575. "A female Nude, holding a Palm Branch, and several Figures sleeping with the holy appearing above," which, he says, is a fine spirited etching.

David Funck, a printer of Nuremberg, towards the beginning of the last century, collected and published all the plates of these artists, amounting to two hundred and thirty, under the title of "Opera Hopferiana!" some of which were found to be executed on plates of iron or tin.

Virgile Solis engraved both on copper and on wood, chiefly from his own designs; was born at Nuremberg in the year 1514, and died in the same city in 1570. Under what name he studied does not appear. His early works resemble those of Beham, but when he came to engrave after Raphael, and other Italian masters, he adopted a style more open and spirited. His prints on wood bear great resemblance to those of Joft Ammon, both in design and execution.

Virgile Solis was a man of ability. His compositions are often judicious, but his drawing of the naked is not equally correct. He is chiefly among the little masters, and used occasionally three cyphers, which will be found in our second plate of the monograms of the German engravers.

Mr. Evelyn says, that for "imitating the style and figures of Aretilin, he had his eyes put out by the sentence of the magistrate." Strutt pretends, that if this story be true, the engravings of Solis must have been copies from those which Marc Antonio did after the design of Julio Romano, (and which he says are still of him his life,) to which the poet Aretin did but supply vermes.

The engravings of Solis amount to upwards of eight hundred, of which it may suffice to specify the following: "The Marriage of Cupid and Psyche;" "The Assembly of the Gods;" and "Mount Parnassus," all after Raphael. "The Bath of the Amabaptists," a small plate, after Aldegrever. A set of four plates of fragments of ancient architecture. A set of six heads of Roman emperors, small. A pair of small fizes, in which are numerous parrots. A set of portraits of the kings of France, from Pharamond to Henry III. The above are on copper, with some few etchings, which are inferior to the rest of his works.

His principal engravings on wood, are a set of one hundred and seventy from Ovid's Metamorphoses, small, and dated 1563. A set for the emblems of Nicolas Reusner, dated 1581. And, another set for those of Andrea Aretinus, both of which books were printed at Frankfurt in the year 1581.

Melchior Lorch, or Lorich, was born at Flensburg, in the duchy of Slefwic, in the year 1527, and died at Rome in 1586. He was distinguished both as an artist and an antiquary: some time about the middle period of his life, he made a voyage to Constantinople, where he painted and engraved the portraits of the grand seignior and his favourite, which are now become very rare, and where he formed that collection of Turkish drestes, which were afterwards engraved on wood, and published in the year 1576, in a folio volume. His engravings are decidedly those of a man of talent; he drew with considerable spirit, and a tolerable degree of correctness. His works on wood are executed with much freedom and boldness, while in those on copper their qualities
GERMAN SCHOOL OF ENGRAVING.

Qualities are in some degree lost in the neatness to which he laboured his finishing. Strutt speaks of a crucified figure, (which is designed so much in the style of Michael Angelo, that he supposes it to be engraved after some work of that great master) as a very extraordinary production. It is executed entirely with the graver, and the left leg and arms are much fore-shortened. He says, "if this figure be not quite correct in all its parts, it is however well drawn upon the whole, notwithstanding the difficulty of the fore-shortenings, and is finished in a style of neatness equal to that of Jerome or Anthony Wieris, while it is superior to them in point of taste." His monograms, which he sometimes surmounted by the date of his work, will be found in our second plate of those of the German school.

The works of Lorioch, which are held in most request among connoisseurs, are: the portrait of Martin Luther, dated 1548. That of Albert Durer, with four Latin verses, dated 1559; a very rare print, done after a statue of a Cameo, and those which were mentioned above of the grand figurer and his favourite sultana, very neatly executed on copper, and very scarce. Ariosto, the Stagyrite, dated 1561. "St. Jerome in the Dafart," dated 1576; and a small upright of a female head, beautifully executed, are also on copper.

His best engravings on wood, are a feat mentioned above, of the costume of Turkey, in small folio, dated from 1570 to 1581. "The Tiburtine Sybil," dated 1574, executed in his best style. "A Woman prevailing her Breech, with numerous Animals below," and inscribed "Ops Saturni conjux materque Deorum," a very spirited engraving in folio, dated 1575. And "The Deluge," a large folio, engraved on two blocks, the impressions from which are afterward pasted together.

Theodore de Bry, or de Brie, the elder, was born at Liege in the year 1528, and died at Frankfort on the Maine in 1598; at which latter place he chiefly resided, but to whom he owed his early initiation to art is not known. He appears to have formed his taste by copying the work of Sebastian Beham. He worked almost wholly with the graver, and acquired a very fine style, which was well adapted to small folio prints, in which numerous figures were required to be introduced, such as fates, and funeral, processions. He drew correctly: his heads in general are spirited and expressive, and his other extremities well marked, and his back grounds, though frequently light, are touched with a masterly hand.

About twenty years before his death he visited England, and engraved at least two large and laborious plates, of which we shall presently speak, in the city of London. He died, as his sons in the 3d part of Boiffard's collection of portraits inform us, March 27, 1598. De Brie marked his plates with the cypher T. B. F. and at other times with that of Rene Boivin; and his principal engravings are those which follow: an etching of "St. John in the Dafart," a rare print. A pair of "The Fountain of Youth," and the "Little Village Fair," copied from Sebastian Beham. A "Bacchusian Procession," from Julio Romano. Three mixtures of the grotesque with theorkspherical and the circular. The Golden Age, a small circle, after Abraham Bloemaert. A pair of portraits en medallion, of Scanderbeg and Donze his wife. A set of nine figures of the muses, in folio. The plates for the four first volumes of Boiffard's Roman Antiquities (of which the two last volumes were completed by the sons of our artist). The plates of the manners and customs of the Virginians, published in "The brief true Report of the New-Foundland of Virginia. by Thomas Harret, servant to Sir Walter Raleigh," from drawings by J. White, printed at Frankfort by J. Wechelius, A. D. 1598, which were afterwards copied by Picart, for his "Religious Ceremonies, &c." The plates to the Latin narrative of Spanish cruelties in America, published 1598.

His largest work appeared in the same year, and is entitled "Decriptio Indie Orientalis et Occidentalis," in nineteen tracts, which are contained in fivefolio volumes.

De Brie is also the author of a work which may be thought still more interesting to British feelings, because connected with British history. It is the procession of the knights of the garter in the 18th year of the reign of Elizabeth, of which Strutt gives a very particular description: "The procession is represented as moving along a portico quite open on the side next the observer, but supported by thirty-three pillars of the Ionic order, on the side from him. Over each knight companion of the order are his arms, intersected with the garter, and, in a compartment below, his name, titles, &c. are written in French. The last ball was vacant, and there is only a fancy portrait given, without name or arms. There are sixty portraits in the procession, each of them between four and five inches in height! Under the arches of the portico is a delightful view of a hilly country, (too likely for an English prospect,) interspersed with castles, churches, hounes, rivers, woods, &c. and an exact view of Windsor castle as it appeared in that reign. The roll is sixteen feet three inches long, and was engraved on twelve plates."

Hollar to his plate of the procession, copied in small from this engraving, in Athanole's order of the garter, says, "the original was designed by Marc Garrerd, who could be then only fifteen years old." Wherefore Strutt concludes this to be a medall, but perhaps Garrerd made a reduced copy from this print, from which copy Hollars plate was engraven, which would reconcile the accounts; for Lord Oxford dates Garrerd's drawing in the year 1584, whereas De Brie's plate was finished in the year 1596; and Strutt, reasoning from the dedication being made in the name of Thomas Davies, Rouge-Crois, concludes that it was designed by him.

Strutt says he never heard of any other impressions from this plate than the proof, which, after belonging to the Norroy king at arms, came finally into the possession of John Fenn, esq. of Earl Durham in the county of Norfolk; but the engraving is mentioned by Huber, and pretensively therefore, is not unknown on the continent.

To this detailed account of this very curious historical engraving, Strutt adds the order of procession, and the names of the sixty portraits of the knights companions and officers of state; and the reader who wishes to be informed on these points, is therefore referred to his biographical dictionary.

The other plate which our artist is known to have engraved in London, is "The Funeral Procession of Sir Philip Sydney," on thirty-four plates, forming, when pasted together, a very long roll, but more frequently forming a book. In the inscription beneath, it is said to be "contrived and invented by Thomas Lant, gent. servant of the honourable knight, and graven on copper by Derick, or Theodore de Brie, in the city of London 1578;" and prefixed is the portrait of Mr. Lant, aged 32.

Jean Theodore de Brie the younger was the eldest son of Theodore, of whom we have just concluded our account. He was born at Liege in the year 1564, and died at Frankfort on the Maine in 1623.

The engravings of Jean Theodore are on the whole superior to those of his father both in taste and precision, and he assisted his father in the literary parts of those works in which
which he engaged, as well as in the engravings; but Jean
Israel, the second son of Theodore, who also assisted, and
succeeded him, was far less successful.

The brothers John, Theodore, and Israel, completed the
plates for Boiflard's Roman Antiquities, and added several
To the collection of portraits of illustrious personages,
which their father had begun to form.

Among other portraits, we find those of Gerard Mer-
cator the celebrated geographer, and Daniel Specklin,
both in 4to.

The bell historical works of Jean Theodore are, a set of
the elements, consisting of four plates in 4to. "The Return
of Rebecca," after Babtazar Peruzzi; "A March of Soldiers;
and 'A March of Soldiers conducting Prisoners," sometimes called "The Triumph of Death," both
of the frieze form, and by some supposed to be after Titian.
"The Village Fete," with a Latin inscription, after Sebald
Beutum, and "The Fountain of Youth," after the same,
both of the frieze form; and a set of twenty-four plates
Accordingly.

Jean Kebertaler was born at Dreiden in the year 1530;
under whom he studied is not known, but he continued en-
graving in his native city, until some time about the close
of the sixteenth century. He engraved some plates after Jean
Marie Noffen, who was sculptor and architect to the elector
of Saxony, of which the following are those of most im-
portance.

"Nimrod building the Tower of Babel;" "The De-
struction of the Babylonian Empire;" "The Empire of
Rome," in the back ground of which is the death of Cesar.
"The Empire of the Church," where the Pope is represented
receiving the homage of Charlemagne; and "An Allegory,
where a winged figure of Death, with two trumpets, is sup-
porting a globe, all of the 4to. viz.

Tobias Stimmer was born at Schaffhausen towards the
close of the sixteenth century, but resided chiefly at Straf-
burg, where he was patronized by the margrave of Baden,
and became both a painter and engraver of eminence. His
engravings are chiefly on wood, and from his own com-
positions; the engravings in the "Novae Tobiae Stimmeri
facrorum Fabricorum figure veritatis Latinis et Germanicis
exposita," are from compositions by Stimmer, though he
was assisted in the engraving by his brother Christopher,
and his pupil Christopher Maurer. Stimmer understood the
human figure very well, and composed with so much taste
and judgment, that Rubens has been heard to declare, that
he had studied Stimmer's bibles with attention and with
great benefit, and Sandart, who relates this anecdote, calls
the book, "A Treasury of Science for the art of Painting."

In the earlier part of his career, Stimmer was unfortunate,
and paft some of his best days in painting the façades of
houses at Frankfort on the Main, and at Strasbourg. But
let no man of talent, who poifees the means of fìewing his
talent, despair; it was the pleasure he received from some
of their, which accidentally caught his notice, that occa-
sioned the margrave to engage Stimmer in his service, and
began the foundation of his fortune. For him our artist
painted the history of his ancestors, and the margrave's own
portrait, and this day afferts the superior powers of Stimmer
in this department of art.

We have given his monograms in our second plate, and his
principal work, excepting his bible, is "The Annunciation,
in folio.

Jean Christopher Stimmer was born at Schaffhausen in the
year 1552, and died at Paris some time about the commence-
ment of the succeeding century. He was the brother and dif-
ciple of Tobias, and engraved on wood a great number of his
compositions with considerable success, for he drew with
ability, and hatched his engravings in a bold, but meadow style.

After the death of his brother, Christopher travelled to
Paris, where he performed some engravings, and was com-
monly known by the name of "the Switz," and where he
died, leaving behind him a son, who also engraved on wood a
considerable number of tablets after Francis Chauveau.

Christopher used the complicated cypher which will be
found among those of our monograms of the second plate of
the German school, and his best engravings are those which
follow:—A set for the New Testament, with the Apocalypse,
printed at Strasbourg in the year 1588. A collection of
portraits of the scholars and theologians of the German
nation, printed also at Strasbourg by Bernard Jobio, in 1591.
"Icones Alphabetiae," a collection of engravings printed in
the same year, all of the 4to. size; and a capital print of an his-
torical portrait of a kneeling figure, inscribed "Contrafaccio

Joel or Iodocus Ammon or Ammon, designer and engraver
on wood and on copper, was born at Zurich in 1539, and
died at Nuremberg in 1591. Not meeting with encourage-
ment in his youth at Zurich, he travelled to Nuremberg, a
City where the arts were reported to be in a flourishing state,
the year he became of age, and in 1577 renounced the
rights of a citizen of Zurich, in order the more firmly to at-
tach himself to his adopted country. Strutt says of him,
that if patience and affinity of themselves could constitute
an artist, Ammon would well deserve that character, from
the multitude of designs which he made, and the great number
of plates which he engraved, amounting, according to Huber,
to more than five hundred and fifty. But though a great genius
may be improved by cultivation, yet is equally certain that
neither pains nor study can create a great genius. Much
merit, however, was certainly possessed by our artist; who
lived at a time when almost every book which appeared was
ornamented with prints, and was employed by most of the
great bookfellers, especially Siegmund Feyerabandt of Frank-
fort.

The engravings of Joel Ammon upon copper are not
equal to those which he performed for the letter press. His
invention was not very copious; his figures are tolerably
proportioned, and the detail of his drawing is careful and
moderately correct; animals in particular he touched with
great spirit. His style of engraving is neat and decided,
but his lines are more regular, they are less free than those of many of his predecessors. He affixed various marks
to his performances, as may be seen in our second plate of
the monograms, &c. of the German school of engraving.

His principal works on copper are, a set of twelve illu-
trious women, beginning with Eve, under the title of "Eva
die Gebrerin;" a set of figures of warriors, small uprights,
marked Joel Ammon inventor 1590; the set consists of eight,
and there is a set of eight others, fighting with swords and
shields. The four scions, and the four elements, dated
1569. A set of the twelve months, perforated, and a set of
fifteen friezes of hunting subjects; a considerable number of
etchings of subjects of piety, after Winckelhaus Jamitzer;
the bombardment of a city, dated 1570, in folio, and the
portrait of Carparis de Cenigoun, D. Calliostro, marked
Joel Ammon Figurarius, 1573.

His best engravings on wood are, "The Creation of
Man;" "The Diet of the Empire," both in folio, the
latter an oval. "The Marriage at Cana," in quarto; a set
of one hundred and fifteen, entitled, "De omnium libera-
liquin mechanicarum et fidementarium artium genera con-
tinentes, &c. Edit. per Hoeltmann Scoperum Francof. 1564." This
work
GERMAN SCHOOL OF ENGRAVING.

work consists of artists and artisans, represented in their respective employments: among them are some excellent figures, and in that which represents the engraver, Amman has given his own portrait. A second edition was printed A.D. 1574, and a third in 1588, but the first is now become very scarce. The book is a large octavo.

A set of one hundred and two, besides the portrait of Feyerabandt, for a Latin edition of Livy, printed at Frankfort A.D. 1572-3, in oblong quarto.

Another set for a folio edition of Pliny, printed also at Frankfurt A.D. 1584. Another set for a quarto book of hunting, printed at Frankfurt in 1582, which book was considerably augmented after the death of Amman, and reprinted in 1617. Another set of one hundred and three of ecclesiastical habits, dated 1565, and another of one hundred and fifty figures, for “Gynaecum, in Theatrum Mulerum, in quorum præcipuarum omnium per Europam, &c.” in oblong quarto, printed at Frankfurt, 1586.

Christopher Maurer engraved from his own compositions, and from those of T. Stimmer, both on copper and on wood. He was born at Zurich A.D. 1558, and died at Winterthur in 1614. His father Johann was an artist, and under the paternal roof he learned the rudiments of art, but was afterwards removed to Strasbourg, and placed under Tobias Stimmer, where both the master and scholar were close students, and soon began to be distinguished by the number of interesting and beautiful works which they produced.

The cypher of Maurer will be found in our second plate of German monograms. After plying some years in the school of Stimmer, he returned to his native city, and added to his reputation by his fresco pictures which adorn the façades of distinguished houses, and by the like likenesses he displayed in his portraits; with the true spirit of a Swiss artist, he always preferred patriotic subjects, and has often painted the origin of the Helvetic confederacy.

Of his engravings, those on copper are most sought after by connoisseurs, particularly a set of bible cuts, and four emblematical engravings relative to proceedings in the courts of law, after which, the death of the artist, were introduced into a Latin book.

Of his letter-press engravings, which are neatly executed, the belt are probably the set of animals of the chase, which he executed in conjunction with his master, and which were published at Strasbourg in the year 1605. And a set of the bible under the title of “Historische Vorstellungen über die ganze Bibel,” which do honour to his inventive talent, as well as to his manual powers as an engraver.

Christopher Janitzer, or Jamnitzer, was born at Nuremberg in the year 1568, and died in the same city in 1617. He performed several etchings which are marked with the cypher which the reader will find among our monograms of the German engravers, but they are far from being of first rate merit.

Of the same family were Bartholomew and Wenceslaus Jamnitzer, whom we pass as unimportant persons.

The bell was cast by Christopher, in which case, the bell of these groups are those which follow: A set of twelve, in 1570; another set of twelve, mounted on marine animals; another set of four combined with swans, flowers, &c.; four children dancing in an armour. A set of grotesque chimeras, in quarto; Christopher Jamnitzer also engraved a portrait of himself fitting in a perspective machine, in the act of drawing or inscribing.

Matthew Greuter was born at Strasbourg A.D. 1564. He travelled more than once to Lyons and Avignon, and from thence to Rome for professional improvement, in which latter city, in the year 1588, he died.

Strutt describes him as a man of genius, but so much praise as is implied in this work, cannot justly be allowed him. He worked partly from his own compositions, but his drawing is by no means correct; his extremities in particular are badly neglected. He sometimes executed his plates with the graver only, in a neat style, and in other instances has employed etching. His principal productions are, the portraits of the popes Innocent X., and Sixtus V.; the latter surrounded with an ornamental border in which the papal coinage is introduced. Cardinal Sarraphinus Olivarius Razzabul, all in quarto.

Of his historical works we shall only mention “The Virgin and Child,” feated in a landscape, after Barcecio. Mary Magdalene leaving her right hand upon a skull, after S. Gaetano, dated 1584; both in quarto. An emblematical print of Venus floating on a globe, with various virtues and vices personified, very neatly finished, and marked M. Greuter int. ex f. 1587, in small folio. “The Fall of Phaeton,” after Windel Dieterlin, in large folio, dated 1588. “The Destruction of Troy,” after Lanfranc, and the magnificent cavalcade of the emperor Charles V. engraved by Greuter in concert with Lucas Vorlcrman, a large print of the frieze form, engraved on several plates.

As Jean Frederic, the son of Matthew Greuter, was born at Rome, and lived and died in Italy, our account of him will be found under Italian School of Engravers.

Matthias Kager was born at Munich in the year 1566, and died at Augsburg in 1594. He studied in Italy, and before ranking high among the historical painters of his time, was an engraver of merit. His style is neat, and performed chiefly with the graver, though sometimes with the admixture of etching. His attachment to liberty, and aversion to the manners of a German court, induced him to quit that of Bavaria, and he became a citizen and finally a burgomaster of Augsburg.

S. Kilian engraved a portrait of him in 1626. The best of his own prints are: “The Adoration of the Shepherds,” dated 1610. “St. John Baptizing Christ in the river Jordan,” both of the folio size, and from compositions by himself: “The Holy Family,” in an oval, also from his own picture, and in 1580, and “St. Francis surrounded by the Monks of his Order, to whom Christ and the Virgin Mary are appearing in the Clouds,” a middling-sized upright from P. Remigius Bozzolo.

Of Adam Eiheimeir, furname Adam of Frankfort, who should else have been mentioned in this place, we have already spoken. See Eiheimeir.

Theodore Kruger, or Cruger, was born in the city of Munich A.D. 1576. He travelled to Italy for improvement, where he formed his style of engraving on that of Francisco Villamena. He handled the graver, which was the sole instrument of his art, with boldness, freedom, and facility, but his chiaroscuro is very defective, and his outlines incorrect and hard.

His principal engravings are: “The Life of St. John the Baptist,” on twelve upright folio plates, after Andrea del Sarto, with the portrait of the painter prefixed, and dedicated to Colme de Medici, dated 1618. “The Last Supper,” in large folio, after the same. “The Return of the Holy Family from Egypt,” where the infant is embracing Jesus Christ, after F. Bigio, also in folio. “The infant Saviour blessing the little St. John,” after the same painter. And “A Prince on a Tribunal, surrounded by divers Statesmen,” after Lanfranco, and inscribed “Vox mildi.”

Cruger has also engraved some portraits after Gabriel Wayer, to which he signed his name, which Cruger he is best known in Italy.

Theodore
GERMAN SCHOOL OF ENGRAVING.

Theodore Cruger, the younger, was born in the year 1648, and was the son of the preceding artist. The Italians call him Della Croce, the Fleming's Verderuy, and the German Kruger. In the year 1710, he engraved, in concert with two others, the Flandern gallery. He also engraved "St. Francis at Prayer," after Carlo Maratti, and a couchant Venus, both in folio, beside several portraits, among which is the daughter of Georgione, after that master; and Ludovico Adimari, after P. Dandini.

Dominique Cuflos, otherwise called Baltos, was the son of Pierre Balshuir Balton, a painter and poet, who had some pretentions also to knowledge in the art of engraving. He was born some time after the year 1560 at Anvers, and died at Augsburg in 1612. His real family name appears to have been Baltons, but he settled at the birth named city, at an early age, under the name of Dominique Cuflos, and marrying there the widow of Barthelemy Kilian, the elder, was enabled to establish a lucrative print trade, which continued to flourish for a long period of time.

Cuflos had several daughters, of whom some were educated to the art of engraving, and proceeded tolerably well. He worked in a neat style, entirely with the graver, but his prints are laboured, tafleleaf, and without harmony of effect. Florent le Comte says he engraved portraits in the taste of Vandyke, but as Strutt properly remarks of this mistaken attention, there is not the least resemblance between the stiff portraits of Cuflos, and those so highly and so justly esteemed by Vandyke.

The principal engravings by this artist, are: the effigies of the German emperors, large whole length figures, in folio, dated 1593.

The portraits of the Fuggera family, of which the first edition, which is now become very rare, and is dated 1593, contains but sixty-four portraits: in the second the number of portraits is increased to sixty-seven: the third contains a hundred and twenty-seven, besides the arms of Fugger, and an ornamented title, but the names are added, of Lucas and Wolfgang Kilian. Another set of portraits of heroes, &c. entitled "Atrium Heroicum, Confarum, Regum, aliquumque famematum ac principium, &c."

The chief of his engravings of separate portraits are those of pope Sixtus V. prince Sigismund in the costume of Moliere, after J. Acha, and from the fame painter Marcus Bragadino, dated 1591. Christianus II. duke of Saxony, Henry bishop of Augsburg, (in an oval,) Johan Philipp, bishop of Bamberg, ditto. Maximillian, duke of Bavaria, and Elizabeth Lotharingia his wife, a pair of ovals, dated 1598, all of the folio dimensions.

The most esteemed of the historical works of this artist, are a set of "Female Saints," half lengths, after Frantz Alprenck. A set of four in folio, of "L'Histoire de l'Enfant prodigue," and "Judith beheading Holofernes," after John Van Asch, of the folio size.

Lucas Kilian, the patriarch of a numerous progeny of engravers, was born at Augsburg in the year 1579. Under whose direction he flailed, is not known, but the works of Henry Goltzius and Muller appear to have been his school. It appears, however, that he went to Italy, in order to complete his studies, where he engraved several plates from the pictures of the great Italian masters: but returned, and died in his native city in the year 1637.

"Few artists have manifested a greater command of the graver than Kilian: whether we consider the apparent facility with which his strokes are turned over each other, or the firmness with which they are executed, one cannot help admiring the artist, though it evidently strikes us that by paying too close attention to this part of his art, he neglected the correctness of his outlines, and fatigued the lights with unnecessary work." Such is the opinion of our countryman Strutt: to which should be added, that his drawing is not accurate, nor his chiaroscuro broad and impresive.

Of the numerous works of Kilian, the following are held in most esteem: "The Adoration of the Shepherds," a middling-sized plate, from the younger Palma. The same subject, a large upright, after Springer. Another of the same subject, after Rotenhauser. And another (a large upright) from T. Heinz. "A Holy Family," from Cornelius de Haerlem, and "The Miracle of the Loaves and Fishes," from the same master: both large uprights. "Christ Praying in the Garden," a small upright, placed at the top, from Frederic Sufties. "A dead Christ," from Michael Angulas. And "A Nymph and Satyr," from J. Heintz, both small uprights. "The Rape of Proserpine," a large folio plate, from the same master. "The Entombing of Christ," an upright, without the painter's name, dated 1665, which perhaps, with many other of the engravings of Lucas Kilian, is from his own design.

The best portraits by this master, are those of himself, aged 55, a rare print in 4to. "Petrus Cuflos, vulgo Balton, Pictor & Poeta Antwerpianus," dated 16.9 Nicholas Christopb, Prince of Rudzivil, both in 4to. The emperor Christianus II. dated 1615. Maria Eleonora Suverorn Gothorum Reginis. Guiflau Adolphus Suverorn Gothorum Rex. And Albert Durer, a half-length; all of the folio size: but whether the latter is from a picture by Rotenhauser, or after Albert Durer himself, the present writer is uncertain.

Wolfgang, the brother of Lucas Kilian, was also of Augsburg, and born in the year 1581. He studied under Dominique Cuflos, and, after his return from Italy to his brother Lucas, whose style he imitated without attaining to the same degree of excellence: his prints are somewhat water, but more stiff and formal.

Wolfgang employed the greater part of his time in engraving portraits, of which the following are those of most importance. Ernent Count Mansfeld. Maximilian of Walrlenflein, dated 1642. Jean Major, mathematician of Augsburg. Frederic Baron de Teufichan. Jean Goedefon, bishop of Wurzburg, and Ferdinand I. king of the Romans, all in 4to. Of the folio size: the archbishops of Mayence, Cologne, and Treves; his own portrait, inscribed "Labor improbus omnia vincit," and a set of twenty-seven of the emperors and archdukes of the house of Austur, from 1233 to 1623, with their lives and eulogiums, published at Augsburg, in 1629.

The most esteemed of his historical works, are the "Baptism of Jesus Christ," after Paolo Veronese. "The Assumption of the Virgin Mary," after Bentoreto. "The Descent from the Cross," after Paolo Farinato, and the "Good Samaritan," after Giacomo Bollino, all in folio. "The Resurreciton of Christ," after the copper after E. Baldino. The four Evangulists, in upright ovals, from his own design; and the "Festival of the Peace of Wolfbia," after Job Sandrart, in large folio, engraved on two plates, and which is now become a rare print.

Bartholomew Kilian, the third son of Wolfgang, was born at Augsburg in the year 1639, and died in the same city in the year 1696. He distinguished himself at a period of life so early, that Sandrart emphatically says, "he was born an artist." At the age of eighteen he engraved a Magdalene after M. Gondelach, which induced his father to place him under M. Merian of Frankfort, after studying with whom two years and a half, he travelled to Paris for further improvement. Here he remained more than three years, availing himself of the instructions of different artists, and

Returning to his native city, he continued to cultivate his art, and produced a great many excellent portraits, with some few historical subjects. Strutt is mistaken in saying he worked entirely with the graver, but is right in what he affords of the originality of Bartholomew's style. He worked in a manner entirely different from those of the Kilians, who had preceded him; sometimes, in order to make a striking distinction between the flesh and the draperies of his figures, he finished the former with dots only; and at other times expressed the darker shades of his flesh by lines, which he blended with dots in the lighter parts. Mariette and Barthelamy talk of him as an example for a painter, but these writers are warmer in his praise than an inspection of his work will fully warrant.

B. Kilian generally marked his engravings, of which the following list contains the principal, with his name at length, but sometimes used only his initials, and at others, according to Huber, a cypher which does not appear to belong to him, but which we have copied, with others of the Kilian family, in the second plate of our German monograms.

Six half portraits, in folio, of celebrated protestant preachers at Augsburg, after B. Kilian. Three medallions of archbishops of Salzburg, with allegorical accompaniments, after Henry Schoenfeldt. Johannes III. king of Poland, after Bloemart, dated 1681, a large bust of learned execution. Maximilian Emanuel, eldest prince of Bavaria, with historical accessories, a celebrated work, and the subject of a theft. The emperor Joseph as king of the Romans, on horseback, the subject of another academical thesis, dated 1694; which Huber pronounces one of the finest prints existing for natural grandeur; all these are in large folio. The portrait of Augustus II. Abbas Einfelden, is a large upright folio, dated 1686.

The bell historical production of Bartholomew is a "Madonna and Child," a beautiful engraving in large folio, after Calpar Sing.

Philippe Kilian was a younger brother of Bartholomew, imitated his style, and confined his talents almost entirely to portraits. He engraved, among many others, the portrait of his elder brother, whom he never equaled, though many of his works possess no small portion of merit.

Strutt mentions another engraving of his family, by the name of Wolfgang Philipp, who flourished in the next century, and who executed a great number of portraits, which however have too little merit for our particular notice.

Yet to show that nature had not exhausted the Kilian stock of talent, we shall here mention a little out of his chronological place, Philippe Andrea Kilian, great nephew of Bartholomew, who was born at Augsburg A.D. 1714, and died in that city in the year 1759.

Descended from a family of artists, he imbibed, in early life, what may perhaps be termed a hereditary taste for fine art. He first studied drawing and engraving under Frederic of Augsburg, and afterwards became the pupil of G. M. Priefer of Nuremberg, where he distinguished himself by engraving some plates for the "Physica Sacer. of Schenckel," and laid the foundation of his future fame.

Some years after, whilst engaged in engraving from the Dresden gallery, the reputation of our artist spread so high, that Augustus III. of Poland emphatically called him "the Magnet of Dresden," and when any other engraver produced an inferior plate from the collection, was said to say, in the way of delicate reproof, that it ought to be re-engraved by Kilian.

But our artist, notwithstanding these honours, felt too much restraint, whilst residing at the court of Dresden, or such passionate desire to return to his native city, that he sought an occasion to make such arrangements as enabled him to quit Bavaria after a residence of some years.

P. A. Kilian is usually reckoned among the most meritorious historical engravers of Germany. On a basis of sound drawing, he erected rather a singular style of execution; he interworked his principal or first course of lines with very delicate strokes, which he crossed with a course of lines exceedingly lozenge upon the first, and sometimes added a third course somewhat more square; at other times he interworked his shadows with long slender "peeks," as they are technically termed among engravers. But the characters of his heads are not equal to his general knowledge of the human figure.

His historical engravings are, "Jesu Christ at prayers in the Garden of Olives," an upright plate of the folio size, from a design of his own. "The Adoration of the Kings," after Paolo Veronese; "The Woman taken in Adultery," after Titoreto; and "The Family of a noble Venetian," after Paolo Veronese, are all large folio plates, executed for the Dresden gallery. "Mary Magdalene washing the Feet of Christ," is from Nicholas Graff; "The Baptism of Our Lord Auguifus," from J. B. Pittoni; and "Herodias with the Head of John the Baptist," from Carlo Dolce, are all of folio dimensions; "Regina Angelerum," where the Virgin appears surrounded by Angels in Glory, after Bergmuller, and another from the life of the Virgin, after C. T. Scheffier, are a large and highly esteemed pair of engravings. But perhaps his most justly celebrated work is a very large plate of "St. Cosmo and St. Damien," after J. Wolfgang Baunegaerter.

The bell portraits from the graver of Philippe Andrea, are those of Francis I. emperor of Germany, in a coat of armour, after Meitens. And Clemens Rezzonics Venetus, Pontiff Max, after G. D. Porta, a pair in large folio. Maria Therefa, queen of Austria, an upright folio. Johann Martin Christel, from a picture by P. A. Kilian, himself. Christoph Henry Andre Geret, after J. Romelli. Field marshall Curtisz Christophel Graf von Schieder, after Stranz. Ferdinand, duke of Brunswick, general in chief of the allied army, after Ant. Pefne; and Godofreus Schurhein, marked P. A. Kilian, p.m. et fepl. 1750, as one of the most dimensions.

George Christopher Kilian, another engraver of the same family, was living at Augsburg when Heineckin published his "Lide generale d'une Collection complete d'Eliampes," and perhaps may be living still.

Iface Major was born at Frankfurt on the Maine in the year 1578, and died in 1630. Discovering an early inclination for the arts of design, he was placed with Roland Savery, under whom he studied landscape painting for a time, but desirous of becoming an engraver, he placed himself, for instruction in that art, with Giles Sadler. He united etching with the work of the graver, but his works want energy, though they were held in some estimation at the time in which he lived. His principal productions are, a set of six middling sized landscapes, wild scenes in Bohemia, from Pietro Stephehi. A very large landscape from Rowland Savery, in which St. Jerome is introduced. Another set of eight mountainous and savage landscapes in Bohemia, in large folio, after J. H. Wolf, and an allegorical portrait of the Emperor in a car of triumph drawn by eagles and swans. Christopher Jegher was a justly celebrated engraver on wood, who was born some time about the year 1590, but the incidents of whose life are but little known. He established himself at Antwerp when he was about thirty years of age, where his extraordinary merit so strongly recommended
mended him to Rubens, that he was engaged by that great master to engrave; a considerable number of his compositions, and it is no small praise to add that he succeeded to the perfect satisfaction of the painter.

After the death of Rubens, Jegher re-purchased most of these engravings, and published them on his own account. Collection is held therefore bear in mind, that these impressions, from which the name of Rubens as the publisher is taken away, and that of Jegher substituted, are of the second edition, and consequently of inferior value to the first.

There is a degree of freedom and vigour in the style of Jegher that is perfectly homogeneous with that of Rubens; his hatchings are broad and powerful, and the imitation of the cross hatchings is so well expressed, that his best prints very much resemble drawings made with the pen and ink. He drew with masterly correctness; the extremities of his figures are very well marked; and his heads, though slight, are full of expression.

His best, and by far the greater of Jegher's productions, are after Rubens, but he has engraved a Crucifixion after F. Franck, which is dated 1637, and some few more from other masters.

The following are after P. P. Rubens: "Susannah surprised by the Elders," "A Repose in Egypt," both in large folio. Some of the latter are printed in chiaro-scuro, (i.e. with an additional colour to add the tints,) and are among the most scarce. "The infant Christ and St. John playing with a Lamb," "The Coronation of the Virgin Mary," and "The Temptation of Christ in the Desert," all middling-sized folios. "Hercules destroying Evny and Difcord," is from the ceiling at Whitehall. "The Conversation of Lovers," is a very large garden-scene, engraved on two blocks. "A drunken Silenus supported by Satyrs," is of the upright form, and a very fine composition of the manner, which was also engraved on copper by Bolfwerdt.

Matthew Merian, the elder, was born at Basle in the year 1593. His first studies were under the direction of Theodore Meyer, who instructed him in drawing. He afterwards became the disciple of Theodore de Brie. He was a man of talent, and his principal engravings are landscapes, which he etched in a light free style, and finished with the graver. His views have much of that rare but valuable topographical quality, the appearance of having been really copied from the places of which they bear the names, and which quality Merian had the skill in imparting to his disciple Wenceslaus Hollar, of whom we have given an account, in our Progress of English Engraving, but whose monograms will be found in our third plate of that of the German school.

Merian married the daughter of his tutor de Brie, by whom he had issue: he died in the year 1657, aged 88, at Frankfort, or, according to some of his biographers, at Schwabach.

His works, according to Le Compte, amount to upwards of five hundred plates. They are well known, and there is not so much disparity in their merits as to make a selection here either easy or necessary. His marks and monograms are five in number, as will be found in our third plate.

Of Matthew Merian the younger, who was for a short time in London, we have made slight mention in a former place.

His daughter, Maria Sybilla Merian, was a much more distinguished character. She was born at Frankfort on the Main in the year 1647. At the age of four years she lost her father, which in modern times is a great misfortune, but not for long, for her mother found in her second husband, Jacques Morell, a kind and indulgent protector, who suffered the infant genius of Maria.

Morell, as is well known, was a distinguished painter of fruits, flowers, and insects, and under his instruction our young artist soon distinguished herself as a painter and natural philosopher, to which attainments she afterwards added the art of etching.

In the year 1665 the married Jean André Graf, a meritorious painter of Nuremberg, who studied in the school of Morell. In 1679 she published the first volume of her "Histoire des Insectes de l'Europe définies d'après nature, et expliqués par Marie-Sybille Merian; où l'on traite de la génération et des différentes metamorphoses des insectes et des plantes dont ils se nourrissent;" and in 1683, she published the second volume of the same work, in the execution of which she paid attention to the engravings, as well as the designs, being the first work wherein is displayed the minuteness which is so important in the eye of the connoisseur, and she managed the etching-needle with the dexterity she had before evinced in the management of her pencil.

In the course of the next year, she returned to Frankfort with her family, and, from a mistaken zeal in religion, separated from her husband; retired with her mother and two daughters to Weil Frieland, and became a member of the society of Labadistes. The fraternal society of Labadistes, (who called themselves brothers and sisters) had then assembled at Peter Yrond, and their head-quarters were the castle of Dr. Boffe, situated between Franeker and Lauwerick, of which the poet's name was Sommerdick. Here she remained a considerable time, and here she had opportunity to inspect at leisure a fine collection of the insects of America, of which she made very exact drawings, and from hence her thirst after professional knowledge led her to make occasional excursions to Amsterdam and other parts of Holland, which at that time abounded with cabinets both of pictures and natural history.

Her enthusiasm now took a new turn, and coinciding with the wishes of the Dutch naturalists, she was induced, in the year 1699, to undertake a voyage to Surinam. On her arrival, after an agreeable passage, a wide field opened to her professional ambition. She painted the insects and reptiles of the country on vellum, and examined with philosophical care their various habits and changes; but the heat of the climate, and her intense application, having injured her health, it became necessary for her to return to Europe in the following year.

She brought home an ample collection, not only of drawing but of shells, dried insects, &c. She now settled at Amsterdam, and immediately set about publishing the fruits of a voyage, than which none had ever been performed more truly interesting to the naturalists of Europe.

Of the sixty large folio plates contained in her "Metamorphoses Insectorum Surinamensium, &c." several were executed by herself, and she also supplied the descriptions. It was published at Amsterdam in the year 1705.

In the second edition, which was published by the physician Jean Marret, in the French language, more plates and explanations were added by the author, who consecrated the remainder of her days to delineations and researches of this nature.

Too far advanced in life to venture on a second voyage, yet knowing that much had been left unaccomplished at Surinam, Maria Sybille now formed the design of sending thither her eldest daughter, who had accompanied and assisted her in her former voyage. Jeanne Helene cheerfully undertook the commission, landed at Surinam, painted with hereditary skill all the remaining subjects of natural history that she could find interesting in the country, added her remarks, and transmitted them to Amsterdam; but death had now intervened to prevent this consummation of the pleasures of Maria Sybille.
Sybille. The supplement was however published by her second daughter Dorothea Maria, who was born in 1678, and herself painted flowers and insects with great ability.

The curious, who would form an adequate idea of the knowledge and talent of this extraordinary artist, should visit the principal cabinets of Holland. Yet in our own national collection at the British museum are some volumes of her paintings on vellum, which are almost daily turned over with wonder by its numerous visitors.

John William Baker was a very meritorious painter and engraver of landscape and history. He was born at Strasbourg in the year 1620, studied under Frederic Brendel, and afterwards in Italy, where he resided a considerable time, and where he was patronized by the duke of Bracciano and prince Guelfianni. In the year 1672 he removed to Venice, and from thence to Vienna, and died there three years afterwards, at the age of forty.

The landscapes which he painted with watercolours on vellum are particularly celebrated, and he engraved a vast number of plates from his own designs, some of which are in a style resembling that of his contemporary Callot, to which he affixed the cypher which the reader will find in the third plate of our monograms, &c. of the German school of engravers.

Melchior Kaeffel compiled the volume of his works, which contains not less than five hundred engravings, after the death of Baur, whom he designs, in the language of Strutt, "in perfect marks of a superior genius, but without cultivation." The cypher with which he usually marked his engravings, of which the following are the names of the principal, will be found in our plate of monograms.

Portrait of Don Paolo Giodandino Ili; Orizio, duke de Bracciano, an oval, dated 1656, a rare print; a set of eighteen, of the costume of different nations; a set of fifteen of the battles of various nations, entitled "Capricci di vari biatelle," in quarto; another set of fourteen of battles; a set of eight landscapes, and another of four, entitled "The Elements." A set of twenty of a superior character, of the battles of "La Guerre Bismarck," and his principal work, consisting of one hundred and fifty plates in quarto, from Ovid's metamorphoses, published at Vienna in 1641. These are slightly etched, and finished with the graver. The figures introduced are generally small and incorrect in the drawing, the back-gounds rather dark, and the trees deficient in lightness and freedom. The architecture, which Baur is fond of introducing, is well designed, and correct in the perspective.

Hans or Jean Ulric Franck was a native of Kaufbeuren, an imperial city of Stamb, born in 1623, and was particularly excellent in painting and etching small figures. He settled at Augsburg, where he died in the year 1692.

In conjunction with Suan Sandrart, A. Zelt and J. Meyer, Franck engraved a set of the Fountains in Rome and its environs. The bell of his other engravings are four combats in quarto, dated 1641, "David and Abigail," and "Alexander defeating Darina," dated 1644, and both in folio.

Joachim Sandrart was born at Frankfurt on the Main in the year 1650, and began his career of art by studying under Theodor de Bue and Mathieu Merian, of whom we have spoken. At the age of fifteen he went on foot to Prague, to visit and obtain instruction from Giles Sachers, after which he placed himself under Gerard Houwhaert of Utrecht, to learn the principles of painting. In 1661, he travelled to England. He afterwards settled in Venice, Bologna, Naples, and Rome, and received instructions from Titian, Paul Veronese, Guido, Grandino, Poulin, and others; in short, if instruction and example alone could have produced a great artist, Joachim should have been the first of his time.

He returned however to Germany, and finally settled at Nuremberg, where he established an academy of art, and where he died ten years afterwards, at the age of 77.

Sandrart was rather an artist of acquirement than of genius, and hence his works are deficient in vividness and warmth. He painted and engraved history and portrait; he was also a man of letters, and his "Academy of Architecture, Sculpture and Painting," which was first published at Nuremberg in the year 1679, though prolix, is still celebrated through Europe.

This book, which contains much historical information, and the biography of the most distinguished artists, is enriched with a considerable number of engraved portraits, besides other prints. It was first published in the German language, but an edition in Latin was printed in the year 1683, and it has since received various additions from the successors of Joachim Sandrart.

His own engravings are performed chiefly with the point, and the bell of them will probably be found to be a half length figure of the goddes Flora, after Titian; an elderly woman contemplating a Cupid in no very delicate action; and "The Death of Cleopatra," from his own compositions, all in quarto.

Jacques Sandrart, the nephew of Joachim, was born at Frankfurt in the year 1650, and died at Nuremberg in 1708. He studied engraving at Amsterdam under Cornelius Dantker, and afterwards at Dantze under W. Hondsies.

He settled finally at Nuremberg, where he pursued his art with singular industry, the number of his portraits alone being not fewer than four hundred, some of them of the folio dimensions, and executed with the graver alone, in a clear and neat style, beside which he published a number of geographical charts and other engravings.

His portraits are not uncommon, and among the most meritorious will be found to be those of his uncle Joachim Sandrart, a half length figure, inscribed "Seculi Nominis Apelles." The busts of Rodolphus II., Ferdinand III., Ferdinand IV., and Federic, prince of Norwega and duke of Silesie; a half length of Hohannes Michael Dithers, after R. Wernfels; Ermuth Sophia, electoral princess of Saxony, &c. Johannes Paulus Auer, painter of Nuremberg; Joachim Sandrart, junior, dated 1688; all in folio.

Jean Jacques Sandrart, the son of Jacques, whom we have just dismissed, was born at Ratisbon A.D. 1655, and died at Nuremberg in 1698. He studied the arts of design under his father and his great uncle Joachim; he works the facility of his invention. He enriched the volumes of Joachim with several tasteful and spirited etchings, and his portraits, which are etched, and finished afterwards with the graver, are deftively held in esteem. His best works are the portraits of Elizabeth Henrietta, princes of Brandenburg, surrounded by emblems; and Sylvis Jacob de Gunckelmann, both in folio, after Adam le Clerc; "The Holy Family," after Joachim Sandrart; "Eneas saving his father from the Flames of Troy," after Raphael, dated 1682; "The Morphonie, or the Statue of the Rhine," among ruined edifices; "The Nile," among ruined monuments of antiquity, all in folio, and the latter pair, with many others after Joachim, are introduced into his "Academy, &c.,"

Jean Jacques also engraved several plates of merit for a folio work, entitled "Sculp Antiquae, Holieum.

Suan Marie Sandrart was the sister of Jean Jacques, and was educated under the direction of her father, and engraver with some ability a considerable number of plates of ornaments.

She engraved also a Bacchus, with the inscription "Im-

mode."

Of Hollar, who flourished about this time at Prague, we have already spoken. See Origin and Progress of English Engraving.

That extraordinary artist, Adrian van Ollade, for an account of whose merits as a painter, see the article Ostade, performed about this time some etchings, which are very fully admired for their freedom and spirit. They are not all executed in the same style, though the same mind be in every where evident. Some are dark and coarse, and were printed just as the aquafortis left them, while others are more neatly executed, and appear to have been subsequefly worked upon with the triangular point, as was the custom of Rembrandt and Worghile. The two marks with which Ollade occasionally subscrubbed his etchings, will be found in our third plate of the monograms of the German school.

The whole of his etchings consist of at least fifty-two plates of various dimensions, all from his own designs, of which the following are perhaps most worthy of being specified: "Several Peasants at the Door of a Cottage," with a fair in the back ground, a middling-sized upright. "A Dutch Wake," the same. "Several Peasants Fighting with Knives," a small plate, lengthways, dated 1658. "The Cottage Dinner," the same, dated 1653. All these in his bold style of etching. Those which follow are such as he finished with more care. "The Painter," with an inscription beginning in this manner: "Pictor Apelle, pingis," and the full impressions of this plate are with the cap considerably above the eyes of the figure; in the second impressions, the cap nearly touches the eyes. "A Mountebank," a small upright plate, arched at the top. "The Spectacle Seller," a small upright plate. "A Man, Woman, and Child, at the Door of a Cottage," a middling-sized plate, lengthways, dated 1652. Several peacants, half figures, at a window, one of them is fingering a ballad, and another holds the candle, a small upright plate. "A Man Leaning over a Platte, blowing a Horn," the same. "A Cottage Entertainment," with figures dancing, a middling-sized plate, lengthways.

The biographers of lieutenant-colonel de Siegen, (an officer in the service of the landgrave of Hesse,) have contended with the friends of the prince Rupert for the honour of the invention of mezzotint. The lieutenant-colonel was born in the year 1629, and, according to the baron Heinmack, executed in that manner a portrait of the princess Amelia Elizabeth of Hesse Calfis, in 1643.

For an account of prince Rupert's pretensions to the discovery, see the article Origin and Progress of English Engraving. "An Holy Family," after Caracci, in folio, is also mentioned (but without a date) as a mezzotinto production of Siegen.

Jean François Ermans, who possessed considerable talents in the art of painting and engraving landscapes and cattle, was born in the environs of Cologne in the year 1621, and died at Nuremberg in 1663. He studied under J. Holzmann and Jean Both, and the following plates, confiding chiefly of landscape scenery, adorned with ruined edifices and animals, were etched by him with great spirit and freedom. A pair of upright landscapes, "A Rocky Scene, and a Composition of Ancient Architecture," in 4to. "A Landscape," in which the figures introduced are a faun and bacchante. Another, with monuments of antiquity. And a pair of "Pastoral Scenes," with shepherds, cattle, and ruined edifices, all of the 4to size.

Matthew Keefell, or Kyfell, was born at Augsburg in 1624, and died there in the year 1682. He successfully mingled the work of the graver with that of the point, and his best prints, which are named in the following list, possess a large share of merit. The portraits of Christopber Benden, in 4to. Carolus Salzer. Adolphus Zobellus. Andreas Winkler Johannes Michael Dilherrus, after Ulricus Mayr (an highly finished head in an octagon border). Leonardus Weilins, after Jos. Wemers, all in folio. A set of forty-two after Ludovico Burnacini, entitled "Il Pome d'oro," and consisting of scene decorations, &c. dated 1668, are folio etchings; and the only historical work from his hand, with which we are acquainted, is "The Virgin and Child," apparently from a composition by himself.

Melchior Keefell, the brother of Matthew, was born at Augsburg in the year 1622, and died in the same city in 1683. Here he acquired the rudiments of his art, but perfected his studies under Merian of Frankfort, from whence, after residing some few years, he returned to Augsburg, and began to engrave the "Iconographia," of Wilhelm Baur, a folio work, which consists of one hundred and forty-eight prints of various sizes, consisting partly of the "Life and Miracles of Jesus Christ," and partly of views of the "Scenepots and Gardens of Italy," which work was published at Augsburg, A. D. 1682.

Quinn says of this artifit, that "there is something very agreeable in his manner of engraving, especially when he confined himself to subjects where the figures are small, for as he drew but incorrectly, his figures appear defective, as they increase in size." Baur was fond of ornamenting the back-grounds of his compositions with superb buildings, which Keefell has executed with much spirit; his rocks also, and mountainous distances, have great merit; but his trees want freedom, lightness, and characteristic determination of their foliage; his chiarofucro is also pretty and fascinating to the eye, if this be not rather the fault of Baur.

Melchior engraved other plates besides those for the Iconographia of Baur, of which the principal are, "The History of Ulysses," from Theodore van Talden; some antique statues, executed entirely with the graver; and the portraits of Sebastianus Kirchmeyers, public professor at Ratibon, after Benj. Block, in folio; Johannes Horius; Maximilanus Curz, dated 1658; and Antonius Schottius, dated 1680, all of the folio size.

Jeanne Sibelle Keefell, born at Augsburg in the year 1646, was the third daughter of Melchior, married Jean Ulrich Kraus, engraved, among other plates, a set of four, of the Satyr and Villagers, Juna, Venus, and Pallas, after Elihuem, and died in her native city in 1717.

Jonas Umbach was also of Augsburg, born in the year 1614, and merits an high rank among the artists of Germany. His prints conflict chiefly of etchings after his own designs, executed with spirit and an appearance of facility. He engraved one hundred and eleven plates, of which the following are the full-length figures of the principal, and died in his native city about the commencement of the seventeenth century. "A Madonna and Child." "An Holy Family." "A Penitent Magdalen," and "St. Peter," all of small dimensions. Four plates from "The Parable of the Good Samaritan." Four ditto of "Infatate Sports." A pair of "Triumphs of Marine Deities." "A Family of Satyrs," all of small sizes; and a set of four landscapes, adorned with ruins of ancient monuments and pastoral figures, dated 1678, in 4to highly esteemed engravings.
German School of Engraving.

Lingelbach, Backhuysen, and Jean Henry Roos, also performed some meritorious etchings in Germany about this time. The animals of the latter are much celebrated, and among his best plates may be reckoned a set of twelve, of "Domestic Animals," in 4to. A pair of "Grand Landscapes," adorned with castles and natural buildings, and "Un Berger endormi au pied, &c." He was born at Otterdorff, in the Palatinate, in 1731, and died at Frankfort in 1781, and his works were Julian Jaredye, and Adrian de Bie.

The family of the Wolfgangs contributed but little to the advancement of engraving; we therefore pass them briefly.

George Andrea Wolfgang was originally a goldsmith and engraver on the precious metals, but afterwards studied engraving on copper under Matthew Kachel, and produced some mezzotintos. He was born at Chemnitz, in Saxony, A. D. 1631, and died at Augsburg in 1716. The best engravings of George Andrea are the portraits of George Frederic, marquess of Brandenberg, after C. Zierl, in folio, and Pierre Muller, Jurconciflti, in 4to. And in history, "A Grand Sacrifice to Diana," after A. Schonsfeld, and "Saul confuting the Ghost of Samuel," after Jof. Werner, both of the folio size.

Andrea Matthew, the son of George Andrea Wolfgang, was born at Augsburg in the year 1662, and died in the fami-

city in 1733. He studied the elements of design under the direction of his father; but embarking for England with his brother, prefumptuously at some port in the Mediterranean sea, they were intercepted by an Algerine corsair, and carried into captivity. On their liberation, which was in consequence of a ransom paid by their father, they both returned to Augsburg, where Andrea Matthew settled, and began to engrave portraits: he also engraved a print of "The Court of Algiers," in which he has represented himself as a slave.

His best portraits are those of George Andre, his father, and Nicolaus Nuremberger, both in 4to., and in folio, John George Bittner, bishop of Frankfort, and Christopher Rad. In mezzotinto he has engraved Charles VI., king of the Romans. But, perhaps, his very best performance is a portrait of the margrave of Anfach.

His younger brother, Jean George Wolfgang, was born in 1664, received the same instructions as Andrea Matthew, and soon after their release from captivity travelled to Berlin, and in 1704 became engraver to the court. He engraved and published there a great number of portraits, among which that of the doctor Frederick William, after Jacob's equestrian statue in bronze, is deferredly held in most esteem, though, in most of his portraits, the flesh is executed with delicacy, and Jean George is, on the whole, as an artist, the flower of the Wolfgang family. He died at Berlin in the year 1704.

Guillauas Andrea Wolfgang was the son of Andrea Matthien. He was born at Augsburg in the year 1662, and, after studying portrait engraving and miniature painting under his father for a time, followed his uncle to Berlin, where he remained for many years, but returned finally to his native country, where he died in the year 1766.

His best portraits, of which the flesh is engraved chiefly in dots, are those of M. Francois Reyter, admiral pour l'Armee navale Anglois en Afrique. Wolfgangus Jacobus Sulzer, Reipublice Augul lance Decemvir, after G. Eichler, and Carl Freyher von Stien; in small folio.

Jean Jacques Thurneien, or Thourneyen, was born in the year 1636 at Bale, in Switzerland, and died in the same city in 1718. After having learned to draw in his own country, he went to Strasbourg to study engraving under Pierre Aubry, where he remained about three years, and removed successively to Lyons, and to the court of Turin.

In 1695, he returned to Vienna, accompanied by his sons; and his great merit, which was called by his rivals his superior fortune, obtained for him the patronage of the emperor Leopold. He was now the object of envy to the artists of Augsburg, where he continued to reside for some years; but as age approached, he wished to see again his native land, and departed for Bale in the year 1699, where, as we have already said, he finished his career.

Thourneyen was a man of a robust frame, vigorous mental powers, and extreme professional affability. His monogram will be found in our third plate of those of the German school. Among the engravings he performed, those which are executed with a single stroke or spiral, in imitation of Melan, have been most admired, though, perhaps, not most justly. He also occasionally imitated the square croffings of F. de Pouilly.

His son, Jean Jacques the younger, worked in imitation of his father, but was less successful. The best engravings by Thourneyen the elder are, the portraits of Laurentius Scutus, after Luca Diamante, dated 1661, Francois Turin, after P. H. F. van der Heyden, professor in the academy of Bale, after L. F. Wettelin, engraved of the folio size, (by the Thourneyen, father and fon,) in 1702.

Of his historical works, our allotted space only allows us to mention "The Virgin Mary, Infant Christ, and St. John," in a circle, after Carl Dauphin, a folio plate, engraved in the fashionable style of Mellan. "An Infant Christ," after Blanchet, in 4to. "La Balianca del Boccabini." Two large folio plates of "Grand Theses in Philosophy," in which whole length portraits of the princes palatine of Neubourg are introduced, and the statues of Laocoon, Antinous, and Latona, in the style of Mellan, for Sandrart's academy.

Francois Ertinger was born at Wyl, in Suabia, A. D. 1640, travelled to Italy for improvement, but died at Paris in the year 1700. As an engraver, neither his judgment nor his taste ranks very high; but the following list of his best works will shew that the subjects of his prints at least were sometimes wisely chosen. A set of eight plates after Rubens, from the History of Achilles. "The Marriage of Can in Galilee," a large folio, after Raymond le Fagi. A set of ten, from the same master of the History of the Counts of Tholoufou.

A large folio, of a Bacchanalian subject after N. Poullin; and the portraits of Nicholas Machiavel of Florence, the celebrated political philosopher, in 8vo. Gabriel de Pinaco, Jurconciflti; and Jean Ferdinand de Beughem, bishop of Anvers, after F. de Cock; both in folio.

Gerard Lairesse was born at Liege in the year 1641, and died at Amsterdam in 1711. He was instructed by his father, Regnier, in the rudiments of art. For an account of his merit as a painter, see the article Lairesse. He etched a vast number of plates, from his own compositions with great freedom, and the feafirs hand of a painter who has other objects in view than the graces or blandishments of manual execution. His chiaro-fcuro is broad and powerful, and so contrived as to conduct the eye of a spectator at once to the principal objects in the composition.

The major part of his designs were engraved by himself, and, as Bajan obfervers, are highly esteemed by connoisseurs, and exceedingly useful to students in art.

The portrait of Lairesse, in folio, surrounded by emblematical ornaments, has been engraved by N. Viflicher.

The most esteemed of his own engravings are, "The Sin of our first Parents," and "Adam and Eve expelled from Paradise," a pair in folio. A rich composition of "Joseph
GERMAN SCHOOL OF ENGRAVING.

*Jocoph and his Brithren,* and another from the History of Solomon, both in large folio. *The Incredulity of St. Thomas;* and another in folio, from the Life of Christ, inscribed *Sapientia uigena Dei Maximus.* *St. Theretif in Extacy,* a large folio. *The parting of Hector and Andromache,* in folio. A rich composition of Marc Antony and Cleopatra, with the motto *quam Mars nungnum, visit Venus.* A march of Amazons, inscribed *Virtus viri computa actionibus probat.* A grand Bacchanalian subject. *Venus lamenting Adonis.* A set of four plates of the leasons. *Diana and Endymion.* *Bacchus Silenus and Nymphs,* all of the folio dimensions; and three large allegorical subjects, in compliment to the prince of Orange.

The prints of Lairesse are generally inscribed with one or other of the four monograms which the reader will find in our third plate of those of the German engravers.

Samuel Betschold was born at Sangerhaufen, in Thueringia, A. D. 1640, and died at Dresden in 1707. He was an artist of taste; and, being possessed of elevated habits of thinking on professional subjects, he was appointed director of the Dresden academy, and inspector of the electoral gallery. His excellence in fresco painting is attested by his picture of *The Defeant from the Crofs,* in the church of St. Martin at Halberstadt, and by several paintings which adorn theackle gardens near Dresden; and his etchings are performed with much picturesque freedom; the general character of his art partaking much more of the grand than the graceful. His principal engravings are, *The Army of Sennacherib defeated by the exterminating Angel,* in folio. A set of four, entitled *Le Don de l'Entendement!* *Le Don de la Science!* *Le Don de la Sagele!* *Le Don de la Force;* in 4to. A set of four parts of the day, with Latin infiripitions. A pair of emblematical subjects, entitled *La Poit et la Patience!* *La Foit! et la Charité!* ovals, in 4to. *Ulystes and Epius,* and a subject from the Life of St. Luke, both of the folio size.

Elias Hainzelman was born at Augsburg in the year 1649, and died in the same city in 1693. He studied engraving at Paris in the school of François de Polly, whose style of manual execution he imitated with great success; and Strutt has well observed, that had his drawing been equally correct, his works would have ranked with those of the greatest masters. They possess, however, especially his portraits, a considerable share of merit.

From Hainzelmann's historical works, the following will probably be found most worthy of felection: *The Silence,* after Annibal Caracci; *so called, because, while the Infant Christ is sleeping, the Madonna holds up her finger to St. John, as he approaches, to prevent his disturbing the Savioir.* This picture has since been engraved by others, but particularly by Bartolozzi in a very superior style. A large upright plate of an Holy Family, after Sebastiano Bourdon; and two others lengthways, of the same subject, from the same painter, in one of which the infant St. John presents a lamb, and in the other an apple, to Jesus Christ. St. Francis, after Domichino. *The tiles nee tangere,* or Christ in the garden, approached by Mary Magdalen, after Albano. *The Madonna and Child,* after Raphael. *Jesu Amabiles,* Mater Amabilis; St. Regard; all of the folio size.

His best portraits are those of Francis Zavier, of the fraternity of Jefuits; George Philip Rifs, after Ulric Mayr; Marcus Haberns, and Juliana Benedicta Winklerin, after the same. David Thomas ab Hagelstein, after de Neve. Agnes van Schoeneberg; Godfreed Eggerus; Gabriel Willer; John Jacob Haller, after D. Sivey, all in folio, and Johann Christolph. ab Adelmansfelden, after C. C. Kretzschmann, in very large folio; the heart, the size of real life.

Jean Ulric Kraus, or Krausse, was born at Augsburg A.D. 1645, and died in the same city in 1719. He was the disciple of Melchior Kuffel, and married Jean Sybille his daughter, and became a close imitator of the works of his contemporary Le Clerc. But all followers are necessarily behind. Though Kraus copied Le Clerc's Life of Christ, (which consists of sixty subjects) it is sufficiently obvious that they are but copies.

His engravings are numerous, chiefly from his own compositions, and the subjects of them, for the most part, views of buildings, or taken from the Old and New Testaments. In imitation of his model Le Clerc, he generally introduced a vast multitude of figures into his compositions, but they are all graceful, and for the most part well drawn. He frequently enriched his back grounds with architecture, which he appears to have well understood, and his chiaro-recto is often judiciously disposed, and his general effects good.

The cypher with which Kraus usually marked his prints will be found in our third plate of German monograms, and the list of his principal works is as follows: a set of sixty subjects copied from Le Clerc's Life of Christ, on small folio plates, two subjects on each, printed at Augsburg 1705. The history of the Old and New Testaments, in 4to, containing four small subjects on each plate, and apparently designed to be bound in 8vo. so as to have two subjects only on a leaf. The number of leaves would then amount to one hundred and eighty-eight, and they are so numbered. The four feasons, and the four elements, designed for the royal tapestries. A set of twelve interesting views of the city of Nuremberg, after Andrea Graf, in folio, and a very large and capital view of St. Peter's church at Rome, after the same master.

Carl Gustave d'Amingl, or ab Ambling, was born at Nuremberg A.D. 1651, and died at Munich in the year 1702. He studied under F. de Polly at Paris, and imitated his style, but with no very great success. He was a painter as well as an engraver, but was chiefly engaged in engraving portraits. When he attempted history, neither his drawing of the naked, nor the expression of his heads is correct, and the general appearance of his prints is cold and metallic.

Yet the race is not always to the swift, nor the battle to the strong, and Ambling, notwithstanding these defects, obtained court patronage, and became engraver to the duke of Bavaria.

Of his numerous portraits, we shall only mention tho'e of Maximilian Emanuel, ecclesiastical prince of Bavaria, after T. Macolinus Muicena, dated 1670, a rare print. Maximilian Emanuel, elector of Bavaria, after J. B. Champagne, both in folio, and the latter esteemed one of his very best performances. An equidrían statue, also of his patron, and Henrietta Maria Adelaide, duchess of Bavaria, after Detallou, dated 1675, an oval, and also of folio dimensions.

Of his historical works the principal are, a set of thirteen plates of different sizes, of the histories of the emperor Otho and Louis of Bavaria, from the tapestries in the castle of Munich, which were executed after P. Camillett. Another set of nine in folio, from the same tapestries, representing personifications of the months September, October, and November, the four Seafons, Morning, and Night.

The family of Meyer flourished as artists, and chiefly as engravers, through two centuries. Joachim was born at Strauburg early in the sixteenth, and distinguished himself by engraving a set of sixty-two prints of combats with the sword.

Andrea was a native of Zurich, and engraved several views of
of towns, to which he affixed one or the other of the singular monograms which will be found in our third plate of those of the German school of engravers.

Dirick was born in the same city, and of the same family, in the year 1570, and his principal work of engravings is a set of portraits of the illustrious persons of Switzerland.

Roderich, and Conrad, Meyer, were the sons of Dirick. The engravings of the former are chiefly portraits, with some few emblematical prints; he was tolerably successful, and marked his prints as may be seen in our plate of German monograms. He was born in the year 1605, and lived only to the age of thirty-three.

His younger brother Conrad was born in the year 1618, and died at Zurich, the city of his nativity, in 1689. He produced a considerable number of prints which were chiefly from his own designs, among which are the cuts for an edition of Erasmus's Praecepta Folly. A set of five, which are termed a comparison of the present times with those of Noah and Lot. "The Deluge;" "The Last Judgment;" and "Memento Mori." A set of fifteen for the Mirror of Christians. A set of cuts for a dance of Death, partly invented by himself, and partly by his brother Roderich. And several sets of portraits of the burgomasters, reformers, and artists of Zurich.

He travelled about the same time, or a little earlier, at Nuremberg, but is presumed by Strutt to have been of the family as the precocious. He etched, among other plates, a set of battles in a flight but spirited style, from his own compositions.

Felix Meyer was more celebrated. He was born at Winterhour, in Switzerland, in the year 1635, and died at Leyden in 1715; his genius developed itself at Nuremberg, whilst studying under F. Ermel, a celebrated painter of landscape, to which he afterwards added the study of nature. His etchings are deservedly held in esteem among connoisseurs, for the freedom and intelligence which they display, combined with effective chiaro-recto. The most important of these are, a set of twelve, ornamented with ruined edifices and rocks, &c. Another set of four of the scenery of Switzerland, with ancient monuments and figures, dated 1701. Another set of four of the same kind of subjects, and another set of the same number, of a more wild, mountainous, and rocky character, all of the 4to dimensions.

Joachim Francois Betch, or Bisch, was born at Munich in the year 1665, and died in the same city, in 1748. He studied the principles of design under his father, who was a painter of Nuremberg, but domiciled at Munich. They both painted landscape and battles, and Joachim travelled to Italy for improvement, where he resided for several years, contemplating the scenery of that classical landscape country, and the works of Gaspur Poussin and Salzvater Roth.

On his return to Munich, he took up the etching point with success, and produced several sets of plates of landscape scenery in a grand style, among which the principal are, a set of eight mountainous landscapes from his own compositions, in 4to. Another set of six. Another set of six with rocks, cataracts, and bauditi, in the style of Salvator Roth, of the folio size.

George Philip Rugendas of Augsburg was born in the year 1666. He learned drawing of Isaak Fichler, but afterwards studied with more advantage from the works of Pietro Tempella, and Bourgognone. He travelled to Vienna, from thence to Venice, and from thence to Rome, where he remained a long time, and resided Augsburg in the year 1695. At this time the war of the Spanish succession was raging in Germany, and our artist had opportunity to contemplate its effects, and draw battles, skirmishes, and sieges, from nature. Among these the bombardment and taking of his native city by the French and Bavarians, formed an interesting subject for his pencil and etching needle, and he published in six prints, their military operations in that neighbourhood during the years 1703 and 1704.

Rugendas deservedly holds a distinguished rank among battle painters. His designs are at once bold and correct, his composition orderly, his pencil facile, and his colouring performed on principle; above all, the varied attitudes and graces of his cavalry are justly admired.

Besides the pictures from his hand, which are not uncommon in the galleries and cabinets of Germany, Rugendas has performed a considerable number of etchings and plates in mezzotinto, of which the subjects are chiefly hunting and battles; some by himself, and others in conjunction with his sons, of whom he had three that were educated to the arts.

The following were produced in conjunction with his sons: A pair of "Mountainous Landscapes," in 4to. A pair of "Combats between Cavalry," A set of four, of "Marches and Halts." Another set of four, of "Camp and Scirmishes," all in 4to. A set of six, of "The Engagements of the Camp." Two sets of Battles, consisting of six in each. A set of eight, of "Marches, Halts, and Combats of Cavalry," all in folio; and a set of twenty of various military subjects, in 4to.

Jaques Christophe le Blond, or Blon, an engraver in mezzotinto, was born at Frankfort in 1670. He travelled to Rome in the year 1696, in the suite of the imperial ambassador, where he studied painting under Carlo Maratti, but his genius being of a mechanical turn, he entered with warmth into various speculations: at length he learned to etch mezzotintas, and discovered a method of printing mezzotinto plates in colours. The Dutch painter Overbeck persuaded him to bring his new discovery to Amsterdam, from whence he emigrated to England.

Eagerly bent on the execution of his new project, he executed in London several large plates in mezzotinto, from pictures by the greatest masters, and disposed of the prints by lottery; but those who obtained the prizes appear not to have held them in any very great estimation. He made known the manner in which he performed and printed these plates, in a book entitled "Coloritto, or the Harmony of Colours in Painting, reduced to mechanical practice, under easy precepts and infallible rules," which were printed both in English and French; but nothing is more common than the failure of infallible precepts, and the spirit of fine art has always evaporated in the various attempts to reduce it to mechanical practice. Le Blond's project did not succeed.

His afterward set on foot a scheme for copying the Cartoons of Raphael in tapestry, and made drawings for that purpose; but though money was subscribed, houses built, and looms erected at the Mulberry-ground, near Chisleth, this project also failed, and poor le Blond, to the no small
difficulties of those who were engaged with him, was obliged to disappear. He died at Paris in the year 1749, in an hospital.

The mezzotintos which he produced are not without a considerable share of merit; but in his colouring process he was not always equally successful. The present writer has been fonder, which, in respect of colouring, may be called good, and others which can scarcely be described as any thing better than bad. His colours are rarely vivid and fresh, but frequently flat and dirty, and his drawing of the naked is incorrect, especially in the extremities of his figures. On the whole, his portraits will probably be found to be his best performances. of which the principal, are those of King George II in large folio, the size of life: his queen, as a companion print. The three children of King Charles I. after Vandyck, in large folio. Carendolet, after Raphael. Sir Peter Paul Rubens, after Vandyck. And a noble Venetian, with a pointed beard, after Titian, all in very large folio, the size of life.

Jean Martin Bernigeroth was the son and pupil of Martin. He was born at Leipsick in the year 1713, and died in the same city in 1749. He professed about the same portion of talent with his father; his best work being a portrait of Jean Adolphus, Duke of Saxe Weissenfelsen, in folio, dated 1735, which scarcely rises above mediocrity.

Antoine Balthasar Koenig was born at Berlin in the year 1679, and died in the same city some time about 1740. His prints, of which the following portraits are those which are held in most esteem, are not without a certain portion of merit. Frederick William, king of Prussia, after Weidemann. Frederick baron de Drefflinger, general of Prussian cavalry. Charles Gottfried Schrader, allei counsellor to the king of Prussia. Alexander Hermann, Count de Wartenfelsen, after Ant. Pern, dated 1716. And the monument of Schrader, with a Latin inscription.

Christian Albert Wortmann was born in Pomerania some time about 1669. He went very young to Berlin, where he studied engraving under Wolfgang, and at the age of twenty-five was fummoned to Cæcil, where he became engraver to the landgrave of Hesse. From Cæcil he went to Dresden, where he engraved several portraits, and among the rest his celebrated head of Christian Frederick Boeitius. In the year 1727, Wortmann was called to the court of Puferburb, but the time and place of his death have not been recorded.

His principal engravings are the portraits of Ernst Louis, landgrave of Hesse Darmstadt. Christian Frederick Boeitius. Joachimius Julius Breithaupt, doctor in theology, after J. A. Rudiger. Johan Samuel Drofisbach. Hermann Joachim Hahn. Anna, empress of Ruflia, after L. Caravac. Alexis, son of Peter 1. In an age and country of low taste, an indifferent painter or engraver of portraits will find encouragement, though an artil of no other description could find subsistence. Among the petty courts of the German electors, there was probably at this time very little taste, yet observation enough to discriminate between two or more set of features; and personal vanity and courtly pomp enough, to catch at the means of attaining a certain species of perilable popularity.

We have passed lightly over engravers of this inferior description, and some we have entirely omitted, as they contributed nothing toward the advancement of art, but rather perhaps retarded its advancement.

From these men of inconstancy, attention turns with pleasure to the contemplation of the extraordinary powers of Jacob, or Giacomo Frey. Frey was born at Lucerne in Switzerland, in the year 1671, and his life presents a curious instance of the indolent and indolent of genius, which it would seem that no rigour of adversity fortune can subdue, and no fire of intermittent passions can consume.

He was apprenticed to the trade of a cartwright, and in spite of his propensities towards the fine arts, was obliged to follow that trade till he attained the age of two and twenty, when he somehow or other made his way to Rome; but in quitting the peaceful and placid vale of Lucerne, he seems to have broken loose from all sordid restraint, and on his arrival in Italy, his passions, which had hitherto been held in check, hurried him into every dangerous excess. Yet, as the fame Po, which roars and rises down the Alps, winds afterward a lately river through the plains of Italy, so it was with our artist: when the ebullition of passion was over, he listened with delight to the advice of Arnold van Wirtzenhout, and the instructions of Carlo Maratti, and from that period began to make surprising progress in the art of engraving.

A Speech of Maratti to Giacomo Frey, which strongly marks his good sense and observation, has been recorded: "The engravers of history (said he) make too much use of the burin, and hence arise a certain hardnes of the contours, from which, however, the best prints of Dorgny are comparatively free. I would advise you to familiarise yourself with the etching point, because it operates in a far more picturesque manner than the graver."

Frey followed this advice. Robert vanAudenarde was at this time his fellow-disciple and liberal rival, but the rapid strides of our artist left him at an immense distance, though a man of ability. He drew with superior taste; had a fine eye for the harmony both of colours and chiaro-fosco; etched with a degree of spirit and freedom, which have very rarely been attained; worked over and refinished his etchings with the graver, at once with firness and facility; incorporating the whole by means of such exquisite feeling of the merits of his originall, that it has been emphatically said of his prints, that they appear rather printed than engraved. He was the Gerard Andran of Italy, and seemed only to differ from Andran himself, as Raphael, Guido, Dominichino, and Guercino, (after whom his principal works are engraved,) differ from Le Brun. In short, his feeling for the peculiar excellencies of the first masters of the Italian schools was of the highest and purest kind; so that it may be said, almost without a metaphor, that in his engravings their forms appear revivified by the spirit of Giacomo Frey. He died at Rome in the year 1752, the adulation of every intelligent artist, yet before he had received more than an earnest of the praises that are justly due to him.

It is to be regretted, that when his plates, which were published by his son Philip, began to wear, they were injudiciously retouched, perhaps by Philip himself, who destroyed all his father's sweetness and harmonious mellowness; so that good impressions of the prints of Frey, in their original
German School of Engraving.

Bernard Vogel was the coadjutor of Heils, some of whose very large plates being engraved by them in conjunction. He was a native of Nuremberg, born in 1685, but removed chiefly to Augsburg, where he espoused the daughter of Heils. In the earlier part of his career, he produced some tolerably good portraits with the graver, but latterly engraved only in mezzotinto. He retired from Augsburg to his native city, probably after the death of his father-in-law, and died there in the year 1757, leaving behind him a son, Jean Christoph, who engraved several plates in mezzotinto, after Kupetzky.

The best works of Bernard Vogel are the portraits, performed with the graver, of Johan Michael Weickmann, after L. C. Eichler; Augustus Hermann Franckius, professor of theology; and Johannes Michael Wefler, senator of Nuremberg, after J. C. Hirthmann, all in folio.

The chief of his portraits in mezzotinto, are those of Johannes Kupetzky, painter, dated the year of our author’s death; Michael Gottfried Witter, a celebrated furgeon, after Kupetzky; and George Biedinger, the painter, all in folio.

Christopher Vogel engraved, in the same manner, the portrait of his father, inscribed “Chalcographus Novus.”

Jean George Bergmuller was born at Dirkheim, in Bavaria, A.D. 1687, and died at Augsburg in 1756. He learned the rudiments of art under Andrea Walt, of Munich, but afterwards studied with more advantage under Carlo Maratti. He painted successfully, both in oil and in fresco, and etched a great number of plates, in an able and masterly style, which he afterwards finished with the graver. He was likewise the author of two works; one on the growth of man, which he called “Antropometria;” the other on mensuration and architecture, published 1752, and became director of the Academy of Arts, which was established at Augsburg. His son, Jean Baptiste, also followed the art of engraving with some success.

Jean Daniel Herz, draughtsman and engraver in aquafortis, was born at Augsburg A.D. 1693, and died in the same city in 1754.

Herz was an artist of original powers, rich in composition, bold and rough in execution, but deficient in grace and harmony of parts. He was appointed director of the imperial academy of arts at Augsburg, and filled the office with credit; but an hereditary director of an academy, nature, and science, will not endure, and his son Daniel, to whom the directorship unfortunately devolved, soon made himself appear ridiculous in this situation, though he was a tolerably good knight of the holy Roman empire.

The style of execution of Herz the elder bears marks of great rapidity, and rapid he must have been, for his plates are numerous, and some of them of very large dimensions.

We have selected the following, as those which, on the whole, are most worthy of the portfolio of the connoisseur; “The Annunciation,” richly compos’d, and in very large folio; “The Resting of the Cross;” “The Affirmation of the Virgin;” “The Adoration of the Kings;” “An Ecce Homo;” “The Crucifixion;” “The Death of Anna;” “The Dispute between St. Paul and the Philosophers;”
GERMAN SCHOOL OF ENGRAVING.

Sphers of Athens." And "The Judgment of Solomon;" all in very large folio. "The Coronation Procession of Queen Maria Theresia at Prefsbourg;" also of very large dimensions.

Jean Elie Ridinger, a very distinguished engraver of animals, was born at Ulm in the year 1695, and died at Augsburg in 1737. His father was a reputable drawing master, and from him our artist received his earliest instructions in the art. He afterwards studied painting under Christophorus Reifels, but as an engraver studied nature alone, and was one of her successful votaries. He formed a style of engraving animals for himself, which confit chiefly of etching, which is performed with characteristic freedom and firmness, tempered and harmonized, without being over laboured, with the graver. He appears to have studied in the wildest and most unfrequented recesses of the forests of Germany, and the back grounds of his savage animals are conceived and executed in a grand and masterly style, occasionally displaying all the wild vigour of luxuriant and uncontrolled vegetation, which can only be contemplated in the depths of untraveled forests, and occasionally in his dens of bears, tygers, lynxes, &c. the mott barren and dismal rocky solitudes, infomuch that the reflecting spectator is led to wonder, either at the bold truths and fertility of a daring imagination, or, if he believes that Ridinger has really visited such scenes, at the danger he must have escaped.

Nor are his portraits of wild and ferocious animals, less than his landscape scenery, the result of vigorous observation, and extensive power over the instruments of his art. In tracing their habits and manners, he combined the exactitude of a naturalist with the talents of a consummate artist.

Several of Ridinger's prints may be called historical, being representations of chafes which really took place in his time, and at which he must have been present, in the forests of Germany, with portraits of the animals that were killed or taken, and that these engravings there is generally a particular description, or history, of the chafe, in the German language.

He did not, however, draw the human figure, nor that of the horse, with equal ability; and though his chiaroscuro he often effective, yet in many instances his lights are too much scattered. He worked from his own compositions, and sometimes painted, as well as engraved, a favourite subject, but his pictures are not common. The most esteemed of his numerous engravings are those which follow:

1. "The Terrestrial Paradise," a set of twelve large folio plates, in which are introduced, in an appropriate manner, all the various animals; the subjects are connected by means of the history of Adam and Eve. These are grand compositions, finely executed, and in England but rarely seen. A set of sixteen fables. A set of heads of wolves and foxes, finely executed. A set of four large upright folios, which by some are esteemed the masterpieces of Ridinger, and two of which, representing "Bears fighting on a Stag," and a haunt of "Wild Boars in a Forest," are more especially to be admired. A pair of "Stag-hunting" and "Bear-hunting," in large folio, both designed from nature. Another pair of hunting pieces, of "The large Wild Boar with double Turtles," and "The Stag in Rutting-time," dated 1755, and 1757, taken by the duke and duchess of Wirtemberg. A set of sixteen hunting pieces of the larger and smaller game, as practiced in the different plates of Germany, with German and French explanations beneath, rich and interlacing compositions. A set of twelve plates of savage and carnivorous animals, all in large folio, and after his own designs.

Ridinger also engraved, with his usual ability, a lion-hunt, after Rubens.

The Preißlers were a numerous family of engravers, whom we shall pass with brief notices, as they rarely rose above mediocrity.

Jean Daniel Preißler, an engraver of portraits, was of Nuremberg, and lived at the close of the seventeenth and beginning of the eighteenth centuries. His son Jean Justin was born in the same city in the year 1695, and died there in 1771. He resided in Italy a considerable time, and became director of the Imperial academy of Augsburg. His most distinguished works are "The Apotheosis of Zenes." A set of the four elements, after Edmond Bouchardon; and another set of the four parts of the day, all in folio. A set of fifty plates of the antique statues preferred at Rome, from drawings by Bouchardon; small uprights. The circulars of the Jesuits' church at Antwerp, after Rubens, consisting of twenty small plates, exclusive of the portraits of Rubens and Vandyke.

George Martin Preißler, a younger brother of Jean Justin, was also of Nuremberg; he engraved, in the family style, a considerable number of portraits, and a set of twenty-one plates of statues, at Rome and at Florence, from drawings by his brother Jean Martin.

The engraving of Valentine Daniel, another son of Jean Daniel Preißler, was chiefly confined to book plates and portraits.

Jean Martin Preißler, the fourth son of Jean Daniel, travelled from Nuremberg to Rome for improvement, and became, on the whole, perhaps, the best engraver of the family. He accepted an invitation to Denmark, and was living in good repute at Copenhagen in the year 1770. His style is clear and neat, but deficient in vigour, and his best prints are; "Christ bearing his Cross," a large folio, from Paolo Veronese. "Semiramis, placing the Crown of Ninus upon her own Head," from Guido, a large folio, engraved with the former, for the Dresden gallery. "A Battle," from Pasaocel, and a Bacchanalian subject, from Pierre, both in large folio.

Jean Alexander Thiele was born at Erfurt in the year 1695, and from the rank of a common soldier rose to be a distinguished engraver and painter of landscapes. A decided taste for this art, and some pictures of Agricola, which it was his good fortune to see and copy in diftemper, introduced him to the notice of that artist, by whose instructions he failed not to profit. He is believed to have been the first in Germany who attempted to paint landscape in engravings, which, though an ineligible mode of art, is a proof of his ingenuity; he afterwards acquired a knowledge of oil-painting under Mencky, in which he gloried, and in which he excelled.

His study was the romantic part of Saxony, and more especially the banks of the Elbe and the Saha. His etchings, of which the subjects of the principal are named below, are rude but masterly. The celebrated Dietrich studied under him at Dresden, where he left a son, and where he died in the year 1752.

A pair of mountainous landscapes, adorned with ruins of ancient buildings, dated 1725, in folio, and very rare; a pair of smaller landscapes, of more rustic character; a set of three mountainous landscapes; a landscape of grander character, adorned with ruined monuments of antiquity, in quarto; a pair of "The Ancient Port or Mouth of the Elbe," drawn from nature, and dated 1742; a pair of views at Naumburg, all in quarto; a set of six of superior execution, from nature, including views of Pilnitz, Konigstein, Müllen, and Dresden, dated 1726, in large folio.

Paul Troger was born at Zell, in the bishopric of Brixen, in the year 1665, and died at Vienna in 1777. He studied the rudiments of his profession in his birth-place, and afterwards travelled.
GERMAN SCHOOL
OF ENGRAVING.

Their grandfather, a general in the Imperial service, lost much of his property by the accidents of war; and the inidelity of the tutor to whom he had entrusted the education of his son, reduced that son to grievous extremities, but his sufferings struck out a talent with which it now appeared that nature had endowed him. He acquired the art of engraving on iron and steel, and ornamented locks and firearms with much taste.

He brought up his sons, the brothers of whom we treat, to the profession of gun-engraving, which they quitted for the more elegant art of engraving on copper. Jean Adam was the eldest, but, in spite of application, could never attain to the eminence of Joseph and Andrea. He engraved, however, for the gallery of Vienna under Altomonte, and his best prints are the portraits of the three empresses Eleonora, Amelia, and Elizabeth.

Joseph and Andrea generally, if not always, worked in concert, and affixed their names, sometimes Joseph and Andrea, as at others Andrea and Joseph, Schmutzer, with brotherly alternation. Joseph possessed dexterity both in etching and re-entering with the graver, and Andrea possessed great facility in managing the tool, which was the necessary result of his being educated to engrave on steel, and to which he added a careful study of the works of Bolivert, and Van Dalem. The best prints from the gravers of these brothers are the portraits of the emperors Charles VI. on foot, after M. de Meytens; the empress Elisabeth Christina, after J. G. Auerbach; Guastavus Adolphus, baron de Gotter, Prussian minister of state; and Leymann, a librarian, of Vienna, all in folio, and the two latter, also after Auerbach. A pair of ancient temples, in large folio, decorated with statues and trophies, after Joseph Galli Bibiena.

But their most distinguished work is three folio plates, from Rubens's life of Decius, in the gallery of the prince of Lichtenstein.

Jacques Schmutzer was the son of Andrea, and had the misfortune to lose his father when he was seventeen years of age. By what further misfortune he came now to be so very young, he was employed partly as a butcher and partly as a shepherd, is not known, but he was employed to watch sheep, sometimes in the fields, but more frequently when penned up for slaughter. The public drawing-school, however, was in the neighbourhood of the sheep-pens, and his love for art often induced him to confide his dog to some indolent comrade, whilst he strolled away to draw with the students of the academy.

The celebrated medalist Matthew Donner, apprized of these circumstances, took some notice of the lad, and invited him home; but by some new accident or impulse, he now began to study architecture, which pursuit he did not afterwards renounce for the arts of design. He was employed for three years as an architect in Hungary, during which time he designed and painted and engraved historical subjects at his leisure hours, and on his return to Vienna, continued occasionally to practice architecture.

He had now the good fortune to become known to the baron de Kettler, a great patron and protector of art and artists, who, charmed with his essays in engraving, solicited the prince Kamenz, and the empress queen, to send the young Schmutzer to Paris; his solicitations were attended to, and our young engraver was placed under the guidance of Wille; here he perfected himself in the art, and in the course of the four years he remained in that celebrated metropolis, learned to use the graver with mastery intelligence. He was now recalled to Vienna, with high rank in his profession, and was named by Maria Theresa a Director of the academy.
academy. He superintended the education of a great number of students in his mature age, and at the close of the last century, was as great at Vienna, as Wille in Paris.

The best of Schmutzer’s engravings are the portraits of Don Emanuel, of the illustrious family of Delvèrs, and Joseph von Sonnenfels, both small; Martin de Meyens, the celebrated painter, after a picture by himself, dated 1756; C. G. E. Debriric, another celebrated artist, after the same, dated 1755; Joseph Weneclaus, prince of Lichtenstein, after V. Fanti; the emperor Francis I., after von Liotard, dated 1769; the companion to which is the engraver Maria Thereza; and two portraits of prince Kaunitz, one after J. Steiner, and the other after Hagenauer, dated 1786, in a circle; a much esteemed and rare piece of engraving.

The above are all in folio. We now proceed to select from his historical engravings, Ulysses discovering Alcyone and Andromache,” after the prince of Saxe Tcthen, dedicated and engraved the archduchess; “Marius Scarsola before Porfella,” from a picture by Rubens in the cabinet of the prince Kaunitz, dated 1758; “St. Gregory refusing to admit the emperor Theodosius into the Church,” after the same master, both plates in folio, and of learned execution; “Venus rising from the Sea,” from a picture by Rubens, in the gallery of count Schoenborn at Vienna, beautifully finished, and four large and interesting landscape views at Neuwaldeck and Dornabach, in which occurs the tomb of Roulleau, and the statues of the Gladiator and the god Mars.

George Frederic Schmidt was born at Berlin A. D. 1712, and died in the same city in 1775. Schmidt was defined by Fortune to be a tradesman, but the voice of Huger, (says Huber,) proclaimed him an artist. His perseverance, after various struggles, at length, surmounted the obstacles that opposed themselves to the gratification of his natural propensities, and he was admitted a student in the school of George Patel Butch at Berlin, from whence his ambition, rather than his parle, in the year 1736, carried him to Paris, where he frequented the school of Nicholas de Larmenin, who honestly and successfully founded the professed public business of Schmidt, by imparting to his disciple all that it was possible to communicate of his knowledge of the art of engraving.

In the year 1742 he was admitted a member of the French academy of Arts, although (which at that time was an important exception) he was of the Protestant religion. At this time Schmidt, Prieiler, and Wille (of whom the reader will find an account under French School of Engravers) were distinguished at Paris by their superior merit in engraving, and were bound together by the ties of friendship, while there reigned between them a noble professed emulation. Schmidt had recommended himself to the friendly regard of the celebrated Rigaud by the very fine portrait of P. Mignard, which he engraved for his reception into the Royal Academy, and Rigaud contributed to his spreading reputation, by seeking and obtaining for him such engagements as were analogous to his wishes and talents.

In two years, however, or a little more, he was summoned to Berlin, and nominated engraver royal, and in the year 1757 he was sent from to Peterburg by the empress Elizabeth, to engrave her portrait, which he executed (with many others, while he remained in Russia) to the great satisfaction, not only of the connoisseurs of the court, but of the best judges throughout the Russian empire.

On his return to Berlin, in 1762, he began to distinguish himself in a new career of engraving, by etching in a picturesque style after the works of Rembrandt, in which he imitated Rembrandt’s own mode of execution, but generally bit-in his plates to deeper tones.

The engravings of Schmidt amount in number to nearly two hundred, beside the vignettes which he did for the works of the king of Prussia. Count Crayon published a catalogue raisonné of the whole, from which we have thought the following most worthy of selection, as specimens of the various powers of our artist.

Portraits performed chiefly with the Graver, and of folio dimensions.—Conlieanisse Scarabatti, prince of Moldavia, a rare and fine print, dated 1738; Charles Gabriel de Tubieres de Caylus, bishop of Axerre, after Fontaine; Louis de la Tour d’Auvergne comte d’Eveux, after H. Rigaud, dated 1742; Johannes Baptista Rofleau, after J. Aved, dated 1740; Charles de St. Alvin, archbishop of Cambrai, after H. Rigaud, dated 1742; Maurice Quinten de la Tour, from a picture by himself, dated 1742; Jean Baptiste Silva, a celebrated physician, after Rigaud, dated 1743; Pierre Mignard, first painter to the French king, after his friend Hysainte Rigaud, engraved in 1744, for Schmidt’s reception into the academy, a piece regarded by connoisseurs as a chef d’ouvre of the masters, and the whole of which is etched in a style so soft and mellow, that it has been emphatically said to be rather painted than engraved. The four last are in large folio.

After his return from Paris to his native city, Schmidt engraved the portraits of Antony Pefne, first painter to the king of Prussia, and Samuel Baro liber de Coceci, both in folio, dated 1751 and 1753, and reckoned among the best portraits from the graver of Schmidt.

Johannes Theodore Eiller, aide-counsellor, &c. after Pefne; and Louis Albertene de Brandt baron de Grapendorff, after de Sueré, are a very rare and beautiful pair of portraits of the folio fize.

Among the best portraits which our artist engraved at Peterburg, are those of Michel de Woronzow, count of the Holy Roman empire, and Nicholas Ellerhazy de Galantha, both in large folio, after L. Toque, and dated 1758; Pierre Comte de Schunallow, grand-maître of the Prussian artillery, from the life, and dated 1760; the empress Elizabeth of Russia, after Schmidt, in a magnificent folio, the accompaniments of the imperial costume; after L. Toque, which Huber calls a superb print, more especially for the execution of the accessory parts, it is dated 1758; Count Cyriliss de Rafuonskoy, after L. Toque, and Jacobus Mounley, from a picture by Schmidt himself, dated 1762, are rare and beautiful, and M. de Katt, field marshal and minister of state to the king of Prussia; the whole portrait from the graver of Schmidt, the head in which is by himself, but the rest finished by Bercy the elder.

Among his historical and fancy works, may be distinguished a pair of “The fair Greek,” and “The amorous Turk,” the two first plates which Schmidt engraved under Larmenin at Paris; “Tahaghe Flamande,” &c. in folio, after Oliade, engraved in a style resembling that of Willich, and dated 1757; “The Virgin Mary fitting with the Infants Christ and St. John,” after Vandyke, dated 1773; “The Virgin at Prayers,” after S. Ferrata; “The Presentation in the Temple,” after Pietro Pellet, for the Imperial gallery at Peterburg; “Alexander and Philip the Physician,” after Annibal Carracci, engraved in imitation of the historical style of Gerard Audran, at Berlin 1759, and “Timocles justified by Alexander,” companion to the above, and after the same painter, both in large folio.

In imitation of the style of Rembrandt.—A half length of a bearded old man with a feathered bonnet, designed by the engraver, and an old woman in profile, after Rembrandt, companion to the above; bust of an Oriental in the style of Callighone, dated 1750; bust of a young man in a Rembrandt.
GERMAN SCHOOL OF ENGRAVING.

Rembrandt head-dress; an old man habited as a Persian, after Rembrandt; portrait of a young female, and portrait of a young figure, from the same master; the Jewish bride, and the father of the Jewish bride, both after Rembrandt, and from the collection of the count de Kamb; the profiles of Salimbeni, and count Algarotti; the portrait of the engraver himself, inscribed "Georg Fridrich Schmidt; Königl. Preufl. Hof. Kupferstecher Mitglied der Maler Academien zu Berlin & Paris," dated 1752.

His best historical works, in the style of Rembrandt, are, "Jesus Christ presented to the People, and buffetted by the Soldiers," after Rembrandt, dated 1756. "The Refutation of the Daughter of Jarius," after Rembrandt, with a very fine chiaro-furo, dated 1767. "The Presentation in the Temple," after Dietrich, companion to the above. "The Philosopher in his Grot," by some called Anchises taking refuge in his grotto during the sack of Troy, in the background of which is a city in flames, after Rembrandt, and dated 1768. "The Repentance of St. Peter," after Fr. Bol. "Lot and his Daughters," after Rembrandt, from a picture in the possession of prince Henry of Prussia, to whom the print is dedicated, and the funeral monument of Sir Andrew Mitchell, knight of the Bath, and ambassador from the king of Great Britain, who died at Berlin in 1771; the two last are of folio dimensions.

Joseph Wagner was born A. D. 1756, at Thalendorf, on the lake of Constance, and died at Venice some time about the year 1790. He learned the art of design under J. Amicoz, whom he accompanied to England and to Italy, and, obedient to the advice of this master, he afterwards travelled to Paris, and studied engraving with very considerable success under Laurent Cars. In the year 1756 he settled at Venice; began to publish there the engravings of himself and pupils, and finally established a beneficial commerce with several parts of Europe. Among his disciples were Flippart, Berardi, and, above all, Bartolozzi, whole talents have done honour to his master, to himself, to Italy, and to England, and who still lives engraving in Portugal and the Dutch East Indies.

The style of Wagner's engraving is particularly easy and engaging, and is in fine art, what in manner we term amiable. It is built on the firm foundation of sound drawing; and partakes highly of the merits of Gerard Audran and Giacomo Frey. Like them he harmoniously mingled etching with the work of the graver and dry needle, and, like them, he evinced a high feeling of the merits of those matters after whom it was his fortune to engrave.

The elements of his style are, vigour tempered with mildness and finitude; hence he is delicately hold, and, without the least appearance of labour, produces, in his best works, an effect of finishing, which other labour after in vain, and which is more particularly observable and appropriate in infantile subjects, or where he has to touch the imagination with indefinite grace. In his figures of the Infant Saviour and St. John, where the characters in his original allowed him to be so, he is, indeed, the flamingo of his art; though if living artists had found a place in our Cyclopædia, that honour mull rather have been awarded to the most distinguished of his pupils.

Wagner's first attempts in engraving are said to have been the portraits of the English princesses Anne, Amelia, and Caroline, daughters of George II. Of his other portraits, the most remarkable are, a pair in folio, whole length figures of the empress Anne of Russia, and Peter the Great, conducted by Minerva. The empress Elizabeth Petrowna, with a Russian inscription, and 'Farselli crowned' by the Mufe of Harmony; all in folio, and after his first master, Amicoz.

A set of large landscapes, ornamented with Italian pastoral figures, after Zucarelli, and executed with much taste, and after Weigler, in conjunction with Bartolozzi.

GERMAN SCHOOL OF MUSIC. Though the language and national style of singing in Germany are much inferior to those of Italy, the instrumental music of that country is indisputably the first in the world. It is true that the violin is infinitely obliged to Corelli, Geminiani, Samis, Tartini, and Boccherini; but for symphonies, and the union of wind-instruments with those of the bow, the Italians have nothing at present, equal to the full pieces of the elder Stamitz, Vanhal, Haydn, and Mozart; nor on key-instruments have they any compositions equal to those of Emanuel Bach, Haydn, Mozart, and several other great clavecinists. And though the best German fingers are, in general, inferior to the piazzas, or streetingers of Italy; yet Germany has, now and then, furnished a vocal performer equal to the best of Italy: such as Raaf, the Mingotti, the Tauber, the Toni, Mars, &c.

M. Suard, ci-devant member de l'Academie Françoise, an extremely severe and finishious critic of the dramatic music of Italy, and a determined Gluckist, begins a chapter on music in the Encyclopædie Methodique on the history of music in Germany, and after the article confines of twelve quarto pages, only four or five of them are bestowed on German music in general, before the author hastens to his hero Gluck, whose life he gives, and an ample list of his works, since he quitted the Italian style of composition for that of France. All this is minutely and ably done, and would be satisfactory to all musical readers, if the author's zeal for Gluck, and his style were not ex适ive, and his cenures so severe, of all that has been admired in Italy, both in composition and performance, by all the rest of Europe, except France. No vocal compositions but those of Gluck escape condemnation. Metastasio's dramas are not written to his mind. The composers are too florid, and the singing too important.

If M. Suard had confided that the style of singing in France was bad, and that its native public fingers were unable to execute such longs as the great Italian masters have composed; and therefore that it was most prudent to have as little singing as possible; the airs very short and simple, no introductory symphonies, or ritornelles to impede the progress of the drama; to let the poet above the composer, and the actor above the singer; with these concessions all Europe would have admitted his reasoning to be just; but when M. Suard infists on all Europe implicitly following the French model in musical dramas; that where great opera composers and refined fingers abound, they are not to be employed,
played, but that the melo-drama, to render it interesting, should never admit an air superior to an elegant ballad, is what lovers of dramatic music, and judges of good composition and good singing, will never subscribe to.

But though M. Suard is so determined a foe to all opera music but that of Gluck, and singing, except that of the natives of his own country, when he speaks of the instrumental music of Germany, he is very just, and celebrates the schools of Vienna, Coblenz, Madeleine, Munich, and Stuttgart; which have produced the Stattzites, the Touchius, Canacchi, Schroeters, Haydns, and innumerable other symphonists, whose compositions are known to all lovers of music. All these different symphonists (fays with great truth M. Suard) have a peculiar character and style of their own; yet, continues he, "it must be allowed that all give way to the inexhaustible Haydn for invention and originality. He unites all the resources of science to the charms of good taste; he is noble and gay, full of grace and force; simple with infinite variety; and unites to movements the most sweet and captivating in melody, the greatest orchestral effects."

This character is written with such truth, intelligence, and feeling, that we forgive the elegant and refined writer much of his bigotry for Gluck, and intolerance for all dramatic music, except that of France.

No praise is too strong for the instrumental music of Germany, in general, by the composers so justly celebrated by M. Suard; but when to these we join Emanuel Bach, and the admirable Mozart, and his scholar Beethoven, it seems as if instrumental music, at least, was arrived at its acme of perfection. This extensive empire has likewise produced masters who have ever equalled the most eminent Italian dramatic composers of the last century; such as Handel, Hasse, Graun, J. C. Bach, Millovecce, Gluck, Naunmull, &c., without mentioning the operas, oratorios, and masses of Haydn, and the dramatic music of Mozart, perhaps the best of its kind. So that Germany may be said frequently to vie with Italy itself in its own belfy of composition.

GERMANY, in Geography, a township of America, in Fayette county, Pennsylvania; containing 1335 inhabitants.

GERMAN Flats, the chief and post-town of Herkimer county, in the state of New York, situated on the N. side of Mohawk river, opposite to Herkimer, and 24 miles E. of White-town; and containing 1637 inhabitants.

GERMAN TOWN, a town of New York, in Columbia county, containing 516 inhabitants.—Also, a town of Philadelphia county, in the state of Pennsylvania, seven miles N. of the city of Philadelphia. It is a corporation, consisting chiefly of High and Low Dutch, and contains about 350 houses, chiefly of stone, some of which are large and elegant, forming one street about two miles in length. The public buildings are a Presbyterian, German-Calvinist and Lutheran church, a Friends' meeting-house, and an academy. Here is a considerable manufacture of flaxworks, made of cotton, thread, and worsted. This is an ancient town, pleasantly situated, and by its vicinity to the metropolis, well adapted for manufactures. The principal congregation of the Mennonites, and the parent of that sect in America, inhabits in this place. A severe battle was fought here between the English and Americans in October 1777.

GERMAN, in Botany. See Teucrium.

Teucrium, &c., the common germander, teucrium chamadry, chamadry minor repens, is a native of England, and flowers in June and July. The leaves and tops have a moderately bitter taste, accompanied with a weak aromatic flavour, diminished by drying the plant. They give out their virtues both to water and spirituous menstrua. The chamadry has been chiefly esteemed in the character of a mild aperient and carborant; it is recommended in uterine obstructions, intermitting fevers, and in the rheumatic and gout. The good effects of the chamadry in the latter disorder are recorded by different authors who have employed it in various forms and combinations, of which the celebrated antimonial, or Portland powder, is an instance. According to Murray the virtues of this plant should be nearly allied to those of marianum, and therefore promises to be useful in syphilitic affections, coughs, and inflammations of the lungs. These virtues, however, are somewhat problematical.

The Marian germamder, or Syrian herb melilot, teucrium marum, flowers from July till September. It is a native of Spain, and is said to grow plentifully also in Greece, Egypt, Creto, and Syria. It was first cultivated in England by Parkinson in 1640, and is now to be found in many of our gardens. The leaves and younger branches of marum, when recent, emit, on being rubbed between the fingers, a volatile aromatic smell, which excites sneezing, but to the taste they are bitterish, with a sensation of heat and astringency. According to Lewis (Med.) it lofts but little of its pungency by being dried; and gives out its active matter partially to water, and completely to rectified spirit. Diluted with the former, it yields a highly pungent, sublimate, volatile, effervescent oil, similar to that of fuscory-grafts, but stronger and of less perilous pungency. Rectified spirit carries off, in the infilpitation of the spirituous tincture, a considerable share of the smell and pungency of the marum, but leaves much the greatest part concentrated in the extract; which, on being boiled, fills the mouth with a durable, penetrating, glowing warmth. Wedelius strongly recommends this plant as an important remedy in many diseases requiring medicines of a flaviant, aromatic, and deoblituent quality; and infusions of its efficacious use have been adduced by Linnaeus, Rothenstein, and Bergius. At present, however, marum is here chiefly used as an emetic, and is an ingredient in the "puvis farii compotitii" of the London Pharmacopoeia. The dose of the powdered leaves is from a scruple to half a dram, which Murray advises to be given in wine.

The water germander, teucrium scordium, is a native of England, in marshy situations, and flowers in July and August. The leaves of scordium have a smell reminding that of garlic, whence its name; and to the taste they are bitterish, and moderately pungent. When moderately and newly dried, they give out, fays Lewis, (Med.) their smell and taste both to water and to rectified spirit. In dissillation their peculiar flavour arises with water, but the impregnation of the distilled fluid is not strong, nor could any essential oil be obtained on submitting to the operation several pounds of the herb. The ancients attributed to scordium a peculiar antiphlogistic and alexipharmic power, and it had for many ages the character of being remarkably efficacious in all pestilential and putrid diseases. With this view it entered into the composition of several official medicines, that were supposed to be antidotes to various kinds of poisons and infections.
ficulties. But, notwithstanding this celebrity, it appears to be a very insignificant article of the Materia Medica, and is therefore very justly fallen into disuse. Borrus, however, states its virtue to be "antiputredinosa. tonica, diaphoretica, diuretica, refolvens;" and some others recommend it to be employed externally in antifeptic cataplams and fomentations. Woodville Med. Bot.

Germâneia, in Botany, named by Lamarck after Monf. de Saint-Germain, a great admirer and cultivator of plants. Lamârc Dict. v. 2. 690. Illustr. t. 514. Jfl. 116. 449. See Phlephantus, which latter appellation, given by l'.Heritier, who was partially near to M. de Saint-Germain nor his admirers, has been universally adopted.

Germânia, in Geography, a port-town of Culpepper county, in Virginia; 82 miles from Washington.

Germânicia, in Ancient Geography, a town of Asia, situated on a plain between mount Taurus and mount Amanus, on the bank of a small river which runs into the Pyræanus, W. of the town.

Germânicopolis, a town of Bithynia, near the Propontis, called by Pliny Helges and Boos-Cate.—Allo, a town of Paphlagonia, called Gangra.—Allo, a town of Iauria.

Germânicus, Cæsar, in Biography, grand-nephew of Augustus, nephew of Tiberius, and grandson of Livia. When Augustus adopted Tiberius, he obliged him to adopt Germânicus, who thus, according to the Roman law, flood in the filial relation to them both. Germânicus married Agrippina, grand-daughter of Augustus, a lady not more illustrious for her rank than her virtues, and he himself grew up in the general affections of the public, on account of the excellence of his temper, and the mildness of his disposition, and was denounced the object of delight of the Roman people." Germânicus was very learned and eloquent, and, at an early age, he became illustrious in warfare, and was raised to the most important offices of the state. When Augustus died, he was engaged in a war in Germany, and the affections of the soldiers unanimously fainted him emperor. He refused the honour, and then appealed the tumult which his indifference to the rank had occasioned. He continued his exploits in Germany, and defeated the celebrated Arminius, and upon his return was rewarded with a triumph. The Germans fought with the greatest bravery, but were at length obliged to yield to superior discipline and generalship. The concluding battle was attended with great slaughter to the Germans, and gave the Roman commander occasion to raise a trophy with this inscription, "The nations between the Rhine and the Elbe subdued by the army of Tiberius Cæsar;" but this subjugation was only a temporary cessation of the contest, and, upon some disaster experienced by the Romans from the elements, the Germans renewed their attack, which afforded Germânicus an opportunity of acquiring new laurels, and he expected to have made an entire conquest of Germany, but the emperor, jealous of his successes, recalled him, with many compliments upon his past conduct, and the prospect of a second conquest. On his return he was honoured with another triumph, which was celebrated with extraordinary magnificence. That part of the spectacles which was most affecting to the Roman people, was the chariot of the victor, filled with his three sons and two daughters. Germânicus was soon sent into the East to quell some disturbances there; the powers entrusted to him on this occasion were very extensive, but the Calliphotus had placed Pifio as a spy and check on the illusory general. Germânicus entered upon his second consulship, having the emperor for his colleague; he visited Athens, and was received in that city with all the adulation usually practised by the inhabitants. He then failed to Euboea and Lebos, thence he touched upon Thrace, and, crossing into Asia, viewed the ruins of Tyre, and consulted the oracle at Colophon. Pifio hastily followed him, and after terrifying the Athenians with a fierce harangue, and throwing out infinuations against Germânicus, embarked for Rhodes, where he would have perished had he not been saved by the humane affiance of the prince, whom he overtook there. Germânicus now proceeded to execute his commission. He placed the crown on the head of Zeno, son of the king of Bruttus, an ally of the Romans. He employed Cappadocia and other places to the face of Roman provinces, and in the ensuing year he made a progress into Egypt, and viewed every thing that was deserving of notice in the country, at the same time opening the public granaries to the people, who were suffering under a scarcity. Upon his return from Egypt to Syria, he found that Pifio had abrogated every regulation which he had established among the legions, and in the cities, and his indignation at this behaviour widened the breach between them. At this time Germânicus was attacked with a disease which afterwards proved fatal, and which was imputed to the effects of poison, but some of our boldest historians, having impartially examined the collateral facts, do not think the evidence sufficient to justify the affirion. Germânicus himself had no doubt that he was the victim of the malignity of Pifio, and, in his last moments, conjured his friends to prosecute with the utmost vigour the authors of his death. He died at Epiphaneia, near Antioch, in the year 19, in the thirty-fourth year of his age. His death was the subject of universal lamentation at Rome. Every other concern was forgotten, and the people, without waiting for an order from the magistrates, forsook the forum, shut up their houses, and allowed every token of universal sorrow. A profusion of honours was decreed to his memory, and even foreign princes and nations joined their testimonies of esteem and regret. He had been highly esteemed not only for his military accomplishments, but also for his learning, humanity, and extensive benevolence. In the midst of war he devoted some moments to study, and he favoured the world with two Greek comedies, some epigrams, and a translation of Aratus in Latin verse. Tacitus, Suetonius, and Univr. Hist.

Germâno, in Geography, a town of Naples, in Lava, containing four parishes, four convents, and about 800 persons. Near this place are the ruins of "Caesaria," destroyed by Theodoric, king of the Goths. The town is situated 43 miles N. W. of Naples. N. lat. 41° 55' E. long. 15° 45'—Allo, a town of the duchy of Urbino; 13 miles E. N. E. of Urbino.—Allo, a town of France, in the department of the Sèvres, late in the lordship of Vercelli; four miles E. of St. Ja.—Allo, a town on the W. coast of the island of Porto Rico. N lat. 18° 20'. W. long. 67° 49'.

Germâns, so called from the name of their country, in Ecclesiastical History, one of the feeblest of rigid anabaptists into which the Flemings were divided; the other being denominations Flamdins and Frieländers. See Flemings.

Germânia, S. or Germânia, in Geography, a borough town of Cornwall, England. was, during the Anglo-Saxon era, a bishop's see. In 981, the Cornish bishop removed his see from Bodmin to this place; but bishop Lévinus translated it to Credington, in Devonshire in 1049. King Athelstan founded a priory for secular canons here; to which the cathedral buildings were annexed. Of these nothing remains but
but the church, which is a curious and interesting specimen of ancient architecture. It consists of a nave, two aisles, and two towers at the western end. Between the latter is a large entrance door-way, with a semi-circular arch, consisting of several ornamented mouldings. Contiguous to the church is Port-Eliot, the seat of Lord Eliot. St. Germans, as a borough, sends two members to parliament, both of whom are nominated and influenced by Lord Eliot. A small market is held here weekly; and two fairs annually. The living is a curacy in the gift of the dean and chapter of Windsor. The Rev. John Whittaker, author of "The History of Mancheller," &c. has published two volumes, quartos, entitled "The ancient Cathedral of Cornwall, historically surveyed." This work contains many curious particulars respecting St. Germans; but the greater part is occupied by theoretical dissertations.

**GERMANUS I. in Biography.** was patriarch of Constantinople in the beginning of the eighth century. His father was badly murdered by the emperor Constantine Pogontur, and himself, by the fame authority, was deprived of his manhood. In 715, he was appointed to the bishopric of Cyzicum, and from that honour he was translated to the patriarchate of Constantinople. He was the chief opponent of the emperor Leo, when he filled his edict for prohibiting the worship of images; during four years the emperor bore with patience all the resistance made to his decrees, till at length the people, irritated by his sufferings, broke out in acts of rebellion; to quell which, Leo assembled a council at Constantinople in 730, by which the patriarch was degraded from his dignity, but permitted to retire to his paternal seat, where he spent the remainder of his days in peace and quietness. He died in 744, and was immediately elevated as a saint in the Greek and Latin churches, on account of his zeal and sufferings in defence of image worship. He was author of several treatises; one, entitled "De lex Synodi Occumenici," &c. has gone through many editions, but that by Le Moyne in his "Varia Sacra," in 1685, is by much the best. He wrote: "An Apology for St. Gregory Nyffen, in opposition to those who accused him of falling into the errors of Origen;" and divers other miscellaneous pieces which are inserted in the Collect. Concli. and in the Biblioth. Patr. Morei.

**GERMANUS II.** was patriarch of Constantinople in the thirteenth century, to which honour he was appointed about the year 1222. In 1233, he held a synod at the city of Nice, where he had fixed the patriarchal residence. He was one of those emperors who, by his misfortune, depeted from his dignity in the year 1249, but restored again just before his death, which happened in 1254. He was a writer of a work intended to illustrate the liturgy, and entitled "Reorum Ecclesiasticarum Theoria," and of numerous homilies, orations, sermons, epistles, decrees, &c.---There was a third Germanus, who was translated to the patriarchate of Constantinople, from the see of Adrianople in the year 1267, but who resigned his dignity within a few months after his election. Morei.

**GERMANY, in Geography.** an extensive country of Europe, situated between 45° 4' and 54° 40' N. lat. and between 6° 30' and 16° 52' E. long. comprises chiefly the present empire of Austria, except Hungary, the greatest part of the Prussian dominions, a part of Pomerania belonging to Sweden, the duchy of Holstein, belonging to Denmark, some parts of Holland, some of the French departments on the Rhine, and all the states of the new confederation of the Rhine, with the formation of which it left its existence as an empire.

**Vol. XVI.**

In ancient times Germany was inhabited by various nations, which the Romans, with whom they waged war for some centuries, considered as Gauls. Of the Helvetii, Boii, Teutonii, and Goths (see Goths, &c.), and the Teutones, who dwelt in the Sinus Godanus near the Cimbri, were among the first that crossed the Rhine, and applied to themselves the name of Germani, probably from the Teutonic word Gete or Guere, a word, affording, as it were, their quality of warriors. The word Guerra, Guerre in the Italian and French, which is not of Latin origin, appears to confirm this etymology. (See the history of the ancient Germans in the sequel of this article.) It is also from the Teutones that, in the German language, the country is called Teutschland, and latterly Deutschland. (See Teutones.) The French gave it the name of Allemacque from the Alemani, one of the German nations. (See Alemani.)

In the middle age the northern and north-eastern regions of Germany got an accession of population from the Vandals and Slavonians; and towards the end of the seventeenth century, some parts of Germany received an inconsiderable increase of inhabitants, by some thousands of French protestant refugees, who left France after the revocation of the edit of Nantes.

Buching flated the extent of Germany at 11,124 German square miles, 15 to a degree; but professor Crome of Gießen, including Silesia, states it at 12,796 German square miles, and its circumference at 500 German miles.

Germany is bounded on the north by the river Elbe, and the canal of Holstein, which separate it from Denmark, and by the Baltic sea; on the east by Prussia, Poland, Hungary, Slavonia, and Croatia; on the south by the gulf of Venice, Italy, and Switzerland; and on the west by the Rhine and the North sea.

Maximilian, grandfather to Charles V., divided Germany into ten circles, and this division was confirmed in the diet of Nuremberg in 1552; but the circle of Burgundy, which contained the fifteen provinces of the Low Countries, having been detached from the empire, it latterly contained only nine circles, &c.

I. The Circle of Aüfeln, which comprised 1. the archduchy of Austria proper; 2. the duchy of Styria; 3. the duchy of Carinthia; 4. the duchy of Carniola; 5. the Austrian Frioul; 6. the Littorale, or the territories of Trias and Fiume; 7. the county of Tyrol; 8. Upper Austria; 9. the bishopric of Trent; 10. the bishopric of Brixen; 11. the commanderies of the Teutonic order in Austria, and on the Estch; and 12. the lordship of Tràfo, belonging to the prince of Dietrichstein.

II. The Circle of Westphalia, which comprised 1. the bishopric of Minden; 2. the bishopric of Osnabrück; 3. the bishopric of Paderborn; 4. the bishopric of Liege; 5. the archduchy of Upper Austria; 6. that of Stablo and Mainz; 7. that of Werden; 8. that of Cornelius Minden; 9. that of Essen; 10. that of Thorn; 11. that of Hervorden; 12. the duchy of Cleves; 13. the duchy of Juliers; 14. the duchy of Berg; 15. the principality of Minden; 16. the principality of Verden; 17. the principality of Nysen; 18. the principality of Eifel Freiland; 19. the principality of Moer; 20. the duchy of Oldenburg; 21. the county of Mark; 22. the county of Ravenberg; 23. the county of Schauenburg; 24. the county of Lippe; 25. the county of Sternberg, which now belongs to Lippe; 26. the county of Bentheim; 27. the county of Steinfurt; 28. the counties of Tecklenburg and Lingen; 29. the county of Huy; 30. the county of Duderloh; 31. the county of Wied; 32. the
II. The Circle of the Lower Rhine, or the electoral circle of the Rhine, which comprised, 1, the electorate of Mayence or Mentz: 2, the electorate of Trevize: 3, the electorate of Cologne: 4, the palatinate of the Rhine; 5, the principality of Arenberg; 6, the county of Lower Hessenburg; 7, the burggravate of Reineck; 8, the county or lordship of Bieleheim; 9, the commandery of the Teutonic order Clothende. The prince of Thurn and Taxis was a member of this circle, without having any territorial possessions in it.

IV. The Circle of the Upper Rhine, which comprised, 1, the bishopric of Worms; 2, the bishopric of Spire; 3, that of Strasbourg; 4, that of Bale or Basel; 5, that of Fulda; 6, the principality of Heltterheim; 7, that of Reichenau; 8, the bishopric of Offenbach; 9, the landgrave of Heil; 10, the principality of Hersfeld; 11, the county of Katzeneben; 12, the county of Hanau-Münzenberg; 13, that of Hanau-Lichtenberg; 14, that of Hanau; 15, the principality of Simmer; 16, the principality of Lautern; 17, that of Veldents; 18, the principality of Deux Ponts; 19, the county of Sponeheim; 20, the principality of Salm; 21, the principality of Naillun; 22, the principality of Waldeck; 23, the county of Solms; 24, the county of Koenigstein; 25, the county of Hessenburg; 26, the possession of the Wald or Woud, or Rau Gravez and Rhine Gravez; in Latin, Comites Saltuarii, Forstarii, Silvestres et Hirsuti; counts of Grumbach, Stein, and Dhaun; 27, the county of Leinington; 28, the county of Wittgenstein; 29, the county of Falkenstein; 30, that of Kirchigen; 31, that of Wartenburg; 32, the lordships of Retzenheim, Dachtil, and Olbrück; 33, the free imperial cities of Worms, Spire, Frankfort on the Main, Friedheim, and Weitzlar; 34, the imperial borough of Friedberg; 35, the imperial villages of Müntzfeld, Stobach, and Soden.

V. The Circle of Saalburg, which comprised, 1, the bishopric of Constance; 2, the bishopric of Augsburg; 3, the abbey of Elwangen; 4, the abbey of Kempen; 5, the duchy of Wirtemberg and Teck; 6, the margravate of Baden; 7, the principality of Hohenzollern; 8, the abbey of Liadar; 9, that of Buchau; 10, the principality of Furthenberg; 11, the county of Oettingen; 12, the principality of Klettgau; 13, the principality of Lichtenhein; 14, that of Friedberg-Scheuren; 15, the abbey of Salamancon; 16, the abbey of Weilburg; 17, that of Odheim; 18, that of Eichingen; 19, that of Yburg; 20, that of Ueberg; 21, that of Kaysersheim; 22, that of Regensburg; 23, that of Roth; 24, the abbey of Weilwies; 25, that of Schauenburg; 26, that of Marchtal; 27, the abbey of Peterhausen; 28, the abbey of Wettenhausen; 29, that of Zwesthal; 30, that of Gengenbach; 31, the abbey of Heggelbach; 32, that of Guttenbach; 33, that of Rottmünster; 34, the abbey of Eichstein; 35, that of Wirthwies; 36, the commandery of Alfeld; 37, the landgraviate of Stühlingen; 38, the landgraviate of Dürren; 39, the county of Truchheim-Waldenburg; 40, the county of Köningen; 41, that of Eberfeld; 42, that of Witter; 43, that of Hohen-ems; 44, that of Hohen-Geroldseck; 45, the county of Neipperg; 46, the county of Bondorf; 47, the lordships of Wielenburg, Haufen, Moerkirk, Tuttlingen, Ulm, Ettlingen, Reutlingen, Nördlingen, Halle, Ulm, Tübingen, Rotweil, Heilbronn, Günzburg, Memmungen, Ludau, Dinkelsbühl, Biberach, Ravensburg, Kempten, Kaufbeuren, Weil, Weingarten, Vins, Leutkirch, Wimpfen, Giengen, Pfullendorf, Buchhorn, Aalen, Bopingen, Buchau, Offenburg, Singen, Zell on the Hammerbach; 49, the imperial village of Alocshaußen.

VI. The Circle of Bavaria, which comprised, 1, the archbishopric of Salzburg; 2, the bishopric of Freyningen; 3, the bishopric of Ratibor; 4, the bishopric of Pfaffm; 5, the principality of Berchtesgaden; 6, the abbey of St. Emmeram in Ratibor; 7, and those of Lower; and 8, of Upper Münster in the same place; 9, the city of Bavaria; 10, the Upper Palatinate; 11, the principality of Neuburg; 12, the principality of Sultzbacht; 13, the landgraviate of Leuchtenberg; 14, the principality of Stellinm; 15, the county of Hagen; 16, the county of Linsm; 17, the lordships of Erthen, Salzburg, Pyrbaum, Hohenwalde and Breitenau; 18, the free imperial city of Ratibor.

VII. The Circle of Franconia, which comprised, 1, the bishopric of Bamberg; 2, the bishopric of Wurzburg; 3, the bishopric of Eisfeld; 4, the commandery of the Teutonic order of Mergenthal; 5, the principality of Calvin, or Bayreuth; 6, the principality of Osnabrick, or Osnabuck; 7, the county of Henneberg; 8, that of Schwartzburg; 9, the principality of Hohenlohe; 10, the county of Cau; 11, the county of Wurttemberg; 12, that of Reichsburg; 13, that of Erfbach; 14, the lordships of Limburg, Schinium, Reichshilberk, Weilheim, Wurzburg, and Haufen; 15, the free imperial cities of Nuremberg, Rothenburg, Windheim, Schweinfurt, and Würzburg; 16, the imperial villages of Gochheim and Sannfeld.

VIII. The Circle of Upper Saxony, which comprised, 1, the duchy of Pomerania; 2, the electorate of Brandenburg; 3, the bishopric of Saxony; 4, the duchy of Saxony; 5, the duchy of Saxony-Coburg; 7, that of Saxe-Meiningen; 8, that of Saxe-Hildburghaußen; 9, the abbey of Hildesheim; 10, the abbey of Naumburg-Zeitz; 11, the principality of Altenburg; 12, the principality of Querfurt; 13, the principality of Anhalt; 14, the abbey of Quedlinburg; 15, the abbey of Weilenburg; 16, the principality of Schwartzburg; 17, the county of Mansfeld; 18, the county of Stollberg and Wernigerode; 19, the county of Barby; 20, that of Hohnstein; 21, the principality of Hatzfeld; 22, the county of Reuß; 23, the county of Schouenburg.

IX. The Circle of Lower Saxony, which comprised, 1, the bishopric of Hildesheim; 2, that of Lubeck; 3, the abbey of Gardener; 4, the duchy of Magdeburg; 5, the principality of Halberstadt; 6, the duchy of Bremer; 7, the principality of Celle; 8, the principality of Gifhorn; 9, the principality of Calenberg; 10, the duchy of Saxe-Lauenburg; 11, the duchy of Wolfenbüttel; 12, the principality of Blankenburg; 13, the duchy of Holstein; 14, the duchy of Mecklenburg; 15, the
the principality of Schwedt; 16, the principality of Ratzeburg; 17, the county of Ranzau; 18, the free imperial cities of Lubbeck, Goflar, Mulhhausen, Northhausen, Hamburg, and Bremen.

The following countries, without forming part of any of the nine circles, were likewise considered as belonging to the German empire: viz. 1, the kingdom of Bohemia; 2, the margraviate of Moravia; 3, the margraviate of Upper Lusatia; 4, that of Lower Lusatia; 5, the duky of Silesia; 6, the county of Montebellard; 7, the three circles of the immediate kingdoms of the Empire, in Swabia, Franconia, and on the Rhine; 8, the lordships of Mecklenburg and Waffenburg, the convent of Schontal, the margraviate of Freudenberg, the barony of Horfgen, the abbey of Cappenberg, that of Ellen, the lordship of Rheda, the abbey of Burichfeld, the lordship of Jever, the barony of Kniphausen, the lordships of Dyk, Mecherinck, Schonau, Wyler, Richold, Stein, Dreyfs, Landikron, Rhade, Saffenbourg, Schaumburg, Oberlein, the county of Homburgh, and the barony of Schauen. The German empire had also several fiefs in Italy.

The climate and temperature of Germany must, in general, be acknowledged to be temperate, yet it is considerably milder in the south than in the northern parts, where the winter is sometimes extremely severe, and of long duration. The air, however, is everywhere serene and healthy, except in a few low marshy places towards the North Sea. The vine thrives, and yields excellent wine, in all the southern parts. The falsify of the climate may likewise be inferred from the longevity of the inhabitants, some of whom arrive to a very great age.

There is perhaps no country in Europe, in which the summer varies more than in Germany. Sandy plains and barren heaths predominate in the north, and swamps and marshes in the north-west; but some of the interior and southern parts have an uncommonly fertile soil, and great attention is generally paid to its improvement. The south and the south-east side is the most mountainous. Bohemia is separated from Silesia by the Riefen Geburgh, or the Giant's mountains; towards Hungary are the Carpathian mountains, towards Italy the Alps. In the interior parts are the Schwarzwald, (black forest,) the Rauhe Alb, the Erzgebirge, the Fichtelgebirge, the Harz, or Hercynian forest, whose highest summit, the Brocken, is only 3,580 feet above the level of the Mediterranean sea. In ancient times Germany was covered with forests, chiefly of oak, birch, pine, fir, larch, and ash trees. Though they have been considerably thinned, and immense tracts of them converted into tillage, there are yet some very large woods, as the Speisart, the Schwartzwald, the Hartzwald, and the Thuringerwald.

The extent of sea-coal on the North sea is not much above 150 English miles, and on the Baltic about 500 English miles. The principal lakes are the Boden see, or lake of Constance, in Swabia, which forms one of the boundaries towards Switzerland; the Chiem see, in Bavaria; the Greitzer see, in Austria; the lakes of Dam, Neuwarp, Maudie, and Wilm, in Pomerania;those of Werbelin, Uckersee, Partleinn, Schwieluch and Ruppin, in Brandenburg; the Dammer see, in the county of Diepholts, besides several smaller ones in Mecklenburg and other parts of the country.

But it is chiefly the great number of rivers, by which Germany is intersected in various directions, that give it immense advantages for trade. It counts five hundred and twenty rivers in all; sixty navigable to a great length, and fix, viz., the Danube, the Rhine, the Mayne, the Weser, the Elbe, and the Oder, ranking among the largest and most noble rivers of Europe. The number of mineral springs and baths exceeds one thousand; the most famous are Carlsbad and Egra, in Bohemia; Warnbrunn, in Silezia; Toplitz, in Austria; Hellbronn, in Bavaria; Witten and Seltzer, in the circle of the Upper Rhine; Freyenwalde, in Brandenburg; Dobberson, in Mecklenburg; Lauchte, in Saxony; and Pyrmont, in Welfphalia.

As almost all climates, or at least all temperatures and soils, are to be met with in Germany, it abounds in almost all productions of nature and their varieties, and chiefly in all kinds of corn: fleck of excellent quality, hemp, hops, tobacco, madders, saffron, rape-seed, rhubarb, excellent garden vegetables and orchard fruits; wine, in greatest perfection on the banks of the Rhine, Mayne, Mofelle, and Neckar. The agriculture of Germany has been considerably improved of late by the efforts of Mr. Thaer and other patriotic writers. In the rearing of cattle and sheep Germany is, however, greatly deficient. The breed of horses, except in Mecklenburg, East Frieland, Oldenburg, Holstein, and some parts of Hanover and Wirttemberg, is very indifferent. The number of oxen is not sufficient either for agricultural purposes or for consumption. The heft breed is in East Frieland, Oldenburg, and Holstein. The number of sheep does not exceed thirteen or fourteen millions. The Spanish breed has been naturalized in some parts of the Prussian and Saxon dominions. The breed of hogs is much neglected; that of goats is encouraged in the mountainous parts, where they also rear ales and mules. The forests are staked with wild boars, stag, deer, and hares. Poultry is abundant. Salted and smoked geese, and goose quills, are exported from Mecklenburg and Pomerania. Some parts of Germany are remarkable for fine larks and thrushes, of a delicious flavour. Others abound with finning birds, particularly Canary birds and goldfinches, which are exported to almost every country of Europe. Bees are least attended to than in ancient times. Silkworms are reared with particular care in some of the southern, and even northern districts.

Of the mineral productions of Germany, gold forms the most inconsiderable part, small particles of it are found in the Rhine, the Danube, the Elbe, and the Sake. Silver is plentiful; its annual produce exceeds 200,000 marks, that of copper amounts to 100,000 cwts. The supply of tin from the mines is sufficient for home consumption. Iron of a very good quality, lead, quicksilver, cobalt, and antimon, and zinc are in great abundance. Brubbles, topazes, amethysts, cornelians, agate, serpentine, and other rare stones, Germany has large quarries of curious marble, and capital mill and barn stones. It abounds with various sorts of fine earth, such as triopk, and porcelain earth, chiefly in the circle of Main in the kingdom of Saxony; terra sigillata, potters' clay, fuller's earth, and others. There are some coal mines, particularly in Welfphalia, and abundance of peat moss. Salt is obtained in seventy-six salt works, of which those near Halle, in the former duchy of Magdeburg, produce the greatest quantity. There is no rock salt in Germany.

The principal manufactures of Germany are those of linen and woollen cloth, cotton, thread lace, china, hardware inferior to none but the English, glass, tobacco and snuff, writing paper, soap, wax, toys and trinkets, and silks, but not equal to the French. Manufacturers flourish most in the Austrian and Prussian dominions, in Saxony, in the present kingdom of Welfphalia, in the grand duchy of Berg, &c.

The towns most remarkable for extensive manufactures are Altona, Augsburg, Berlin, Brunswick, Bremen, Caffel, Chemnitz.

Situated almost in the centre of Europe, bounded by the Baltic and North sea, and interfaced by many large rivers, Germany has enjoyed, till very lately, a most extensive commerce. Its principal sea ports are Hamburgh, Altona, Kiel, Lubeck, Wilmar, Rostock, Straflund, Stettin, Emden, Bremen. Inland towns of great trade are Bronfick, Magdeburg, Leipzig, Naumburg, Francfort on the Mayne, and Francfort on the Oder, Vienna, Augsburg, Nurnberg, Delfau, and Ulm. The principal articles of exportation are timber, corn, fruit, wine, tobacco, madders, cobalt, fennels, potash, horse, oxen, salt and seasoned meat, butter, cheese, honey, wax, leather, wool, cotton yarn, linen cloth to the amount of six millions sterling, Linen yarn, thread lace, cotton stuffs, hardware, lead, copper, brass, quicksilver, china, earthen-ware, mirrors, glass, wooden toys and trinkets, &c. Germany imports corn, oxen, and horses chiefly from Hungary, Poland, and Denmark, hogs from Hungary, butter from Ireland and Holland, silk and cotton, all sorts of colonial produce, wine and fruit, silk and cotton stuffs, paper, jewellery and trinkets. It carries on a most important trade with European Turkey, from whence it gets by land as far as Semlin, and from thence upon the Danube by way of Vienna, an immense quantity of raw cotton, which is distributed all over the north of Europe, Germany and Switzerland. As it has to pay annually from three to four millions of piasters in hard cash to the Turks, these money transfections are carried on by means of the bankers of Vienna. The principal insurance companies are at Hamburgh, Lubeck, and Bremen. Weights, measures, and coins differed in every petty principality of Germany, and this circumstance was one of the disadvantages which travellers at least experienced from that number of free cities and small states for which Germany was particularly remarkable. It is true, as has been justly observed by the intelligent author of an essay on the Reformation of Luther, that all these cities and principalities of moderate extent had their principle of life active, peculiar, and independent. Each prided itself on making industry, sciences and arts flourish in its little capital.

By the treaties of Paffau in 1555, of Augsburg in 1555, and of Muncther in 1648, the Roman Catholic, Lutheran, and reformed religion, were acknowledged as dominant in Germany: but all other sects enjoyed a complete toleration, and the number of Jews in some parts is very considerable.

According to Mr. Charles Villier's view of the present state of ancient literature and history in Germany, in his report to the third class of the French institute, the German literati possess a great facility in entering into the spirit of nations and of ages, different from those of the present day, and are eminently successful in archeological researches, and in the interpretation and translation of the ancient, particularly of the Greeks, perhaps on account of some secret affinity between the two nations, as the analogy of the two languages seems to indicate. But if any species of literary production can be said to belong to Germany, almost exclusively, it is the history of literature. The German literary and critical journals, especially those published at Jena, Halle, Leipzig, and Gottingen, rank among the best in Europe. Before the revolutionary wars, the number of authors exceeded 14000. Their literary productions found a ready market at the two fairs of Leipzick in the spring and autumn of every year. The number of new books published at those fairs was rarely under 4000: but since the fall of Prussia, in 1307, it has never exceeded 1500. Two hundred German, and about thirty foreign bookellers, used to meet at Leipzick, to barter their respective publications; the amount of these exchanges was generally above 200,000, sterling. Anciently German authors wrote most of their works in Latin. In the beginning of the seventeenth century, there were at least 400 out of 700 written in that language; towards the end of the eighteenth century the proportion was only 200 in 1800. Before that period the literary labours of the Germans were confined to theology, jurisprudence, and biblical and classical criticism: but during the latter half of the last century they have been extended to every branch of science and literature; mineralogy, natural history in general, chemistry, alchemy, and geometry have been cultivated with an intelligent ardour and perseverance that have been rewarded with many brilliant discoveries. Statitics, which elucidates the theoretical tenets of political economy, and furnishes important materials to the historian and the geographer, is indebted alike for its origin and its improvement to the literary industry of the Germans. In metaphysics they have incurred the reproach of dogmatical obscurity, and in their dramas and novels they are justly accused of a disfiguring affectation of morbid sentimentality. But their epic and tragic poets, and their moral philosophers, have immortalized themselves by works, which have been eagerly translated into all the idioms of modern Europe. To the great names of Luther, Kepler, Leibnitz, Haller, Euler, Moelhe, Pufendorff, Pott, Maggraff, Hagedorn, Leffing, Gleim, Kleit, Heyne, Rebener, Klopotock, Ramler, Gellner, who live in the records of literary fame, must be added those of Bernouilli, Lambert, Keitner, Wieland, Schiller, Goethe, Herder, Zolliker, Spalding, Bloch, Moses Mendelssohn, Klaproth, von Humboldt, Volf, Holty, Michaelis, J. A. Eberhard, Von Zach, and many others, whose merits are as conspicuous as they are generally acknowledged.

The German language is of Teutonic origin, and may be regarded as a primitive one, as it is the mother tongue of the Dutch, Flemish, Danish, Swedish, and English languages. Its dominion extends from the boundaries of Lapland and Finland, to those of France and Italy. In the middle ages, the similarity between the idioms derived from the German was great, that the German and English missionaries that went to Sweden, Denmark, and Norway, had no difficulty in making themselves understood in those countries. The learned Thre, in his introduction to his Sueo-Gothic Glossary, has also discovered a striking conformity between the old Teutonic and Perman languages. That which it bears to the Greek in its construction is not less striking. The dialect known by the name of Low German, or Low Dutch, is now diffused in writing, and wholly confined to the vulgar in the kingdom of Belgium, in the duchies of Mecklenburgh and Holstein, and in Pomerania; it comes very near the Dutch. The High German, or High Dutch, has been considerably improved since Luther's time; it is remarkable for strength, richness, bold inversions, and compound words, which render it admirably fit for the higher strains of epic poetry. The learned dictionaries of Adelung, Eberhard, and Campe, have served to elucidate the meaning of every one of its terms, so that it may now be considered as fixed. It is spoken in its greatest purity in Upper Saxony, part of Lower Saxony, and on the banks of the Neckar and the Mayne. There are still some traces of the Slavonian language left on the shores of the Baltic, in some districts of Pomerania, in Silefia, Bohemia, and Moravia; but it is disappearing very fast.
No country can boast of more and better institutions for the acquisition of knowledge and science than Germany. Notwithstanding the great extent of territory ceded to France, there are still 30 universities, of which 17 are Protestant, 11 Catholic, and two mixed, viz. ; Griesswalde, Jens, Leipzick, Wittenberg, Gottingen, Halle, Helmildt, Kiel, Rothen, Aider, Erlangen, Rinteln, Gießen, Marburg, Stuttgart, Tubingen, Frankfurt on the Oder, are Protestant universities; Bamberg, Witzburg, Paderborn, Fulda, Dillingen, Freyburg, Infruck, Vienna, Ingollstadt, Saltzburgh, and Prague, are Catholic universities; and the two mixed ones are Erfurt and Heidelberg. The oldest of them is that of Prague, which was founded in 1348, and the most modern that of Erlangen, founded in 1743. Most of these learned seminaries, which have furnished the northern regions of Europe with able teachers, are provided with extensive libraries, anatomical theatres, museums of natural history, botanical gardens, and astronomical observatories. The professors are animated with the noble ambition of extending the fame of the university in which they teach by their writings, and as the students pay a liberal fee for their board and lodgings, the professors have a useful function among the teachers. Every student is at liberty to select what lectures he chooses to hear, and may employ his time as he likes. He has only a severe examination to undergo when he offers himself as a candidate for any situation in the law, administration, or church, or when he wants to take his degree as a doctor in medicine, without which degree he cannot be admitted into any college of physicians. All the other useless scholastic formalities have long since been abrogated.

Besides these universities there is a great number of public or free grammar schools, lyceums, and other learned schools in Germany. The methods of teaching have been considerably improved within the latter half of the eighteenth century, when Baderow, profiting by the hints thrown out by J. J. Rousseau, opened the Philanthropinum at Détain, and set an example of liberal and scientific education, which was soon imitated by men of enlightened views and extensive information. Campe, Valleine, Saltzmann, Trapp, and latterly Pellelozzi, have eminently contributed to introduce better modes of instruction. There are also many establishments defined to train young men for particular employments, such as military, mineral, commercial, and even agricultural schools. Females are mostly educated at home under the eyes of their mothers, who are particularly anxious to guard their daughters against the baneful influence of ladies boarding schools.

The numerous literary societies of all kinds, public libraries, reading clubs, circulating libraries, critical journals, and other means of disseminating and preferring knowledge, afford another proof of the high state of civilization to which most countries of Germany are arrived. The most distinguished of its learned societies are the imperial academy of natural philosophy at Vienna, the royal academy at Berlin, the academies at Cœfl, Erfurt, Gottingen, Mainz, Munich, Cæstit, and Zella. The best public libraries are those of Berlin, Dresden, Gottingen, Gotha, Hanover, Leipzick, Mainz, Munich, Stuttgart, Weimar, Vienna, and Wittenbac. Though Germany may boast of being the cradle of the art of printing, England and France bear the palm. The generality of German books are printed without title, with had types, and on had paper. A few splendid editions have, however, been attempted at Leipzick, and met with merited success. The liberty of the press, which was never general all over Germany, has received its death-blow from the fiery which the French government exercised in every one of its counties, since the peace of Tilsit.

Of the fine arts, music is that in which the Germans excel. They vie with the Italians, and the names of Handel, Bach, Haydn, and Mozart are reverenced by their rivals. Germany has also produced some good painters and engravers, but few statuaries and architects. With respect to dancing, it is far behind Italy and France. The principal academies for the encouragement of the fine arts are at Berlin, Dresden, Leipzick, Mainz, and Vienna. The most celebrated galleries of pictures are at Dresden, Vienna, Sans Souci, near Potsdam, Duffeldoff, Mannheim, and Cæsæl.

The influence of the arts on the manners of a people is of no more striking than in Germany, where concerts and musical parties, together with dancing, form the chief amusement; and the manners of the middle orders are polite and amiable.

Before the peace of Utrecht in 1801, the population of Germany was rated at 27 millions of inhabitants; but as it fell 57000000 individuals, through the cession of the countries situated on the left shore of the Rhine, its present population is very little above 23 millions.

The history of Germany in its ancient state, its gradual advancement towards extent of territory and dominion, and its recent decline and fall, presents to our notice a subject that is in a variety of respects peculiarly interesting. The western monarchy of Rome was first refounded, then invaded, and at length overturned by the warlike inhabitants of Germany; and it was from the woods of this country that the most civilized nations of Europe issued; and we may still distinguish in the rude institutions of these barbarians the original principles of our laws and manners. Ancient Germany, excluding from its independent limits the provinces westward of the Rhine which had submitted to the Roman yoke, extended itself over a third part of Europe. Almost the whole of modern Germany, Denmark, Norway, Sweden, Prussia, Austria, and the greater part of Poland, were peopled by the various tribes of one great nation, whose composition, manners, and language deviated a common origin, and preferred a striking resemblance. On the west, ancient Germany was divided by the Rhine from the Gallic and the east by the Danube, from the Illyrian provinces of the empire. A ridge of hills, rising from the Danube, and called the Carpathian mountains, covered Germany on the side of Dacia or Hungary. The eastern frontier was faintly marked by the mutual fears of the Germans and the Sarmatians, and was often confounded by the mixture of warriors, and confederating tribes of the two nations. Such was also the case with respect to the Gauls on the west, where it is still more difficult to fix their boundaries on account of their constant fluctuation. In the remote darkness of the north, the ancients imperfectly deferred a frozen ocean, that lay beyond the Baltic seas, and beyond the peninsula, or islands of Sarmatia. But their nearest northern limit was the Hercynian forest, at that time supposed to be impenetrable. It appears from authentic documents that the climate of ancient Germany was much colder than that of the country in its more modern state. For the evidence of this fact, and the explication of it, we refer to the article Climate, where the reader will also find some reflections on the influence which variety of climates is supposed to have on the minds and bodies of the different inhabitants of the globe. The keen air of Germany contributed, without doubt, towards forming the large and masculine limbs of the natives, who were, in general, of a more lofty stature than the people of the south, gave them a kind of strength better adapted to violent exertions than to patient labour, and inspired them with
GERMANY.

with constitutional bravery, which is the result of nerves and spirits. " In hos artus, (fays Tacitus, Germania, iii. 20.) in hae corpora, quae miramur, excrecutem." The fatigue of a winter campaign, that chilled the courage of the Roman troops, was feebly felt by those hardy children of the north, who, in their turn, were unable to reft the thinner heats, and dissolved away in languor and sickness, under the beams of an Italian sun.

As to the origin of the Germans, although we cannot allow with Tacitus, that they were "Indigenes," or natives of the soil, yet we must admit that ancient Germany was not peopled by any foreign colonies, already formed into a political society; but the name and nation received their existence, as we have already observed in the beginning of this article, from the gradual union of some wandering barbarians, probably of the same nation with the Celtae and Gauls, and both, perhaps, descended from the ancient Gomerians, or descendants of Gomer, the elder son of Japhet. (See Division of Mankind.) The Germans, however, were very much intermixed with the old Scythians and Sarmatians, on that side which joined their territories, and particularly between the two great rivers, Rhine and Danube; and they, without doubt, had adopted many of their customs, as well as intermingled some portion of their language with their own; but in all other parts of Germany, we find such an exact conformity in their religion, laws, customs and language, as affords a very strong presumption that they were descended from the same ancient stock with the Celtae or Gauls, and that they came by gradual and successive migrations from Asia. (See Celta.) How this country came to be denominated Germany, and whence its inhabitants derived the appellation of Germans, it is not easy to determine. The most probable conjecture is, that they were so called, either from their affinity to the Celts, or from the Celtic words "gar man," a warlike man; but this was not their original name, any more than the appellations of "Teutones" or "Alamanni," by which, as we have already observed, they were occasionally denominated. This name was of a more modern date, and seems to have had its rise on the other side of the Rhine, when the Condurfs, Eburones, Cenomani, and Parlemi, crossed that river, after the example of some others of their countrymen, and settled in Gaul. Thence, it seems, were the first to whom the appellation of Germans was given, and which, therefore, extended no farther than the Rhenish shore on the Gallic side, but soon after passed over to the other, and became common to other people of the same language and customs, till at length it became the general name of the whole nation, and the country was called from them Germania or Germany.

Whatever may be supposed to be the remote origin of the Germans, they appear to have been in a savage and uncivilized state on their first settlement in this country. The account given of the country itself by Caesar and Tacitus is so unfavourable, that it seems to be almost incredible, that a brave nation, for such we must allow the ancient Germans to have been, would have been contented to remain in it, when they were deficient of neither strength nor courage to have forced their way into others more pleasant and fruitful. The ancient barbarians describe it as wholly barren and uncultivated; and even its variety of soil and climate added to the horror of it, from the dreadful forests, putrid and insalubrious bogs, the inclemency of its winds, dampness of its seas, lakes, and rivers, and sterility of its soil. The uncivilized state of the ancient Germans may be inferred from the account given of them by Tacitus; for in his time they were unacquainted with the use of letters (German, ii. 15); and the use of letters is the principal circumstance that distinguishes a civilized people from a herd of savages incapable of knowledge or reflection.

Of the useful and agreeable arts of life the ancient Germans were wretchedly destitute. Modern Germany is said to contain about 2,500 walled towns, whereas, in a much wider extent of country, the geographer Ptolomy could discover no more than ninety places, which he decorates with the name of cities, though, according to our ideas, they would not deserve that splendid title. We can only suppose them to have been rude fortifications, constructed in the centre of the woods, and designed to secure the women, children, and cattle, whilst the warriors of the tribe marched out to repel a sudden invasion. Such is the account given of them by Caesar; and Tacitus afferts that the ancient Germans had no cities. Even in their hamlets or villages they did not build their houses contiguous to each other. They considered it as a badge of servitude to be obliged to dwell in a city surrounded with walls. Each barbarian fixed his independent dwelling on the spot to which a plain, a wood, or a stream of fresh water had induced him to give the preference. Neither stone, nor brick, nor tile, were employed in these first habitations. They were, indeed, no more than low huts of a circular figure, built of rough timber, thatched with straw, and pierced at the top to leave a free passage for the smoke. That they considered cities as places of confinement rather than of security, appears from the following circumstance: when one of their tribes had shaken off the Roman yoke, their countrymen required of them, as an evidence of their having recovered liberty, to demolish the walls of the towns which the Romans had built in their country. The Romans built several cities of note on the banks of the Rhine. But in all the vall countries from that river to the coasts of the Baltic, there was hardly one city previous to the ninth century of the Christian era.

In the most inclement winter, the hardy German was satisfied with a scanty garment made of the skin of some animal. The natives, who dwelt towards the north, clothed themselves with furs; and the women manufactured for their own use a coarse kind of linen. The game of various sorts, with which the forests of Germany were plentifully studded, supplied its inhabitants with food and exorcised. Their plentiful herds of cattle, left remarkable for their beauty than for their utility, formed the principal article of their wealth. A small quantity of corn was the only produce exacted from the earth. The use of orchards, or artificer meadows, was unknown to the Germans; nor can we expect any improvements in agriculture from a people, whose property every year experienced a general change by a new division of the arable lands, and who, in that strange operation, avoided disputes, by suffering a great part of their territory to lie waste and without tillage. Gold, silver, and iron, were extremely scarce in Germany. Its barbarous inhabitants wanted both skill and patience to investigate those rich veins of silver, which have since liberally rewarded the attention of the princes of Brunswick and Saxony. Although the various transactions of peace and war had introduced some Roman coins (chiefly silver) among the barbarians of the Rhine and Danube; yet the more distant tribes were absolutely unacquainted with the use of money, carried on their limited traffic by the exchange of commodities, and prized their rude carthens, vessels as of equal value with the silver vases, the presents of Rome to their princes and ambassadors. If we contemplate a savage nation in any part of the globe, a supine indolence and a carelessfruhs of futurity will be found to constitute their general character. This was decidedly the case with respect to the ancient Germans. The care of the house and family, the management
of the land and cattle, were delegated to the old and infirm, to women and slaves. The lazy warrior, delitute of every art that might employ his leisure hours, confined his days and nights in the annual gratifications of sleep and food. Nevertheless, the found that summoned the German to arms was grateful to his ear. It riled him from his uncomfortable lethargy, gave him an active pursuit, and, by strong exercise of the body, and violent emotions of the mind, restored him to a more lively sense of his existence. In the dull intervals of peace, these barbarians were immediately addicted to deep gaming and excessive drinking; both of which, by different means, the one by inflaming their passions, the other by extinguishing their reason, alike relieved them from the pain of thinking. They gloried in passing whole days and nights at table; and the blood of friends and relations often stained their numerous and drunken assemblies. The poftition and the enjoyment of property are the pledges which bind a civilized people to an improved country. But the Germans, who carried with them what they mott valued, their arms, their cattle, and their women, cheerfully abandoned the vain illusion of their woods for the unbounded hopes of plunder and conquest. The innumerable swarms that swelled, or seemed to swell, from the great store-house of nations, were multiplied by the fears of the vanquished and by the credulity of succeeding ages. And from facts thus established, and facts gradually embellished, and has been supported by writers of distinguished reputation, that in the age of Caesar and Tacitus the inhabitants of the north were far more numerous than they are in our days. On this subject sir William Temple and Monetfquieu have indulged the usual livelinet of their fancy. A more serious inquiry into the causes of population, seems to have convinced modern philosophers of the falsehood, and indeed the impossibility, of the supposition. To the names of Mariana and of Machiavel, we can oppose the equal names of Robertson and Hume.

A warlike nation like the Germans, without cities, letters, arts, or money, found some compensation for this savage state in the enjoyment of liberty. Their poverty secured their freedom, since, says Gibbon, our defires and our poffessions are the strongest fetters of despotism. Caesar and Tacitus inform us, that the state of society among the ancient Germans was of the rudest and most simple form. They lived entirely by hunting or pastoral. They neglected agriculture, as we have already seen; their chief food was milk, cheese, and flesh. While seventy remains in this simple state, men, by uniting together, leisurely relinquishing any portion of their natural independence. The authority of civil government was extremely limited among the Germans. In times of peace they had no common or fixed magistrate; but the chief men of every district dispensed justice and accommodated differences. In the far greater part of Germany, the form of government was a democracy, tempered indeed, and controlled, not so much by general and positive laws, as by the occasional ascendant of birth and valour, of eloquence and oration. Some tribes, however, on the coast of the Baltic, acknowledged the rights of kings; but their kings had not absolute or unbounded power; their authority consisted rather in the privilege of advising than in the power of commanding. Matters of small consequence were determined by the chief men; affairs of importance, by the whole community. As soon as a youth, born of free parents, had attained the age of manhood, he was introduced into the general council of his countrymen, solemnly invested with a shield and a spear, and adopted as an equal and worthy member of the military commonwealth. The assembly of the tribe was convened at stated seasons, or on sudden emergencies. The trial of public offences, the election of magistrates, and the great business of peace and war, were determined by its independent voices. Sometimes these important questions were previously confidered, and prepared in a more select council of the principal chieftains. The magistrates might deliberate and persuade; the people only could resolve and execute. When timid, though just and prudent, counsels were proposed, they expressed their dislike by a hollow murmur. But whenever a popular orator proposed to vindicate the means of citizen from either foreign or domestic injury, whenever he called upon his fellow-countrymen to assist the national honour, or to pursue some enterprise full of danger and glory, a loud clashing of shields and spears expressed the eager applause of the assembly; for the Germans always met in arms. On occasions of danger a general of the tribe was elected; and in circumstances of preying and extensive danger, several tribes concurred in the choice of the same general. The bravest warrior was named to lead his countrymen into the field, by his example rather than his commands. His power expired with the war, and in time of peace the German tribes acknowledged not any supreme chief. Princes were, however, appointed, in the general assembly, to administer justice, or to conduct differences (among the officers, Cafer) in their respective districts. To the choice of these magistrates, birth was regarded as much as merit. To each was assigned, by the public, a guard, and a council of 100 persons; and the heir of the princes appears to have enjoyed a pre-eminence of rank and honour, which sometimes tempted the Romans to compliment him with the regal title. The Germans respected only those duties which they imposed on themselves. The most obscure soldier refilled with disdain the authority of the magistrates. Every individual among the ancient Germans was left at liberty to choose whether he would take part in any military enterprise which was proposed; it became, of consequence, the great object of every person, who aimed at being a leader, to gain adherents and to attract them to his person and intiret. Caesar calls these adherents Ambacti and Clients, i. e. retainers or clients. Tacitus calls them Comites, or companions. The chief distinction and power of the leaders confided in being attended by a numerous band of chosen youth. This was the cause of the great power and reputation of the emperors. The power of the leaders was absolute, and it was the duty of the subjects to support their power and to obey their orders. The leaders gained, or preferred, the favour of these retainers by presents of armour and of horses, or by the prof-use though inelegant hospitality with which they entertained them. But even after they united in society, the Germans circumferibled the criminal jurisdiction of the magistrate within very narrow limits, and exercised almost all the rights of private revenge and revenge. Their magistrates had the absolute disposal of the landed property within their district, and they distributed it every year according to a new division; but they had not the power of imposing, or of inflicting any corporal punishment on a private citizen. Every individual was obliged to avenge the wrongs which his parents or friends had sustained. Their enemies were hereditary, but not irreconcilable. Even murder was compensated by paying a certain number of cattle. A part of the fine went to the king or state, a part to the person who had been injured, or to his kindred. Chastity is not reckoned, without exception, to the wives of the ancient Germans. Polygamy was not in use, except among the princes, and among them only for the sake of multiplying their alliances. Divorces were prohibited by manners rather than by laws. Adulteries were punished as rare and inexcusable crimes; nor was seduction justified by example.
example and fashion. Tacitus evidently indulges an honest pleasure in the contrast of barbarian virtue with the dilatory conduct of the Roman gods; yet there are some striking circumstances that give an air of truth, at least of probability, to the conjugal faith and chastity of the Germans.

The German huts, open on every side to the eye of indiscretion or jealousy, were better safeguards of conjugal fidelity than the walls, the bolts, and the eunuchs of a Persian harem. Besides, the Germans treated their women with esteem and confidence, confined them on every occasion of importance, and fondly believed that in their breasts resided a faculty and wisdom more than human. Some of their interpreters of fate, such as Valleda, in the Batavian war, governed, in the name of the Deity, the nearest nations of Germany. The reft of the sex, without being adored as goddesses, were respected as the free and equal companions of soldiers; associated, even by the marriage ceremony, to a life of toil, of danger, and of glory. In their great invasions, the camps of the barbarians were filled with a multitude of women, who remained firm and undaunted amidst the found of arms, the various forms of destruction, and the honourable wounds of their sons and husbands. The women denounced death much less than servitude. If the day was irrecoverably lost they well knew how to deliver themselves and their children, with their own hands, from an inflicting victor. Heroines of such a cast may claim our admiration; but they were most assuredly neither lovely, nor very susceptible of love.

Conscious pride taught the German females to suppress every tender emotion that stood in competition with honour, and the first honour of the sex has ever been that of chastity.

The religious system of the Germans was dictated by their wants, their fears, and their ignorance. They adored the great visible objects and agents of nature, the sun and the moon, the fire and the earth; together with those imaginary deities who were suppos'd to predece the great part of the most important occupations of human life. They were perfused that by some ridiculous acts of divination, they could discover the will of the superior beings, and that human sacrifices were the most pious and acceptable offering on their altars. If there was any difference between the Gauls and Germans in point of religion, it consisted only in this, that the latter, being more fierce and untractable, were not only more tenacious of their superstitions rites, but likewise more cruel and inhuman in them. It appears, from the testimonies of Caesar, Tacitus, Dio, Suidas, Strabo, Athenaeus, and other ancient authors, that the Germans had no temples, but performed their religious rites in groves erected for that purpose, or in woods, forests, and defert places. Temples were not introduced in Germany till long after the Gauls had erected them; and the inferior divinities introduced among the Gauls, such as Jove or Jupiter, Mars, Apollo, Mercury, Venus, Diana, &c. were also adopted by the Germans, though some of them were represented under different names and attributes. Jupiter was worshipped under the name of Thor or Taran, &c. the Thunderer; this name was given by the Gauls to Mars; and the Germans bestowed it on their Odin or Woden; but the name of Jupiter was never adopted by the Gauls, nor by the Germans. Both Gauls and Germans agreed in worshipping the supreme deity under the name of I hust or Efhus, and under the emblem of an oak, which was consecrated to him. The goddesses Hertha was one of their ancient deities, and her idol was preserved in a wood or grove, "Calum neum," upon a covered seat, and the bad but one priest to pinnifer to her, who was the only person that was allowed to approach her. The worship of this goddess corresponded with that which the Romans and others paid to the "Earth," under the name of "MATER." A solemn procession was occasionally celebrated in the present countries of Mecklenburg and Pomerania. The unknown symbol of the "Earth," covered with a thick veil, was placed on a cartage drawn by cows; and in this manner the goddesses, whose common residence was in the isle of Rugen, visited several adjacent tribes of her worshippers. During her progress, the found of war was hushed, quarrels were suspended, arms laid aside, and the reftles Germans had an opportunity of tafting the blessings of peace and harmony. The "Truce of God," so often and so ineffectually proclaimed by the clergy of the 11th century, was an obvious imitation of this ancient custom.

The influence of religion on the minds of the ancient Germans was far more powerful to inflame than to moderate their fierce passions. The consecrated standards, long regarded, as trophies of superflity, were placed in the front of the battle; and the hostile army was devoted with dire exorcisms to the gods of war and of thunder. A brave man was the worthy favourite of their martial deities; and the wretch who had lost his shield was banished alike from the religious and the civil assemblies of his countrymen. Some tribes of the north seem to have embraced the doctrine of transmigration; others imagined a grofs paradise of immortal drunkenees. (See the Edda, fable 20.) All agreed, that a life spent in arms, and a glorious death in battle, were the best preparations for a happy futurity, either in this or in another world.

It is said that the Germans, as well as Gauls, were early taught by their Druids, as fundamental truths, an overruling providence, and the immortality of the soul; but the noble principles of religion and virtue were soon corrupted as irritments of divination and superstition. Caesar says, indeed, (Com. i. vi. c. 21.) that the Germans had no druids, as the Celts had; but Tacitus, who was better acquainted with the Germans, speaks frequently of their priests, who held office and authority, as he states them, were similar to those of the Gaulish druids, and they seem to have been of the same order of men, though perhaps they did not bear the fame name. As to the immortality promis'd by their priests, it was in some degree conferred by the bards, who by their military songs kindled in the breasts of their audience the enthusiasm of arms and glory. The view of arms and of danger heightened the effect of these songs; and the pations which they tended to excite, the desire of fame, and the contempt of death, were the habitual sentiments of a German mind. A contempt of danger and of death was one of the principles which they instilled into the minds of their youth, and a regard to which their priests inculcated as the furest means of reputation and wealth, and also of happiness in a future life. Under the influence of this principle their armies, which consisted more of infantry than cavalry, were easily rafed and maintained. Like the Gauls and Britons, the Germans fought in separate cantons or tribes; and thus they were induced to exert themselves with the greater firmness and vigour in defence of their relations, neighbours, and friends, and for the honour of their respective communities. We are told, indeed, that some of them, especially the Cimbri, formed their whole infantry into one square battalion, and placed their wives, children, and baggage behind a fence made of their wagons; and when they were prepared for an attack, a signal was given, which was re-echoed by an universal shout, and repeated till the engagement commenced. They used no art or stratagem in fighting, but wholly confided in a furious outlet
G E R M A N Y.

out on the enemy, which they maintained with a deliberate
intrepidity till the day was won or lost: if they were once
thrown into disorder they seldom rallied, but became depe-
rate, and either fought till they were slaughtered, or
took themselves to flight; for it was reckoned inglorious to
yield themselves prisoners. The military weapons of the
cavalry among the Germans were shields and spears, which
they used in common with the foot, but the later had, be-
side their darts, bows and slings, and seldom had recourse
to their pikes and swords. Their arms were adorned with
their favourite furniture and chief ornament; so that they never
appeared in public without them. The sword was so favored,
that the most solemn and obligatory oaths were those which
they took upon a naked blade. Nor did they affect in any
solemn rite, without their sword, shield, or spear. They
then wore them at their familiar visits, banquets, and reli-
gious dances; and they were frequently to be seen or bur-
ried with them, when they died. The sports, games, and
exercitcs of the Germans, were of the masculine kind, and
such as invited them to the operations of war. It was a
long time before they acquired any knowledge of the liberal
arts, or even that of writing; and we are told, that Charles the
Great caused some of their barbarous poems, which they had been accustomed to sing from memory,
and which celebrated the illustrious actions of their ancient
kings and heroes, to be committed to writing for their use,
and in way of encouraging them to learn to read. The
Saxons, it is said, had such a contempt for letters, that they
refused to learn to read the gospels till they were put into
verse, and set to fuch tunes as they could easily sing. Even
their laws were not reduced to writing till about the 12th or
13th centuries.

The native disposition of the ancient Germans displayed
itself chiefly in their martial genius, and in their singular fide-
licity. In some cases their love of liberty, and hatred of ty-
ranny and oppression, precipitated them to acts of treachery
and even of murder; for in such cases they were easily in-
centcd, and extremely vindictive. On other occasions, Tar-
cetiae fay, they were noble, magnificent, and beneficent,
without ambition to aggrandize their dominions, or to invade
those from whom they received no injury; rather chufing to
employ their strength or valour defensively, than offensively;
to preferve their own, than to revenge their neighbours.
In their own houses, furniture and diet, they were distinguished
by their plainness and simplicity; but at the same time, they
were no less distinguished by their hospitality to strangers,
and by their readiness to succour those that were in distress.
Although in most of their customs the Germans very much
resembled the Gauls, yet, with regard to their funerals, they
were very different. The latter performed these obsequies
with pomp and profusion; whereas the Germans discharged
their last offices to the dead with plainness and simplicity;
the only grandeur they affected, was to burn the bodies of their
great men with some peculiar kinds of wood; and afterwards
they flung each man's armour into the funeral pile, and
sometimes his riding drefs. They then deposited their ashes
in urns, like the Gauls, Romans, and other nations. It may
be observed in general, that as the fuperstition for the dead,
the reverence made to them at their funerals, and the other superfluous rites performed on these occasions,
were all the result and the evidence of an established belief,
that the soul was immortal.

The ancient Germans were a brave and independent race
of men, and peculiarly distinguished by their love of liberty
and arms. They opposed the Roman power, after it had
arrived at maturity. After their contest with Caesar, who
was provoked by the Treviri to invade their country, and
their revolt against Augustus, which was suppressed by
Agrrippa, and the insurrection which commenced among the
Roman legions in Pannonia, quelled partly by Drusus, and
finally by Germanicus; their other more considerable wars
with the Romans were waged against the emperors M. Aure-
lius, Alexander, Maximian, Valerian, Aurelian, Probus,
Constantius, Julian, Valentinian, and some of his succeffors.
Some notice is taken of these conflicts under the names of the
Alemanni, Geretides, Franks, Suevi, Heruli, and Burg-
dundians. Their country was divided into a number of petty
foreigncities, independent of each other, though occasionally
connected by a military union, until it was reduced to the
condition of a Roman province; and when the Roman em-
pire was shattered by the Northern barbarians, Germany was
over-run by the Franks about the year 480; and continued in
subjection to chieftains of that nation, who governed over
the Saxons, Alemans, Frisians, Saxons, Thuringians, and
Bavarians, until the end of the eighth century, when Char-
lemagne united all Germany into one kingdom, as part of the
Frankish monarchy. The conquered German nations
had hereditary dukes of their own at first, and were govern-
ed by their own laws: but Charlemagne put an end to the
former, and governed the different German provinces by
counts and royal delegates, and in the year 800 he assumed
the title and dignity of emperor. But the empire of Char-
lemagne was a structure erected in fo short a time, that it
could not be of long duration. Under his immediate suc-
cceflor it began to totter, and soon after fell to pieces.
The crown of Germany was separated from that of France, and
the descendants of Charlemagne established two great mon-
archies, one at Rome, as to give rife to a perpetual rivalfhip
between them. But the princes of the race of Charlemagne,
who were placed on the Imperial throne, were not altogether
degenerate as thoee of the same family who reigned in
France. In the hands of the former, the royal authority re-
tained some vigour; the nobles of Germany, though poffef-
sed of extensive privileges and ample territories, did not fo early
attain independence. The great offices of the crown con-
tinued at the disposal of the sovereign, and during a long pe-
niod, they remained in their original state without becoming
hereditary in the families of the persons to whom they had
been granted.

At length, the German branch of the family of Char-
lemagne became extinct upon the death of Louis IV. His
foible descendants who reigned in France had funk into
fuch contempt, that the Germans, without looking
{229}towards them, excerciced the right inherent in a free people;
and in a general assembly of the nation at Worms, in the
year 911, offered the imperial crown to Otho, duke of Sax-
ony, who declined it on account of his great age, and recom-
{230}mended Conrad, count of Franconia. The latter was unani-
mously elected emperor. His reign was disturbed by the dif-
obedience of some nobles whom he subdued, and by the pre-
tenfions of Henry, fon of the duke of Saxony, his benefactor.
Their quarrels, however, did not prevent Conrad from ac-
knowledging the merit of that prince in the fame manner as
Otho had done his. He recommended Henry as the fittest
prince to be his fuccelfor, and the ledgment being approved
by the nation, he went to Henry, without waiting for the hour
of death, the crown, the sceptre, the lance, the sword, and
other imperial ornaments.

Henry I. ascended the imperial throne of Germany in
919. He was surnamed the Fwedcr, because he was paffion-
ately fond of hawking. To confirm his authority, he made
more use of perfuafion than of arms. His defendants, the
three Othus, were placed in fucceffion on the imperial throne
by the suffrages of their countrymen. The extensive terri-

Vol. XVI
otaries of the Saxon emperors, their eminent abilities, and en-
tering genius, not only raised new vigour to the imperial
dignity, but raised it to higher power and pre-eminence. Otto
the Great marched at the head of a numerous army into
Italy, and, after the example of Charlemagne, gave law to
that country. On his arrival at Rome, he was consecrated
by the pope, and crowned emperor of the Romans. He
created popes and deposed them by his sovereign mandate.
He annexed the kingdom of Italy to the German empire.
Elated with his successes, he assumed the title of Caesar Aug-
gustus. A prince, born in the heart of Germany, pretended
to be the successor of the emperors of ancient Rome, and
claimed a right to the same power and prerogative. See the
Biographical Article Otto.

But while the emperor, by means of these new titles and
new dominions, gradually acquired additional authority and
splendour, the nobility of Germany had gone on at the same
time extending their privileges and jurisdiction. The situation
of affairs was favourable to their attempts. The vigour which
Charlemagne had given to government quickly relaxed. The
imperial power of the emperors was found insufficient to have
encouraged valiant, less enterprising than the nobles of that
age, to have claimed new rights, and to have afforded new
powers. The civil wars in which other emperors were en-
gaged, obliged them to pay perpetual court to their subjects,
so whole support they depended, and not only to convoy at
their usurpations, but to permit and even to authorize them.
Elefs gradually became hereditary. They were transmitted
not only in the direct, but also in the collateral line. The
iniquity of them was demanded not only by male but by
female heirs. Every baron began to exercise sovereign jurisdic-
tion within his own domains, and the dukes and counts of
Germany took wide steps towards rendering their territories
disunited and independent states. The Saxon emperors ob-
erved their progress, and were aware of its tendency. But
as they could not hope to humble vassals already grown too
potent, and as they had turned their whole force and atten-
tion to that enterprise, and as they were extremely intent on
their expeditions into Italy, which they could not undertake
without the concurrence of their nobles, they were solicitous
not to alarm them at the same time by their prudence. They
aimed, however, at undermining their power. With
this view, they inconsiderately bestowed additional territories,
and accumulated new honours on the clergy, in hopes that this
order might serve as a counterpoise to that of the nobility
in any future struggle.

The unhappy effects of this fatal error in policy were
quickly felt. Under the emperors of the Franconian and
Swabian lines, whom the Germans, by their voluntary elec-
tion, placed on the imperial throne, a new face of things
appeared, and a fece was exhibited in Germany which ablo-
nished all Christendom at that time. The popes, hitherto
dependent on the emperors, and indebted for power as well
as dignity to their beneficence and protection, began to claim
a superior jurisdiction, and in virtue of authority, which
they pretended to derive from heaven, tried, condemned, ex-
communicated, and deposed their former masters. These
pretensions gave rise to the factions of the Guelfs and
Ghibellines, of which the former was attached to the popes,
and the latter to those of the imperial house. Emperor Gregory VII. had ob-
served that the princes and nobles of Germany had acquired
such considerable territories and such extensive jurisdiction,
as rendered them not only formidable to the emperors, but
dispelled them to favour any attempt to circumscribe their
power. He forewove that the ecclesiastics of Germany, raised
almost to a level with its princes, were ready to support any
person who would stand forth as the protector of their pri-

vileges and independence. With both of these Gregory ne-
gotiated, and had secured many devoted adherents among
them, before he ventured to enter the lists against the head of
the empire. He began his rupture with Henry IV., upon a
pretext that was popular and plausible. He complained of
the venality and corruption with which the emperor had
granted the indulgence of benefices to ecclesiastics. He con-
tended that this right belonged to him, as the head of the
church; he required Henry to confine himself within the
bounds of the civil jurisdiction, and to abstain for the future
from such sacrilegious encroachments on the spiritual
mission. All the censures of the church were denounced
against Henry, because he refused to relinquish those powers
which his predecessors had uniformly exercised. The most
considerable of the German princes and ecclesiastics were ex-
cited to take arms against him. His mother, his wife, his
funs, were brought upon to diffuse all the ties of blood
and duty, and to join the party of his enemies. At length,
the emperor was even obliged to appear as a supplicant at
the gate of the castle in which the pope resided, and to
bknd the chance of three days in痞求的ent, implo-
ing a pardon, which he obtained with difficulty.

This act of humiliation degraded the imperial dignity.
The two factions kept Germany and Italy in perpetual agi-
tation during three centuries, and, notwithstanding the re-
turn of some short intervals of vigour, under the administra-
tion of a few able emperors, the imperial authority continued
to decline. During the anarchy of a long interregnum, sub-
sequent to the death of William of Holland, it dwindled
down almost to nothing.

In the year 1273, Rodolthus of Hasburgh, the founder
of the house of Austria, was elected emperor, not that he
might re-establish and extend the imperial authority, but
because his territories and influence were so inconsiderable as to
force to his various nobles, who were willing to
prefer the forms of a constitution, the power of which
they had destroyed. Several of Rodolhus's successors were
placed on the imperial throne from the same motive, and al-
most every remaining prerogative was wrested out of the hands
of feeble princes, unable to exercise or to defend them.

During this period of turbulence and confusion, the con-
stitution of the German empire underwent a total change.
The princes, the great nobility, the dignified ecclesiastics,
and the free cities extended their usurpations. They claimed
and exercised the right of governing their respective terri-
tories with full sovereignty. They acknowledged no supe-
rior with respect to any point relative to the interior admi-
nistration and police of their domains. They enacted laws,
imposed taxes, coined money, declared war, concluded peace,
and exerted every prerogative peculiar to independent
states. The forms of feudal subordination formed the only
connection among the various members of the community.
This bond of union, however, was extremely feeble.

From the accession of Rodolph of Hasburgh, to the
reign of Maximilian, the empire felt every calamity which
a state must endure, when the authority of government is so
much relaxed. The diffusions among its members gave rise
to perpetual private wars, which were carried on with all the
violence that accompanies resentment when unrestrained by
superior authority. Rapine, outrage, exactions, became un-
iversal. The variety of expedients employed to restore order
and tranquillity, prove that the grievances occasioned by this
state of anarchy had become intolerable. Arbitrators were
appointed to terminate the differences among the several
states. The cities united in a league to check the extortions
of the nobility, and the latter formed confederacies to main-

Germany.  

Certain tranquility among their own order. Germany was divided into ten circles, in each of which a provincial jurisdiction was established. But all these remedies proved ineffectual. At length Maximian instituted the imperial chamber, a tribunal composed of judges named partly by the emperor, partly by the several states, and vested with authority to decide finally concerning all differences among the members of the Germanic body, and thus restored some degree of vigour to the imperial authority.

But by diminishing the salutary effects of these regulations, the political constitution of the German empire, at the beginning of the sixteenth century, was of a species so peculiar as not to resemble perfectly any form of government known either in the ancient or modern world. It was a complex body, formed by the association of several states, electors, princes, dignitaries of the church, counts, barons, and free cities, each of which possessed sovereign and independent jurisdiction within its own territories. Of all the members which composed this united body, the emperor was the head. In his name all decrees and regulations, with respect to points of common concern, were placed; and to him the power of carrying them into execution was committed. But this appearance of monarchical power in the emperor was more than counterbalanced by the influence of the princes and states of the empire in every act of administration. No law extending to the whole body could pass, no resolution that affected the general interest could be taken without the approbation of the diet of the empire held at Ratisbon. In this assembly every sovereign prince and state of the Germanic body had a right to be present, to deliberate and to vote. The decrees or resolutions of the diet were the laws of the empire, which the emperor was bound to ratify, and to enforce. In this respect the German empire was similar to the Achæan league in ancient Greece, or to that of the United Provinces of the Netherlands, and of the Swiss cantons in modern times. But, as the acute historian of the emperor Charles V. observes, the Germanic body was not formed by the union of members altogether distinct and independent. All the princes and states, joined in this association, were originally subject to the emperors, and acknowledged them as sovereigns. They originally held their lands as imperial fiefs, and owed the emperor all those services which feudal vassals are bound to perform to their liege lord. But though this political subjection was entirely at an end, the ancient forms introduced while the emperors governed Germany with authority not inferior to that which the other monarchs of Europe possessed, still remained. Thus an opposition was established between the genius of the government and the forms of administration in the German empire. The formers considered the emperor only as the head of a confederacy, the members of which, by their own volition, chose him to that dignity; the latter seemed to imply that he is really invested with sovereign power. The emperors were distinguished by the most pompous titles, and by such marks of dignity as intimated their authority to be superior to that of all other monarchs. The greatest princes of the empire attended and served them, on some occasions, as officers of their household. They exercised prerogatives which no other sovereigns ever claimed. They retained pretensions to all the extensive powers which their predecessors had enjoyed in any former age. But, at the same time, instead of possessing that ample domain which had belonged to the ancient emperors of Germany, and which stretched from Baill to Cologne, along both banks of the Rhine, they were stripped of all territorial property, and had not a foot of land that belonged to them as heads of the empire. Their revenues were reduced almost to nothing, and the extraordinary aids which, on a few occasions, they obtained, were granted sparingly, and paid with reluctance. The confluence of this ill-compacted frame of government was, that the emperors imagined themselves to be the real sovereigns of Germany, and aimed continually at recovering the exercise of those powers which the forms of the constitution seemed to vest in them, and which their predecessors Charles-magne and the Ottos had actually enjoyed. The princes and states, aware of these pretensions, watched the motions of the imperial court to curtail the power within limits still more narrowed. This salutary of the imperial authority increased confederately from the time that the elective power was vested in a few princes of chief dignity.

During a long period, all the members of the Germanic body had a right to assemble, and to make a choice of the person whom they appointed to be their head. But amidst the violence and anarchy which prevailed for several centuries in the empire, seven princes, who possessed the most extensive territories, and who had obtained an hereditary title to the great offices of the state, acquired the exclusive privilege of nominating the emperor. This right was confirmed to them by the golden bull (see Bull); the mode of exercising it was afockerted, and they were dignified with the appellation of Electors. (See Elector.) The nobility and free cities, being thus stripped of a privilege which they had once enjoyed, were left connected with a prince, towards whose elevation they had not contributed by their suffrages, and came to be more apprehensive of his authority. The electors, by their extensive power, and the distinguishing privileges which they possessed, became formidable to the emperors, with whom they were placed almost on a level in several acts of jurisdiction. Thus, the introduction of the electoral college into the empire strengthened the principles of discord in the Germanic constitution, which were continually alimented by the various and repugnant forms of civil policy in the several states. The free cities were small republics, in which the maxims and spirit peculiar to that species of government prevailed. The princes and nobles to whom supreme jurisdiction belonged possessed a sort of monarchical power within their own territories. Their common deliberations could not be carried on with the same spirit while the love of liberty and attention to commerce were the reigning principles in the cities; and the desire of power, and ardour for military glory, the governing passions of the princes and nobility. The secular and ecclesiastical members of the empire were as little fitted for union as the free cities and the nobility. Considerable territories had been granted to several of the German bishops and abbots, and some of the highest offices of the empire, having been annexed to them unalienably, were held by the ecclesiastics raised to these dignities, while the younger sons of noblemen of the second order, who had devoted themselves to the church, were commonly promoted to these stations of eminence and power; and it was no small mortification to the princes and great nobility, to see persons raised from an inferior rank to the same level with themselves, or even exalted to superior dignity. The education of these churchmen, the genius of their profession, and their connection with the court of Rome, rendered their character, as well as their interest, different from those of the other members of the Germanic body, with whom they were called to act in concert. Thus another source of variance was opened.

To all these causes of disfension must be added one more, arising from the unequal distribution of power and wealth among the states of the empire. The electors and other nobles of the highest rank not only possessed sovereign jurisdiction, but governed such extensive, populous, and rich countries.
countries, as rendered them great princes. Many of the other members, though they enjoyed all the rights of sovereignty, ruled over such petty domains, that their real power bore no proportion to this high prerogative. The electors and emperors, by turns, endeavoured to extend their own authority, by encroaching on those feeble members of the Germanic body, who sometimes defended their rights with much spirit, but more frequently, being overwhelmed or corrupted, tamely surrendered their privileges, or merely favoured the designs formed against them.

But the empire of Germany comprehended countries of such vast extent, and was inhabited by such a martial and hardly race of men, that when the abilities of an emperor, or zeal for any common cause could rule this unwieldy body, it was still able to act with force. Charles V. grand son of Maximilian, and heir to the kingdom of Spain, in right of his mother, was elected emperor in the year 1519. In his reign happened the reformation of religion caused by Luther, which occasioned incessant wars till 1648. (See Luther and Reformation.) There were moments when Charles V. flattered himself with the hope of being able to hold the balance between the Roman Catholics and the Lutherans. But the contending parties were too much inflamed with animosity, and in addition to his wars against Francis I. of France, he was forced to sustain a violent one in the heart of the empire. Fortune, which smiled upon him in the beginning of his reign, forsook him towards its end. He abdicated the imperial throne, in 1558, in favour of his brother Ferdinand I., who had the address of getting his son Maximilian II. declared king of the Romans, or successor to the imperial crown in his lifetime. This precaution became familiar to the house of Austria, and kept the imperial sceptre in that family, until the extinction of the German empire. By his last will Ferdinand ordered that if either his own male issue, or that of his brother Charles should fail, his Austrian estates should revert to his second daughter Anne, wife to the elector of Bavaria. This circumstance is the origin of the opposition made by the house of Bavaria, in later times, to the Pragmatic sanction in favour of Maria Theresa, mother of Joseph the second.

The reign of Maximilian II. was disturbed by internal commotions, and an invasion from the Turks. He died in 1576, and was succeeded by his son Rodolph, who was involved in wars with the Hungarians, and in differences with his brother Matthias, to whom the empire devolved at his death. Having no children, Matthias conferred the crown of Hungary on his cousin Ferdinand arch-duke of Austria, and caused him to be elected king of Bohemia, which election proved the source of a long war. Ferdinand perfecuted the numerous sectaries in Bohemia. They took up arms; the brave Mansfeld fought at their head, and Matthias, who came to the assistance of his kinsman, died of vexation, for not having been able to obtain a complete triumph over the Bohemians. A tender of the imperial crown was made to Maximilian, duke of Bavaria, but he prudently declined the offer. Ferdinand was therefore proclaimed emperor in 1619, but the Bohemians, maintaining that the same individual could not wear the crown of Germany together with that of Bohemia, conferred the latter on Frederick, the elector palatine. Yielding to the intrigues of his fiancee Elizabeth, daughter of James I. of England, against his own conviction, Frederick made a splendid triumphal entry into Prague; but a few days after, his army was attacked on the heights near the town, and completely routed. He was obliged to fly with his wife and children, and found at last an asylum in Holland. His defeat was the beginning of the thirty years' war which ravaged Germany, from the Danube and the Rhine to the shores of the Baltic, without little intermission from the battle of Prague to the peace of Weilphalia. The unfortunate Frederick, who had been put under the ban of the empire, died broken-hearted. Ferdinand's arms were almost constantly victorious against the Protestant princes for the space of ten years. He was on the point of crushing their party when Guilielmus Adolphus of Sweden rushed upon him. In vain did the Imperialists commanded by Tilly endeavour to check his career; they were defeated and disheartened. Ferdinand was going to sue for peace when the fall of the Swedish monarch at Lutzen re-animated his hopes: Wallenstein's defection did not arrest his arm. He continued fighting against his Protestant vassals till the hour of his death, which happened in 1637. The war raged with unabated fury under his son Ferdinand III., who was appointed his successor on the imperial throne. The Protestant cause was ably defended by the heroes brought up under the great Guilielmus Adolphus. History will never forget the names of the duke of Saxony, of Brandenburg, of Austria, of Tuscany, and many others who shook the Austrian power, till at length a general peace was concluded in 1648, which being guaranteed by Sweden and France, has been considered for a century and a half as forming the basis of the political system of Europe, under the name of the peace of Munster or peace of Weilphalia.

Leopold I., who was elected emperor of Germany, after the death of his father Ferdinand III. in the year 1657, had to combat the French on one side, and the Turks on the other. The latter advanced to the walls of Vienna, but were compelled to raise the siege by the valour of John Sobieski, king of Poland. The fertile province of Alsace was conquered by France, but the Turks, having been repeatedly defeated by prince Eugene of Savoy, were forced to cede Transylvania by the peace of Carlowitz. During Leopold's long reign, the duke of Hanover was admitted into the electoral college, the elector of Saxony obtained the elective royal crown of Poland, the elector of Brandenburg was acknowledged hereditary king of Prussia, and a prince of the Bourbon family was seated on the Spanish throne. Leopold died in 1705. The reign of his son Joseph I. lasted but six years, and is remarkable only for the victories which the great duke of Marlborough gained in his cause over the French. As he left no male issue, the elector of Mayence exerted all his influence to procure the imperial crown to his brother the archduke Charles, who was at that time in Spain, disputing the crown of that kingdom with Philip of Anjou, grandson to Louis XIV. The elevation of Charles to the empire terminated the contests which had harassed Spain and Germany. The peace of Utrecht, concluded in 1713, was followed by that of Baden with France in 1714, and that of Passawitz with the Turks in 1717.

Charles VI. intent upon securing his hereditary dominions to his archduchess Maria Theresa his daughter, framed that famous Pragmatic sanction which was soon to disturb again the peace of Germany. Happily for him the crown of Great Britain devolved to the house of Hanover, which circumstance drew the connection of Austria and England against their common enemy more close. Charles VI. married his daughter to Francis duke of Lorraine, and died in 1740. No sooner was he in the grave than the Pragmatic sanction was attacked on all sides. The great Frederick of Prussia conquered Silesia, and Spain and Bavaria preferred their claims on several provinces. The intrigues of France caused the imperial throne to be filled, after an interregnum of two years, by the elector of Bavaria, who took the name of Charles VII., and was proclaimed emperor in 1742. But
But after five years of disastrous warfare, he died deprived nearly of all his states. Maria Theresa had sufficiently influence to place her husband on the throne of the empire in 1745. Francis I. was acknowledged as emperor of Germany by the king of Prussia at the peace of Dresden, signed on the 25th of December 1745, and by the French, at the peace of Aix-la-Chapelle in 1748.

The interval of peace which Germany enjoyed was not of long duration. Frederick the Great of Prussia having discovered the plots which were formed against him by the emperor, the elector of Saxony, Russia and France, and being beseiged by England, occupied Saxony, and refilled the attacks of his numerous enemies with alternate successes, for the space of seven years. Peace was at length signed once more at Hubertsburgh on the 15th of February 1753. Francis I. died two years after. His son Joseph II, who had been declared king of the Romans in 1764, was proclaimed emperor after his death. His attempt to polish himself of part of the dominions of Charles Theodore, the last elector of Bavaria, who died in December 1777, disturbed the peace of Germany. No battle of any consequence was fought: the Austrians routed the Prussian armies; but the severe winter campaign of the latter end of 1778, and the beginning of 1779, having thinned the ranks of both, the treaty of Teschen was concluded on the 13th of April 1779, and the peace of Wilhelmina appealed to, and confirmed for the last time. Maria Theresa left her hereditary dominions to her son Joseph II. at her death, which happened in 1780. Frederick the Great of Prussia, who was the last pilar of the Germanic constitution, died in 1786.

Ambitious of imitating the example of his illustrious opponent, Joseph II. introduced many salutary reforms in the administration of his dominions, proclaimed an unbounded religious toleration, suppressed a number of useles convents, abolished the use of the rack in criminal inquisitions, and extinguished the remains of servitude and vilainage which oppressed the peasants of his dominions. But his well-intended innovations were too sudden. Discontents broke out in the Netherlands, which he vainly attempted to stifle by force instead of adopting conciliatory measures. The rebellion of his Flemish subjects broke his heart. He died childless, though he had been married twice; and his brother Leopold, grand duke of Tuscany, succeeded him on the imperial throne in 1790. His unfortunate engagement with the king of Prussia and the elector of Saxony, to oppose the French revolution with all their might, and to assist the emigrants in their attempts to re-enter France by force, hastened the violent measures of the war party in France, which ultimately led to the extinction of the German empire. He died on the 1st of March 1792. His son Francis II. was raised to the imperial throne in the middle of July following. He embarked in the confederacy formed against France, left the Austrian Netherlands, the Brugia, and all his possessions in Italy, and was at length obliged to abdicate the imperial throne of Germany, and to be contented with the title of emperor of Austria. See CONFEDERATION OF THE RHINE.

The peace of Wilhelmina, which had been regarded as the basis of the political system of Europe, had, in fact, done the death of the division of the German empire, by conferring on each prince and state of the German empire the privilege of contracting alliances in their own name. Their interests were continually clashing with each other. The irresistible force of revolutionary France has only accelerated a disorganization, which would infallibly have taken place, through the rivalship of the Austrian and Prussian monarchs, supported, one by the Catholic, and the other by the Protestant states. Composed of such discordant materials, it is rather a matter of surprise that its existence as a state should have been protracted to the length of one thousand years.

The Germans never formed a nation united by the ties of similar habits, laws and religion. These differed in almost every petty principality, and the tie of language, from its many idioms and different pronunciation, was so weak, that the national hatred of the inhabitants of the Prussian dominions against those of the Austrian states was as great as that which prevails between the English and the French. The difference between the Protestant and Catholic countries was also so considerable, that whilst farmers in the former enriched their labour by study, the clergyman in the latter were even ignorant of the first four rules of arithmetic. Politzell, a Saxony farmer, who was a fellow of the Royal Society of London, died in 1788, and six months before his death a clergyman was wanted, in the gazette of Cologne, capable of teaching the rudiments of common arithmetic.
The only feature which may be marked as a national one in the Germans of all perfusions and places, is the industry which prevailed among the middle and lower ranks, and the pride and haughtiness of the nobility. As soldiers, the Germans, when ably commanded, have always shown themselves endowed with steady courage and perseverance of strength. But the name of German is extinct. Henceforth the traveller must inquire into the peculiar character and disposition of the Austrian, Prussian, Saxon, Bavarian, Westphalian, and the inhabitants of Wurttemberg, Baden, Berg, Hesse, Darmstadt, Nassau, and the other smaller states of the confederacy of the Rhine. GERMANY, in Geography, a town of America, in Adams' county, Pennsylvania, containing 1013 inhabitants.

GERMEN, or GERM. See EMBRYO.

GERMEN, in Botany and Vegetable Physiology, the rudiments of the fruit, constituting one of the two essential parts of the flower, the stigma being the other; the style, which usually elevates the latter, not being indistinguishable, nor always present. The Latin word, germ, properly means a bud, or sprout (see GEMMA); which latter, in scientific language, is now universally used in its stead. Linnaeus therefore applied the word technically, and very happily, to the seed—bud, or origin of the future offspring, which had as yet no appropriate name. In this he is generally followed, even by the only person who could effectively have contended with him in such a point, the celebrated Buffon. Nevertheless, Gartner, affuming some well-founded authority on account of his valuable labours reflecting fruits and seeds, prefers the word exuvium, borrowed from anatomists, for it is not classical Latin. The only reason for this innovation is, as he is pleased to express it, that Linnaeus "falsus imprudens" calls this part germ. The authority of Gartner has unfortunately misled one excellent writer of late to adopt the term exuvium, by which we object, not so much for its want of classical authority, as it might well be defended on the ground of analogy, but because it is not appropriate, and is not used by Gartner in the original anatomical sense, but in a new and arbitrary one. Vegetables have no such organ as the exuvium of animals. Plants, much more correctly, calls the germ the uterus; but this is improper for plants with naked seeds; whereas germ is applicable in all cases to the rudiment of the fruit, whatever its nature may
may be. Such a comprehensive term is of the more value, as not having any respect to the disputable point of whether any seeds be really naked or no. We agree with Gartner that they cannot in their origin be naked, but must have some integument through which they are impregnated; see *Reconstitution of Plants*. In an advanced state the same able author could not but allow the existence of naked seeds in a certain sense, that is, such as have only their own external integuments, but no external *pericarpium* or seed-veil.

Gartner's erroneous conclusions the Linnaean hypothesis, that the germinates the pith of the plant, as the Ramses from the woody part. This idea was purely hypothetical, and is unsupported by any anatomical fact, however ingenious the theory of generation deduced from it by the illustrious Swede.

The germinates as early as any part of the flower, of which indeed it frequently constitutes the base. Before the stigma is ripe for impregnation, all the internal parts of the germinates, especially the young seeds, receive their due shape and structure, except only the embryo, the rudiments of which can scarcely be detected at that period. If no impregnation takes place, the germinates, and even the seeds sometimes continue to grow, but a cavity only in such case will be found in the place of the embryo, which has at least proved abortive and withered away, if it ever had any existence. More frequently indeed only the husks or withered rudiments of seeds are found in an advanced unimpregnated germinates; and still more generally the whole germinates withers if the husks and stigmas have not performed their office.

Germinates are either solitary or numerous, simple or aggregate, in different genera of plants. With respect to situation, it is important to note whether the germinates be superior, that is, above the bases of the calyx and corolla, or inferior, below them. Such a difference commonly marks a very essential generic distinction, yet in that most natural genus *Saxifraga*, some species have a superior and others an inferior germinates. This proves, on a careful anatomic investigation, to depend merely on a greater or less degree of elevation of the organ in question within the cavity of the calyx. Indeed such an investigation of flowers in general will shew that there is perhaps no such thing as an inferior germinates, strictly speaking, because there must necessarily be a continuation of the integuments of the flower and their veils, in some form or other, along the outer part of what is commonly deemed an inferior germinates, to the stalk whence their nourishment is derived. But this "were to consider too curiously." The line is in almost every case drawn with sufficient distinctness for all useful purposes, and is generally indicated in due time by a spontaneous separation of parts. *Sanguinaria* is erroneously judged by Linnaeus to have the germinates below the corolla though above the calyx, a drague and unexampled circumstance indeed! He was misled by the close adhesion of the thin papillose tube of the corolla to the germinates. In *Adonis*, however, there is an approach towards such a singularity of structure, the calyx being inflected half way down, while the corolla crowns the germinates, for this plant, being akin to *Saxifraga*, partakes of that irregularity of position in the germinates which we have already described.

Nothing is more wonderful than that difference of vascular constitution in the germinates of different genera or natural orders, by which, though in all cases nearly equally juicy while young and growing, in some it becomes corymbose, or woody, and dry, as it ripens, while in others it attains a soft pulpy consistence, which obliterates all its original natural structure. The wise ends answered by these differences are indeed apparent, but the means by which they are accomplished are, if not inferable, at least unexplained.

GERMEN, Sr., in Geography, a town of France, in the department of the Oise; 12 miles W. of Beauvais.

GERMERSHEIM, a town of France in the department of Mont Teenere, and chief place of a canton, in the district of Spire; 5 miles S. of Spire. The place contains 1251, and the canton 11,735 inhabitants, in 16 communes. It is situated at the confluence of the Queich and the Rhine, and was erected into a town by Rodolphus II., who died here in 1290. It was taken by the French in 1794. N. lat. 49 12. E. long. 8 25'.

GERMINATION, in Vegetable Physiology, the first beginning of vegetation in seeds, is accomplished by moisture, heat, and air, acting mechanically and chemically on the substance and component parts of the seed, as well as stimulating its vital principle. These agents must perform their functions together, in order to produce a vital effect, otherwise the vital principle, or the chemical properties of the seed, may be stimulated or spoiled, nor must their application, generally speaking, be longer delayed than usually happens in the ordinary course of nature. Some seeds, indeed, may be kept out of the ground for years, or may remain buried far beneath its surface, we know not how long, without losing their vegetative power; while others must scatter themselves in their own way, immediately from the seed-veil, in order to succeed with certainty. A seed absorbs, through the velum of its base, or face, any moisture that comes in its way, and it soon meets with such a supply when committed to the ground, at the same time receiving throughout its whole substance, a definite portion of heat, some seeds requiring more than others. Atmospheric air is also necessary to the germination of seeds, on account of the oxygen gas which makes a part of its composition, and which modern chemists have found to be absorbed by seeds, in the moments of incipient germination, from or through the surrounding soil. This appears from their being incapable of vegetation while buried deep in the earth, or while under the exhausted receiver of an air-pump; though such as have been so situated immediately grow, when the atmosphere has access to that part of the foil in which they lie. By the above agents the bulk of the seed is increased, and its vital principle stimulated. The integuments burst, and the radicle, or young root, protrudes, which being most susceptible of the influence of moisture, for that reason (as Dr. Darwin ingeniously judged,) elongates itself in the direction where it meets with this influence, increasing chiefly at the extremity, and descending into the earth. It is a well-known fact that the radicle takes this direction, in whatever position the seed may happen to lie. Dr. Darwin's seen to us the full explanation of this curious law of the vegetable constitution, and preferable to any one founded on principles of mechanics or of gravitation. Accordingly, the rudiments of the young plant, constituting the cotyledons and plumula or bud, being most stimulated by air, raise themselves out of the ground, entirely for the most part, in pursuit of it. If some few cotyledons do remain and wither under ground, it is only because they have already met with a sufficiency of air or oxygen to answer their destination. See COTYLEDONES.

During the process of incipient germination, the immediately necessary fulplings of nourishment, till the young root can derive any from the soil, are furnished by the *albumen*, a substanee either constituting a separate body of itself, as in grapes, corn, palms, &c., which, from a hard, dry, and scttlec mats, changes, by the action of water and oxygen, into a milky or facehairy fluid, withes the operation
tion of making; or the same substance is lodged in, or united with, the bulk of the cotyledons, as in the leguminous tribe. If the albumen happens to suffer chemical deterioration, by keeping or otherwise, the feed germinates more feebly, or not at all. Hence gardeners prefer old feeds of melons and cucumbers, as producing less luxuriant plants, and more fruit in proportion. We presume the consequences of keeping affect the chemical qualities of the albumen before the vital principle suffers, because of the success of recent French chemists, who by the copious application of oxygen restore their original nature. See this whole subject more fully detailed in the Transactions of the Linnean Society, vol. 9. p. 202—217. 8.

GERMISCH, in Geography, a town of Germany, in the province of Fresny, 21 miles S. of Weilheim.

GERMONIO, Anaxiastes, in Biography, was born at Salo, in Piedmont, in 1551; his education was almost entirely neglected till he had attained the age of manhood. Feeling, at this period, his own deficiency, he applied himself with so much diligence, that in the course of a few months he felt equal to engage in the study of the law. He took his degree at the university of Turin, and was appointed to the professorship of the canon-law, an office which he held, in conjunction with other posts of honour and emolument, till his archbishop was created a cardinal; he then accompanied him to Rome, and acquired the esteem of Sixtus V. and the succeeding pontiffs. He was appointed by Clement VIII. to assist in compiling the seventh book of decrees, in which were inserted the decrees of the council of Trent, with explanations. After this he was entrusted by the dukes of Urbino and Savoy with the management of their concerns at the see of Rome. So high was his reputation, that two bishops were offered him which he refused, but at length accepted the archbishopric of Taranto, in Savoy. He was next sent embassador, by duke Charles Emanuel, to the court of Madrid, where he died in 1627. Besides his notes on the Decrees, and other smaller pieces on the Digest and Code, he published "De Sacerorum inimicittatis Lib. tres, &c." printed at the Vatican, 1591:—"Pomeridianæ felicium in quibus Latina Linguæ dignitas defenditur," &c. His writings are highly esteemed for the purity of the language and the accuracy of the refutation. Moreri.

GERMS, in Geography, a town of Austria; 62 miles W.N.W. of Vienna. N. lat. 48° 32'. E. long. 15'.

GERMUK, a town of Asiatic Turkey; 45 miles W. of Diarbeikir.

GERN, a town of Russia, in the government of Tav; 28 miles W.S.W. of Tula.—Also, a town of Bavaria; 15 miles W.N.W. of Braunau.

GERNACH, a town of Germany, in the principality of Wurzburg; 5 miles W.N.W. of Gerdhoien.

GERNOI, a fortress of Russia, in the government of Kolivan, seated on the Irithich; 204 miles S.W. of Kolivan. N. lat. 51° 45'; E. long. 78° 14'.

GERNOI, a fortress of Russia, in the government of Kolivan, on the Irithich; 196 miles S.W. of Kolivan. N. lat. 52° 30'; E. long. 77° 14'.

GERNORITZKOW, a fortress of Russia, in the government of Kolivan, on the Irithich, 180 miles W.S.W. of Kolivan. N. lat. 52° 45'; E. long. 77° 34'.

GERNRODE, a town of Germany, in the principality of Anhalt Berinh, in which was an abbey founded in 666, and richly endowed for ladies, by Gero, margrave of Lusatia, which was secularized in favour of the house of Anhalt, at the peace of Weilphalia; 30 miles W. of Delhau. N. lat. 51° 45'; E. long. 11° 20'.

GERNSHEIM, or Gernsheim, a town of Germany, given, in 1802, to the landgrave of Hesse-Darmstadt; 81 miles E.E. of Mentz.

GERNOSZEG, a town of Transylvania, on the river Maros; 10 miles S.W. of Kerefattur.

GEROCOMIA, of sacred, and religious, i.e. religious; a term used by the ancients for that sort of medicinal practice which treated of the proper regimen to be observed in old age.

GEROLA, in Geography, a town of Germany, in the territory of Eichfeld, with a rich Benedictine abbey; eight miles N.E. of Duderstadt.

GERODOT, a town of France, in the department of the Aube; nine miles E. of Troyes.

GEROLDSHOFEN, a town of Germany, in the bishopric of Wurzburg; 26 miles N.E. of Wurzburg.

GEROLDSTEIN, a town of Germany, in the county of Katzenelnbogen; seven miles S. of Naftede.

GEROLSTEIN, a town of France, in the department of the Sarro, and chief place of a canton, in the district of Prum; 24 miles N. of Treves. The place contains 550, and the canton 2892 inhabitants, in 29 communes. N lat. 50° 16'. E. long. 6° 58'.

GERON POINT, a cape of Ireland, in the county of Antrim, on the east coast. W. long. 5° 50'. N. lat. 55° 3'.

GERONA, or Gironne, Lat. Gerunda, a town of Spain, in the province of Catalonia, the see of a bishop, suffragan of Tortosa. This is a fortified town, of nearly a triangular form, situated on the side and at the foot of a steep mountain; the river Tur runs through it. The streets are narrow and crowded, but the houses are tolerably well built. It has several churches and convents; and its population amounts to about 14,000 persons, a fourth of which number consists of priests, monks and nuns, scholars and students. Several provincial councils have been held in this place, one in 517, another in 1068, &c. The trade of this town is inconsiderable, and its only manufactories consist of a few looms for flockings, coarse cloths, and woollen and cotton stuffs. The cathedral and collegiate churches are the two most remarkable edifices in Gironne. The treasury of the cathedral is richly furnished with chalices, crozets, shrines, relics, &c. of gold and silver set with jewels. In the Capuchin convent there is an Arabian bath, constructed in the most elegant style, and consisting of columns standing on an octagon stylobate, or low-labs, encircling a referror to contain water. The university of Gironne, founded in 1521 by Philip II., was abolished in 1715 by Philip V. After the suppression of the Jesuits, public instruction was concentrated in one college, accommodating 920 students, who are taught the Latin grammar, rhetoric, philosophy, and theology. The library is little and extensive. Schools are kept by the community of the Beguine nuns for the gratuitous instruction of poor girls; 47 miles N.E. of Barcelona. N lat. 41° 10'. E. long. 2° 35'.

GERONIMO, 777, a town of Mexico, in New Biscay; 90 miles N. of Parral.

GERONTE, a small island in the Mediterranean, near the coasts of Tarentum, and N.W. of Taranto, is 20° 30' W. long.
The female of gerentes were called *gerusfas*, that is, assembly or council of old men.

The gerentes were originally instituted by Lycurgus; their number, according to some, was twenty-eight; and, according to others, thirty-two. They governed in conjunction with the king, whose authority they were intended to balance, and to watch over the interests of the people. Polybios defines their office in few words, when he says, "per ipsos, et cum ipsos omnia administrati." None were admitted into this office under sixty years of age, and they held it for life. They were succeeded by the Ephors.

Geronessa, in Geography, a small island in the Gulf of Enga; four miles south of Enga.

Gerontoxon, in Surgery, a little ulcer, shaped like the head of a dart, and making its appearance occasionally on the cornea of old persons. The term is derived from *pterus*, an old person, and *pteros*, a dart.

Gen. Ch. Common calyx simple, of numerous upright, lanceolate, somewhat awl-shaped, keeled leaves, longer than the corolla. Cor. compound, somewhat imbricated, uniform; each floret hemeraphrodite, with a corolla of one petal, ligulate, abrupt, five-toothed; the outer ones equal in number to the calyx-leaves, inner ones fewer and shorter. Stam. Filaments five, very short; anthers united into a cylindrical tube. Pet. Germen oblong; style thread-shaped, the length of the flower, stigma a sigmas two, thread-shaped, recurved. Picros, none, except the permanent, oblong, upright, gaping calyx. Seeds of the circumference awl-shaped, as long as the calyx; their crown stalked, of five spreading rough bristles; those of the disk awl-shaped, but shorter, their crown feathered. Recept. naked.

Eff. Ch. Receptacle naked. Calyx simple, of many leaves. Seeds of the disk with a feathery crown; those of the circumference with one of five naked rays.

Obs. Linnaeus originally described the receptacle as naked, which is confirmed by Gartner, Wildenow, and Jacquin. Afterwards he attributed feathery secales to this part, which is adopted by Schreber, but, as we believe, without foundation. Jacquin, in consideration of the etymology, properly makes this genus, as well as *Tragopagon* and *Aridopogon*, of the masculine gender.

Two certain species of *Geropogon* only are known. They have the cloffel natural affinity to *Tragopagon*, but differ in the brillying, not feathery, crown of their external row of seeds. The genus is merely artificial, as not at all supported by habit, nor is the difference in the crown of the seeds greater than what occurs amongst indubitable species of one genus in others of this natural order.

1. *G. globus*. Linna. Sp. Pl. 1109. Jacq. Hort. Vind. v. 1. t. 32.—Leaves smooth. —Native of Italy. One of the Levant, sometimes kept in botanic gardens for curiosity only. It is annual, with a branched stem, 12 or 18 inches high, clothed with many alternate, clasping, long, grasy, smooth leaves, each branch terminated by a small, inconspicuous, pale pink flower, like the pink hawkweed, but far less handclaw. The seeds are larger and more remarkable. The herb abounds with milky bitter juice. Nothing can be more closely allied to this plant than *Tragopagon porrfusius* of Linnaeus: see Engl. Bot. t. 638.

2. *G. hisbarus*. Linna. Sp. Pl. 1109. (Tragopagon graminisfoliis, funerabenre flore; Column, Euphr. t. 231.) —Leaves hairy. —Found by Columba, who alone of all botanists seems actually to have seen this species in a wood of wild pear-trees near Cambod in Italy, flowering in May. It appears to differ from the preceding, chiefly in the roughness of its leaves, which nevertheless is so precisely and forcibly indicated by Columba, that we dare not prejudice it not to be a sufficient distinction. All authors have adopted this plant from Columna, nor had Linnaeus a specimen.

A third species occurs in recent writers, *G. calcisculus*; Linna. Syll. Veg. ed. 13. 572. (Tragopagon calcisculus; Jacq. Hort. Vind. v. 2. 48. t. 166.) This was received by Jacquin from Italy, and he sent a specimen to Linnaeus, who referred it to *Geropogon*. The habit is that of a Scorzoner. Root perennial. Flower-stalk, calyx, and upper leaves hairy. Calyx of a double row of scales, shorter than the calyptra, which is yellow. Crown of the seed slightly hairy, and, as far as we can perceive, uniform. —This is certainly no genuine *Geropogon*, and we are convinced it is the identical *Scorzoner hisbarus* of Linnaeus, well figured in Columna's Euphrasius. t. 233, though unfortunately we cannot prove it to demonstration, there being no specimen of the latter in the Linnaean herbarium. The plant in question is however the *Geropogon hisbarus* of Allioni, Fl. Pedem. v. 1. 229, as his synonym *Grew*, though he took it to be annual. S.

Gerard, in Geography, a county of Kentucky, in America, containing 6838 inhabitants, of whom 1234 are slaves.

Gerards, Peter van Zyl, in Biography, a painter, born at Amsterdam in 1607. He came to England and lived in the fame house with Vandyke on terms of friendship and intimacy. He réussi his manner successfullly, and on his return to Amsterdam he was so highly thought of, as to bear the name of the second Vandyke.

Geres, Gerull, or Gerilo, in Laclzology, names given by the Venetians to a fish common in that part of the world. It is the sinars, or main alba of authors. Artedi very judiciously makes it a species of the Iparus, and distinguishs it from others, by its having a black spot on each side, and the pectoral and tail-fins red.

Gerha, from among the Greeks, wicker hurdles, resembling the Roman *cicera*, which the Romans held over their heads to shelter themselves.

Gerhá, or Gerri, in Ancient Geography, a people of Scythia, in Europe, S. of the Daube.-Allo, a people of Alать Sarmatia, not far from the Caspian sea.

Gerlius, a river of Sarmatis, which runs into the Palaus Moctides.-Allo, a river of Alia, in Albania.

Gerlii, in Geography, a town of Spain, in Catalonia; 27 miles N. of Balangner.-Allo, a town of Africa, in Nubia, situated on the Nile; containing about 140 houses; 150 miles N. N. E. of Semmaar. N. lat. 16° 17'. E. long. 33°.

Gerlish, a small island, near cape Neddick, close to the main land of the district of Maine, in America.

Gerry, a township of America, in the state of the Massachusetts, and county of Worcester; incorporated in 1766, and containing 14,500 acres of land, in which are 822 inhabitants; 50 miles N. W. of Worcester.

Geris, a river of France, which rises near La Barthe de Nezes, in the department of the Upper Pyrénées, traverses the department of the Gers, and runs into the Garonne, about three miles S. E. of Agen.

Geris, one of the nine departments of the fourth, or Garonne province of France, bounded on the N. by the department of the Landes and the Lot and Garonne, on the E. by the department of the Upper Garonne, on the S. by the
the departments of the Upper and Lower Pyrénées, and on the W. by the department of Landes. This department is composed of Condommois, Armagnac, and Comminges, and takes its name from the river which crofes it from north to north. Its capital is Auch. It is situated in N. latt. 43° 40'; its territorial extent is 7,524.84 square kilometres, or about 3,393 square leagues, and the number of its inhabitants is estimated at 291,845. It is divided into five districts, viz. Condour, containing 67,104 inhabitants, Lectoure, with 57,445, Auch, having 52,825, Lombez, with 57,392, and Mirande, with 77,979 inhabitants. The number of its cantons is 35, and of its communes 700. The total of its contributions, personal, funtuary, and on moveable and immovable, &c., is 2,685,169 francs, and the expense of administration, justice, and public instruction, is 278,498 francs. The soil of this billy department is indifferently fertile, yielding moderate crops of grain, wine, fruits, and good patures.

GERSA, or GAIRSA, an island of Scotland, five miles E. of Elhnaw, two S. of Weir, and one E. of Mainland, is two miles long and one broad, and contains 50 inhabitants. The greatest part confits of a conical hill; steep on the W. side, and towards the E. more plain and fertile. The only harbour is that of Millburn on the E. coast. See GAIRSA.

GERSAU, or GERSAU, a village or town of Switzerland, at the foot of the Rigis, and the smallest republic in Europe. Its territory is about a league in breadth, and two leagues in length; intuated partly on a small neck of land at the edge of the lake of Schwiitz, and partly lying upon the rapid declivity of the Rigis. It contains about 1,200 inhabitants, having their general assembly of burgesses, their landammann, their council of regency, their courts of justice, and their militia. In the whole republic there is not a single horse; and the only way of arriving at the town is by water, except in the narrow path down the sides of the mountain, which is almost impassable. Geriau is entirely composed of scattered holues and cottages of a very neat and picturesque appearance; each dwelling is provided with a field or small garden. The inhabitants are much employed in preparing flk for the manufactures of Basle. This little republic is under the protection of the four cantons, Lucern, Uri, Schwiitz, and Underwalden; and in case of war furnishes its quota of men. The town is fix miles distant S.W. from Schwicitz. N. lat. 46° 55'. E. long. 8° 20'.

GERSCHITZ, a town of Bohemia, in the circle of Koningesgratz; nine miles N.W. of Koningesgratz.

GERSCHITZ, a town of Germany, in the principality of Bayreuth; six miles E. of Bayreuth.

GERSDORF, a town of Germany, in the principality of Querfurt; four miles N.E. of Juterbog.

GERSON, in Biography, chancellor of the church and university of Paris at the beginning of the fifteenth century; according to whom the ground-work of all diligent was the plain chant; and in his treatise upon the education of children the choir of Notre Dame, he enjoins a particular attention to chanting, counterpoint, and dissonant, as the three most essential branches of their instruction and study. (Magister cantus flatutis horis decet pueros planum cantum principaliert, et contrapunctum, et aequos dissonantiles decent et boner melodies.) He likewise tells us, that in this cathedral, during his time, the choiristers were only allowed, by the statutes, to practice dissonant till their voices broke. (Nec faciat eos tantum inferiore in talibus, quod per- dant in grammatica profectum; attento maximo quod in ecclesia nostra dissonant non cæt in ufu, fed per flatutam pro-hibitus, faltum quod voces non mutata dicuntur). The Abbe Lebeuf understands thee last words as we have translated them: (Le deixant n'est point au ufage dans l'eglise de Vol. XVI.

Paris, et qu'aut contraire il estoit defendu par les flatutes, au moins a l'egard des voix qui avoient passe le temps de la mutation. Tradit Hilt. sur le Contr. Eccles. p. 92.) The indefatigable Abbe Lebeuf found in the king of France's library the flatutes here alluded to, which had been framed in the 13th century, and from which the chancellor had been ordered to make extracts in 1406. He concludes the fourth article of his tract, which relates to psalmody, by informing us that no written dissonant was allowed in church missals or gradual, except for the exercise and improvement of the singing boys. (Nec debet in cantu notulato regulariter immittari dissonant, pueris exceptis propter exercitationem suam. Ger- fon, tom. iv. ultima edit. p. 717.)

GERSPACH, in Geography, a town of Germany, in the county of Eberlein, on the Rigis; taken by the French in 1794; three miles S.E. of Baden. N. lat. 48° 48'. E. long. 8° 26'.

GERSPRINTZ, a town of Germany, in the county of Erbach; seven miles N.W. of Erbach.

GERSTEN, Christian Louis, in Biography, was born at Gieflen in 1701; here he was educated, and in the year 1733 he was appointed professor of mathematics and the mechanical sciences in that city. On account of some dispute he was dismissed from his office, and left Gieflen in 1744; he went first to Altona, and from thence to Peter- burgh; but meeting with no encouragement, he returned and attempted to get reinstated in his office, but failing in his design, he infilted the landgrave, was arrested at Frankfort in 1748, and doomed to perpetual imprisonment in the castle of Marburg, with an annual allowance of 200 florins. Here he employed himself in teaching the mathematics to those young persons who came to his prison for instruction, and his leisure moments were occupied in studying the phenomena of the atmosphere, and the changes which take place in it, so as to become very expert in the science of meteorology. In the year 1760 he was liberated from his confinement, but his freedom was not complete; he was admitted at large for a time by way of proving whether he was entitled to a general discharge: escaping however from his shackles he went privately to Frankfort, where he kept himself concealed, or at least quiet, till he died in 1762. His works were numerous, and written in the Latin language: they chiefly relate to meteorology, to the methods of calculating eclipses, and to the structure of artificial instruments. He was esteemed by his contemporaries for his integrity and his learning. He sent some papers to the Royal Society of London, of which several were inserted in the volumes of their Transactions. Moreri.

GERSTUMEN, in Geography, a town of Germany, in the principality of Eisleben, on the Werra; 8 miles W. of Eisleben.

GERSWALDE, a town of Germany, in the Ucker Mark of Brandenburg; 9 miles S. of Prenzlau.

GERTHAUSEN, a town of Germany, in the county of Henneberg; 15 miles W. of Kuhlungen.

GERTRUDENBERG, a town of Germany, in the bishopric of Osnabruck; mile E. of Osnabruck.

GERTRUIDENBERG, Sr., a town of Brabant, but in later times subject to Hollant, with a good harbour, formed by the Merw, which here extends to a considerable lake, called Ee Bouch; over which is a passage of two hours to Dort. It is built in the form of a crescent, with regular fortifications, good battlements, and forts with sluices: by means of which they can lay the adjacent country under water. In ancient charters it is called Mons Litoris, the mountain of the shore. In 643., Pepin de Landen, duke of Brabant, gave it to his daughter Gertrude, who built
built a church dedicated to St. Amand, bishop of Tongres; but the place afterwards becoming celebrated by the death and pretended miracles of St. Gertrude, it has since been called "Mont de St. Gertrude," or Gertrudenberg. The caflle was built in 1321. After passing through many vicissitudes, it was锤oned by the French in February, 1793, and taken; but soon after evacuated. The French took it again in 1795. It is distant 10 miles S.E. of Dort, and 7 N.E. of Breda. N. lat. 51' 40'. E. long. 4' 44'.

GERTZ, a town of Germany, in the principality of Wurzburg; 5 miles W.S.W. of Munsterflct. GERVAIS, Armand Francis, in Biography, was born at Paris about the year 1662; he was educated with the Jesuits, and at fifteen years of age he entered among the bare-footed Carmelites. At the age of twenty-two he was appointed by his superiors to teach theology to the younger members of the order; and he was at the same time distinguished as a pupil orator. Some years after this he withdrew into the monastery of La Trappe, where he successively filled very important offices belonging to that order. The changes which he introduced, and the reforms which he meditated, created an alarm; and in 1698 he resigned his office, and quitted his residence in the monastery. From this period he wandered about, from solitude to solitude, following the fame ascetic course of life which he had been in the habit of practicing in the college. Having, in 1710, published the history of the Cistercian Order in France, in which was a severe attack upon the Bernardines, he was arrested and imprisoned in the abbey of Notre Dame des Reclus, in the diocese of Troyes, where he died in 1751, at the age of ninety-one. He published, besides the work alluded to, "The Life of St. Cyprian," with an abridgment of his works, including notes and dissertations: "The Lives of Peter Abelard and of his wife Heloise;" "The History of Suger, Abbot of St. Denis," in three volumes; "The History of St. Irenæus," in two vols. 12mo. Also lives of St. Paul, Epiphanius, Rufinus, and other eminent persons. He was distinguished as a controversy. was and the opponent of Father Courayer on the subject of English ordinances. He is characterized as a man of great learning and singular virtues, but his manners were austere, impetuous, and forbidding. Moreiri.

GERVAIS, Sr. in Geography, a town of France, in the department of the Puy de Dôme, and chief place of a canton, in the district of Riom; 15 miles N.W. of Riom. The place contains 2183 inhabitants, and the canton 10,904 inhabitants, on a territory of 2823 square miles, in 11 communes.

GERVAIS-de-Mafey, Sr. a town of France, in the department of the Orne, and chief place of a canton, in the district of Domfront; 9 miles N. E. of Domfront. The place contains 1668, and the canton 17,228 inhabitants, on a territory of 1324 square miles, in 14 communes.

GERVAIS-des-Villes, Sr. a town of France, in the department of Herault, and chief place of a canton, in the district of beziers. The place contains 1263, and the canton 8641 inhabitants, on a territory of 1374 square miles, in 10 communes.

GERVASIO, the nephew of Bernado; was also a painter of considerable merit in the flame styie of colouring, as is evident in a picture of St. Sebastian, in the church of St. Agatha at Cremona, where it is united to the design of the antique; and also in the Martyrdom of St. Cecilia, at S. Pietro, in the same city.

GERVASONI, Sr. in Geography, a town of Italy, in the department of the Mela; 15 miles S. of Brescia.

Ger. Ch. Cal. Perianth inferior, of one leaf, flat, five-toothed, small, green, permanent. Cor. Petals five, lanceolate, abrupt, spreading, thicke as long as the calyx, white. Nectary, a thick ring surrounding the germen, bearing the flaments on its outer edge. Stiam Filaments five, erect, half the length of the corolla; anthers erect, triangular. Fil. Geranium glabrous, deeply imbered in the nectary; style thread-shaped, small; stigma three, widely spreading, red, wedge-shaped, emarginate at the extremity. Petal superior, ovate, of four or perhaps five cells, and as many valves. Seeds two, in each cell, oval, inferted into a triangular white pulp; one of them often abortive.

Eff. Ch. Calyx with five teeth. Petals five, abrupt. Nectary, a ring round the germen. Stigmas three, emarginate. Capsule superior, ovate, of four or five cells. Seeds two, affixed to a pulpy receptacle.

1. G. alba. Leaves alternate, oval-oblong, somewhat serrated.

This is all that can be gathered from Forskall's account, and it forms a botanical enigma. Some circumstances indicate an affinity to Juliflora's Euphorbia. The accounts of the stigma and of the fruit are the most remarkable. Nothing is said of the habit, duration, or possible qualities.

GERUNDI, in Grammar, a sort of tense, or time, of the passive mood: very like to the participle, but indeclinable.

The word is formed of the Latin gerundin; and that from the verb gerere, to bear.

The gerund expresses not only the time, but also the manner of an action; as, he fell in running poth. It differs from the participle, in that it expresses the time, which the participle does not. And from the tense properly so called, in that it expresses the manner, which the tense does not.

Grammarians are much embarrassed to settle the nature and character of the gerund: it is certain they are no verbs, because they do not mark any judgment of affirmation of the mind, which is supposed to be the essence of a verb; and besides, they have their several cases, which verbs have not.

Some, therefore, have likened them to be adjectives passive, whose substantive is the infinitive of the verb; on this footing they denominate them verbal nouns, or names formed of verbs, and retaining the ordinary regimens thereof.

Thus, say they, tempus et leges librorum, vel librorum, is as much as to say, tempus et leges librorum, vel librorum. But others dispute this decision.

The Greeks have neither gerunds nor supines; but instead of
GESNER, in Geography, a town of Germany, in the county of Feldkirch; 4 miles E. of Feldkirch.

GESENDORF, a town of Prussia, in Oberland; 7 miles S. E. of Saale.

GESMOLD, a town of Germany, in the bishopric of Ofenbruck; 12 miles S. E. of Vorden.

GESNER, in Geography, a town of Germany, in the county of Feldkirch; 14 miles S. E. of Vorden.

of them they make use of the infinitive, in the same maner as the French; προτετινη χιλιών; pour boire. When the article happens to be made use of, then its genitive is put for the gerund in δι, as τῶν κατηκρίνοντος, factendi, of doing; the dative or ablative is put for the gerund in δο; and the nentor for the gerund in δυμ. But the infinitive in this tense is often expressed without the article, as ἀρτυρο ἀναίρετα, juculandi portiis, an excellent archer; ζευς ἀναίρετα, ferendum debit, he gave it to carry. In Greek, however, the termination σιε corresponds to the Latin gerunds; thus, from ἀποκρίνεσθαι, to say, is deduced κινετόν, discendam, it must be said. These verbal adjectives, as they may be called, sometimes denominated gerunds, are used occasionally either in an active or a passive sense; τον την χειρισμον, it is for thee to cultivate the ground: το γνωρισθαι εκστητος εἰς θυγατέρα, και εὐγενικά τον τον τοπον εἰς τον, the body should be accustomed to obey the understanding, and be disciplined with toils and sweat. Xenophon.

An ingenious grammarians observes, that the Latin gerunds in δο, do, and dum, are but the participle in das in the oblique cases; and as this is taken from the precent participle, they have its tense, namely, an active tense. On the same principle that participles express powers or habits in action, and their tendency is to dignify those powers, and not their operation, i.e., to become adjectives; the oblique cases of the participle in das, when alone, become in their nature abstract nouns. Hence gerunds, being thus nouns in reality, are governed like other nouns in the genitive, dative, accusative, and ablative, either with or without a preposition; as ratio ferendi, the art of writing; charta utilis feriendo, paper is useful for writing; promptus ad audiendo, ready for hearing, or to hear; memoria expendendo auger, the memory is increased by cultivating. Gerunds also, having the nature of nouns, may govern a genitive; as fowlatas agrorum sui latronibus condonandi, the power of the beholding of his lands on his thieves. The gerunds, however, as retaining in a degree their verbal character, govern the case of their respective verbs, as visendi domum portis, venit ad recipiendum pecuniam, parceo viatis. As adjectives, assume the nature of nouns when used alone in the neuter termination, so the gerunds in dum, the neuter of participles in das, become substantives, denoting, with of, necessity and obligation, as eundum off mili rite, living must be to me, or I must live well. Jones's Grammar of the Latin Tongue.

GERY, St., in Geography, a town of France, in the department of the Lot, and chief place of a canton, in the district of Cahors, 5 miles N. W. of Cahors. The place contains 1352, and the canton 5355 inhabitants, on a territory of 180 kilometres, in 9 communes.

GERYON, a name given by some of the affected chemical writers to quicksilver.

GERZAT, in Geography, a town of France, in the department of the Puy de Dôme; 4 miles N. E. of Clermont.

GERZEN, a town of Bavaria; 11 miles E. of Landshut.

GESAN, a town of the Arabian Iraq; 8 miles S. E. of Mendil.

GESAS, a town of Sileia, in the principality of Nellie; 3 miles S. E. of Paschau.

GESEKE, a town of Germany, in the kingdom of Westphalia; 9 miles E. S. E. of Lipstadt.

GESERICH, a lake of Prussia, in Oberland, near Dutch Eyau.

GESERVAGHERD, a town of Persia, in Chorfan; 30 miles S. of Esfahan.

GESHEN, Rocks and rivers of; See Amhara.

GESHURITES, in Scripture Geography, a people who dwelt beyond Jordan, in the half tribe of Manassath.
liished the same year, with a very affectionate and consolatory epistle to the father of the author.

The principal works of Conrad Gesner are the following, not to mention various little treatises relating to Botany, or to the Materia Medica, which from time to time came from his ready and prolific pen, some of them accompanying the books he edited for other people.

"Bibliotheca universalis," or a catalogue of Latin, Greek, and Hebrew books, printed at Zurich, 1545, in one volume folio, with criticisms, and often specimens of each. This seems to have given Haller the idea of his own "Bibliotheca Botanica," and "Bibl. Anatomic." "Historiae Animalium," comprised in five books, making three great folio volumes in a very small type, with numerous wooden cuts. The first was published at Zurich in 1551, the last in 1587, after the decease of the author. There is also an edition in German. This is a vast compilation, and critical revision of all that had been done before him in Zoology, with every thing that he could lay of his own knowledge to illustrate the subject, and many incidental botanical, as well as medical remarks. Instead of being the work of a physician, who raised and maintained himself by his practice, and who was cut off in the middle of a most active and useful life, one would suppose it the labour of a recluse, shut up for an age in his study, and never digested from his object by any other cares. This work is arranged according to the plan of Aristotle, only the oviparous quadrupeds are separated from the viviparous. It does not extend to insects or fishes. The former however had not escaped the attention of Gesner, for his labours respecting them make a part of the work of Musset, entitled "Insectorum five Minimorum Animalium Theatrum," published at London in 1634, the earliest book on entomology.

The "Icones Animalium," with their nomenclature, form a separate publication from the above, consisting of the wooden cuts and names only.

"Aquarium Animantium Enumeratio Juxta Plinium," a little 8vo, printed at Zurich in 1556. A list of the German and English names is subjoined.

A little work in Latin, "De Lacte," treating of milk and its preparations, from various authors. Zurich, 1541, in 8vo.

"De Secretis Remedii Thefauros," a Pharmacopeia, which has gone through a number of editions in various languages.

"De varis et admirandis herbis, quae five quod notit lucet, five alia ob causas, Luminarix nomenclatur." A curious and learned little work, with wooden cuts, in 4to. Zurich, 1555. It is accompanied with a description of the celebrated mount Pilat, or Mont Fratius, the northern extremity of the Alps, which Gesner visited in 1555. Several alpine plants are here, for the first time, noticed.

"De omnibus Plathum generis," Zurich, 1565, 8vo. Alfo "De rerum Plathum, Lapidum et Gemmarum maxime figuris," with wooden cuts, more curious than useful.

The botanical remarks relative to the scientific arrangement of plants, on which the supcrominent merits of this great man are founded, are chiefly to be gathered from his letters, which were published after his death. From the number of wooden cuts, and of drawings, which he had prepared, it is probable he meditated a general botanical work, the future arrangement of which frequently occupied his thoughts, and prompted many of these letters.

Gesner married at the early age of 20, for which he was accused of imprudence, but it does not appear that he had any reason to repent. His wife survived him, and notwithstanding the dangerous nature of his disease, which was accompanied with a pestilential carbuncle, she did not desert his death-bed, for he expired in her arms. He left no offspring. His remains were honourably interred, the day after his decease, in the cloister of the great church at Zurich, near those of his intimate friend, Fryius, who died the preceding year. Abundance of Latin, and some Greek verses, were composed to his honour and his life, written by his countryman Jonas Simer, was published in the ensuing year. From this work, and Haller's Biblioth. Bot. much of the above information is derived. Haller mentions Gesner as probably the first person who, being short-sighted, found the advantage of concave glasses. S.

We have received the following additional account of C. Gesner, in relation to his medical profession.

His father, who was a workman in hides, was killed in the Swiss civil war, and left him in such poverty, that he went to Strafsburg, and entered into a situation as a servant. His master, having observed his great inclination to reading, allowed him to employ the time, which was not absolutely necessary to his services, in study; and he made such progress while at Strafsburg, that, having acquired a little money, he went to Paris, where he first attained an ample knowledge of the Latin and Greek languages, and of rhetoric, and afterwards applied to the study of philosophy and medicine: but as he soon found the means of subsistence fail, he was under the necessity of returning to his native country, and of teaching the languages and philosophy for a livelihood. This expedient was successful, and even procured him the means of visiting Montpellier, where he resumed the study of medicine, which he completed, by taking the degree of doctor at Basl in the year 1540. He then determined to settle at Zurich, where his merit procured him the appointment of professor of philosophy, and he discharged the duties of that office, with universal reputation and esteem, during twenty-four years. These duties, and his studies in the cloist, prevented him from entering largely into the practice of medicine; in which, however, his extensive knowledge furnished him with such numerous resources, that his practice was extremely successful, and he rose superior to the prejudices of his contemporaries. Gesner had always a decided predilection for the study of botany, which he early conceived and retained through life, as we have already mentioned in the former part of this article. It was not without great trouble and difficulty that he became a scientific man; for he was of a delicate and sickly constitution; but his spirit and courage gave him strength to support the fatigues of body and mind. Notwithstanding the delicacy of his habit, he traversed the Alps in search of plants; and among other journeys over those mountains, he made one with Jean Bauhin in 1561. He even culled plants from the waters, and has been known to plunge into the lake of Zurich to procure those which grew there. Ever animated by the same spirit, he visited Paris again, travelled through the southern provinces of France, and thence passed into Italy. In order to study the nature of fishes, he went to Venice with a view to investigate those of the Adriatic, and sometimcs afterwards he repaired to Strafsburg to examine those of the Rhine. From these sources of information, from a constant personal observation, combined with the study of the writings of the ancients, he obtained the means of accomplishing that immensity of treatises, which a man, who only attained to 40 years of age, could hardly be supposed capable of producing.

GESNER, JOHN MATTHIAS, was born at Roth, in Anspach, in 1691, where his father was a clergyman. He received the first part of his education at the gymnasium of Anspach, and
and was quickly distinguished by his progres in the ancient and oriental languages. From Anspach he went to Jena, where he exhibited his learning and talents in several publications. In 1715 he was appointed co-rector of the Gymnasium of Wemar, and keeper of the public library. In 1716 he accepted the rectorship of Thomas's school at Leipzig, and on the establishment of the university of Gottingen he was invited to be the professor of rhetoric, an office in which he was so greatly distinguished, as to acquire the reputation of being the most able philologus of the age. He was at the same time made librarian and president of the German society, and to his inspection all the schools of Gottingen were given. On the appointment of the Royal Society at Gottingen he was the first member of the historical chiefs, and was afterwards appointed a counsellor of state, and perpetual director. He died in 1761. His works are much too numerous to be named in this place, but they were such as to entitle him to almost the highest rank in the literary world. Among others may be noted his "Index etymologicus Latinitatis," and his "Theaurus Latinarum et Eruditionis Romanae," 4 vols. fol. Gefner, in this elaborative work, followed the order of Stephanus, but added such notes and other improvements as appeared necessary. These additions confound chiefly in the number of remarkable phrases and passages from the Roman classics, with illustrations. Gen. Biog.

**GESNER, SOLOMON.** was born at Bocklow, in Silesia, in the year 1559. Having received the early part of his education at his native place, he was sent to Brestlaw to pursue the studies necessary to his future profession. From this place he went to Strasbourg, where he was so fortunate as to obtain an academic exhibition for five years, which he employed in the study of philosophy, the mathematices, and the learned languages, as well the Hebrew, Chaldee, and Syrian, as those of Greece and Rome. He now became private tutor to a noble Livonian, and when he was 24 years of age he was admitted to the degree of M. A. In 1592, he was invited to fill the theological chair in the university of Wittemberg, and almost immediately entered upon the duties of his office, and was at the same time admitted to the degree of D. D. He also occupied the important posts of dean and rector of the university, almonor in the ecclesiastical curtilogy, and first preacher in the church. His close application to study injured his health, and he fell a victim to a consumption of diversers in 1605, having only 26 years to the 46th year of his life. His works are a Latin translation of "The Prophecy of Hosea," "Disquisitiones in the Psalms," treating of the dignity, the use, the argument, and the connection of the Psalms, and many other works of a theological and controversial nature. Gen. Biog.

**GESNER, JOHN.** a canon of Zurich, and professor of natural philosophy and mathematics in that university, probably belonged to the same family as the great Conrad. He was the intimate friend of Haller, in whose society he studied at Leyden and Baile, and with whom he maintained a close correspondance during the life of that distinguished man. Their taste for botany was the same, and their characters similar. His letters make an interesting part of the "Epistolae ad Hallerum," and abound with solid and curious botanical criticism and information. He paid much attention to the cryptogamic plants, and other difficult branches of the science, as well as to the anatomy and phytology of plants. He survived his learned friend 12 years, dying in 1705, at the age of 81.

This author published two phylogonic dissertations on plants in 1749 and 1741, reprinted at Leyden in 1743, along with Linnaeus's "Oratio de peregrinatione intra patriam." In these he treats of the life and structure of vegetables, their propagation, sexes, elastic motion of some of their filaments, and their methodical classification. He reviews the experiments and observations of Leeuwenhoek, Malpighi, Grew, Hales, &c. announces the then novel system of Linnaeus, whom, with a kind of prophetic spirit, he calls a man destined to reform all natural history." These dissertations are the best and most comprehensive epitome possible of all the botanical science of that day, in which the improvements of each writer are set in the most just and instructive point of view for their mutual illustration.

With all his knowledge, the subject of our present article, and even his friend Haller, were imposed on by one of the grossest deceptions. A person prefented him with a common meadow Crowfoot, on some branches of which were fluck flowers of the common Daisy. He immediately published, in 1753, a learned dissertation on vegetable monstors, entitled "De Rannuncio bellidifloro," in which he exhibits a figure of this strange anomaly. As Haller had given his sanction to the discovery, botanists could scarcely supposse it was an evident mistake, till for Joseph Banks obtained the original specimen after Gfner's death. On its being freshened with boiling water, in the presence of several botanists, amongst whom was the writer of this, the stem of the "Rannunculus" came out of the pale of the flower, as from a seedling, and indeed the different segments of each went very diligraphous before their separation. A history of the whole is given by Mr. Konig, in his Annals of Botany, v. i. 368, with a plate drawn for Joseph Banks by Mr. Bauer, and signed by all the witneffes.

Gefner published at different times eleven dissertations in quarto, from 1759 to 1773, under the general title of "Phytographia Sacra." Some of the latter only are illustrative of the plants of scripture, the rest being of a general nature, containing various anatomical and physiological, as well as botanical and economical matter. He adopts the Linnean system, and furnishes many remarks confirming the sexual doctrine.

He meditated a very extensive work on the characters of plants, for which he had prepared a considerable number of exquisitely engraved, though too much crowded, plates, some of which are in our hands; but this publication never took place.

He wrote also on extraneous fossils, and compiled an index to Weimann's "Phytographia," printed in 1757 in 8vo. A catalogue of his library for sale was published in 1798, by which it appears to have been one of the best collections of botanical books ever offered to the public. S.

interrupted in the middle. Seed very numerous, minute. 

Gestation is also a term in the Ancient Medicine, used in a chariot, or a boat; or even in rocking him in his bed, if he could not endure a more violent agitation. -

Gesta, in Geography, a town of Switzerland, in the canton of Uri; 15 miles S. of Altorff.

Gestricia, a province of Sweden, about 51 miles long and 10 wide; bounded on the N. by Hellinghard, on the E. by the gulf of Bothnia, on the S. by Upland, Westmanland, and Dalecarlia, and on the W. by Dalecarlia.

The inhabitants do not concern themselves with agriculture, but derive their chief support and wealth from mines, forests, fine lakes, and rivers. The capital of this province is Gofle, which they call Goesten.

Gestungshausen, or Geshhausen, in Geography, a town of Germany, in the principality of Coburg; seven miles E. of Coburg.

Gesture, a motion of the body, intended to signify some idea or passion of the mind.

Quinilian defines gesture, totius corporis motus & conformatio. Gestures are a kind of natural language, which supplies the use of speech in those naturally dumb. The mimics and pantomimes were very great proficiency in the style of gesture.

Gestures consists principally in the action of the hands and face; and may be defined, a suitable conformity of the motion of the countenance, and of several parts of the body, in speaking of the subject matter of the discourse. (See Action.) With regard to oratory, gesture may properly be called the second part of pronunciation; in which, as the voice should be fitted to the impressions it receives from the mind, so the several motions of the body ought to be accommodated to the various tones and inflections of the voice. When the voice is even and moderate, little gesture is required; and nothing is more unnatural and disgusting than violent motion, in discoursing upon ordinary and familiar subjects. The motions of the body should, therefore, rise in proportion to the vehemence and energy of the expression, as the natural and genuine effect of it.

Gestures is either natural, or from imitation. The former denotes such actions and motions, either of the whole body, or of some particular part of it, as naturally accompany our words, just as these result from the impressions of our minds. As to the whole body, it should not continue long in the same position, but be constantly changing, with a gentle and moderate motion. As to the several parts of the body, the head is the most considerable; to lift it up too high, has the air of arrogance and pride; to stretch it out too far, or throw it back, appears clownish and unmanly; too hanging it downwards on the breast, throws an unmanly bashfulness and want of spirit; and to suffer it to lean on either shoulder, argues sloth and indolence; in calm and sedate discourses, the head should keep its natural state and upright posture, occasionally moving, and turning gently, sometimes on one side, and sometimes on the other, as occasion requires, and then returning back to its natural position. It should always accompany the other actions of the body, except in aversion,

...
The passions are principally represented by the countenance; and the several parts of the face contribute to the proper and decent gesture of the whole. In a calm and sedate discourse, all the features retain their natural situation. In sorrow, the forehead and eye-brows lower, and the cheeks hang down; but in expressions of joy and cheerfulness, the forehead and eye-brows are expanded, the cheeks contracted, and the corners of the mouth drawn upwards. Anger and resentment contract the forehead, draw the brows together, and thrust out the lips; and terror elevates both the brows and forehead. To these natural signs of the passions, the orator should endeavour to conform.

The motions of the eyes require the most careful management; because, as Cicero observes, (De Orat. lib. iii. cap. 59.) other parts of the countenance have but few motions; whereas all the passions of the soul are expressed in the eyes by so many different actions, that cannot possibly be represented by any gestures of the body, if the eyes be kept in a fixed posture. Thus, in speaking on pleasant and delightful subjects, the eyes are bright and cheerful; but they fink and are languid in delivering any thing melancholy and sorrowful. In anger, the eyes discover a certain vehemence and intenfeness; in expressions of hatred and detestation, the eyes are turned either aside or downwards; thus Virgil has expressed Dido's retentive and disdainful looks:

"Illa sole fixos oculos avera tenerat."  

The eyes are also sometimes turned downwards, to express modesty; and they should be always turned towards the object which is addresed. A gentle and moderate motion of the eyes is commonly most fittable, whereby they may be directed to some of the audience with an air of respect and modesty; but their motions ought to vary, according to the different nature of the passions which they are designed to discover in the speaker, and convey to his hearers.

The shoulders should neither be elevated nor depressed; a continued motion of the arms should be avoided; their action should be very moderate, and follow that of the hands, which need never be idle: Quintilian lays great stress on the action of the hands, when he says, "The hands, without which all gesture is lame and weak, have a greater variety of motions than can well be expressed: for they are almost equal to our words. Do we not direct with them, promise, call, difcours, threaten, deceive, detest, fear, inquire, deny? Do not they express joy, sorrow, doubt, confession, penitence, measure, plenty, number, and time? Do not they excite enmity, pride, admiration, and shame? That in so great a variety of speech among all nations and countries, this seems to me the common language of mankind."  

As all bodily motion is either upward or downward, to the right or left, forward or backward, or circular, the hands are employed by the orator in all these, except the left; and as they should correspond with our expressions, they ought to begin and end with them. In admiration, and addresses to heaven, they must be elevated, but never raised above the eyes; and in speaking of things below us, they are directed downwards. Side motion should generally begin from the left, and terminate gently on the right; in demonstrating, addressing, and on several other occasions, they are moved forward; and in threatening, sometimes thrown back: when the orator speaks of himself, his right-hand should be grafted on his breast. When no other motion is necessary, the hands should be kept about as high as the breast, so as to make nearly a right angle with the arm. They should never be suffered to hang down, nor to rest upon the cushion or bar. The left-hand should never move alone, but accommodate itself to the motions of the right: in motions to the left, the right-hand should not be carried beyond the left shoulder; in promises and expressions of compliment, the motion of the hands should be gentle and slow; but in extortations and applause, more quick. The hands should be generally open; but in expressions of compassion and anger, they may be closed. Neither the breast nor the belly should be thrust out; the trunk should be easy and flexible, fitting itself to the motions of the head and hands; and the feet should be kept steady.

There are other gestures, which arise from imitation, as when the orator describes some action, or performs another speaking: but here he should be careful not to overact his part, by running into any ludicrous or theatrical mimicry, or changing his action or voice in a manner unfittable to his own character. See farther on this subject, Ward's Oratory, vol. ii. p. 344, &c. p. 362, &c. Sheridan's Lects. on Eloquence, lec. vii. p. 113, &c. See also Action, Imitation, Pronunciation, and Voice.

Gestus Bonus, in Law. See Good Nature.

Gesvaldo, in Geography, a town of Naples, in Principato Ultra; 13 miles N.W. of Conza.

Gesves, a river of Africa, which runs into the Atlantic, a little to the north of the island of Bifagos.

Gesula. See Gezula.

Geta, Septimus, in Biography, second son of the emperor Severus, and brother and partner of Caracalla, was born at Milan in 189, and was raised to the title of Augellus. In the eighth year of his age he was moved with compassion at the fate of some of the partisans of Niger and Albinius, who had been ordered to be executed, and his father, struck with the humane feelings of his child, remitted the sentences. Though he was not free from the vices of an heir to the empire, yet the mildness of his disposition made him a greater favourite with the people than his brother, and this circumstance inflamed their mutual hatred. On the death of Severus both princes succeeded to a joint sovereignty, but their union was of short duration. Caracalla, jealous of his brother's popularity, ordered him to be poisoned, and when he found the infamous act could not be effectual, he murdered him with his own hands in the presence of his mother Julia, who, in the attempt to defend her favourite son, was severely wounded in the arm by Caracalla. Gete had not reached the twenty-third year of his age when he felt a victim to the brutality of his brother. Before his death, Severus had, in the anguish of a disappointed father, foretold that the weaker of his sons would fall a sacrifice to the stronger, who, in his turn, would be ruined by his own vices. Univer. Hist. Gibbon's Rom. Hist. See also the article Caracalla.

Geta, in Geography, a town of Sweden, on the N. coast of the island of Alman. N. lat. 60 25'. E. long. 9 52'.

Getae, or Getes, a tribe of Scythians, who, according to Herodotus (I. iv.), inhabited that part of Thrace which is near the Iler or Danube. Strabo says (I. viii.) that they had the same language with the Thracians, and he represents them as occupying those arid and uncultivated plains which lie along the sea-coast between the mouths of the
the Ister and that of the Tyras, in which the army of Darius, in its march against the Scythians, was in danger of perishing for want of water. Pthie (l. iv. c. ii.) says, that they inhabited that declivity of Mount Hemus which is turned towards the Danube. Under the empire of Trajan, the Gete were subjected to the Roman dominion. Herodotus speaks of Zamboks as the legislator of the Gete; and he says that from him they derived the dogma of the soul's immortality; and Trajan attributed to this principle the inviduity with which they encountered death in the perils of war. The Gete possessed only a small space along the coast, but their territory extended to a considerable distance in the interior of the country. Those who inhabited the western part in ascending the Danube, were called "Dacians." But those who were more appropriately denominated Gete, occupied the eastern parts near the Euxine sea; and those who inhabited the banks of the river Tyras, were called "Tyrigetes." They had all the same language. Those people were continually intermixing themselves with the Scythians, Balts, Thracians, and Thracians. The Gete were without doubt the same people with those who were called Gotti, and whose migrations were so extensive. See Gottis.

GETCHAO, a town of China, of the third rank, in Chang-tong; 27 miles E.S.E. of Lo.

GETE, part of the country of the Eluts, in Chinese Tartary, so called even to the time of Timur, is regarded by some geographers as the country of the ancient Maffage, towards the lakes of Palkari, Balhak or Tengis, and Zaizen. The contafch, or great Khan, used chiefly to reside at Hacres, or Erts, on the river Il, which flows from the S.E. into the lake of Balhak. See Jatts.

GETHSEMANE, in Scripture Geography, a village in the mount of Olives, whither Jesus sometimes retired, and in a garden of which he endured his agony, and was taken by Judas. Matt. xxvi. 36 &c.

Gen. Ch. Cal. none, except an obliquely truncate cylindrical fleshy. Cor. of one petal, superior; tube very long, thread-shaped; limb widely spreading, regular, in six deep, elliptical-oblong, equal segments. Stam. Filaments fix, inserted into the mouth of the tube, shorter than the limb, often divided; anther linear, vertical, rolled inwards, often two to each filament. Petic Germen inferior; style simple, capillary, longer than the flaments; stigma capitate. Petal. Berry club-shaped, obtuse, radical, sessile on the bulb itself, somewhat fleshy, of one cell. Seeds imbedded in pulp, globose, smooth, lying over each other in a triplicate series.

Obf. Linnæus, misled by the occasional luxuriance of the flowers, placed this genus in the class Dodecatulria.

Four species are defined in Willdenow, besides his and Jacquin's G. phaca, Hort. Schoenbr. v. i. 42. t. 80, which is Hypoysis phaca of Linnæus, and we are at a loss to discover why it is removed to Gethyllis, for which no reason is given, nor does the description in Jacquin foggest any, except the length of the tube. The fruit, when known must decide this question.

G. floribunda. Roxb. Corom. v. i. 61. t. 87.—Native of forests on the coast of Coromandel, where it was first noticed by Kenig, flowering in February and March. The stem is woody and climbing, with long, round, leafy branches, downy like the whole plant. Leaves opposite, falcate, ovate, acute, entire, about two inches long. Flowers in axillary and terminal, compound leafy clusters, with opposite flanks, inodorous, greenish-white. Seed and permanent calyx of a milky hue. The natives call this shrub Band-bey-mooroodooe.

We have no doubt of the propriety of Lamarc's fynom, which our lamented predecessor, the Rev. Mr. Wood, not knowing the Gethizia, could scarcely ascertain. (See Calycoperis.) If we be right, the main branch in Lamarc's plate is diminished, the separate fruits only, and permanent stamens, being of the natural size.

GUTTYSBURGH, in Geography, a small post-town of America, in the state of Pennsylvania and Adams county, situated at the head of Rock creek, one of the head-waters of the Monococy; containing about 30 houses; 9 miles N. of the Maryland line, and 118 W. by S. from Philadelphia.

GETZENDORFF, a town of Austria, seated on the river Kaffencoph; 12 miles S.E. of Vienna.

GEVAI, a town of the Arabian Irak, on the Tigris; 95 miles S.E. of Bagdad.

GEVAUDAN, a mountainous country of France, so called
call'd before the revolution, situated in Languedoc; of
which Mende was the capital.

GEVES, a town of Africa, situated on a river of the
same name, S. of the river St. Domingo.—Also, a town of France,
in the department of the Lower Meuse; 5 miles N. of
Wyck.

GEUM, in Botany, is mentioned by Pliny, though we
learn nothing from that author respecting the derivation
of its name. Ambrozinus conjectures that it comes from γεως,
to be flanged, because its beautiful flowers and seeds are the
boat and glory of the Alps.—Avens, or Herb-bennet.—
Lamarck. Illust. t. 443. Mart. Mill. Dict. v. 2. 6m. Pl.
t. 151. Lamarck. Dict. v. 1. 596.) Clafs and order, Ico-
formia Polygynia, Nat. Ord. Semilonga, Linna. Rapha-
Is.

Gen. Ch. Cal. Perianth of one leaf, in ten segments, ra-
ther upright: the alternate segments very small, acute. Cal.
Petals ovate, round, clawed narrow, the length of the
calyx, into which they are inserted. Stem. Filaments nu-
merous, awl-shaped, of an equal length with the calyx, and
inserted into it; anthers short, broad, obtuse. Pist. Ger-
nerous, numerous, collected into a head; styles inserted into
the side of each germen, hairy, long; stigma simple. Peric.
none; common receptacle of the seeds oblong, hairy, placed
on the reflexed calyx. Seeds numerous, compressed, rough; each
tipped with the long geniculate style.

Seeds with a jointed awn. Receptaculum columnar.

Only five species of 
Genus are described by Linnaeus in
the last edition of his Species Plantarum, though in Willde-
now's edition we meet with eleven of this genus, of which
number G. urbiunm and rivale are the only British ones, and
to which we are enabled, by the assistance of Dr. Smith,
to add two nondecripts from his herbarium.

ulas rounded and cut. Flowers erect. Awns of the feeds
hooked, naked.—Frequent in woods and hedges, perennial,
flowering from May to August. The root is fibrous, and
flavily aromatic. Stem erect, about two feet high, branched
at the upper part, clothed with deflexed hairs. Leaves un-
equally ternate, hairy, lobed and cut. Stipulae very hairy.
Flowers terminal, solitary, erect, yellow, with petals shorter
than the calyx. Seeds rather hairy, with naked purplish
awns.

t. 106. — Radical leaves lyrate. Stipulas ovate, acute,
cut. Flowers drooping. Awns twisted and feathered.—
Found in meadows and moist woods more commonly than is
usually imagined, perennial, flowering in June and July.
Root spreading, woody, altrigent and aromatic, sometime
of use in intermittent fevers. Stem about a foot high, droop-
ing at the top. Lower lyrate, or confluent pinnate, fer-
rated, hairy. Petals erect, never fully expanding. The
general appearance of this elegant species, an universal favourite
amongst botanists, is thus justly described in English Botany,
"the rich combination of the dark-green wrinkled leaves,
with the glowing red-brown of the stem and calyx, and the
naturally delicate colour of the petals, added to the graceful
position of the flowers, render this one of the most pict-
refsque of our native plants."

(G. canadens; Jacq. Hort. v. 2. §2. t. 175.) — Stem
VOL. XVI.

leaves ternate; the upper ones lanceolate. Stipulas oblong.
Flowers erect. Awns of the feeds naked, hooked.—
Native of North America, from whence it was introduced by
Mr. P. Miller in 1739. It is fairly allied in habit to G.
urbium, but the petals, which are shorter than the calyx,
are white, and the whole plant is of a greener hue. Its
leaflets are also more attenuated towards the base. Its
flowers in June, and is a hardy perennial. Root inodorous. Rad-
cial-leaves generally bipinnate. Seeds smooth.

1113. (G. stylites; Jacq. Jard. v. 1. 10. t. 93.) —
"Stem-leaves pinnate; leaflets and stipulas claven and cut.
Flowers erect. Petals longer than the calyx. Awns of the
seeds naked, hooked."—Native of North America. A
hardy perennial, flowering in June and July. Flowers
yellow. Fruit hairy. The whole plant is covered with
whitish hairs.

"There is no figure of this species, which is perennial,
and grows in Japan. Stem round, rather more than a foot
high. Flowers terminal, with petals as long as the calyx.
Seeds ovate, covered with greyish hairs.

1115. (Caryophyllata pyrenaica, amplissima et rotundobor
folio, mutante flore; Tourn. Inf. 295.) — "Flowers drooping.
Petals longer than the calyx. Awns hairy, twisted at the
base."—This is taken up by Willdenow from Tournesort,
and is perennial, found on the Pyrenees. Its appearance
is similar to G. rivale, but differs in the larger size of its
radial leaves, and shape of its awns, which are thinly covered
with hairs, and naked at the top. Stem erect, about a foot
and half high. Seeds very woolly.

pl. v. 2. 1116. Desf.-Atlas. v. 1. 402. — Lower-
leaves pinnate. Stem generally single-flowered. Fruit hairy.
Awns twisted.—A native of Mount Atlas, perennial.
Stem nearly two feet high, simple. Stipulae large, ovate,
cut. Flowers yellow. This is nearly allied to G. montana,
but differs in having fewer leaflets, a taller stem, and twisted,
not bearded, awns.

v. 2. 1116. (Dryas georgie; Jacq. Hort. v. 3. 53. t. 68.) —
"Leaves pinnate, toothed. Stem with about two flowers.
Calyx of the fruit erect. Awns straight, naked."—Native
of the mountains of Siberia, and introduced into Kew gar-
dens in 1780 by Dr. Pallis. We have it from Chelsea gar-
den. It flowers in June, and is a hardy perennial. Root
inodorous, but with an aromatic taste. Petals yellow, Larga-
than the divisions of the calyx. Seeds 
with long awns.

pl. 717. Jacq. Aud. v. 4. t. 573. — "Leaves pinnate,
hairy; the outer leaflet very large, round; the lower ones
regularly degrading. Stem single-flowered. Awns upright,
flaggy."—This, and the following species (G. repens) are
found most abundantly on the highest alps of Austria and
Switzerland, where they are extremely ornamental during
the months of July and August. Mount Conis is deftended
by travelers as a favourite habitat of these beautiful plants.
The root of G. montana is fibrous, aromatic, and sometimes
indistinct. Stem round, leafy, from three or four inches to
a foot in height, erect, generally single-flowered, simple.
Petals round, yellow, longer than the calyx. Seeds oval,
brown, with a long feathery awn.

Jacq. Aud. v. 5. 33. t. app. 22. — "Leaves pinnate, cut,
hairy,
GEU

Awns upright, flaggy. — Place of growth and time of 

flowering same as in the preceding species. Root yellowish. 

Runners long, reddish. Flower-folks erect, reddish, flaggy. 

Petals five or eight, sometimes ten, large, yellow. Seeds 

retaining the style, which is broken off in the middle and 

looks like a jointed awn. 

v. 2, 1117. — Leaves pinnate, smooth; leaflets wedge- 

shaped, toothed at the top. Stem single-flowered. Awns 

upright, flaggy. — There is no figure of this rare species 

extant. Willd. has very properly reduced it to Geum, 

though the plant was formerly known as Dryas pentapetala. 

(Linn. Sp. Pl. 717.) Native of Kamtschatka. Root per- 

renial, throwing out filiform, woody creepers. Stipules nar- 

row. Petals five, large, round, white, spreading. Seeds 

turned, tipped with a hairy awn, and longer than the 

flower. It appears by the Linnaean Herbarium to be a very 

elegant species. 

12. G. parviflorum. Small White Avens — Radical leaves 

lyrate, taller than the stem. Stipular cut. Flowers nearly 

sefille. Petals shorter than the calyx. Awns feathery. 

Gathered by Commerson in the straits of Magellan. 

The radical leaves are interruptedly lyrate, hairy, bluntly 

cut and crenate, about three inches long, most resembing 

those of G. rivale. Stem solitary, scarcely two inches high, 

clothed with short dense hairs, and bearing two or three 

terminal wedge-shaped leaves, and as many small, nearly se-

fille flowers, which appear to be somewhat drooping, but 

this can scarcely be determined by the dried specimen. 

Petals, said by Commerson to be white when fresh, are 

smaller than the segments of the calyx. Geum hairsy 

G. rivale. 

13. G. colchisphium. Marsh-marigold leaved Avens — Ra-

dical leaves kidney-shaped, almost circular, sharply crenate; 

on flabby leafy stalks. Calyx turbinate, with lanceolate 

segments. Awns hairy — Gathered by Mr. Menezies on 

the west coast of North America. — This is remarkable for 

the resemblance of its radical leaves in shape and size to those of 

Colchis phylleis, except their being slightly hairy, and their 

long toothed leaves being furnished with a few little oblong or 

three-lobed leaflets, indicating an approach to a lyrate leaf 

altogether. Stem above a foot high, erect, bearing three or 

four smaller, little rounded leaves, more deeply crenate or 

cut, and terminating in about three flowers, on flabby stalks. 

Calyx hairy at its base, turbinate; its segments oblong-lan-

cescent, obtuse, at length erect, the larger ones equal in 

length to the petals which are yellow and broad, like those 

of a common Crowfoot. Awns straight, bluntish, hairy in 

the lower part, possibly becoming hooked at an advanced 

period. 

GEUM Urticum, in the Materia Medica, is a common 

British plant, called Aow, in woods and hedges, flowering 

from May till August. The root, which is the part medi-
cally employed, has an aromatic and somewhat afflicting 
taste, and a pleasant smell of the clove kind, especially 

when it is produced in dry and warm soils. It gives out its 

afflicting matter equally to water and spirituous menstrua; 

but its aromatic part most perfectly to the latter. In di-

tillation with water it yields a small quantity of whitish con-

crete oily matter, of a very grateful fragrance. This plant, 

though little used in the Continent, is held in great estimation 

for various virtues on the continent; but the character, under 

which it has been received since the year 1582, is that of a 

febifage; many illnesses having been adduced of its ef-

terces in obsolete incumens, after the Peruvian bark 

bark had failed. It is said that a tincture of the roots, made in the 

proportion of four ounces of the root digested with a quart 

of brandy in a sand heat, and given in the quantity of half 

an ounce or more, two, three, or four times a day, seldom 

fails to cure agues. Others have given it with equal success 

in decoction, powder, or electuary, in the proportion in 

which the Cinchona bark is commonly employed. This 

root has also been found useful in several chronic disorders, 

as a general tonic and afflicting; and experiments made by 

Buehle have evinced its antifeptic power to exceed that of 

GEWOLJUNG, in Geography, a town of Austria; eight 

miles S. of St. Polten. 

GEVREY, a town of France, in the department of the 

Côte d'Or, and chief place of a canton, in the distri-

ct of Dijon; 7 miles S. of Dijon. The place contains 

1128, and the canton 7894 inhabitants, on a territory 

of 260 kilometres, in 36 communes. 

GEVUNA, in Botany, a barbarous Chili name, adopted 

by Molina. — Jaff. 424. — Claws and order, Didynamia 

Gen. Ch. Cal. none. Cor. Petals four, placed cross-

wise. Stem. Filaments four, two of them very short. 

Pist. Germen superior, simple; style one; stigma thickish. 

Pet. Capule nut-shaped, corticious, of one cell. Seed foli-

tary. A tree, native of Chili, where Dombey and Molina 

have gathered it. The leaves are pinnate, composed of 

four or five pair with an odd one. Flowers terminal, 
situated, two together, many of them abortive. Fruit 

etable, like a hazel-nut, whence the Spaniards call it Acetabul. Seed 

descriptive of albumen. Capule much like that of the Cala-

philois, Jaff. 

GEWUS, JOHN MICHAEL, in Biography, was born in 

Holstein in 1735. His father undertook the care of his 

education, and found in his son a turn for mathematical and 

philosophical pursuits, which he encouraged, and by 

which he became distinguished, and was chosen professor of 

the mathematics in the university of Copenhagen. His 

principal work was the "Theory of the Art of constructing 

Mines," in the composition of which he was assisted by the 

MSS. of Defor, which he had the good fortune to 

obtain, though they had been suppressed in France, after the 

death of that able engineer. He published also a "Treatise 

on the Art of constructing Mines." He gave a translation 

in the German language, from the Danish, of Olafsen 

and Povelsen's voyage to Iceland, which was printed in 

two volumes 4to. He lent several valuable papers to Brehm's, 

Ingenieur-und-Artillerie Magazin, and published a set of 

logarithmic tables. 

GEUTZ, in Geography, a town of Germany, in the 

duchy of Anhalt-Cöthen, near Cöthen. 

GEWICZE, Gcwtz, or Gewitz, a town of Moravia, 

in the circle of Olmutz; 24 miles west of Olmutz. N. 

lat. 49° 47' E. long. 16° 35'.

GEWOLD, CHRISTOPHER, in Biography, flourished in 

the seventeenth century. He was one of the able coun-

sellors of Maximilian, first elector of Bavaria, who confided to 

his care the archives of the duchy, in order that he might 

make use of them as an historian. His works relate chiefly 

to the history of his own country; of these we may men-

tion "Genalogia Serenissimorum Bojaric Ducec, 1623;" 

"Chronicon Monasterii Reicherpergenii." "Delinatio 

Norici veteris, ejusque Continuam;" and "Commentarius de 

Septem viratu Romani Imperii," Moreri. 

GEX, in Geography, a small territory of France, in 

the eidevant province of Burgundy, extending from Fort 

d'Ecluse to the village of Croissy, and from the town of 

Gex to Geneva, being seven leagues in length and three in 

breadth,
GEZ

breath, watered by the Rhine and other streams, and bounded on the west by mount Jura, which yields excellent pastures. The principal articles of trade are cheese, wine, and coal. It now forms a part of the department of Lake Leman.

Gex, a town of France, in the department of Leman, and chief place of a canton, in the district of Geneva, situated at the foot of mount St. Claude; 9 miles N. N. W. of Geneva. The place contains 2,614, and the canton 9,299 inhabitants, on a territory of 212 ½ kilometres, in 14 communes. N. lat. 46° 20'. E. long. 6° 8'.

GEYER, a town of Germany, in the circle of Erzgebirg, situated in the midst of mines, and having manufactures of vitriol, sulphur, alum, and arsenic; 6 miles S. W. of Wolkenstein.

GEYERSBERG, a town of Bohemia, in the circle of Konisingrätz; 28 miles E. N. E. of Chrudim.

GEYRACH, a town of the duchy of Stiri; 9 miles S. S. E. of Cilley.

GEYS, or GEYS, a town of Germany, in the bishopric of Fulda, situated on the Ulter; 15 miles N. E. of Fulda. N. lat. 50° 43'. E. long. 10°.

GEYS Rucken Jaffeek, a mountain of Germany, which separates Upper Carniola from the county of Cilley; 6 miles N. E. of Stein.

GEYSZING, New, a town of Saxony, in the margraviate of Meifen; 12 miles S. E. of Plihutz.

GEZAL, a town of the Arabian Iraq, on the Euphrates; 120 miles W. N. W. of Baffora.

GEZAN, or Djezen, a sea-port town of Arabia Felix, in the principality of Abu-Arish (see Abu-Arish); 23 miles W. of Abu-Arish, the capital of the principality. This province of Gezah, situated on the Arabian gulf, and in a fertile country, carries on a considerable trade in lamma, of which great plenty is furnished by the circumjacent territory, and also in coffee, which is brought hither from the mountains of Hafshid-u-Bakil. It has a trade likewise with the ports on the opposite side of the Arabic gulf; but has no intercourse with the subjects of the Imum.

GEZEID, a town of Egypt, on the right bank of the Nile; 27 miles N. N. W. of Cairo.

GEZIRA, or Jassera, a town of Asiatic Turkey, and capital of a pashalic, in the province of Diarbekir, on the right bank of the Tigris. The whole province of Diarbekir is also called "Al Gezira;" 75 miles S. E. of Diarbekir. N. lat. 37° 16'. E. long. 40° 42'.

GEZIRA CUBROS, in the Materia Medica of the Ancients, a name given to a taw by Avicenna, Serampon, and others. These authors do not give any explanation of what sort of substance they mean by this name, but seem to suppose it a thing universally known, and only give a hint of its qualities.

GEZIRAT AL DAHAB, or Gezirat Iddตลอด, or the Golden Island, in Geography, an island in Lower Egypt, formed by canals cut from the left bank of the Nile, opposite to Faoon.

GEZIRAT AL TËRR, or Island of Birds, an island in the Red sea. N. lat. 23° 18'. E. long. 37° 56'.

GEZULA, or GESSULA, an inland province of the empire of Morocco, E. of the province of Suez, and N. of Ville de Nen; this, together with the province of Dra, lies in the vicinity of mount Atlas which, in this southern part of the country, extends almost to the sea. The inhabitants of this province are considered as the most ancient people of Africa. The country produces a great quantity of barley, and affords pasture for cattle; it has mines of iron and copper, of which are made various utensils, that are exchanged for cloth, spices, horses, and other necessaries. It has every year a fair, which lasts two months, for the sale and exchange of cattle and merchandize in general. The people are free, being allies rather than subjects of Morocco. Their arms consist of fabes, large sharp two-edged swords and lances. They are numerous, but have no towns, and they generally live in camps and villages.

GFOILL, a town of Austria; 8 miles W. N. W. of Crone.

GHALESA, a town of Arabia Felix, which was once a famous city and sea-port, but now sunk into decay, about 20 cottages only remaining to show the place where it stood, and the inhabitants are provided only with dates, and the milk of a goat to drink; 20 miles S. of Hodeida.

GHALGHULUWA, in Zoology, the Ceylonese name of a species of Earl Indian serpent, a mace of a pale brown, variegated with transverse streaks of white, and found among rocks and stones.

GHAN is a name given in Mucfory to caravanserai.

GHANA, as Edfrid and Abulida call it, or GHINNY, in Geography, a city and capital of a kingdom in Africa, situated nearly midway between the Indian sea and the Atlantic on the E. and W.; and between the Mediterranean and the Ethiopian seas on the N. and S.; and, therefore, considered by major Renell as the point on which the oriental and eurpian positions depend. This country lies on the borders of the Neel-Aheed, or Guin river, and is bounded on the N. by Caffa or Kaffina, on the E. by Wangara, on the S. by Melli or Lambe and on the W. by Mezkara and Kaffina. The city is placed in Renell's map on the north bank of the river. According to Edfrid, Ghana is distant 37 journeys (each day's journey of Edfrid being about 1926 geographical miles) from "Germā," through Agadez, or Agadoff. Ghana is an ancient and ruined city of Fezzan, about four journeys E. S. E. of Mouzourzouk, in N. lat. 27° 25'. E. long. 16° 20'. Agadez is 25 of Edfrid's journeys from Ghana, being by W. or S. S. W. from the capital of Fezzan. Ghana is 12 days of Edfrid's scale to the southward of Agadez, or about 229 geographical miles. It appears that Ghana lies somewhat to the east of the line which passes through Agadez from Germa, and Mr. Mathew has taken 700 as the general line of distance from Germa to Ghana. Mr. Mathew was told, at Morocco, that Ghinny (Ghana of Edfrid) was 40 journeys from Kabora, the port of Tombuctoo, along the bank of the Niger. These, taken at the caravan rate between Fezzan and Egypt, Morocco and Jarras, &c. that is, at 150 per day, produce 6522 geographical miles. The restriction of this line with that from Germa places Ghinny in N. lat. 16° 10'. E. long. 13° 21'; in which position it stands at 750 miles from the city of Benin, on the coast of Guinea. For the further settlement of this important point in adjusting the map of Africa, see Renell's Proceedings of the African Association, p. 119, &c.

GHANARA, a city of Africa, the capital of Wagara, situated on a river, which runs into the Niger, or rather into a lake (the Lybia Palms of Ptolemy) formed by the Niger. N. lat. 13° 40'. E. long. 15° 40'.

GHASSA, or GAMA, capital of a district in the northern part of Butten, in the East Indies, and the station of a zoonoom, or provincial governor. The highest mountain in its neighbourhood, whose head is eternally covered with snow, sends forth a spring of water at its base of so great a degree of heat, that few are found capable of bearing, even for a short time, any part of the body immered in it. It is situated near the spring-head of Pathick river. N. lat. 27° 53'. E. long. 89° 18'.
GHENT, a small island in the river St. Lawrence. N. Lat. 43° 26'; W. long. 93° 26'.

GHAZAN, a town of Persia, in the province of Iran; 25 miles E. of Isphahan.

GHAZAN. See GEBAN.

GHEBAHRA, a town of Persia, in the province of Isphahan; 15 miles N.W. of Isphahan.

GHEBI, a town of Italy, in the department of the Hela; 10 miles S. of Brescia.

GHEDEMIC. See GARAMIS.

GHEDEA, a town of Asia Minor, in the government of Sivas; 15 miles S. of Amasya.

GHEDEMAN, a town of Persia, in Chebar; 18 miles S. of Herat.

GHEIRA, a town of Asia Minor, in Natalia; 38 miles N.N.E. of Mocha.

GHELIVE, a town of Asia Minor, in Natalia; 20 miles E.N.E. of Mocha.

GHELIA, a town of Asia Minor, on the coast of the Red Sea, anciently called "Odessa," 48 miles S.S.E. of Mocha.

GHELEN, SIGMUND, in Biography, was born of a respectable family at Prague. When he had attained to a proper age for improvement by foreign travel, he went into France and Italy, and acquired an accurate knowledge of the languages of those countries. On his return he joined through Belf, and made himself known to Eratosthenes, at whose recommendation Ptolemy engaged him as his corrector of the press, by which he gained a small but competent maintenance. He soon attained a higher office than that of corrector of proof-sheets, and joined to it the duties of a critic and translator. He published a dictionary of the Greek, Latin, German, and Dalmatian languages; and annotations upon Phylae and Livy. He translated from the Greek into Latin the Antiquities of Josephus, some Homilies of Chrysostom, and many other learned works. Just before his death, which happened in 1554, he had employed his talents on, and nearly finished, a version of Justin Martyr's works. Besides those already mentioned he was editor of many other works. He was acute and ingenious, and wrote with elegance and fluency. In his private character he was mild and placable, simple and sincere. Moretti.

GHEMAR. See GEMARA.

GHEME, in Geography, a town of Italy, in the department of the Gonia; 13 miles N.W. of Novara.

GHEMIS, a town of Asia Minor, in the government of Sivas; 24 miles W. of Amasya.

GISUNA. See GISUNA.

GHENT, a city of France, and chief place of a district, in the department of the Scheldt, formerly capital of Austrian Flanders, situated on the confluent of the rivers Scheldt, Léie, Meuse, and Lieve, which, together with a number of canals, intersect it in a variety of directions, and divide the town into 26 small islands. It is encompassed by walls about 15 miles in circumference, and includes gardens and corn-fields. Since the French revolution it has been divided into four quarters, viz. North, South, East, and West, and as many cantons. The former contains 15,000, and the corresponding canton 17,454 inhabitants, on a territory of 223,000 square miles, in two communes; the second, or south, contains 16,000, and its canton 16,499 inhabitants, on a territory of 35 square miles, in two communes; the third, or east, includes 15,000, and its canton 16,073 inhabitants, on a territory of 35 square miles, in three communes; and the fourth, or west, contains 13,000, and its canton 13,319 inhabitants, on a territory of fifteen square miles, in three communes. This city was first chosen for their habitation by the Nervii, and afterwards occupied by the Vandals, who gave it the name of "Wanda," whence the present appellation of Gand, or Ghent, is supposed to be derived. It was encompassed with walls by Odosceus, grand monarch of Flanders, and has since been frequently enlarged, particularly in the year 1397, by order of Philip the Bold, 25th count of Flanders. The inhabitants were always warlike, and often engaged in military contests with their own princes, and with their neighbours, which were conducted in many instances with savage cruelty, and terminated in extensive and formidable slaughter. Ghent was the birth-place of Charles V., of whose nativity in their town the inhabitants had little reason to boast, as he loaded them with frequent and heavy impositions, chafed them with rigour for their occasional revolts, and subjected the magistrates and several of the chief citizens to the most humiliating treatment. This conduct on his part inflamed their disposition to revolt, and the consequence was, that one of the small cities in Europe was reduced to a state of perfect solitude. However, it afterwards regained four small portions of its ancient splendour, and became, at least previously to times of recentconfusion, confederable. In November 1576, was concluded in this city the famous treaty called the "Treaty of Ghent," containing 25 articles, and amongst others, granting them full power for settling that the Spanish and foreign troops should leave the country, that the provinces of Holland and Zeeland should remain united with the others, that the Catholic religion should be maintained, and that the ancient privileges of the country should be secured; and this treaty was approved and ratified by Philip II., king of Spain. In 1678 Ghent was taken by Louis XIV., king of France, but restored to Spain at the treaty of Nimègue in the same year; and it remained in their possession till it was taken by the allies in 1706, after the battle of Ramillies. It was seized by the French in 1708, but recaptured by the allies under Prince Eugene and the duke of Marlborough, in the same year. Ghent was erected into a bishopric in 1559 by pope Paul V., at the solicitation of Philip II., king of Spain, subject to the archbishop of Malines. It had, besides the cathedral, six parish churches, and many religious houses; some of the streets are broad and well-paved, and the market places spacious, in the midst of one of which is a statue of Charles V., in his imperial habit. Ghent carries on a considerable trade in cloths, linen, lace, and silk manufactures, and is much admired, in favourably times, by two navigable canals; one to Saxe-Ghent, and another to Briggs, Olen, &c. The magistracy consists of burgomasters, ceucons, and common-council. John, the third son of Edward III., king of England, was born in this city, and from this circumstance called John of Gaunt. In November 1572, the French took possession of this city, but evacuated it on the retreat of Damourier; however, they afterwards regained it in their progress through the country: 30 miles S.W. of Antwerp. N. lat. 51° 3', E. long. 3° 43' 20".

GHER, a town of Africa, in the county of Suldumfia, or Sisiliaa, on the Ziz, near mount Atlas; 90 miles N.W. of Suldumfia.

GHERANGOL, a town of Africa, in the country of the Poulohs, on the S. side of the river Senegal. N. lat. 14° 40', W. long. 14°.

But neither of these canoes produces the effect ascribed to them. Vaillant supposes that it is a mark of distinction, adopted by their ancillors, when at war with neighbouring nations, by which they might know one another; but that account is no less fanciful and improbable than any other. Whatever is the cause from which this practice originates, it is performed by the father, commonly at the birth of the child; though it is sometimes deferred till the child has completed his third year.

GHEZ, a town of Grand Bucharis; 24 miles S.S.E. of Balk. N. lat. 36 16'. E. long. 65 40'.

GHEZAN. See GEZAN.

GHEZZI Pier Leone, called Cavaliere Ghezzii, in Biography, a painter who was a pupil and imitator of Pietro Cortona. He was selected with Luigi Trevianni, and other artists of the same style, to paint the prophets in St. John Lateran; and executed many other works of less consequence, but he obtained most celebrity by his skill in caricature, which he freely indulged.

GHIABUNDER, in Geography, a town of Bengal; 25 miles S.S.W. of Gorapat.

GHELIELNS. See GHELIELNS.

GHiCKERS, an appellative given to those who inhabited the northern and largest division of the hilly tract situated between the Belaut, the Sinde, and Cabhmore, in Hindoostan, by way of contrast to the Jauds, who occupied the southern and least division.

GHIDORE, in Geography, a province of Bengal, bounded on the N. by Bahar, on the N.E. and E. by Curruckpore, on the S. by Birkoon, and on the S.W. by Curricolede and Moy. The chief place is Ghidore; which is 70 miles S.E. of Patna. N. lat. 24 51'. E. long. 86 23'.

GHIETZ, a fortress of Persia, in the province of Irak, taken by the Afghans in 1723.

GHIILAN, or KILAN, synonymous with the ancient Gela, a province of Western Persia, bounded on the N. by the provinces of Aderbajian or Anderbeizaun and Schirvan, on the N.E. by the Caspian sea, on the E. by the Caspian sea and the province of Mazanderan, on the S. by the Persian Irak, and on the W. by the provinces of Aderbajian and Curdisun; about 200 miles from E. to W., and 150 from N. to S. This is one of the most beautiful and fertile provinces of Persia, producing silk, olives, rice, tobacco, and most excellent fruits of all kinds, and in such abundance, as not only supply the wants of its inhabitants, but sufficient to provide for a great part of Persia and Armenia. The manufactures and silk of Ghiilkan are esteemed the best in Persia, and have been in such repute for many years, that Ralfid, its capital, is become one of the first commercial towns in this part of Asia. The small fort is usually white, and chiefly built into the interior cities of Persia, or sold to the Turks; the interior kind is yellow, and principally disposed of to the Rullians. Ralfid supplies the bordering provinces of Persia, and the independent neighbourine states, as far as Georgia, with European merchandise, except the goods which are transported immediately from Anfiran, through Kilker and Metsko, to the nearly part of Georgia, and of the neighbourine mountains; and those sent from Shamakake to the Lignje Tatars, and other independent tribes. In this province are seen whole forests of mulberry, box, and walnut trees. Every peasant has a garden to his cottage, planted with orange trees, citrons, figs, and vines. For a further account of the trade and government of this province, we refer to the articles Caspian Sea and Persia.

GHELIELNS. See GHELIELNS.
no rival, except Hidæst, khan of Ghilan, whom he forced to fly from Rahîl or Rahad, his place of residence, and who was killed near the port of Simîlî. In consequence of these events, Asûtî became monarch of the whole of Western Persia, and having been made an emir in his infancy by order of Nadîr Shâh, he nominated for his successor his nephew Baha Serdar.

GHILDI, a town of Africa, on the Senegal; 30 miles N.W. of Gallam.

GHILON, a town of Cardifian; 30 miles S.S.W. of Erbil.

GHINAILA, a town and territory of Africa, on the river Rio Grande, near its mouth. N. lat. 11° 15'. W. long. 14° 15'.

Gen. Ch. Cal. Perianth of one leaf, tubular, permanent, inferior, its orifice with five pointed spreading teeth. Cor. of one petal, irregular; tube long, narrow; limb of two lips, the upper one larger, roundish, concave, ascending; lower in three deep roundish segments, the middlemost larger, deflexed, emarginate. Stam. Filaments four, inserted into the tube above its base, two of them longer than the roll; anthers each of two separated oblong cells, one of them terminal, fertile; in the longer flamen only, the other like a little fleece in the middle of each filament. Pip. Germin roundish, superior; style thread-shaped, the length of the tube; stigma four-lobed. Peric. Drupa turbinate, auricular, dry, projecting beyond the permanent calyx. Nut angular, of four or five cells. Seeds solitary.

Eff. Ch. Calyx with five sharp spreading teeth Cortex ringlet, two-dipped; the lower lip three lobed. Nut coated, furrowed, involuted with the calyx. Seeds solitary. Another of two distinct lobes.

Obs. We think this genus ought to be placed in Diny- naim, along with Verbena, to which it is nearly skin, though only the longer flamen appear to be perfect; but this may happen, and cannot be determined without repeated examinations of wild specimens.

Native of several parts of the West Indies, where Howlett and Swartz have gathered and examined it. This is an annual and rather humble herbaceous plant, with a branched stem, ovate deeply serrated leaves, and long loose spikes of small whitish flowers.

Native of Guiana and Cayenne. Much like the former, but with downy leaves, and unarmed fruit, and the middle segment of the lower lip of the corolla, according to Swartz, is emarginate in this, entire in the preceding. Neither of them have much beauty, nor any other qualities to recommend them for cultivation with us in the lowe, though perhaps they might be planted out for the summer, if desirable, like other tender annuals.

GHINNA, or GHENNE, in Geography, a town of Egypt, on the E. side of the Nile, opposite to Kiffa, or Koptos, on the other side, and distant from Coëssor, or Kolire, on the Red Sea, about 90 geographical miles. N. lat. 26° 11'. E. long. 32° 45'.

GHINUE, a town of Asiatic Turkey, in Natolia; 24 miles N.W. of Sinoe.

GHIO. See Kemillik.

GHIO, a town of Africa, belonging to the Foulahs, on the Senegal; 12 miles S.W. of Gunnel.

GHIR. See Gir.

GHJRGIN. See Gunugin.

GHIRLANDATIO, DOMENICO, in Biography, a painter, of whom Vafari speaks as being of the first rank in his time. His real name was Corradelli. He at first was employed by his father, in his own profession of goldsmith, at Florence, who obtained the name of Ghirlandaio, by having been the first to make little metallic ornaments (Ghirlandi) for children to wear. Domenico continued to paint, after he had adopted painting as his profession, for the churches and palaces in Florence, both in fresco and in oil. He, like other artists of the time, introduced into his pictures the portraits of his friends, but gave them more character pertaining to the subject, than had hitherto been done; and he was the first who left off gilding in pictures, and attempted to imitate its effects by colours. He was called to Rome by Sixtus IV. to adorn other palaces employed in painting his chapel. His works there were afterwards spoiled to make room for those of M. Angelo. He was highly honoured, and employed nobly; but his greatest glory is, having had the great hero of the art, M. Angelo, for a pupil. He died in 1493, at the age of 44. His brothers, David and Benedetto, imitated many of his works, and educated his son Ridolfo to the art, who afterwards made great progress, and obtained esteem from Raphael himself, who invited him, but not successfully, to work in the Vatican. In Ridolfo's pictures, Mr. Fuseli says, there is something analogous to the genius of Raphael; although, in the vivacity of the face, the choice of the colours, the tender idealizing of the features, the soft adoration, and fondness expressed, with inferior powers. He died in 1566, aged 75.

GHIRNAH, in Geography, a river of Hindoostan, which runs into the Taptar; 36 miles S.B. of Burhanpore.

GHISCIOLA, a town of Italy, in the department of the Upper Po; 15 miles S.E. of Cremona.

GHISETELLES, a town of France, in the department of the Lys, and chief place of a canton, in the district of Bruges; 11 miles S.W. of Bruges. The place contains 2,500, and the canton 11,424 inhabitants, on a territory of 18,211 square kilometres, in 18 communes.

GHIWIRA, a town of Italy, in the department of the Olloa; 30 miles N.W. of Milan.

GHIZNI, or GAZNA, an ancient empire of Hindooftan, founded by Abilfagi, governor of Khorasan, A.D. 956, who revolted from the king of Bucharâ. Ghizni confided chiefly the tract which comprised the kingdom of Bactria, after the division of Alexander's empire; that is, the countries lying between Parthia and the Indus, and south of the Oxus. The Ghizni empire, subjected to the same causes of decay as his predecessors, was, in 1358, forcibly divided; the western, and largest part, and which still retained the ancient name of the empire, being seized on by the family of the Ghaurides, (to
demominated from Gaur, or Ghor, a province and city lying beyond the Indian Caucuas), while the provinces contiguous to both shores of the Indus, remained to Chuforo, or Ciftro, who fixed his residence at Lahore; and even his proclivities were, in 1184, driven out of their kingdom by the Gaurides. The death of the emperor Mahomed Gori, in 1205, occasioned a new division of the Ghizni empire; the Persian part remaining to Elkoze, and the Indian part to Cutilub, who founded the Patan, or Afghan dynasty, in Hindooстан.

In 1221 Genzic Cawn, among his extensive conquests, accomplished that of the empire of Ghizni; putting an end to the dynasty of Charsam, which then occupied that throne, and driving before him the unfortunate Gahib, son of the reigning emperor, who forced the Indus to avoid his fury.

The ancient empire of Ghizni is nearly comprehended by the kingdom, known at present by that of Candahar. See Candahar.

Ghizni, or Gaizna, a city of Candahar, once the reputed capital of the Ghizni empire, and placed among the western sources of the Indus, and not far from the Indian Caucuas. The position of Ghizni is erroneous; fixed by M. D'Anville in the N.W. extreme of Cabul; whereas it appears to be almost in the very heart of that province. It is termed the "Second Medina," on account of the great number of illustrious persons whose remains have been interred there. Wonderful stories are related concerning its extent and population in ancient times; nevertheless, Lasser expresses his surprise at its having ever been pitched on for the seat of any empire. Ghizni is distant about 56 geographical miles S. by W. from Cabul, about 1676 miles from Candahar, and about 88 miles from Esmahan. N. lat. 33° 45'; E. long. 86° 28'.

Ghodan. See Gorax.

Ghoga, a town of Holland, in Overijssel, on the Rijcker; 10 miles N.N. E. of Borkeloe.

Ghor. See Givan.

Ghora, a town of Arabia, in the country of Yemen; 15 miles E. of Labbo.

Ghoup, a mountain of Southern Africa. This, and also Nieuweld, are a continuation of the Roggeveld mountain, and join the divisions bearing the same name in the district of Graaf Reinet. They have lately been defunct, on account of the number of Booshefman Hotentots, who dwell close behind them.

Ghurband, a town, and district of Cabul; 42 miles N.W. of Cabul. N. lat. 33° 55'; E. long. 87° 5'.

Ghouri, a town of the kingdom of Balk. N. lat. 35° 40'; E. long. 66° 56'.

Ghule el Alijan, a town of Arabia Felix; 10 miles N.E. of Chamir.

Ghulpaigan, a town of Peria, in the province of Iraq, taken by the Afghans in 1723; 100 miles N.N.W. of Ispahan. N. lat. 33° 45'; E. long. 50° 40'.

Ghumischkana, a town of Afghan Turkey, in the government of Trebizond; 50 miles S.S.W. of Trebizond.

Giumufede, a sea-port of Arabia, on the Red Sea, belonging to the sherry of Mecca. All vessels which carry coffee to Jidda are compelled to anchor here, and pay a duty; 145 miles S. of Mecca. N. lat. 29° 7'.

Ghuni, one of the smaller Cape Verde islands, being little more than a rock.

Ghirman, a town of Peria, in Segelatan; 50 miles N.E. of Ferahe.

Ghayaspour, a town of Hindooстан, in Bahar; 20 miles W.S.W. of Chuprab.

Gia, an Italian adverb, used in Myce for already, formerly, e ci sono; as "Gia maestro di cappella del Duce di Milano," formerly maestro di cappella, or composer, to the cathedral of Milan.

Giaabur, in Geography, a fortress of Asian Turkey, in the province of Diarbekir; 120 miles S.S.W. of Diarbekir.

Giacomelli, Gaemiano, in Biography, of Parma, composed for the theatres of Venice, between the years 1754 and 1756, seven or eight different dramas, written chiefly by Apollolo Zeno and Maffia. He was the scholar of Capigli; but adopted a more high and flighty style, with which the Venetians were much captivated, before they heard the more graceful and expressive airs of Vaci and Hail.

Giacomo, Sr. in Geography, a town of Italy; three miles S. of Verona.—Also, a town of the Valdaine; two miles N.W. of Chivazan.

Giacomo, Sr., valley of, a valley of Switzerland, which is part of the county of Chivazan. It is narrow, and watered by the torrent Lira; contains about 10 parishes, is under the jurisdiction of the commissary, and possesses several important privileges that preserve the inhabitants from the oppression which their neighbours endure. All cause are tried in the valley. The criminal matters are those of Chivazan, with this difference, that instead of the silence, the valley chews four persons, who are always present at the examination; and without whose concurrence, torture cannot be inflicted, nor sentence passed. The valley has its own code of jurisprudence, and courts independent of the commissary, from the decision of which an appeal lies to the diet.

The lower part of the valley produces vines and corn; the upper, rye, barley, and pulate, mixed with large groves of fir and pine.

Giacomo Arkadel, in Biography, a Netherlander, and a disciple of Juquin, enumerated by Adami among the fingers and composers of the pontifical chapel in the 18th century. He was maecistro di cappella some time at the cardinal of Lorrain, and had acquired great fame by his madrigals, of which he published at Venice, between the years 1530 and 1575, five books. In one of which is the celebrated madrigal, "Il bianco e dolce Cigno cantando muore," which was in high favour all over Europe.

Giaiden, in Geography, a town of Arabia, 60 miles W. S.W. of Mecca.

Giadila, a town of Arabia, in the province of Nedsjed, 60 miles S.W. of Kariatin.

Giadri, a town of Albania, on the Drino; eight miles N. of Alepfo.

Gigats of Africa. See Jages.

Giachi, or Jachagi, a cycle of twelve years, in use among the Turks and Cathays.

Each year of the giachi bears the name of some animal; the first that of a mouse; the second, that of a bull; the third, of a lynx or leopard; the fourth, of a hare; the fifth, of a crocodile; the sixth, of a serpent; the seventh, of a horse; the eighth, of a sheep; the ninth, of a monkey; the tenth, of a hen; the eleventh, of a dog; and the twelfth, of a hog. They also divide the day into twelve parts, which they call giachs, and distinguish them by the name of the same animals. Each giach contains two of our hours, and is divided into eight lbs, as many as there are quarters of hours in our day.

Gialakowa, in Geography, a town of Euroca, or Turkey, in Romania; 60 miles N.E. of Filippopoli.

Giallollino, in Natural History. See Nafas Yellow.

Giamani,
GIANMANI, in Geography, a town of Persia, in the province of Chufillian; 15 miles S.S.W. of Suzer.

GIAMBASSI, a town of Asiatic Turkey, in Natolia; 20 miles S.S.E. of Smyrna.

GIANAL, a town of Persia, in the province of Kerman; 50 miles E. of Sinojan.

GIACAZZO, St. a town of Naples, in the province of Otranto; 12 miles S.W. of Brindisi.

GIANNONE, Petrus, in Biography, was born at or near Naples about the year 1630. He was educated for, and practised in, the law, but was much more distinguished as an historian. In 1723, he wrote a "History of Naples," in four volumes 4to. The style is pure, but the freedom with which he discussed several topics relating to the origin of the papal power gave so much offence to the court of Rome, that he was obliged to exile himself from his native country. He found an asylum with the king of Sardinia, who did not, however, dare to afford him his protector, but chose rather to represent his situation as that of a prisoner. Giannone died in Piedmont in 1748. Extracts from his history were afterwards printed in Holland under the title of "Anecdotes Ecclesiastiques." His pathomous works were given to the world in a quarto volume, containing, among other miscellaneous matter, his "Professor of Faith," and a justification of his history.

GIANOTTO, a performer on the double-bass in the opera at Paris, from the year 1730 to 1757, who published, in 1750, a treatise built on the principles of Ramo, entitled "Guide du Compositeur," the Composer's Guide: a work much admired by the followers of Rameau. The author of this treatise having been long in the practice of explaining the system of the fundamental base to his scholars, has drawn up his own work in a clear and intelligible manner.

GIANNUTI, in Geography. a small island in the Mediterranean sea, near the coast of Italy. N. lat. 42° 24'. E. long. 11° 30'.

GIANT, 7ft. 4in., a man of extraordinary, enormous stature and bulk.

The reality of giants, and of nations of giants, is much controverted among the learned. Travellers, historians, and relations, both sacred and profane, furnish various instances of them; a great part of which naturalists and antiquaries assert.

There are among the ancients who speak of giants, as historians, and all men there were such beings, are Caesar, de Bello Gallico, Lib. i. Tacitus, de Morib. German. and Amil. Lib. ii. Florus, Lib. ii. pap. 2. St. Augustin, de Civit. Del. Lib. xx cap. 9. and Saxo-Grammaticus, at the end of his history among the moderns, Hannon, Magnus, Miscellan. de Gigantibus, Chauquesius, de Gigantibus; Kircher, Mund. Sotterr. Lib. viii. sect. 2. and many others, that Stobæus, in his notes on Saxo-Grammaticus, affirms, nothing can be more extravagant than to deny or allegorize the such stories we have concerning them.

Dr. du Chaton observes, that though we read of giants before the Flood, Gen. vi. 4, and more plainly after it, Numb. xiii. 33, yet it is highly probable the size of man has always been the same from the creation; for as to the Nephilim, Gen. vi. the ancients say about them, some taking them for men of impurity, others for rapine, tyranny; as to those, Numb. xiii. who were evidently spoken of as men of a gigantic size, it is probable the tears of the fish might add to their bulk.

But this as it will, it is manifest, that in both these places giants are spoken of as raptists and wonderers of the age, out of the common nature; and such inances we have had in all ages. But it is not at all improbable, that the first men were of a strength and stature superior to those of mankind at present, since they lived a much longer time; long life being commonly the effect of a strong constitution. There are many fabulous relations; such as we take to be that of Thleuto-bocchus, who is said to have been dug up anno 1613, and to have been higher than the trophies, and twenty-six feet in height; and no better we suppose the giants to have been, of whom Ol. Magnus gives an account in his fifth book; such as Herthen and Starchater, among the men; and among the women, "reperta est (faith he) quaela—in capite vulpes, mortua, induta chlamyde purpurea longitudinis cubitorum 50, latitudinis inter humeros quantura." Ol. Mag. Hist. lib. v. cap. 2.

But, as in the more credible relations of Goliath, whose height was six cubits and a span, (1 Sam. xvii. 45.) which, according to bishop Cumberland, is somewhat above eleven feet English, of Og, king of Bashan, (Deut. iii. 11.) whose bed was nine cubits long and four wide, of Maximinus the emperor (who was nine feet high), and others in the reign of Augustus and other Roman emperors, of about the same height; to which might be added the dimensions of a skeleton, dug up in the place of a Roman camp, near St. Alban's, by an urn inscribed Marcus Antoninus, of which an account is given by Mr. Chefefield, who judged, by the dimensions of the bones, that the person was eight feet high, Phil. Trans. N. 333; these antique examples and relations, we say, may be matched, may outdone, with modern ones; of which we have divers in J. Ludolph. Comment. in Hist. Æthiop. lib. ii. cap. 2. sect. 22. Magnus, Conringius, D. Hakewel, and others; the last mentioned writer speaks from Nannos, of porters and archers belonging to the emperor of China, fifteen feet high, and of others from Purchas, of ten and twelve feet high, and more. See that learned author's Apol. p. 288.

The existence of a race of men above the common stature, on the coast of Patagonia in South America, has been the subject of dispute for the last two centuries. In one century almost all navigators, of every country, affirmed that there were such persons: and in the next the fact is denied by the greater number, and their predecease are treated as timid or boasting fabulists. The Yrca Garcellato de Vega, in his history of Peru, relates, that according to a tradition universally received, a number of vessels or junkes came to St. Helena with a company of giants on board, of a stature so enormous, that the natives of the country were not higher than their knees; that their eyes were as broad as the bottom of a plate, and their limbs proportionately large. But these are fables, similar to those relative to the same subject in other parts of the world. See GIANTS' legs.

Turner, the naturalist, reports that he had seen, near the river Plata, on the coast of Brazil, a race of giants, who went stark naked, one of whom was twelve feet high; but he acknowledges that he saw no others so tall. The ocular witnesses on the affirmative side of the question are, Magellan, Loaifa, Sarmento, and Nodal, among the Spaniards; Cavendish, Hawkins, and Knivet, among the English; Schull, De Noort, Le Mair, and Spilberg, among the Dutch; and among the French, those who went in the expedition from Mareilles and St. Maloes, in the year 1724.

Knivet affirms that he measured several dead bodies, which he found buried at Port Defire, which were from fourteen to sixteen spans high; and that he had frequently seen at Brazil one of the Patagonians, who, though a youth, measured no less than thirteen spans; and that the English prisoners at Brazil affirmed him, that they had seen many men of the same gigantic stature upon the coasts of the island; this account is also confirmed by Schell de Wel, and Oliver de Noort. Arie Clia,
GIANT.

Clair, a commissary on board Le Maire's fleet, declares that he found, in the fuculches on the coast of Patagonia, the bones of men who were between ten and eleven feet high. Nodal and Sir Richard Hawkins merely relate, that these fossils were a head taller than the inhabitants of Europe, and of such a stature, that the people on board their vessels called them giants.

Those who bear testimony to the contrary, are Winter, the Dutch admiral Herrmitz, Froger in De Gennes's Narrative, and Sir John Narborough. Sir Francis Drake also is silent with respect to the stature of the inhabitants of Patagonia; but Winter positively affirms, that the accounts of their being giants are falsehoods invented by the Spaniards. Narborough measured the skulls and the print of the feet of the fossils on the coast of the Strait of Magellan, which, he says, were of the common size; and he had often seen companies of them at Port St. Julian, who were neither taller nor bigger than other men. However, it may be observed in general, that the greater part of those who hold the affirmative in this question, speak of people that inhabited the desert coasts of Patagonia to the east and west; and that, on the contrary, those who hold the negative, speak of those who inhabit the Strait upon the sides of the utmost point of America to the north and south. Frezier relates, not from his own knowledge, but from the testimony of eye-witnesses, that there was, at a considerable distance within the country from the coast of Chili, an Indian nation, called by their neighbours Caucouhnes, who sometimes came down to the Spanish settlements, that were more than nine feet high, and were the same race with the Patagonians who live on the easter coast. It appears from various relations, that the inhabitants of the two borders of the Strait are of the common stature, and that the race, distinguished by the name of Patagonians, make their constant residence upon the desert coasts, scarcely accessible to any but themselves; and when European ships frequented the Strait, they removed and settled in the interior part of the country; however, the current testimony of late navigators, particularly commodore Byron, captain Wallis, and captain Carteret, will put an end to the doubts that have been hitherto entertained of the existence of such persons. Commodore Byron, who visited the coast of Patagonia in the year 1764, speaks of the inhabitants as of a gigantic stature; but he did not measure any of them, and only concluded, by the proportion of their stature to his own and that of his companions, that they could not be less than six and a half, or seven feet in height, and proportionably strong and bulky.

Captain Wallis had an interview with these people in 1766, and found, by measuring them, that the stature of the greater part of them was from five feet ten inches to six feet, though there were some who were five feet five and five feet six inches, and one who was five feet seven inches. Captain Carteret, who accompanied captain Wallis on this occasion, confirms the above account in his letter to Dr. Maty. See Phil. Trans. vol. iv. art. 2. p. 29, &c. See Hawkesworth's Voyage, vol. ii. Introd. and p. 28. 154.

GIANTS, Rebel, in Ancient Mythology, were the sons of Terra, or the Earth, by Cacus, who made war against Jupiter and the celestial deities, to avenge the defeat of the Titans. These giants are represented as of an enormous height and size, having a wild and dreadful aspect, and killed by strength proportioned to their bulk; each of them had a hundred hands, and from insted of legs. Being determined to dethrone Jupiter, they reared Mount Ossa upon Pelion, and Olympus upon Ossa, and from thence attacked the gods with huge rocks, some of which fell into the sea and became islands, and others fell on the earth and formed mountains. Jupiter summoned a council of the gods, and being informed that it was necessary to obtain the assistance of some mortal, with the advice of Pallas he called up Hercules, and with the aid of this hero, exterminated the giants Enceladus, Polhub, Akyon, Phorphyrio, the two sons of Atyus, Ephialthus, Others, Eurystus, Clythus, Tythus, Pallas, Hippolitus, Agrimus, Thoim, and Typhon, the last of whom it was more difficult to vanquish than all the others. Jupiter having thus gained a complete victory, called the rebels down to Tartarus, where they were to receive the full punishment of their enormous crimes: according to the account of some of the poets, he buried them alive under Mount Etna and different islands.

For the explanation of this fable, some have supposed that Jupiter (for whose history, see JUPITER) destroyed the robbers that infested Thessaly, and that there are the pretended giants; for we have already observed (in the preceding article) that the appellation "Nephilim," occurring in Scripture, and translated giants, signifies people addicted to all kinds of licentiousness and violence, or robbers and ruffians. Jupiter, when he left Crete to visit the other parts of Greece, usually resided on Mount Olympus, where he had probably built a strong citadel. This Mount Olympus, highly elevated, was afterwards taken for heaven itself, and the most ancient poets, especially Homer, to describe it. The banditti now mentioned, determined to make an attack on that prince, besiege him in his citadel, which afterwards gave rise to the fiction of their having attempted to scale heaven, and of their having made an assault upon it. It is added, that with this view they pried Ossa upon Pelion, importing, as it is conjectured, that they had fortified these two mountains, which are also in Thessaly, and at no great distance from Olympus, whither they retired after their excursions, and kept Jupiter's garrisons in awe. For other particulars, see Baner's Mythology, vol. iii. See also TITANS.

GIANTS' BONES, a name too hastily given by the vulgar to certain bones and parts of skeletons, of an enormous size, found in England and other places. Of all the numbers of thefe, which have been publicly thrown about as wonders in nature, not one but has proved, on examination, a bone of an elephant, or else of a whale, or of some other terrestrial or aquatic animal not perhaps extinct; the first, however, is usually the case, as the bones of elephants are much more frequently found buried in the earth than those of the whale.

Sir Hans Sloane mentions a vertebra of the loin of a whale sent him from Oxfordshire, where it was dug up under ground, and afterwards used as a stool to sit upon, and vulgarly supposed part of a human back-bone. Now, if the whole size of the body had been calculated from this piece, the account would have presented such a size as would have far exceeded all the fabulous stories of giants' skeletons extant in the world.

Many skeletons of this kind have been found which have been called the skeletons of giants: such are those of Pholadnatus, which are said to be the bones of men of twelve, twenty, and even thirty cubits high; that found in a mountain of Crete, and mentioned by Plato and Pliny, forty-six cubits high; another of sixty cubits, found near Tanger in Moorsia, mentioned by Plutarch and Strabo, and supposed to be the skeleton of Anteus; the skeleton of Pallas, the son of Evander, found in Rome, and said to be taller than the walls of that city; another, found in England in 1171, fifty feet long. St. Aulin allées, in proof of the existence of giants. Before the flood, a gringer tooth, which he saw on the shores of Utica, was in reality that of
GIANT.

The regular figure of the flone, composing this caufeway, is not more wonderful than its quantity. The whole country for many miles being full of it, and a vall mafs running far into the fea; for, before what vulgarly goes by the name of the Giants Caufeway, which is itself of vall ex-tent, there are great numbers of the fame pillars at distances in other places.

There are two other smaller and imperfect caufeways to the left hand of the great one, and farther in the fea, a great number of rocks flew themselves at low water, which appear plainly all to confift of the fame fort of column. In going up the hill from the caufeway there are found, in different places, a vall number of the fame columns; but these do not stand erect, but are laid finking upwards in different angles and directions. Beyond this hill, eastward, also, at feveral distances, there stand a great number of the fame pillars, placed ftraight and erect, and in clusters of different fizes. These are feen scattered, as it were, over the vell parts of the hills.

One parcel of them is much admired, and called by the country people the looms of the organs. It flands in an elegant form, and faces the bottom of the hill. The columns, of which this clufter confifts, are about fifty in number, and they are fo nicely put together, that the tablet fland in the middle, and the shorter gradually on each fide of it to the end, fo that they look like the pipes of a church organ viewed from the front. The tablet one of all these, which flands exactly in the centre, is forty feet high, and confifs of forty-four diftinct joints.

What is emphatically called the Giants Caufeway is, in fact, a small portion of that vall basaltic area, of which the promontories of Bengore and Fairhead confift, and which extends over a great part of the neighbouring country. These two great promontories, which have been examined by many, and lately by Dr. Richardson, fland at the distance of eight miles from each other, and are the leading features of the whole caft of Antrim. The former of them, situated about seven miles Wefl of Ballycastle, represents it elf at a distance, and in profile, as an extensive headland, running out from the caft a coniferable length into the fea; but, frivolly speaking, it is made up of a number of leffer capes and bays, the whole of which forms what the fenmen denominate the headland of Bengore. These capes are compofed of a variety of different ranges of pillars and a great number of strata, which, from the abruptnefs of the caft, are very confpicious, and form an unrivalled pape of natural architecture, in which all the neat regularity and elegance of art is united to the wild magnificence of nature. The promontory of Fairhead raifes its lofty fummit more than 500 feet above the fea, forming the eafhern terminal of Ballycastle bay. It prfents to view a vall compact mass of rude columnar flones, the forms of which are extremely grofs, many of them being near 150 feet in length, and of a vall texture. The base of these gigante columns fixes a wild wall of natural ruins, of an enormous fize, which, in the course of fuccedance ages, have been tumbled down from their foundation by flones, or foine more powerful operations of nature. The maffe bodies have sometimes withstood the flock of their fall, and often lie in groups and clumps of pillars, refeemblying many of the varieties of artificial ruins, and forming a very novel and striking landscape. Befides these two promontories, there are feveral other parts of the county of Antrim which exhibit a fimilar columnar basaltic structure. Thus the mountain of Dunmull, between Coleraine and the river Bush, abounds in fuch basalt, particularly at the craigs of Illamore, where two different ranges of columns may be discovered; they may be seen

7

150
GIANT.

also at Dunluse-hill, near the castle of Dunluse; in the bed of the river Buth, near the bridge of Buth-mills; on the summit of the mountain of Croogimon; in many parts of the high land over Ballintoy; in the island of Raghery, opposite Ballycastle, and various other places, through an extent of coast about fifteen miles in length and two in breadth. Beyond this tract, which abounds in perfect pillars, an attentive observer will be able to trace the same materials and stratification in very distant parts of the country, as far as the northern shore of Loughnag, and the mountains of the county of Derry; in many places of which imperfect columnar forms may be observed; so that the great cause which generated this species of stone has been exercised through a space of more than forty miles in length and twenty in breadth; that is, through above eight hundred square miles.

Of the different varieties observable in the columns that compose the Giants Caufeway and those of the other parts of the coast, the following comparative view has been given by Mr. Hamilton. 1. With respect to form and magnitude: the pillars of the caufeway are comparatively small, not very much exceeding one foot in breadth and thirty in length; sharply defined, neat in their articulation, with convex or concave terminations to each joint. In many of the caps and hills they are of larger size, more imperfect and irregular in their figure and articulations, having often flat terminations to their joints. At Fairhead they are of a gigantic magnitude, sometimes exceeding five feet in breadth and a hundred in length; often apparently delitute of joints altogether. 2. With respect to situation: the pillars of the Giants Caufeway stand on the level of the beach, from whence they may be traced, through all degrees of elevation, to the summit of the highest grounds in the neigbourhood, as at the old fort of Drumill, and on the top of Croogimon, fix hundred feet at least above the level of the sea. 3. With respect to disposition and arrangement: at the caufeway, and in most other places, they stand perpendicular to the horizon; in some of the caps, and particularly near Ulbent harbour in the isle of Raghery, they lie in an oblique position; at Doon-point, in the fair island, and along the Ballintoy shore, they form a variety of regular curves. 4. With regard to colour and grain: the Giants Caufeway basalt is blackish, close, and uniform; its varieties of colour are blue, reddish, grey; and of grain, all that can be effuped from extreme fineness to the coarse granulated appearance of a stone, which resembles imperfect granite abounding in crystals of horn, chiefly black, though sometimes of various colours. 5. With respect to texture: though the Giants Caufeway basalt be in general compact and homogeneous, yet the upper joint of each pillar, where it can with certainty be ascertained, is always rudely formed and cellular. The grofs pillars also, in the caps and mountains frequently abound in these air-holes through all their parts, which sometimes contain fine clay and other apparently foreign bodies: and the irregular basalt beginning where the pillars cease, or lying over them, is, in general, extremely honey-combed, containing in its cells crystals of zeolite, little morrels of fine brown clay, sometimes very pure flaxite, and in a few instances bits of granite.

The inland pillars, upon the whole, differ from those which run into the sea, and are called the caufeway, only in the following particulars; some of the inland pillars are much larger than those of the caufeway, being two feet and a half in diameter, and among these there are only found such as have three, four, five, and six sides, none of them having yet been found to have seven or eight sides, as many of those of the caufeway itself have. And, finally, these inland pillars, though composed of as many joints as those of the caufeway, yet have not that curious articulation of the ball and socket, but are only joined by the laying one smooth surface on another; so that a joint of a single column may be dipped off from the red, by a considerable force prifling against it. There is something like this observable also in some of the columns of the caufeway itself; for among the numbers which are jointed by the ball and socket, there are some which do not adhere by being applied surface to surface. This is found only in a few of the columns, however, and they always stand within the chisels, and are composed of less than seven sides. In those also the joint is not made by the application of two horizontal planes, but by such as flant, so that it looks very like the breaking of an entrochus or sileria.

The joints, as we see the pillars above the surface, are usually as many in number as the pillar is feet high; but they are not regularly each of a foot long, for they are shortened at the upper part of the columns, and run gradually longer and longer as they approach the bottom. This is observed both in the inland columns, and in those of the caufeway; but though the length of the joints differs, their convexities and hollows are much the same in all parts of the column.

There are other basaltic columns, similar to those above described, in our own island; particularly at Staffa, one of the western islands of Scotland; in the mountain of Caderidris, near Dolgelly, in Merionethshire; where they probably form a group as in other places. Mr. Strange has given an account of two groups of prismatic basaltic columns, which he discovered in the Venetian slate in Italy; one in Monte Roffo, about seven miles near south from Padua, and the other in Monte del Diavolo, near San Giovanni lllarione, about ten miles north-west of Vicenza. The form of the latter is nearly circular, resembling that of the Giants' Caufeway; that of the former approaching more to an oblong or oval figure; the columns of San Giovanni are much about the same figure, just about about a foot in diameter; those of Monte Roffo are very unequal; the one being a foot, while others scarcely exceed three inches in breadth. This is the case of both the Venetian groups manifest all the varieties of prismatic forms observable in the Giants' Caufeway, and other such groups; but they are commonly of five, six, or seven sides, and the hexagonal form seems mostly to prevail. The texture of the former is solid and uniform; the surface smooth, and the internal parts of a dark iron-grey colour; those of Monte Roffo have a rough and knotty surface; and, when broken, manifest a varied coloured, and unequal texture of parts; resembling an inferior sort of granite, of which the mountain is formed, and which serves as a base for this range of columns. Other groups of articulated basaltic columns have also been observed in the province of Velay and Auvergne in France; particularly by M. De Varennes, at Bland near Langec, and by M. Defmarets, near le Mont d'Or; and M. Sage mentions another near St. Alcon, in the same province. Kircher has long ago described a group of the same columns near Viterbo in Italy. Mandrus Subterraneus, lib. vi. cap. 9. &c. And Mr. Strange mentions another at Castel Nuovo, in the Euganean hills, about four miles south-west of that of Monte Roffo.

For the various controversies with regard to the origin of these basaltic columns, and of the flint-trap-rocks in general, see Trap.

GIANTS' HEAD, in Geography, a cape on the east coast of
of the island of St. Christopher, a little to the east of Ragged Point.

GIAR, a town of Perú, in the province of Farriñan; 70 miles E. of Schinas.

GIAR. — See DjEBAR.

GIARABUR, in Botany, a name given by Avicenna, Serafin, and the rest of the Arabic writers, to the potamogeton of those times. This is translated by some the water-lily, but that is founded on an error: it is certain that the plant thus called by the Arabs was very different from the potamogeton of our times. Avicenna tells us, it had flowers resembling those of the water-lily; and it seems either to have been the fagitta aquatics or water arrow-head, or else the butomus, or some of the smaller species of nymphæa.

GIARAF. CAPE, in Geography, a cape on the coast of Tripoli. N. lat. 34° E. long. 11°.

GIARDINI, Felice, in Biography, in many respects the greatest performer on the violin during the last century. He was a native of Piedmont; and when a boy was a choicerl in the Duomo at Milan, under Paladinì, of whom he learned singing, the harpsichord, and composition; but having previously manifested a disposition and partiality for the violin, his father called him to Turin, in order to receive instructions on that subject from the famous Sonus. But, though he possessed the violin, upon which he soon became the greatest performer in Europe, seems a lucky circumstance, yet he had talents which would have made him a superior harpsichord player, had he continued to practice that instrument; but he used to say, that he was perfectly cured of that vanity at Paris, by the performance of Madame de S. Maur, a scholar of Rameau, who played in such a manner, as not only made him ashamed of his own performance, but determined him never to touch the instrument again in serious practice. He went to Rome early in his life, and afterwards to Naples, where, having obtained a place among the ripienos in the operatic orchestra, he used to flourish and change passages much more frequently than he ought to have done. "However," says Giardini, of whom we had this account, "I acquired great reputation among the ignorant for my impertinence; yet one night, during the opera, Jonelli, who had composèd it, came into the orchestra, and taking himself close to me, I determined to give the maestro di cappella a touch of my taste and execution; and in the symphony of the next song, which was in a moderate style, I gave loose to my fingers and fancy; for which I was rewarded by the composer with — violent flap in the face; which," adds Giardini, "was the best lesson I ever received from a great master in my life." Jonelli, after this, was however very kind, in a different way, to this young and wonderful musician.

Giardini came to England in the spring of 1750. His first public performance in London, at which we were present, was a concert for old Cuzzoni, who sang in it with a thin cracked voice, which almost frightened out of the little theatre the easy-market the fans of those who had heard heard his; the great theatre in the fame faces, with exacty. But when Giardini played a solo and concertos, though there was very little company, the applauses was so loud, long, and furious, as nothing but that bellowed on Garrick had ever equaled. We had not him the night before at a private concert, with Giardini and Frélia at the house of Napoleon Trump, who was himself one of the best dilettante performers on the violin. At that time, and we were all equally misguided with the various powers of Giardini, at no early period of his life. When, besides solo of his own composition of the most brilliant kind, he played several of Tartini's, in manuscript, at sight, and at five or six feet distance from the notes, as well as if he had never practiced any thing since. His tone, bow, execution, graceful carriage of himself and his instrument, and performing a M.S. piece of a young composer in the room, he declared that Giardini had so improved it as to make it better than he intended, or had imagined it to be in the warm moments of conception; and lally playing variations extempore, during half an hour, upon a new but extraordinary kind of birth-day minuet, which accidentally lay on the harpsichord—all this threw into the utmost astonishment the whole company, who had never been accustomed to hear better performers than Featling, Brown, and Collet! Of his academy, scholars, manner of leading at the opera and oratorio, performance in private concerts, compositions vocal and instrumental, we shall say nothing here, left our praise should be too much for others, and too little for our selves.

He soon got possession of all the posts of honour in this country. He was engaged and cared for at most of the private concerts of the principal nobility, gentry, and foreign ministers; at the Castle and King's Arms concert in the city, and in 1756, at the opera band; in which he introduced a new discipline, and a new stye of playing, much superior in itself, and more congenial with the poetry and music of Italy, than the hasty manner of his predecessor Featling; who, except one or two seasons, when Veracini was at the head of the orchestra, had led the opera band from the time that Caffarucci was diffmiffed, till the arrival of Minigotti. In 1756, on the failure and flight of the Imperfario or undertaker of the opera, Vancesi, the Minigotti, and Giardini joined their interests, and acquired for a while the sovereignty of the opera kingdom, by which gratification of their ambition, these two great performers were soon brought to the brink of ruin, as others had been before them. But though great applauses was acquired, and appearances were favourable, yet the profits to the managers were so far from foly, that they found themselves involved at the end of the season in such difficulties, that they were glad ti resign their short-lived honours, and flink into a private fortune.

Giardini, while in the opera management, besides arrangiing partie dustresses, set several dramatic and instrumental pieces; but though he had to great effect on his instrument, so much fancy in his cadences and solos, yet he had not sufficient force or variety to supply a whole evening's entertainment at the Lyric theatre. Yet after he had resigned his throne in the orchestra, he frequently threw in a single air or rondeau into the opera of other matters, which was more applauded than all the roll of the drama; of this kind were the favourite airs of "Vo' anamiti," and "Ah non so perche tu mi, &c."

In 1762, on Mattei quitting the management of the opera, in spite of former miscarriages, Giardini and Miinigotti again resumed the reins of opera government. But after struggling two years against the storm, during the decline of Minigotti's favour, and after an inauspicious season, at the end of 1763, Giardini and his partner again abdicated their thrones. From this period, Giardini, always looking over his former Lyric kingdom, without the power of invading it, or bringing about a resurrection, was forced to content himself with teaching bands of rank and fallowing to find and produce of a great annual benefit. He continued here, unrivalled, as a leader, a solo player, and a composer for his instrument, till augmenting the importance of his instrument and our national prosperity for the sake of his country, till the admirable productions and great performers of Germany began.
Regan to form a Teutonic interest and Germanic body here, which, before Giardini’s departure from London, became very formidable rivals to him and his Roman legion.

At the end of 1764, he went to Italy, and refined a considerable time at Naples, with Sir William Hamilton, one of his first scholars on the violin after his arrival in England.

Remaining on the continent till the summer of 1769, Giardini returned to this country, bringing with him a female pupil and her whole family, attempting a burletta opera at the little theatre in the Haymarket, while the great opera-house, which had been burned down, was rebuilding; but his prima donna not being approved, their speculation failed, and he had her and her whole family on his hands. During his absence the public had learned to do without him, and reconciled themselves to his loss; his health, hand and eyes were impaired; he was droptical, his legs were of an enormous size, and little of his former superiority on his instrument remained, but his fine tone. He composed quartets that pleased very much, but in which he never played any other part in public than the tenor. The style of music was changed; he printed many of his old compositions which used to please; but now could gain neither purchasers nor hearers, so that about the year 1795, he went to Petersburg with his burletta troop; which seems to have pleased as little there and at Moceau, as in London, and he is said to have died in this last city in great wretchedness and poverty!

But before we try to account for this melancholy termination of so brilliant a career, let us endeavour to do justice to his professional abilities.

It is the business of every artist to endeavour to arrive at the head of his profession during the age in which he lives, but no one can be expected to aspire to superiority over all mankind, past, present, and to come. Homer, our own Shakespeare, and Milton, have, perhaps, succeeded in that, if ever they formed it, and Dryden and Pope have gained two out of three of these ears. If Giardini has been surpassed by a few in tale, expression, and execution, his tone and graceful manner of playing are still unrivalled, nor does any one of all the admirables and great performers on the violin, surpass all others in truth at once as Giardini did, when at his best, all the violinists in Europe.

That a man with such talents and intellects as art and nature fearlessly ever allowed to the fame individual, who might have realized 40 or 50,000l, should, by extravagance, caprice, and a total want of benevolence and rectitude of heart, die a beggar, unfriended and unpitied, is fearfully credible! It is painful to probe the private character of such a man; yet it should not be concealed. Truth and morality require it to be recorded. The kings of Egypt used to be tried after their decease.

And if young musicians of great talents, who are prone to deivate from propriety of conduct, should chance to read this article, it may serve as a beacon, and remind them of the possibility of surviving favour and talents, however great, and terminating their excellence in misery and mortification.

A respectable professor, who, from Giardini’s first arrival in England, was constantly attached to him, and a fierce admirer of his concerts, his wit, and even the ingenuity of his person and Wit; before his quitting this country in 1784, delineated his character in the following manner, a copy of which came lately to our hands, accidentally.

Sketch of the private character of a great musician.—“There exists a man who would rather gain half a crown by superior subtlety and cunning than a guinea by useful and fair means; who is of so difficult a commerce, that the utmost circun-
and distinguished by its agreeable situation and salubrious air; 15 miles W. of Turin.

GIAUF, A1, a district of Egypt, in the S.E. part of the Delta.

GIAVI, a town of the island of Sardinia; 21 miles E.S.E. of Algeri.

GIAUKIRI, a town of Asiatic Turkey, in Natolia, anciently "Sigeum," chiefly inhabited by Greeks.

GIZA, a town of Italy, in the Veronese; 14 miles N.N.E. of Verona.

GIB, in Agriculture, a sort of flax with a hook at the end, which is sometimes useful in making and repairing hedges, and for various other purposes.

GIB, in Mechanics. See Crane.

Gins, or Tobings, in Mining, are pieces of wood from two to four or more feet long, with a bird's-mouth or notch cut in each end, that are placed as struts between the four upright poles, at the corners of square or rectangular shafts, which are supported with wood, instead of being girded or bricked.

GIBAU, in Geography, a town of Moravia, in the circle of Olmutz; eight miles N.E. of Olmutz.

GIBBAWAYS, an Indian tribe residing in Upper Canada, on the E. side of Detroit river, opposite to fort Gibralter.

GIBBEN, a town of the duchy of Courland; 32 miles N.E. of Pyltn.

GIBBETHON, in Scripture Geography, a city of Dan, allotted to the Levites (Josh. xxi. 23); probably the same as Gabba; 12 miles from Elutheropolis. Here they flewed the tomb of the prophet Habakkuk.

GIBBON, Edward, in Biography, was born at Putney in 1737. His father was a gentleman of fortune, and some years member of parliament. The subject of this article was a very delicate and sickly child, insomuch that his parents had but little hope of rearing him. From nine years of age to twelve, he was under the tuition of Dr. Woodelon at Kingston-upon-Thames. Here he acquired the elements of classical learning, and he mentions his twelfth year as particularly "proportion to the growth of his intellectual nature," because at this period he read a variety of English books of poetry, romance, history and travels.

He then went to Westminster school, but his ill state of health prevented him from making a regular progress in the studies of the place. For several years he was chiefly the object of medical care, till at length, and, as it were, very suddenly, his constitution acquired firmness, and his father immediately sent him, as gentleman-commoner, to Magdalen college, Oxford. He was probably ill prepared to receive the benefits of an university education, and he signified the fourteen months that he spent there as the most idle and unprofitable of his whole life. To a total neglect of religious instruction he has attributed a very remarkable incident which took place at this time. He had from an early age been addicted to disputation on topics of divinity. His leisure from other pursuits induced him to turn his attention to the controversies between the Papists and Protestants. His mind was overflourished by the arguments of the former, and in 1753 he had an interview with a popish priest in London, when he solemnly alleged the errors of Protestantism. He immediately wrote an elaborate letter to his father, in which he avowed the change in his sentiments, and justified the measure which he had taken. With all the zeal of a new convert he has since declared, "I am proud of an honest sacrifice of interest to conscience: I can never blush if my tender mind was engaged in the folly of that seduced the acute and manly understandings of Chillingworth and Bayle." He was sent by his father to Lausanne, and placed with a Calvinist minister, by whose judicious efforts, aided by his own sound reason and mature reflections, his faith in the Romish articles gradually gave way, and on Christmas day 1754, he received the sacrament in the Protestant church. During the time he spent at Lausanne, he laid the foundation of that knowledge in the languages, and in the art of logic, which enabled him to make so conspicuous a figure in the literary world. To the "History of the Decline and Fall of the Roman empire," we have had occasion frequently to recur for an elucidation of facts, we may therefore be allowed to speak somewhat at large of the author of that work. His ruling passion, that of reading, completely developed itself in Switzerland, and he went to the excitements to industry, from a tutor, Belles lettres, and the history of man, and the human mind, were his favourite objects of study; for the mathematics he had no inclination, and what he did not, and perhaps could not pursue, he was ready to condemn, and congratulated himself that he escaped from them "before his mind was hardened by the habit of rigid demonstration, so destructive of the finer feelings of moral evidence." That this view of the effect of mathematical studies was unjust, might be proved from a variety of instances in which the ablest mathematicians have been equally celebrated for their fine taste and excellent judgment in other branches of literature. In the year 1758 he returned from Lausanne to London, where he was kindly received by his father, and he found in a mother-in-law, a new relative, who in time conciliated his good will and confidence. He now began laying the foundation of a copious library, and soon set about preparations for appearing before the public as an author. In 1761, he printed his "Éloge de l'Étude de la Littérature," in one volume 12mo. It was a very respectable juvenile performance, and was highly praised in the foreign journals. At home it obtained but a small share of public notice. While he was composing this work, at least before it was published, he was engaged in the military profession, which was but ill calculated for a person of his turn. The peace, in 1763, set him free from a commission which he had held in the militia, and he immediately paid a visit to Paris, and having spent some months in that capital, he went to Lausanne, where he published a year in cultivating society, and in collecting materials for a profitable journey into Italy. This he undertook in 1765, and it was, as he felt muttering amidst the ruins of the capital, while the friars were singing vespers in the temple of Jupiter, that the idea of writing his great work, "The History of the Decline and Fall of this City," rushed into his mind. He had, previously to this, proceeded some way in another interesting design, and composed, in the French language, the first book of a History of the Swiss liberty; but this, perhaps on account of its style, was condemned by a literary society of foreigners in London, to whom it was read, and he committed it to the flames. In 1767, he alluded in compiling a critical work, entitled "Mémoires Littéraires de la Grande Bretagne," the succees of which was but trifling. In 1770 he published, in his native tongue, a pamphlet, entitled "Critical Observations on the fifth book of the Envid," which was intended as a refutation of Dr. Warburton's hypothesis concerning the meaning of the deceit of Janus; and in the same year, by the death of his father, he succeeded to an estate considerably involved, and from the perplexities of which he fearlessly ever extricated himself. His circumstances were, however, fairly suited to the task he had undertaken as an author: for he thought himself, that had he been either much poorer or much richer, he should never have accomplished it. Leifure and books were necessaries on the
the one hand; on the other, the stimulus of a handborne increase of property. His acquaintance was large, but he compensated the hours devoted to them by early rising and close application. In 1774, he was, through the interest of Mr. Elliot, introduced to a seat in parliament, which he occupied during eight years, and gave, says he, many a silent vote in support of the rights, though not, perhaps, the interest of the mother country. Early in 1776 the first volume of his "History" made its appearance; its success was very great, and far surpassed the most favorable expectations of the authors. "The first impression," says he, "was exhausted in a few days; a second and a third edition were freely adequate to the demand, and the bookseller's property was twice invaded by the pirates of Dublin." It was received with general applause, but the prospect of fame was so keenly relished by Gibbon, as that of the two celebrated historians, Hume and Robertson, who, instead of viewing his rising fame with jealousy, promoted it with liberal commendation. In the midst of his triumph, his two chapters, concerning the growth and progress of Christianity, raised a storm against him, which, as he had not foreseen, he regarded with some alarm. He was attacked on all sides, but as he professed to have written only as a historian, he declined entering the lists as a controversialist. In one infallible fidelity, as an historian, was attacked; here he felt that he was called on for a "Vindication," in which it was admitted that he successfully repelled the principal charges, and returned them on his antagonist. It was fig叶ally, in the two chapters referred to, that the progress of Christianity was peculiarly favored by secondary causes, and of course that its origin was not divine: though this theory had not been destitute of advocates among sincere believers in the truth of the Christian system, yet there is little doubt that Gibbon was an impartial hand, but that his pre inclination was to reason in this part of his work under the mask of a friend. His pretensions were unveiled by many excellent writers, who ranked high in the established church, and by others who were not in the church, but who were equally alive to the spread of sceptical principles, and active in opposing their propagation. After he had refumed his work, he was solicited by ministers to write an answer to the manifesto of the court of France, on its declaration of hostilities. On this occasion he published his "Memoire justificatif;" it was written in French, and much admired for its style and its reasoning, and was delivered, as a state paper, to the courts of Europe. For this service he was rewarded with the appointment of one of the Lords of Trade, by which a handsome addition was made to his income, and little to his engagements. In 1781 the second and third volumes of his History appeared, which supported the reputation which he had already acquired. Upon the dissolution of lord North's ministry, the board of Trade was abolished, as occasioning only an useless expense to the state. The defalcation in Mr. Gibbon's income no longer permitted him to support the same style of living in his own country, and he removed his residence to Lauffane: here, in an elegant retreat, he finished his History, in three other quarto volumes, which were published in 1788. It was with real regret that he dismissed an occupation, which had given to many years of his life that zest which an interesting object of pursuit can alone impart. He came to England to superintend the printing of his work, and then returned to Lauffane, to spend, as he hoped, the remainder of his days; but the storms of the French revolution, which menaced the quiet and happy regions of Switzerland, gradually loosened his attachment to Lauffane, and he began to look towards England for a refuge. He regarded the events that were taking place in France with the utmost abhorrence, and he either was, from habit, or had become so from the occurrences of the times, a decided enemy to every species of public reform. He avowed his affiet to Mr. Burke's creed, which he had vindicated in his "Reflections:" "I admire," says he, "his eloquence, I approve his politics, I adore his chivalry, and I can almost excuse his reverence for church establishments." Mr. Gibbon returned to England in 1793, but after a few months residence his attention was forcibly called to the progress of a disease, which had fulfilled in a small degree for thirty years, and which now terminated his existence, Jan. 16, 1794. He has characterized himself in the following words: "I am endowed with a cheerful temper, a moderate sensibility, and a natural disposition to repulse rather than activity; some mischievous appetites and habits have, perhaps, been corrected by philosophy or time. The love of study supplies each day, each hour, with a perpetual source of independent and rational pleasure." "He was," says his biographer, "easy in society, and fond of it; he was beloved by his friends, and had, in an eminent degree, the manners and habits of a gentleman. Early indulgence and habit had made the conveniences and graces of cultured life essential to his comfort, and he was not one who could have been content with the coquettishness of mental superiority in an humble state. His great work, which will long be a monument to his fame, is a performance of vast and accurate research, and of enlarged and philosophical thinking; it abounds in splendid passages, and its style displays a thorough mastery of the whole compass of the English language." After his death two quarto volumes of his miscellaneous works were published by lord Sheffield, containing, among other things, memoirs of his life and writings, composed by himself; to which the reader is referred for more particulars relating to this celebrated man.

**GIBBONS, ORLANDO,** without exception, the best composer for the church during the reign of king James I. and though not blemish with longevity, yet, during his short life, he contributed amply to the music of the church, which he enriched with numerous compositions, that are still fresh and in constant use among the best productions within its pale.

This excellent musician, a native of Cambridge, was brother of Edward Gibbons, bachelor of Musick, organist of Bristol, gentleman of the Chapel Royal, and master of Mathew Lock; and of Ellis Gibbons, author of two madrigals in "the Triumphs of Oriana," who is filled by Ant. Wood, "the admirable organist of Salisbury." In 1653, at the age of twenty-one, Orlando was appointed organist of the Chapel Royal, in the room of Arthur Cock. In 1622, he was honoured at Oxford with a doctor's degree in music, at the same time as his friend Dr. Heyther, when both were conterminous and favoured with indulgencies in the university in consequence of letters from the learned Camden, who recommended them with friendly zeal to its notice. According to Ant. Wood, the academical exercise in fix or more parts, performed at this time for Heyther's degree, was composed by Orlando Gibbons, "as one or more eminent musicians then living had several times told him." So that grown-gentlemen, as well as boys, through illincliances or ignorance, are sometimes reduced to the humiliating necessity of having recourse to the charity of friends, before they can exhibit an exercise.

A manuscript copy of the exercise performed for Dr. Heyther's degree, is said to have been found, signed with the name of Orlando Gibbons. It is an anthem for eight voices, taken from the forty-seventh psalm; and appears to be the very same composition as the anthem of Orlando Gibbons.
GIB

Gibbons, to the words "O clap your hands together, all ye people!" Printed in Boyce's Cath. Mus. vol. ii. p. 59.

The harmony in Gibbons's service in F, printed by Dr. Boyce, is pure, clear, and grateful; and the melody more accented and flowing than we have found in any chorale music of equal antiquity.

The two parts of one of the Gloria Patris, though they may be the cause of some confusion in the words, discover no restraint or difficulty in the melody, which continues to move with the same freedom, as if no caesur had existence. And though the partibus, on account of the confusion arising from the parts flagging different words at the same time, pronounce the style, in which his full anthems are composed, to be vicious; yet the lovers of fugue, ingenious contrivance, and rich, simple, and pleasing harmony, must regard them as admirable productions, a la Palestrina, a style in which Tallis and Bird acquired so much renown.

Besides his admirable chorale compositions, O. Gibbons was author of melodies in two parts to the hymns and spiritual songs of the church, translated by George Withers, and of several other works which are mentioned elsewhere. See Fantasia and Partehia.

Dr. Tudday, in the dedication of the first volume of his manuscript, "Collection of the most celebrated Services and Anthems used in the Church of England," addressed to Lord Harley, for whom it was made; after a just and warm eulogium on the abilities of Tallis and Bird, says that "none of the later composers could ever make appear so great a faculty in compositions for the church, except that most excellent artist, Orlando Gibbons, organist and servant to king Charles I. whose whole service, with several anthems, are the most perfect pieces of church compositions which have appeared since the time of Tallis and Bird; the air so solemn, the fagges and other embellishments so just and naturally taken, as must warm the heart of any one, who is ended with a soul fitted for divine raptures." To this encomium every candid judge of harmony will readily subscribe; but when the doctor tells us, that the celebrated service in F was composed by Orlando Gibbons in 1635, he furnishes no very favourable proof of his knowledge in chronology; as it is recorded on the monument erected to his memory by his widow, that he died ten years before that period. For in 1645, being commanded, ex officio, to attend the solemnity of the marriage of his royal master, Charles I., with the princess Henrietta of France, at Canterburay, for which occasion he had composed the music, he was seized with the small-pox, and dying on Whitmasday, in the same year, was buried in that cathedral.

GIBBON, Dr. CHRISTOPHER, was the son of Orlando Gibbons, and scholar of his uncle Ellis Gibbons, organist of Bristol. He had been honoured with the notice of Charles I. and was of his chapel. At the restoration, besides being appointed principal organist of the Chapel Royal, private organist to his majesty, and organist of Welfinster Abbey, he obtained his doctor's degree in music at Oxford, in consequence of a letter written by his majesty Charles II. himself, in his behalf, which is inserted by Dr. Wood in his Fasti Oxonienses, vol. ii. Col. 158; who says, that he completed his degree in an act celebrated in St. Mary's church, July 11, 1664.

The compositions of this master, which were not numerous, seem never to have enjoyed a great degree of favour; and though some of them are preferred in the Museum collection, they have long ceased to be performed in our cathedrals. His abilities on the organ, however, must have been considerable, to entitle him to the stations he filled, at a time when the style of playing that instrument was so much more complicated and elaborate than at present. Dr. Blow, who, in singing and composition, was educated by Captain Cook, is said to have been a scholar on the organ of Dr. Christopher Gibbons, who died 1676.

Orlando Gibbons had two brothers, Edward and Ellis, the one organist of Bristol, and the other of Salisbury. Edward was a Cambridge bachelor of music, and incorporated at Oxford, 1592. Before being organist of Bristol, he was priest-vicar, sub-chantier, and master of the choristers in that cathedral. He was sworn a gentleman of the chapel, March 21, 1624, and was the master of Matthew Locke. In the Triumphs of Oriana, there are two madrigals, one in five, and the other in six parts, composed by Ellis Gibbons. Wood styles him the admired organist of Salisbury. Of Edward Gibbons, it is said, that in the time of the refolution he challenged king Charles I. with the sum of one thousand pounds; for which infinace of his loyalty, he was afterwards very severely treated by those in power, who deprived him of a considerable estate, and thrust him and three grand children out of his house, though he was more than four-score years of age.

GIBBOUS, in Surgery. See SIR W. CURTIS OF.

GIBBOUS, is used in reference to the enlightened parts of the moon, where she is moving from full to the first quarter, and from the last quarter to full again; for all that time the dark part appears horned, or falcated, and the light one bunched out, convex, or gibbous.

GIBBOUS, is, gibbosa, in Ichthyology, a name given by Mr. Ray to the fish called by the Dutch kromm Rodrig. It is a smooth fish without scales, its belly is white, its fins and tail black. It grows to a considerable size, sometimes to four feet. It is caught all over the East Indies, near the sea shores, and is very firm, and much esteemed at table. It has its name from the remarkable rising of its back, which is like that of the perch, but much higher. Ray's Ichthyology, Append. p. 4.

GIBBY, in Geography, a cluster of small islands, in the East Indian sea, about twelve leagues in circumference, well inhabited, situated on the equator. E. long. 120° 3', a town of Arabia, in the province of Ndesk; 150 miles E.N.E. of Hajar.

GIBEAH, in Bibliaire Geography, a city of Benjamin, the birth-place of Saul, the first king of Israel. (Josh. xvi. 24; Ezra ii. 26; Nehem. vii. 26.) Gibeah was about two leagues N. from Jerusalem. In Jerome's time it was entirely destroyed.

GIBEL-EL-TOR, a mountain of Palestine, anciently called Mount Tabor, which see.

GIBELET, or GIBHEL, a sea-port of Syria, anciently called "Gabala" and "Gabulon," situated on the coast of the Mediterranean, at the mouth of the river Jebel; 12 miles S.S.W. of Tripoli.

GIBELIN, a town of Palestine; eight miles E. of Gaza.

GIBELINS, GIBELINS, Gibelles, or Gibelines, a famous faction in Italy, opposite to another called the Guelphs.

The Guelphs and Gibelines ravaged and laid waste Italy for a long series of years; so that the history of that country, for the space of three centuries, is only a detail of their mutual violence and mortal wars.

The Guelphs frequently altered the power of the see of Rome, as the Gibelines did the emperor's right of sovereignty.
We have but a very obscure account of their origin, and the reason of their names: the generality of authors affirm, that they arose about the year 1240, upon the emperor Frederick the 11th's being excommunicated by pope Gregory IX.

That prince, fearing, to make a tour among the cities of Italy, gave the name Gibelins to such as he found well affected to him; and that of Guelphs to those who adhered to the pope. But as to the reason and signification of these words, there is a deep silence; Gibelin might be possibly formed of gebier, imperator; whence gebieretide, imperiope. Of gebier, the Italians might make, by corruption, Gibelin; so that Gibelins, in this light, should be the same with Imperiales, or such as followed the emperor's party.

By the way, some writers maintain, that the two factions arose ten years before; though full under the same pope and emperor.

Other historians relate, that Conrad III. marching into Italy, in the year 1149, against the Neapolitans, Roger, count of Naples and Sicily, in order to defend his states, called to his assistance Guelph duke of Bavaria; and that one day, when the two armies were ready to join in battle, the Bavarians cried out in High Dutch, lie, Guelph! or, as others say, in Flemish, hie, Guelph! that is, he, Guelph! and that the Imperialists answered on their side, with the words hie, or hier, Gibelin! here, Gibelin! calling the emperor by the name of the place where he had been bred.

Hornius refers the names to the war in 1149, between Henry the Proud, duke of Bavaria and Saxony, and Conrad III. duke of Swabia; the two princes preparing to engage near the town of Winberg, the Bavarians began to cry out Guelph, which was the name of duke Henry's brother; and the partisans of the emperor Weibelingen, which was the name of the place where that prince was born and bred, in the duchy of Wirtemberg, whose surname he bore: from which Weibelingen the Italians at length formed Gibelin.

This account is confirmed by Martin Cruiisus: "Initium Gibelinarum (Wibelinæ à patria Conradi regis) et Welfecne concertationes." Conrad being of Weibelingen, that word, says Cruiisus, gave rite to gikelinge, and that to gibelling, Gibelins, Gibelin.

Platina, on the other hand, affurses us, that the name Gibelins arose from that of a German at Piltaya; whose brother, named Guelph, gave likewise his name to the opposite faction: the two brethren, it seems, bearing an irreconcilable hatred. Others maintain, that the emperor gave the appellation Gibelin to those of his party, from the German word gieff, signifying ridge, or top; because the empire refted on them, as the rafters of a house leaue on the ridge, which joint them a-top.

Karus, a learned canon of Stralbourg, in the lives of the emperors of the house of Brunswick, is of the second opinion above related: in a battle, says he, between the Welf, or Guelph, and Frederic, the army of the first crying out, lie, Welf, lie, Welf! the second commanded his to cry out lie, Gibeling! lie, Gibeling! the name of his birth-place: and the French and Lombards asking the signification of those words, they were anfwered, that by Welf was meant the pope's party; and, by Gibelin, the emperor.

Yet others contend, that the word Gibelin is only a shortening of the word gibelinins, or gibelerteins; and that it arose from Guipert, an antipope, set up by the emperor Henry III. in the year 1080.

Among many other conjectures, Mainzbourgh, in his Hist. de la Decad. de l'Emp. adveine another opinion.

Vol. XVI.

that the two factions, and their names, arose from a quarrel between two very ancient and illustrious houses on the confines of Germany, that of the Henrys of Gibelinge, and that of the Guelphs of Adorf. See Machiavel.

It is said by fome, that the Gibelins, when driven out of Italy long after the year 1229, at which period the contell between them and the Guelphs ran very high, and settled at Amplieran, were the inventors of the mercantile practice of re-change, or re-exchange, on bills of exchange, on account of the damages and charges they were put to, and the interest of the money of their bills protested, which had been given to them for the effects they had been obliged to leave behind them. Anderson's Hist. Commerce, vol. i. p. 110. See Guelphs.

GIBELLO, in Geography, a town of the duchy of Parma, on the right bank of the Po; 16 miles N.W. of Parma. N. lat. 45° 1'. E. long. 10° 7'.

GIBEON, in Scripture Geography, the capital city of the Gibeonites, who availed themselves of the oaths of Joshua, and of the elders of Israel, on an artful representation which they made of their belonging to a remote country. (Joth. ix.) Joshua and the elders made an unavowed league with them; but upon a discovery of their misdeed, they spared their lives, and condemned them to the servile office of carrying water and water to the tabernacle, and other work of a similar kind, in token of their pufillanimitv and duplicity, as flaves and captives. In this rate of servitude they remained till the entire dispersion of the Jewish nation, A. M. 2553. The Gibeonites were defended from the Hivites, the old inhabitants of the country, and possessed four cities, viz. Cepherah, Beeroth, Kirjath-jeirm, and Gibon; the capital, afterwards given to Benjamin, excepting Kirjath-jeirm, which was defignated to Judah. The Gibeonites submitted to the burthen imposed upon them by Joshua, and continued faithful to the Israelites. Nevertheless Saul destroyed a very great number of them (2 Sam. xxii. 1, 2, 3, &c.); but God, as a punishment of his cruelty, in the reign of David, caused a great famine, which lasted three years (A. M. 2982. B. C. 1517); and David was informed by the prophets, that this calamity would continue as long as that cruelty, which Saul had exercised against the Gibeonites, remained unremitting. The Gibeonites, being asked what satisfaction they required, answered, "Seven of Saul's sons will we put to death, to avenge the blood of our brethren." Accordingly the Gibeonites crucified them in the beginning of spring, when, in Palestine, the barley-harvest commenced. From this time we find no mention of the Gibeonites, as forming a separate people. But they were probably included among the "Nethermen," who were public slaves appointed for the service of the temple. (1 Chron. xi. 2.)

Gibeon was situated on an eminence, as appears by its name, denoting a hill; it was 40 furlongs N. from Jerualem, according to Josephus. It is called "Gabaon" (see 2 Sam. v. 25, compared with 1 Chron. xiv. 16.) We find mention of the fountain and pool of Gibeon. (2 Sam. ii. 13.) The tabernacle and altar of burnt offerings, made by Moses in the wilderness, were removed to Gibeon. (1 Chron. xxix. 28, 30.) When Solomon was seated on the throne, he went to sacrifice at Gibeon, because this was the most considerable of all the high places where sacrifices were then tolerated, the temple not being yet built. (1 Kings iii. 4.)

GIBERT, BALTHASAR, in Biography, was born at Aix in 1602. He was educated partly at Paris and partly at Soissons. At the age of twenty-two he was appointed to teach philosophy at the college of Dauphine, and in 1688 he obtained...
GIB

obtained the professorship of rhetoric in the college of Ma-
varin at Paris, which office he filled with great reputation
more than fifty years. He was a zealous defender of the
privileges of the university, of which he was several times
denounced. He obtained other preferments connected
with the university, but on account of his opposition to the
revocation of an appeal made by the university against the
jailer Unigenitus, the court, in 1542, exiled him to Auxerre.
He died in the following year at the age of seventy-nine.
He was author of many works, in which are displayed
much erudition and solidity of judgment, but the style is
somewhat involved. Among his publications are "De la
veritable Eloquence;" "Reflexions sur la Rhetorique;"
"Jugemens des Savans sur les Auteurs qui ont traité de la
Rhetorique," in three volumes 12mo. Moreni.

GIBERT, Giambattista, a very learned prelate of the
church of Rome, was born at Palemon towards the close
of the fifteenth century. He visited Rome when he was
but twelve years of age, where he was distinguished for
the brilliancy of his talents, and was introduced to pope
Leo X., who entertained a great regard for him. He had
a thrill for polite literature, but was, at an early age, taken
from the pursuit, and placed in the service of a person
of high rank. By pope Clement VII., he was employed
in some very important legations to the king of France
and other potentates. In 1523 he obtained from his
patron the government of Tivoli, and in the following
year he was created bishop of Verona: he was not, how-
ever, allowed to take possession of his see, but was kept
at Rome as the adviser and friend of the pope. In 1527
Giberti was given as one of the hostages by the pope to
the Imperial army, on which occasion he underwent much
ill treatment, and was more than once threatened with
a shameful death. He was, at length, through the inter-
position of his friend, Cardinal Pompeo Colonna, restored
to his liberty, and retired to his bishopric, on which he con-
tinued to reside till his death, except when occasionally
summoned to Rome by Paul III. He died in 1543, and
his works, which were numerous, have been published col-
lectively; they chiefly consist of his constitutions and regu-
lations for the government of his church, which under his di-
finition became a model of ecclesiastical discipline. He
eradicated many abuses, and was profuse in alms to the poor.
He was the patron of learned men who returned to his palace,
among whom was the celebrated poet Flaminio. He
printed at his own expense, and under his own eye, several
works of the fathers, and in order to render his editions
correct, he entertained several Greek copyists. Moreni.

GIBET, or Gibbet, a machine in manner of a gallows
whereon notorious criminals, after execution, are hung in
iron, or chains; as spectacles, in terremor.

The word in French, gibet, properly denotes what we
call gallows; it is supposed to come originally from the
Arabic gîbe, mound, elevation of ground; by reason gibets
are usually placed on hills, or eminences.

GIBETS, the offals or entrails of a goose; including
the heart and liver, with the feet, gizzard, &c.

The word is supposed to be formed of gibeis, from the
French gieou, mouthful.

Gibets make a considerable article in cookery: they
boil gibets, stew gibets, make ragouts of gibets, glibets-
pies, &c.

GIBELEN, in Geography, a town of Egypt, on the
left bank of the Nile; 14 miles N. of Ama.

GIBLOS, a city on the coast of Phoenicia, between
Tripoli and Berytus; called also Byblis, which see.

GIBON, a town of the island of Cuba; 22 miles
N.E. of Bayamo.

GIBRALTEO, a town of Spain, in the province of
Seville, on the river Odell, with a harbour for small sailing
vessels; containing about 150 houses in two parishes, and
situated about 150 miles from the Atlantic on 44 miles of
Seville. N. lat. 37° 20′ W. long. 1° 14′.

GIBRALTEAR, derived from Gibr, an Arabic word
signifying mountain, and Tariik, the name of a Moorish ge-
neral, who conquered Spain and disembarked here in the
year 712, is a town of Spain, in the province of Andalusia,
but belonging to Great Britain, situated on a rock, at the
south extremity of Europe, and reckoned one of the
keys of Spain. This rock forms a promontory from Spain
into the sea, opposite another promontory extending from
Africa, bounding a narrow sea, which unites the Atlantic
with the Mediterranean, called in Latin "Fretum Herce-
num, or Gaditanaeum," and in English the Strait of Gibral-
tar. The length is about eight leagues, and the breadth,
in the narrowest parts, nearly five. On these two promo-
ntories are placed the famous mountains of Calpe in Europe,
and Abila in Africa, known to the ancients by the name of
the pillars of Hercules. From the top of the promontory
of Calpe, the eye commands an extent of 40 leagues, two
foss, and five kingdoms, viz. Seville and Granada, in Spain,
and Barbary, Fez, and Marocco, in Africa. In deca-
vooring to trace the town mentioned by Mela, Strabo, and
Pliny, under the names of Calpe, Cartheya, Melaria, Belo,
and Belepo, and also the promontory of Juno, situated
from east to west on the shore of the straits, no vantage is perceived,
except the mountain and city of Cartheya; which latter
was passed from the possession of the Phcenicians to that of
the Carthaginians, and is now reduced to a mere heap of
ruins, fearlessly defensible in the bay of Gibraltar, where
the Carthaginian tower was also situated. This ground is
now occupied by a mean farm. On ealling your eyes over
the kingdoms of Granada and Seville, you see the lofty
ridges of the desert du Corvo, as well as the mountains
of Hagen and Sarorra, and towards the east, opposite to
Gibraltar, the new town of Alzira. In the middle of this
incline you distinguish the ruins of Great Cartheya; at
a short distance, on a little hill, the town of St. Roche
is situated; on the east you perceive the chain of mountains,
called the Sierra de Ronda, abounding in fruits and aromat-
ics plants. Near these stood the town of Munda, so cele-
bated in Roman history as the scene of the battle between
the sons of Pompey and Augustus, when they were disputing
the empire of the world. The objects which bound the
horizon on the right are the Sierra Neveda, and the Alpujara-
na; on which the snow lies all the year. The mountains supply
a number of fountains and rivulets of clear water, forming
the sources of the Xouil and the Darro; rivers which water
the city of Granada and give fertility to the rich province of
Andalusia.

The promontory on the European side is joined to Spain
by an illusus, or neck of land, so narrow, that from some
places the rock has the appearance of an island. The length
of the illusus is about 200 paces; across which the
Spaniards have drawn a line and fortified it, to prevent the
garrison from having any communication with the country.

The form of the rocky mountain, on which the fortresses
of Gibraltar is built, is oblong; its summit is a sharp craggy
ridge, extending nearly from N. to S., almost three miles,
and in breadth no where exceeding 2 of a mile. The line
of its ridge is undulated, and the two extremes are some-
what higher than the centre. The summit of the Sugar-
loaf, which is the highest point towards the south, is elevat-
vated to the height of 1439 feet; the Rock-mortar, which is the highest eminence to the north, is 1350 feet; and the Signal-houses, which is nearly the central point between these two, is 1276 feet above the level of the sea. The western side of the mountain forms a series of rugged flanks, intersected with abrupt precipices. Its northern extremity is perfectly perpendicular, except towards the N.W., where what are called the Lines intervene, and a narrow passage of ground that leads to the illums, and is entirely covered with fortification. The eastern side of the mountain molly consists of a range of precipices; but a bank of sand, rising from the Mediterranean in a rapid ascendency, covers a third of its perpendicular height. Its southern extremity falls in a rapid slope from the summit of the Sugar-loaf into a rocky flat of considerable extent, called Windmill Hill. The principal malls of the mountain rock consists of a grey, dense marble; the different beds of which present to Spain a face of 1350 feet of perpendicular height, in a conical form. The bed, or strata, are of various thicknesses, from 20 to upwards of 40 feet, dipping in a direction from east to west, nearly at an angle of 35 degrees. In some parts of the solid mass of this rock, we find tectonic bodies entirely transmuted into the constituent matter of the rock, and their interior hollows filled up with calcareous spar; but these do not occur often in its composition, and its beds are not separated by any intermediate strata. This rock is suffering a slow, but constant deposition; and the uncovered parts of it present holes of various sizes, hollowed out of the solid rock, and apparently formed by the attrition of gravel or pebble, set in motion by the rapidity of rivers or currents in the sea; whence it is presumed, that, however high the surface of this rock may now be elevated above the level of the sea, it has once been the bed of agitated waters. On the west side of the mountain, towards its base, strata occur, which are of a different kind from the mountain rock. (See Major Imrie's mineralogical Description of Gibraltar in the Transactions of the Royal Society of Edinburgh, vol. iv.)

The first, or highest, forms the segment of a circle, its convex side being towards the mountain, and its slope being in that direction. This stratum consists of a number of thin beds; the outward one, which is the thinnest, is in a state of decomposition, and is mouldering down into a blackish-brown or ferruginous coloured earth. The beds below this increase progressively in breadth to 17 inches, where the stratification rests upon a rock of an argilaceous nature. This last bed, which is 17 inches thick, consists of a blackish-blue colour, in the septa or cracks of which are found quartz crystals, colourless and perfectly transparent. These crystals are composed of 18 planes, disposed in hexagonal columns, terminated at both extremities by hexagonal pyramids. The largest seen by major Imrie, did not exceed one-fourth of an inch in length; they generally adhere to the rock by the sides of the column, but are detached without difficulty. Their great degree of transparency has obtained for them the name of "Gibraltar diamonds." The rock is completely bathe with batteries, thrown up at all points, where the ascent could not be rendered completely inaccessible; so that from Europa Point, which advances farthest into the sea on the south side, to the highest part of the rock, which is that of the north (at about two miles distance from the other), there is not a single point, which is not put into a defensible condition. On the sides nearest Spain, the internal fortifications, made since the time Gibraltar was besieged by the combined armies of France and Spain, are anonishing. These improvements are principally owing to General O'Hara, the late governor; a great number of workmen having been employed about it, for eight years, at an immense expense. In order to form some idea of the labour expended on these fortifications, it will be sufficient to observe, that the excavations effected by the force of gun-powder, in the centre of the mountain, and in the solid rock, form vaults of such height and extent, that during a siege they are capable of containing the whole garrison. These caverns, of which the most considerable is the hall of St. George, communicate with the other batteries, established along the mountain by a winding road, passable on horse-back. On returning towards Europa Point, as you enter the town, your attention is engaged by considerable fortifications, barracks, magazines, and batteries, placed wherever the nature of the ground would admit. On the highest point of land the tower of St. George was built, under the directions of general O'Hara, who intended to raise it to a sufficient height for commanding the whole of Cadiz, and observing all that passed in that port; but the undertaking, being disapproved by the British government, was left in an unfinished state. Along the mountain are several grottos, or natural excavations, the most famous of which is that of St. Michael; the height of the entrance being 43 feet (varas) yards above the level of the sea. The cavern below is at least 70 feet, and contains columns of crystallizations and stalactites, resembling all the orders of architecture. About 100 paces from its gate is another beautiful cavern, 65 varas square, and the vault 21 varas high. On the right is a second excavation, adorned with capitals of marble similar to those of the former, but so regularly disposed, that it has the appearance of a temple. Perhaps this was formerly used for consulted some oracle, probably that of Hercules, who was the principal divinity of the place, as well as of the cave in the promontory of Ampelusia, on the coast of Africa. From the entry of this cavern you discover the whole of the bay of Gibraltar, two leagues across from east to west, and three from north to south. You also command a view of the country-houses, the flower and kitchen gardens, which the inhabitants have formed one above the other, on the side of the mountain, up to the royal road, and the public walk, extending for about half a mile from the town of Gibraltar to the new town on the south. The English have spared no pains in covering the rock with trees and flowers, in supporting the earth with walls and props, in cutting a number of roads through the solid rock, and in making them passable on horse-back and in carriages up to the very summit. They have even some artificial mounds for their flocks. From the grotto of St. Michael, situated on the southern part of the mountain, at an almost equal distance, the Signal tower and the Sugar loaf, the entrance of which is 8000 feet above the level of the sea, you discover the magazines, the batteries, the new town; from the south, the marine hospital, which is a handsome and convenient building. The view extends over a number of country-houses, to some of which beautiful gardens are attached; in time these new buildings will form a town as considerable as that of Gibraltar. Near these are eight magnificent cisterns, large enough to contain 40,000 tons of water, and bomb-proof; they receive all the water which flows down the side of the mountain, previously purged in copper cisterns for the purpose. On the south side you perceive a number of mountains, called Tarres; and near them formerly stood a very ancient tower, with a citadel and wall. In a cave not far distant several holes have been found with human bones above the corner lies; so strongly inclosed, they seem to form one solid mass. (See Pala/aces.) From Europa Point to the gate on the land-side, H}
are several moles, which facilitate the unloading of ships, and enable them to cast anchor in security. Before you arrive at the south gate you observe a handsome, large, square, surrounded with trees, now called the Field of Mars, formerly the Red Sand; of such a size, that the 6000 men, usually composing the garrison, can perform their manoeuvres without inconvenience. Here the guards always mutter, and on Sundays and holidays they make it the grand parade.

The prevailing forms of religion in this promontory are the Catholic, that of the church of England, and the Jewish, each of which has its own burying ground, among the sandy earth of the mountain.

The town of Gibraltar is on the west side at the foot of the mountain; it is large, well built, fortified with strong walls, battlements, and works to cover them; a large fort protects and marks the mole, built in the form of a bridge, 350 feet long; a church is built near it; and on the land side is another mole, which covers the part fortified by a fort with a tower, and two or three broad-works, thrown up at front. On entering the town by the south gate, you perceive on the left an edifice, containing the library of the officers of the garrison; containing many of the works of modern authors. The governor's house is built on the ground formerly occupied by the convent of Franciscans; to which is attached a beautiful garden, which, on Thursday and Sunday evenings, during the summer, is the promenade of the officers of the garrison and inhabitants of the city. The principal street into which you enter on leaving the governor's house, is the residence of the merchants, and on the right is the Catholic chapel, rebuilt in an excellent style of architecture; this street extends almost through the whole length of the city, being more than half a mile long, and on each side it has handsome flat pavements, and a number of shops from one end to the other. All the houses are built in the English style, with small doors, flat roofs, and enormous bow windows, behind which the prime goods of all sorts are exposed to sale. The inhabitants are chiefly military; the commerce with Africa is neither certain nor regular; and although the contraband trade with Spain, both in money and goods, is one of the principal branches of trade, that cannot be sufficient (says La Borde) to indemnify England for a million and a half of plate, which on an average it costs annually to maintain this point in the Mediterranean, where in other respects the duties collected are very small. This place is advantageously situated for victualing the fleets, and the protection of the coast of Africa, from whence the English procure their corn, and as a place of refuge for their privateers and sloops of war. The port is a key to the Mediterranean and to the Atlantic; confus'd from all the states of Europe and North America usually refide there. The Americans, as well as the Swedes, Danes, and Dutch, in time of peace, carry on a direct commerce with Gibraltar, by supplying themselves with the articles they want, and leaving in exchange fluff, cord, pitch, and tar, wines, rum, maize, rice, flour, ginger, pepper, sugar, cotton, aniseed, and the other articles of commerce, which they procure from Asia, Africa, and Europe. The exports of Granada, Seville, and Catalonia, furnish wine, and Africa wax and fresh meat in great quantities; they also import from Spain brandy, raisins, almonds, oranges, lemons, oil, salt, &c., which the vessels from the north carry back in exchange. Gibraltar contains altogether 9000 inhabitants, including eight regiments, amounting to 6000 men; so that this place is rather a military colony than a commercial establishment. The population of Gibraltar extends one mile to the south, and nearly as much towards the top of the mountain; and if we may judge from the new buildings lately erected, it is certainly increasing. All the houses are painted black on the outside, with white borders or ledges, shewing the number of stories, which are generally two or three. This mode is well suited to a country where the reflection of the sun is so violent. The police is well conducted; no persons are to be found here; the streets are prepared clean and fabulous; and though they are all well lighted at night, no one is allowed to walk without a lanthorn, and a permission from the general; sentinels requiring answers to their challenges being stationed in the town, as well as patrols and watchmen. All forms of religion are tolerated without inconvenience, and the number of Jews, who live here more securely than in any other part of Europe, is very considerable. Gibraltar has a theatre, which, though small, is well laid out and adorned with taste. For want of regular actors, the officers of the garrison perform, during the greater part of the year, a number of English plays.

On the opposite side of the straits of Gibraltar is the town of Ceuta. The traveller, who wishes to cross over into Africa, may take advantage of the N.W. winds, and of the small vessels which are continually plying and stopping at this place. This fishery is of little consequence; but it is held in the obscurity of time. It is certain, however, that the Phoenicians, the Egyptians, and other ancient people, landed at Gibraltar; and the name of the pillars of Hercules, by which this place was known, is nothing more than a tradition preferred among the Phoenicians, who people this coast, and brought their gods and religious worship with them. But it is not known whether the straits or columns existed in the remotest antiquity, and if the inscription "non plus ultra" meant that nothing was more wonderful than the separation of the two continents, or as is more probable, that no one had dared to navigate beyond this point. However this be, it is probable that the first navigators of the Mediterranean landed at Gibraltar, or its environs. This opinion is supported by the authority of Pomponius Mela, who, being born at Cadiz, may be supposed to feel more interest in others in whatever related to this coast. The Moors seized on Gibraltar in the eighth century, and held it without interruption till the fourteenth, when, in the year 1310, it was taken from them by Perez de Guzman; but they retook it in the year 1352, and held it till the year 1462, when it was retaken by the Spaniards, and it has continued in the hands of the Christians from that time. The English took it from the Spaniards during the war of the succession in Spain; the fort surrendered to the united fleet of England and Holland under Sir George Rook, in 1704; and the allies took possession of it in the name of Charles III. The place was ceded to the English by the treaties of Utrecht and Seville; it was besieged at several times without success. Since the English have been masters of the place it has been so much improved and strengthened, as probably to bid defiance to the utmost efforts of an enemy. In the course of the American war, the Spaniards again besieged it; but their memorable attack with floating batteries of upwards of 200 cannon, in ships of all sizes, terminated only in disappointment, in the destruction of the ships and men employed, and in the immaterial honor of the brave defenders; 16 miles N. of Ceuta, 70 S. of Seville, N. lat. 36° 44', W. long. 5° 19' 46".

GIBRALTAR, an ancient town of South America, in the government of Caracas, and province of Venezuela, situated on the E. coast of the lake Maracaibo. The country in its vicinity is well watered with rivers, and furnishes coca of the best quality, and very large eddars. The best Spanish tobacco is produced here, called Tobago de Maracaibo, from which is made the valuable fluff, vulgarly called "Mackaba" fluff. The air is very infaubrous in the rainy season, and therefore...
the merchants and planters retire at that time to Maracaybo, or Merida; 100 miles S.S.E. of Maracaybo. N. lat. 16° 4'. W. long. 67° 36'.

GIBRALTAR Point, is the western extremity of a sandbank, in Upper Canada, which forms the harbour of York, and upon which block-houses are erected for its defence. There is another place of this name on the fide of lake Memphramagog, in the town of Bolton, in Upper Canada.

GIBRIN, a town of Syria; 10 miles S.E. of Aleppo.

GIBSON, Richard, in Biography, the Dwarf, was placed by a lady at Mortlake, to whom he was page, with Francis de Clyne to learn to paint, both in water and in oil; but he informed himself more by studying the works of Lely, and gained considerable reputation.

GIBSON, Edward, in Biography, was born at Bampton, in Wernsland, in the year 1660. He received the early part of his education at the free-school in his native town, and at the age of seventeen he was sent to Queen's college, Oxford. In 1681 he was admitted to the degree of B.A., and in the same year, having already applied himself most diligently to the study of the northern languages, he published a new edition of William Drummond's Polonia, Middiana, and James V. of Scotland's Cantikena Rafience, quarto, illustrated with notes. In 1692, he gave a translation in the Latin language, together with the original, of the "Chronicum Saxonicum," likewise a work entitled "Librorum Manuscriptorum in duabus insignibus Bibliothecis, altera Dugdaliana Oxoni, Catalogus," with a dedication to Dr. Tennison, afterwards archbishop of Canterbury, which proved the foundation of the author's subsequent fortune under the auspices of that prelate. He next published a correct edition of Quintilian "De Arte Oratoria," and a new edition of Somner's treatise on the Roman ports and forts in Kent. In 1694 Mr. Gibson commenced A.M., and shortly afterwards was elected fellow of his college, and admitted into deacon's and priest's orders. In 1695 he published an English translation of "Camden's Britannia." This work was patronized by lord Somers, who offered Mr. Gibson a living in the isle of Thanet, which he declined, on account of ill-health, and in the following year he was appointed librarian at Lambeth, by the archbishop, Dr. Tennison, who received him into his family, and who appointed him morning preacher at Lambeth church. His publications during this period were, "Vita Thomas Bodleii, Equitis Aureus," together with "Historia Bibliothecae Bodleiana" also, "Reliquiae Spelmanniae; being the posthumous works of Sir Henry Spelman, relating to the Laws and Antiquities of England, together with the Life of the Author." He was now appointed domestic chaplain to the archbishop, through whose means he obtained the lecture-ship of St. Martin's in the Fields, and was presented to the rectory of Stifled in Essex. His promotion in the church went on rapidly, but it did not render him indifferent to the ease of literature, and in 1714 he published his celebrated work, entitled "Codex Juris Ecclesiasticus Anglicani; or the statutes, constitution, canons, rubrics, and articles of the church of England, methodically digested under their proper Heads." The scheme of church power vindicated in this volume was excepted against, not only by dissenters, but by the found and most constitutionall lawyers within the pale of the church; who maintained that the principles and claims advanced in it would be sufficient, if acted upon, in their utmost extent, to establish a facerdotal empire, which must draw all power to itself, and render the civil magistratise its minister and dependent. In 1715 our author, who had taken his degree of D.D., was consecrated bishop of Lincoln, and in 1723 he was translated to the see of Lond
don. In this situation, on account of the weak health of Dr. Wake, then archbishop of Canterbury, almost every thing relating to the affairs of the church was confided to him. His great zeal for the established religion, and his opposition to the dissenters, who were endeavouring to obtain the repeal of the Corporation and Test acts, invited him in the estimation of the prime minister, for Robert Walpole; and he was, about the same time, rendered obnoxious to men in power, by several attacks on the principles in his "Codex," which the authors contended were inimical to the civil constitution of this country, and favourable to a spirit of intolerance and persecution. Of these attacks, one of the most able was conducted by the recorder of Brittol, afterwards Mr. Justice Fuller, at the desire of lord Hardwicke, lord chief-justice of the court of king's bench. Bishop Gibson's constitution was naturally strong and vigorous, but he exercised it with almost incredible labour, so that, at length, it might be said to be fairly worn out by his studies and exertions. For some time before he died, he became sensible that his end was approaching, and in 1748 he breathed his last at Bath, being in his seventy-ninth year. Besides the works already enumerated, the bishop was author of several others, highly esteemed by the learned. He wrote and published many pastoral letters, addressed to the clergy and laity of his diocese, intended to oppose the growth of indulgence and enthusiasm; some visitation charges, occasional sermons, and small tracts against the prevailing vices of the age. These smaller pieces have been frequently reprinted, and it is said that the bishop received more real satisfaction on account of the repeated demand for his practical works, than from the honours conferred on him by his larger and more learned treatises. He possessed the social principles in an eminent degree, and his benevolence and charity were very extensively, though privately, exercised. An instance of liberality is recorded, which redounds greatly to his honour: Dr. Crow had left him by his will 25£, which bishop Gibson freely gave to Dr. Crow's own relations, who were in indigent circumstances. Wob., Brit.

GID, or GIDDY, in Rural Economy, a morbid condition occurring in sheep and some other animals, in which there is a constant vertigo or turning round. The affection is generally considered as a kind of hydrocephalus, or encysted collection of watery matter in the head, between the dura and pia mater.

It has, however, been suggested by some as depending upon a worm or maggot under the horn on either fide of the head; in support of which Mr. Collins has been informed of cows having the disease, and being cured by having a perforation made near the horn, and the worm or maggot taken out; but this is no doubt another sort of disorder.

Some farmers consider this complaint as the most common among sheep that are richly fed, and know it by the name of the flurry evil, the cure being attempted by the use of small bleeding and astringents; and in order to guard against a relapse, the sheep should be put into a chilly or elevated situation.

Among the graziers in the county of Lincoln the disease is known by the terms flurry, and bladder on the brain, and in its remedy a sort of SOPPRESSES process has been recomended, by which great numbers of sheep are supposed to be faved. The person who performs the operation raises the scalp with a strong hooked knife just over the part affected, to the extent of about half a crown piece, after which, nearly the same extent of the skull-bone is elevated, letting it hang as by a hinge on one side; then by means of a quill, cut planting to a point, in the form of a spear, and lanced on each side, the bladder is sought for and brought out whole, the
bone being immediately put down again, and covered with a
plaster.

The South Down sheep farmers, when the animals are af-
fected in this way, say they are paterif.

Various other modes of cure have been proposed, but
they do not seem worthy of much attention. See Sheep.

GIDDA, in Ancient Geography, See JIDA.

GIDDATOOR, in Geography, a town of Hindoostan, in
the circuit of Ciscále: 16 miles S.W. of Cofimcutta.

GIDDINESS, in Medicine, a sensation as if the objects
surrounding the person were in a state of circumjegation,
or whirling motion, accompanied with an inability to main-
tain the erect posture, or to move forward in a straight line;
in technical language this is denominated Vertiges; which
see.

GIDDRI, in Geography, a town of Albania: 8 miles
N. of Achilles.

GIDEA, a river of Sweden, which rises in the Lapp-
mark of Aicle, and traversing Angermanland, runs into the
gulf of Bothnia. N. lat. 16° 20'. E. long. 18° 54'.

GIDELI, a town of Candahar: 50 miles S.E. of Cal-
bul.

GIDID, a town of Africa, in Dar-fur, nearly S.E. and
about 22 miles from Cobbié, on the road from Cobbié to
Ril. This town has a competent supply of water; and yet
the Fukkara, who populate it, are supposed to be so deftite
of hospitality, that they will hardly furnish a traveller suf-
ficient to allay his thirst. In this town are many houses,
and some of them belong to merchants who derive their ori-
gin from the southwards. — Allo, a town of Nubia: 55 miles
S. of Gerii.

GIDI-SHEHRI, a town of Asiatic Turkey, in Nato-
lia: 8 miles S. of Beilbeh.

GIDOLA, a town of Libya, in the government of Wi-
buig: 20 miles N. of Wiburg.

GIEH, a town of Germany, in the bispohric of Bam-
berg: 7 miles N. of Bamberg.

GIEDKULISZKI, a town of Samogitia: 24 miles S.
of Roiffonne.

GIEDROYCE, a town of Lithuania, in the palatinate of
Wilna: 24 miles N.N.W. of Wilna.

GIEDDUNGEN, a town of Norway, in the diocese of
Christianland: 18 miles N.W. of Stavanger.

GIEGUZIN, a town of Lithuania: 15 miles S. of
Witkermes.

GIER, in Botany, the Ceylon name of a small fruit,
described by Gortzer v. 2, 486. t. 186, of which nothing
more is known. The nucleus is singularly fitted, like a Ru-
lus, but if the figure be in all points correct, it cannot be
2 grain of the fruit of that genus. The internal parts, which
were decayed, might have afforded somethings decisive,
especially the situation of the embryo.

GIELLUM, in Geography, a town of Norway, in the
diocefe of Aggerhus: 55 miles N. of Chiriltiana.

GIEI, a town of France, and principal place of a
district, in the department of the Loiret, seated on the Loire;
32 miles S.E. of Orleans. The place contains 5117, and
the canton 11,356 inhabitants, on a territory of 410 kilo-
meters, in 11 communes. N. lat. 48° 45'. E. long. 10°
13'.

GIENE'. See KEN.

GIENSOR, a town of Africa: 10 miles S. of Tri-
poli.

GIER, a river of France, which runs into the Rhine,
12 miles below Lyons.

GIERACE, a town of Naples, in Calabria Ultra, the
see of a bishop, suffragan of Reggio: containing 13
churches, and 4 monasteries. Near it are some sulphureous
baths: 34 miles N. of Reggio. N. lat. 38° 6'. E. long.
16° 30'.—Allo, a town of Sicily, in the valley of Demo-

nes: 30 miles S.W. of Milletta. N. lat. 37° 48'. E. long. 14°
22'.

GIERANONY, a town of Lithuania, in the palatinate of
Wilna: 20 miles N.E. of Lida.

GIERGA, a town of Bengal: 48 miles S.E. of Doc-
fa.

GIESIM, a town of Nubia, between Sennar and Abyb-
fiita: 150 miles E.S.E. of Sennar. N. lat. 13° 16'.
E. long. 35° 15'.

GIESSEN, a strong town of Germany, in the princip-
ality of Upper Hesse, situated in a fertile country, on the
Lahn. It is defended by a good citadel and arsenal.
An university was founded here in the year 1605; 36 miles
N.E. of Mainz. N. lat. 50° 35'. E. long 8° 43'.

GIEZIN, a town of Samogitia: 22 miles E.S.E. of Ro-
iffonne.

GIPFE, a term in Surgery, signifying dwellings behind
the ears.

GIFFEN, Hubert, in Biography, a lawyer and philo-
logist, was a native of Gueldres in France. He studied at
different universities, as those at Louvain, Paris, and Or-
leans, and in 1567; he took his degrees in the law. He
went to Venice in the train of the French ambasfaador, and
from thence to Germany, and taught philosophy and juris-
prudence at Strafiburg, Altdorf, and Ingolstadt. He was
educated in the principles of Protestantism, which he re-
nounced for the Catholic religion previously to his being
invited to the imperial court, where the emperor Rodolph
bowed upon him some important offices. Being sent into
Bohemia, he died at Prague in the year 1604, being about
seventy years of age. His principal works are "Comment,
de Inip. Juliano": "Index Hist. Rerum Romanorum"; and
notes and comments upon Arifiotis's politics, ethics;
also upon Luceritus. Moreri. Bayle.

GIFT-MEHL, the name given by the German cheme-
ists and metallurgists to the first appearance of arsenic,
or the grey flowers arising from the roasting of cobalt;
and sticking to the long wooden funnel, which they carry from the
furnaces.

The word gift-black is German, and signifies poisonous
meal or brand.

GIFHORN, in Geography, a town of Germany, in the
principalities of Luneburg-Zell, seated on the Aller: 19
miles E. of Zell.

GIFONI, a town of Naples, in Principato Citra: 7 miles
E. N. E. of Salerno.

GIFT, or GRANT, in Law, a method of transferring
peronal property, anferring in some measure to the con-
veyances of real estates. Gifts and grants are thus to be difin-
guifed from each other, that gifts are always gratuitous,
whereas grants are upon some consideration or equivalent.
With regard to their subject-matter, they may be divided
into gifts or grants of chattels real, and gifts or grants of
chattels personal. Under the former chufs may be included
all leaves for years of land, assignments, and surrenders of
these leaves; and all the other methods of conveying an estate
less than freehold; though these very seldom carry the out-
ward appearance of a gift, however freely bellowed; being
usually expressed to be made in consideration of blood, or
natural affection, or of the property possessed by, or
owed to the grantor; and in case of leaves, always referring a rent,
tough it be but a pepper-corn — any of which considerations
will, in the eye of the law, convert the gift, if execut-
ated, into a grant; if not executed, into a contract.

Grants
Grants or gifts of chattels personal are the act of transferring the right and the possession of them; whereby one man renounces, and another man immediately acquires, all title and interest therein: which may be done either in writing or by word of mouth, attested by sufficient evidence (Park. § 57.), of which the delivery of possession is the strongest and the most essential. But this conveyance, when merely voluntary, it somewhat suspicious; and is usually confined to be fraudulent, if creditors or others become sufferers thereby. And, particularly, by statute 3 Hen. VII. c. 4, all deeds of gift of goods, made in trust to the use of the donor, shall be void: because otherwize persons might be tempted to commit treason or felony, without danger of forfeiture; and the creditors of the donor might also be defrauded of their right. And by statute 13 Eliz. c. 5, every grant or gift of chattels, as well as lands, with an intent to defraud creditors or others (3 Rep. 82.), shall be void, as against such persons to whom such fraud would be prejudicial: but, as against the grantor himself, shall stand good and effectual; and all persons partakers in, or privy to, such fraudulent grants, shall forfeit the whole value of the goods, one moiety to the king, and another moiety to the party grieved; and also, upon conviction, shall suffer imprisonment for half a year.

A true and proper gift or grant is always accompanied with delivery of possession, and takes effect immediately; as if A. gives to B. a cask of wine, and puts him in possession of them directly, it is then a gift executed in the donor; and it is not in the donor's power to retract it, though he did it without any consideration or recumence (Litt. 109.); unless it be prejudicial to creditors; or the donor were under any legal incapacity, as infancy, coverture, durea, or the like; or if he were drawn in, circumvented, or imposed upon by false pretences, bribery, or surprize. But if the gift does not take effect, by delivery of immediate possession, it is then not a proper gift, but a contract; and this a man cannot be compelled to perform, but upon good and sufficient consideration. See Contract.

The conveyance by gift, "donatio," is properly applied to the creation of an estate-tail, as feuominium is to an estate in fee, and lease to that of an estate for life or years. It differs in nothing from a feomium, but in the nature of the estate passing by it; for the operative words of conveyance in this case are do or dedi (Welt. Symbol. 256.); and gifts in tail are equally imperfect without littery of feomium, as feeominiums in fee-simple. (Litt. § 59.) See Feeominium. This is the only distinction which Littleton seems to take, when he says (§ 57.), "it is to be understood, that there is feomium and feuominium, and donor and donee, lefser and lefser;" while, scorr is applied to a feuominium in fee-simple, donor to a gift in tail, and lefser to a lease for life, or for years, or at will. In common acceptance gifts are frequently confounded with grants. (See Grant.) Blackf. Com. B. ii.

Gift-day, in Rural Economy, is a term implying a boon-day, or a day's work given from the tenant to the lord, or from neighbour to neighbour.

Gifts, New Tear. See STRANGE.

GIG. Fish. See FISH-gig.

GIGA, Ital. Giglio. Fr. a jig, the name of a gay dance, and of its tune. The Cruton Dict. defines this word from Dante, par. 14. strumento musicale di cordi; a musical instrument with strings. The Cruton, likewise, says, that it is an instrumental movement, so called.—Walther's derivation from Scigo, Germ. a violin, or fiddle, comprehends both the tune and the instrument upon which, originally, it was most frequently played. The time of the gig, or jig, is always quick, and in triplets of 6, 9, or 12.

Corelli's jigs were long in favour; but, being in the fine time as most of our old country-dances, they are almost all become vulgar, except the giglio in his 5th solo, and 11th sonata, op. ii.

Roufseau says that jigger are now wholly out of fashion in Italy and France; but the movement is only improved by new and more elegant passages: for, whatever is played quick, in triplets of 6, 9, or 12 quavers in a bar, is still a gig, or jig.

GIGAIA, GIGHA, GIGA, or GIGO, in Geography, one of the smaller western islands of Scotland, about 7 miles long and 2½ broad, partly rocky and partly arable. Situated in N. lat. 55° 46', W. long. 5° 43', and separated from the peninsula of Cantyre, or Kintyre, by a channel 38 miles broad. There are no trees in this island; but oak are sometimes dug up in the morasses. Near its centre is Dun-cliff, a high steep rock, flat at top, which appears to have been a strong fortification. At Kilchattan is a rude column, 16 feet high, 4 broad, and 8 inches thick, and near it is a cairn. On the western shore, which is bold and rocky, there are two remarkable caves; and on the S. coast is a subterraneous passage 133 feet in length. Between the projecting points and fink rocks on the E. coast are creeks, in which veslets may be safely moored. This island contains 592 inhabitants.

About 1½ mile S. from Gigha, is the island Caray, or Cara, near a mile long and half a mile broad, containing 22 inhabitants. The shores are everywhere high and rocky, except at the N. E. end, where is the only landing place. The Mull of Cara, at the S. end, is a perpendicular rock 167 feet high. At the N. E. end, the soil is a mixture of hills, sand, and common mould; the rest of the island, at the surface, is a stratum of peat earth. Between Gigha and Cara is Gigulam, a small uninhabited island.

GIGANTES, a cluster of small islands among the Philippines, N. W. of Sibu. N. lat. 11° 42'. E. long. 123° 20'.

GIGANTIC. See Giant.

GIGANTIC, Or Architectura, a name given by Scamozzi and others to the Tuscan order.

GIGANTOMACHIA, the battle of the giants against the fabulous gods of the ancient heathens. See Giant.

The word is Greek, γίγαντομαχία, formed of γίγαντα, giant; and μαχαί, combat, of μαχαίρι, pugn., fight.

Several of the poets have composed gigantomachias: that of Scarron is the finest of all his pieces.

GIGANTOPHONTES, is a name given to Minerva, on account of the assistance which she gave to Jupiter in his combat with the giants.

GIGAY, in Geography, a small island of the Hebrides, on the E. coast of Burray, yielding tolerable pasture, but difficult of access.

GIGERI. See JUEL.

GIGERIE, a term used by some writers to express the offals of poultry of any kind, including the intestines, extremities, and whatever else is thrown away before the dressing. See Giblets.

GIGG, GIGA, or JIG, in Music and Dancing. See GIA.

Gigos, among Farriers, small bladders or blisters on the inside of a horse's lips. They must be laid open, and cleansed with salt and vinegar, or alum-water.

GIGGE, in the Manufacture of Flax, denotes a hole made in the earth, where fire is made to dry the flax laid over it.

GIGGE, Anthony, in Biography, a learned Italian, who flourished in the early part of the seventeenth century, and was admitted to the degree of doctor by the Ambro-
G I L

fian college at Milan. He was author of many learned works, but that on which his reputation is chiefly established, was entitled "Thefaurus Linguæ Arabicae, seu Lexicon Arabico-Latinum;" published in four volumes folio, in 1632.

As a recompence for the learning and industry which it exhibited, pope Urban VIII. nominated the author to an honourable post in a college at Rome; but he died before he could enter upon its functions, or enjoy its emoluments. Gen. Biog.

GIGLIO, or ISOLE DEL GIGLIO, in Geography, a small island in the Mediterranean, near the coast of Italy, anciently called Agilum, or Isigum. N. lat. 42° 28'. E. long. 10° 53'.
Gilbert, or Gilbert, William, a physician, was born in the year 1653, at Coleheffer, of which borough his father had been recorder. After studying some time at Cambridge, he travelled abroad for farther improvement in those branches of science to which he was particularly addicted; and took the degree of doctor of physic in some foreign university.

He returned to his own country with a high character for philosophical and chemical knowledge, and was made a member of the College of Physicians in London, where he lived and died. He was distinguished as a learned man, and had a high reputation and success. The vacancies from the duties of his profession which he succeeded in the pursuit of philosophical experiments, particularly relative to the magnet, and in these he was assisted by a pension from Queen Elizabeth. We are informed of no other circumstances concerning the life of this learned man, who died, unmarried, November 20, 1683, aged 63, and was buried in his native place, where a handsome monument was erected to his memory by his brothers. He left all his books, globes, mathematical instruments, and cabinet of minerals, to the College of Physicians. His picture, which represents him as of a tall stature and cheerful countenance, is in the gallery over the schools at Oxford.

The capital work of Dr. Gilbert, entitled "De Magnete, Magneteque Corporibus et de Magneto Magnete Tellure, Physiologia Nova, plurimis argumentis et experimentis demonstrata," was first published at London in 1600, and has been reprinted in Germany. This is not only the earliest complete system of magnetism, but also, one of the first specimens of a philosophical system built upon experiments, after the manner so much insisted on afterwards by the great lord Bacon. Akin, Biog. Mem. of Med. Loyal.

Gilbert, John, the son of Mr. Thomas Gilbert, a gentlemanpossessing an estate of about 300l. a year, was born in the year 1723. His eldest brother had a liberal education, with a view to the bar, and became afterwards a member of parliament for Newcastle and Litchfield; but the subject of this article had only such instruction as the obscure village of Farley, in the neighbourhood of his father's house, could afford. At the age of twelve or thirteen years, he was bound apprentice to Mr. Bolton, father of the well-known and justly celebrated Matthew Bolton, of Soho, near Birmingham; between whom and Mr. Gilbert an intimacy subsisted, as long as the latter lived. At the age of 19 he left his father; and as he died of extensive liverworks, they required attention. Accordingly Mr. Gilbert, in order to undertake the superintendence of them, quitted his connection with Mr. Bolton, who very reluctantly parted with him, and devoted himself to the management of his own family concerns. Notwithstanding the disadvantages under which Mr. G. had laboured in early life, he possessed talents, which, matured by age and experience, could not fail of recommending him to notice. But the most remarkable circumstance in the history of this ingenious person, and that indeed which has induced us to give a brief account of him, was his introduction to the duke of Bridgewater, at the time when he was projecting improvements of his collieries, in the neighbourhood of Manchester. Mr. Gilbert's brother was then steward to the duke; and he advised him to inspect and examine his Grace's collieries at Worsley. After viewing the works, it immediately occurred to him, that if the coal on that part of the duke's estate could be brought to market in such a populous town as Manchester, and for the supply of the numerous works in its vicinity, the collieries, which, in the state it was at the time of his inspection, yielded little profit, would become extremely valuable. It is said, that he induced himself altogether from company for two days, at the Bull inn at Manchester, to consider how this might be done by water-carriage, as that by land was very expensive, and, on account of the badness of the roads, very inconvenient, and almost impracticable. Having digested his scheme, he communicated it to the duke, who was no less struck with the proposition suggested by Mr. G. than the projector himself. Accordingly the work was taken in hand after began. Mr. G.'s name has seldom or never occurred in connection with this very important and lucrative undertaking; and as he proceeded Mr. Brindley in the business, of which we have ample and satisfactory evidence, we thought that justice required a candid and impartial statement of the facts. Mr. G. was so fortunate, in the prosecution of this work, as to find line upon the duke's estate, which much otherwise would have been brought by land from Buxton, at the distance of near 50 miles; and in a work of this great extent, this was no incommoder saving. The tunnel was entirely executed, as well as planned, by Mr. G.; who, being acquainted with Mr. Brindley as a neighbour, and knowing him to be a very ingenious and excellent millwright, engaged his assistance in the conduct and completion of the arduous undertaking, and introduced him to the duke for this purpose. The duke was so well satisfied with his agent and projector, that at first they lived together for two or three months in the year, and for several of the last years of Mr. Gilbert's life, he spent half his time with him. In June, 1757, he removed with his family to Worsley, that he might, with greater convenience, attend to the prosecution of the business he had undertaken. As a further evidence of the duke's regard for Mr. G. we may here add, that he gave his son, who was educated for the church, the second-bast preferment at his disposal, to the amount of about 1200l. per annum. We might mention many other concerns in which Mr. G. was engaged, and in which he had an opportunity of manifesting his skill and judgment, in the conduct of canals, mines, and other improvements relating to rural economy. We shall merely add, that he is said to have been the first person who suggested the use of gun-powder in obtaining rock-fall. Mr. G. was probably too modest and unassuming, that he did not, during his life-time, lay claim to the honour which belonged to him, with respect to the duke of Bridgewater's canals and collieries; and we have introduced his name into the Cyclopaedia, in order to do him justice, without meaning to detract from the merit of his coadjutor and successor, Mr. Brindley, to whom we have already paid ample and deserved respect under his biographical article. Mr. Gilbert's general character commanded the esteem of all who knew him, and his death, even after a prolonged life of about 75 years, which happened at Worsley, on the 4th of August, 1757, was, without doubt, regretted by his friends, and especially by the noble duke, who was in the house at the time.

Gilbert's Island, in Geography, an island near the S.W. coast of Terra del Fuego. Lat. 53° 57' W. long. 74° 17'.

Gilbert's Town, a town of America, in the state of Virginia, seated on the Shenandoa, 30 miles N. of Charlottesville.

Gilbertines, in Ecclesiastical History, an order of religious, thus called from St. Gilbert, of Sempringham, in the county of Lincoln, who founded the same about the year 1148: the monks of which observed the rule of St. Augustine, and were accounted canons; and the nuns that of St. Benedict.
The founder of this order erected a double monastery, or rather two different ones, contiguous to each other, the one for men, the other for women, but parted by a very high wall.

St. Gilbert himself founded thirteen monasteries of this order, viz., four for men alone, and nine for men and women together, which had in them seven hundred brethren, and fifteen hundred sisters. At the dissolution there were about twenty-five houses of this order in England and Wales.

GILBERTUS ANGLICUS, in Biography, the first practical writer on medicine, whom this country produced, is placed by Bale, (who calls him Gilbertus Legenus, and says he was physician to Hubert, archbishop of Canterbury,) in the reign of King John, about the year 1210. But Leland, without stating the grounds of his opinion, makes him more modern. Dr. Freind observes, that it is obvious, from the work by which he is principally known, (a "Compendium of Phyfic,"') that he must have lived several years later in the thirteenth century; very probably in the beginning of the reign of Edward I. "For he quotes Avrerehs;" Dr. Freind remarks, "who reached to the close of the twelfth century; and whose works could not have been translated to early, and indeed were not translated till the middle of the thirteenth, as Bacon, a good voucher, informs us; and the mention he makes of a hook, "de Speculius," which, without doubt, is written by Bacon, and what he transfers from Theodoric, concerning a leprosy, evidently shews that he lived lower in this century, &c." (Hist. of Phyfic, vol. ii. p. 267.) According to Leland, he maintained a high character for his knowledge in philosophy and physic, which he had acquired by great study and much travelling; and he was very successful in his practice. His writings are principally compiled from those of the Arabian physicians, like the works of his contemporaries in other nations; sometimes, indeed, he transfers the whole chapters word for word, especially from Rhazes. He is represented as the first English physician who ventured to expose the absurd practices of the superstitious monks, who at that time engrossed much of the treatment of diseases, and is said to have contrived with them the methods recommended by the ancients. The principal work of Gilbert, entitled "Compendium Medicina tam morborum univerfalis quam particularium," was corrected by Michael Capella, and printed at Lyons in 1510; and afterwards at Geneua, in 1608, under the title of "Laurea Anglaca, seu Compendium totius Medicinae." His other treatises were, "De viribus Aquarum;" "De Res Herbaria;" "Theaurum Pauperum;" and "De tuenda valetudine." Eloy, Dict. Hist. Freind, loc. cit.

GILBING, in Geography, a town of Prufin, in Ermland; 12 miles W. of Allenheim.

GILBOA, in Scripture Geography, a mountain of Palestine, celebrated on account of the defeat and death of Saul, and his son Jonathan. (1 Sam. xxxi. 1, 2, 3.) Ezechias and Jerom place this mountain six miles from Bethan, otherwise Scevthopolis.

GILD, or GUILD, originally signifies a fraternity, or company.

The word is formed from the Saxon gildan, to pay, because every man was gildcr, i.e. to pay something towards the charge and support of the company. Hence also our Guild-hall, q. d. the hall of the society or fraternity, where they meet, and make orders and laws among themselves.

The origin of gilds, or guilds, is thus related: it being a law among the Saxons, that every freeman of fourteen years old should find aventure to keep the peace, or be committed; certain neighbours, consisting of ten families, entered into an association, and became bound for each other, either to produce him who committed an offence, or to make satisfaction to the injured party: that they might the better do this, they raised a sum of money among themselves, which they put into a common floc; and when one of their pledges had committed an offence, and was fled, then the other nine made satisfaction out of this floc, by payment of money, according to the offence.

Because this association consisted of ten families, it was called a decennary; and from hence came out later kinds of fraternities.

But, as to the precise time when these guilds had their origin in England, there is nothing of certainty to be found; since they were in use long before any formal licence was granted them for such meetings.

It seems to have been about the close of the eleventh century, says Anderson, in his History of Commerce, vol. i. p. 70, that merchant-guilds, or fraternities, which were afterwards styled corporations, came first into general use in many parts of Europe. Mr. Madox, in his Sira Burgi, chap. i. § 9, thinks, they were hardly known to our Saxon progenitors, and that they might be probably brought into England by the Normans; although they do not seem to have been very numerous in those days. The French and Normans might probably borrow them from the free cities of Italy, where trade and manufactures were much earlier propagated, and where possibly such communities were first in use. See Charters of Community, City, and Corporation.

Edward the Third, in the fourteenth year of his reign, granted licence to the men of Coventry to erect a merchant's guild and fraternity, of brethren and lifters, with a master, or warden; and that they might find charters, below alms, do other works of piety, and constitute ordinances touching the same.

So Henry the Fourth, in his reign, granted a licence to found a guild of the Holy Cross, at Stratford-upon-Avon.

GILD, in the royal boroughs of Scotland, is still used for a company of merchants, who are freemen of the borough.

Every royal borough has a dean of gild, who is the next magistrate below the bailiff. He judges of controversies among men concerning trade; disputes between inhabitants touching buildings, lights, watercourses, and other nuisances; calls courts, at which his brethren of the gild are bound to attend; manages the common flock of the gild; and enormes, and collects fines.

GILD, or Gold, according to Camden, also signifies a tribute, or tax. See Gold.

GILD, according to Crompton, also signifies an amercement. As in foot-gild, which he interprets a pretation within the forfeit.

Hence, to be quit of all manner of gild, is to be discharged of all manner of prelutions to be made for gathering heaves of corn, lamb, and wool, to the use of foresters.

GILD, or Geld, is also used among our ancient writers for a compenation, or malte, for a fault committed. See Un-Geld.

Hence, =eurgeld is the price of a man; or geld is the price of cattle; angeld, the fingle value of a thing; twigeld, the double value, &c.

There are divers other words which end with gild, and these the kinds of payments, as dancergeld, wood-geld, fargeld, bordergeld, falseld, gendigeld, &c. which see.

GILD, or Guild rents, are rents payable to the crown by any
any gild, or fraternity; or such rents as formerly belonged to religious gilds, and came to the crown at the general dissolution: being ordered for sale by the flat.

22 Car. II.

GILDABLE, or GELDABLE, denotes a person tributary, that is liable to pay tax, or tribute.

Camden, dividing Suffolk into three parts, calls the first gildable, because liable to tax; from which the two other parts were exempt, because ecclesiastic.

GILDABLE is also explained in an ancient MS. to be that land or lordship which is sol dijtritaone curie vicem.

GILDAS, in Biography, furnamed the Wulf, a British monk, and the most ancient British writer now extant, was born in the year 520. He is known among many authors by the name of Badonius, by which he is distinguished from Gildas Albianus, who is said to have lived at an earlier period. His surname Badonius is derived from a memorable victory gained by the Britons over the Saxons, at the hill of Badon, now Bath, about the time of his birth. Having been carefully educated according to the manners of the times he became monk of Bangor, where he diligently applied himself to the learning of that period, and particularly to the study of the scriptures, with a view of qualifying himself for the duties of a public preacher. He is said to have visited Ireland at the request of Americus, afterwards king of the country, where he distinguished himself by his zeal and succeds in converting Pagans, confuting the heresies of the age, establishing monasteries, and in reforming the corrupt state of principles and manners which had become prevalent among the Christians in that island. Upon his return to his native country he visited the monastery of Llan-cavan, lately founded by a pious nobleman of South Wales, and endeavoured, by all the means in his power, to engage other persons, eminent for rank and fortune, to follow his example. He spent some time in the northern parts of Britain; visited France and Italy, and then returned home, where he acquired a high reputation as a most indefatigable preacher who never hesitated to confute the prevailing vices of the age. He is supposed to have died at the abbey of Bangor in the year 590; though, according to some writers, this event happened at Glattonbury, full twenty years prior to this. The chief work of this author is; "Epitola de Excidio Britanniae, et Cafligatione Ordinis Ecclesiastic," containing lamentations over the miseries and almost total ruin of his countrymen, and very severe reproofs of the corruption and profligacy of manners in which all ranks were sharers, and of which he drew a most alarming picture. This curious remain of British ecclesiastical antiquities was first printed by Polydore Virgil in 1525, from an imperfect copy. It was afterwards published in 1568 by John Jofille, from another, and a more perfect manuscript copy, but the first edition was published by Dr. Thomas Gale, in the first volume of his "Histories Britannicae, Saxonicæ, &c." Gildas wrote several "Letters," of which there are numerous fragments in an old collection of canons preferred among the MSS. in the Cottonian library. Other pieces have been ascribed to him, but these are considered by the best judges, as not really his; among them is the "Histories de Gildis Britonum." Moreri.

GILDAS-de-Bois, St. in Geography, a town of France, in the department of the Lower Loire, and chief place of a canton, in the district of Savenay. The place contains 859, and the canton 5527 inhabitants, on a territory of 233 kilometres, in five communes.

GILDER. See GILDER.

GILDAHALLA TEUTONICORUM was used for the fraternity of Eaterling merchants in London; called also the filliard.

GILD-HALL, q. d. Gilda aula, the chief hall in the city of London. See GULD-HALL.

GILD-MERCHANT, Gilda Mercatoria, was a certain privilege, or liberty, granted to merchants, whereby they were enabled, among other things, to hold certain pleas of land within their own precincts.

King John granted gildum mercatorum to the burgesses of Nottingham.

It is held, that if the king grants to a set of men to have "gildam mercatorum," a mercantile meeting or assembly, this is alone sufficient to incorporate and establish them for ever. 10 Rep. 30. 1 Roll. Abr. 513.

GILDING, or GILDING, the art, or act, of spreading or covering certain substances with gold, either in leaf or powder, or in amalgam with quicksilver. See an account of these preparations of gold under GOLD.

The art of gilding was not unknown among the ancients, though it never arrived among them at the perfection to which the moderns have carried it. For this purpose the gold was beat into plates, with which the walls of apartments, dishes, and other vessels were covered. In early ages these plates were thick, so that this mode of gilding was very expensive. (See the proeès employed for gilding, in this manner, the horns of the ram brought by Nelfor, as an offering to Minerva, in Homer's Odyssey, l. iii. v. 492.) In procès of time, however, the expense was much lessened, because the art was discovered of making these plates thinner, and of laying them on with a fire.

Pliny affures us, that the first gilding seen at Rome was after the deftruction of Carthage, under the censorship of Lucius Mummius, when they began to gild the ceilings of their temples and palaces; the Capitol being the first place on which this enrichment was bestowed. But he adds, that luxury advanced on them so hastily, that in a little time you might see all, even private and poor persons, gild the very walls, vaults, &c. of their houses. "When we cover our houses with gold," says Senecca, (Epit. 115.) "what else do we than rejoice in deception? for we know, that coarse wood is concealed under that gold." We need not doubt but that they had the same method with us, of beating gold, and reducing it into leaves; though, it should seem, they did not carry it to the fame height; if it be true, which Pliny relates, that they only made seven hundred and fifty leaves, four fingers square, of a whole ounce. Indeed, he adds, that they could make more; that the thickest were called bratticum psalmata, on account of a flattens of the goddes Fortune at Prancelle, gilt with such leaves; and that those of the thinner fort were called bratticum gosvariae.

The modern gilders also make use of gold leaves of divers thickneses; but there are some so fine, that a thousand do not weigh above four or five drachmas. The thickest leaves are used for gilding on iron, and other metals; and the thinnest on wood. But we have another advantage above the ancients, in the manner of using and applying the gold: the secret of painting in oil, discovered of late ages, furnishes us with means of gilding works that shall endure all the injuries of time and weather, which to the ancients was impracticable. They had no way to lay the gold on bodies that would not endure the fire but with whites of eggs, or fize; neither of which will endure the water: so that they could only gild such places as were sheltered from the moisture of the weather.

The Greeks called the composition on which they applied their gilding on wood, luminum, or luminorum; which
which is described as a sort of glutinous compound earth, serving, in all probability, to make the gold thick, and bear polishing. But as to the particulars of this earth, its colour, ingredients, &c. the antiquaries and naturalists are not agreed.

There are several methods of gilding in use among us: viz. gilding on an oily size; gilding on a water size; gilding by the fire, which is peculiar to metals; gilding of books, &c.

We may distinguish, in general, two kinds of gilding, one with, and the other without, the application of heat. The first method is practised on those substances, such as wood, paper, leather, silk, lacequered and japanned ware, &c. which would be injured, and even destroyed at the temperature requisite for the other sort of gilding, which is employed on substances that are not liable to alteration by exposure to a moderate heat, such as metals, and sometimes glais and porcelain.

There are two methods of gilding on wood, viz. oil-gilding, and burnished gilding.

Gilding in oil, or an oily size, is performed by cementing the gold to the ground by means of fat oil. Linseed oil may be prepared for this purpose, by putting such a quantity of it into a broad vessel as may cover the bottom about an inch deep, and adding to it as much water as will rise fix inches or more above the bottom. Let the vessel be exposed to the sun and rain, and the contents be occasionally thredded for five or six weeks, till the oil appear of the consistence of treacle. Then separate the oil from the water, and place it in a long bottle, or separating-funnel, used by the chemists, in such heat as will render it perfectly fluid; pour off the clear part, and strain the remainder through a funnel, and the whole will be fit for use. The water helps to clear and bleach the oil, and improve it in other respects.

In order to prepare the wood for gilding, it must first be covered or primed with two or three coatings of boiled linseed oil and white lead, in order to fill up the pores, and conceal the irregularities of the surface, occasioned by the veins in the wood. If greater nicety and perfection in the work be required, the wood should be first rubbed with fife-skin, and then with Dutch ruffs.

When the priming is dry, the next operation is that of sizing the work, or laying upon it, by means of a brush, or a large pencil, a thin coat of gold size; care being taken that the brush or pencil be made to pass into all the cavities and projecting parts, if the subject be carved. This gold size is prepared by grinding calcined red ochre with a due proportion of the fat, or thickish drying oil that can be procured, (the older the better); and this size, in order to fit it for working more freely, is to be mixed, previous to its being used, with a small quantity of oil of turpentine, till it acquire a proper consistence. Sometimes the work is sized with fat oil, and the japanner's gold size (see Gold Size), ground also with ochre. If a high degree of perfection be required, the work should be sized a second time, and some add a third sizing, before the gold is laid on. In order to ascertain its fitness for this purpose, it is touched with the finger; and if it feel somewhat adhesive or clammy, or, as the gilders call it, "tacky," but not so as to be brought off by the finger, it is in a fit state for gilding. But if it be too clammy as to daub, or come off on being touched, it is not sufficiently dry; or, if it has no clammy-fe or sticking quality, it is too dry, and must be sized over again before it is gilt. When the gold size is good, it will be sufficiently dry in about twelve hours for the application of the gold. In this process, when the surface is sufficiently large and plain to contain them, the gold leaves may be laid on entire, either by means of a squirrel's tail, or immediately from the paper which originally contained them, which last method, practised by those who have acquired the necessary dexterity, is the simplest and most expeditious, as well as the best, for the perfection of the work. The leaves, being laid on the proper parts of the work, must be set to the ground, by gently compreissing those, which seem to want it, with the squirrel's tail on a cotton ball; and if any part of the gold has flown off, or has been displaced, so as to leave any spot uncovered, a piece of another leaf, of a corresponding size and figure, must be laid upon it. When the parts are too small to admit of laying on whole leaves, or when vacancies are left, after laying on whole leaves, which require to be covered with the splits or fragments of leaves, those that are to be used are turned from the paper upon a cushion. (See Gilding Cushion and Cushion.) They are then cut into slips, of a proper size, by a blunt pallate knife (see Gilding Knife); and each slip is taken up on the point of a fine brush, or by an instrument called the "tip" (see Gilding Tip), which, being moistened by breathing upon it, will take up the leaves, or any fragments of them from the cushion. When these are thus applied to the borders of the work that were to be covered, they are gently pressed down by the cotton ball, till they lie everywhere upon the ground; and the gold will immediately adhere to the fleshy surface of the size. Where the work is very hollow, and small pieces are wanted to cover parts that lie deep, they may be taken up, by the tip already mentioned, or the point of a flesh pencil, first breathed upon, and then conveyed to, and set in their proper places. The whole of the work, being thus covered, should be suffered to remain till it be dry, and it may then be brushed over by a camel's hair pencil, or soft horsehair brush, in order to clear away any loose particles of the gold leaf. If, after brushing, any defective parts appear, such parts must be again sized; and treated as before. The squirrel's tail used in gilding is cut short, and sometimes spread in the fan-fashion, by means of a piece of wood formed like a pencil-stick, but broad at both ends, and split to receive the tail; but it will equally serve in its own form, when the hair is cut to a proper length. The cotton should also be formed into a ball, by tying it up in a piece of fine linen rag; for if it be used without the rag, the fibres adhere to the gold size, and embarrass the work.

This sort of gilding is chiefly used for domes, and the roofs of churches, courts, banqueting-houses, &c. and for figures of plaster, lead, &c. that are to stand exposed to the weather.

This oil-gilding is the most simple and easy, least expensive, and most durable, as it will not be readily injured when exposed to the open air; and it may be also cleaned with a little warm water and a soft brush; but, as it cannot be burnished, it wants the high lustré which is produced by the method we shall next describe.

Gilding, Burnished, or in Dijtemper, or an Water-size, is that kind of gilding which is generally used for picture frames, mouldings, icaco, and such wooden works as are sheltered from the weather, and not subject to dampness. In order to prepare the wood for this sort of gilding, those parts that admit of it should be first well rubbed with fife-skin, and then with Dutch ruffs. It should then be carefully covered with strong size, made of shreds, &c. of white leather, such as that used by gloves, or clippings of parchmen boiled in water, in the proportion of about a pound of the
GILDING.

The shedding or clippings, to fix quarts of water, to the confidence of a jelly, and then strained through flannel while hot. When this coating is dry, eight or ten more must be applied, consisting of the fame size, mixed with fine plaster of Paris, or washed chalk, or powdered whiting; which mixture must be made by steeping the mix, and throwing the whiting, &c. gradually into it, stirring them well together, that they may be thoroughly incorporated. This is laid on with a stiff brush, and often or seldom repeated, according to the nature of the work; for pieces of sculpture, fifteen to twenty layers; for flat, or smooth works, they use ten or twelve. In the latter case they are applied by drawing the brush or pencil over the work; in the former, by dabbing it smartly on, that the size may enter all the dents of the carving.

After the last coat is laid on, and before it be quite dry, a brush pencil, dipped in water, should be passed over the whole, to smooth it, and take away any inequalities that may have been formed; and when it is dry, the parts that admit of it should be again brushed over till they are perfectly even. The work should then be repaired, by freeing all the cavities from the priming; after which a water polish should be given to the parts designed to be burnished, by rubbing them gently with a fine linen rag moistened with water.

When the whole work is become quite dry, a moderately thick layer must be applied, composed of size and bole, or yellow ochre. Dolfey, in the Handmaid to the Arts, gives the following recipe for the simplest compositions, used as the proper cement or gilding size in this kind of gilding: "Take and mix any quantity of bole argenteum, and add four times its weight of water to it, so that it may soak till it grow soft. Leave it then on the bone, but not with more water than will prevent its being of a stiff confidence, and add to it a little purified fust or tallow scraped; and grind them together. When this is wanted for use, dilute it to the confidence of cream, by parchmen or glowers' size, mixed with double its quantity of water, and made warm. Some melt the fust or tallow, and mix it previously with five or six times its weight of chalk before it is put to the bole, to facilitate their commixture, to which in this wet state they are somewhat repugnant. It is also sometimes practised to put foap fuds to the bole; which will contribute to its uniting with the tallow." (See Gold Size.) Let this composition be diluted with warm size mixed with two-thirds of water, and let it be spread with a brush over the whole of the work, and then suffer it to dry; and then let the same mixture be applied in the same manner, at least once more. After the last coat, it should be rubbed in the parts to be burnished with a soft cloth, till it be perfectly even. Some add a little vermillion to the gilding size, and others colour the whole size car-red, before it be laid on, with yellow and the glowers' fize; to which a little vermillion, or red lead, should be added. This last method is designed to give the appearance of gilding to the deeper and obscure parts of the carving, where the gold cannot, or is not thought necessary to be laid on. But this practice is much disliked; and instead of it such parts of the work are coloured after gilding; which operation is called "Matting."

The work being thus prepared should be set in a position somewhat declining from the operator; who, having at hand a cup of clean water, and some hair pencils, moistens a part of the work, and then applies the gold leaf to the part so moistened in the manner already directed under the article Oil-Gilding, till it be completely covered, or till it be too dry to take the gold. This will immediately adhere on being pressed with the cotton ball. The operator proceeds to moisten the next part of the work, and apply the gold as before, repeating the operation till the whole is completed. If, in examining the work, any parts should appear to need being repaired, they should be moistened as before, and covered with the gold; but care should be taken that no part be milled in the first operation, as it is not so easily mended as in oil-gilding: nor should any drops of water be suffered to fall on the perfect part of the gilding, as the gold is very apt to turn black in this state. The work being thus far gilt, when dry, and fit for the purpose, which it must be in about twenty-four hours, remains, either to be burnished, or matted.

The proper period for this purpose can only be ascertained by experience, and varies at different seasons. The mode of distinguishing the fitness of the work to take the burnish, is to try two or three particular parts at a distance from each other; and if these take the polish well, the whole may be concluded to be in a fit state. But if the gold peel off, or be disorder'd by the rubbing, the work must be deemed not sufficiently dry; and if the gold bear the rubbing well, and yet receives the polish slowly, it is a proof of its being too dry, which should be prevented by watching the proper time. For the work, when too dry, both requires much more labour to burnish it, and fails at last of taking to fine a polish.

To burnish it, is to smooth and polish it with a burnisher, which is usually a dog's or wolf's teeth, or a blood-stone, an agate, or a pebble, or something else very smooth, fitted in a handle for that purpose.

To mat, is to give it a light tick in the places not burnished, with a pencil dipped in size, wherein a little vermilion sometimes has been mixed. This helps to preserve it, and prevent its flaying, when handled. Or, it is to cover the hollow parts with a colour the nearest in appearance to gold.

Some recommend for this purpose red lead, with a little vermilion ground with the white of an egg; but yellow ochre, or Dutch pink, with red lead, would better answer the end; or the terra di Siena, very slightly burn't, or mixed with a little red lead, would have a much better effect, and be more durable than any other mixture so near the colour of gold in flame. Finials size will likewise supply the place of the whites of eggs. This operation of matting supersedes the necessity of yellowing, which is intended to give the appearance of gilding to the deeper and obscure parts of the carving where the gold cannot, or is thought necessary to be laid on.

The last thing is to apply a vermeil, or lacquer, in all the little lines and cavities; and to flop and anoint any little faults with shell-gold.

The composition here called vermilion is made of gum guuta, vermilion, and a little of some reddish brown colour, ground together with Venice varnish and oil of turpentine. Some gilders, in lieu of this, content themselves with fine lacco, or dragon's-blood, with gum-water.

Sometimes, instead of burnishing the gold, they burnish the ground or composition laid on last before it; and content themselves afterwards to wash the part over with size. This method is chiefly practised for the hands, face, and other nuditides in relief; which, by this means, do not appear to so very brilliant as the parts burnished; though much more so to the parts perfectly flat, or matted.

To gild a work, and yet preserve white grounds, they apply a layer of Spanish white mixed with a weak linum-glue, on all the parts of the ground whereon the yellow, or the layer next under the gold, might run.
GILDING

Gilding, japanning, is performed by means of gold powder, or imitations of it, cemented to the ground by a kind of gold size; for the method of preparing which, see Goldsize. This kind of gilding may be practiced on almost any substance whatever, whether wood, metal, leather, or paper; nor is there any preparation necessary, but this is merely the surface on which the size is to be laid, even, and perfectly clean. Then spread the japanner's size, mixed with a due proportion of oil of turpentine and varnish, with a brush over the work, if the whole surface is to be gilt; or draw with it, by means of a pencil, the proper figure desired, avoiding carefully any other parts; when it is almost dry, so as to be capable, by its clanniness, of receiving the gold, dip a piece of wash-leather wrapped round the finger in the gold powder, described under Skill-Gold, and rub it lightly over the sized work; or spread the powder with a soft camel's hair pencil; and with a camel's hair brush clear away the loose powder, after the gilded surface is dry. When leaf gold is used, the method of fixing must be the same as for the powders; but great care is necessary in laying them on, while the size is in a proper state of dryness.

There is a false kind of gilding, in which a colour of gold is given by painting and varnishes, without employing gold. Thus a very fine golden colour is given to brass and to silver, by applying on these metals a gold coloured varnish, which, being transparent, shews all the brilliancy of the metals underneath. Many ornamented brasses are varnished in this manner, which is called gold lacquering, to distinguish them from those that are really gilt. Silver leaves, thus varnished, are put upon leather, which is then called gilt leather; and many picture-frames have no other than this counterfeit gilding, which may be discovered by washing it with a little rectified spirit of wine; for the spirit will dissolve the varnish, and leave the silver leaf of its own whiteness. For plain picture frames, thick tin-foil may be used instead of silver; the tin leaf fixed on with glue is to be burnished, then polished with emery and a fine linen cloth, and afterwards with putty applied in the same manner; being then lacquered over with the varnish five or six times, it looks like burnished gold. (See Lacquering.) Among the false gildings may also be reckoned those which are made with thin leaves of copper or brasses, called Dutch leaf. In this manner are made all the kinds of what is called gilt paper. See Gilding of Paper.

Gilding of Books. There are various methods, with respect to the cement used, by which the edges of books or paper may be gilt. Strong gum-water or ingilafs size, or glover's size may be employed; but as the gum-water, and weaker sizes are apt to run beyond the edge, and thus cause the leaves to stick together, ingilafs, melted with the addition of some common proof spirit of wine, and the fifth part of honey or sugar-candy is much to be preferred; to which must be added a third of bole armeniac well powdered.

The following composition may be used for this purpose: Take bole armeniac, and sugar-candy well powdered; mix them with the whites of eggs, beaten to an oily confection; and the cement will be fit for use. In applying any of these cements, the paper, in quires or in books, should be well cut and polished on the edge to be gilt, and well burnished over by a prefs; in this state, it is to be burnished dry, or laid with a little of the cement without the sugar-candy or the bole; and when that is dry, either with the cement above given, or any other solution of gum or size with the proper proportion of the bole; after which it may be suffered to dry; and then water-polished, by rubbing it with a fine linen rag slightly moistened. It is then fit for receiving the gold, provided it be moistened at that time; and the leaves may be then laid on, being cut according to the breadth which they are to cover, and presed closely down by a cotton ball; and after the gilding is thoroughly dry and firm, it may be polished. See Book-binding, and Gilding of Paper.

Gilding on china-ware. The gold is very much valued on china-ware, and would be much more so, were it not that it is very liable to lose its luster, and to rub off. The Chinese have at present a method of preventing both these accidents, in a great measure, by means of a sort of polishing, which they give it after it is laid on. They prepare for this purpose a fine piece of agate, which they polish on one surface in as perfect a manner as possible. With this they rub over the gold, as it lies on the porcelain, several times, when it first comes from the baking. This gives the gold a lustre which it would not otherwise have, and fixes it down to the ware in such a manner, that it cannot easily be got off. The principal mishap to which gold thus laid on is subject, is the tarnishing, or growing dull; this is remedied by the same sort of means. They wet the veffel, upon which they would revive the luster of the gold, in common clean water; and while it is wet, they rub it with the same polished agate, adding a little fair water at times to keep it moist. If the gold has not been well laid on at first, this may possibly raise it or take it off in some places; but if it was originally put on with the help of this stone, as all the gold on porcelain now is, the rubbing it with it a second time never gives it any scratches, but recovers its pristine lustre and beauty. It must be observed, that the rubbing with this stone must be all done one way, both in the first laying on the gold, and in the brightening of it up afterwards. This may serve as a method for us as well as the Chinese, not only to recover the beauty of our tarnished gilt china-ware, but also to lay gold upon some of our home manufactures of this kind. Observe, fur les Coutumes de l'Afri. See Porcelain.

Gilding on enamel and glasses, is performed by burning or annealing, i. e. by producing a cohesion of the gold with the glafs or enamel, by the intermediaison of a flux, or by producing the like effect without any. In both these methods, the gold is made to adhere to the enamel or glafs, in consequence of the fusion or approach to that state, either of the flux used, or of the body of the enamel or glafs itself, by which the gold is cemented to such bodies. The flux, when any is used, may be either simple glafs of borax, or any of the preparations of fluxes powdered (see Flux); and the gold is used, either in the form of leaf gold, or in that of powder made mechanically, or by precipitation. (See Gold powder.) When leaf gold is employed without any flux, the enamel or glafs may be moistened with a very weak solution of gum arabic, and again dried. After being thus prepared, it should be breathed upon till it becomes a little adhesive or ficky, and then laid upon a sufficient number of leaves of gold: when the gold is thus united to the enamel or glafs by the cementing quality of the gum arabic, the work is ready for burning. If a flux be used, it should be finely levigated, tempered with a very weak solution of gum arabic, and very thinly spread on the part of the work to be gilded: and when the gum water is almost dry, the leaf gold should be laid on that part thus prepared for it, which is then in a state proper for burning. In the present practice, the aurum sulvianum, or precipitation of gold by alkaline farts, is made by those who use glafs in the greatest perfection; and the volatile alkal is employed for the precipitation by the chemist, who prepares it for this purpose. But when this kind of precipitate is chosen, the use of any flux must be avoided, and a very considerable degree of heat.
heat applied. The manner of using the precipitate powders of gold, the aurum fulminens excepted, as well as the leaf gold, may be varied, by adding to it or omitting any flux; but in what way forever the powder is used, it is to be tempered with the oil of spise, and worked as the coloured colours; and the quantity of flux, when any is used, may be a third of the weight of the gold. In cafes where the glass is very hard, or where the opportunity of a strong heat cannot be conveniently obtained, the expedient of using a flux in the following manner may be adopted with great advantage. Grind glasses of borax to a fine powder; and having tempered it with oil of spise, lay it on the glasses where the gilding is to be made; then burn the glasses with a degree of heat, that will cause the borax to run; and when it is cold, apply the precipitate or leaf gold, and burn it again, as in other cafes. After the work is burnt, if it be intended to be burnished, a proper Luther may be given to it, by rubbing the gilded part with a dog's tooth, or with a fine agate, or iron burnishers. Handmaid to the Arts, vol. i. p. 374, &c. See Ruby Glass.

Gold may be laid upon white earthenware or glasses, by drawing your design, upon the vessel to be gilt, with jappaners' gold fuse, moistening the fuse, as you find necessary, with oil of turpentine. Set the work in a clean place to dry for about an hour, and then place it so near the fire that you could but just bear the heat of it with your hand for a few seconds. Let it remain there till it feels quite tarry or clammy; then, having procured a cushion and some leaf-gold, cut it into slips of the proper size, and lay it on with a little cotton-wool. When the gold is all on, put the work into an oven to be baked for two or three hours.

Drinking glasses, with gilt edges, have been much admired in this country; the best of these are brought from Germany: those that are made in England, though equal in beauty to the foreign, being greatly inferior in the durability of the gilding. Dr. Lewis made several experiments with a view of discovering this art; from which he concludes, that the gold is cemented to them by means of an intervening matter, which will adhere to glasses so as not easily to be rubbed off. He tried milkfish, and other reinous bodies rubbed warm on the glasses, and several spirituous varnishes; but none of these were found to adhere sufficiently to the glasses. He recommends to the trials of the arts in this way the harder oil varnishes: and glasses have been since prepared in England, probably on the principles which he has pointed out, with as durable gilding as those brought from Bohemia and Thuringia.

M. Zeigler, in a German translation of the "Commerceum Philosophico-Technicum," describes a varnish for this purpose, with the method of using it, which appeared from his experiments to be the best. This varnish is prepared by boiling fine transparent amber; reduced to powder, in a brass vessel, to the cover of which a valve is fitted, with as much drying oil as will just cover it; and by diluting the above solution with four or five times its quantity of oil of turpentine. This varnish may be made to dry fooner, and acquires greater firmness by grinding it with a little white lead, or rather with a mixture of white lead and minium. It is to be applied very thin on the glasses, and the gold leaf laid lightly on the varnished part; when the varnish is thoroughly hardened, the gold may be burnished, by laying a piece of smooth paper between the leaf or feel burnisher, and the gold. This gilding, M. Zeigler observes, is durable, and of a fine lustre. Com. Phil. Techn. p. 65; and 674.

Gilding of figures and letters on paper, and for the embellishment of manuscripts, is performed with shell-gold, tempered with gum-water; or the characters may be drawn with a milky solution of gum-ammonium made in water, and gold-leaf applied upon them when almoft dry, or if all or any part of them is become quite dry, they may be again sufficiently moistened for receiving the gold by breathing on them. Letters raised from the surface of paper or parchment, in the manner of embossed work, such as are seen on ancient manuscripts, may be formed either by friction on a proper body with a solid piece of gold, or by leaf gold. The former method is practised by tempering pulverized crytal with strong gum-water, and with this paste forming the letters; when they are dry, they are rubbed with a piece of solid gold, as in polifhing, and the letters will appear as if gilt with burnished gold. The letters are formed with an embossed figure, either of the separate letters, or of whole words, cut in steel; and each letter of these flamps, when they are used, is anointed evenly with a feather dipped in oil. Then fill the concave letters with the above paste, and strike the flamps in a perpendicular direction on the paper or vellum, laid over some sheets of paper.

When the embossed letters are formed with leaf gold, the following, or a similar composition must be used. Thicken beaten whites of eggs with as much vermillion as is necessary to give them the confluence of paste; use the flamps as before; and when the letters are dry, moisten them by a small pencil with strong gum-water: and when this is almoft dry, cover the letters with leaf gold, preding it close to every part of them with cotton or soft leather; after the gilding is dry, polish it with proper burnishers. Com. Phil. Techn. p. 64 and Handmaid to the Arts, p. 450, &c.

Gilding of ivory-fish, as ewr-fish, cars, &c. may be performed without injuring the fish, by means of a cement; which Mr. Hooke, in his posthumous papers, directs to be prepared in the following manner: Put some Burgundy pitch into a new earthen pot, and warm the vessel till it receives so much of the pitch as will stick round it; then flame some finely powdered amber over the pitch when growing cold; add a mixture of three pounds ofinstead oil, and one of oil of turpentine: cover the vessel, and boil the contained ingredients over a gentle fire; grind the mixture as it is wanted, with so much plainsize-tome in fine powder as will reduce it to the confluence of paint. When the fish has been wiped dry, this mixture is spread upon it, and the gold leaf laid over it, and gently pressed down; after which, the fish may be immediately put into water, and the cement will harden, and be in no danger of falling off.

Gilding on leather. See Lacquering.

Gilding of metals may be done by cleaning the surface of the metal, and applying gold leaves to it, which, by means of rubbing with a polished blood-plate, and a certain degree of heat, are made to adhere perfectly well. In this manner silver leaf is fixed and burnished upon brafs, in making French plate; and sometimes also gold leaf is burnished upon copper and upon iron. For this purpose, the metal, being previously polished and quite clean, is heated to about the temperature of melted lead, and covered with a double layer of gold leaf; then a blood-plate burnisher, applied gently at first, and gradually increasing the pressure, will cause the surfaces of gold and copper to touch each other in almost every part, and then adhere with a force proportioned to the completeness of the contact. The first layer being thus burnished, a second is made to adhere in the same manner, and sometimes a third, if the gilding is intended to be very solid. This method of gilding is tedious, and is subject to the almost impossibility of using a sufficient prealure without injuring the edges of the gilded surface. In cafes where these objections do not apply, there cannot be a more effective

Gilding.
GILDING.

Gilding on Wood. See the three first articles in Gilding.

Gilding on Metals by the Fire. There are two ways of gilding by fire; viz., that with liquid gold, and that with leaf gold. For the latter, see Gilding of Metals, supra.

The former, technically called "water-gilding," is performed with gold amalgamated with mercury, in the proportion of about six or eight parts of mercury to one of gold.

In order to this operation, they heat some pure quicksilver in a clean crucible, and, when it is nearly boiling, put about a sixth of its weight of fine gold in thin plates heated red-hot, and stir them gently about, till the gold be found melted and incorporated into a mass with the mercury. It is then allowed to cool; and when cold, it is to be put in a piece of soft leather; and by gradual pressure, the fluid part of the amalgam, confining almost wholly of mercury, may be forced through the pores of the leather, while the gold, combined with about twice its weight of mercury, will remain behind, forming a yellowish filvery mass, of the confluence of soft butter.

This, after having been bruised in a mortar, or shaken in a strong phial with repeated portions of salt and water, till the water cease to be fouled by it, is fit for use, and may be kept for any length of time, without injury, in a corked phial. It is of indispensible importance that the materials of this amalgam should be perfectly pure; and therefore, the mercury employed in the preparation of it should be procured from the distillation of the red precipitate (nitrous red oxyd of mercury), either alone, or mixed with a little charcoal powder.

When silver is the metal to be gilt, it is prepared for the operation by soaking it in warm dilute muriatic acid, so that the surface may be rendered perfectly clean; it is then washed in clean water, which should be two or three times changed, in order to free it from the whole of the acid; and being afterwards dried, and made moderately warm, a little gold-amalgam, also warm, is to be evenly spread upon the silver, to which it will immediately adhere. In applying the amalgam, the operator uses a little knife, or a brush made of brafs wire, for the purpose; and giving the work a gentle heat before the fire, he dabs or spreads the amalgam with the brush farther and more evenly upon it.

Thus far advanced, the metal is set over the fire, upon a grate, or in a sort of cage, under which is a pan of charcoal, yielding a heat just sufficient for evaporating the mercury; by which means the mercury is raised in flames, and leaves the gold alone adhering to the work; in proportion as the mercury, evaporating and flying off, discovers places where gold is wanting, they take care to supply them, by adding new pieces of amalgam with the knife or brush.

If a thicker gilding be required than can result from so much of the amalgam as is applied at once, the metal, after the first quantity has left its gold fixed on the surface, has more of the amalgam spread upon it. After the evaporation of the mercury from this, another quantity may be applied in the same manner. When the mercury is evaporated, so that the surface becomes uniformly of a pale yellow colour, the metal is made to undergo other operations, by which its colour and lustre are heightened. For this purpose, it is first rubbed with a scratch brush, composed of fine brafs wire, till its surface is made clean and smooth, but the pale yellow colour still remains; then it is covered over with a composition called gilding wax, and again exposed to the fire till the wax be burnt off; and this application is repeated till the gold appears of a proper colour. This gilding wax is composed of bees' wax, mixed with the following substances; viz.

Effectual mode of gilding, as we perceive in the manufacture of gilt silver and copper wire. The bar, before it is committed to the wire-drawer, is plated with gold, by having several leaves of gold successively burnished down upon it, and then burn them into the strong compression that takes place in wire-drawing, the gold and the other metal become so perfectly united, as to form, in a manner, one substance. See Gold Hire.

Some metals, and particularly silver, may be gilt in the following manner: dip pieces of linen in the solution of gold by aqua regia, and then burn them to ashes; rub these ashes on the surface of the wire, well cleansed from any unctuous matter, with a wet linen rag, dipped in salt water, and the particles of gold contained in them will thus be applied to the wire, and adhere to it, without the application of heat, or intervention of any other body. Burnish the silver with a blood-stone, till it acquires the colour of gold. Most gilt ornaments on fans, snuff-boxes, and other toys of much flew and little value, are nothing but silver gilt in this manner. Lockmann (Hill of Inventions, vol. i.) suggests, that this method of gilding, sometimes called dry, and sometimes cold gilding, is a German invention; and that foreigners, at least the English, were first made acquainted with it about the end of the 17th century; for Robert Southewell dispenses it in the Phil. Trans. for 1698, and says, that it was known to very few goldsmiths in Germany. See Gilding of Metals by the fire.

Gilding on paper, parchment, and vellum. There are various methods used for this purpose, according to the several ends which the gilding is designed to answer. But for the most part, fire, properly so called, and gum-water, are used as the cement, and the powders are more generally employed than the leaf gold. See the three first articles in Gilding.

The gilding proper to be used with water-colours may be either with the leaf-gold or powder; the leaf-gold may be laid on the defignd ground by means of either gum-water, or ifinglass sizer; observing, that the gum-water or size be of the weaker kind, and laid sparingly on the ground, and that proper time be allowed for it to be dry; and then the gold is applied to it, as in the articles above recited; and it may be polished, if necessary, by the dog's tooth, or other kind of burnisher. In gilding larger surfaces, it will be found useful to colour the ground with the gall-flone; and when colours are to be laid on the gilding, the gall of any beast bruised over the gold will adapt it for receiving the colours. When the gold powders are used along with paintings in water-colours, they are previously formed into shell-gold.

The gilding proper for the coloured paper used in binding books, and for other such purposes, is performed much in the same manner: only that the gum-water and size may be much stronger, and that they are generally conveyed to the ground by means of a wooden plate or print, or by an engraved roller, which makes an impression of the intended figure or design. In this kind of gilding, the japoner's gold-size may be also commodiously employed; and this should be always used when the embossed appearance is wanted in the greatest degree; and for this purpose it should be thickened with yellow ochre, mixed with as much red-lead as the proper working of the print will admit. Instead of the genuine leaf-gold, or gold powder, the German powder, formed of the leaves called Dutch gold, is commonly used in this kind of gilding. The edges of books or paper are gilt in the manner directed under the article Book-binding and Gilding of books.

Gilding on Thread and Wire. See Gold-thread, and Gold-wire.
The colour of the gilding is heightened by a perfect dissipation of some mercury; remaining after the former operation. The gilt surface is then covered over with a false composition, consisting of equal quantities of nitre, sal ammoniac, green vitriol, and verdigris; finely powdered, and mixed up into a paste with water or urine; or, this is used instead of the gilding wax. The piece of metal thus covered is heated till the mixture smokes, and quenched in water or urine. This effect seems to be produced by the acid of nitre, which is diffused by the vitriolic acid of the alun, or other vitriolic salt, during the exposure to heat, acting upon any particles of copper which may happen to lie on the gilded surface. If the colour of the gilding be not sufficiently heightened by the first application, a succeeding one will complete the desired effect. Some artists think they give an additional lustre to their gilt work, by dipping it in a liquor prepared by boiling some yellow materials, as sulphur, orpiment, or turmeric. The only advantage of this operation is, that a part of the yellow matter remains in some of the hollows of the carved work, in which the gilding is apt to be more imperfect, and to which it gives a rich and solid appearance.

Copper, and the alloys formed by its combinations with zinc, are gilded much in the same manner as silver; but their affinity for mercury being considerably less than that of silver, it is not easy to produce a complete adhesion of the amalgam of gold to the burnished surface of these metals by the same means, and with the same evanesce as in the former case. Advantage is here taken of the nitric acid for facilitating the adhesion of the copper and mercury in the following manner. The piece of copper, e.g. a button, is first cleaned by steeping it in acid and subsequent washing, and it is then burnished in a lathe, or by other means; after this, it is dipped in a neutralized solution of nitrat of mercury, and in a few seconds, on account of the strong affinity of nitric acid for copper, the mercureial salt is decomposed. The copper takes the place of the mercury, and at the same time the mercury is deposited in the metallic plate, on the surface of the copper, covering it entirely, and strongly adhering to it. The gold amalgam is now applied, and the rest of the process is the same as that which has been already described. Thus a given quantity of gold may be made to cover a larger surface than in any other way of gilding on metals; five grains of gold completely gilding both the upper and under surfaces of a 144 copper buttons, each of them an inch in diameter. (Phil. Mag. ix. 20.)

Iron cannot be gilt by amalgamation, unless it be previously coated with copper, by dipping it in a solution of blue vitriol, or rubbed with the vitriol itself a little moistened. Iron may also receive a golden coat from a saturated solution of gold in aqua regia, mixed with spirit of wine; because the iron, having a greater affinity for the acid, precipitates the gold from it.

In the gilding of iron, or rather steel, by means of an amalgam, peculiar difficulties occur. If recourse be had to the method of simple burnishing down, the heat requisite for this purpose will, in many cases, bring the temper of the steel too low; on such occasions the mode already described of gilding copper is sometimes practiced: that is, the parts of the steel to be gilded are precipitated with nitrat of mercury by which they are covered with a slightly adhering coating of mercury; then the amalgam is applied, and the gilding is finished in the usual way. The objections to this process are, first, that a considerable heat is required, though inferior to that requisite for burnishing down; and, secondly, that, even with all possible care, the gilding is apt to be rough and to scale off.

A very considerable improvement on this method is to trace the figure of the gilding on the steel first of all with a brush charged with a strong solution of sulphated copper, in consequence of which a pretty thick plate of this metal is deposited on the steel to which it may be made to adhere with considerable firmness by means of the burnisher; thus the gilding is, in part, performed upon the copper.

A new method of gold gilding upon steel has lately been published (see Phil. Mag. xi. p. 144), possessing many advantages over the others, and capable of ultimately attaining a very high degree of perfection. This method depends upon the well-known fact, that if sulphuric ether and nitro-muriat of gold are mixed together, the ether will, by degrees, separate from the acid nearly the whole of the gold, and retain it for some time in solution in nearly a metallic state. If ether, thus charged with gold, is spread, by means of a pen or fine brush, on the surface of highly polished steel, the ether presently evaporates, leaving the gold behind in close contact with the steel, and the adhesion is considerably improved by the subsequent application of the burnisher. The deaerated, and especially the rapid volatility of ether, are objections; but may be obviated by using a spirit oil of turpentine instead of the ether, which has nearly the same efficacy in decomposing the nitro-muriat of gold, and is both cheaper, and not so very quickly evaporable.

On the subject of gilding by amalgamation, Dr. Lewis has the following remarks: "There are two principal inconveniences in this business; one, that the workmen are exposed to the fumes of the mercury, and generally, fomer or later, have their health greatly impaired by them; the other, the loss of the mercury; for though part of it is laid to be detained in the cavities made in the chimney for that purpose, yet the greatest part of it is lost. From some trials I have made, it appeared that both these inconveniences, particularly the first and most considerable one, might be in a good measure avoided, by means of a furnace of a due construction."

If the communication of a furnace with its chimney, instead of being over the fire, is made under the grate, the alispit door, or other apertures beneath the grate, closed, and the mouth of the furnace left open, the current of air, which otherwise would have entered beneath the surface of the water, passing through the grate to the chimney, carries with it completely both the vapour of the fuel, and the fumes of such matters as are placed upon it. The back part of the furnace should be raised a little higher above the fire than the fore-part, and an iron plate laid over it, that the air may enter only at the front, where the workman stands, who will be thus effectually secured from the fumes, and from being incommoded by the heat, and at the same time have full liberty of introducing, inspecting, and removing the work.

If such a furnace is made of strong forged (not milled) iron plate, it will be sufficiently durable. The upper end of the chimney may reach above a foot and a half higher than the level of the fire; over this is to be placed a larger tube, leaving an interval of an inch, or more, all round between it and the chimney, and reaching to the height of ten or twelve feet; the higher the better. The external air, passing up between the chimney and the outer pipe, prevents the latter from being much heated, so that the mercurial fumes will condense against its sides and not over-burn the chimney, which falling down to the bottom, is there caught in a hollow rim, formed by turning inwards a portion of the lower part, and conveyed by a pipe at one side into a proper receiver.

Another method is mentioned by authors of gilding upon metals, and also upon earthen-ware and glasses; which is, to fuse gold with regulus of antimony, to pulverize this mass,
and spread the powder upon the piece to be gilt; afterwards, to expose it to such a fire that the regular is evaporated while the gold remains fixed. But Dr. Lewis mentions the following incompatibilities to which this method is subject: the powder does not adhere to the piece, and cannot be equally spread; part of the gold is disintegrated along with the regular; glass is incandescent. For the evaporation of regulars of antimony; and copper is liable to be corroded by the regular, and to have its surface rendered uneven. Lewis’s Com. Phil. Techn. p. 77, &c. p. 81, 88. and 186. Macquart’s Dict. Chem. Eng. ed. 1777; and Aikin’s Dict. of Chemistry, art. Gilding.

Gilding: Cofîtes, is formed by a few folds of flannel, or a quantity of tow or wool, secured in a piece of wood of any size from eight to fourteen inches square by a light covering of leather, and fastened tight round the edges. The surface should be perfectly flat and even, and it is usually furnished with a handle. See Cushion.

Gilding Knife, a slip of the hollow Spanish cane, cut up to a smooth and sharp edge, with a good penknife; this cane knife cuts the gold leaf better than one of steel, as it is apt to stick to this hall. This knife may in all respects be the same as those used in painting, called “pallet knives”; the blade of which may be of six or six inches long, and somewhat more than half an inch in breadth, with a proportionable handle.

Gilding Pallet, a flat piece of wood, about three inches long, and an inch broad, covered with a piece of fine woollen cloth. By breathing upon this pallet, to moisten the cloth a little, and then clapping it gently down upon the gold leaf, this may be raised from the cushion, and conveyed to the work to be gilded.

Gilding Tjg., a tool made by fastening the long hairs of a squirrel’s tail between two cards, and used for taking up the gold leaf after it is cut, and applying it to the artie to be gilded.

Gilding Wax. See Gilding of Metals.

GILD, in Biography, a powerful lord in Mauritania, served the emperor Theodosius, in his brother’s revolt in 373, with so much fidelity, that he was raised to the chief command in Africa. During the reigns of Arcadius and Honorius he maintained a kind of independence, and ruled, at his pleasure, the provinces under his command, which he oppressed by every species of tyranny. In the divisions between the eastern and western empires, he was perfidious by the minster Eutropius to acknowledge Aecadius: for this he was condemned as a public enemy by the Roman senate. About the same time a deadly quarrel had arisen between Gildo and his younger brother Maesezel, in which the latter had taken refuge in the court of Honorius. Gildo, with a brutality that can never be sufficiently execrated, satisfied his disappointed vengeance upon the two children of his brother, whom he barbarously murdered. Maesezel, anxious for revenge, landed a body of troops in Africa, and encamped in the face of a numerous army of Moors collected by Gildo. Thrice, intimidated by the superior discipline of the Europeans, fled almost without a blow. Gildo escaped to the sea-shore, where he embarked for a foreign country, but, being driven back by adverse winds, he was seized by the inhabitants and thrown into a dungeon. There a voluntary death fared him from the cruel fate, which his conscience told him he might expect from his injured brother. The revolt of Gildo, says the historian, was considered as an event of so much importance to the empire, that the poet Claudian made the “Gildonic war” the subject of one of his pieces, to the honour of stilicho, who was the commander in it, against the subject of this article. Gibbon. Univ. Hist.

GILEAD, Balm. See JALSAM.

GILEAD, Bath. Balm of. See Dracoothphalam.

GILEAD, in Scripture Geography, mountains of Palestine, which lay E. of Jordan, and separated the lands of Ammon, Moab, Reuben, Gad, and Manasseh from Arabia Deserta. According to Esdras, Mount Gilad reached from Libanus northward to the kingdom of the Amorites, which was ceded to the tribe of Reuben; so that it must have extended above 70 leagues from north to south. This mountain, or rather chain of hills, was much celebrated for its excellent balm. Jer. vii. 22, xxvi. 11. &c. 8. Gen. xxxvi. 25. See Balsam.

Gilead derived its name from Giel-laad, 6. d. the heap of witnesses, in reference to the heap of stones raised as a monument of the covenant between Jacob and Laban. Gen. xxxi. 21.

GILES, in Biography, a learned Italian prelate, and cardinal of the sixteenth century, distinguished himself by the procris which he made in different branches of literature; and was appointed professor of philosophy, and then of theology, in his order, that of the hermits of Augsburg. In 1507, he was raised to the post of general of his order, and was employed by pope Julius II. to open the council assembled at the Lateran in the year 1512; and, in 1517, was sent legate into Germany by Leo X., on which occasion he was promoted to the office of cardinal. After this he was sent into Spain, and employed in many difficult negotiations. He was nominated bishop of several important sees at different periods, and also patriarch of Constantinople. He died at Rome in 1532, and left behind him a very high character for learning. He was, during his life, perpetually consulted in difficulties that occurred to the literati in the Oriental as well as the Latin and Greek languages. He was the author of many works that bear testimony to his reputation, among these are, Remarks on the early Chapters of the Book of Genesis, Commentaries on some of the Psalms of David; Dialogues, Epistles, Poems, &c. In the third volume of “Amphitrite Collectio veterum monumentorum,” many letters of this prelate and his correspondents are inserted, which contain numerous facts as well relating to his own history, as to that of the period in which he flourished. Moreri.

GILFORD, in Geography, a small port and market town of the county of Dublin, Ireland. The river Barrow runs through the centre of it, over which there is a very handsome bridge, highly ornamented with hewn stones, of twenty-two arches. It is a handsome neat town, and the country about it is highly improved; the houses are good, and chiefly inhabited by wealthy and reputable linen-drapers. The linen trade is carried on very extensively here, and the cloth is as remarkable for the fineness of its texture, as the river is for giving it an excellent bleach. Nothing can exceed in beauty the vale from Banbridge to Moyallen through Gilford, on the borders of the Barrow, for a continuance of six miles; the river in delightful meanders, the rising grounds surrounding it adorned with woods, and the bottoms variegated with bleach-greens, afford views the most beautiful and picturesque. Gilford is 62½ miles N. from Dublin, and 11 miles from Armagh.

GILGAL, in Scripture Geography, a celebrated place, W. of Jordan, where the Israelites encamped after their passage of this river, and where a considerable city, famous for many events, was afterwards built. It was about a league from Jordan and from Jericho.

GILGE, in Geography, a town of Prussia, in the circle of Sand...
G I L

Samland; 28 miles N.W. of Königsberg. — Also, a river of Prussia, which branches off from the Memel about 8 miles below Pillit, and runs into the Curische Haff, N. lat. 55° 10', E. long. 21° 24'.

GILGEN, St. a town of Austria, 10 miles N.W. of Efferding. — Also, a town of Sticla; 5 miles N.N.E. of Marburg.

GILGENAU, a town of Prussia, in Oberland; 15 miles N.N.W. of Soldau.

GILGENBURG, a town of Prussia, in Oberland; 60 miles E. of Culm. N. lat. 53° 17', E. long. 19° 57'.

GIGUL HAMMETHIN, a Hebrew phrase, literally signifying the rolling of the dead. To conceive the use of this expression it is to be observed, that the Jews have a tradition that, at the coming of the Messiah, no Israelite shall ride anywhere but in the Holy Land. What, then, shall become of all the faithful interred in other parts? Shall they perish, and remain in the state of death?

No, say the Jewish doctors; but God will dig them subterraneous canals, or cavities, through which they shall roll from their tombs to the Holy Land; and, when they are arrived there, God will blow on them, and raise them again.

This imaginary passage of the carcases, or ashes, of the Jews from their tombs to the Holy Land, by rolling underground, is what they call gigul hammethin, the rolling of the dead.

GILBERTIA, in Betony, named by Prof. Gmelin of Gottingen in his faulty edition of the Syll. Nat. of Linneaus, v. 2. 682, in honour of John Emanuel Gilbert, author of a Flora Lithunicana, printed in 1781, octavo, which was suppressed by authority of the government of Poland, on account of its alleged imperfections, but which was reprinted by its author afterwards at Lyons, where he also edited various works of Linneaus—Wild. Sp. Pl. v. 2. 531. (Quivilia; Cavan. Diff. 367. Juss. 264. Lamarck. Fl. t. 302.)—Clats and order, Decandria Monogynia. Nat. Ord. Tribulata, Linna. Melle, Juss.

Gen. Ch. Cal. Perianth inferior, of one leaf, bell-shaped, with four or five teeth, permanent. Cor. Petals four or five, ovate, obtuse. Nectary of one leaf, cup-shaped, shorter than the petals, embracing the germen, with ten marginal teeth. Stem. Filaments none; anthers eight or ten, ovate, erect, fleshy on the teeth of the nectary. Pist. Germen superior, globose, furrowed, shorter than the nectary; style simple, rising above the nectary; stigma globose, thick, furrowed. Peric. Capsule ovate, coriaceous, splitting half way down into four acute recurved valves, with longitudinal central partitions, separating it into four cells. Seeds one or two in each cell, ovate, smooth, affixed to the columella.

Eff. Ch. Calyx with four or five teeth. Petals four or five. Nectary cup-shaped, bearing the anthers on its margin. Capsule ovate, of four seeds. Seeds mostly follicled.

1. G. decandra. (Quivilia decandra; Cav. n. 531. t. 211.) — Leaves alternate, elliptic-lanceolate, undivided. Flowers five-cleft, decandrous, racemose. — Gathered by Commeron in the islands of Mauritius. An evergreen shrub, with numerous, alternate, zig-zag branches. Flowers alternate, flatly expanded, an inch or inch and half long, elliptic-lanceolate, entire, more or less acute, smooth, with one rib and many transverse veins, without stipulas. Flowers from five to nine in each axillary cluster, with downy flacks and calyx. Petals white, elliptical, thrice as long as the calyx, silky at the back, each about a quarter of an inch in length. Nectary white, about half as long. The habit of the shrub and aspect of the flowers, resemble a Limonia.

2. G. heterophylla. (Quivilia ovata; Cav. n. 532. t. 212; and Qu. heterophylla; n. 533 t. 213.) — Leaves ovate, undivided, fimbriated, or pinnatifid. Flowers four-cleft, oxtandrous, somewhat umbellate. — Gathered by Commeron in the islands of Bourbon and Mauritius. The leaves are rather smaller than in the last, and remarkable for their variety of shapes, being either ovate and blunt, or somewhat pointed, or either undivided, or more or less slightly waved or fimbriated, or deeply and accurately pinnatifid like an oak-leaf; all these varieties are found on the same specimen, nor can we separate Quivilia ovata, though all the leaves of one plant happened to be undivided, for the original specimens accord in every other particular. The flowers are much smaller than in the first species, and grow from two to four together in rather an umbel, than a cluster. Capule the size of a pea, pointed, slightly filty.

3. G. oppolifolia. (Quivilia oppolifolia; Cav. n. 534. t. 214.) — Leaves opposite, elliptical, undivided. Flowers somewhat umbellate. — Native of the Mauritius. Leaves broadly elliptical, obtuse, uniform, two inches long, all nearly opposite, as well as the branches. We have not seen the flowers. The fruit is rather umbellate than racemose. The size of a large pea, furrowed, depressed, clothed with shining tawny down, and opening into four or five parts on the same branch.

4. G. ruifolius. — Leaves alternate, ovate, pointed, undivided. Flowers somewhat racemose. — Gathered by Commeron in the Mauritius with the former, but not described by Cavanilles or Willdenow. The leaves are almost as large as the leaf, but more pointed, often oblique, and always alternate. Branches zig-zag. Clusters short, racemose, though appearing like little umbels, about the length of the footstalks, each of from three to five flowers, their flasks very slightly downy Petals filky at the back, a line long. Fruit of four cells, globose, four-furrowed, the size of a pea, clothed with short, dense, rigid, golden-coloured pubescence.

Commeron, the only botanist who has gathered any species of this genus, seems to have intended naming the decandrous ones Baretia, and the oxtandrous Ahabella, but they cannot be separated on any botanical principle whatever. All go by the name of Reade Queir among the French in the islands of Mauritius and Bourbon, whom Cavanilles contrived his barbarous name Quivilia. Of their qualities or uses nothing is mentioned. The names of Baretia and Ahabella were both intended to commemorate a young woman, who, being desirous of failing round the world, put on men's cloaths, and engaged herself as a sailor, her real sex being concealed from all on board, except Commeron, to whom she devoted herself, passing as his servant. At length, on the arrival of the ship at Otaheite, the more intelligent natives discovered the secret which had escaped the penetration of her companions, to their no small advantiment. Commeron contrived the word longifolia as a specific name, to express her fidelity. The Otaheitians, had they understood Latin, would probably have invented a better.

GILMER, or GILMUR, in Biography, is the last king of the Vandals in Africa, a descendant of Generic, succeeded to the throne of his depoted cousin Hilderic. The emperor Julianus acknowledged the cause of the dethroned soveraign, and determined for him the African provinces to the more to the Roman dominion. Belisarius was chosen to execute the design, who failed in 533. Zeno, the brother of Gilmer, was, at this time, engaged in the conquest of Sardinia, by which circumstance the force of the Vandals was divided, while a considerable party at home still adhered to the late king Hilderic. Gilmer assembled his troops to resist the invader, but being defeated with great slaughter he was glad to resign his crown to his brother, Zeno, and submit to the Romans.
fired to the Numidian deferts, having first exercised the tyrant's policy, by commanding the execution of Hilderic and his captive friends. Carthage submitted to the victorious Belfarius; but Gilius collected his scattered forces, and being joined by Zano, who had returned from Sardinia, a second action ensued, in which Zano lost his life, and Gilius again retreated. The loss of the African provinces succeeded, and the defeated king was forced to take refuge in the inaccessible mountains of the interior of Numidia. Even here, he was surrounded by a part of the Roman army under Pharus, and reduced to the utmost distress, which to him was peculiarly afflictive by its contrast with the luxury and effeminacy in which he had been accustomed to live. So detestable was his situation, that he is reported to have applied to Pharus for a lye, a sponge, and a loaf of bread; the first he said was to sooth his froward; the second to dry up his tears; the third he asked as an humble delicacy, of which he had not tasted for a long time. His diffidences at length obliged him to submit to the conqueror; he descended from the mountains, and followed Belfarius to Coisantinople, marching in the train of his triumph; on which occasion, he suffered neither tear nor sigh to escape, but frequently exclaimed, in the language of Solomon, "Vanity of vanities, all is vanity!" The emperor received him with respect, and dowered him with attention and kindness; he would have raised the fallen monarch to the dignity of patrician, could he have been persuaded to renounce the Asin doctrine, in which he had been educated. He was put in possession of a large estate in Gaetia, where, in the bosom of his family, he ended his days in peace. The extinction of the Vandal kingdom in the person of Gilius is to be dated from the year 554. Gibbon, Univer. Hist.

GILION, in Geography, an island in the East-Indian seas, about 36 miles in circumference. S. lat. 7° 6'. E. long. 114° 37'.

GILS, Sr., a town of France, in the department of the Seine, and chief place of a canton, in the district of Termonde. The place contains 3228, and the canton 16,770 inhabitants, on a territory of 95 kilometres, in six communes.

GILZTAIN, a town of the duchy of Carinthia; 10 miles E.N.E. of St. Veit.

GILL, in Agriculture, a term sometimes applied provincially to the pair of wheels and frame on which timber is conveyed.

GILL, John, in Biography, was born at Kettering, in Northamptonshire, in 1657, and devoiing, when very young, an uncommon capacity for learning, his father, who was a deister of the Baptist persuasion, sent him to a grammar-school in the neighbourhood, where he soon outstripped his companions in classical attainments. When he was but eleven years of age he had read several of the common school books in Latin, and made a considerable proficiency in the Greek. Owing to the more correct circumstances of his parents he was put to business, but he did not fail to improve his leisure moments by an attention to classical literature, so that by the time when he had attained his sixteenth year he had read all the Greek and Latin authors that had fallen in his way, and had diligently studied logic, rhetoric, moral and natural philosophy. He had likewise studied Hebrew so as to be able to read the Old Testament in the original with pleasure. In 1716 he was baptized, and soon after commenced preaching in private. He now removed to Hitcham Ferrers to prosecute a regular course of studies under Mr. Davis, a man of considerable learning, and pastor of a Baptist church in that place. His stay here was short, and after about a year he returned to his native town, and became assistant preacher to the congregation there; and in 1719 he received and accepted an invitation to become pastor of a Baptist congregation in Southwark. The duties of this situation he discharged with great fidelity and usefulness more than half a century. He died in 1771 in the seventy-fourth year of his age. His sentiments in religion were strictly Calvinistic; and his moral conduct was unimpeachable and truly exemplary. He was author of many works, particularly of "An Exposition of the Old and New Testament;" in nine volumes folio: "A body of Divinity," in three volumes 4to.; "A Supplement to Mr. Whiston's Essay towards restoring the true text of the Old Testament." In the year 1748, when he had published the third volume of his "Exposition of the New Testament," the degree of doctor of divinity was conferred upon him by the university of Aberdeen without his solicitation or knowledge; information of the fact was communicated to him by two of the learned professors, who declared that his diploma was presented to him, "on account of his great knowledge of the scriptures, of the oriental languages, and of Jewish antiquities, of his learned defence of the scriptures against Deists and infidels, and the reputation gained by his other works." Dr. Gill had, indeed, from the time of his settling in the metropolis, paid a most unwearied attention to the oriental languages; he had studied the writings of the fathers, ecclesiastical history, the accounts of the rites and customs of the eastern nations, all which he knew were adapted to enrich his stores of biblical learning, and to qualify him for the duties of his profession. Gen. Biog.

GILL, in Botany. See GLECHOMA.

GILL, in Geography, a township of America, in the state of Massachusetts and county of Hampshire, situated on the north bank of Connecticut river, 90 miles from Boston; containing 700 inhabitants.

GILL, or RAIK, is a name in several English counties for a brook, rivulet, or small stream of water.

GILL, a measure of ale or beer, is 1/4th of an ale pint = 8.9352 cubic English inches = 1.220779 wine gills = .0160624 cubic links.

GILL of wine, cider, oil, &c. = 1/4th of a wine pint = 7.21875 cubic English inches = .8191490 ale gills = .0145367 cubic links.

GILL, Scotch measure, = 1/4th of a maltshilling = 1/16th of a Scotch pint, the cubic content of which varies much in different places. See Scotch Pint.

GILLAROO, TROTL. See TROUT.

GILLIEN'S BAY, in Geography, a bay on the S. coast of the island of St. Christopher; two miles W. of Baffet-terre.

GILLE-LA VICOMTE, Sr., a town of France, in the department of the North Coast; six miles N.W. of Clermont.

GILLES-LES-BOUCHERIES, Sr., a town of France, in the department of the Gard, and chief place of a canton, in the district of Nimes; 12 miles S.E. of Nimes. The place contains 5356, and the canton 6577 inhabitants, on a territory of 180 kilometres, in two communes.

GILLES-SUR-VIC, Sr., a town of France, in the department of the Vienne, and chief place of a canton, in the district of Les Sables-d'Olonne; 13 miles N.N.W. of this latter town. The place contains 760, and the canton 12,535 inhabitants, on a territory of 4321 kilometres, in 17 communes.

GILLES, Peter, in Biography, was born at Albi in 1490, and became distinguished as a scholar and traveller. Having acquired an extensive knowledge of the learned languages...
GILLS, Lofi of the. See Folium branchiocranum.

GILLY-FLOWER, in Gardening, the common name of a fine fragrant flowery plant, common in gardens, &c. See DIANTHUS.

GILLY-FLOWER, Queen's. See HIPPEASTRUM.

GILLY-FLOWER, Stock. See CHEIRANTHUS.

GILLY-LOUGH, in Geography, a lake of Ireland, in the county of Sligo; and on the river by which its waters are discharged into the sea stands the town of Sligo. This lake exhibits a variety of charming prospects which bold hills, wooded lawns and large islands clothed with verdure and crowned with trees, united with a great extent of water, cannot fail to produce. Beaumont.

GILMANTOWN, a post-town of America, in Strafford county, New Hampshire, S.W. of lake Winnipigosee, and 52 miles N.W. of Portsmouth; incorporated in 1727, and containing 3752 inhabitants.

GILMARQUEY, a town of Hindooistan, in Douttabad; 13 miles N.E. of Nander.

GILOH, or GELO, in Scripture Geography, a town of Palestine, situated in the mountains of the tribe of Judah. John xi. 51.

GILIOLO, in Geography, one of the Moluccas islands, in the East-Indian ocean, of considerable extent, and in its rugged form resembling a large loaf of bread. Its length is about 250 British miles, and the breadth of each limb fathom above 40. The shores are low; but the interior rises to high peaks, perhaps of granite. This island is said to have been once governed by one sovereign, a chief from Mecca; but the fultans of Ternate and Tidore now seem to share in between them, the former poising the northern part with Mortay, Bakian, Motir, and some Celebesian islands, and part of Papua; while the fultan of Tidore holds the southern part with Myof, and some other isles. One of the chief towns is Tatamay, situated on a point or promontory of the eastern limb, faced with precipices, so as to be accessible only by ladders. Giglio abound with oxen, buffaloes, goats, deer, and wild hogs; but the sheep are few. The bread-fruit and fago-tree are common; and, in spite of the Dutch extermination, there are probably cloves and nutmegs. The natives are industrious, particularly in weaving; but their exertions are suppressed by Batavian jealousy. The equinocital rivers through the southern part of the island. E. long. 128°.

GILLOCH, in Argyleshire, Scotland, is a kind of gulf branching from Loch Fyne on its W. side, which is navigable for vessels to the entrance of the Crinan canal, through which they pass to Loch Crinan, and the Irvine frae. See CANAL.

GILPIN, BERNARD, in Biography, was born at Kentmire, in Westmorland, in the year 1517. He was defined by his parents for the church, and educated with that view. At sixteen years of age he was entered at Queen's college, Oxford, where he became distinguished for the diligence with which he applied to his academical studies. He was led to think for himself, and freely, by the writings of Erasmus; and as he determined to apply himself to the study of theology, he set about acquiring a thorough knowledge of the Greek and Hebrew languages, in order that he might investigate the scriptures in their original tongues. In 1539 he took his degree of B.A., and in 1541 that of M.A., and about the same time he was elected fellow of his college, and admitted into holy orders. Shortly after he was invited to become a member of cardinal Wolsey's new foundation at Chirll-church, which he accepted. Here he continued his former studies, but it does not appear that his course of reading had produced any doubts in his mind respecting the

GILORSI, an island on the coast of West Florida, divided from Dauphin island by a very narrow channel, through which a boat cannot pass without some difficulty; and between Gillori and the main land, on the west side of Mobile bay, there is a chain of small islands and oyster shells, through which is a passage of four feet, called 'Passe au Heron.'

GILLS, BRANCHLE, in Medical Science. See Fish, Organ of Respiration.
the popular religion, for he even entered into a vindication of the Catholic doctrines in a dispute with Hooper, afterwards bishop of Winchester. The dispute was however favourable to his improvement and candour, as it afforded him the opportunity of discovering that his own opinions were not so well supported by scripture as he imagined. Upon the accession of Edward VI., Peter Martyr was sent, under the patronage of that prince, to Oxford to read divinity lectures, a duty which he performed in a strain to which that university had been but little accustomed. He attacked many established doctrines, which had been long regarded as the truth, and the only truth. Gilpin was looked up to, as capable of defending the established doctrines in opposition to modern innovations, but his faith was shaken, and he chose to remain an unprejudiced spectator, ready to embrace whatever should appear the truth, after deliberately weighing the arguments which the discussion might produce. At length, however, he contented to enter the lists with Peter, and the dispute ended in the conviction of Gilpin that there were great corruptions in popery, and that there was need of a total reformation. He continued at Oxford till he was thirty-five, and took his bachelor's degree in divinity. In 1552 he was presented with a living in Durham, but before he went to reside there, he was appointed to preach before his majesty at Greenwich. The king was not present, but Gilpin's discourse was a serious and very hostile attack on the prevailing avarice and corruption of the age; he spared neither the court, clergy, magistrates, nor gentry. The freedom which he made use of at this time recommended him to the notice of many persons of the first rank, particularly of Sir William Cecil, afterwards lord Burleigh, who obtained for him a general licence for preaching. While Mr. Gilpin was in London, he frequently visited his uncle Tonitall, bishop of Durham, at that time a prisoner in the Tower, under a sentence of imprisonment for treason. When Mr. Gilpin was settled in the country, he felt many doubts how to proceed in the instruction of his people; he had not made up his own mind on many important doctrines, and therefore felt but ill qualified to teach others, or indeed to guard them from the prevailing errors. He accordingly resigned his living, and determined, at the advice of Tonitall, to spend some time abroad. He had now an opportunity of re-examining all his opinions; he began to have just notions of the doctrines of the reformed; few things in a clearer light, and felt a satisfaction in the change that he had made, to which he had hitherto been a stranger. On the death of king Edward, Tonitall was released and reinstated in his bishopric; he immediately offered his nephew a good living, which was respectfully refused on conscientious principles. He returned from the continent in the year 1556, and immediately visited bishop Tonitall, who received him with great friendship, and presented him with the archdeaconry of Durham, to which he annexed the living of Earlington. He now repaired to his parish, determined to do what good he was able in improving vice, and encouraging virtue. His zeal and fidelity in the good work of reformation made him many enemies, and the cry of heresy was continually founded against him, but by the skilful management of his uncle, the charge, though formally and publicly brought, was disdained. After this, he resigned his preferment in the church, and became domestic chaplain to the bishop. Mr. Gilpin did not remain long without a benefice, but was inducted to the living of Houghton-le-Spaw, and upon his arrival at the place, people crowded to him from all quarters, perceiving that he was a teacher very different from those to whom they had been accustomed, and by his truly affectionate treatment of them, he quickly gained their confidence, respect, and attachment. The bishop was still anxious for the advancement of his nephew, and presented to him a vacant prebend in the cathedral of Durham, which Mr. Gilpin modestly, but firmly declined, and told the prelate, "that by his bounty he had already more wealth than, he was afraid, he could give a good account of, and he hoped his lordship would rather bestow this prebend on one by whom it was more wanted." A fresh set of articles of impeachment were drawn up and presented against him, and he was again protected by his uncle, but from this period the bishop's favour to him manifestly declined, and he struck him out of his will. He was exceedingly concerned to have in any way offended so good a benefactor, but he could not compromise the matter; he was bound to satisfy his conscience, and Tonitall was vexed that he should carry his piety and zeal to what he thought an excess. The notice of Mr. Gilpin's enemies was not satisfied with the loss which he had experienced in his uncle's eleemosyne; they accused him before the savage Bonner, who, in the moment of his frantic zeal, declared that he would bring him to the stake in a fortnight. Gilpin refused to listen to the entreaties and intercessions of his friends by leaving the country, but was prepared to suffer for the truth, as he had been zealous in propagating it. He accordingly waited with great composure for the arrival of the bishop's messengers. He was apprehended, but fortunately, before he could reach London, an account of the Queen's death met them on the road, an event not more favourable to our worthy pastor, than important for the country at large. The meretricious ravage might now gastrify his teeth, but he could no longer inflict the venom of his malignity upon the unoffending reformers. Gilpin, thus almost miraculously delivered, returned to Houghton through crowds of people, who regarded him as a father, and who expressed their utmost joy, and offered up their thanks to Almighty God for his deliverance. Mr. Gilpin was soon nominated to the bishopric of Carlisle, which he declined, giving as a reason, that in this diocese he had many friends and acquaintance, of whom he did not think very highly, and that he must compound at many irregularities, or draw upon himself so much hatred as to prevent his usefulness. In 1561 he was offered the provostship of Queen's college, Oxford, which he like-wise declined; contenting himself with the living of Houghton, the duties of which he performed in the most exemplary manner. He employed much of his time in endeavouring to improve the minds of the younger part of his parish, suffering none to grow up in an ignorance of their duty, but urging all to intermix religion with labour, and amidst the cares of this life, to have a constant regard to the next. He was assiduous in preventing lawsuits among his parishioners, and his bail was frequently thronged with people of his own or neighbouring parishes, who came to settle their differences. He had a tender concern for all under affliction, and was a much readier vizient at the house of mourning than at the house of feasting. To strangers and travellers there was always a generous welcome at the house of Mr. Gilpin, and he could suit himself to persons of all ranks in life. Once he received an unexpected visit from lord Burleigh, and the reception of the noble stranger was so liberal, that his lordship was accustomed to say, that he could not have expected more at Lambeth. When the great statesman left his host, and had travelled about a mile from his residence, he turned his horse to take one more view of the place in which he had experienced so much content, and having kept his eye fixed some time, he exclaimed, "This is the enjoyment of life, indeed! Who can blame that man for not accepting a bishopric! What does he want, or what can he possess to make him greater or
or happier, or more useful to mankind." Mr. Gilpin's labours extended beyond his own parish; he every year visited divers neglected parishes in Northumberland, Yorkshire, Cheshire, Welfordmore, and Cumberland; and that his own flock might not suffer, he was at the expense of a constant assistant. In all his journeys he did not fail to visit the gaols and places of confinement; and by his labours and affectionate manner of behaviour, he is said to have reformed many abandoned persons in those abodes of human misery. He had set places and times for preaching in the different parts of the country, which were as regularly attended as the alms houses towns of a circuit. If he came to a place in which there was a church, he made use of it; if not, of barns, or any other large building, where great crowds of persons were sure to attend him, some for his instructions, more, perhaps, to partake of his bounty; but in his discourses he had a sort of enthusiastic warmth, which caused many to a sense of religion who had never thought of anything serious before. The dangers and fatigues attending this employment were, in his estimation, amply compensated by the advantages which he hoped would accrue from them to his un instructed fellow-creatures. He did not spare the rich; and in a discourse before the bishop of Durham, who had already conceived a prejudice against him, he spoke with so much freedom, that his bel friends dreaded the result; they solicited him for giving the prelate a handle against him, to which he replied, "If the discourse should do the good he intended it by, he was regardless of the consequences to himself." He then waited on the prelate, who said, "Sir, I propose to wait upon you home myself." When they arrived at the rectory, and entered the house, the bishop turned suddenly round, and grasped him eagerly by the hand, saying, "Father Gilpin, I know you are litter to be bishop of Durham, than I am to be patron of this church of yours. I ask forgiveness for past injuries. Forgive me, father, I know you have enemies, but while I live bishop of Durham, none of them shall cause you any further trouble." Upon queen Elizabeth's recommending the establishment of free-schools, Mr. Gilpin undertook to build and endow one, a design which he immediately put in execution. This school was no sooner opened than it began to flourish; and there was so great a report of young people to it, that in a little time the town was scarcely able to accommodate them. He procured able masters from Oxford, and took every method to encourage those of his pupils who were most diligent in their studies. In the latter part of his life Mr. Gilpin went through his various duties with much difficulty; his health was impaired, and his constitution broken down by the great fatigue which he had undergone for many years. In addition to his infirmities, he met with an accident which had nearly proved fatal to him, and from the effects of which he never perfectly recovered. As he was crossing the market-place at Durham, he was thrown down, and almost trampled to death by an ox. After a long and tedious remission, he was able to get out of bed, and lived as long as he lived. He died in 1783, in the 66th year of his age. Such were the life and labours of Bernard Gilpin, who, for his exemplary piety, laborious virtue, and unbounded benevolence, deserves to have his name transmitted to posterity with respect and reverence, and who obtained, and mellowed deservedly among his contemporaries, the title of the Northern Apostle. By his unwearied application he had amassed a great stock of knowledge, and was indeed ignorant of no part of learning at that time in fashion. He had given more than common attention to the study of the dead languages, to hist ory and divinity; he is said to have excelled in poetry, but he expended little time in the pursuit of any thing that was foreign to his profession. His temper was naturally warm, but, by degrees, he succeeded in obtaining an entire command of himself. His disposition was serious, yet, among his particular friends, he was cheerful and even facetious. His severity had no other object but himself: to others he was mild, candid, and indulgent. Biog. Brit.

GILPIN, SAWREY, who lately practised horse painting with so much success, was born at Carlisle in 1753, from whence, after having acquired some relish for the art from his father, who was a captain in the army, came to London, and was articled to a ship-painter. His first interesting works were composed of some market groups which struck his eye from his window. Soon after he went to Newmarket, being encouraged by the late William, duke of Cumberland, who executed many compositions which might have vied with Hogarth in point of character. In the duke's flnd he acquired that knowledge of the horse which he has displayed with such superior spirit and beauty, and when we fee with what felicity he applied it to the higher departments of the art, to historic compositions in the triumph of Camillus, the election of Darius, the story of Phoebus, we must lament that such talents should have been drawn aside to the meaner employment of horse-portrait-painting, which occupied too much of his valuable life. His drawings of animals, in pencil and water-colours, display a degree of taste and skill seldom attained. As a man he was equally esteemed for probity of character and simplicity of manner, and, as a member of the Royal Academy, he added honour to the institution. Tufnell's Pilkinson.

GILSON, in Geography, a township of America, in Cheshire county, New Hampshire, containing 484 inhabitants; situated on the E. side of Ahaulet river, and joining Keene on the south.

GILT, in Rural Economy, a term signifying a young female pig, whether in an open or penned sty.

GILT-HEAD, in Ichthyology, See Aurelia and Sparus.

GIMAR, in Geography, a town of the island of Cuba; 6 miles E. of Havana.

GIMBLET, in Carpentry, a small boring tool, which enters the wood with a screw; the part above is cylindrical, both inside and out; its use is to make a way for nails, in order to drive more easily, or to prevent the wood from splitting.

GIMBLETING, in Sea-Language, is applied to the anchor, to denote the action of turning it round by the stock, so that the motion of the stock appears similar to that of the handle of a gimlet, when it is employed to turn the wire.

GIMBOLS, denote the brass-rings by which the steering is suspended in its box that usually stands in the blossom.

GIMIESCH, in Geography, a town and castle of Hungary; 10 miles W. of Bukans.

GIMIGLIANO, a town of Naples, in Calabria Ultra; 3 miles E. of Nacifara.

GIMMER, a town of Africa, in Darfur; 40 miles N.N.W. of Coblé.

GIMMER HOG, in Rural Economy, a name applied to a female sheep of the first year.

GIMMER LAMB, a term applied to a female lamb.

GIMONT, in Geography, a town of France, in the department of the Gers, and chief place of a canton, in the district of Auch; 12 miles E. of Auch. The place contains 2366, and the canton 8413 inhabitants, on a territory of 230 square kilometres, in 13 communes.
GIN

GINZO, in Scripture Geography, a city of Judah, which the Philistines took from Ahaz. 2 Chron. xxviii. 18.

GIN, in Geography, a town of China, of the third rank, in P'otcheh; 10 miles S.E. of Chuseo.

Gin, formed probably by corruption from engin, in Artillery and Mechanics, is a machine for raising great weights, composed of three long legs, two of which are kept at a proper distance by means of two iron or wooden bars fixed to one of the legs by means of a bolt at one end, and by the other end to the other leg with a bolt and key, so that it may be put on or off at pleasure. At three feet from the bottom is a roller moving in sheets, that are fastened to these poles by two iron hands and two iron bolts. The three legs of this machine are joined together with an iron bolt, about which they move; to this bolt is fixed an iron half ring to hook on the windlass, containing two brafs pulleys. When the gin stands upright, and its legs are at a proper distance, one end of the cable is fixed to the dolphin of a gun or mortar with another windlass, containing likewise two brafs pulleys, and the other pulses through the pulleys and round the roller, which is turned round by means of handspikes passing through the holes in the ends of the roller; while a man holds the cable tight, the gin is raised to such a height as to admit a carriage being put under it.

The gin is used in loading a timber-carriage with timber; it consists of an acute triangular frame, in the lower part of which is a roll or windlass: at the apex is a set of pulleys, and a hole to receive the top of a strong pole, which is set up opposite the triangular frame, which by this means forms a sort of tripod (or triangle, as it is commonly called among workmen) standing across a tree to be raised and loaded: the gin-rod is then recved through a movable block of pulleys, fastened by a chain to the tree, through that in the top of the gin and round the roll; and then, by means of hand-spikes or levers used to the roll, the tree is drawn up to a sufficient height for the timber-carriage to be paffed under it. Long trees are raised at one end first, and then of the wheels of the timber-carriage are paffed under them; when the other ends are raised in like manner, and the other two wheels (which are made to separate for this purpose) are paffed under them, and then are joined to the other wheels by the long adjustable pole with which the carriage is furnished. See Timber-Carriage.

An erect axis or drum, turned by the force of horses walking in circles, and used for raising coal and other weights, is also called a gin; the buckets being attached to the opposite ends of a rope, which passes round the drum, and which is drawn by means of its adhesion to the drum, One of the bucket's descends empty, while the other is drawn up full; and when the motions of the buckets are to be changed, the horses are turned, or the wheels are made to impel the axis in a contrary direction, when any other moving power is employed.

For shallow mines or shafts, these are worked by horses, and are called horse-gins; and in deep mines thus worked, it is usual to have two levers projecting from the shaft, to as to employ two horses, and even four in some cases, with a bay to each pair, or single horse, to stop and turn them, as to draw from the other side of the lever, as often as a curve or basket arrives at the top of the shaft. See the article Coal.

The increasing depth of the pits, and demand for coals at N'wesle, occasioned Mr. Smeaton, the engineer, to apply to the proprietor of Long Benton colliery, to contrive them a mode of drawing more expeditiously, and larger baskets of coals than the horse-gins then in use, and he accordingly erected for them a water-gin, the supply for which was raised by the steam-engines employed at the pits. Since the above period, small steam-engines, called winneys in many places, have been applied to the winding of coals, and other minerals, and have already superseeded all other modes of drawing at the large collieries; these several modes of drawing or winding we shall describe particularly in the article Winding-Engine.

GIN, in Mining, horse-gin, or coal-gin, is a machine used for drawing buckets or curves of earth or minerals up a mine-shaft or tunnel-pipe of a canal; it consists of a large vertical drum or barrel, on which a rope winds, which is conducted to pulleys over the shaft; and usuafly as one bucket or curve descends another ascends. See the preceding article and Mine Winding Engine.

GIN-driver, is the man or boy who attends the gin-horse and turns him, when a full bucket or curve has arrived at the top of the mine-shaft.

GINAIRI, in Geography, a town of Africa, in Kumbo.

GINANNIA, in Botany, so called by Scopoli and Schreber in memory of Count Joseph Giannelli, a native of Ravenna, whose pithy humorous works in Italian, comprising two folio volumes, with about 90 plates, were published in Venice in 1755. They chiefly relate to the marine productions of the Adriatic, as corals, sea urchins, &c. but are perhaps not too severally charactarized by Linnaeus, in a letter to Gerard, as of no manner of use." The author was recommended to the study of natural history by his friend Valpieri, as a cure for hypochondriac disorders, but this is hardly a sufficient reason for the publication of his book. Haller appears to have seen the first volume only. Schreb. 271. Mart. Mill. Dict. v. 2. (Paloue; Aubl. Guian. 365. t. 141. Paloue; Jull. 351. Brownea pauciflora; Wild. Sp. Pl. v. 3. 716.) GIN

GINGEE, in Geography, a town and fortress of Hindoe-stan, in the Carnatic, once the capital of a kingdom of the same name, situated on a mountain and defended by three coves: 33 geographical miles from Pondicherry and 23 from Trinomally. N. lat. 12° 16'. E. long. 79° 36'.

GINGER, in Botany. See Amonum.

Gingsen, Zingiber, in the Materia Medica, &c. Ginger is either black or white. In Jamaica this plant attains its full height and flowers about August or September, and fades about the close of the year. When the stalks are entirely withered, the roots are in a proper state for digging, which is generally performed in the months of January and February. After being dug, they are picked, cleansed, and gradually feethed, or scalded in boiling water; they are then spread out, and exposed every day to the sun till sufficiently dried; and after being divided into parcels of about ten, weight each, they are packed in bags for the market: this is called the "black ginger." "White ginger" is the root of the same plant, but instead of scalding the roots, by which they acquire the dark appearance of the former, each root is picked, scraped, separately washed, and afterwards dried with great care: by this operation more than double expence is incurred, and the market price is proportionably greater. 

This warm aromatic root appears, says Lewis, to be much less liable to the corruption than might be expected from the penetrating heat and pungency of its taffe, and the fixedness of its active principles. But Dr. Cullen is of opinion, that there is no real foundation for this remark. It gives part of its virtue to water, and the whole to rectified spirit, tinging the latter of a deep, and the former of a pale yellow colour. This latter property it possesses in so considerable a degree, that if a watery infusion of this root be boiled down to a thick consistence, dissolved in a large quantity of water, and strongly boiled down again, the heat and pungency of the root remain, but with little or nothing of its taffe. It is used medically as an antispasmodic and carminative. The cases in which it is more immediately serviceable are flatulent colics, debility and laxity of the bowels and intestines, and in torpid and phlegmatic confluxions to excite brisker vascular action. It is seldom given but in combination with other ingredients. In the Pharmacopoeia it is directed to be administered under the form of a syrup and tincture; it is also preferred as a condiment, and as a subsidary ingredient in many compositions. The syrup of ginger is prepared by macerating two ounces of the ginger root sliced in a pint of boiling water for twenty-four hours, and then draining, and adding two pounds of refined sugar, as in other syrups. The tincture of ginger is formed by macerating two ounces of ginger root sliced in two pints of proof spirit for 14 days, and then draining the liquor. The dietetic qualities and uses of ginger are well known; and it is employed under various forms. It is not uncommon to candy the root, when green, with sugar and honey; having first steeped it some time in water, to take away part of its acrimony, and to dispoze it to let go the outer skin. This candied ginger, brought from abroad, is moderately aromatic. They also make a marmalade of it, and dry cakes.

The northern people make great use of this confection, as holding it sovereign against the feverry. The Indians eat the root, when green, by way of fallad, first chopping it small, mixing it with other herbs, and seasoning it with oil and vinegar.

Ginger may be preferred by washing it, and laying it to steep for ten or twelve days in white wine, and water, stirring them every day; then boil a pound of roots with two quarts of white wine, and about a pint of lemon juice, for a quarter of an hour; then add two pounds and a half of fine sugar, and boil it to a syrup, semmising it as it rifes; let it by till the next day in a glazed pan; then boil it for half an hour, and repeat this boiling at the same interval till the ginger is clear. Put it into glafes, and cover them with paper, and it will afford a fine fwerment for the winter. A wine is made of ginger, which is a pleasant and palatable beverage.

GINGER, in Geography, one of the smaller Virgin isles in the West Indies; 10 miles S. W. of Virgin Gorda. N. lat. 18° 5'. W. long. 62° 53'.—Alfo, a town in Egypt, on the E. branch of the Nile, opposite to Mansorah.

Gingerbread, a richer kind of bread; the flavour and taffe of which are heightened and improved with spices, and particularly ginger; whence the name.

There are various forms and preparations of gingerbread: we shall content ourselves with the following receipt, which is well recommended.

Into a pound of almonds, blanched and pounded, grate a penny white loaf; sift and beat them together; to the mixture add an ounce of ginger, diced fine; and liquorice, and aniseed in powder, of each a quarter of an ounce; pour in two or three spoonfuls of rofe-water, and make the whole into a paffe, with half a pound of sugar; mould and roll it, print it, and dry it in a flove. Others make it of treacle, citron, lemon, and orange-peel, with candied ginger, coriander, and caraway-seeds, mixed up with as much flour as will make it into a paffe.

GINGERNO, or Lendero, in Geography, a kingdom of Africa, situated on the S.W. of Abyssinia. N. lat. 6° E. long. 12°.

GINGHAM, a town on the north coast of Sumatra. N. lat. 5° 10'; E. long. 96° 10'.

GINGIDUM, in Botany, a name adopted by Forster, Nov. Gen. t. 21, for an umbelliferous plant, found on the hills of New Zealand, which he himself suspected to be Liguicium, and which has been so confidered by following botanists. It is Liguicium Gongidum of Willd. Sp. Pl. v. 1. 1428. See Ligusticum.

The 357868 of Diofcorides appears to be likewife of this natural order, but the species can scarcely be determined with certainty. Dr. Sibthorp fupposed it might be Daucus Gongidum of Linneus, merely from the coincidence of the names, for it agrees better with D. Pisonaga, Anini Pisonaga, Prod. Pl. Grec. n. 652; not that any thing can be gathered, from the description of Diofcorides, to quote him, in fuch a cafe, with any propriety. He fays it is "by fome called Lepidium, and grows very abundantly in Cilicia (now Caramania) and Syria. It is a little herb, like wild carrot, but more flender and more bitter, with a whifh and bitterfl fcript." This will be found to accord equally well with many plants of those countries. Matthiolus, indeed, as it seems, either by a Latin verion, or by the opinion of thofe who take the 357868 of Diofcorides for the Pajmnaca, or Parphn, whereas it is evidentally by the description a Daucus, or Carrot, took for the 357868 a Syrian plant, firft defcribed by himfelf, and which indeed is smaller and flenderer than the Parphn, though larger and broader than the Carrot. Hence he confiders thofe who have taken the Chervil, Scandia Cerfeedium, for the herb in quefion, though they really appear to be more in the right than himfelf. However this may be, the plant of Matthiolus is the Daucus Gongidum of Linneus, as well as his D. Judiculis.

LIX
GIN

Linnæus having in the first instance defined it from the wooden cut of Matthiolus, and in the latter described it from a specimen in the Upala garden. The history of this mistake is given at length, by the writer of the present article in the Transactions of the Linnean Society, v. 4. 131.

GINGO, in Mining, meaning or flaming, signifies the lining of a mine-shaft with rocks or bricks for its support. Shallow shafts, where the measures are adapted to stand, are sunk first, and the lining of them with stone, or ginning, is begun from the bottom and carried up at once to the top; but in sinking deep shafts, after a great depth is done at once as the nature of the measures will permit, a further depth is sunk in the bottom, beginning with the shaft, and the shaft of that diminished diameter for 18 or 18 inches, according to the soundness of the measures in that place, when it is gradually enlarged to the full size as the sinking proceeds, and sunk from yards lower, until upon reaching a bed of stone, or as great a depth as is judged safe, according to the nature of the sinking, the ginning begins, and carried up to where the diminishing of the shafts begins; when the same is picked out to admit the necessary courses of stone or bricks, as high as is judged safe, then the removal of the remainder of the support for the first ginning is commenced, by cutting out a piece, wide enough to admit of one or two courses of stone bricks, being built up like a pier, which is firmly keyed or underpinned to the ginning above by means of tile-hulls or thin plates if necessary: a similar piece is then cut out and underpinned on the opposite side of the shaft, and then another between each of these, and so on, until the ginning of the lower and upper part is entirely joined and all round the shafts.

The shaft is then deepened within the last ginning and fired, first narrow and then of its proper width, as far as is judged safe, when a new ginning is begun, and carried up, and joined to that previously finished, as above described. Solid stone-hulls or permanent rocks, which are met with in sinking, are not ginned, but the shaft is sunk through such rocks, of the same diameter as the inside of the ginning, which stands upon their top and is pinned up beneath the bottoms.

GINCO, or GINGROS, in Geography, a town of the Valais; 10 miles W. of Aigle.

GINOA, in Antiquity, a kind of dance used at funerals.

GINGRA, in Antiquity, a kind of dance used at funerals.

GINGRAS, or GINGRAS, in the Ancient Music, a dance performed to the sound of flutes.

GINGRIMA, in Antiquity, a name given to a small kind of flute used for beginners.

GINGRAS, and GINGRAS, Musical Instruments of the Ancients. The Phrygians, according to Athenaeus, had flutes of only a palm in length, which produced a sweet, but plaintive sound. The Carians made use of them in their funerals; perhaps by Carus the Phrygians are meant here, as in Cora and Bathylides. These flutes derive their name from the Incantations of the Phrygians at the death of Adonis, whom they called GINGRAS. Encycl. Suppl.

GINHEIM, in Geography, a town of Germany, in the county of Hanau, Munzenberg; 11 miles W. of Hanau.

GIN-HOA, a town of China, of the third rank, in Quang-tong; 22 miles N. of Chao-tehuen.

GIN-VOAL, a town of China, of the third rank, in Se-tchenen; 32 miles S. of Tehel-leou.

GINGPALIAGARUM, a town of Hindostan; 25 miles E. of Calicute.

GINKGO, in Botany, Linn. Mant. 531. ramp. Amoen. 811. t. 812.—The Japanese name of a tree, as large as a Walnut-tree, with leaves resembling an Adiantum. The male flowers are in catkins, the female solitary, on flanks, producing a drupa, whose not reimbs that of a Pteridium, with a white, somewhat astringent, kernel, which is eaten in Japan, being supposed to afford digestion. This tree is hardy in our gardens, sometimes bearing catkins, but no fruit. The late Mr. Gordon sent a living plant to Linnæus, who mentions it in an appendix by the above appellation, not being able either to define the genus, or to name it properly, till he knew the fructification. Mr. Salicinus having with great advantage determined its essential characters, it was dedicated to him, by Dr. Smith in the Trans. of the Linn. Soc. v. 3. 520 and his botanical merits will ever justify the appellation. See Sarracen.

GIN-KIA-CENTZE, in Geography, a town of Chinese Tartary. N. lat. 41° 45'. E. long. 125° 29'.

GIN-KIEOU, a town of China, of the third rank, in Pech-ehi; 17 miles N. of Hsok-ien.

GINLIA, a town of Naples, in Abruzzo Ultra; 12 miles N. E. of Teramo.

GINNAI, Francis, in Biography, was born at Ravelia in 1716. He was educated in his father's house, and at the age of fourteen was placed at Parma, as page to the duke of Antony Farraffe. The duties of this situation did not prevent him from pursuing his studies, and he was particularly attentive to natural history, under the direction of his uncle Joseph Ginnari, who was well known for his researches into marine productions. He devoted himself to a retired and studious life, and was the inventor of divers agricultural instruments and other machines, useful as well as curious. His writings, which relate to almost all the departments of natural history, obtained for him an admission into the learned societies of London, Paris, Bern, and Perugia, and he held a literary correspondence with many of the most eminent natural philosophers of the age. In private life he was courteous, modest, and benevolent; and he was particularly observant of the duties of religion. He died at the age of forty. His principal work was a treatise on the diseases of corse, with observations on the caudles and remedies. He published an account of the natural productions in the museum of Ravelia, and he greatly interceded himself in the institution of the society of that town. He left behind him some manuscripts, among which was a "Natural and Civil History of the Pine Forests of Ravelia." Gen Bug.

GINNIS, in Geography, a town of Turkish Armenia; 21 miles W. N. W. of Erzerum.

GINNISH, a town of Hindoostan, in Guzerat; 56 miles S. of Ambedabad.

GINOYAN, a town on the E. coast of the island of Leyta. N. lat. 10° 27'. E. long. 123° 10'.

GIN

Gen. Ch. Col. Perianth inferior, of one leaf: tube bell-shaped; limb fix-cleft; segments lanceolate, spreading, coloured, permanent. Cor. Petals fix, roundish, spreading, longer than the calyx, with long claws inserted into the neck of the calyx. Stam. Filaments 12, awl-shaped, the length of the calyx and inserted into it; anthers kidney-shaped. Pet. Germin roundish, depressed; style awl-shaped, as long as the corolla, not deciduous; stigma obtuse. Pers. Capsule roundish, depressed, thinning, coloured, with about four furrows and four valves, of one cell, gaping at the top. Seed numerous; receptacle roundish, large. Eff. Ch. Calyx fix-cleft. Petals fix. Capsule of one cell, with four valves, coloured, with many seeds.

1. G. americana. Linna. Sp. Pl. 652. Jacq. Amer. 91.—Native of the rocky and gravelly banks of rivers in the island of Cuba. This beautiful shrub has much of the aspect of a myrtle, and bears its flowers and ripe fruit in December. It rises erect to the height of three or four feet, and its branches are round, smooth, and woody. Leaves lanceolate, entire, smooth, spreading, on short footstalks, opposite; an inch and half long, numerous. Stalks single-flowered, slender, axillar and terminal. Flowers inodorous, with a reddish calyx, blue corolla, and dark-red capsule, containing a most beautiful berry. Seeds whitish.

The capsule remains entire for some time after the seed is fixed, together with the calyx and part of the style. The natives call this plant Roja del rey, or river Rose.—It has never been introduced into the gardens of Europe, nor have we ever seen a dried specimen.

GIN-PIN, in Geography, a town of China, of the third rank, in Chin-chang; 17 miles N. of Tong-chang.

GIN-SENG, or Nin-seng, in Botany. See Pinax.

GIN-seg, in the materia medica, is one of the principal medicines of the Chinese and Tartars; and their most eminent physicians have written many volumes concerning its virtues.

It is known among them by divers other names, expelling only spirit, or the pure spirit of the earth; the plant gives immortality, &c. It makes, in effect, the whole materia medica for the people of condition, but is too precious for the populace.

All the writers of the Chinese affairs make mention of the gin-feng: as Martinus, in his Atlas; F. Kircher in his China Illustrata; F. Tuchard, in his Voyages; and F. Le Comte, in his Memoirs.

And yet we know but very little of this plant before F. Jartout, a Jesuit, and missionary in China; who, being employed, by order of the emperor, in making a map of Tartary, in the year 1729, had an opportunity of seeing it growing in a village about four leagues from the kingdom of Corea, inhabited by Tartars, called Cola-Tutza.

That father took this opportunity to make a draught of the plant, and give an accurate description of it, with its virtues and manner of preparing it. The gin-feng, according to his description and drawing, has a white root, somewhat knotty, about three inches of the stem, and which grows tapering to the end; at few inches from the head it generally parts into two branches, which gives it some resemblance of a man, whose thighs the branches represent; and it is hence it takes the denomination gin-feng, which signifies a figure of a man.

It is hard to say, why the Chinese should call it gin-feng, a word which signifies figure or representation of a man: neither that father, nor any he enquiring of, could ever find, that it bore more resemblance to the figure of a man than is ordi-

narily seen among other roots. The Tartars, with more reason, call it oroba, that is, the first of plants. It grows to the height of about eighteen inches.

The plant dies away every year; the number of its years may be known by the number of stalks it has shot forth, of which there always remains some mark.

Those who gather the gin-feng prefer only the root; and all they can get of it in ten or fifteen days time they bury together, in some place under ground; then they take care to wash it well, and scour it with a brush; then dip it in cold water, and prepare it in the furnace of a fort of yellow millot, which gives it part of its colour. The millot is put in a vessel, with a little water, and boiled over a gentle fire; the roots are laid over the vessel, upon small transverse pieces of wood, being first covered with a linen cloth, or some other vessel placed over them.

They may also be dried in the sun, or by the fire; but then, though they retain their virtue well enough, they have not that yellow colour which the Chinese so much admire. When the roots are dried, they must be kept close in some very dry place; otherwise they are in danger of corrupting, or of being eaten by worms.

As to the place where this root grows, it is between the thirty-ninth and forty-seventh degree of north latitude, and between the tenth and twentieth degree of east longitude, reckoning from the meridian of Pekin. Here is found a long tract of mountains, which thick forests, that cover and encompass them, render almost impassable; it is upon the declivities of these mountains, and in these thick forests, upon the banks of torrents, or about the roots of trees, and amidst a thousand other different sorts of plants, that the gin-feng is found; it is not to be met with in plains, valleys, marshes, the bottoms of rivulets, or in places too exposed and open.

If the forest takes fire and be consumed, this plant does not appear till two or three years after; it also lies hid from the sun as much as possible, which favors that heat is an enemy to it.

The places where the gin-feng grows are, on every side, separated from the province of Quang-tong by a barrier of wooden flakes, which encompases this whole province, and about which guards continually patrol, to hinder the Chinese from going out and looking after this root.

Yet, however vigilant they are, greediness after gain incites the Chinese to lurk about privately in these deserts, sometimes to the number of two or three thousand, at the hazard of losing their liberty, and all the fruits of their labour, if they are taken either as they go out of or come into the province.

The emperor, in order that the Tartars should reap all the advantage that is to be made of this plant, rather than the Chinese, gave orders, in 1759, to ten thousand Tartars, to go and gather all they could find of the gin-feng, upon condition that each person should give him two ounces of the herb, and that the reil should be paid for, weight for weight, in pure silver.

It was computed, that, by this means, the emperor would get this year above twenty thousand Chinese pounds of it, which would not cost him above one-fourth part of its value.

We met, by chance, says F. Jartout, with some of these Tartars, in the midst of their frightful deserts; and their mandarins, who were not far out of the way, came one after another, and offered us oxen for our subsistence, according to the commands they had received from the emperor.

L. 12
This army of herbalists observed the following order: after they had divided a certain tract of land among their several companies, each company, to the number of a hundred persons, spread itself out in a right line, to a certain fixed place, every ten of them keeping at a distance from the rest. Then they searched carefully for the plant, going on leisurely in the same order; and in this manner, in a certain number of days, they run over the whole space of ground appointed them. When the time was expired, the mandarins, who were encamped in their tents in such places as were proper for the sublimation of their horses, sent to view each troop, to give them fresh orders, and to inform themselves if their number was complete.

If any one of them was wanting, as it often happened, either by wandering out of the way, or being attacked by wild beasts, they always looked for him a day or two, and then returned again to their labour as before.

Gin-feng was formerly supposed to grow only in Chinese Tartary, affecting mountainous situations, shaded by clove woods, but it has now been long known that this plant is also a native of North America, whence M. Sarrafin transmitted specimens of it to Paris in the year 1754; and the gin-feng since discovered in Canada, Pennsylvania, and Virginia, by Lafitau, Kalm, Bartram, and others, has been found to correspond exactly with the Tartarian species, and its roots are now regularly purchased by the Chinese, who consider them to be the same with those of eastern growth, which are known to undergo a certain preparation above-mentioned, by which they assume a somewhats different appearance. This plant was first introduced into England in 1749 by that indolent naturalist, Peter Collinson. The dried root of gin-feng, as it is imported here, is scarcely as thick as the little finger, about three or four inches long, frequently forked, transversely wrinkled, of a horn color, and both internally and externally of a yellowish white colour. To the taste, says Lewis (Med. Med.), it discovers a mucilaginous sweetness, approaching to that of liquorice, accompanied with some degree of bitterness, and a slight aromatic warmth, with little or no smell. It is far sweeter, and of a more grateful smell, than the roots of fennel, to which it has by some been supposed similar; and differs likewise remarkably from those roots, in the nature and pharmaceutical properties of its active principles; the sweet matter of the gin-feng being procured entire in the watery as well as the spirittuous extract, whereas that of fennel-roots is destroyed or dissolved in the infusipation of the watery extract. The slight aromatic impregmentation of the gin-feng is likewise in good measure retained in the watery extract, and perfectly in the spirittuous.

The gin-feng, we have observed, is an ingredient in most of the medicines which the Chinese physicians prescribe to the better sort of patients: they affirm, that it is a sovereign remedy for all weakneces occasioned by excessive fatigues, either of body or mind; that it attenuates and carries off pititious humours; cures weakneses of the lungs and the pleurisy; stoppeth vomitings; strengthens the stomach, and helps the appetite; disperseth fumes or vapours; fortifies the breath; is a remedy for short and weak breathing; strengthens the vital spirits, and is good against dizziness of the head and dimness of sight; and that it prolongs life to extreme old age. Nobody can imagine, that the Chinese and Tartars would set so high a value upon this root, if it did not constantly produce a good effect: those that are in health often make use of it to render themselves more vigorous and strong. And I am persuaded, adds father Jartoux, above-mentioned, it would prove an excellent medicine in the hands of any European who understands pharmacy, if he had but a sufficient quantity of it to make such trials as are necessary to examine the nature of it chemically, and to apply it in a proper quantity, according to the nature of the distemper for which it may be beneficial.

It is certain, that it sublimes, increases the motion of, and warms the blood, that it helps digestion, and invigorates in a very sensible manner.

After I had designed the root, he goes on, I observed the state of my pulse, and then took half of a root, raw as it was, and unprepared; in an hour after I found my pulse much fuller and quicker; I had an appetite, and perceived myself much more vigorous, and could bear labour better and easier than before. Four days after, finding myself so fatigued and weary, that I could scarcely sit on horseback, a mandarin, who was in company with us, perceiving it, gave me one of these roots: I took half of it immediately, and an hour after I was not in the least sensible of any weariness. I have often made use of it since, and always with the same success. I have observed also, that the green leaves, and especially the fibrous part of them, chewed, would produce nearly the same effect. The Tartars often bring people the leaves of gin-feng instead of tea: and always find myself so well afterwards, that I should readily prefer them before the beet tea; their decoction is of a grateful colour, and, when one has taken it twice or thrice, its taste and smell become very agreeable.

As for the root, it is necessary to boil it a little more than tea, to allow time for extracting its virtues, as is practiced by the Chinese, when they give it to sick persons; on which occasion they seldom use more than the fifth part of an ounce of the dried root.

To prepare the root for exhibition they cut it into thin slices, and put it into an earthen pot well glazed, with about half a pint of water: the pot is to be well covered, and let to boil over a gentle fire; and, when the water is consumed to the quantity of a cupful, a little sugar is to be mixed with it, and to be drank immediately after this, as much more water is to be put to the remainder, and to be boiled as before, to extract all the juice, and what remains of the spirittuous part of the root.

These two doses are to be taken in the morning, and the other in the evening. Phil. Trans. N° 337, or Abridg. vol. iv. part ii. p. 314, &c.

Gin-feng has been considered by the Chinese as a powerful aphrodisiac; but a fact to the contrary is alleged by Dr. Cullen in his Med. Med. v. i. p. 261. High as the virtues of this root have been extolled by the Chinese, and by others, upon their authority, we know of no proofs, says Dr. Woodville (Med. Bot.), of its efficacy in Europe, and from its sensible qualities, we judge it to posses very little power as a medicine. It is recommended in decoction, viz. a dram of the root to be long boiled in a sufficient quantity of water for one dose; but it has been omitted in the last edition of the London Pharmacopoeia.

GIO, in Geography, a cape of Scotland, on the N. coast of the island Shapmuka.

Gio, St., a town of Italy, in Friuli; 11 miles W. of Palma la Nova.

Gio di Fiore, St., a town of Naples, in Calabria Citra; 16 miles W.S.W. of Umbratico.

Gio in Pelagia, St., an island in the gulf of Venice, near the coast of Thrace. N. lat. 45° 15'. E. long. 13° 49'.

GIOAR, in the Materia Medica of the ancient Arabians, a word
a word applied to several different substances, and sometimes used as the distinct names of them; sometimes only as an epithet to them. It is generally used by Avicenna as a name for arsenic, sometimes for antimony; and in Scopion, we often find it standing for any of the mineral poisons. The original meaning of the word is no more than what the Greeks expressed by the word σέληνου, falsehood; but it became applied to several things most eminent in their way; as to arsenic, the most fatal of poisons; to antimony, supposed at that time the most valuable of medicines; and to pearls, as the most valuable of gems.

GIOBAR, in Geography, a town of Afinic Turkey; in the province of Dinarbekir; 20 miles N.W. of Tebrit.

GIOCONDO, FRAN. GIOVANNI, in Biography, who flourished in the sixteenth century, was a native of Verona, where he taught the learned languages for a subsistence. Among his pupils was the celebrated Julius Caesar Scaliger. He afterwards became a monk, and was claimed as a brother both by the Dominicans and Franciscans. He was extremely learned in mathematics, and contributed much to the revival of classical learning, by the collection of ancient manuscripts and manuscripts. He presented to Lorenzo de Medici a collection of ancient inscriptions which he had compiled in Rome. Giocondo was some time at the court of the emperor Maximilian. He visited France, and was employed to build two bridges over the Seine. After this he obtained the title of Architecht-royal in France. The time of his death has not been ascertained; it is supposed he did not survive very long, the year 1521, as he calls himself an old man, eight years before this, in the dedication of a work to Juliano de Medici. He materially served the cause of literature by several works, which did him much credit as a writer, as they likewise extended his fame as an artist. He published an edition of Pliny's epistles, and gave a correct edition of Vitruvius, illustrated with figures, which he dedicated to pope Julius II. He took a part in editting many other works of the ancients, and was the first person who gave a design of Caesar's bridge over the Rhine. In 1506 he wrote four dissertations, addressed to the magnificency of Venice, concerning the waters of that city. He was employed with Raphael and San Gallo in superintending the erection of St. Peter's. His last work was, probably, the rebuilding of the Rome bridge of Verona. Gen. Biol.

GIOFAR, AI, in Geography, a town of Arabia; 8 miles S. S. E. of Raboghe.

GIOGI, a town of Transylvania, situated near the Maros; 14 miles S. W. of Millenbach.

GIOJA, or GIOVA, FLAVIO, in Biography, was born at Pafion, near Amalby, in the kingdom of Naples, about the year 1520. Little is known of the history of his life, except that he is thought to have been the discoverer of the directive power of the magnet, by which it dispenses its poles along the meridian of every place, or nearly so, and to have applied this important fact to the purposes of navigation, under the form of a compass. As a proof that this instrument was the invention of a subject of the king of Naples, who was a junior branch of the royal family of France, it is said he marked the north point with a fleur-de-lis, by which it is distinguished by the people of every country. As a memorial of this discovery, the territory of Principato, in which Gioja was born, bears, for its arms, a compass. It must not, however, be concealed, that the French and the English have claimed for themselves the honour; and many authors of reputation have given it to the Chinese, who are reported to have known its use long before their intercourse with Europeans, and that the secret was brought to Italy by Marco Polo. Moreri. See the article Compass.

GIOJA, in Geography, a town of Naples, in the province of Barri; 14 miles S. S.W. of Converiano.—Alfo, a town of Naples, in Abruzzo Ultra; 7 miles S. E. of Celano.—Alfo, a town of Naples, in Calabria Ultra; 7 miles S. of Nicotera.

GIOVELLI, a body of the falibis, or hordes, in the service of the grand signor.

GIONI PIANO, Sr. in Geography, a town of Naples, in Capitanata; 8 miles S. S. W. of Lefina.

GIOARASH, a town of Arabia, in Yemen; 60 miles N.W. of Saude.

GIORDANI, VITAL, in Biography, was born at Bitonto, a town belonging to the kingdom of Naples, in 1653. He was intended for the church, but deserted the studies necessary for that profession, and married when he had no means of providing for the support of a family. After this he led an idle life, quarreled with his relations, murdered his brother, and fought for safety by leaving his country. He entered as a common soldier on board the galleys, which pope Innocent X. sent against the Turks in the Levant. He was present in several actions, and gave abundant proofs of his courage and heroism. His talents led him to promotion and he was made purfer, a situation which obliged him to improve himself in arithmetic, of which he scarcely knew the elements. What his duty required him to learn, his inclination led him to pursue with pleasure and delight; he became an able mathematician, and was at length chosen professor of mathematics to Chrillina, queen of Sweden. Lewis XIV. appointed him professor of the same branch of science in the Academy of Sculpture and Painting. This was in 1666, and in 1672 pope Clement X. made him his engineer, and professor at the College de Wildom. By his great prudence, regularity, and temperamce, he redeemed his character, and died in his 78th year. His principal work is "Euclide Riffuto," 1666, folio. "Fundamentum Doctrinae Motus Gravorum," and "Ad Hyacinthum Chiliphorum Epistula." Moreri.

GIORDANO, LUCA, an historical painter, born at Naples in 1629. His father was an artist of no great repute, who, fancying his son Luca had an inclination to painting, employed him very early in the practice of the art; by which means he acquired an uncommon facility of handling the pencil, and succeeded in imitating the works of great masters. By this, when very young, he gained for his parents considerable wealth; and so eager was his father to make advantage of his ingenuity, that he scarcely allowed the youth time to eat his meals, but was continually urging him to pursue his labours by repeating so incessantly "Luca fa peflo, (Luca male baffe)," that his prece became his nick-name among his companions.

His first matter of any note was Joseph de Ribera, called Spagnoletto; to whose style he, for a time, so much adhered, as to puzzle the most discerning critics. From him he removed to Rome, where he industriously studied the style of his countrymen, and the works of eminent masters in the art. He fixed himself sufficiently with Pietro Cortona, by which it is probable his brilliant imagination was taught to expand itself in a more imperfection and trifling manner than it was originally capable of entertaining. His ready hand, and the freedom, boldness, and precision of his touch, was exactly what Cortona required, and with him he wrought upon many noble works in fresco; and was so incredibly expedient in that way, that he could dispatch as much work in a day, as any other painter could in a week. His imagination was exceedingly fertile; and this, with the readiness of his hand, and the conqueant abundance of his...
his productions, soon spread his fame over Europe. The
king of Spain (Charles II.) desiring to see his pant, and
to have the Eucharist adored by his hand, invited him there,
offering him to be paid 1500 ducats de Plata for the voyage,
and allowing him to freight the ship that brought him over
duty free. He also made him groom of the bed-chamber,
 honouring him with a golden key, but disdaining with his
attendance, that he might be more his own master.
Velasco says, that it is impossible to express the num-
ber and beauty of his compositions in Madrid, Toledo, and
at the Eucharist; and that he employed only two years to
paint ten arched ceilings of the church and bedside of that
palace. He was exceedingly indefatigable, generally painting
his or seven hours every day; and being highly favoured by
the king, became exceedingly rich. It was in 1692 that he first
arrived at Madrid, and did not return to Italy till 1721,
when he accompanied Philip V. to Naples, and in 1724
died there.

Previously to his going into Spain he had executed num-
erous works in Rome, Genoa, Milan, and other places; and
had produced a vast number of pictures in imitation of
Titian, Tintoret, Giorgione, &c. &c. which are extremely
correct, and exhibit the amazing power of his memory, and
the veracity of his genius. The extraordinary facility of
painting which he possessed, enabled him to work with great
facility in fresco, as well as in oil. This very facility is,
however, the cause that Giordano’s works will never be re-

garded as standards in the art of painting. Too great a
degree of freedom is an enemy to grandeur of style, and
the person who possesses it is apt to be too easily satisfied with
his productions; and indulging himself in the pleasure afforded
by the freehand and characters of colour and effect pro-
duced by it, is unwilling to disturb it in order to render the
parts more positively correct; and thus, though ever agree-
able, yet works wrought in this manner are too often flimsy
and weak in their effect on the mind. This is the charac-
ter of Luca Giordano, who, though a great master in the
art, ranks only in a second or third rate. One of his most
considerable productions is the altar-piece of the church of
the Assumption at Naples, representing the fall of Lucifer.
And in the Durazzo Polai at Genoa, is a time picture of
Seneca dying in the Bath; of which, also, there is a dupli-
cate in the gallery at Dresden.

GIO GIO

GIORGIO, in Geography, a town of Walachia, on
the N. side of the Danube; 40 miles S.W. of Bucharest.
In June 1771, the Rusians defeated the Turks near this
town, killing 5000 of them, and taking 180 pieces of can-
non, with artillery and baggage for 30,000 men. N. lat.
43° 38'. E. long. 25° 18'.

GIORGIO ANTONIOTTI, in Biography, an Italian
writer on music, who, having been a considerable time in
England, had a work entitled "L’Arte Armonica," trans-
lated into English, which he published in two vols. folio, by
subscription, under the title of "A Treatise on the Compo-
sition of Music," in three books, with an Introduction on
the History and Progress of Music from its beginning to this
time, written in Italian by Giorgio Antoniotti, and trans-
lated into English, 1763, printed by Johnson, Cheaps-
side.

We had at this time no well digested, clear, and ample
treatise of composition in our language. Morley’s treatise
was become scarce, obscure, and totally defective in every
thing that concerns modern music. We had indeed Mal-
colm’s treatise published in 1721, and that of Dr. Pepusch
in 1721. The first is dark and awkwardly written; the
second, though excellent as far as it goes, has some preju-
dices of the old school, which were totally abandoned in
1763, and it is too concise in many particulars to enlighten
or satisfy the doubts of young students in many essential
points, which were now necessary to be explained, and
which in the year 1731 had no existence. Gemmanini’s “Guida
Armonica,” so long expected, and published about the year
1746, puzzled thecafe, and disappointed every reader.
Much therefore was expected, even by professors, from a
work of two vols. folio, written by a famed Italian, and
nearly half the bill of subscribers consisted of the names of
the principal composers and organists of the time.

We had a miserable translation of Ranconni’s treatise,
written originally in a musical technics, totally different from
that to which we were accustomed, which, with the ungram-
matical and bad English into which the reit was translated,
tossed every one who attempted to read it into despair.
The sonatas and concertos of Corelli, published in score
by Dr. Pepusch, and the works of Handel and Gemmanini,
for those who took the trouble to score them, were excellent
lemons of counterpoint, if they had been properly fluided.
But it is astonishing how long even great performers on
instruments remain in utter ignorance of composition. Jack
James, Magnus, and Kiloway, though admirable organists,
ever attempted composition, and if they had, after a cer-
tain time, they would never have been bare of their ground,
but even in making a solo to a minuet or country dance
would have discovered to real judges, that they were not
regular bred contrapuntists.

Signor Antoniotti, we believe, was a perfect judge of
the mechanical rules of harmony; but his method is not
clear and intelligible to a student out of the reach of a
matter. His introduction, and historical account of the
progres of music from the system of the Greeks to the pre-
ent time, will amuse, though not accurately instruct, curious
readers.

He ascribes to Guido the invention of harmony, and to
John de Muris the invention of musical characters, as had
been long done by others, who, trudding to tradition, had
never seen the Micrologus of Guido, nor the Compendium
of John de Muris, by which it has been lately proved, that
the laws of harmony were unknown to Guido, and that de Muris
himself affirms the invention of musical characters to Magif
Francesco, who flourished 1647, near 300 years before John de Muris was born. (See FRAENCO and DE MURIS.)

So much for sig. Antoniotti’s historical part.

When he comes to practical music, his definitions are so
far from clear to readers in the first stages of counterpoint,
that they multiply the student’s doubts. His plates have
prima facie so feminine an appearance as to frighten a princi-
plante as much as teaching geometry or algebra would do.
His examples of notation are methodically placed; but the
joining the old and modern characters in the same table will
confuse the student’s idea. He begins with three characters
no longer in use, and the minuce, now the first and longest
note, ranks only as the fourth.

His general scale and system of intervals will terrify a
young student by the manner in which it is represented; his
system of harmonic combinations the same. Plates 14
and 15 of transposed scales are clear and useful, as are the
scales in the several ele
cs.

The rige he of the octave seems unknown to the author,
and his plain counterpoint is written entirely on a series of
elevens to have rising or falling by fourths and fifths totally
without modulation. No instructions are given for the use
of disords, but in examples a due et a he gives disords in
discriminately to every note, without informing the student
when and where to use them, or speaking of accented or un-
accented parts of a bar.
At plates 48 and 49 the answers to short examples of figure and imitation are clear and ingenious; but no instructions are given for melody throughout the work. And musical composition consisting of the union of melody and harmony, it seems, at least, to have merited a definition. He might have told the student that it consists of a pleasing series of figure notes of various lengths, arranged with grace, divided into equal measures by bars, phrased and governed by rules.

At pl. 49, ex. vii there are suppositions of lyrics in abundance between the second and third lines, unnoticed by the author.

Page 106, vol. i. the author very justly confines vocal fugues and canons, in which the several voices are fingering different words and syllables at the same time; but Roumieu had done this before, in his "Letter unre la Mélodie Française," 1751. His examples of fugue and canon, which he allows to have an admirable effect in instrumental music, are few and artless. No other examples are given of melody than chords broken into very common passages as variations. Nor of harmony or melody do we find more than two or three examples in triple time, and those of a very common and unmeaning fort.

We remember that the public was much disappointed by this work, which was silently put on the shelf, and has scarcely ever been mentioned since its publication.

GIORGIO GANDINI, a painter, fancied "del Crema." He was of Parma, and, if we believe Olandi, not merely one of Correggio's school, but a pupil, whose works the latter himself retouched. The principal picture in St. Michele, erroneously ascribed to Lebre Orb, is claimed for him by P. Zoppa; a performance, though in parts capriciously conceived, of an impulso, a relief, a sweetness of colour and pencil, to confer honour on the belt of that school. The eclect in which he was held by his fellow-citizens may be conceived, from the composition which they unanimously conferred on him after the decease of Correggio, viz., to paint the Tribune of the Duomo. Death prevented him from the execution of it, and the composition fell to a third, to Giradone Mazzuolo, though not yet ripe for an enterprise of such magnitude. Fuchel's Pilkinson.

GIORGIO, Sz., in Geography, a town of Naples, in Calabria Ultra; 17 miles S.E. of Nisotera.—Alfo, a town of the island of Letna; 44 miles E. of Letna.—Alfo, a town of France, in the department of the Po; six miles N.W. of Chiavado.—Alfo, a town of Naples, in the province of Otranto; four miles E. of Taranto.—Alfo, a town of Naples, in the same province; three miles N.W. of Nardo.—Alfo, a town of Naples, in the province of Principato Ulta; three miles S.E. of Benevento.—Alfo, a town of Italy; 10 miles N.W. of Verona.—Alfo, a town of Italy, in the department of the Reno; 11 miles N. of Bolagna.

GIORGIONE DA CASTEL FRANCESCO, or GIORGIO BAREARELLI, in Biography, was a painter of most uncommon talents, who disputed the rank of head of the Venetian school with Titian. He was born at Callato-Francio in 1477, and acquired the name of Giorgione as well from his superior mode of feeling in art, as from the beauty and elegance of his person and manner. He at first became a scholar of Giovanni Bellini, but soon shook off the minuteness and trifling labour of that school, and sublimated breath and fulness of handling and effect. Vafari observes, that Giorgione, having seen some works of Leonardo da Vinci, wherein the grand style of chiaroscuro was effected, was struck by them, and endeavoured in future to imitate that character in his own pictures. If this be true, which is doubted by some, he, in adopting that style, did not scruple to vary it, to suit his own more pleasing taste; and certainly differs exceedingly from it in line, as much as in colour and effect. The former confines the eye almost to a single point, the latter diffuses the lights and shades; and though art be apparent, still nature more truly predominates.

He painted in fresco with great vigour and beauty, but little of his labour in that way now remains. He was engaged to paint the bridge of the Rialto in Venice, where he died altogether related: Vafari, while he praises the beauty of the colours and execution, condemns the work, as wanting sublimity. Many of his oil pictures are in this country, and they cannot be too much extolled for their excellence in character of colour, or fulness and freedom of handling; with a rich impasto, and a softness in the roundings, that render them delightfully pleasing to contemplate. One large picture of a Holy Family is in possession of the marquis of Stafford, which is highly honoured as to effect. But, perhaps the most perfect work of his in this country, is a small picture in the collection of the card of Carlisle, a portrait of Gablon de Foix, with a servant putting on his armour. We are not acquainted with any picture that has more truth or beauty of colour, and dryly of character to recommend it. His portraits, in general, have every excellence required in that interesting branch of the art, and he may be justly styled the father of portrait painting, as since handed down to us by Titian, Van dyke, and Sir Joshua Reynolds; the three great luminaries that have at different periods succeeded him. It is told of him, that having a dispute concerning the superiority of sculpture or painting; and it being argued, that sculpture had the advantage, because the figures it produces may be seen all around; he took the adverse side, maintaining that the necessity of moving, in order to see the different sides, deprived it of its superiority; whereas the whole figure might be viewed at one glance, in a minute. To prove his position, he painted a figure, and surrounded it with mirrors, in which all the various parts were exhibited, and obtained great applause for his ingenuity. He died of the plague, at the early age of 34, in the year 1511.

GIORGY, Sr., in Geography, a town of Schavonia; 16 miles N.N.W. of Verovitzia.

GIORNICO, called by the Germans Irrn, a town of Switzerland, in the Leventine valley, famous for the victory which 600 Swiss gained, in 1478, over the troops of the duke of Milan, amounting to 15,600 men; a victory which inspired to the Swiss an honourable and advantageous peace. In the vicinity of this town, there are many vineyards, and the walnut and chestnut trees are of a very large size, some of them being not less than 50 feet in girth; 13 miles N. of Bellinzona.

GIOSTALLI, a town of Africa, in the country of Multibbiil, at the bottom of a bay not far from Sofala.

GIOTTO, in Biography, a painter, conspicuous among those who revived the knowledge of the art in the 15th century. His father was a labourer, who lived at Vetignano, near Florence, and whose name was Bondoni; but he gave the name of Giotto to his son, who was born in 1276, and whom, at an early age, he placed with some shepherds to aid in tending their flocks. Whilst engaged in this employment, he was found by Cimabue drawing a sheep in the field with too much ingenuity, that that painter was induced to ask him of his father, that he might teach him the art of painting. In a short time he not only learned to imitate his master, but also to paint from nature; and, throwing off the dry Gothic manner which reigned till then, endeavoured to give the actual imitation of nature. He soon became far superior to his
GIOVANNI, in Geography, a town of Perugia, in the province of Kerman; 57 miles E. of Sigirian. — Alto, a town of Perugia, in the province of Farflla; 10 miles N. of Schiria.— Alto, a town of Perugia, in the province of Schierini; 55 miles W. N.W. of Zara. — GIOVANA, a town of the republic of Lucca; seven miles N. of Lucca. N. lat. 44°. E. long. 10° 40'.

GIOVANNI ASSANI, in Biography, a celebrated Italian opera singer, with a tenor voice. His first appearance on the stage was at the theatre royal at Copenhagen, where he remained three years. In 1772, he left and heard him at Hamburg, and in 1773 he went to Amsterdam, where, as well as at Hamburg, he only sung at concerts, there being no opera established in those cities at that time. In 1775 and 1776, he sung at Turin with the Aguiari. In 1777 at Naples with Rubinielli. In 1779 he arrived in England, where he found Roncaglia, who had possessed abilities, excited an ambition in the tenor singer to take the part of the soprano. Anfani had one of the best tenor voices we had ever heard on our opera stage. It was sweet, powerful, even, and of great compass and volatility. Nor could any defect be justly ascribed to it, except perhaps a little want of variety, spirit, and animation, in passing allegro, to distinguish joy from sorrow. For there was a natural melancholy and pathos in his tones on all occasions, which rendered his performance somewhat monotonous. He was of such a disinterested and irritable disposition, that "trifles light as air" occasioned perturbation. He and Roncaglia had been at variance in Italy, and here their enmity broke out anew, with double violence.

GIOVANI, St. in Geography, a town of Naples, in Capitanata; six miles N.E. of Acerno. — Alto, a town of the duchy of Carniola; two miles N.W. of Daino. — Alto, a town of Italy; 19 miles N. of Bergamo. — Alto, a town of Ifria; nine miles N.E. of Pola. — Alto, a town of Naples, in Abruzzi Ultra; 13 miles S. of Celano. — Alto, a town of Naples, in Baliciana; 17 miles S.W. of Matera. — Alto, a town of Italy, in the duchy of Piacenza; six miles W. of Piacenza. — Alto, a town of Etruria; 18 miles S.E. of Florence.

GIOVANNA, St. or St. John, an island in the Mediterranean. N. lat. 36° 27'. E. long. 26° 24'.

GIOVANNI RATTAC, St. a town of Naples, in Capitanata; 10 miles N.W. of Manfredonia.

GIOVAR, a town of Perugia, in the province of Farfllan; 55 miles S.S.W. of Schiria.

GIOVANNIO, a town of Cori; 25 miles E. of Corte.

GIOVENARIO, a town of Naples, in the province of Bari, situated near the sea, the seat of a bishop, containing four churches, four convents, and defended by a fort, and eight miles W. of Bari. N. lat. 41° 17'. E. long. 16° 43'.

GIOVI, a town of Etruria, on the Chieno; five miles N. of Arzno.

GIPPING, a river of England, in Suffolk, which joins the Orwell, and falls with it into the Stour.

GIPSIIES. See EGYPTIANS; under which article the reader will find an account of their supposed origin, migration,
Some of the people who have been frequently banished from various districts, and who have kept up their race, and carry on their trade of petty pilage and deception.

GIR, OR GIR, in Geography, a river of Africa, which Ptolemy delineates as equal in length to the Niger, the course of each being probably about 1300 British miles; but running from east to west, till it be left in the same lake, rent, and divided, the Nile, which for its Arabic geographer Edrih seems to indicate the river, when he speaks of the Nile of the Negroes, as running to the west, and left in an inland sea, in which was the isle Ulih. Some have supposed the Gir of Ptolemy to be the river of Borno, or Yel-al-Gaza, which joining another considerable river, flowing from Kuku, discharges itself into the Kubia Palus, or Kikina, and it is so delineated in Remondi's map; but others apprehend, seemingly with better reason, that the Gir of Ptolemy is the Bahir Kulla of Browne, in his history of Africa. This river, the Niles Nigir, as well as the Nile of Egypt, have their source in the mountains of Kumi, which Browne lays down in N. lat. 7. The banks of the river Kulla, according to this ingenious traveller's information, abound with pimento trees, and the ferry-boats are partly managed by poodles, partly by a double tar. The trees are so vigorous, from the quantity of water and deep clay, that canes are hallowed so large as to contain ten perches. Ptolemy seems to have described the first with the Gir, which falls river be clearly deduced from must have trive to be, i.e., to correspond with the Bahir Kulla, though he be a stranger to remote sources. This river is represented by Ptolemy as receiving two tributary streams from two lakes; and among other cities on its bank, is a metropolis called Girn. The termination of the Gir is not a little obscure, but it seems to be delineated, as passing under a chain of hills, on the N. of the Lybia Palus, or central lake of Africa, and afterwards joining the Niger in its course to the west. The Pangaon of Ptolemy, between the Gir and the Niger, may be the Wangoor of the Arabs; and his Lybia Palus, which forms the termination of the Niger eastward, seems to be mean, or Russell's observer, either for the larger of the lakes, or for the lake of that country (of which there are) collectively. From an accurate examination of Edrih, who wrote in Sicily in the 12th century, and who, from his minute attention to eastern Africa, has been called the Nubian geographer, it will appear, that this and the Nile of the Negroes, which he says runs to the west, has been mistaken for the Niger, he really knew nothing of that river; and his Nile of the Negro was the Gir of Ptolemy, terminating in an inland lake, in which was the island of Ulia, one day's sail from the mouth of the river; and in which island another Arabian geographer places the capital city of all Soudan. Beyond this island, Edrih appears to have had no knowledge of central Africa; all the regions and towns he mentions seeming to belong to the Gir, his Nile of the Negroes, running to the N.W.; and from his account it would appear that Wangoor is the Delta of the Gir.

GIR, in Botany, a species of grapes growing plentifully near Ras el Feed, on the borders of Abyssinia. It begins, says Mr. Bruce, to fruit in the end of April, and spread advances to its full height of about thirty feet during four months. It is ripe in the beginning of May, and days naturally fruit afterwards. This species of grapes was one of the acquisitions of our author's travels. It was not before known in Europe, nor when he published his work had the seed produced.
produced a plant any where but in the garden of the late French king.

GIRA, in Geography, a town of Persia, in the province of Mezanderan; 18 miles S. of Sari.
GIRAFE, in Ancient Geography, a metropolis of Libya interior, situated on the river G. Ptol. See GIR.
GIRAGLIA, in Geography, a small island near the N. coast of Corinthus, 23 miles N. of Bafila. N. lat. 43° 1' U. long 9° 56'..

GIRALDI, GIULIO GREGORIO, in Biography, one of the most learned men of his time, was born at Ferrara in the year 1489. He pursued his studies at his native place, and having attained to considerable eminence in the language he was chosen by the countess Rangrone as successor to her son Hercules, afterwards a cardinal. He accompanied the countess to Rome during the pontificate of Leo X., and had apartments assigned him at the Vatican. He appears to have been employed in the instruction of various young persons in polite literature, and continued at Rome during the two next pontificates. He enjoyed but a slender pension of health, and at the close of Rome he lost all his property, and even his books. This was the year 1552, when, having lost his friend and patron the cardinal Rangone, he was obliged to leave the capital. In his dilations, which was very fierce, he composed for Carna, and for Mucedola, where he met with a very kind friend in Giovanni Pico. This patron was murdered in 1553, and Giraldi with great difficulty escaped to Ferrara with his life. His poverty was now extreme, but he was not without friends, by whose liberality, especially that of the duchess Renata, he was enabled to lay up a store for the future. He died, after a life of much torture, in the year 1552. So varied was his life, and severe his afflictions, that towards the close of life he complained that he had always to combat against three enemies, Nature, Fortune, and Injustice. His great work was entitled “Syntagma de Dii Gentium.” This is the first treatise in which mythology is discussed in a truly learned manner, and it is a treatise which exhibits the vail extent of the author’s reading, and for which the learned world is under very great obligations. He was author of several other treatises, “On the Muses;” “The Life of Hercules;” “Explanations of the Pythagorical Symbols;” and other ancient enigmas: “A Treatise of Years and Months, with Greek and Latin Calendars, and thirty Dialogues on subjects of Turkefs and Persians;” “A History of the Greek and Latin Poets,” and of “The Poets of his own Time.” He was a considerable Latin poet, and it is thought a few of his own misfortunes induced him to write two small pieces against ingratitude, entitled “Progymnasmata adversus litteras et litteratos.”

Morei.

GIRALDUS, SILVESTRE, CAMBRENIS, one of the most learned and eloquent divines of his time, was born near Pembroke, in South Wales, 1145. Among his numerous works that have been preserved, printed and manuscript, we shall here only advert to an extraordinary passage relative to music, in his “Cambria D.criptio, cap. X.” which has been lately quoted by musical writers, and on which great stress has been laid by Eximeno (Dobbio sopra il Faggio fond. post. di contrap. di L. Martini) and by Mr. Ed. Jones, Mod. Recits of the Welsh Bards.

After all the enquiries that we have made concerning the origin and antiquity of counterpoint, or music in parts, the passage to which we have allude surprized us extremely. Many ecclesiastical historians tell us that the organ was first admitted into the church at Rome by pope Vitalian, 666, the same pontiff who two years after sent fitters into Kent, to finish the work which Autius, the first Roman millenarian, had begun. In 680, according to Bede, John, the preceptor of St. Peter’s in Rome, was sent over by pope Aga-tho to instruct the monks of Weremouth in the manner of performing the ritual, who opened fchools there and in other places of the kingdom of Northumberland for teaching music.

This may, perhaps, reconcile to probability some part of the following account, which Giraldus Cambrenis gives of the peculiar manner of singing that was practiced by the Welsh, and the inhabitants of the north of England, about the end of the twelfth century.

“Th Britons,” says he, “do not sing in union, like the inhabitants of other countries; but in many different parts. So that when a company of singers among the common people meets to sing, as is usual in this country, as many different parts are heard as there are performers, who all at length unite in conformation, with organic sweetness. In the northern parts of Great Britain, beyond the Humber, on the borders of Yorkshire, the inhabitants use the same kind of symphonious harmony; except that they only sing in two parts, the one murmuring in the base, and the other warbling in the acute or treble. Nor do these two nations practice this kind of singing so much by art as habit, which has rendered it so natural to them, that neither in Wales, where they sing in many parts, nor in the north of England, where they sing in two parts, is a simple melody ever well sung. And, what is still more wonderful, their children, as soon as they attempt using their voices, sing in the same manner. But as not all the English sing in this manner, but those only of the north, I believe they had this art at first, like their language, from the Danes and Norwegians, who used frequently to invade and to occupy, for a long time together, those parts of the island.”

This extraordinary passage requires a comment. And first, it may be necessary, before we reason upon the circumstances it contains, to be certain of their authenticity. Giraldus Cambrenis is indeed an author who has been often suppos’d inaccurate and fabulous; and the glaring improbabilities in the above account, with the manifest ignorance of the subject in question, by no means contribute to augment his credibility. For whoever is acquainted with the laws of counterpoint, or with the first difficulties attending the art of singing in parts, can not exalt the idea of the harmony of an untaught crowd, turbæ cantuum, or suppose it to be much better than the dissonant peals of a good-humoured mob; in which the parts would be as various as the pitch of voices of which their chorus was composed. But how all these united at last in the conformation of organic melody, and the soft sweetnefs of B mollis, will long remain an impenetrable secret:

“As true no meaning puzzles more than wit.”

With respect to what he afferts of the people in Northumberland singing in two parts, it is more reconcilable to probability, from the circumstances just mentioned, of the cultivation of music in that part of the world under Roman mallets, who may probably have first brought over the art of diatant, or double singing, which the newly invented organ had suggested, by the facility it afforded of founding two or more notes at a time; which art, when practic'd by voices, was thence called organum, organizans. But as to what Giraldus says of children naturally singing in this manner as soon as they were out of the cradle, the reader will afford it what degree of weight he pleases; but for
our own part, we must own that it is not yet admitted into our musical creed.

GIRAN, in Geography, a town of Algiers, anciently called Arinsa; 45 miles S.E. of Oran.

GIRANA, a town of Abyssinia; 60 miles N.W. of Gonder. N. lat. 13 °. E. long. 36° 37'.

GIRANDOLE, a large kind of branched candlestick. See Branch and Jessi.

GIRAIPA TRA, in Geography, a town of the island of Candy; 16 miles S.W. of Sattia.

GIRAR, a fortress of Hindostan, in Malwa; 40 miles S.W. of Chandernagore. N. lat. 24° 24'. E. long. 79° 18'.

GIRARD, Gabriel, in Biography, a distinguished member of the French academy, known as the author of a work entitled "Symphonies Françoises," the object of which is to prove that the French words, usually accounted synonymous, have, almost all, certain shades of difference, which, in correct speech, should prevent them from being used indiscriminately. No grammatical work was ever better received by the public, and it was the opinion of Voltaire that it will suffice as long as the language. This work has been imitated in English, in one entitled "The difference between words esteemed synonymous in the English language, and the proper choice of them determined," in two vols. 12mo. 1766. The abbé Girard also wrote a French grammar, entitled "Princes de la Langue Françoise," which has much merit in its plan and theory, but is thought very defective in point of style.

GIRARDON, Francis, an eminent sculptor, intended by his father, who was a founder, for the profession of the law. His inclination for the fine arts could not be controlled, and he was educated as an artist. He was brought up at Troyes, but having acquired much reputation and practice there, he went to Paris to improve his taste and judgment under the sculptor Anguier. His performances obtained for him a high degree of reputation; he was noticed by the king, and by him lent with a liberal pension to Rome. In 1657 he was admitted into the academy, and was patronized by Le Brun. Girardon is reckoned to have had more correctives than invention; and he is said to have modelled with more facility than he worked in marble. His principal works are, four figures composing the group of the bath of Apollo, and the cape of Proserpine in the gardens of Verailles; the equilibrant statue of Lewis XIV. and the mausoleum of cardinals Richelieu, in the church of the Sorbonne. He cultivated the friendship of the fine writers of the age, several of whom have done honour to his merits and memory. He was nominated to the chancellorship of the academy in 1695. After having adorned the capital and many other parts of the kingdom with a number of works, and risen to the very head of his profession, he died in 1715 at the age of eighty-five. Moret.

GIRBE, in Geography, a town of Egypt, on the right bank of the Nile; 26 miles N. of Syene.

GIRBEH, a river of Switzerland, which runs into the Aar, two miles S. of Berne.

GIRCH, a river of North Wales, which runs into the sea, near Pwllheli, Caernarvonshire.

GIRCHSBECK, a town of the duchy of Holstein; six miles W.S.W. of Oldenbrooke.

GIRZENI, a town of Moldavia; 50 miles N.N.E. of Galatz.

GIRDERS, or Girning beams, in Carpentry, are those large beams thrown across a room, in order to shorten the bearing of the joists.

When the bearing is not very great, the girder consists of a single beam; when it is more than common, the bundle, or piece of wood out of which the girder is made, is fawn down the middle, and the two pieces are reversed and bolted. In great buildings the girder is framed like the principals of a roof, for the construction of which we refer our reader to the articles Carpentry, and Naked Flooring.

No girder ought to be less than ten inches in the wall, nor ought they, or any principal beam, to be placed over an aperture. They ought to be of the most hearty wood, and as free of knots as possible; for knots depress the continuity of the fibres, and consequently impair the strength.

GIRDING-GIRT, in Sea Language. The seamen say a ship is girt, or hath a girding-girt, when her cable is so tight or strained, that upon the running of the tide she cannot go over it with her stern part, but will lie across the tide.

GIRDLE, Cingulus, or Zone, a belt or band of leather, or other matter tied about the loins, to keep the part more firm and tight.

It was anciently the custom for bankrupts, and other insolvent debtors, to put off and furrander their girdle in open court. The reason was, that our ancestors used to carry all the necessary utensils, as purse, keys, &c. tied to the girdle: whence the girdle became a symbol of the estate. History relates, that the widow of Philip I. duke of Burgundy, renounced her right of inheritance by putting off her girdle upon the duke's tomb. Accordingly the girdle among the ancients was used for a purse. Our Saviour forbids His apostles to carry money in their girdles. Matt. xii. 9. Haggai, i. 6. Horace says, that he who has lost his girdle (his money) is ready for anything. "Ibit có quo vis, qui zonam perdedit." Hor. Ep. I. ii. c. 1. The Romans always wore a girdle to tack up the turcica, when they had occasion to do any thing; this custom was so general, that such as went without girdles, and let their gowns hang loose, were reputed idle, dissolute persons.

GIRDLE, Mirad' or Virginia'. It was the custom among the Greeks and Romans for the husband to unite his wife's girdle. Homer, lib. xi. of his Odysseus, calls the girdle cphysarm, zygem, mird's girdle. Feuich relates, that it was made of sheep's wool, and that the husband united it to bed; he adds, that it was tied in the Hercules knot; and that the husband untied it, as a happy presage of his having as many children as Hercules, who, at his death, left seventy-nine behind him.

The poets attribute to Venus a particular kind of girdle, called effer, to which they annexed a faculty of inspiring the passion of love. See Ester, Quicksilver, in Medicis; is a sort of girdle smeared over with mercury, or having mercury inclosed within it. It is made of leather, linen, cloth, cotton, stuff, or the like; and the mercury is prepared or killed various ways; as with falling spittle, fat, or the like.

It is applied as a topical medicine about the waist, sometimes with good effect; but frequently it proves dangerous, principally in weak constitutions, and those subject to convulsions. Its intention is, the cure of the itch, driving away vermin, killing lice, &c.

GIRDLE, Queen's, is an ancient duty or tax, raised a Paris every three years, at the rate of three deniers upon each midiat of wine, and fixed for each quantity: it was intended for the maintenance of the queen's household: afterwards they augmented and extended it to other commodities, as coals, &c.

Vignere supposed it to have been originally thus called, because the girdle anciently served for a purse; but he adds, that a like tax had been raised in Paris, and under the same name, above two thousand years ago; it appears from Platos, in his Philostrat. Cietto, Athenian. &c.
GIRLIE, Christians of the. Motawakkil, tenth caliph of the family of the Abassides, enjoined the Christians and Jews, in the year of the Hegira 235, of Jesus Christ 856, to wear a large leathern girdle, as a badge of their profession; which they wore to this day throughout the East, from which time the Christians of Asia, and particularly those of Syria and Mesopotamia, who are almost all Nestorians or Jacobites, have been called "Christians of the girdle."

GIRLIE, Order of the, the order of Cordeliers. See Cord and Cordeliere.

GIRLIE, in Architecture. See Cincture.

GIRLIE, among Jewellers, the line which compasses the stone parallel to the horizon; or, which determines the greatest horizontal expansion of the stone.

GIRLIE Wheel, a small spinning-wheel, made for hanging to a woman's girdle or apron-string, so that the may spin with it though walking about.

GIRLIE, in Mining, is the name used in Cumberland, and some other counties, to denote the uncertain strata, or chance beds, of stones and different substances that are met with in some districts; which, instead of occupying the whole space, of the same or nearly an equal thicknes throughout, are only local, preferring, however, contantly the same relative situation to that of the strata, wherever they appear; that, is, they are peculiar to particular places in the series of strata, and known, according to the numerous enquiries and observations which Mr. Farey, Sen., has made on these anomalous masses in the stratification, to be peculiar in their shape, always ending insensibly or with sharp-edges on all sides, like extremely flattened nodules; and, except in shape and size, and their rarity, he conjectures that they differ nothing from the nodules which are so very common in particular strata, as of iron-flour in the beds and strata of most coal-fields, and in the grit-flours of stone; those of pyrites in many coal-frames, those of the nodules of flint in the upper chalk strata, &c. &c. Particular strata in the British strata are found to be subject to these chance beds, or strata, within their mass; some of which large nodular masses afford a confusely crystallized structure, and seem to occasion large hills and even mountainous tracts, as Charnwood Forest, in Leicestershire, whose white and slate, &c. have been referred, by the gentlemen named above, to the anomalous manner of growth or marble strata, &c. See Philosophical Magazine, vol. xxxii. page 40.

GIRDINESS, in Geography, a cape on the E. coast of Scotland. N. lat. 57° 4' W. long. 2° 2'.

GIRELLI, Agulare, in Biography, a female opera singer, who arrived here the fame seconious Miller, in 1772. Her style of singing was good, but her voice was in decay, and her intonation frequently falte, if she arrived here; however, it was easy to imagine from what remained, that she had been better. She remained here only one season, and was succeeded by Miss Cecilia Davies.

GIRMANO,
GIRMANO, in Geography, a town of Prussia, in Samland; 25 miles N.W. of Königsberg.

GIROMAGNY, a town of France, in the department of the Upper Rhine, and chief place of a canton, in the district of Besfert. The place contains 1700, and the canton 9752 inhabitants, on a territory of 150 kilometres, in 19 communes.

GIRONDE, in Geography, a learned Spanish prelate, who flourished towards the close of the 16th century, was born at Talavera. In the course of his studies he had paid a marked attention to philosophy and theology; to history and the councils, with which he became intimately conversant. He lived in a retired way as a canon, till his uncle resigned to him the archdeaconry of Guadalajara, which is one of the dignities belonging to the church of that city. In 1585, Philip II., king of Spain, sent for him to court, made him master of the royal chapel and almoner; and likewise entrusted to his care the education of his son Philip, infant of Spain. In 1596, Cardinal Albert assumed the government of the Low Countries, and appointed Gironde his delegate over the archbishopric of Toledo; to which valuable see he was himself afterwards preferred. He died in 1599, and his death has been imputed to the chagrin which he felt for the neglect shown him by his pupil, who had lately succeeded to the throne. He was author of a valuable collection of Spanish councils, under the title of "Collectio Conciliorum Hispaniae, cum Notis et Emendationibus." Moreri.

Giron, in Geography, town of Africa, on the ivory coast.—Also, a town of S. America, in the province of Quito; 25 miles S. of Cuenca.

Girou, or Girons, in Heraldry, denotes a triangular figure having a long sharp point, not unlike a wedge, terminating in the centre of the effeteleon.

The word is French, and literally signifies the giroum or leap; because, in letting, the knees being supplexed somewhat abender, the two thighs, together with a line imagined to pass from one knee to the other, form a figure somewhat similar to this.

When a coat has fix, eight, or ten of these girons, meeting or centering in the middle of the coat, it is said to be girons or girons.

GIRONDE, in Geography, a river of France, formed by the union of the Garonne and Dordogne; 12 miles N. of Bourdeaux, which runs into the Atlantic, after a course of about 275 miles N. N. W.

Gironde, one of the nine departments of the south-west, or Garonne region of France, deriving its name from the river Gironde. It is a metropolitan department, comprised of a portion of Guienne, in N. lat. 44° 40', and bounded on the N. E. by the department of the Lower Charente, on the E. by the departments of the Dordogne and Lot and Garonne, on the S. by the department of the Landes, and on the W. by the sea. Its capital is Bourdeaux. This department contains 11,270 kilometres, or about 573 square leagues, and 519,685 inhabitants, and is divided into six districts: viz. Blaye, comprehending 4 cantons, 61 communes, and 52,066 inhabitants; Libourne, including 9 cantons, 143 communes, and 125,576 inhabitants; La Reole, comprising 6 cantons, 118 communes, and 53,705 inhabitants; Bazas, containing 7 cantons, 68 communes, and 47,549 inhabitants; Bourdeaux, comprehending 18 cantons, 153 communes, and 233,021 inhabitants; and Lépinac, containing 4 cantons, 37 communes, and 30,868 inhabitants. Its contributions amount to 5,553,653 francs, and the expenses for administration, justice, and public instruction to 533,564 francs. The soil of this department is various: the east and northeast districts are the most fertile. In the valley between Agen and Bourdeaux, the soil, though light, is of an excellent quality. The west and south-west districts are sandy, marshy, and barren, or indifferently fruitful. The products of the soil are grain, hemp, delicious wine and fruits, pastures, considerable forests of pines, slime quarries, mineral springs, &c.

GINONELLA, a town of Spain, in Catalonia; 7 miles E. N. E. of Solsona.

GIRONNE. See Gerona.

GRONS, St. a town of France, and principal place of a district, in the department of the Arriège; 21 miles W. of Tarascon. N. lat. 42° 59'. E. long. 1° 13'. The place contains 2504, and the canton 13,083 inhabitants, on a territory of 2873 kilometres, in 16 communes.

GROST, a town of Perla, in the province of Kennera; 123 miles S. of Sarjon.

GIRROCK, in Hebrew, the common English name of the fish called the Lacerus, a large species of garfish, caught in the Mediterranean and English seas.

GIRONNILE, GIRONY, in Heraldry, is, when a shield or coat is divided into several girons, which are alternately colour and metal.

When there are eight pieces, or girons, it is absolutely said to be gironné: when there are more, or fewer, the number is to be expressed: gironné of four, of fourteen, &c.

Some, instead of gironné, say, parti, coupé, tranché, and tailles, because the girons are formed by such divisions of the field. Four girons form a faltier, and eight a crois.

GIRT, in measuring timber, is used for the circumference of a tree. See Coggehull's Sliding rule and Demometer.

Some call the fourth part of the circumference the girt, and supposo the square of this equal to the area of the section of the tree.

GIRT, in Architecture, the same with fillet. See Fillet.

Girt, girdle, in Sea Language. See Girding-girt.

Girt-line is a rope passing through a single block, on the head of the lower mails, to hold up the rigging thereof: this is the first rope employed to rig a ship, and by means of this all the rest are drawn up and fixed; after which it is removed till the ship is to be unrigged.

GIRTHS of a Saddle, the long straps, made of a canvas stuff called girth-web, which being buckled under the horse's belly, serve to fix the saddle.

GIRTIN, Thomas, in Biography, a draftsman of uncommon capacity, who lately adorned our days, and if he had not been cut off by an early death, would probably have exhibited unrivalled talents in the peculiar branch of the art he adopted. He was born in 1775, and was one of those who have contributed to raise almost a new species of art by the use of water-colours in landscape painting. He drew with a ready hand, in a style entirely his own, and with great taste and effect; though not always with a strict adherence to truth. He died of consumption, brought on by irregularity, at the early age of 27.

GIRU, in Geography, a town of Perla, in the province of Mazandran; 5 miles E. of Tehrabad.

GIVAN, a sea-port of Scotland, in the county of Ayr, situated at the mouth of the river Givan, which rises in the N. E. part of the county, and runs into the sea a little below the town. It has a commodious harbour, capable of great improvement. The chief employment of this town, which is a burgh of barony, governed by bailies and councillors, annually elected, is weaving of cotton and woollen cloths. In 1801 the number of inhabitants was 226, of whom 1360 were employed in trade and manufactures. The
neighbourhood abounds with limestone and coal; 21 miles S S W. of Ay.

N. lat. 55 18'; W. long. 4 44'.

GISHARM, or GUISARMES, in our Old Writers, an habi-
tobert or hand-ax: it comes from the Latin bas armas, because it
wounds on both sides. Sene.` "El armorium genus longo manubiro et perretta curisipide." It is mentioned in the itinare 1 Edw. I. cap. 6.

GISBOROUGH, in Geography, a market town and
parish in the North Riding of the county of York, is seated
near the mouth of the river Tees, 8 miles from Stockley,
and 248 from London. By the population returns, printed
by order of parliament in 1801, this parish contains 383
houses and 1719 inhabitants. In the time of King James I.
the same alum mines were discovered here, and were worked
for several years with great success. The bay at the mouth
of the Tees forms a commodious harbour. In this town
was formerly a spacious monastery, of which some consider-
able ruins remain. Here are a weekly market on Friday,
and five annual fairs.

GISCALA, in Scripture Geography, a town of the tribe
of Asher, in Lower Galilee; S E of Jotapa.

GISEKJA, in Botany, named by Linnaeus in honour of
his pupil Dr. Paul Dietric Giiseke, professor of Natural
History at Hamburg, and editor of the Predicaciones in Ordens
Naturalis Plantarum, compiled from his own notes and those
of Fabriacus, taken from the mouth of Linnæus, and pub-
Sp. Pl. v. 1. 1547. Mart. Mill. Dict. v. 2. Juss. 315. La-
naric Haftr. t. 221. (Kreuterea; Marr. Comm. Nov.
Geett. v. 3. 37. t. 2. f. 1.)—Clas and order, Pentandria

Gen. Ch. Col. Perianth of five ovate, concave, obtuse,
leaves long, with membranaceous edges. Cor. none. Stam.
Filamentus five short, awl-shaped, ovate at the bafe; anthers
roundish. Pist. Germin superior, roundish, retuse, deeply
five-lobed; styles five, short, recurved; stigma obtuse.
Peric. Capsules five, roundish, slightly compressed, rough,
obtuse, close together, each of one cell. Seed solitary, ovate,
smooth.

Spec. Ch. Calvin of five leaves. Corolla none. Capsules
five, approximated, roundish, singed-feaded.

1. G. pharnacoides. Linn. Mant. 562. Native of the
East-Indies. A smooth annual herb, with the aspect of an
Illecebrum or Pharmacum. The flera are prostrate, a foot
or two in length, narrowed along their upper side, alternately
branched. Leaves opposite, stalked, obovate, entire, light
green, rather hairly. Flowers small, green, in little axillary
umbels. Fruit blackish. On the short axillary branches, the
leaves, as Jullien well observes, are opposite. No other
species has been discovered.

GISELO, in Geography, an island on the E side of the
gulf of Bodnia. N. lat. 61 40'; E. long. 21 22'.

GISGI, a town of Transylvania, near the Maros; 14
miles S W of Milbenbach.

GISHI, a town of Georgia, in the province of Kaketi;
15 miles S E of Telish.

GISHUBEL, a town of Bohemia, in the circle of
Königgratz; 20 miles E N E of Königratz.

GISING, a town and castle of Hungary; 14 miles
S W of Steinam-Anger.

GISIO, a town of Sweden, in Angermanland, on the
Gidsa; 16 miles W. of Nordmalling.

GISLAVY, a town of Sweden, in the province of Sma-
land; 40 miles S. W. of Jönköping.

GISON, or Gerard, in the Jewish Antiquities, a little
wall about broad high, made round the temple properly so
called, and the altar of burnt sacrifices, to keep the people
at a distance. Josephus, in his Book of Antiquities, makes
it to be three cubits high; and but one, in his History of the
Jewish war. J. Antiq. lib. vii. cap 2 p. 262. et de

GISORS, in Geography, a town of France, in the depa-
partment of the Eure, and chief place of a canton, in the
district of Les Andelys; 27 miles N E of Evreux.
The place contains 3500, and the canton 9246 inhabitants, on
a territory of 1474 square kilometres, in 23 communes. N. lat.
49 17'; E. long. 2 50'.

GISINGHEIM, a town of Germany, in the county of
Wertheim; 15 miles S of Wertheim.

GISANT, a town of Spain, in Arragon, situated on a
bridge in the Pyrenées, on the confines of France, having
in its vicinity mines of cobalt; 15 miles N. of Alfa.

GISTO, a small island in the Adriatic. N. lat. 44 36'.
E. long. 14 51'.

GISUND, a town of Norway, in the diocese of
Drethom; 24 miles N W of Drontheim.

GITAGO, in Botany, a name used by some authors,
particularly by Fluyt, for the lollum or darnel-grass.

GITI, in Geography, a town of Thibet; 334 miles N E
of Delhi. N. lat. 32 10'. E. long. 79 50'.

GISVOUR, a town of Mocampour; 47 miles S W
of Macampour.

GITSCHIN, a town of Bohemia, in the circle of
Königgratz; 22 miles N W of Königsgratz. N. lat. 50
E. long. 15 20'.

GITTITH. This word occurs frequently in the Pslams,
and is generally transliterated give-thee. The conjectures
of interpreters are various concerning this word gittith. Some
think it signifies a sort of musical instrument; others, that
the Psalms, with this title, were sung after the vintage;
Lastly, others, that the hymns of this kind were invented
in the city of Gath. Cabnet is rather of opinion, that it
was given to the class of young women, or songgirls of
Gath, to be sung by them. (P. vii. i. xxxii. 1. iv.) Dr.
Hammond thinks that the Psalms, with this title, were all
set to the same tune, and made on Goliah the Gittite.

GIVA, in Geography, a town of Asoitic Turkey, in
Natalia; 52 miles S E of Miles.

GIVAROTONDO, a town of Naples, in Capitanata;
9 miles W of Monte Carlo.

GIVEL, a small island near the south coast of Sar-
dinia. N. lat. 27 18'; E. long. 9 3'.

GIUDUCCA, L. A., or ZUCCA, one of the islands
adjoining to the city of Venice, which is said to owe its
name to the Jews, who formerly resided there. It contains
10 churches, 4 monasteries, and as many nunneries.

GIVEN, DATUM, a term very frequently used in Mat-
hematics, signifying a thing which is supposed to be known.
Thus, if a magnitude be known, or we can find another
equal to it, we say, it is a given magnitude, or that such a
thing is given in magnitude.

If the position of any thing be supposed as known, we
say, given in position.

Thus, if a circle be actually described on a plane, its cen-
tre is given in position, its circumference given in magnitude,
and the circle is given both in position and magnitude.
A circle may be given in magnitude only; as when only
its diameter is given, and the circle not actually described.
If the kind or species of any figure be given, they say,
given in species. If a ratio between any two quantities is
given, they are said to be given in proportion. See DATA.

GIVET, in Geography, a town of France, in the depar-
tment of the Ardennes, and chief place of a canton, in the
district of Rocroy; 15 miles N E of Rocroy. N. lat. 50 7'.
E. long.
GIU

E. long. 4° 51'. The place contains 3335, and the canton
8445 inhabitants, on a territory of 130 kilometres, in 20
communes.

GIUF, LA, a district of Arabia, in the province of
Nejd; E. of mount Ramleh.

GIULA, a town of Hungary, situated on the river
Keres; 52 miles N. N. W. of Temesvar. N. lat. 46° 35'.
E. long. 20° 55'.

GIULAB, a town of Asia, Turkey, in the govern-
ment of Diarbekir; 18 miles N. N. E. of Ourfa.

GIULENI, a small island in the Gulf of Bari; 130
miles S. of Afrachan. N. lat. 44° 15'. E. long. 42° 49'.

GIULLA TROVA, a town of Naples, in Abruzzo Ultra,
on the coast of the Adriatic; 12 miles E. N. E. of Ta-
naro.

GIULIA, St. a town of France, in the department of the
Stura; 12 miles S.S.W. of Acqui.

GIULIANO, St. a mountain of Etruria, near Pisa, at
the foot of which are warm baths, known in the time of
Phily.—Alfo, a town of Naples, in Capitanata; 9 miles
W.S.W. of Dragedora.—Alfo, a town of Naples, in the
county of Molife; 13 miles S.S.E. of Molife.—Alfo, a
town of Naples, in the province of Otranto; 17 miles
S.S.W. of Brindif. —Alfo, a town of Italy, in the de-
partment of the Olona; 7 miles S.E. of Milan.

GIVORS, a town of France, in the department of the
Rhone, and chief place of a canton, in the district of Lyon;
12 miles S. of Lyon. The place contains 5200, and the
canton 15,550 inhabitants, on a territory of 95 kilometres,
in 18 communes.

GIVRY, a town of France, in the department of the
Saone and Loire, and chief place of a canton, in the district
of Chalons-sur-Saone; 4 miles W. of it. N. lat. 49° 47'.
E. long. 4° 52'. The place contains 2582, and the canton
11,145 inhabitants, on a territory of 132½ kilometres, in
13 communes.

GIUSEPPE APRIE, See TENDUCCI.

GIUSEPPE ARNA, in Biography, an able composer of Ne-
apes, whose ftyle had much of the accomplishment of that school.
In 1741 he fet the fermano drama of Tigrane, written by
Goldoni, to music, for the great theatre of St. John Chry-
sotom, at Venice, which eiftablished his character.

GIUSMARK, in Geography, a town of Curdiuf; 80
miles S.S.E. of Bafis.

GIUSTENDIL, a town of European Turkey, in Bul-
garia; 24 miles S. of Sofia.

GIUSTINELLI, in Biography, a second-rate Italian
finger in foprano, arrived here, in 1762, with De Amicis
and her family, as fhril fanous in the burletta operas.
He had a good voice, and sufficient merit to supply the place
of fectand fan on our Hage, in the ffage operas, for feveral
years after.

GIUSTINIANI, AUGUSTIN, was born at Genoa
1470, was educated for the church, and in 1514
was made bishop of Nebbio in Corsica. He published, in
1516, a Pflifer in four languages, viz. the Hebrew, Greek,
Arabic, and Chaldee, with interpretations: this was the firfl
of the Polyglot editions of the books of Scripture. After
this, he was invited by Francis I. to Paris, and appointed to
the professorship of the Oriental languages in that university,
an office which he held about five years. During this period
he received a pension from the crown, and was enabled to
collect a very choice library, which he afterwards prefered to
the republic of Genoa. In the year 1536, in passing by
sea to his bishoprie, he was lost with his ship. The prelate
revived and edited the treatife written by Porcheri, entitled
"Victoria adversius impios Judaeos." Some time after his
death, were published his "Annals of the Republic of Ge-
no," from the foundation of the city, to the year 1528: this
work is highly efteemed for its information, and for the
veracity of the facts. Moreri.

GIUSTINIANI, BERNARD, a Venetian nobleman, born in
1468, was educated under the most learned persons of his
time, and obtained a very celebrated for his own knowledge
and eloquence. He was employed on several honourable oc-
casions by the republic. In 1451 he was appointed to re-
cord the emperor Frederic III. when he passed through the
Venetian territories. He was afterwards selected as a lit per-
fone to be sent on embaylly to Ferdinand, king of Naples, to
several of the papacy, and to Lewis XI. king of France,
who honoured him with knighthood. In 1467 he was made
captain commandant of Padua, and admitted to almost all
the honors of the state, and finally procurator of St. Mark.
He died in 1486. He was author of many works: as pub-
lic orations: the life of his uncle "The bleffed Lorenzo
Giustiniani," three pieces on the life, the translation, and
the appearance of St. Mark: a version of the book of Socrates
in Nicoleon; some Latin letters of his father Leonardo;
and the ancient history of Venice, written in Latin. This
last was translated into Italian by Lodov. Domenichi. It
was the work of his old age, but is highly efteemed, because
the authorities are drawn from the best sources, and the au-
thor rejects the fables handed down by some other writers.
Moreri.

GIZE', GIZAH, or JIZA, in Geography, a considerable
town of Egypt, extending along the well bank of the Nile, on
the other side of the island of Roskada, or Raonda, with respect
to Cairo; 3 miles S.W. of Cairo. This town was fortified by
Ibnai Bey, who also built a palace there, completed and fin-
ished by Murad Bey, who has established a very famous
foundery. Here is also a manufacturer of fial ammoniac.
The walls of Giza are of great extent, and have only one gate to
the country; they are ten feet high, three feet thick, and
have five half-moons; but are only fit to repel cavalry, the
original intention in raising them. Murad Bey has suffered
the iron-work about the loop-holes to be plundered or ruined.
The palace is in the southern quarter of the city, close to the
water; it has numerous apartments for the Mamluks, and
every convenience for ease or luxury. Murad Bey has, of
late years, thought it necessary to institute a marine; having
purchased some vessels of the Europeans, and built three or
four others. The largest of these vessels carries 24 guns: those
which are occasionally moored before Gize cannot be navigat-
ed, except during the time of the Nile's increafe. The mariners
are chiefly Greeks of the Archipelago. Not far north of Gize
is "Geziret-el-ahab," a small island, which Diodorus Siculus denominated "Venus Aurea." N. E. of the city are gardens, and some spacious houses, oc-
cupied by the affluent and great, who occasionally leave the
city to amuse themselves in this retreat; and they have there
an open space where the Mamluks perform their military
evolutions, and exercise their horses. The ground under the
mountains to the east is filled with tombs. The moun-
tain is of white sand and calcareous flone, and dellinated
of verdure. The numerous date-trees by which Gize is sur-
rounded, interperfered with the lofty turrets of the mosques,
and the river, whose waves wash the very foundation of the
houses, give it, at a distance, a very pleasing appearance. Dr.
Shaw is of opinion, that the ancient Memphis flood on the
site of Gize; but this is disputed by Savary and others.
(See MEMPHIS.) This is the nearest spot, fays Semm, to
the most valuable monuments which ancient Egypt has left
behind of her glory and her power. The nearest pyramids
are at the distance of three leagues, and they are indifferi-
nately
It is chiefly in writing for Conti and Anibali that the conformity to a different style from his own appears.

Domenico Anibali, who should have had an article in the letter A, had he been remembered, shall be characterized here, in apology for the omission. His first air in the opera of "Armindo," in which he performed with Conti and the Strada, discovers his voice to have been a contralto, which Handel gave him an opportunity to display by a fault, _ad libitum_, at the beginning; but no peculiar taste, expression, or powers of execution, appear in his part; his bravura air in the second act, _Si caddi_, contains only common and easy passages. His abilities during his stay in England seem to have made no deep impression, as we never remember him to have been mentioned by those who constantly attended the operas of those times, and were raptures in speaking of the pleasure which they had received from fingers of the first clas. But to return to Conti, who, after he quitted England, studied with such diligence, that being engaged at Madrid to sing in the operas under the direction of Farinelli, he turned the tables on that wondrous finger, in whom it has been said, that he excited envy by his new and refined taste and pathos.

He was one of the constellation of great fingers which the king of Portugal had assembled together in 1755.

There were, according to Paccini's account, Elifl, Manzoli, Caffarelli, Gizziello, Veroli, Bobbi, Luciani, Raaf, Raina, and Guadagni. No females were then allowed to appear on the opera stage in Portugal. Gizziello, narrowly escaping with his life during the dreadful earthquake which happened at Lisbon that year, was impressed with such religious turn by that tremendous calamity, that he retired to his monastery, where he ended his days. It was soon after this event, that Guadagni first himself up in the fame convent not so much for spiritual consolation as musical counsel; which he so effectually obtained from the friendship of Gizziello, that from a young and wild finger of the second and third clas, he became, in many respects, the first finger of his time.

GLABALX, in Geography, a town of France, in the department of the Dyle, and chief place of a canton, in the district of Louvain. The place contains 239, and the canton 6771 inhabitants, on a territory of 120 kilometres, in 19 communes.

GLABELLA, in Anatomy, from gras, smooth: the space between the two eye-brows, which is ordinarily not covered with hairs.

GLABER, in Biography, a Benedictine monk, who flourished in the 11th century, and who has rendered his name memorable by a "Chronicle or History of France," written in the Latin language. It consists of five books, of which the first relates to the events of the monarchy previous to Hugh Capet, and the four subsequent ones to those following it, as far down as the year 1046. This work is distinctive as a composition, and, at the same time, full of fabulous stories, yet it contains much valuable information relative to those remote ages. He was author of a life of William, abbot of St. Benignus at Dijon. Morei.

Gum. Ch. Col. Perrinaths inferior, of one leaf, tubular half as long as the corollas, cut half way down into five equal lobes.
obtuse, broadish teeth. Cor. Petals five, lanceolate, obtuse, equal. Nectary surrounding the germen, and consisting of five oval-shaped, crept, coloured bodies, the length of the calyx. Stam. Filaments thirty, capillary, the length of the calyx, united by their base into five parcels of fix filaments each, ranged alternately with the nectaries; anthers kidney-shaped. Pjfl. Germen superior, nearly globular, four-foled; style thread-shaped, as long as the filaments; stigma fimple. Peric. according to Rumphius, a mucilaginous drupa, of one cell, containing a hard oval nut.

1. G. tofo. Linn. Mant. 276. (Lignum lave minus; Rumph. Amb. v. 3. 71. t. 44.) Native of the lofty and close woods of Amboyna. Rumphius describes and figures two kinds of this Lignum lave, very similar to each other, nor does it appear on what authority Linnæus adopted one as a synonym in preference to the other. The specimens in his herbarium have flender leafy branches, with a smooth greyish bark. Leaves alternate, on short thick stalks, ovato-lanceolate, pointed, entire, three or four inches long, very smooth and shining above; pale grey beneath, as if hoary, but they are rather clothed with a fibrous grey skin, minutely dotted all over, which soon leaves the rib and veins. Species none. Flower-stalks axillary and terminal, branched irregularly, the partial ones somewhat umbellate, all clothed, as well as the calyx, with minute umbilicated ruffly scales, exactly like those on the leaves and flowers of the Druis; see that article. The flowers are small. Fruits, according to Rumphius, an aromatic black drupa, the size of a pea, flanding on the permanent calyx.

If the Druis belongs to Malaces, we are persuaded this genus must likewise be placed in that order, but otherwise we should have had no such idea, nor does the fruit confirm it. The light fibrous silky nature of the wood, which while wet is close, but has large fissures when exposed to the sun, favours our supposition.

GLACIALIS. Icy, of glacier, ice, something relating to ice; and particularly a place that abounds in ice.

Thus we say, the Marc Glacialis, or Congelation, that is, the Icy or Frozen sea; called also the Chronian or Sarman- tian sea.

GLACIERS, a denomination applied to large sheets or fields of ice among the Alps, and which are numerous in Switzerland and Savoy. Of these there are five, that stretch towards the plain of Chamouny, and unite at the foot of Mont Blanc; they are called Tacoma, Botons, Montanvent, Argentiere, and Tour. The origin of these glaciers, extending into fields of corn and pasture, and lying, without being melted, in a situation where the heat of the sun is powerful enough to bring vegetation to maturity, is a very curious subject of investigation. Mr. C. C. has given us an abstract of the theory of Grauner, with regard to their formation, and other particulars respecting them, confirmed and amended by that able naturalist Saulure; which appears, upon the whole, to be the most simple and natural. If a person, says this interesting traveller, could be conveyed to such an elevation as to embrace, at one view, the Alps of Switzerland, Savoy, and Dauphiné, he would behold a vast chaos of mountains, intersected by numerous vallies, and composed of many parallel chains, the highest occupying the centre, and the others gradually diminishing in proportion to their distance. The most elevated, or central chain, would appear bristled with pointed rocks, and covered, even in summer, with ice and snow, in all parts that are not perpendicular. On each side of this chain he would discover deep vallies clothed with verdure, peopled with innumerable villages, and watered by many rivers. In considering these objects with greater attention, he would remark, that the central chain is composed of elevated peaks and diverging ridges, whose summits are overgrown from the snow; that the declivities of the peaks and ridges, excepting those parts that are extremely steep, are covered with snow and ice, and that the intermediate depths and spaces between are filled with immense fields of ice, terminating in those cultivated vallies which border the great chain. In purifying this general survey, and moreover observing that the branches most contiguous to the central chain would present the same phenomena, only in a lesser degree, the glaciers would be obviously divided into two forts; the first occupying the deep vallies situated in the bosom of the Alps, and termed by the natives \textquoteleft Valles de Glace,\textquoteright distinguished by Mr. C. C. by the name of \textquoteleft Lower Glaciers:\textquoteright the second, which clothe summits and sides of the mountains, are denominated \textquoteleft Upper Glaciers.\textquoteright The former are much the most considerable in extent and depth. Some stretch several leagues; that of Des Bois in particular is more than 15 miles long, and above three in its greatest breadth. These lower glaciers do not communicate with one another, and few of them are parallel to the central chain. They mostly stretch in a transverse direction, being bordered at the higher extremity by inaccessible rocks, and on the other side extending into the cultivated vallies. Saulure found the general depth of the ice in the glacier des Bois from 80 to 100 feet; but there is reason to believe that its thickness in some places exceeds even 600 feet. These immense fields of ice usually rest on an inclined plane being pushed forwards by the pressure of their own weight, and weakly supported by the rugged rocks beneath, they are intersected by large transverse chains, and present the appearance of walls, pyramids, and other fantastic shapes, observed at all heights and in all situations, wherever the declivity exceeds 30 or 40 degrees. But in those parts where the plane on which they rest is nearly horizontal, or genteel inclined, the surface of the ice is nearly uniform; the chaflensfs are few and narrow, and they are crooked without much difficulty. The surface of the ice is less slippery than that of ponds or rivers; it is rough and granulated, and only dangerous to those who pass it in deep defcents. It is not transparent, is very porous, and full of small bubbles, and is of course less compact than common ice. Its perfect resemblance to the congelation of snow impregnated with water, in opacity, roughness, and the number as well as smallness of the air-bubbles, led Saulure to conceive the following simple and natural theory concerning the formation of the glaciers. An immense quantity of snow continually accumulates in the elevated vallies enclosed within the Alps, as well from that which falls from the clouds during nine months in the year, as from the mafles incessantly rolling from the steep sides of the circumjacent mountains. Part of this snow, not diffused during summer, impregnated with rain and snow-water, is frozen during winter, and forms that opaque and porous ice of which the \textquoteleft Lower Glaciers\textquoteright are composed. The \textquoteleft Upper Glaciers\textquoteright may be subdivided into those which cover the summits, and thole which extend along the sides of the Alps. The former owe their origin to the snow that falls at all seasons of the year, and which remains nearly in its primitive state, being compelled into a hard subsistance, and not converted into ice. The subsistance which cloths the sides of the Alps is neither pure snow, like that of the summits, nor ice which forms the Lower Glaciers, but an assemblage of both. It contains less snow than the summits, because the summer heat
has more power to dissolve it, and because the liquefied
flow descending from above, swells absorbs a larger
quantity of water. It contains more snow than the Lower
Glaciers, because the dilution of the snow is com-para-
tively less. Hence the ice is even more porous, opaque, less
compact than that of the Lower Glaciers, and of so doub-
ted a texture, as renders it, in many parts, difficult to
decide, whether it may be called ice or frozen snow. In a
word, there is a regular gradation from the snow on the
summits to the ice of the Lower Glaciers, formed by the
intermediate mixture, which becomes more compact and less
porous in proportion as it approaches the Lower Glaciers,
until it unites and affinitizes with them. And it is evident,
that the greater or lesser degree of density is derived from
the greater or lesser quantity of water, with which the mas
is impregnated.

It has been a contested point among naturalists, whether
the glaciers are in a state of increase or diminution. The
following observations may be alleged in proof of the lat-ter
alternative. In 1785, the interior ice of Grindelwald
was diminished at least 400 yards since the year 1776; in
the valley of Chamouny, the glacier called "les marmilles de
glace," from their resemblance to walls, and which rise in
very thick, foli'd, parallel ranges to a height of 150, or, as
some say, 400 feet above their real bed, and forming the
border of the glacier of Ballon, no longer existed, and
young trees had shot up in the parts which were there-fore
covered by the glaciers of Montanvert. The advocates for
the increase of the glaciers, notwithstanding these facts, appli-
cable, as they say, to the lower regions, assert, both from theo-
ry and observation, that more snow falls, and more ice is an-
ually formed in the Alps than can be annually dissoluted.
From theory they argue, that the cold occasioned by the mas
of ice already formed ought to augment it still further: and
from experience they deduce, that within the remembrance
of the present generation, many mountains have been cover-
ed, many pastures and habitations invaded, and many pas-
fages irrecoverably obstructed by the ice. In reply to the
argument from theory it is maintained, that the causes which
lead to the diminution of the ice are no less powerful than the
augmentation of the cold, which is first supposed to occur in
indistinct incursions, and finally invade and fix in the ele-
avated regions, evaporation, defacement of the snow and ice,
both precipitations and gradual heat of the atmosphere,
and mean temperature of the earth, which is always
above the freezing point, as is evident from the heat of
the springs which issue from the bowels of the earth. With
regard to the argument derived from experience, it is thought
sufficient to observe, that while the facts that prove the pro-
gress of the ice are admitted, it by no means seems to fol-
low, that its mass is perpetually increasing. For the ad-
vocates of this opinion, while they scrupulously enumerate the
places which have been invaded by the ice, do not take no-
tice of those parts, no less numerous, from which the ice
has receded. Upon the whole we have reason to conclude,
that if the collection of ice and snow gains in some places, it
is diminished in others, and that, upon an average, the ag-
gregate quantity is nearly the same. Cocks's Travels in
Switzerland, vol. ii.

GLACIES MARITI. See Specularis Lapidis.

GLACIS, in Building, an easy imperceptible slope or decliv-
ity. The defect or inclination of the glacis is less steep
than that of the talus. In gardening a defect sometimes
begins in talus, and ends in glacis.

The glacis of the corniche is an easy imperceptible slope in
the cymatium of the corniche, to promote the defect and
drain off the rain-water.

GLACIERS, in Fortification, is particularly used for that of
the covert-way, being a sloping bank, which reaches from
the parapet of the covert-way, or covert-way, to the level
side of the field, at the distance of about twenty
fathoms.

The construction of the covert-way and glacis is more dif-
tinctly illustrated in Plate V. Fortification, fig. 6. When
the body of the place, and all the necessary out-works are
constructed, lines are drawn parallel to the outermost con-
terforcas of the ditches, at six toises distant from it; and
the space m n m, included between that line and the con-
terforca, will be the covert-way required. If lines are
drawn parallel to the lines which terminate the covert-way,
and the places of arms m n, &c. at twenty toises distant
from them, the space x y z between these lines will be the
glacis. A, in this figure, represents the arrow: B, the
detached redoubt; e, the travelles; z, the sally-
ports. When the ground is low, and water to be found,
there is often a ditch of about ten or twelve toises made round
the glacis; beyond which there is a second covert-way of four
toises, with travelles and places of arms, and a final glacis
from fifteen to eighteen toises broad. Muller's Fort. p. 42.
See Military Construction.

GLADBACK, or GLADBACH, in Geography, a town of
Germany, in the circle of Wellphalia, and duchy of Juliers; 16 miles N. of Juliers. N. lat. 51° 14'. E. long.
6° 15'.

GLADDON, or GLADWIN, the name of a plant, other-
wise called fpargewort.

GLADE, in Agriculture, Gardening, &c. a villa, or
open and light passage made through a thick wood, grove,
or the like, by lopping off the branches of trees along the
way.

GLADE, in Zoology. See Glad.

GLADENBACH, in Geography, a town of Germany,
in the principality of Upper Hesse; 12 miles N. of Gie-
ßen.

GLADIATORS, in Antiquity, persons who were re-
tained to fight ordinarlly in the arena, for the entertain-
ment of the people.

The gladiators were usually slaves, and condemned crimi-
inals, who fought from necessity; though, sometimes, free-
men made profession of this practice, like our prize-fighters,
for a livelihood. After a slave had served on the arena three
years, he was dismiffed.

The Romans borrowed this cruel diversion from the Asis-
tics: some suppose that there was policy in this practice,
the frequent combats of gladiators tending to accustom the
people to despise danger and death.

The origin of such combats seems to be as follows: From
the earliest times with which we have any acquaintance with
profane history, it had been the custom to sacrifice captives,
or prisoners of war, to the names of the great men who had died
in the engagement; thus Achilles, in the Iliad, b. xxiii.
sacrifices twelve young Trojans to the names of Patroclus;
and in Virgil, lib. x. ver. 81. Aeäus leads captives to
Evaier, to be sacrificed at the funeral of his son
Pallas.

In course of time they came also to sacrifice slaves at the
funerals of all persons of condition; this was even effec-
ted a necessary part of the ceremony: but, as it would have
appeared barbarous to have sacrificed them like beasts,
they were appointed to fight with each other, and endeavore
to save their own lives by killing their adversaries. This
seemed somewhat less inhuman, because there was a possi-
Bility of avoiding death by an exertion of skill and
courage.

This
This occasioned the profession of gladiator to become an art; hence arose masters of arms, and men learned to fight and exercise this art.

These masters, whom the Latins called lanista, bought slaves to be trained up to this cruel trade, whom they afterwards sold to such as had occasion to present the people with so horrible a show.

They were at first performed near the sepulchre of the deceased, or about the funeral pile, but were afterwards removed to the circus and amphitheatres, and became public spectacles. See BUSTUARIUS.

The first show of gladiators, called manus gladiatorum, was exhibited at Rome, according to Valerian Maximus, by M. and D. Brutus, upon the death of their father, in the year of the city 483; though Livy (ix. 40) speaks of it in the 444th year of Rome, as practiced among the Campanians. On the exhibition by M. and D. Brutus, there were probably only three pairs of gladiators; in the year of Rome 537, the three sons of M. Emilius Lepidus the augur, who had been three times confidé, entreated the people with the cruel pleasure of seeing twenty-two gladiators fight in the forum; and the show continued three days. In the year of Rome 541, the first Africanus diverted his army at New Carthage with a show of gladiators, which he exhibited in honour of his father and uncle, who had begun the reduction of Spain. In the 452d year the sons of M. Valerius Laevinus exhibited 25 pairs of gladiators; and in 569, 75, and in 578, 74 fought on the like occasion. In process of time, the Romans became so fond of these bloody entertainments, that not only the heirs of any great and rich citizen lately deceased, but all the principal magistrates, pretented the people with shows of this nature, to procure their affections. The divi, pretors, consuls, and, above all, the candidates for offices, made their court to the people, by entertaining them frequently with these fights: and the priës were sometimes the exhibitors of the barbarous shows; for we meet with the ludi pontifices in Suetonius, August. cap. 44, and with the ludi sacrorum, in Pliny, Epit. lib. viii. As for the emperors, it was so much their interest to gratify themselves with the populace, that they obliged them with combats of gladiators almost upon all occasions, and as they increáed, the number of combatants increáed likewise. Accordingly, Julius Caesar, in his adlocutio, diverted the people with three hundred and twenty couple; Gordian, before he was emperor, gave these shows twelve times in a year. In some of these there were 500 pairs of gladiators, and never less than 50.

Germanicus and Claudius, both sons of Drusus, gave combats of gladiators in honour of their father. Nero's and Domitian's combats of gladiators are noticed in the sequel of this article. Otho employed 2000 gladiators in the war against Vitellius (A.D. 69), and Vitellius hired gladiators to fight in all the streets of Rome for the amusement of the people. The inhuman fights of gladiators, though long authorized by custom, afforded no pleasure to Vestal. Titus, however, exhibited a show of gladiators, wild beasts, and representations of sea-fights, which lasted a hundred days; and Trajan continued a solemnity of this nature for a hundred and twenty-three days, during which time he brought out ten thousand gladiators. And Adrian, on his first visit to Rome, after his promotion to the empire, gave combats of gladiators for six days successively. Before this time, under the republic, the number of gladiators was so great, that when the conspiracy of Catiline broke out, the senate ordered them to be dierated into the garrison and secured, lest they should have joined the disaffected party. See GLADIATORS' War.

Thefe sports were become so common, and their consequences, in a variety of respects, so dangerous, that Cicero preferred a law, that no person should exhibit a show of gladiators within two years before he appeared candidate for any office. Julius Caesar ordered, that only a certain number of men of this profession should be in Rome at a time. Augustus decreed, that only two shows of gladiators should be presented in a year, and never above sixty couple of combatants in a show. And Titus provided by an order of council, that no person should have the privilege of gratifying the people with such a solemnity, unless he was worth four hundred thousand sestertii. They were also considerably regulated by Nerva.

The emperor Claudius restrained them to certain occasions; but he soon afterwards annulled what he decreed, and private persons began to exhibit them at pleasure, as usual: and some carried the brutal satisfaction so far, as to have them at their ordinary feasts.

And not slaves only, but other persons, would hire themselves to this infamous office.

The matter of the gladiators made them all first swear, that they would fight to death: and if they failed, they were put to death, either by fire, or swords, clubs, whips, or the like.

It was a crime for the wretches to complain when they were wounded, or ask for death, or seek to avoid it, when overcome; but it was usual for the emperor, or the people, to grant them life, when they gave no signs of fear, but waited the fatal stroke with courage and intrepidity: Augustus even decreed, that it should always be granted them. But fear and want of spirit were very rare on occasions of this kind; infomuch, that Cicero more than once propounds the principle of honour which actuated the gladiators as an admirable model of courage and constancy; by which he intended to animate himself and others, to suffer every thing for the preservation of liberty and the defence of the commonwealth. (Tusc. ii. 44, Philip. ii. 35.)

From slaves and freedmen, the inhuman sport at length spread to people of rank and condition; so that Augustus was obliged to issue a public edict, that none of the senatorian order should become gladiators: and soon after he laid the same restraint on the knights; nevertheless, Nero is related to have brought upwards of four hundred fenators, and six hundred Roman knights upon the arena; though Lupus takes both those numbers to be falsified, and, not without reason, reduces them to forty fenators, and sixty knights. Not only fenators, but even women of quality, bought in public in one of Nero's combats of gladiators. On occasion of the triumph of Probus, A. D. 281, about four-score gladiators, together with near 600 others, exhibited the most desperate courage, for the inhuman sports of the amphitheatre. Dismaying their blood for the amusement of the populace, they killed their keepers, broke from the place of their confinement, and filled the streets of Rome with blood and confusion. After an obstinate resistance, they were overpowered and cut in pieces by the regular forces; but they obtained at least an honourable death, and the satisfaction of a just revenge (Zosimus, l. i. p. 66.); yet Domitian, that other monster of cruelty, refined upon Nero, exhibiting combats of women in the night-time.

Before Rome was become the capital of the known world, Antiochus Epiphanes, king of Syria, in imitation of the Romans, had introduced the combats of gladiators in his dominions. It is remarkable, however, that the Athenians, who were naturally beneficent and humane,
GLADIATORS.

never admitted bloody shows into their city: and when it was proposed to establish combats of gladiators there, in order not to give place to that respect to the Corinthians, "Vide Juv.," exclaimed an Athenian in the midst of the assembly, whose name was Demoxus, a famous philosopher, who flourished in the reign of Marcus Aurelius, "the altar which our forefathers above a thousand years ago erected to Mercury."

Some Pagan emperors, lamenting the bad effects of this savage custom, endeavoured, as we have already seen, to moderate it. With this view Marcus Aurelius restrained the enormous expenses employed in these combats, and would not suffer the gladiators to fight with each other, except with very blunt swords, like foils; so that they might throw their address, without any danger of being killed. But the honour of suppressing these combats was reserved for Christianity; and it cost many efforts and much time to effect this purpose. So rooted was the evil, and so much had it established itself by the long prescription of many ages, and the opinion of the world, that these combats were acceptable to the gods, to whom, for that reason, they offered the blood of gladiators lately shed, by way of sacrifice, as several of the Christian fathers observe.

Constantine the Great is said to have first prohibited the combats of gladiators in the East; at least, he forbade those who were condemned to death for their crimes to be employed; there being an order still extant to the prefects pretorii, rather to send them to work in the mines in lieu thereof; it is dated at Berytus, in Phoenicia, the 11th of October, 325.

But, notwithstanding this edict, which condemned the art and amusements of shedding human blood, the heinous law expressed the wishes of the prince, without reforming an inveterate abuse, which degraded a civilized nation below the condition of savage cannibals. Several hundred, perhaps several thousand, victims were annually slaughtered in the great cities of the empire; and the month of December, more peculiarly devoted to the combats of gladiators, still exhibited to the eyes of the human people a grateful spectacle of blood and cruelty. Amidst the general joy of the victory at Pollentia, gained by the emperor Honorius, Prudentius, a Christian poet, exhorted the emperor to extirpate, by his authority, the horrid custom which had so long inflicted the voice of humanity and religion. The pathetic representations of Prudentius were less effectual than the generous boldness of Telenachus, an Asiatic monk, whose death was more useful to mankind than his life. The Romans were provoked by the interruption of their pleasures; and the rash monk, who had defended into the arena, to separate the gladiators, was overwhelmed under a shower of stones. But the madness of the people soon subsided; they respected the memory of Telenachus, who had defied the honours of martyrdom; and they submitted, without a murmur, to the laws of Honorius, which abolished for ever the inhuman sacrifices of the amphitheatre. The citizens, who adhered to the manners of their ancestors, might perhaps intimate, that the last remains of a martial spirit were preserved in this school of fortitude, which accustomed the Romans to the sight of blood, and to the contempt of death—a vain and cruel prejudice, so foolishlyconfirmed by the value of ancient Greece, and of modern Europe.

It must be observed, however, that the practice was not entirely abolished in the West before Theodoric, King of the Ostrogoths. Honorius, on the occasion first mentioned, had prohibited them; but the prohibition does not seem to have been executed. Theodoric, in the year 526, abolished them finally.

Some time before the day of battle, the person who presented the people with the shows gave them notice thereof, by programmes, or bills, containing the names of the gladiators, and the marks whereby they were to be distinguished; for each had his formal badge, which was, most commonly, a peacock's feather, as appears, from the Scholia of Juvener, on the 15th verse of the third Satire, and Tuirnebus Adver. lib. ii. cap. 8.

They also gave notice what time the shows would last, and how many couples of gladiators there were; and it even appears, from the 53d verse of the seventh Satire of the second book of Horace, that they sometimes made representations of these things in painting, as is practiced among us by those who have any thing to show at faire.

The day being come, they began the entertainments by bringing two kinds of weapons: the first were flaves, or wooden files, called rudes; and the second were effective weapons, as swords, poniards, &c.

The first were called arma laesio, or excercitatoria; the second decreatoria, as being given by decree or sentence of the prator, or of him at whose expense the spectacle was exhibited. They began to fence or skirmish with the first, which was to be the prelude to the battle; and from these, when well warmed, they advanced to the second, at the sound of the trumpets, with which they fought naked.

Then they were said vertere arma; the terms of flinking were petere and petere; of avoiding a blow, elire; and when one of the combatants received a remarkable wound, his adversary or the people cried out, habes, or habes.

The first part of the engagement was called ventilate, praelirter; and the second, dimicari ad victoriam, or vertere arma fregare; and some authors think, with much probability, that it is to these two kinds of combat that St. Paul alludes, in the passage 1 Cor. iv. 26, 27. "I fight, not as one that heareth the air; but I keep my body, and bring it into subjection."

If the vanquished surrendered his arms, it was not in the victor's power to grant him life; it was the people during the time of the republic, and the prince or people during the time of the empire, that were alone empowered to grant the boon.

The reward of the conqueror was a branch of palm-tree, and a sum of money; probably collected among the spectators; sometimes they gave him his congé, or dismissed him, by putting one of the wooden foils or rudi in his hand; and sometimes they even gave him his freedom, putting the plumes on his head.

The sign or indication whereby the spectators showed that they granted the favour, was fretum pollicium, which M. Dacier takes to be a clenching of the fingers of both hands between one another, and holding the two thumbs upright, close together; and, when they would have the combat finished, and the vanquished slain, they verterunt pollicium, bent back the thumb; which we learn from Juvenal, Sat. iii. ver. 36.

"Munera nume edunt, et verfo pollicie vulgi Quemlibet occident populariter." Juv.

The gladiators challenged or defied each other, by flewing the little finger; and, by extending this, or some other, during the combat, they own themselves vanquished, and beggred mercy from the people: *Vidit odenan digiti vertit um populo polliciabatur," says the old Sclavish on Per-

"Munera nume edunt, et verfo pollicie vulgi Quemlibet occident populariter." Juv.

GLA

There were divers kinds of gladiators, distinguished by their weapons, manner, and time of fighting, &c. &c.

The andabates, of whom we have already given an account under ANDABATE.

The caturarii, who always fought in troops or companies, number against number; or according to others, who fought promiscuously, without any certain order.

Lip. Saturn. lib. ii. cap. 16.

The conumbrati, whom authors mention as a species of gladiators, the fame with the radulirii and veteranii; founding the opinion on a passage in Pliny, lib. viii. cap. 7. But Lippius shews, that they have maltreated Pliny. Saturn. lib. ii. cap. 16. and Turneb. Advers. lib. xxx. cap. 36.

The cubicularii, which are a little precarious, being chiefly founded on a passage in Lampadius, in the life of the emperor Commodus: "Inter hæc, habuit victimæm, victimas immolavit, in arena rudibus, inter cubicularios; gladiatores pugnavit lucentibus aliquando murmuros."

Turnebus reads radulirii instead of cubicularius; and understands it of those who had been dismembered, and could no longer be obliged to fight, except with foils.

Salmianus reads gladiator; and refers it to the emperor, who fought not only on the arena, and with foils, or blunted instruments, but at home, with his servants and valets de chambre, and with sharpers.

Lippius will have nothing altered in the text: <the gladiatores cubicularii> he observes, were those who fought at private houses, during feasts, &c. &c.

Accordingly, Dion says, that the Commodus sometimes fought at home, and even killed some persons in such recreations; but that, in public, he only fought with blunted weapons.

The dimaches, who fought armed with two poniards, or swords; or with sword or dagger. Lip. Saturn. lib. ii. cap. 13.

The effedaris, who fought in cars; called also, in an inscription lately discovered at Lyons, affedaris. Saturn. ferm. lib. ii. cap. 12.

The fistasles, or Cesariani, who belonged to the emperor's company; and who, being more robust and dexterous than the reff, were frequently called for, and therefore named allo popolatitii. Saturn. lib. ii. cap. 16.

The other kinds were, the kaplmachii, meridiani, myrmidones, ordinaries, pinutras, provocatores, retardil, radulirii, Sammites, sectores, fpedidores, and Turvani: which see described under Meridiani, Rettaihi, Sectores, &c.

Some authors, and particularly Vigeniere on Livy, rank the obsequentes, mentioned by Spartan, in his life of Marcus Aurelius, among the number of gladiators; Lippius ridicules him. Saturn. lib. ii. cap. 12. and with some reason: the obsequenter properly were the troops which that emperor raised among the gladiators; or whom of gladiators he made foldiers.

GLADIATORS' war, bellum Gladiatororum, or Spartacianum, called also the slave war, was a war which the Romans sustained about the year of their city 680. Spartanus, Oenoas, having escaped with other gladiators, to the number of seventy-four, out of the place where they had been kept at Capua, gathered together a body of slaves, put themselves at their head, rendered themselves masters of all Campania, and gained several victories over the Roman pretors. At length they were defeated, in the year 682, at the extremity of Italy; having, in vain, attempted to pass over into Sicily.

This war proved very formidable to the Romans.

Crasius was not able to subdue it: the great Pompey was forced to be sent as general.

GLADIATOR, dying, is a most valuable monument of ancient sculpture, which is now preserved in the palace of Cligeti. This man, when he had received the mortal stroke, is particularly careful, ut pacentur homines, that he might fall gracefully; he is seated in a reclining posture on the ground, and has just strength sufficient to support himself on his right arm; and in his expiring moments, it is plainly seen that he does not abandon himself to grief and dejection, but is solicitous to maintain that firmness of aspect, which the gladiators valued themselves on preferring in this scene of danger, and that attitude which they had learnt of the matters of defence. His fears not death, nor seems to betray any tokens of fear by his countenance, nor to fixed one tear; "quis mediciosis gladiators ingenuit, quis victum mutavit unquam, quis non modo detexit, verum etiam decubuit turpiter," says Cicero, in that part of his Tusculan, where he is describing the astonishing firmness of these persons. We fee, in this instance, notwithstanding his remaining strength, that he has but a moment to live, and we view him with attention, that we may fee him expire and fall: thus the ancients knew how to animate marble, and to give it almost every expression of life.

GLADIOLE, in Beny. See Butomus and Lobelia.

Gen. Ch. Cal. Spatha inferior, shorter than the corolla, of two oblong permanent valves; the outermost larger, enclosing the inner one. Cor. of one petal, superior; tube cylindrical, swelling upwards, curved; limb somewhat bell-shaped, irregular, in fixed deep, oblong, slightly spreading, unequal segments, the upper and lowermost either without or within the lateral ones. Stam. Filaments three, inserted into the mouth of the tube, thread-shaped, ascending, shorter than the corolla; anthers ovate, incumbent. Pelt. Germ. inferior, triangular; style thread-shaped; stigma three, spreading, folded, recurved, obtuse, downy. Peric. Capsule ovate, triangular, obtuse, thin, of three cells and three valves. Seeds numerous, smooth, surrounded with a membranous wing.

Twelve-four species of this genus are defined in the 14th edition of Linnæus's Systema Naturæ, of which the rume- tus pull, Sp. Pl. 53, belongs, we believe, to Asia, or some of its near allies. Willdenow makes 50 species, but Mr. Ker (late Gawler) has, we think, with great propriety, established the old genus Ixionitis, to which none of them are removed; while others go to his Tritonia or eliwhare, so that he names but 28 species in Sims and Konig's Annals above quoted. He is followed by Mr. Dryander in the new edition of the Hortus Kewensis, except with regard to his hirsutus, there called hirsutius, after Willdenow and Jacquin; while a most distinct species figured in Curt. Mag. t. 574, by Mr. Ker as a variety of hirsutus, is properly retained as being the true hirsutus itself. Five of Mr. Ker's species are not found in Hort. Kew.

We judge it necessary to give a view of the whole genus in
GLADIOLUS.

its reformed fate, adding the Linnean G. inbriecus to what the above-mentioned writers have defined.

1. **G. Convallaris.** Curt. t. 51. (Antholyza Convallaria; Linna. Sp. Pl. 54. Vahl. Enum. v. 2. 121. Curt. Mag. t. 345. Redout. Lil. t. 12.)—Leaves linear-fork-shaped. Upper segment of the corolla very long; lower very small. Native of the Cape of Good Hope, nor does it appear to grow, as Linneus asserts, in Peru. Removable for the vivid heart of its fragrant and beautiful flowers, the three upper segments of whole corolla are broadly elliptical and vultured, the middlemost projecting far beyond the other two; while the three lower are very small, and greenish. This is a hardy green-house plant. See Antholyza, n. 3.

3. **G. quadrangulata.** Ker in Curt. Mag. t. 567. (G. abbreviata; Andr. Repof. t. 166. Antholyza quadrangularis.) Bayl. Fl. Cap. According to Mr. Ker, “Leaves with four angles and four furrows. Upper segment of the corolla very long; lower very small and sharp.”—Imported from the Cape of Good Hope, by those excellent cultivators Meffrs. Lee and Kennedy in 1799. It first flowered with them in March 1801. The quadrangular leaves distinguish this from most others, except the trifflis, n. 10, and formabilis, n. 7; the flowers more agree with G. Convallaria, at least in their large vaulted upper segment, but all the lateral segments are extremely short, obtuse and acute, the lowermost being the leaf of all. The tube is yellow streaked with orange; large segment of the limb purplish; all the rest variegated with dull green and brown. According to the Linnean idea of hybrid species, this might be classified to have originated from G. Convallaria impregnated by G. trifflis.

4. **G. galactus.** Andr. Repof. t. 122. (G. nanaqueinis; Ker in Curt. Mag. t. 552.)—Upper segment of the corolla vaulted; two lateral rhomboids; three lower pendulous, flatulate, blunt with a little point. Leaves coriaceous, ovate. Native of the Namby country, a confiderable distance from the Cape of Good Hope; easily propagated by seeds or offsets, and blooming freely. The leaves are very thick, many-rhribed, obovate, obtuse, curved or oblique. Stem low, bent or zig-zag, covered with bracteas and flowers. The latter are large and flowy, their three narrow dropping lower segments, each half green half scarlet, strikingly contrasted with the large broad upper ones, which are of a rich scarlet, green white and purple at the base. No authority can induce us to prefer such a specific name as nanaqueinis, it being contrary to rule as the name of a country, and to peculiar barbarous in style. The G. galactus of Jacquin is Sparrman galata of Ker.

5. **G. albus.** Linna. Sp. Pl. 53. Herb. Linna. Andr. Repof. t. 8. Ker in Curt. Mag. t. 586.—Upper segment of the corolla obvolute, recurved; two lateral rhomboids; three lower pendulous, flatulate, pointed. Leaves rigid, lanceolate. Common about the Cape of Good Hope; easily encrusted by leaves or bulbs, but rarely flowering with us. Bears a considerable resemblance to the last in form and colors, but the leaves are narrower and very differently shaped, the lower segments of the corolla more lanceolate, the upper one reflexed. Linneus once called this species lobalis, but his son changed it to albus, in allusion to the wing-like lateral segments.

6. **G. virens.** Ker in Curt. Mag. t. 688. (G. albus; Jacq. Inc. Rat. t. 259. G. ochridiflorus; Andr. Repof. t. 241.)—Upper segment of the corolla flatulate, arched, incurved; two lateral rhomboids; three lower flatulate, pendulous, acute. Leaves straight, linear-fork-shaped. Native of the Cape; rare in our collections. Plinnet's rude figure, t. 224. f. 8, is supposed to belong to this species rather than to the last, for which it is quoted by Linneaus. This differs from the two preceding in having long erect narrow leaves, and flowers variegated with dull green and purple, which are luciously fragrant. The stem is tall, and sometimes branched.

7. **G. penduliflorus.** De la Roche Diff. t. 27. t. 2. Ker in Ann. of Bot. v. 1. 121.—Leaves awl-shaped, quadrangular, erect. Upper segment of the corolla broadest, vaulted, undulated; two lateral narrow-rhomboid; three lower flatulate, acute, recurved at the points. Native of the Cape of Good Hope. We know it only by De la Roche's figure and description. He says the flowers are of a very pale violet, diluted with purple and yellow. The name alludes to their being pervious between the segments, but this is not peculiar. That fpposed variety of trifflis, figured by Jacquin, Inc. Rat. t. 244, seems to be very near the present species.

8. **G. varfoeder.** Ker in Curt. Mag. t. 1642 and 564. Andr. Repof. t. 19.—Leaves linear-fork-shaped, with three ribs on each side. Segments of the corolla longer than the tube, pointed, recurved.—Native of the Cape, from whence it was received by Meffrs. Lee and Kennedy in 1794. Its flowers are among the largest of its genus, with peculiar long undulated recurved segments, and are remarkable for changing colour several days successively. In the morning it is of a purplish brown, but becomes grey in the course of the day, and finally of a light blue in the evening. The most wonderful, and, as far as we know, unique circumstance is, that the original brown hue returns in the course of the night, and this happens for nine or ten following days. There are moreover some varieties of colour observable in different plants, some assuming more of a yellow hue. It differs essentially from the following in having a fork-shaped, not a quadrangular, keel.

9. **G. trifflis.** Linna. Sp. Pl. 53. Ker in Curt. Mag. t. 272. t. 158. Inc. Rat. t. 245 and 244. (Liliajgladiolus bifolius et bivlorus, folis quadrangulis; Trew. Ebrct. t. 39.)—Leaves with four angles and four furrows. Segments of the corolla nearly equal, pointed.—Frequent at the Cape, and not uncommon in our green-houses, where it is jufly admired for its rich evening scent, like a pink, or a bergamot pear, especially in the most common or partly-colored variety, to which the first-quoted figures of Curtis and Jacquin refer. The deeply furrowed quadrangular leaves, like those of the Snake's head Iris, tuberosa, distinguish it clearly from the last, for which Mr. Ker, we presume by mistake, quotes Jacquin's t. 245. He likewise cites and blames Trevis Ehret as the yellowish variety, which is a fine plate, though rather too pink, of the particoloured one.

10. **G. hyalinas.** Jacq. Inc. Rat. t. 242. Ker in Ann. of Bot. v. 1 t. 231. Willd. Sp. Pl. v. 2. 211.—Leaves linear, erect, the length of their joints. Segments of the corolla ovate, acute; the uppermost largest, erect.—Native of the Cape. Jacquin says it flowered with him in December. We do not find it in the Hortus Kewensis, but Hortus Curtius.
GLADIOLUS.

Cantabrigiensis, nor have we seen any specimen. The short, upright, filiform leaves are remarkable. The flowers are smaller than in the two last, scented; the base of their segments semi-transparent, the extremities yellowish, slightly rippled and dotted with purple. The upper segment is by far the largest; the others gradually smaller, to the lower one, which is leaf of all. Tube funnel-shaped, semi-elliptical, very pale purple, as long as the largest segment. —Jacquin first called this species *fritizi* : see Collect. v. 4. 170.

11. G. tenellus. Jacq. C. R. t. 248. Coll. v. 3. 255; and v. 4. 169, t. 3. 1. Ker in Ann. of Bot. v. 1. 231.—Leaves linear, convoluted, smooth. Stem zig-zag. Segments of the corolla elliptical, bluish, nearly equal, shorter than the tube. Native of the Cape. Jacquin, from whole figures alone we are acquainted with this plant, says it bloomed with him in November. The stem is a spath high, curved and zig-zag. Flowers one or two, yellowish, more or less variegated with pale purple, slender, about an inch and half long.

12. G. fimbriatus. Thunb. Diff. 18. Linn. Suppl. 96. Ker in Ann. of Bot. v. 1. 231 —"Leaves linear-brilliate-shaped, Corolla ringent. Stem bracted." —Native of the Cape of Good Hope. "Stem bearing many spikes of flowers; very rarely simple; upright, somewhat zig-zag, four inches high; branches round and erect. Lower about three, linear-lanceolate, the upper ones gradually shorter; the lowermost as tall as the stem. Flowers alternate, white, ringent; their tube scarcely longer than the spatha." —Thunb.

13. G. gratilis. Jacq. C. R. t. 246. Ker in Curt. Mag. t. 562.—Leaves linear, ribbed, deeply furrowed on each side, with a very light midrib. Corolla somewhat bell-shaped; segments ovate, nearly equal —Native of the Cape, readily cultivated with us, blooming in March or April. Flowers watery, pale blue, more or less speckled with black and white on the two lower lateral segments; without scent. Bulb very small. Stem variously bent, slender, two or three feet high.

14. G. recurvus. Linn. Mant. 28. Ker in Curt. Mag. t. 578. (G. carinatus; Willd. Sp. Pl. v. 1. 211. Ker in Ann. of Bot. v. 1. 231. G. panducatus; Jacq. C. R. t. 247. G. ringens; Andr. Repof. t. 27 and 227. Redout. Lith.-Lilles, t. 123. G. alatus; Schneck. C. t. 12.)—Leaves linear, flat; rib prominent on each side. Radical sheath speckled. Segments of the corolla nearly equal, ovate, recurved. —Native of the Cape, cultivated and badly figured by Miller, and now frequent in gardens, where it is valued for the fine violet fragrance of its blue and yellow blossoms, more than even for their beauty or size, which equals that of most species. The leaves have a strong rib, prominent on each side, and the first sheath from the root is curiously speckled with brown, like the flasks of *Arum Dracunculus*. Thunberg confounded this and *gratilis* with *frizio*.

15. G. brevitus. Jacq. C. R. t. 249. Dryand in Curt. Mag. t. 592; and t. 727. G. carneus; Andr. Repof. t. 240.—"Leaf of the barren bulb solitary, linear, slightly downy; of the flowering one feehernay. Corolla somewhat ringent." —Native of the Cape, readily cultivated and encouraged with us. The flowers are, among the smaller sized, all bearing one way; variously tinged with pale purple or rose-colour, with some yellow; their three lower segments most speckled, and nearly of equal size, the uppermost one rather large, vaulted, recurved at the summit. The leaves are minutely downy, upright, linear or slightly lanceolate; very short, or rather mere scales, on the flowering stem; solitary and larger on the bulb, which produces no flowers.

16. G. biflora. Jacq. C. R. t. 250. Dryand in Curt. Mag. t. 574. (G. roseeus; Andr. Repof. t. 11.)—"Leaves linear sword-shaped, downy. Corolla nearly regular." —Native of the Cape; introduced into our green-houses in 1795, when it first flowered in the collection of Mr. Orde at Fulham. The broadish, downy, red-edged leaves are remarkable. The flowers are large and fragrant, rose-coloured; their segments elliptical, pointed, nearly equal. Jacquin's figure is indeed a poor one, but we can scarcely suppose, with Mr. Andrews, that it is drawn from a dried specimen, as the author says it flowered in his green-house, nor does he, like Pallas, often practise this without acknowledgment.

17. G. fimbriatus. Thunb. Diff. 9 t. 1. Linn. Suppl. 95.—Leaves linear, involute. Corolla ringent; segments elliptical-lanceolate, nearly equal, shorter than the tube. Stem zig-zag.—Gathered at the Cape by Thumberg, from whom we have a wild specimen. The stem is a spath high, irregularly curved, and zig-zag. Leaves feathery, short, linear, acute, smooth, involute. Spadix large, feeling, sharply pointed. Flowers very pale pink-coloured, with red ribs; tube capillary, an inch and half long; segments of the limb narrow, nearly equal in size, but ringent.

18. G. carneus. Jacq. C. R. t. 255. Ker in Curt. Mag. t. 591. (G. cistidatus; Andr. Repof. t. 147. Redout. Lith. t. 36.)—Leaves sword-shaped, many-ribbed. Segments of the corolla shorter than the tube: the uppermost broadest, with an involute recurved point; the three lower narrowest, well-ribbed. —Native of the Cape. A tall and handsome plant, with several many-ribbed leaves. Flowers inodorous, two-ranked, large, fusc-coloured with a rosy hue; their three lower segments oblong, bluish, each marked with a red rhomboid central spot; the three upper broadest, especially the top one, with long recurved points, whole edges are involute. The tube is slender, longer than the limb, twice as long as the spatha. This freely flowering species is a desirable ornament for the green-house in the spring.

19. G. cistidatus. Jacq. C. R. t. 257. Ker in Curt. Mag. t. 582. Redout. Lith. t. 176. Andr. Repof. t. 219. (G. undulatus; Linn. Mant. 27.)—Leaves sword-shaped, many-ribbed. Segments of the corolla half the length of the tube, nearly equal, pointed, undulated, reflexed. —Native of the Cape; now become pretty frequent in gardens, for the sake of its elegance of form and colour, and its fragrance in an evening. The very long narrow segments of the corolla, each of which has a recurved, channelled, undulated point, and the much greater length of the tube, are striking characters. The colour is pale greenish yellow, or buff, with a remarkable lanceolate spot, blazed with purple and red, on each of the three lower segments. Anthers deep blue. The Linnaean name ought to have been retained for this species, but to change the present appellation would now cause more trouble than advantage.

20. G. blanctus. Curt. Mag. ed. 2. v. 1. 98. Ker in Curt. Mag. t. 625. 643. 648. Andr. Repof. t. 99. (G. carneus; Del. Rev. Collet. 50. t. 4. Redout. Lith. t. 65. G. albida; Jacq. C. R. t. 255. G. composita; Andr. Repof. t. 188.)—Leaves many-ribbed. Tube of the corolla shorter than the spatha, equal to the limb, which is ringent, bell-shaped; its upper segment conic; three lower narrow, spotted. —Native of the Cape. Succedaned with us in the open ground, but the bulbs must be taken up every year. —This is an elegant species, with...
leaves of the sword-shaped many-ribbed kind like the two last. The flowers vary in colour, from white to a pale pink, their three lower segments bearing each generally a pair of crimson spots. They vary also in size, sometimes varying in this respect with the larger ones. They have no scent.

We cannot but complain of those authors who burden the public with figures of trifling varieties of this and other plants, for which a single plate ought to have been sufficient; nor does the centinences of a new name, though it may conceal the implication, by any means store for it.

Jacq. IC. Rar. t. 252. Ker in Curt. Mag. t. 602. Andr. Repol. t. 589. Mill. IC. t. 142. f. 2. — Leaves linear; midrib prominent on each side. Tube of the corolla longer than either spathe or limb; three lower segments ovate; three lower each marked with a triangular spotted scale. — Native of the Cape, from whence it was early introduced into the Dutch gardens. It is readily increased, but does not flower freely, otherwise its elegance could not fail to render it a general favourite. The narrow leaves, compared with those species nearest akin to this, and especially the three spade-like marks of the blossom, which are confluent, mark it sufficiently.

22. G. undulatus. Jacq. IC. Rar. t. 251. Ker in Curt. Mag. t. 538. 647. Schenck. IC. t. 19. Redout. Liliac. t. 121. (G. frutet. Andr. Repol. t. 111.) — Leaves sword-shaped, many-ribbed. Flowers erect, funnel-shaped; segments wavy, bluish; three lower ones much the smallest. — Native of the Cape; often cultivated in our gardens. The leaves are numerous, broad and upright. Flowers yellowish-white, or pale bluish-coloured, each segment always marked with a deep crimson central stripe which runs down into the tube. The latter is seldom longer than the spathe, often shorter. — The name of undulatus, which Linnaeus applied to our cupulatius, has been misapplied to this, with which however it agrees tolerably well, and we have already given our reason for retaining it. This species is the angustif of Thumberg, an appellation which seems corrupted from angustif, a totally different plant in every possible respect, nor are his quotations of Breynius, and of Linn. Mant. left erroneous. There is no end of correcting indifferent names, but undulatus ought, as Mr. Ker now allows, to have remained with the Linnean plant; if so, undulatus, in allusion to the somewhat familiar Armorvilia undulata, might have served for the species before us, though indeed it also suits the following.

23. G. floribundus. Jacq. IC. Rar. t. 254. Ker in Curt. Mag. t. 618. (G. grandiflorus; Andr. Repol. t. 118.) — Leaves sword-shaped, many-ribbed. Flowers erect, funnel-shaped; segments nearly equal, flatish, emarginate, the uppermost broadly rounded. — Native of the Cape; introduced into England by Lee and Kennedy in 1788. Bulb large. Leaves broad, with a thick edge, and often falcate. Flowers numerous, generally larger than in most other species, very pale pink, blue, or white, with a dark central stripe to each segment. The summits of the segments are emarginate, with a little point, and they are usually at undulatus.

24. G. Millari. Ker in Curt. Mag. t. 632. Alt. Hort. Kew. ed. 2 v. t. 101. (Antheion, &c; Mill. IC. t. 49.) — Leaves with many prominent ribs. Flowers inclining one way, bell-shaped; nearly regular; upper segment rather narrower than the next; tube flabby, slender. — Native of the Cape, but rare in gardens. Millar raised it from seed in 1757, and figured it as in Anthrop., It is of the same tribe as the two last, but differs in having a more inclined and more equal corolla, at full white then yellowish, with a darker purplish central stripe on the three lower than on the three upper segments. The tube, according to Mr. Ker's remark, though externally slender and exactly cylindrical, is peculiarly flabby, resembling a flower-flank. The outer perianth is inflated and convolute, often longer than the tube.

25. G. cardinalis. Curt. Mag. t. 155. Schenck. IC. t. 27. Redout. Liliac. t. 112. — Leaves many-ribbed. Stem branched. Flowers erect, in one row, funnel-shaped; segments elliptical; three lowermost small, each with a lanceolate white spot. — Native of the Cape, from whence it was brought to Holland, and from the latter country to England by Mr. Grafft; before 1789, unites we are greatly mistaken. It will bear an open border in a warm situation, but the bulbs must be taken up yearly to make it in which we have, the rich scarlet of its blossoms, and its three white spots, distinguish this fine species. Its green has a graceful call, and the stem is properly branched, two or three feet high.

The same alludes to the scarlet colour, like that worn by the cardinals at Rome, as used by Linnaeus in Lobelia and Linxia. The pious Scopoli thought the application proper, and changed it in the latter instance to fuchsia. See his Annus primus, 139.

26 G. byzantinus. Mill. Dict. ed. 8. n. 3. IC. t. 142. f. 1. Ker in Curt. Mag. t. 874. Dryand, in Alt. Hort. Kew. ed. 2. v. t. 102. Park. Parad. 191. f. 3. — Leaves many-ribbed. Spike two-ranked. Flowers horizontal; upper segment covered laterally by the next; three lowermost equal, each with a linear-lanceolate stripe. Supposed to be a native of Turkey, it being found for near two centuries a hardy inhabitant of our gardens, under the name of the Byzantine corn-flag, though generally confused, as G. commutis of Linnaeus, with the two following. We readily submit to Mr. Ker's corrections of this error.

The three segments of the lower lip are each marked with a central white or yellowish stripe, bordered with deep red, and more or less dilated in the middle. The flowers of the present species are larger than either of the other two, their three lower segments very nearly equal in size and shape; the uppermost is embossed and covered at its sides by the lapping over of the two lateral segments, so that the flower is closed, not pervious, at that part. It blossoms in June, rather before the commutis, but, according to Mr. Ker, never bears seeds in England, nor does it increase by root so rapidly as the other two.

27. G. communis. Linn. Sp. Pl. 52. Curt. Mag. t. 86. Riv. Monop. Irr. t. 116. (G. natobenris; Ger. ed. 104. Park. Parad. 191 f. 1.) — Leaves many-ribbed. Spike one-ranked. Flowers horizontal; upper segment covered laterally by the next; three lowermost each with a linear-lanceolate stripe; the central segment very large. — Native of fields in the south of Europe, especially in moist situations, where it is a troublesome weed. It is now kils commonly kept in our gardens than the last, from which it differs in the smaller size of its blossoms, which are approximately nearly into one row, only a little spreading alternately, and whose lowermost or central lobe is as broad as both the other two, and considerably longer. This is viable, even in dried specimens.
Gla
specimens. We have this species from M. Favrod's herbarium, gathered wild in Switzerland, so that it appears to be Haller’s n. 1261, the smaller variety; his larger being probably the following species. There is much difficulty in determining the synonyms of old authors, their cuts not being correct in those parts on which our characters are founded; Parkinson’s G. italicus, for instance, Parad. 191. f. 2, has precisely the lower lip of this present species, but not the indorscence, whilst his f. 1 does not show the lip so well as the position of the flowers. As however he mentions but two white stripes in his description, so many only being visible, as the segments naturally and in our communis, we have little doubt of his synonym. The communis of the Linnean herbarium is our’s, and has winged seeds, so that we trust this name will remain fixed, as belonging to the most common and general species, whatever Linneus might comprehend under it as varieties.

28. G. figatum. Ker in Curt. Mag. t. 719. Dryandr. in Ait. Hort. Kew. ed. 2. v. 1. 102. (G. communis; Bulbiard. Herb. de la France, t. 8. Sm. Pl. Grec. Sibth. v. 1. 27. t. 37. 39. Lamarck Illufr. t. 32. Tourn. t. 190. G. italicus; Ger. em. 104.) Leaves many-ribbed. Spike one-ranked. Flowers horizontal; upper segment dwarfed; three lowermost equal, each with a linear-lanceolate bordered stripe.—Native of corn-fields in the south of Europe, common in Italy, Greece, and the neighbouring countries. Flowering in the spring; rarely, but not the least frequent in gardens. It is distinctly represented in the Hortus Eystettensis, by the name of Pictoria rotunda; Ord. Eff. 4. t. 10. f. 2, though the other Gladoli of that huge book are less precise. This is distinguishable from the last by the distance between the uppermost lobe of its blossoms and the two next, which are peculiarly narrow; while the seeds, according to Mr. Ker, are round, with a somewhat pulpy coat, not flattened and winged as in the whole of the genus beside, which is a most material specific distinction, and even forms an exception to one of the generic characters. Mr. Ker suspects the existence of other European species, still confounded as varieties of these, and which may perhaps account for anomalies and incongruities in the figures of authors. Whether t. 38. of Flora Graeca may be one of these, we must submit to future enquiry. Though small, it is said to be a native of fertile ground; the three upper segments seem more approximated, and the three lower ones united by a longer base, than in t. 37. our G. figatum; but this we learn merely from the figure, and was not the least acquainted with the characters subtilely found out in this tribe, so as to give peculiar authority to what he has expressed in his drawing. The acquisition of living specimens at some future time can alone settle the question.—It is proper to mention that G. figatum of the Linnean herbarium, alluded to by Mr. Ker, is a Siberian specimen, with very broad lateral segments to the corolla, and as far as we can judge seems rather to be communis, if not, as is possible, a species hitherto undefined. It is probably different from the African plant of Van Royen, intended in Sp. Pl. ed. 1, nor has it the authentic marks of originality. What might chance to be compared with it in the Bankian herbarium, when none of the parties present had any precise ideas about these plants, we cannot answer for, but our specimen was then voted to be communis.

29. G. imbricatus. LINN. Sp. Pl. 52. Lamarck. Dict. v. 2. 725. Leaves many-ribbed, spike of numerous, crowded, upon flowers; upper segment rather dilated; three lowermost nearly equal. Gathered by Gerber near Luban in Livonia. His own specimen in the Linnean herbarium is the only one we have seen, nor do recent writers appear to know anything of this species, which appears to us very distinct, akin to the three lal in leaves and habit; but differing widely in its curved ascending spike, and crowded erect flowers, which are smaller than those of G. communis, of a purple or crimson colour, persiant at the base, in consequence of a considerable distance between the claws of the upper and lateral segments, while their upper parts seem to fold over each other; but of these characters we cannot, of course, speak absolutely, from the dried flowers; the three lowermost segments seem equal and rather narrow. No white stripe is discernible in their present condition. The leaves rise above the spike of flowers, and have each an oblique point, but this may not be constant.

Whatever species of Gladoli (exclusive of such as are now referable to the genera Sparaxis, Anomolobus, Tritonia, Watsonia, Mesolophus, or Balhana of Mr. Ker), may be found here and there in authors, we decline describing without seeing living specimens. The discrepancy between several of the figures, above quoted for the same species, proves how variable many of them are, especially from accidental circumstances in cultivation. The Botanical Magazine is now become a faithful and valuable repository of this family, so that however botanists may differ about definitions, the memory of the plants can never be entirely lost.

GLADIOLES, in Gardening, comprises plants of the tuberous-rooted, flowering, perennial kind; of which the species mostly cultivated are the sword-lily, or corn-flag (G. communis); the iridescent flowered gladiole (G. imbricatus); the square-flaked gladiole (G. tridix); the narrow-leaved gladiole (G. angustifolium); and the superb scarlet gladiole (G. cardinals).

There are several varieties of the first species, as the Italian and French corn flags, with the bluifli, the white, and the small purple colour'd.

Method of Culture.—In the first fort and varieties the culture may be readily effected by planting the off-sets from the old roots in the beginning of the autumn in the places where they are to grow. And the other off-sets may be raised in the same way as well as by seeds. These should be planted in a warm border, and be protected in the winter by glafs or some other means, when there is a necessity for it, as during very severe weather, &c.

When increased by seed it should be sown towards the end of August, in pots filled with light earth, placing them in a shady situation at first, but afterwards where they may be exposed to the sun, being protected during the winter in a hot-bed frame, free air being admitted when the weather is mild. In the spring the pots should be removed to a shady situation, with only the morning sun. When the stems decay, the roots should be taken up and kept in sand in a dry place till the time of planting. In the second year’s planting they should be put in separate small pots, filled with mould formed from the turf or earth.

With respect to the old roots they may be taken up every two or three years, to have the off-sets taken off from them, in order to their future increase.

All the off-sets afford a fine effect and variety in the flower borders and other parts among other plants of the flowery kinds, being properly arranged in mixture with them.

GLADIUS, Sword. "As Gladoli, or right of the sword," is used, in our ancient Latin authors; and in the Norman laws, for supreme jurisdiction.

Cassiodorus, in Britannia, writes "Comitatus Flitus pertinet ad gladium Certrie;" and Selden, Tit. of Honour, p. 960, "Curiam suam liberam de omnibus placitis, &c. exceptis ad gladium ejus pertinenticibus."

And it is probably hence, that at the creation of an
GLA

earl, he is gladius facinus; to signify, that he had a jurif-
diction over the county.

GLADUS jficus, in Italology, a name used by many for the
sword-fish, called also the aperian, which see.

GLADEKA, in Geography, a fort of Kiffia, in the go-

government of Caucaus, on the Malva; 36 miles W. of
Kiffa.

GLADWIN. See Iris.

GLADWIN, John, in Biography, the late organist of South
Audikey chapel, was the first performer on the organ of
Vauxhall, after the building of the orchestra in the middle
of the garden, and the establishment of a regular band. He
was a playing player in his day, and a worthy man, who
lived to a great age, and died in 1700.

GLAIR of Eggs, is the same as the white of eggs, and is
used as a varnish for preferring paintings. For this purpose
it is best to an uncertain confidence, and commonly mixed
with a little brandy or spirit of wine, to make it work more
freely, and with a lump of sugar to give it body and prevent
its cracking; and then spread over the picture or painting
with a brush.

GLAIZE, At; in Geography, a S.S.W. branch of the
Miami of the lake in America, which interlocks with St.
Mary's river. By the treaty of Greenville, the Indians
have ceded to the United States a tract of land, six miles
square, at the head of its navigable waters, and six miles
square at its confluence with the Miami, where port Defiance
now stands. See CAMILLUS.

GLAMMISS, in Geography, a small town in the county
of Forfar, Scotland, contains 385 houses, and 151 inhabi-
tants. Here are two small manufactories of yarn, and coarse
linen cloth. The earls of Strathmore formerly poifoned, and
occupied a noble caille in this parish. The remains of this
baronial fortress are still very considerable, and occupy a
commanding site on the banks of the river Dean. In this
parish are several ancient obelisks, or stone crosses; also many
caves. These are traditionally laid to commemorate the
murdered king Malcolm II. Glamis is divided into two
parts respectively, called the New, and the Old Town.

GLAMORGANSHIRE, the south maritime county of South
Wales, is supposed to have derived its name from
having afforded a temporary, though lucrative, retreat to an
ancient prince, at a very early period of British history.
The story is briefly recapitulated by Spenser, in his Chronicl
of British kings. (Fairy Queen, b. ii. c. 10.) Glamorgan
was in succeeding ages an independent sovereign prin-
cipality, distinct, as those who profess to be acquainted with
the ancient history of Wales allert, from the rule and go-

government of South Wales. The principality, or sovereign
lordship of Glamorgan, as their persons say, contained the
present counties of Glamorgan and Monmouth, the southern
and eastern parts of Brecknockshire, and that part of Here-
fordshire lying to the west of the river Wye.

The lordship of Glamorgan was subdivided, at an early
period, into a great many petty lordships, in every one of
which their lords exercised "ius regalum," referring, how-
ever, to the subject a right of appeal to the court of the
chief lord, or, as he was termed, the lord paramount.
There are at least 50 ancient buildings still remaining in the
district, universally understood to be the halls in which the
courts of legislation and of justice were held for the respec-
tive petty lordships. They are now commonly called
"Church-houses," and belong to the parishes in which they
stand. They are at present used as school-houses, and occa-
sionally for dancing an amusement still common in Glamor-
gan, though now beginning to decline. The ground-

floor apartments under these halls are used as alms-houses
for the poor of the parish. From ancient surveys and other
accounts of the lordships it appears that before the reformation
a market was held in each of these halls every Sunday morn-
ing, till the tolling of the first bell, which is said to have
been intended as a notice for the Llanfèds of the market to
coast. The second bell was a signal of preparation for
church, and the third for the commencement of divine ser-
vice, during which no door, but the church door, was allow-
ed to be open.

This county, extending about forty-eight miles from east
to west, and 27 from north to south, is bounded on the N.
by Brecknockshire; on the E. by Monmouthshire, from
which it is separated by the river Kenfig, on the S. by the
Bristol channel, and on the W. by Caermarthenshire. The
greatest part of the sea-coast forms a semi-circular curve;
the western extremity being formed into a narrow beak be-
tween the open channel on the one hand, and an arm running
round to the Caermarthenshire coast on the other. See
GOWER.) An ample account of the manner in which the
lordship of Glamorgan was obtained by its conquerors, is to
be found in Powell's History of Wales, written in the time of
Elizabeth, or in Evans's edition of Wyne's History of
Wales. The following abstract is taken from Malkin's
work. Jeflin ap Gargant, a petty prince of odious charac-
ter, waged war, in the year 1489, against Rees ap Tudor, and
was assisted by Encon ap Collwyn. Unable to make any
inroads upon his enemy's dominions, Jeflin considered
Encon to go to England, and to procure force more power-
ful ally. His propositions were eagerly received by Robert
Fitzhawen, and twelve other Norman adventurers, who came
to Glamorgan on an expedition, professedly for the purpose
of retrieving the affairs of Jeflin. The allies, marching against
Rees ap Tudor, came up with his forces on the borders of
Brecknockshire. In a battle which ensued at a place called
Hirwin, Rees was entirely defeated: and in his flight was
taken prisoner, and put to death. On this occasion, Jeflin
betrayed his characterisf treachery, by violating his agree-
ment with Encon, to whom he had promised his daughter in
marriage, as a recompence for his services. Encon, justly of-
fended, was determined on revenge: and therefore, when the
Normans, after having fulfilled their engagements, and hav-
ing obtained satisfaction for their services, quietly returned
home, Encon represented the injuries he had sustained by the
treachery of Jeflin, and also the hatred of the country
to its tyrant. He also stated how easy it was to obtain po-
fession of this fertile country, with the aid of the different
princes at variance with Jeflin. R. Fitzhawen, and his fol-
diers of fortune, availing themselves of the favourable mo-
ment, turned their arms against their employer, who was
unprepared for so formidable a reverse, and overran the
country; whilst Jeflin saved himself by flight, and died soon after,
unhonoured and unremembered. Fitzhawen, upon a division
of the conquered territory, took for his own share the castles of
Cardiff and Kenfig, with the market town of Cowbridge,
and the demesne of Llantwit; appropriating to himself the
lands belonging to them, together with the sovereignty of
the whole country. The other parts were distributed in va-
rious proportions among his followers. Encon ap Collwyn,
in particular, poifoned Caerphilly, with Jeflin's daughter in
marriage, the prize which occasioned the contest. (See
WALES.) With respect to the picturesque character of this
county, it is distinguished by unbounded variety. It has
its mountains, valleys and rivers; and it is said to resemble
North Wales in general aspect more than any of the fix coun-
ty. Its mountains are not so high as those of Breck-
nockshire, but they present, in a considerable degree, the
appearances.

The antiquity of the cottages is a strongly marked feature in the appearance of this county. Many of them are probably as ancient as the castles, to which they were attached. Their architecture is particularly pleasing to the eye. The pointed doorways, and pointed windows, sufficiently evince their date; and though Welsh towns are universally adorned by strangers, for the inutility and inconvenience of their houses, the direct reverse is the fact with respect to the habitations of the peasantry. There is one circumstance, besides their general structure, that of many of which is the ancient Gothic, which adds to the respectable appearance of the cottages, and that is, the universal practice of lime-whitening them. This has been the custom of the county from very remote ages, and is extended even to the houses and stables, to the walls of yards and gardens. It is noticed and praised in the most ancient Welsh poems, and certainly evinces a very early sensibility to the arts and deprivations of life. The price of provisions in this county has of late very much increased, and is comparatively very high, on account of the increased demands of the manufacturing districts, which are numerous. The price of labour is equally enhanced from the same cause. The increase of population, owing to the influx of commerce, and the magnitude of its establishments at Swansea, Merthyr-Tydvil, Neath, Aberavon, Mumbles and Bridgend, near Cardiff, where are the largest tin works in the kingdom, &c. afford another reason why the cheap comforts and elegancies of life are no longer to be sought for here.

The dreariness of Glamorganshire is not so strongly marked as in some other counties, except that the women universally adopt the man's hat; but they wear it with a very good grace, and are remarkably neat in their attire, as well as in their persons, and graceful in their carriage; which may probably be attributed to the habit of dancing, which is their favourite amusement. Their modes of greeting are mutually affectionate, sometimes bordering on the ludicrous, particularly among the women, who are constantly seen flattering each other at market, and on the most ordinary occasions of business, as well as on occasions of distress. At a wedding it is the custom of all who are invited, both men and women, to ride full speed to the church porch, and the person who arrives there first has some privilege or distinction at the marriage feast. In case of death, the bed on which the corpse lies is always draped with flowers, and the same custom is observed after it is laid in the coffin. It is an invariable practice, both by day and night, to watch a corpse; and the hospitality of the country is nowhere remarkable on meanness than on joyful occasions; for the invitations to a funeral are very general and extensive; and the refreshments are not light, and taken standing, but substantial and prolonged. The grave of the deceased is constantly overgrown with plucked flowers for a week or two after the funeral; the planting of graves with flowers is considered to the villages, and the poorer people. It is an invariable custom to dress the graves on Whit Sunday; and other festivals, when flowers can be procured.

The Roman stations, forts, and camps, in this county, are generally understood to be at Cardiff, Caerphilly, and Caernarvon, which lies between Wenlock, a large handsome house built in the castellated form, and the Cardiff road. The great Roman road was over Newton Down, leaving the present road on the right, and passing through Kennig to Margam, and as straight as the nature of the country will admit, through Abecavon parish to Neath. Glamorganshire contains one episcopal town, viz. Llandaff, and several others, as Cardiff, the capital of the county, Caerphilly, Llantrisant, Cowbridge, Bridgend, Neath, Merthyr-Tydvil, and
GLAND, in Anatomy, is a name applied to those organs of the body, which separate from the blood conveyed to them by their blood-vessels various substances, generally of a fluid nature, and discharge them through one or more tubes, called excretory ducts. The term however has been, and is employed more extensively, having been applied to various organs, which, although analogous in their structure, on superficial observation, to those already designated, do not refer them at all in their functions. Thus, the small bodies belonging to the lymphatic system have been called lymphatic or conglobate glands; although the knowledge hitherto acquired by physiologists concerning the action of these bodies, and their anatomical relations and connections do not warrant us in ascribing to them any function similar to those exercised by the glands properly so called: the account of these will be found under the articles ABSORPTION and ABDUCTION. The pineal, thyroid and thymus glands, the renal capsules and the spleen, have all been included in the glandular system of the body, but will not be considered in this article, as we know nothing at all of their offices, and have no reason to suppose that they secrete any fluid. Our definition will include the salivary, lacrimal, and Meibomian glands, the tonsils, the serous glands of the ear, and the sebaceous glands of the face, the mammary glands in the chest; the liver, pancreas, and kidneys in the abdomen; the prostate, testicle, Cowper’s glands, and glandular odoriferous about the penis; and the extensive fleshy mucous glands about the head and trunk. These parts, although differing widely from each other in many respects, agree in a sufficient number of points to allow of their being arranged in one organic system, which has been named the glandular: the other organs thus enumerated, belonging to this only in name, are excluded from the arrangement by their texture and properties, their mode of vitality and functions. The extremities contain no parts belonging to the glandular system; the fluids formed in the different organs of this apparatus belong almost entirely to the organic functions, while the limbs are particularly designed to execute the offices of the animal life.

As the physiology of these organs cannot be conveniently separated from the history of their structure, we shall consider the vital properties as well as the organization of the glandular system; and we should make a very unnatural and arbitrary division of the matter, if we did not give at the same time a view of secretion in general. We shall present the reader, in the first place, with an enumeration and arrangement of the secreted matters; we shall proceed, fecondly, to give a general view of the organization of the glandular system; and shall exhibit, in the third and last place, the opinions of physiologists concerning the mode of action of the glands and the subject of secretion in general. The reader will observe that the present article is of a general nature; the structure of the particular organs will be described on other occasions, and detailed accounts of the nature and properties of the various fluids will be found under their respective titles, or in other articles of the work.

The blood, apparently an homogeneous fluid, is composed of various matters, which chemical examination can detect and separate. It contains gelatine, albumen, fibrine, acids, alkalis, earths, saline and colouring matters, which are employed for the renovation of the solids and fluids of the body. It presents these to the various organs, which, by converting them into their own substance, derive the means of supplying the waste occasioned by the natural actions of the parts, or form out of them various products, distinguished by new characters, and extraneous to their own composition.
tion. The former of these processes is nutrition or assimilation; the latter secretion: they resemble each other in their commencement, in which the organ, by some powers of a nature entirely unknown to us, but peculiar to living bodies, and forming part of that complicated notion, which we express by the term vitality, affects from the blood such principles as suit its nature or functions; but they differ in the employment of what is thus selected, which is retained in the body, and assimilated to the already existing organisation in the former case, and applied to some other purpose in the latter. The subject of nutrition does not come under our notice at present.

The products of secretion result from an essential change in the compound conveyed to the organ, from a new combination of the principles contained in the blood, which is transformed by the specific action of the various organs into different fluids, retained in or expelled from the body, according to the qualities of each. Hence, there are organs which, after forming certain fluids, collect and retain them; while others secrete and expel their secretions from the body. The object of the secretions is, to collect those which are defined as full important uses in the body; while that of the excretions is, on the contrary, to expel matters which would be injurious to the frame. The two functions then of secretion and excretion resemble each other in multiplicity; there is in both a separation and collection of fluids. The difference consists in this, that in the former case the separated fluid remains in the body, while it is expelled in the second. Thus secretion always precedes excretion; and, in order to understand the latter, it is necessary to know how the former takes place.

The word secretion, derived from secernere, I separate, signifies simply the act of separating; and its physiological import is conveyed in that notion. It denotes, in physiology, that function of living bodies, in which various fluids, differing from the blood and from each other, are prepared from the common mafs of the blood, the same fluid being constantly formed in the same organ. No part of physiology is more obscure, and more difficult in its investigation, than this very function. Malpighi, who had bestowed great labour on the structure of the glands, and was considered to have unveiled, in a great measure, the mysteries of their organization, confesses his ignorance on this subject; and, as the avowal, from such a quarter, is interrelling, we subjoin the passage, observing that the remarks here made, concerning the kidneys, apply equally to all other secretions. He says of the urinary secretion, "quam arti id contingat obscurifimum: licet enim gland darum minimis totum loco subfequi rationi fit couumum, quoniam tamen minima illa, simplexque meatum in gladdis structura nos latet, idae quaedam tantum mediari possit nos, ut huic quaestu probabilitatis satisfaciencium. Necesse est hanc machinam interna configurationem separatifam opus peragere; an vero his, que ad humanos usus paflim uspum, quibus fere conftimlia effignia, confofed, dubium; licet enim occurrit analagae fponzia, incerti fulituram ciborumque structuram, in tam ex his conftimlia undequeque fit renum fabrica, difficillimi- mum eft aflignare, et cum naturae operandi industria fecundissima fit, efdem ignoto nobis reperientur machine, et quas nec mente quidem aliefi licet. Iliad miror tam copia, diversaque corpora separari per has glandulas in natura flatu, ex eim subflantiqna aqua cum salinis, fulphureis et conftimlia particulas, et ex morbo etiam aliefiinam robiquae, et totius quandoque corporis inquinamenta separantur de traditis linguinis particularis," &c. De Vicerum Structura; De Renibus, cap. 6. The whole business is carried on in the minute, and, as we may call them, elementary parts of the vicerum and glands, the structure of which eludes the research of our senses, and can still be developed by reasoning or reflection. Observation cannot follow the work throughout; nor does it admit of elucidation by experiment, like some other subjects which have been explained by artificial imitation of the proceedings of nature.

Unwilling to confess their ignorance and leave their systems imperfect, physiologists have attempted to raise, on hypotheses, that structure, for which anatomy afforded no foundation. Their notions, resting merely on probabilities and loose analogies, have flourished and fallen in succession; and we shall find that the lift of truths and ascertained facts is much shorter than that of opinions and errors.

The composition of the secreted fluids presents various differences in the nature and proportions of their constituent parts. They posse, in common, all the general characters which belong to animal subfiances: but each has certain particular distinctive qualities, depending on the various simple or compound principles, the union of which determines its specific nature. Thus, setting aside the remembrance of all our fluids, considered as animal productions, fat does not resemble bile; the latter is very different from milk; which, again, has no resemblance to the salivary, gastric, pancreatic, seminal fluids, &c. which must be referred to so many different classes.

The arrangement of the animal fluids is more difficult than we should have expected at first sight. The false and imperfect notions, which were long entertained of their chemical composition, lead to classifications founded on the uses to which they seemed to be defined. Those employed in the nourishment and growth of the body were called recrementitious, such as chyle, blood, serum, lymph, &c. The excrementitious included those which are expelled from the body; as the urine, perspiration, &c. A third class was made up of such as partake of the characters of both these; of which a part is rejected as noxious, while the rest is retained, in order to answer some particular purpose. Under the head of excremento-recrementitious humours, were arranged the saliva, bile, pancreatic juice, mucus of the intelleines, &c. The objections to such an arrangement are too obvious to need enumeration. This division, as well as that before alluded to, of excretions and secretions, cannot be adopted with any benefit, while the nature and objects of many secretions are not understood, that we cannot determine whether they are expelled as noxious, or serve very useful purposes in the economy. The bile, for example, has been commonly deemed an excrementitious fluid, but by a completely arbitrary assumption; what proof have we that perspiration separates any thing noxious from the blood? For what reason is the secretion of the pancreas placed in one rather than in the other of these divisions?

Pitcairne, who was followed by Michelotti, divided the animal secretions in a manner which has, at least, the merit of simplicity, and leads to no false notions concerning their uses; he distinguished them merely as being thick or thin.

Haller distributed the fluids into four classes, according to the chemical notions of his time, and to the degree of complication in their elements. I. The aqueous fluids. These have a very large proportion of water in their composition; hence they are distinguished by their fluidity, and have no rupines. Fire dilates them almost entirely, excepting a very small proportion of earthy refuse; neither alcohol nor acids coagulate them. Besides a little earth, they
by a chemist of the present day, would be found open to objection at all points. The deficiencies of the classification are too obvious to render it necessary that we should particularize them.

Blumenbach hasclassed the products of secretion on a somewhat different principle. "The secreted fluids," says he, "display on one hand so much variety, while on the other they seem to be joined by so many points of affinity, that their arrangement in classes must be in great measure arbitrary. They may, however, be disposed in the following order, according to the lighter or more effe\ntual changes and modifications which their elements, contained in the mufs of the body, undergo in the secretory organs. Milk may be placed in the first rank, as consisting apparently of a very simple modification of chyle, and formed from the blood by a very easy process after the influx of the chyle. The watery secretions come next, so called from their fluidity and transparency, although they differ materially from water in the nature of their constituent elements, particularly in containing a portion of albuminous coagulable matter—including the fluids of the eye; the tears, the matter of perpiration, the exhalations in the external surface of the skin, and in the external and abdominal cavities, to which the liquid pericardial and the fluid of the ventricles seem to be analogous. The urine, ordinarily referred to the aqueous fluids, is distinguished by very remarkable peculiarities. The salivary fluids, concerned in the functions of mastication, digestion, and exhalation, seem to be rather more changed. Then follow the mucous secretions, spread over the surface of most of the visera belonging to the natural and organic functions, as well as the cavities of the nose, larynx, and respiratory organs. The mucus in the interior of the eye, as well as that under the epidermis, do not appear to differ essentially from the preceding. Under the title of adipous fluids may be classed, besides the common fat, the medulla of the bones, and the albuminous matter of the skin (including also the cornum of the ears). The fatty matter formed under the prepuce about the corona glandis of the male, and the similar production in the female pudenda, may be referred to the same class; as well as the secretion of the Meibomian palpebral glands. The fluid contained in the early months of conception between the chorion and amnios, of which the vesicle umbilical, and that which surrounds the vesicles of the umbilical cord, is as yet little understood. The contents of the Graafian vesicles, and the prostatic fluid, seem to be truly serous or albuminous. The male femen is quite a peculiar product, not to be compared to, or classed with, any other; and the fame remark will hold good also of the bile." Inutito, Physiolog. sect. 32.

The division of this able physiologist would be natural and instructive, if the animal fluids deviated from the nature of chyle by gradations which could be easily perceived and named. But we really cannot establish among them any order corresponding to their natural composition; and the differences observable between chyle and fat, between the aqueous fluids and bile, constitute intervals, which we cannot appreciate or measure. Indeed there are so many differences and so few relations between one fluid and another, that we can scarcely compare them at all.

The vast progress which chemistry has made of late years, and the valuable discoveries with which the analysis
of animal substances, as well as other parts of the science, has been enriched; might have led us to expect that the classification of the fluids would have been reformed according to their constituent principles, and brought into a condition corresponding to the rest of the science. Fourcroy has indeed given such a distribution of the subject in his Elements of Chemistry; but he does not seem to value the arrangement very highly, as he has not continued it in his later work, the "Système des Connaissances Chimiques." In proportion as the various animal products are analyzed with more accuracy, they are found to possess specific characters which distinguish them from each other; and therefore render it impossible to refer them without inimicity to any general heads: accordingly in the most recent and able chemical works, they are enumerated and considered separately. In this point of view, therefore, the exactness and perfection of modern analysis renders our attempts at a general arrangement of the animal fluids unavailing; and it has only served hitherto to show the defects of such methods.

Dumas, in his "Principes de Physiologie," adopts a different plan, which he calls a natural physiological one, and to which he attributes the advantage of connecting closely the knowledge of the fluids with that of their uses. "This method," he observes, "is the most natural and useful of all, as it refers the fluids to the various organic systems in which their secretion takes place, to make a class of humours for each system, to consider each of them as inapplicable from the system to which it belongs, and to conduct the study of both together. We shall therefore have as many different classes or species of fluids as there are organic systems in the body. This simple and natural method of considering the subject appears to me to be preferable to the more laboured arrangements founded on the essential nature and chemical composition of the fluids, because it is not exposed to that uncertainty, which the imperfection, the variations, and even the progress of our knowledge concerning the nature and properties of animal matters, must unavoidably occasion. It is, moreover, the most easy and instructive way to consider the secreted fluids in their relations to the solid organs, with whose functions they are concerned. The distribution of the animal fluids with regard to the seven organic systems of which the human body is composed, will be better understood by presenting it in a tabular view, where their relations, influences, and uses, will be immediately perceivable.

Fluids of the nervous or sensitive system.

Fluid of the ventricles of the brain,
Aqueous, vitreous, and crystalline humours of the eye,
Tears,
Methanion secretion,
Mucus of the nose,
Cerumen,
Fluid of the labyrinth of the ear,
Saliva.

Of the muscular or moving system.

Fibrine,
Scrivity,
Fat.

Mucus of the trachea and air-veins,

Of the vascular or caudal system.

Fluid of the pericardium,

Mucus of the mouth, pharynx, and alophegus.

Rumach,
Intelines,
Kidney and bladder.

Gastric fluid,
Pancreatic fluid,
Intestinal fluid.

Expiration of the abdominal cavity,

Bile,
Liquor of the rectal capillaries,
Urine.

Residue of all the fluids, and of nutrition,
Lymph,
Fat of the cellular tissue,
Mucous fluid.

Prostatic liquor,
Mucus of the urethra,

Vagina.

Seminal fluid,
Expiration of the tunica vaginalis,
Contents of the ovarian vessels,
Liquor amni,
Mecosum.

Galline,
Medulla,
Synovia.

Of the fluids just mentioned, some are secreted in certain organs belonging to their respective systems; e.g., those of the compound glands, of the glandular viscera, &c.; others are formed over whole organic systems, without any particular apparatus, as the exhalation in the cellular membrane, that of the circumference of organs, &c.; while others are not the produce of secretion, but move freely through all parts of the system in which they are concerned, as the blood and contents of the absorbing system. With the latter we have nothing to do at present; neither does the organization, from which the fluids of the middle class are produced, come under our consideration in this article, but it will be described in INTESTINES, MEMBRANE, AND CELLULAR SUBSTANCE.

The physiological theory of the secretions must be founded on a perfect knowledge of the nature of the animal fluids, and of the structure of the secretory organs. The solution of the interesting problems arising out of this subject, can be expected only from the union of anatomy, enlightened by just views of physical science, with chemistry, supported and directed by physiological observation. The secretory organs are of various kinds, and preserve a constant relation to the kind of secretion, and the manner in which it is effected. Those fluids, which seem to be derived from the blood, with the least change, are not produced by a complicated organic apparatus. The exhalation, which moisture the surfaces of the circumference of organs, the aqueous vapour of the lungs, and the entaneous perspiration are formed by organic systems, composed chiefly of vascular ramifications, without possessing any thing that is at all analogous to glandular structure. The arrangement of the fibrous tissue of muscles, and of the bone fabric, admit of the same remark; if we suppose that these organs habitually secrete fibrine or bony matter. But these are cases, which come under the description of nutrition, and in this line all parts of the body may be called secretory organs,
Gland.

The mucus fluids, which appear to differ more considerably from the materials in the blood, are generally separated by particular glands, which are called cysts or follicles, contained in the subflance of the membranes or viscera. But it seems probable, that these also may be separated from the blood by arrangements of a simple membrinous texture, without any express glandular structure, as in the case of several visceral membranes. It remains therefore for us at present to explain, in a general way, the anatomical structure of the various glands, by which the other animal fluids are secreted.

The glandular differs from most other systems, in the animal economy, in this circumstance, that its peculiar tissie is not exactly identical in all the organs belonging to it. The fibres of any voluntary muscle would serve equally well to compose any other of the same kind. Tendinous fibres, cartilaginous and bony structures, are the same everywhere. The subflance of the liver, on the contrary, is widely different from that of the kidney; which again is very distinct in its character from that of the salivary glands. The glandular system, therefore, is marked in its various parts with very few general attributes, which also suffer many exceptions.

Situation, form, division, &c. of the glandular system.—

Glands have two different situations in the body. Some are superficial, as the breasts and salivary glands; others deeply seated, as the liver, kidneys, pancreas, and most of the mucous glands, and consequently, not exposed to the action of the external bodies. Many of them occupy situations where there is much motion, as the salivary glands near the jaw, the mucous in close contact with a plane of muscular fibres, the liver in the vicinity of the diaphragm, &c. These facts have led to the supposition that the neighbouring motion, extraneous to their functions, determined the excretion of the secreted fluids. But, in the first place, the palatine glands, the pancreas, the tricusps, and even the kidneys, are so situated, as to be out of the way of such external afflication. And we observe, further, that mucus is secreted as abundantly by the pituitary membrane, as in any other part, although there is no muscular plan here; that the lining of the bladder produces an equally copious supply, when the vices is paralytic; and that various causes augment the secretions, without any connection with the circumstance first alluded to, as salagogue medicines, or the fight of food in the cafe of salivary glands. We cannot doubt, therefore, as Boreus has observed, that this mechanical cause has nothing to do with the matter, and that the essential cause of all excretion consists in a peculiar vital action.

Some glands are single, as the liver and pancreas; others are arranged in pairs, as the kidneys, salivary, and lacrymal glands. The latter are similar on both sides of the body; but the resemblance cannot be compared, in respect to its exactness, to that of the double organs in the animal life. One kidney is lower than the other; their arteries, veins, and nerves, are not analogous in length or tone; often various branches exist in one, and not in the other; the same observations will apply to the salivary glands.

Generally the forms are not determined in a very certain manner in this system: they are subject to innumerable modifications in volume, direction, and the different proportions; and differ remarkably, in these respects, from the precise and rigorous laws which govern the conformation of the organs of animal life. Take some one organ, by way of example, from both lives. A small brain will be found to possess a corpus callosum, thalami optic, and corpora striata of corresponding size; while, on the contrary, a large liver often has a small lobus Spigelii, and vice versa.

A kidney will often be larger in its upper portion only, or in the lower. These variations in the animal life affect the whole organ; while they frequently are observed in some part only in the organs of Bichat, who makes this remark, endeavors to explain the fact, by his opinion concerning the necessity of a harmony of action in the animal life. If one side of the brain were developed more than the other, or one eye, one ear, or one side of the face exceeded the corresponding organs, the operations of the mind, the sense of sight, hearing or smelling, would be inevitably disturbed: while the secretion of bile or urine would go on equally well, although some particular part of the secreting organs were proportionally larger or smaller than the others. The glands, which are surrounded by membranes, as the liver, kidneys, and even the pancreas, are left subject to these variations of figure, than those which are contained in the cellular subflance, without any membranous covering, as the salivary, lacrymal, mucous glands, &c. Thoie of the latter description in the mouth, and along the trachea, are never alike in two subjects. The parotid sometimes is prolonged over the malletur, and at others leaves that muscle uncovered; and when either of these glands is fo deformed, as to be incapable of continuing its functions, that on the opposite side of the body either increases in bulk, as we may sometimes observe in the kidneys; or its secretion is augmented.

The surface of such glands as are not covered by membranes is uneven and tuberculated; it may be in contact with muscles, vessels, nerves, &c. even with bones, as in the salivary and lacrymal glands. In general, they are surrounded by a cell:ular tissie, than organ which have considerable motion. That which is in immediate contact with them is dense, like the exterior covering of arteries and veins, but it is not firm. It does not usually contain fat; and by isolating the gland to a certain degree, it is analogous to the peritoneal covering of the liver, or to the proper membrane of the kidney or spleen. Anatomists have very commonly divided the glandular system into the conglobate and conglomerate glands. The former name denotes the gland-like bodies belonging to the lymphatic system, and was designed to shew that each formed only one mass. The latter term is most properly applied to the salivary and lacrymal glands and pancreas, which are made up of numerous smaller particles united together. It cannot well be given to the liver and kidneys, which possees nothing of a conglomerate structure; and these, accordingly, have been generally called glandular viscer.

Organization of the Glandular System.

1. Peculiar tissie of this system.—The glandular tissie differs from most others, in posseing no marks whatever of a fibrous disposition. Its component elements are not placed by the side of each other, according to longitudinal or oblique lines, as in the muscles, the fibrous stylen, the bones, nerves, &c.; but they are heaped together, by a kind of confud, and, as it were, calinal approximation, and adhere together but weakly. Thus, while organs, which possees distinct fibres, have considerable powers of resistance, particularly in the direction of their fibres, glands are torn easily by slight degrees of violence. The broken surface is uneven, full of projections and depressions, which distinguishes these organs from cartilage; the rupture of which is generally smooth. The prostate, tonsils, and mucous glands resist much more powerfully than the liver and kidneys, in which the phenomenon just mentioned is the most easily observable. The pancreas and salivary glands are elongated by any distracting force, without tearing; but this circum-

uation
f articulate structure of the glands; but these researchers do not at all contribute to explain the mechanism of secretion. In the hope of accomplishing that object, anatomists began, as soon as the improved condition of the science furnished the means of prosecuting such investigations, to subject the various secretory organs to a very attentive and close examination, and endeavoured to view the nature of the acini, into which milk of the glands were essentially reducible. The aid of magnifying glasses, and of anatomical injections, was resorted to on this occasion; but the opinions of two individuals, who had devoted much time to the subject, were contradictory at variance, and gave rise to a controversy, which had, at least this good effect, that it occasioned a very thorough examination of the subject. Multrigh taught that the acini are hollow, that the arteriae distributed on their surface depoited the secreted fluid in their cavities, and that it is conveyed thence by an excretory duct, that the union of these tubes forms larger excretory canals, &c. He claims the mucous glands of the alimentary canal, mouth, &c. to be the most simple forms of glandular structure, and considers that the larger glands differ only in consisting of an aggregation of such simple ones. ance arises from the abundant cellular tissue distributed throughout their substance, and not from any peculiar property of their glandular tissue. Their lobes are separated in proportion as the intermediate cellular laminae are elongated.

The glandular tissue, which anatomists have generally called parenchyma, is disposed in three different ways. 1. In the subcutaneous, lacrymal, and pancreas glands, which are properly called conglomerate, the secretions are made of distinct portions, connected together by a loose and copious cellular tissue of which the textures, vessels and nerves. These are again made up of smaller lobes united in the same way; and the divisions are more easily pursued when water has penetrated into the connecting substance. Repeated divisions give us smaller and smaller component portions, till we come at last to very small bodies, still confpicionis to the naked eye, and called glandular acini (grains glandulares, Fr.) These component parts are firmer in proportion to their smallness, as they are surrounded and connected to the adjoining portions by shorter and shorter cellular substance. We can easily follow the 2d, 3d, and even the 4th division of these lobes with the naked eye. The acini are of a roundish figure and pale colour, and distinguishable from any thing of a muscular nature by the absence of fibres. When examined with magnifying glasses, they are seen divided into smaller portions by cellular interfaces, and we can hardly come to an end of these divisions, if we employ successively greater magnifying powers. 2. There are no traces of the primary divisions just described, but large and succeeding lobes, in the liver and kidneys. They consist of a uniform and even tissue made up of glandular acini, closely united together into one substance. The connecting cellular structure of the particles, if there be any, is very small in quantity and short; hence the facility with which those bodies may be torn, and the kind of granulations which their rupture produces. 3. The prostates, tonsils, and all the mucous glands, have no appearance either of primary or secondary lobes or acini. The first of these consists of a dense parenchyma: the latter of a soft and almost pulpy substance. They cannot be torn, like the liver and kidneys. Controversy concerning the structure of the glandular acini.—It is easy to proceed thus far in analysing the composition of the gland; but these researches do not at all contribute to explain the mechanism of secretion. In the hope of accomplishing that object, anatomists began, as soon as the improved condition of the science furnished the means of prosecuting such investigations, to subject the various secretory organs to a very attentive and close examination, and endeavoured to view the nature of the acini, into which milk of the glands were essentially reducible. Von. XVI.
blood-vessels into the excretory ducts; * e.g. in the kidney and liver. As Ruyfch continued his investigations, he found that the bodies considered as glandular and hollow acini by Malpighi, are mere blood-vessels; after accurately infusing the livers and kidneys and macerating them in water, he found them resolved into small clusters of blood-vessels, and proved this so clearly by his preparations, that Boerhaave, who had been a warm defender of Malpighi's doctrine, in defence of which he wrote the Epilola de Fabrica Glandularum, adv. F. Ruyfch, was induced to renounce his opinion. The elegant preparations of Ruyfch, and his appeal to the evidence of dissection, and other anatomical investigations, brought most anatomists over to his opinions, which, indeed, are generally received in the present day. Haller gives the following summary of his opinions on this subject. "Vieceram nempe secretiones definitas, eorumque imprimis acini, glandulairum conglomeratas, meris compansi vaculis, cellulae telae conjunctae, eo cum vinculi robusti ut conflitut acini, aque fulmis, laxoribus fibris annexis, totus et integer deduci potuit. In quolibet pratera acino, vasaorum glomerus, eadem fententia, duces excretorius efi, plane ductuli, qui de arteriis minima, tanquam ramulis minor et fangunium impervius, decidere videtur, quae fabrica in reo certum repertur, in aliis quidem excretae communicae cum specie ex conjectura adhaerentes. Secretio adae a vulgari fanguis circuitus hactenus differt, quod in illa quidem arteria minima cylindricis, in venam fibras sequatur, ut amblorem continuetur, quae fanguinem recipere apta sit, in humerum vero ductus excretorius, rubro vaculo arterio minor, tanquam ramus ex eo vaculo prodret." Element. Physiolog. lib. 7. sect. 2. § 14. The opinions and arguments of Ruyfch may be collected in his answer to the letter of Boerhaave mentioned above, in some of his other epistles, and in various of his Thefauri. He has given several figures representing the distribution of the minute vessels in various organs, and proves satisfactorily that the bodies called acini by Malpighi are merely minute vessels; he throws this concerning the spleen and brain, as well as in the glandular vicera. On the subject of this controversy, we may observe, that its importance does by no means warrant the pains bestowed on it, and the noise made by the combatants in conducting it. The nature of the investigation, which is carried on entirely in the minute elements of the body, and proceeds far beyond the power of any infusive Philippics, and consequently is, as the great anatomists have been pleased to term it, concerning the whole mystery. Let us admit with Ruyfch that the excretory tube is continuous with the secreting artery; shall we then understand how such infinitely diversified products, all differing from each other, and from the blood, are formed from the common maps of that fluid? Shall we be able to point out the precise spot in the continuous canal where the blood ends, and the bile, urine, or milk begins? and to explain how the change is effected? If, on the contrary, we suppose, with Malpighi, that arteries, ramifying on small membranous cavities, deposit the new products in thse receptacles, our ignorance of the points in question is neither more nor less complete than in the other case. Too much labour has been already spent on these idle questions, and many anatomists have judged wisely in abandoning them, and in preferring the task of collecting facts concerning the natural and deformed structure and functions of our frame.

Thus the appearances, concerning the value of these pur-

The organization of all the glands is by no means so uniform as to admit of our referring the mode of glandular secretion to any one mechanism. The mammary and tellis do not resemble the texture of the organs already described. In both of these, which again are widely different in all their sensible properties from each other, there is a vast congregation of secretory tubes, infinitely convoluted, with vascular ramifications copiously distributed among them. In the ultimate elementary parts of these glands, as far as our senses can perceive them, we discover nothing but minute, perforated, and very slender tubes; which are particularly obvious in the country of tellis, with the tiny trace of Malpighian or Ruyfchian acini. In the breast, indeed, the existence of these bodies has been a matter of dispute, and arguments, not deficient in plausibility, have been adduced on both sides of this important question, which, like many religious mysteries, is involved in just so much obscurity, as to make it a very suitable subject for polemical ex-cretes.

The organs of the mucous secretion, in general, do not fall within the description already given of the glandular structure. These seem to exhibit, in many instances, a very simple form of gland, of which, however, the action is no more understood, than that of the more complicated kinds. They consist of small receptacles, lined by the membrane covering the part, receiving the secretion, and pouring it out by a single orifice in the centre. Very simple glands of this kind are seen at the root of the tongue; their figure is circular or elliptical; the cavity is lined by a thin membrane, surrounded by a pulpy vascular substance, which causes a superficial promincence, in the centre of which is a simple aperture, affording mucous on pressure after death.

In these membranes, the membraneous part is more conspicuous, and the glandular substance less considerable, or indeed hardly perceptible, so that the whole seems to be formed merely of membrane. These have been called cryptes, folliculi, &c. Their figure is generally circular or oval, and they are lined by continuations of the membrane, to which they belong. They are placed in the cellular substance, and may possess more or less of the pulpy vascular matter. They have simple excretory tubes, commencing from the hollow of the membranous cavity, and terminating by open orifices on the surface of the part to which they belong, as the mouth, fauces, trachea, or intestines. Pre-ßure forces the secreted mucus from the open orifice. To these claus may be referred the glands of the lips, cheeks, epiglottis, pharynx, and ephymus, thoes of the soft palate, trachea, stomach, and intestines.

These more simple kinds of cryptes or follicles are united in different instances, so as to compose larger masses. Sometimes they are simply contiguous, connected by loose cellular substance, and poises each its proper duct: * e.g. at the back of the tongue, and about the arystoid cartilages. Such have been called glandular congregrations. In other instances, numerous follicles, included in a common covering, deposit their mucus in one or more large cavities, into which several follicles open. The tonsils afford an example, and have been called glandular conglutinates.
GLAND.

The secretion of mucus is often performed in a species of structure, which does not seem to possess any thing of a glandular nature: in small membranous canals, which will admit needles for about half an inch in length, ending by blind extremities in the cellular substance, and terminating by oblique apertures on the surface of the mucous membranes to which they belong. Neither acini nor round follicles can be discovered opening into such canals, which are technically named funnels or lacunae, and which, in the urethra, have a perfectly smooth surface. Some of these are simple, as in the septum narium, the urethra of both sexes, the entrance of the vagina, &c.; others are ramified, as in some inclusions in the male urethra; in the neck of the uterus, &c.

The glands, which produce various matters of an unctuous description, appear to be very simple in their structure, but they are mostly so small as to prevent us from entering into much detail concerning their organization. The serous glands of the ear are small round bodies, differing in the interstices of the cellular substance; and each of which possesses a duct, penetrating the integuments of the meatus auditorius, and ending on its surface by an open mouth. They seem to consist of simple membranous cavities. The organs, which secrete fibro-sebacous matter, in various parts of the integuments, differ from these in being much more numerous, and united by numerous vacular ramifications, opening on the surface of the part to which they belong, with or without the intervention of a simple duct. Where they produce a fluid which concretes, it may be expressed from them in the form of a slender white thread. The areola of the nipple, the nympha, and the other external female organs, the corona glands of the male, the nose, and particularly the cavity between its ala and the cheek, the upper lip, and the hollows of the external car, possess numerous glands of this description. The Meibomian apparatus of the eye-lids is only a rather complicated speciment of the same structure; several simple glands open into a common duct.

The prostate possesses a peculiar structure, which can hardly be referred with propriety to any of the species first enumerated.

The glandular tissue, cut in slices and dried in the air, loses its original colour, acquires a dark hue, and even a blackish tint in the liver and kidney, on account of the large quantity of blood which they contain: if the latter vessels are repeatedly washed before they are dried, they continue to appear moist. The glandular tissue, in its dried state, is remarkably hard and brittle. If kept moist and exposed to the air, it becomes putrid very rapidly, and exudes in that state a highly disagreeable odour. A greater quantity of amoniacal matter is formed. The liver is particularly distinguished for the insupportable stench caused by its putrefaction. The kidney goes less rapidly into that state. When boiled, the glandular substance produces at first a greasy fluid, which troubles the water uniformly at first, and is then collected in an abundant froth at the top. This product is most abundant in the present, the muscular, mucous, and cellular syphons; and last in the cartilaginous, tendinous, fibrous, &c. The froth produced by its boiling is of a deeper colour, and seems to contain more numerous principles, than that derived from the white organs.

Like all other syphons, the glands grow hard at the first periods of ebullition, but instead of becoming softer afterwards, as the others do, the continued boiling makes them more and more hard; so that after five or six hours of ebullition, their firmness is triple or quadruple that which belongs to them naturally. This phenomenon is most remarkable in the liver. When removed immediately after the first corrugating effects of the hot water, they do not display the elasticity which the other syphons possess at this time. A tendon or muscle in such a state, if drawn, returns itself immediately, while a piece of liver breaks. The absence of fibrous matter perhaps is the real cause of this difference. The sudden action of naked fire crisps and corrugates the surface, as in all the other solids, and produces a hard exterior crust.

Maceration in water produces different effects on the different glands. The liver refills longer than the kidney, which, after two months, is reduced to a reddish pulp swimming in the water, while the former still preserves its form and density, and had undergone no other change than from a red to a bluish brown colour. The salivary glands exhibit much of the whitish, unctuous and firm matter, which is seen in all cellular organs after long maceration. This does not arise from an alteration of the glandular tissue, but from the fat contained in the abundant cellular texture of these parts.

Acids act on the glandular tissue nearly as upon the others. They reduce it into a pulp, varying in its colour, and in the promptitude of its formation according to the nature of the acid employed. The sulphuric acts most quickly, and gives a black pulp, while the nitric renders it yellow. They act much more slowly on the glands after boiling than before. Generally speaking, the glands are much less digestible than most other animal substances, particularly in their boiled state; for cohesion produces in them quite opposite effects to those which it exerts on the cartilages, tendons, and all the fibrous organs, which are rendered less dense, more gelatinous and viscid, and more speedily dissoluble by the gastric juice. The glands would probably be digested more easily, if eaten raw. Liver is less digestible in proportion as it is longer boiled. Bichat made a comparative trial of it in a raw and dried state: the former was reduced into a pulp in the stomach of a dog, when the latter had undergone a very slight alteration.

Excretory tubes.—All glands have tubes for the purpose of conveying away the fluids, which they secrete from the blood; and these canals are only found in glands, their conformation belonging to that of the peculiar tissue of the gland. The excretory ducts have an uniform origin in all glands. They arise like veins, by an infinite number of capillary tubes, which appear to begin at the acini, where their exit is. Each acinus is linked to have an arterial and venous, as well as an excretory tube. Arising in this way from all the ramifications of the gland, they unite, in one or more considerabel tubes, which generally run in straight lines through the glandular tissue, unite to each other, and form at last one or more large tubes.

Glands are to be distinguished into three kinds, with respect to their excretory tubes. 1. Some transmit their secretion through several ducts, each formed by smaller ones, and opening near together, but distinetly, and without any communication. In some cases these separate apertures are found on a more or less distinct prominence, as in the breast, profuse, and sublingual glands. Sometimes the orifices are found in a depression, in a kind of cul-de-sac, as in the tonsils, the foramen cecum of the tongue, &c. 2. Other and numerous glands pour out their fluids by a single tube, and there is nothing remarkable in general in the orifice. 3. Some glands deposit the product of their secretion in a reservoir, where it is retained, in order to be expelled at particular times. Such are the kidneys, liver, and testicles. In this case there will be two excretory tubes: one to convey the secretion from the gland to the reservoir, and the other to transmit it to its final destination. These reservoirs are therefore evidently connected with the excretory tubes.
Although the two first classes of glands have no reserved, we may in some degree regard the different ramifications of their excretory tubes as supplying their place. These, indeed, as well as in the glands, which have reserved, are habitually full of the secreted fluid. Under whatever circumstances the glands may have died, we may always produce a considerable flow of prostatic fluid by pressure on the gland. The papilla of the kidney affords a useful on the surface of the liver, and the convolutions of the kidney, as the hepatic duct, and the lacrimal vesicles are full of milk, for which there is no other substitute. From variations in the quantity of fluid, in the latter instances, the greater or less size of the breast, during fasting, certainly depends.

It appears in general that the passage of the secreted fluids in the excretory duct is much slower than that of blood in the veins, or of lymph in the absorbing vessels. Ureine is constantly flowing through the ureters; but a much greater proportion of blood would pass through a vein of equal diameter, while the bladder is smaller. The rate of motion however varies under different circumstances, the former is carried much more quickly during a meal, and urine passes off much faster after watery drinks.

The size of the excretory tubes varies very considerably.

1. Whence several are produced from one gland, they are very small, and some times scarcely perceptible to the naked eye. They have no diaphragms, but communicate open immediately on quitting the gland.

2. Those which are large, bearing a proportion however to the size of the gland, excepting the hepatic duct, which is mostly very small in comparison to the bulk of the liver. They pass for some distance after quitting the gland, and are produced by the union of such tubes as belong to the left mentioned class; so that if their isolated excretory tubules were to be united together, a common flexible duct would be formed resembling the second kind. The pancreas is the only instance in which the common duct is concealed in the substance of the gland; and there is no other instance, but the teat, where it forms evaginations, so as to be much longer than the usual through which it passes.

Whatever the arrangement of the excretory tubes may be, they all pour their fluids either on the surface of the body, as in the serous and acinous glands, or into the breast, as on the surface of mucous membranes, as the mucous, salivary, pancreatic and hepatic excretory. The skin and mucous membranes, therefore, are the only parts which drain the ducts of the gland, excepting those on the external surfaces. The excretory ducts of the serous acinous glands would form an exception to this observation, if the glands existed. They never terminate in the cellular membranes, and if a communication should take place, by accident, the fluids are formed by the superfused vessels, or in urinary follicles; or inflammation occurs in the tissue of the extrava-ular duct, producing ulcers, which persist the cellular apparatus in a more extrusive inflammation. Thus the alimentary canal is admitted in as great a kind of general excretory structure, superior to those of the liver and pancreas, &c., and giving some rise to the fluids it conveys, it passed through these vessels, and, not to enter the general circulation as a separate, but to be assimilated to a very considerable quantity. The connecting vessels are very short and slender in the teat. In those glands, which have a dense parenchyma, as the liver, kidney, prostate, and mucous organs, there is very little cellular tissue, and the facility with which some of them may be torn. Their substance never contains fat. The secretions of the liver in various diseases does not invalidate this observation; for the fat then enters into its composition as an essential element of the organ, and is suffused in place of the colouring matter, which disappears; it is not contained in cells. That may be seen also in the interior of the kidney, but it is round the pelvis, and not the proper parenchyma of the gland. The tonsils, prostate, and mucous glands, never contain any. Serous fluids are never thrown out in the substance of glands, which have a loose parenchyma; they are not affected in cases of the most general and extensive anaemia. We cannot, however, doubt the existence of cellular or serous in such glands; mention is not made of it.

The excretory ducts, but one vessel, as mem-
The development of rectomatos tumours in the liver, of cossus cyst in the kidneys, and of hydrates in both, without the secreción being at all disturbed. The liver is sometimes encreased from the four-fold by internal tumors the surface of the falivary and lacrymal glands, the pancreas, &c. They inot run between the lobes, penetrate into the smaller divisions, and are finally disposed on the acini. The branches coming from different quarters arallomone freely in the gland.

Where the organ is surrounded by a membrane, as in the liver, kidney, saliv, &c, the arteries penetrate on a wholesale, generally at a more or less deep notch, and in a single considerable trunk, which, however, is sometimes previously divided into a few smaller branches. This part, in which the artery enters, is always the first to receive the action of external bodies; a remark which is common to all important organs, as the lungs, intestines, liver, &c. The convex surface of these, where the vessels are smallest, and where hemorrhage would consequently be attended with the least danger, is always turned outward. When it has entered the gland, the main artery quickly divides into various branches, which diverge and are subdivided as they approach the convexity. They have various branches in the body of the organ, as they proceed; and end by producing a large number of capillaries, covering the surface of the organ. Sometimes they come through, are visible on the surface, and ramify between it and the investing membrane. The most favourable method of observing the distribution of the arterial system in this organ is to inject them with hæmorrhage, and to destroy the animal substance by means of immorcellation in the spleen, or nicotine pads; a caust of the vascular system, even to its very minute divisions, may be obtained in this way, and such preparations, on account of their elegance, are contained in all cabinets. Raylech, who was remarkable for his dexterity in these processes, found that the small arteries were differently arranged in the different organs. In the kidney they are convoluted, fo as to form, through the whole substance of the organ, small granular bodies less than a pin's head, which are the acini already alluded to. The surface of the liver is covered, after a successful injection, with innumerable capillaries arranged in a filiated form, and giving the appearance of little tufts of minute arteries, when the part is corroded, which have been compared to canal's hair pencils; and this arrangement has been termed the pellucid. A similar disposition is observable in the spleen.

Some have conceived that the large arterial trunks of glands communicate to the organs an interior motion very favourable to the execution of their functions. These bodies are placed, for the most part, in the trunk, and therefore near to the heart; and their vessels generally enter after a short course, so that the impulse has been considered, from this cause, to be more powerful. The pulmonary artery is a remarkable exception to this observation, and the flowery of the femoral infection has been explained from this cause. We own that we cannot discover any very convincing argument in proof of these opinions. The veins accompany the arteries throughout, in their distribution to the glands; we have no distinct here of a superficial and deep-dilated set. The liver is the only example in which red blood enters on one side, and black goes out in the opposite direction.

Blood of the glands.—The quantity of blood contained habitually in these organs differs remarkably in the different parts of the body. 1. The conglomerate glands contain very little. It imparts no colour to these organs, which are whitish in their appearance, and only require the water to be changed two or three times in an experiment. 2. The mucous glands, prostate, and seminal vesicles contain a larger quantity. 3. The liver and kidney have such a considerable portion, that they differ visibly in this respect from the rest of the glandular system. They contain a large quantity even after death from hemorrhage, or when the glands are suddenly removed from a living animal. Hence, when we excise these organs, it is necessary to renew the water at least twelve times before it ceases to be bloody; when we preserve them in alcohol, long previous maceration is necessary, to prevent the spirit from becoming turbid by the blood. This large quantity of blood occasions the glands, new under consideration to be heavier than the other parts of the body; hence, too, their distinguishing color red, which is not more essentially inherent in their tissue, than in muscular surfaces or vessels: in fact repeated washing will blead in as essentially. The liver then exhibits a green appearance, which appears to be the proper colour of its tissues, as alike to that of the muscular fibre. The tip of the kidney often becomes red immediately by the blood. It retains a degree of colour after frequent removals of the circulating water; and the pulp produced by having it in water for some months, with frequent changes, will have the red tinct, although less deep than in the recent state. Does the state of the secretion influence the quantity of blood contained in glandular organs? 1 There more blood flow to the kidney, when the urinary fluid is separated suddenly, than when it profits off slowly? or is there less returned by the veins in the former case?

Nerves.—Glands receive two kinds of nerves. 1. The lacrymal and salivary glands, the tonsils, &c, are supplied almost exclusively from the cranial nerves. 2. The testicles, prostrate, and liver, derive nearly an equal portion from the brain and the ganglia. 3. The kidney and most of the mucous glands, &c, are almost entirely supplied from the ganglia. These nerves apply to these nerves only, which are unconnected with the arteries; for each arterial trunk penetrating a gland, is surrounded by a nervous network belonging to the system of the gland, and very manifest in the larger organs, as the liver and kidney, where theplexuses come from the familiar ganglion, in the salivary glands, where it is derived from the superior cervical, in the teal from the lumbar, &c.

The nerves are small compared to the size of the glands. We must not decide on this subject from those which enter the parotid and submaxillary; for the nerves merely travel those organs, leaving a few branches behind them. But the liver obviously produces as small a supply as any organ in the economy, which receives nerves at all. Nerves enter the glands, like the vessels; that is, they come in on all sides where there is no surrounding membrane; and enter at the notch in other cases. They divide and subdivide, as soon as they reach the gland, and are quickly lost. There are never any ganglia in the interior of the glands.

We know but little of the exciting and absorbing vessels in the substance of glands, where they are merely indifferent to the purposes of nutrition.

Properties of the Glandular Tissue.—1. Properties derived from their Organization.—These are very
very lightly marked in this sytem, probably from its texture not partaking at all of the fibrous nature. In order that an organ should be susceptible of elongation and subsequent contraction, without injury, its component particles must possess a certain degree of cohesion; and this attribute particularly belongs to fibre. The glandular system, too, is subject much less frequently to causes of dilatation and contraction, than those which are made up of fibre. Where the liver contains a large quantity of blood after death, in consequence of the various sytems being overloaded, its bulk remains the same; its substance is compressed by the vessels. The enlargement of the teatific in gonorrhoea, and of the parotid glands under certain circumstances, and their speedy subsequent reduction, prove that these organs possess a certain degree of extensibility and contractility.

Are the liver, kidney, and other internal glands subject to similar acute enlargements? The phenomena now alluded to may take place in the cellular tissue of the glands, and therefore suppose a less degree of extensibility in the proper substance of the gland than might at first have been supposed.

2. Vital properties of the glands, and physiology of secretion.—The remainder of the investigation is much more difficult than what we have already gone through. The nature and properties of the fluids, and the structure of the secreting organs, may be determined in a great measure by the evidence of our senses; but when we endeavour to explain why each particular fluid is separated by its respective organ, the determination of the question implies a knowledge of the hidden substance of the minute elements of our body, about which we must either be silent, or attempt conjectural explanation, at some risk of exposing ourselves. The object then is, to show, why, in the healthy state of the body, saliva, and no other fluid, is constantly separated from the blood in the parotid gland, bile in the liver, and urine in the kidney; and how it happens that the nature of the secretion never changes, so that urine should be formed in a salivary gland, saliva in the kidney, bile in the mammary glands, &c. The difficulty of the undertaking is increased, and the prospect of arriving at a satisfactory conclusion diminished, by this circumstance; that in the different classes of fluids, each is not constantly separated in an organ of a particular structure. If that were the case, it would only be necessary to determine the relation which the structure of the gland bears to the nature of the secreted fluid; but the very contrary is the case. Fluids of each kind are produced by every variety of glandular apparatus; thus water is formed by the arteries of the skin, without any glandular arrangement, by conglomeration in glands, in the inflance of the salivary apparatus, and by a glandular vicosus in the cells of the kidney: mucous is secreted by membranous surfaces, and by different kinds of glands; and lastly, oily matter are poured from the arteries of the cellular membrane, from various tubaceous glands, from the vesicles of the skin, from the liver, &c. Again, there are influences in the body, of organs, of which we should, à priori, have pronounced, without hesitation, to be glandular, and which yet perform no secretion. Such are the spleen and thyroid gland, to which we may perhaps add the thymus and renal capsule. The spleen is a remarkable instance of the arrangement of the minute arteries, called the penicillium, which is seen also in the liver, and considered to have much connection with the peculiar functions of the secreting organs. In this place, too, we should mention the curious facts, concerning the formation of certain fluids, under particular circumstances, by other glands than those which ordinarily produce them.

Haller has collected, in his great work, a vast number of facts of this description; of which, if we should reject all that may seem insufficiently authenticated, there will remain quite enough to prove the point decisively. To the chapter in which these details are contained, he prefixes this sentence: "Sine quilibet humor per quodcumque column separari potest," and the cafes which he cites, fully justify his conclusion. Paragraphs: "Quando habet duos repetitum, confabulat, non glandula unica aliis diversis humoribus, sed eorum secola commutare, sed citam per muci organa aquam, per muci, aquam et adipis eola lymphan et fanguium, per aquam, muci et lymphae vias adscip, bilem fanguinamque fecern, atque adae comitum, nullum in animato corpore separatorium organum effe, quod non omnium effa classes homo fluis com dominus fecernere quot." Element. Physiologib, cap. 1, § 9. When these circumstances are considered, it will very probably be suspected that the causes of the differences in the secreted fluids cannot be traced in the obvious structure of the glands; but that the reason why a peculiar fluid and no other is separated from each gland, in the healthy state of the body, lies much deeper, and shows from some conditions of the organs, which are inaccessible to our senses.

We shall endeavour to illustrate the subject as far as well authenticated facts will assist us, and shall mention the opinions which have been most prevalent on the subject. It will be an easier task to show how unsatisfactory most of these are, than to sublimate any thing more rational in their place. We proceed to point out the vital properties of the glands.

No part of the sytem produces animal contractility, or the power of voluntary motion. Different glands seem to be differently circumstanced with respect to the corresponding species of sensibility. The peculiar and oppressive sensation occasioned by compression of the teatific, is well known. Considerable and continued pressure on the parotid gland has produced great suffering; but large nerves pass through this organ. The liver may be injured in a living animal, without causing any of the usual signs of pain; and Haller makes the same observation concerning the glandular fluid in general, but his statement is not perfectly explicit: "Univera glandulae experience minime irritabiles videntur, neque vehementer aut morbos fermit, aut illatas a profectore injurias." Elem. Physiol. t. 2. p. 377. Stones in the kidneys often cause very severe pain. From these apparently contradictory circumstances, we can only conclude that animal sensibility, which is variously modified, may exist in organs, where certain agents do not excite it at all, while others develop it very readily. In fact, various morbid alterations render this property very manifest in the glands. The pain of inflammation bears, indeed, a peculiar character in the glandular systems; it is generally obtuse and heavy.

Properties of the organic life.—Sensible organic contractility does not exist in the glandular sytem; but the two other organic powers are exhibited in their highest state of development, and are almost constantly in operation, being concerned in secretion, excretion, and nutrition. Organic sensibility enables the gland to distinguish in the mals of blood those materials which are suitable to its secretion; and by its insensible contractility, it has the power of rejecting whatever is heterogeneous. The blood contains the materials of all the secretions, of the nutrition of all organs, and of all the exhalations. From this common reservoir each gland draws what is requisite for its secretion, each organ for its nutrition, and every serous surface for its exhalation. The peculiar mode of organic sensibility enables each living part to distinguish what its functions require. The whole business of glandular action rests on the two powers just mentioned;
mentioned; and as this action is nearly confluent, they are almost incessantly exerted.

It is evident that all glandular affections must imply a disorder in the powers above-mentioned; since diseases of an organ are particularly determined by alterations of the leading properties; of those which constitute the peculiar life of the part. Observation proves this; we see these properties, when augmented or diminished, produce on one side increased secretion, as in diabetes, mercurial salivation, cholera morbus, &c; on the other, a decreafe or even suspension of the function, as in acute diseases, where all the secretory tubes seem, as it were, closed for a time; for instance, in supplicative inflammation of the urinary organs, &c. On other occasions the nature of the glandular sensibility is changed, and it harmonizes with tabes which are not admitted in the healthy state; hence the innumerable varieties of the secreted fluids under circumstances of disease. The cystic bile in the dead body presents numerous varieties of taste, smell, colour, and consistence. The numerous alterations of the urine are very well known. The faff is less liable to change; but how different is it in many diseases of its ordinary condition. Nothing can lefs resemble urine or bile than the fluids often discharged from the bladder and liver: whence then arise these differences? From the variations in the organic sensibility bringing the part into a relation with those tabes which were foreign to it in its natural state. Thus the same gland, without any change in its structure, but merely by altered modifications of its vital powers, may be the source of infinitely varying fluids. Might not this be carried to so far as to allow that the kidney, by affuming a sensibility analogous to that of the liver, may actually form bile? why should it not secrete bile, since it does secrete other fluids so widely different from those from which they are derived? In the healthy state, the mode of sensibility in each gland is nearly uniform; and the secreted fluid is conveniently nearly the same in its composition and properties. But the mode is changed by numerous causes in disease. An hysterical attack comes on; suddenly the kidney refuses to transmit the principles which colour the urine, and that fluid is consequently discharged limpid; as the paroxysm subsides, the natural type of the sensibility is restored, and the urine has its accustomed characters. In an epileptic fit, a thick frothy fluid is discharged from the mouth in abundance; as the attack goes off, the falyre secretion returns to its natural state.

The various changes in the organic sensibility, and the insensible contraction of the glands, do not affect the function of secretion only; but when they last for some time, they influence nutrition also. From the disturbances of this process arise those various organic affections, of which the glandular system offers the most abundant harvest to the pathological anatomist. We cannot avoid noticing, in inflicting wounds, the numerous diseases observed in this part of the body compared to others. The glands, the skin, the mucous, serous, and cellular tissue, hold the first rank in this respect; and in all thee the two properties above-mentioned exist in the highest degree, and are called into action, not merely by nutrition, but also by various other functions, which reside in the capillary system, as exhalation, absorption, and secretion.

The preceding account of the physiology of secretion, chiefly derived from the "Anatomie Generale" of Bichat, seems to amount to little more than this, that each secretory organ produces its peculiar product, in consequence of its possessing peculiar vital properties, which, when variously modified under particular circumstances, enable the organ to secrete very different fluids from the blood. And this we believe to be a pretty correct statement of the extent of our knowledge of this subject. But anatomists and physiologists, not satisfied with this simple fact, have endeavoured to develop the exact mechanism of the process, and it will be necessary for us to recount some of their opinions. In all observations on this subject, it will be well for us to remember that secretion is not confined to the animal kingdom, but prevails also in the vegetable world. We frequently observe the sap giving origin to peculiar and different juices in the various parts of the plant, and reformers from analogy have gone so far as to admit the existence of a glandular system in vegetables. We shall be induced, by this circumstance, not to lay too much stress on the peculiar structure of the secretory organs in the more complicated animals, as essential to the business of secretion. Many of the facts already noticed, concerning the separation of perfectly similar, or at least very closely resembling fluids, by means of totally dissimilar organs, will tend to the same deduction. And this mode of argument may be still further supported by various examples in comparative anatomy; where we find fluids of the same class secreted in animals of different orders, in organs of very different external appearance. The kidneys of birds are really conlomerate in their structure; and a fluid, exactly resembling the pancreatic fluid of warm-blooded animals is formed by the tubular pyloric appendages, variously conlomerated in different genera of fishes.

Of the different explanations, by which physicians have successively attempted to elucidate the function of secretion, most are completely hypothetical and improbable. In most instances they have been ascribed to the various animal fluids being all contained in the blood; and secretion, according to this opinion, consists simply in their separation by means of the glands. Differences in the diameter, length, and folds of the vessels, and supposed varieties in the holes with which the glandular system is supposed to be perforated, have been employed as the means of rendering the mechanism of secretion intelligible; hence the expressions of sieves, filters, and strainers, so frequently employed in physiology. We are diverted from the necessity of commenting on the glaring absurdity of comparing a gland to a sieve or filter, and of deciding which of these mechanical explanations is the most exquisitely foolish, by the completely gratuitous nature of the fundamental proposition. The modern analysts of the blood have no longer even the shadow of an excuse for regarding this fluid as a mixture of all the animal liquors, and for supposing that it is formed of saliva, bile, gastric juice, urine, &c. since we can discover no trace of such fluids in it. Although all the elements necessary to form these products, as well indeed as those of the solids, are in fact found in the blood, they exist in it in a different state of combination. The blood is manifestly an homogeneous liquor, capable of forming all animal matters from the most transparent and pure water, as the cutaneous exhalation, to the firm fabric of the bony system; from it are formed saliva, bile, and urine; and it serves also for the nutrition of muscles, membranes, and nerves; but none of these modifications of animal fluid are contained in it perfectly formed.

Their precipitation, says Flourez, in the tissues to which they belong, cannot be regarded as a simple separation; since it is accompanied by a modification in the properties, nature, and composition of each. Thus the crystalline pulp is not exactly the same albuminous matter as that in the serum of the blood; the gelatine is not isolated in this fluid, as in the membraneous tissue; the mucin is not completely identical in its character with that which exists in the blood; and the phosphate of lime is not associated in the latter to the gelatine in the former, which unites its particles.
cles in the bony system. Hence secretion always implies some change or modification in the matter which results from its exertion. Compend. Chem. sect. 8. ord. 4. art. 5.

Another notion, as a definition of all solid formation is to be formed, i.e., that the blood undergoes certain changes as it arrives at the glands; that it affords a peculiar constitution before it partakes the organs. It has been asserted that the blood-vessels are arranged so as to produce particular modifications in the contained fluid, and that this is a distinction preparatory to the final process. "The hepatic secretion has been considered to afford the clearest example of such previous changes. The structure and number of the vessels which surround and enter the organ, the proportion of these which carry blood or white fluids, the different temperatures supposed to depend on the proportions, in a word, all those points of constitution which can possibly influence the nature of the blood, are said to be sufficiently diversified in order to produce in the chemical properties of the fluids a condition favourable to the formation of fat in the neighborhood of the salivary glands, of urine in that of the bladder, &c. This disposition, depending on the vascular apparatus, has been represented to consist particularly in the variation, acceleration, cooling or warming of the blood, or in the last, by absorption, some of its principal constituents. But what fanciful can produce these effects? Is not the blood now through the trunks which are going to the glands just as in other vessels? In short, what is the change? The imposition in question is a complete assumption not supported by a single fact, and contrary to observation as far as our knowledge hitherto extends. Thus, after drinking copiously of watery fluids, we find a much larger portion of urine secreted; and the cutaneous exhibition is often augmented from the same cause.

In our endeavors to discover the mechanism of secretion, it will be better to seek the most simple mode of this function. Now the evolution from serous membranes, and the mucous fluid covering many of the surfaces of the body, are examples of this kind. We can discover nothing in these organs but vascular ramifications united by cellular substance. Hagedorn holds in the dead body follow the same course which the secreted fluids follow in the living. And the same observation may be applied also to the case of secretions in some of the more complex instances. "Water," says Haller, "tinged with colouring matter, impregnated or oil of turpentine, thrown into the arteries of a young stork, and occasionally even fish, in the experiments of Forich and Albinus, have existed in numerous cases upon the skin, after the removal of the cuticle covering the water, so as to insist very closely the proceedings of nature. I have repeatedly been seen, coloured with blue, and injected into the lungs through the inferior cava, run out with much fluid from the trachea. In the vixen, in general, or at least in the cubs through the cutaneous patches. Gel de poisons and excreta have passed into the embolus of the external carotid from the arteries; in the same way injected water imitates the course of the tears, and exudes abundantly from the whole internal surface of the eyelids." Elemen. Physiol. 2 p. 374. Physiologists have indulged in considerable disputes concerning this kind of secretions. "Some," says Blumenbach, "assert that all separation of fluids from the mass of blood is accomplished merely by pores in the blood-vessels, and throes, as they say, of an inorganic nature; while others deny altogether the existence of secretory pores. I suspect that this difference of opinion must be resolved into a verbal dispute. On the one hand, I must confess, unequivocally, that to make any notion what form of inorganic pores in an organized body, since all the openings in these vessels must belong to their organic nature, and be regulated by their vital properties. On the other side I do not conceive that the orifices or pores in the coats of the vessels, the existence of which cannot be doubted, differ essentially, in regard to their functions, from the cylindrical ducts, in which secretion is performed in the conglomerate glands, and in the glandular vasa; since it is probable that the formation of fluids depends more on the vital properties than on the forms of the secretory organs." Institut. Physiolog. sect. 32. § 469, note b.

However simple the process of secretion may be deemed in the case just specified, and however closely the proceedings of nature may be imitated by the experiments with injections, we shall find ourselves entirely ignorant of the essential circumstances of the process; i.e., we cannot explain the formation of the new product from the blood, and the formation of such totally different new combinations in organs where no difference of structure can be detected.

Thee, who wish to see the various attempts at explaining the mechanism of secretion, may find ample gratification in the third section of the seventh book of Haller's great work: where he gives his usual detail of all that has been written on the subject. The reader will be very willing to spare us the task of recounting all these dreams, and the still more disgusting toil of refuting them. We shall merely mention one opinion, on which physiologists lay some fire on even in the present day. This refers the difference of the secreted matters to the peculiar arrangements of the minute arteries of the glands. Ruyfela, who exceeded in the art of making anatomical preparations, was led to remark, in his employment of injections, that the ultimate arterial ramifications differ in the different secretory organs, and indeed that there are characteristic differences in this respect in all the structures of the body. This explanation may possibly be true, and we cannot perhaps completely overthrow it; but this is all that we can say in its behalf. We must observe, in the first place, that a correct account of the facts, and an exact description of the different vascular networks, is yet a deformity for this question concerns the very smallest capillaries, from which the tubules conveying the new product commence. How the larger ramifications, in fact, for instance, as will admit several of these, do not differ sufficiently from each other to account for the diversity of the fluids produced in the various organs. Indeed similar vessels often produce the most opposite products. The structure of the cortex cerebri, of the pharynx, and of the placenta, is very much alike with the most dissimilar results. The veins, too, are arranged like the arteries, as we should conclude, certainly not for the purposes of secretion. Very different arrangements of the veins may be seen in various membranes which produce the same kind of exhalation.

There has been a scheme of the science of chemistry, in order to explain the nature of secretion, but so far as I know, hitherto
Gland.

Hitherto derived from this source in unfolding the mystery. That the changes, by which the new products coagulating the animal fluids are produced from the blood are purely chemical, cannot be doubted, but we are equally in the dark as to the circumstances which determine or modify these alterations. We cannot doubt indeed that the whole essentially depends on a vital power of which chemistry cannot neither detect the nature, nor appreciate the force. If, however, we cannot be too cautious in expecting from this science a development of the immediate agent by which secretion is effected, much light may, probably, be thrown on some parts of the subject by accurate chemical investigations. We may apply generally to the observation of Dr. Thomson concerning the kidneys: "the changes operated on the blood in the kidneys are at present altogether unknown, but they must be important. Provided the method of analyzing animal fluids was so far perfected as to admit of accurate conclusions, considerable light might be thrown upon this subject, by analyzing with care a portion of blood from the emulent artery and vein separately, and ascertaining precisely in what particulars they differ from each other." Sygum de Chemist., vol. 5, p. 749. Poureroy, too, in considering how far secretion admits of explanation on chemical principles, speaks rather of what may be done than of what has been effected in this way. "The hitherto chemistry can only furnish some general statements on this subject; and if we look to this science for an explanation of the causes and products of the secretions, and for a demonstration of what passes in every kind of secretion in particular, we must wait till the experiments are much more numerous, the investigations more exact, and the animal analyses considerably multiplied. We must determine the temperature, confidence, and nature of the cerebral blood, of that in the vena portorum, and in the renal arteries, before we can understand the mechanism of the secretions performed in the brain, liver, and kidneys." Syll. des Conn. Chimi. v. 10, p. 385.

We should always bear in mind, in our attempts at chemical explanations of the animal functions, that the effects of the vital power are more particularly observable in counteracting and preventing the exertion of those affinities, by which dead animal matters are regulated; and consequently, that if secretion be an example of chemical affinity, it is so modified by the vital powers, that we can have very little hope of imitating it by experiments out of the body.

In what manner, and to what extent, are the secretions influenced by the nerves? The fact that glands have a supply of nerves, leads us to expect à priori that the effects of their operation will be very obvious; but the laws, which regulate this matter, are hitherto by no means clearly ascertained, and even the kind of influence is very obscure. There is a want of direct evidence, from experiment, on this subject. "I divided," says Bichat, "the nerves of the telencephalic in a dog: the gland inflamed and suppurred; but the latter occurrence shows that nervous influence is not necessary for secretion, since suppuration is accomplished in a manner analogous to that of the latter functions. Physicians know very well that paralyzed limbs may inflame and suppurate. Excision and expedition of the fermen may occur, when the lower half of the body is paralyzed, and when the nerves of the prolate at least must have entirely lost their influence. An example was related to me of a soldier, who contracted a gonorrhœa in this state. In complete paralysis of the bladder, mucus is still secreted in sufficient abundance. The nostril of the affected side is as moist as usual in hemiplegia; and an equal quantity of cerumen is produced in the meatus auditorius of the same side. The glands of the uvula do not cease to act, where that organ is paralyzed. After cutting the nerve of the eighth pair on one side in a dog, the air-vessels are equally full of mucus on that side. In the convulsed state of such parts as pousse glands, where the nerves of these organs must consequently be unusually excited, there is no augmentation of the secretion." Anatomie Generale, tom. 4, p. 624. We may observe further, that when the influence of the brain on the organs of the animal life is completely suspended in apoplexy or compression, where sensation and voluntary motion are lost, the secretions continue undisturbed. On the other side we may adduce numerous phenomena, which can be accounted for only through the agency of the nervous system. Under this head we may mention the flow of saliva on the sight of food, the increased lacrymal secretion produced by various affections of the mind, the suppressed discharge from the skin from the same cause. The urinary secretion is often suddenly affected in hypochondriacal persons; distempering news will occasion it to be secreted in great abundance, and of a very pale colour; and many remarkable instances have been recorded, where the biliary secretion has been decidedly and suddenly affected by mental emotions. It has been affected, but we know not on what authority, that a cow, after being milked by the same individual for a long time, will give much less milk, if the operation be performed by a stranger. These and other analogous facts have led many physiologists to admit of a nervous influence in the affair of secretion; the mode and degree of this action have been variously estimated. De Bourde ascribed the cause of the secretory organs was kept up by the nervous fluid; De Natura Humana, p. 122. Quevai reffered the difference of the secreted fluids to various degrees of sensibility in the secretory vessels; Examen du Eon. Anim. t. 3, p. 437. De Borde ascribed great influence to the nerves on the secreting arteries; Recherches fur les Glandes, p. 522. Stahl and his followers, who ascribed the power of guiding the vital motions to the soul (anima), conceived that it governed the humours of secretion also; and A. F. Hoffmann ascribes the difference of the fluids entirely to the anima, which regulates the secretory orifices by sphygmeters and valves, now closing them to prevent the entrance of particles heterogeneous to the fluid intended to be formed, and now opening them for the entrance of the suitable molecules; Nov. Hypothet. Phyllolog. p. 13. After recounting these opinions, Haller observes that they ascribe too great an influence to the nerves, and reminds his reader that secretions of various kinds are performed in plants, without the assistance of nerves; and that balsams, resins, gums, and coloured milky fluid is formed from the common liquor taken in by the roots of the vegetable. On this subject, we may observe, with Bichat, that the expression nervous influence has generally been used by physiologists in a very indefinite manner. When the irritation, division, or paralysis of a nerve supplying a voluntary organ interrupts, or entirely destroys its functions, we can observe and appreciate the influence of the nerves on such organs; but, with what propriety we can employ the same term to designate the power, which the nerves may possibly have over the secretory organs, when their division or paralysis does not at all disturb the functions of the part?

The secretions may be affected by the direct action of external irritants, although mechanical or chemical irritation in the living body produces no sensible motion or contraction of the organ. Thus, any acid matter will augment the flow of mucus from those surfaces which secrete it; and the slightest irritation of the conjunctiva increases the secretion.
of the lacrymal gland. The presence of food in the mouth excites the salivary organs; and the act of sucking or milking produces a secretion of milk, &c. &c.

The fame powers by which secretion is effected accomplish the passage of the fluid, when produced, through its excretory tubes: it is the innenfible organic contriuffility by which this is effected. Experiments on the ducts of glands in living animals, shew that they are not affected by chemical or mechanical irritation, and hence many have concluded that they possess no power of contraction; but the phenomenon render it necessary to allow them such a property, which may exist in parts, although the trials just mentioned should not render it obvious. External pressure on eXtraneous influence of other kinds have been referred to, in order to account for the expulsion of the fluids contained in excretory tubes, on the idea that these canals possessed no contriuffile powers in themselves. Such explanations are quite gratuitous assumpfions in all causes; and in many instances are totally, and manifestly inadequate, because the organ is exposed to no agency of the kind.

The secreted fluid in some instances is not conveyed immediately to the point of its ultimate destruction, but is either retained in the excretory tubes, or kept in particular referrers; and it has been supposed that various changes take place in its nature and properties under these circumstances. "Frequent sifmme," says Haller, "hoc mechanismo naturæ utitur, ut humorem secrerent retineat, pericicat, inspielt, ad definitus usus contemperat, legitima occasione efffant." Elem. Physiol. t. ii. p. 445. The urinary and gall-bladder are the most remarkable instances of this description; we may mention also the vesicle feminales, and the mucous ducts of the urethra and female organs of generation. That the secreted fluids in these, and in several other instances, are considerably altered after the time of their first production, cannot admit of a doubt, as mere inspection is sufficient to prove it; the particular changes produced in each cafe will be considered in the account of the various organs. The opinions entertained concerning the general effects of thefes referrers, are, that the fluids are impoverished by an absorption of the aqueous part, that they are depurified, or rendered more active, and variably mixed together; it is added, that their retention in the heat of the living animal body in many fancies renders them acrimonious, and that this change, in many cases, as in the bile and femen, promotes the views of nature. These notions are not very confident with each other, nor very clear in themselves; the latter suppoifion, concerning the acrimonious tendency of the fluids, is founded on the observation of the changes occurring out of the body, and is not at all warranted by observation of the living subject, in which chemical alterations are re-"filled by the vital powers.

We have every reason to suppose that much of the secreted fluids is taken up and carried into the circulation by the absorbents; but our knowledge does not enable us to determine the exact extent or nature of the modification, which the function of secretion undergoes from this cause. The experiments of Bichat prove that the various animal products, even those which we should at first have regarded as the most noxious, may be introduced into the venous system without effential injury to the animal; so that the blood may be deemed a common fluid, receiving and retaining various principles, which may vary according to circumstances. "I injected," says Bichat, "into the jugular veins of several dogs, cystic bile taken from other dogs opened at the same time. During the first days they appeared weary, did not eat, were very thirly, had a dull look about the eyes, and were constantly lying down; in a little time, however, they gradually recovered their original vigour. I have since employed human bile in similar experiments; the results were the same, except that hicouage and vomiting took place soon after the experiment. In one instance the animal died three hours after the injection; here I had used bile of an extremely deep black colour, like thick ink, such as is occasionally seen in the gall-bladder, and seems to form an essential part of the black vomitings observed in certain cafes. When similar trials were made with saliva, the consequent languor was less sensible. I then tried mucus of the nose suspended in water. Lastly urine itself, not of the aqueous kind, but that of coition, was employed; the consequent illneces was more severe, but one animal only died, and I suspect that this fatal event happened from the un guarded introduction of a little air at the time of the experiment." Anatomie Generale, t. 4. p. 587. He observes afterwards that the injection of any animal fluids into the carotid artery is immediately fatal, from the effects produced on the brain: but they may be thrown with impunity into other parts of the arterial sytem, as, for instance, into the intestinal sytem.
