The conception of to into do, as to become a verbal index, is a concept of this writer, equally unwarantable. Do, as we have shown, is the identical Latin do, to give, to place, to produce, or put forth, where it has such meaning, in the following phrase—do euram, to put forth euram, i.e. to exert, endeavour. And yet Mr. Tooke has been followed and supported by all subsequent grammarians in the above incorrect and inconclusive reasoning. "The form," says Dr. Cromer, p. 83, of the infinitive to loves, doubles, the same as to love, thus denoting the simple energy of the emotion, signified by the noun love, and t being kindred letters, and easily convertible. To love, therefore, means act love, do love, the word do or to involving the noun with a sort of verbal character. The infinitive, then, expresses simply the action or energy of that attribute which is denoted by the verb, uncompounded with the various accidents of mood, tense, number, and person. This last sentence is a full description of the infinitive mood which Dr. Lowth very properly calls the subjunctive mood; and it is a correct description of an abstract verbal noun. How then can to or do involve the noun with a sort of verbal character; when, if it be an index of any thing, it is an index of a verb changed into a noun? A respectable writer on grammar, in the New British Encyclopaedia, p. 31, following the track which Horne Tooke has pointed out, thus adds: "The infinitive mood, as it is commonly called, is the verb divulged of its peculiar force, viz. of affirmation, and uncompounded with the words which render it expressive of person, number, tense, and in the modern languages of time; but it seems erroneous to consider this as the fundamental form of the verb, where it has any distinguishing termination; it is then the noun flat of the word, with a termination added to it, to show that it is to be employed as a verb. Thus, in the Anglo-Saxon tean, the is the fundamental form of the verb, and an is the verbizing adjunct. Now, as the imperative form of the verb is nothing more or less than the simple verbal name, unattended with the inference of affirmation, this may be considered the fundamental form; and in the Latin in particular the variations of flexion are traced with the greatest advantage from this source."

It is curious to observe the contradictions and absurdities into which writers plunge themselves, when they have adopted erroneous opinions to account for the phenomena of language. Mr. Tooke, alluding to the ancient Storks, thanks the pure flat of the verb to be the infinitive, and yet agrees with his followers in making affirmation or affixion to be the efficacy of a verb. But it is allowed that a verb drops its affirmation in the infinitive; so that, according to this reasoning, a verb is in its pure flat when it has no efficacy. Again, the infinitive is here not improperly called the new flat, i.e. an abstract noun, with the prefix to in our tongue; but in the Anglo-Saxon with the affix an, to show that it is a verb; and as this is a new idea, an in a new language, is called the verbizing adjunct. But what evidence is there for saying that an performs this office? No evidence at all, but a false assumption. We have already said that the Gothic and Anglo-Saxon an is but the Greek infinitive an, or (in verbs in an), an, which is the same without the change of a letter. We have this further evidence of the derivation of the Northern language from the Greek, in this respect, that in this latter the imperative, instead of being the fundamental form of the verb, is, by corruption, derived from the infinitive. Thus, the was the old infinitive; the was also the imperative; but the final being, by degrees, dropped, it became . And it is remarkable, that in the Anglo-Saxon the imperative is derived from the infinitive, in the same manner precisely as the imperative is from the infinitive in Greek; and this correspondence, added to the identity of the termination, we deem a sufficient proof that the Northern, in this respect, is no other than the Greek tongue. The Latin imperative is borrowed from the Greek, as is evident on inspection— the verb, the verb.

The position, that the variations of flexion may be traced with advantage from the Latin imperative, is a fancy, which is contradicted by that broad analogy by which the Latin verbs are formed from the proteronic. It is worthy of remark, that the old Greek accords with the Hebrew, where the imperative is the same with the imperative, and succeeds it in the paradigm of verbs. We shall only, on this subject, express our surprise that if such sensible men were deceived by adopting the notions of Mr. Tooke, they were not repelled by what appears to us to be contradictions. This grammarians wholly that deliberate art had no concern in the formation of language: yet, in examining its phenomena, he recurs to minute mechanism and petty artificialities, which, as being unwilling to allow the agency of a rational law in the human mind, he calls the constrictions of language.

We now proceed to consider briefly the usual divisions of verbs into active, passive, and neuter; and this division of verbs we pronounce to be extremely unphilosophical. And first, as the expression of active qualities is essential to verbs, there is no such thing as a neuter verb. There are, indeed, verbs which denote off, or the cessation of motion; but we cannot use these without connecting with them positive ideas; and as action is necessary to destroy or support action, we can resolve all apparent neuter into active verbs. Thus to flound, is to cause to flound, to flound, is to enjoy repose; to sit in to hold one's feet. Secondly, the division of verbs into active and passive, though convenient in some languages, is incorrect and even absurd in our own tongue. For all active verbs imply passion; while all passive verbs on the other hand, imply action. Hence the one may assume the form of the other without altering its nature. Thus, he aman parents, he loves his parents, is the same in French as parents amant ab ilis, his parents are loved by him. The only difference is that, in the first instance, the agent is nominative, and the object accusative; in the second, the object, becoming the subject of the verb, is put in the nominative, and the agent in the ablative. An agent, while it acts, is acted upon. Every active verb, therefore, has the compound tense of active and passive. Thus, in the above sentence, he loves his parents, the first part, he loves, is active; the hall, he loves his parents, is passive. In the same sentence, converted into the passive form, his parents are loved him: the first part is passive, and the hall active. In the minuteness of language, the distinction of active and passive was in all probability not known. In Hebrew, the difference but imperfectly exists, and in the early periods of it probably did not exist at all. In Arabic, the only distinction which obtains, arises from the vowel points; a late invention, compared with the antiquity of that language. And in our own tongue the names of active and passive would have been unknown, if they had not been imported from the Greek and Latin.
GRAMMAR.

Latin grammars. In English the passive form of the verb is expressed by the connecting verb to be, and the perfect participle; and in converting an active into a passive proposition, we need only change the verb to its perfect participle, and append it to the connecting verb in the same mood and tense, and annexing the agent with its correspondent proposition in the ablative case. Thus, we worship God, because God is worshipped by us. Hence it appears that verbs which are transitively active can be made passive, because they have an object, which, in the passive form, is made the subject of dative case; and that verbs intrinsically active cannot have a passive form, because they have no object.

The passive voice, in all languages, is expressed by the connecting verb, and the perfect participle for its predicate; and it is curious to observe, that this combination is its origin in the Greek tongue, the subject of dative case being combined with the personal pronoun in the dative case. Thus, *κατεστάρασε καθότερον τοίμησεν*, which do not, as before, clothe an agent with a subject, but as a subject with the perfect to whom it belongs, and for whom it was intended. Hence their combination came to convey the idea *I am bowed*. I am built; for the auxiliary am serves only to assert that bowed or built belongs to the proposition preceding it, and to cement their union in the mind as subject and predicate. In the same manner, if *κατεστάρασε καθότερον τοίμησεν* be annexed to the word *κατεστάρασε*, we have *κατεστάρασε καθότερον τοίμησεν* for thee, bowed for him. And these contractions, by slight changes, became *κατεστάρασε καθότερον τοίμησεν*, I am built, thou art built, he is built.

A verb, if its operation passes over to another thing, or if it have an object to express the effect of that operation, may be called transitive; but if its influence do not pass over, or if it have no object, it is intransitive. Verbs, on the other hand, not expressing action, but being, stand, stand, and serving to associate two things, as a subject and predicate, may with propriety be called connecting verbs. Of this class is am, with all its branches, or the corresponding verbs in Latin and Greek. And here it is proper to observe that verbs of motion came in all languages to signify continuance, purpose, and the like, because we can measure duration, or even effort, and privation of motion, only by ideas consequent on motion. Thus, in our own tongues, a diligent boy will become a learned man. *By thee dispatched into congenial soil, finds each attractive plant*; *i. e. is dispatched*. So in Latin, *Quum placidum ventis functem maris*, when the sea flood in the past continued, tranquillized from the winds. Veneti lenior, the will come milder, *i. e. will be or become milder*. Vixisset flamandibus vas, he would have lived, *i. e. he would have been a filthy pig*. Ego meco regina, I walk a queen, *i. e. I am a queen*. Theorurum, speaking of the irascibility of Pan, writes *κατέσταρασε καθότερον τοίμησεν*; *i. e. is intimated*. Keen anger always fits in his nose. *i. e. the breath of anger always continues in his nostrils, or, he is ever irascible*. On this principle it is that *οὖ* in Greek, as implying continuance or purpose, came to have the fene of *am*— *καθότερον*, I am well; and that *οὖ* in Latin, I am and *οὖ* I go, were originally the same language.

And in Latin *esse* became, for a similar reason, into *cerno*, which occurs in Lucianus in the sense of *see*. From *esse* the Italians have derived *vedere*, to go out, end, and *vedere*, exist; a door, or entrance. Hence we have derived to *yer* the Italian *lato*, *essen* owes its derivation from *flö*, to the same mode of thinking. All verbs then, are either transitive or intransitive, or connecting verbs. And this division appears to us obvious, useful, and philosophical.

The properties of verbs are mood, tense, number, and person. On these properties, as they are discussed in all grammars, (see L. Murray's valuable Grammar of the English Tongue; Dr. Crompton on Etymology and Syntax; Dr. Priestley's Philosophical Grammar, and particularly Mr. Pickburn's excellent Dissertation on the English Verbs,) we shall content ourselves with a few observations. Mr. Tooke, vol. ii 472, says that mood, tense, number and person are no parts of the verb. But this opinion will appear to be erroneous, if we reflect on the manner in which verbs are derived from nouns. For the personal pronouns in each number enter into the composition of a verb in the ancient languages, where it is distinguished by personal termination; though we acknowledge the affixion to be just in English, where the verb is known only from the annexed pronoun, or its connection with the agent and object. Again, if we reflect on a verb in its formation, we perceive it to contain an idea, the result of observation and experience, which, as well as certain, absolute, and unconditional. This certain, absolute, and unconditional form is essential to the verb, and it constitutes that *made or unmade* called the indicative mood. As the indicative mood respects the past time, to the subjunctive, in respect to it, regards the future. And in all future events, at least with respect to man, are uncertain, relative, and conditional. All verbs, expressing an uncertain, relative, or conditional, uses, are in the indicative mood, so called from its being *foliowied* to a verb in the indicative mood. All verbs, moreover, expressing an *end* or *intention* as being from their nature uncertain, are used in the subjunctive mood, and for this reason it might be called the *final mood*. In this view it has a close affinity to the *infinite*, which, as we have already observed, is only an abstract noun with the proposition to be, denoting the end or object to which the preceding verb is directed. Accordingly, they may be subordinated one for the other, in all instances. Thus, *I desire to learn*, I desire the object of my desire being learned; *I desire that I should learn*, I desire, that being my end, I should learn. Hence it follows that the subjunctive mood is not essential to language, and for this reason it does not exist in Hebrew and some other tongues. As a command is necessarily given in the time now, the imperative has no tense but the present, nor can it, in strict propriety, have a first person, singular or plural; because it would be absurd in a preten to command himself. Let me love, then, is not the first but the second person, as may appear by substituting for its equivalent *let Perin* thou me to love.

Finally, if we reflect on the verb in its element, we shall find that *time past* is essential to it, because the conversion of a noun and the annexed pronoun into a verb is in consequence of past experience or observation. But as present facing or consciousness coalesces with our reflection on the past, the verb, which owes its existence to the past, comes to signify also the present. And this is the reason why in Hebrew, the most ancient language, the same form of the verb expresses the past and the present time; and this, too, appears to be the reason why in English and all other languages a verb in the present tense is used, in an extended sense, to comprehend all time, present and past. As, *the sun rise every day*; *birds fly*; *truth is always true*. In these and similar instances no reference is made to the future; unlike the future, by association, inessential in our minds coalesces with the past. But men soon became sensible of the necessity of limiting the verb in regard to time. They soon acquired a distinct notion of the three divisions of time into present, past, and future; and in order to vary the terminations of the verb, so as to correspond to these divisions, nothing more was necessary than to follow the impulse of association acting on accidental corruptions. Hence the origin of tenses, which, as the word implies, are the extenion of the verb by distinguishing terminations to express the divisions of time. And here we cannot help observing, how improper it is to call tenses
and similar contrivances, abbreviations, (as is done by Mr. Tooke,) a name, the very reverse of what a tenet purports to be. The formation of the tenets in Hebrew is worthy of attention, and shews that the human mind, under the influence of a rational law, without perhaps the express exertion of reason, may produce a contrivance for its beauty and simplicity truly admirable. In that language the distinguishing termination is the personal pronoun, annexed or prefixed. Now, suppose ָּ, a fragment of the first personal pronoun, to mean I. It will also become a natural index of the time now, whenever the speaker uses it in connection with a verb, because he measures the present moment by the use of it, or by reflecting on himself when using it. This being the case, a verb preceding ָּ will be a past verb, by pointing, as it were, the attention backward, as Pegasus, visited I, or I visited; while a verb succeeding the same particle expresses the future time: the pronoun, being the index of the present time, points now the attention forward, as ָּ, meaning I will visit.

But for ָּ, the other fragment of the personal pronoun, is used ָּ. In modern languages, which have no distinguishing terminations, the notification of time future is but an inference drawn from verbs of volition or desire, in consequence of the constant association of the object of that volition or desire with time to come: as I will learn, which meant, at first, I am resolved to learn, and then the time when the resolution is to be performed. Thus ָּ and ָּ, which are the Hebrew ָּ, ָּ, and the Greek ָּ, ָּ, is in a secondary sense becomes indices of time to come. It is here of importance to remark, that though ָּ, ָּ, with ָּ, ָּ, and, are called auxiliaries, they are still leading verbs, and govern theo, which they are supposed to subserve, in the indicative mood.

The Greek has been represented as very like the Sanskrit; but in truth, the old Æolic dialect, whence the Latin is derived, claims a much closer affinity with the great Indian language, and in that dialect of it which is spoken in Bengal, the mark of the future tense is ָּ. Thus ָּ, I shall be, is the future of ָּ; but so is the Latin ָּ, the future of ָּ; ָּ being originally ָּ, a form of the verb denoting conjunctive, and hence expository, or transition in regard to time. Mr. Tooke, indeed, in his usual manner, supposes ָּ to be an abbreviation of ָּ, ָּ, ָּ, see vol. ii. 433. But the primary sense of ָּ is to ָּ, or deliberate; and upon the same principle that this verb became an index of future time, any other verb or form of a verb would be made an index of it by associating its object with futurity. The ideas which this graminarian had of language are altogether mechanical; and by rejecting the principle of mind, while continually hunting after blind mechanism, he forced us to see that he had fulfilled the character of a philosopher in explaining its phenomena.

The Origin and Properties of Participles.

Mr. Harris's account of participles is as follows: Every complete verb is expressive of an attribute of time, and of an affront. Now if we take away the affront, and thus destroy the verb, there will remain the attribute and the time, which make the essence of a participle, p. 184. This statement has conciseness and simplicity to recommend it, though we do not regard it as correct. Mr. Tooke gives us the following account of participles. "This sort of word is by no means the same with a noun adjective. The participle has all that a noun adjective has; and for the same reason, verbs for the purpose of adverb. But it has likewise something more than a noun adjective has; because the verb has something more than the noun. And that something more (as Perizonius proceeds to assert) is not only the adsignification of time, for every verb has a significational distinct from manner and time. And language has as much occasion to adjective the distinct significational of the verb, and to adjective also the mood, as it has to adjective the time. And it has, therefore, adjectives all three—the distinct significational of the simple verb, and the verb with its moods, and the verb with its tenes. I shall at present notice only the verb adjectives, which we now employ in English, viz. the simple verb, itself adjective; two adjective tenes, and three adjective moods.

We had formerly in English only the simple verb-adjective, and the past tenes adjective. In addition to these two, we have now the convenience of four others, which I must call the potential mood active adjective; the potential mood passive adjective; the official mood passive adjective; and the future tenes active adjective. As the noun adjective always signifies all that the unadjectined noun signifies, and no more, except the circumstances of adjection; so must the verb adjectives signify all that the unadjectined verb signifies, and no more, except the circumstance of adjection. But it has been usual to suppose, that with the indicative mood, as it is called, is conjoined also the signification of the present time, and, therefore, to call it the indicative mood present tense. And if it were so, then indeed the word we are considering, besides the signification of the verb, must likewise adsignify some manner and the present time; for it would be then the present tense adjective as well as the indicative mood adjective. But I deny it to be either. I deny that the present time, or any time, or any manner, is signified by that which is called improperly the indicative mood present tense. And, therefore, its proper name is merely the verb—indicative, if you please, i.e. indicative of being merely a verb."

Our readers, we are sure, will not be able to peruse this account without surmise; and we shall endeavour to set it aside by a more simple and rational account of the participle. The present participle denotes the operation of a verb without regard to any agent; the perfect participle denotes the state, power, or habit, generated by that operation in a person or thing which is the object of it. If this statement be just, the participle in its genuine state is rather a verbal noun than a verbal adjective, and has a close affinity to the infinitive mood. Hence, we can account for the origin and use of the participle. The Hebrew, and more especially the Arabic, form their verbal nouns by what is called naming, or the syllable or added to the verb; and this is the Greek participle in, which the Latins have converted into ens; but which we, by giving n a nasal sound, have corrupted into ing.

As the participle is a verbal noun, we see the reason why in all languages it is either used as a noun, or gives birth to various classes of abstract nouns. The present participle, as expressing an operation, naturally coalesces with an agent, and this is the reason why in Hebrew, in Greek, and sometimes in Latin, it denotes a deed, or a person who acts; as ἡ χρήσις, he was writing, the writer; amans, he loving, the lover. From its facility to coalesce with a noun, the participle loses its nominal character, and becomes an adjective; and as it denotes an active quality, or a power in energy, it forms, with the connecting verb to be, the three active compound tenes—I am writing—he was writing—they shall be writing.

Further, as all operations are in time, and we acquire the idea of time present by reflecting on successive operations, the present participle implies time unlimited, and in its affi-
cited effect time present, i.e. time present, not absolute, but relative. Thus, I am writing, i.e. I am now writing; I was writing, i.e. I was writing at the time then present.

And, in general, the participle is derived by the concomitant verb in the sentence which may be either present, past, or future. If the verb be past, it marks the past time as then present; if future, it marks the future as hereafter present. And thus is rephrased the opinion of Mr. Tooke, that there is no adfiguration of time in the present participle. But as he may pronounce this argument a mere eviotion, I will illustrate it by a parallel instance in Greek. The subjunctive verb πασχέω, νικάω, &c. is thought to be the present tense; but it is really the future tense, and this is proved by its signification as well as by analogy, for in all instances this expresses a future time, not indeed absolutely so, but future in regard to another verb connected with it in the sentence. For example, "If they told him, leaving, if it be lawful to heal on the sabbath-day, that they might accuse him," ἐπεστηκα, πασχάω, νικάω. To accuse him was their end in asking, and in regard to that act was future, though now long past. Finally, things which act in consequence of actions are designated by a participle to act, just as bodies when moved have a tendency to move. Repetition, moreover, imports to the acting quality additional strength, protestion, and permanence. To express it with the propriety and vigour thus attained by use the participial termination, as in Greek is added to a noun or to an adjective, which, as receiving an additional meaning, is called an augmentative. Thus, ἐπεστηκα, speaking, means also one who is prone to speak, which is the character of the scoler or diffembarer; ἐπανεστηκα, deceiving, one given to deception, a great deceiver; κατακλαμνα, κατακλαμνα, more so, excessive in so-called. And from this the Italians have derived one way of qualifying their nouns. Hence, our falcon, (a great half), balloon, and, perhaps, policeman, the augmentative of paltry.

The perfect, or past participle, is certainly derived, as Mr. Tooke represents, from the past tense.—Amavit, amatus; amatorius; amatorius—decinit, decinitus; dictor, dictus; legitus, legitus, legitus; legis numeri; additus, additus, additus; orbis, which is the Greek ἱεραρχός, is added to the third person as the analogical termination of nouns, to show that the verb is not abstracted into a verbal noun, denoting the effect of the action. Accordingly amatus, dictor, legitus, additus, and the like, are every one either abstract nouns of the fourth declension, or verbal adjectives coalescing with another noun. And here we shall quote a passage from the Encyclopaedia Britannica, (p. 86.) to show into what errors grammarians have fallen, by not having attended to the nominal character of the participle: "From these observations and examples," says the writer, "we shall be able to understand the uses of the adjectives. It is either employed to signify or modify a general term; or the abstract substantive contained in the adjective is modified by the noun with which, in the concrete or substantive form, that substantive is conjunctive. The first may be called the direct, the second the inverse acceptance of the adjectives. Livy, speaking of the abolition of the regal authority at Rome, says; "Regnum visitam et clementiam et literatum annos ducentos quadraginta quadruor," Monarchy subverted at Rome, not from the city built (which would convey no meaning,) but from the building of the city, to its deliverance. Both the participles clementia and literatum are here used inversely, i.e. the abstract substantives contained in clementia and literatum are modified and restricted by the substantives urbe and urbem, with which they unite. Again, Ovid, speaking of the contest between Ajax and Ulysses for the arms of Achilles, has these lines:

"Qui licet eloquio fidum quoque Nestor invenit
Haud tamem efficaci dejectum ut Nestor crimen
Nullam esse robor."  

Here also the adjective or participle dejectum is taken inversely, and the general notion of dejectum contained in it is modified or rendered particular, by being joined with the substantive Nestor. The meaning of the passage is, "I will never be induced to believe, that the dejection of Nestor was not a crime."

Were dejectum to be taken directly as an adjective, modifying its substantive, the sentence must be translated, "I cannot believe that Nestor dejected was not a crime." But it is evident that this is nonsense; as Nestor, whether dejected or not dejected, could not be a crime."

This writer was led by Mr. H. Tooke to consider every adjective as a noun in its nature; he then makes a discovery in which he seemingly blames himself, which is this; instead of the adjective qualifying its noun, the noun inversely qualifies its adjective! This able writer would not have used this language, if he had trusted to his own understanding, and had not allowed himself to be misled by his guide. The participles condita and literata, though they here coalesce with another noun, still retain their original character of a substantive, and the historian has apprized his readers of this character by the collocation, where condita is rendered prominent and emphatic by succeeding the qualified uke. The same observation applies to dejectum Nestor, which is equivalent to dejectum Nestoris.

As the past participle expresses the effect of an operation, it has been called the pastive participle; but when the subject of an operation is a moral agent, that effect is held, or a voluntary principle of action. And thus it is, that the perfect participle often expresses or implies action; as, admiriatus, having admired; locatus, having spoken. Sometimes in Greek and Latin it conveys a reflex sense; as ferox membra, having provoked his limbs; πιστίς ἁρκας, havingEffects from me. And lastly, as the perfect participle is derived from a past verb, and, as it signifies an effect already produced, it points to time past; nevertheless, that effect is a habit or power capable of action, it implies time present, and thus the past participle, comprehending both times, answers to the denomination of perfect past.

The Origin and Properties of Prepositions.

Mr. Harris defines a preposition to be a part of speech, devoid itself of signification, but so formed, as to unite two words that are significant, and refine to coalesce or unite of themselves. This definition is undoubtedly erroneous, and has been justly censured by Mr. H. Tooke. We venture, however, to affirm, that the account given by the last-mentioned writer, is by no means such as a philosopher, who accurately understood his subject, would give of prepositions. "As the necessity, says he, vol. i. p. 319. of the article, or of some equivalent, follows from the impossibility of having in language a distinct name or particular term for each particular individual idea; so does the necessity of the preposition, (or of some equivalent invention) follow from the impossibility of having in language a distinct complex term for each different collection of ideas, which we may have occasion to put together in discourse. The addition of a substanative of any one idea, to a collection, makes it a different collection; and if there were degrees in the collection of ideas, it is still more impossible to use in language a different and distinct complex term for each different and distinct collection of ideas, than it is to use a distinct particular term for each particular and individual idea. To supply, therefore, the place of the complex terms which are wanting in a language, is the preposition employment.
ed, by whose aid complex terms are prevented from being infinite or too numerous, and are used only for those collections of ideas which we most frequently occasion to mention in discourse. And this is obtained in the most simple manner in the world. For having occasion, in communication, to mention a collection of ideas, for which there is no one single complex term in the language, we either take that complex term which includes the greatest number, though not all of the ideas we would communicate, or else we take that complex term which includes all, and the fewest more than those we would communicate; and then, by the help of the preposition, we either make up the deficiency in the one case, or retrace the superfluity in the other. For instance, "A house with a party wall," "A house without a party wall." In the first instance, the complex term is deficient. The preposition directs to add what is wanting. In the second instance, the complex term is redundant. The preposition directs to take away what is wanting."

Now this statement appears to us to be more properly descriptive of conjunctions than of prepositions; it being made altogether in reference to with, which has, in the above instance, only a conjunctive use; as, a house and a party wall, i.e., a house with a party wall, or, Mr. Tooke explains, with a house of a party wall. The following we deem a more just representation. Prepositions express the relations of things; and, as our ideas of relations are affected effects, arising from our ideas of things, so the words expressing relations are borrowed from the things related, that is, prepositions originate in nouns and verbs. But we have seen, that the relations of things are also expressed by prepositions. Cafes, therefore, and prepositions, have the same meaning; the former, indeed, being no other than the latter combining with nouns, and thus giving them different terminations, bearing distinct forms. The three leading relations we have farther seen expressed by cases, are beginnings, inferior or medium, and end. Tho' prepositions, then, which signify beginning, require the noun preceding them to be in the original state or position, or, agreeable to the usual language, govern the genitive case. Those signifying inferior or medium govern their dependent nouns in the instrumental or modal, or, as it is commonly called, the object case; while those denoting the object or end to which an action or motion relates, to which it tends, and in which it terminates, have their governed nouns in the final or dative case.

We now proceed to ascertain the meaning of the leading prepositions, by deducing them from their origin. And we shall find that Mr. Tooke, as his ideas are unsatisfactory and unapparent in regard to the use of prepositions, is mistaken in almost every instance, in respect to the forces in which they originated. And here we must premise, that our ideas of beginning, medium, and end, are so palpable and distinct, and so essential to distinctness in our other conceptions, that they are nearly coeval with our ideas of things and of motions; and consequently must have existed in the language of men, as soon as it reached a form deriving of that name. And as we maintain, that all the varieties of human speech which now exist, or have ever existed, are but branches propagated by various causes, (like the human race itself,) from a few parental stems in the one primeval language of mankind; so we maintain, that most prepositions in different languages, are but the same original words, differently corrupted, agreeable to the genius of the people who borrowed them from their ancestors; and that the English prepositions, in particular, are antecedent to Anglo-Saxon and Gothic corruption, or, as Mr. Tooke would say, abbreviations, and originated in oriental words, derived in many instances through the medium of Greek and Latin. The derivation of the conjunctions and prepositions is, indeed, the most specious part of Mr. Tooke's system; and not only in his own opinion, but in the opinion of the public, he lies so strongly fortified, that no adversary can disprove him. We shall, however, make an attempt for this purpose.

"I imagine, says he, p. 367, that of (in the Gothic and Anglo-Saxon after or on,) is a fragment of the Gothic and Anglo-Saxon ofa or ona, purpose, aiming, that it is a noun substantive, and always meaning purposes, offering, succour, or follower." Now as to offer it is nothing but the Greek ἑκάστος, produce, from ἑκατόν, and the meaning of of is quite therewith of confunde, &c. Thus, in the plural, rays of the sun, points to the sun as the origin of rays. It means, therefore, a source, origin, and its derivation is ἑκάστος, ab. root, stem, etc., etc. The genitive case, which corresponds to of, further proves this, ἑκάστος ὀφθαλμος, where if, annexed to end, surely does not mean that the sun is a confederation of the rays, but that it is the origin of the rays. The source or cause of a thing is before that thing in the order of nature. Hence, according to the usual arrangement in Latin, the noun in the genitive case, as sun, can never be followed by a preposition. But if a preposition is annexed to it, as, from, it is always with, with the sun, the sun from this, and this is the reason why in English we always say father's house, (father is house,) and never house father's, having copied not only the genitive termination of the third declension, but also the collection of the noun affected by it. Moreover, not of but after came from the Gothic of after, because this, meaning offering, came also to denote successor, or that which comes after those who gave it birth. And in the Gothic it is used as a preposition signifying poff, after, where the t is introduced to humour the pronunciation, as δ is inserted in udo, for uo, or uo.

As of begins, it has the same sense with from, which Mr. Tooke derives from the Gothic and Anglo-Saxon from, meaning follow, beginning. This may be admitted. But whence did from originate? The Latin, it is well known, converted the Greek termination into m. Thus the accusative a became in or m; the genitive plural ess, etc., and the neuter ending ess, is also in Latin. On this principle m, is the parent of primus. This laid the Gothic of Wallachia, where, as Michaelis observes, a Latin colony had been established, and whole language, after this blending with the Latin, is the only specimen of the Gothic preserved in modern days, have borrowed and corrupted in the form of from, which retains the original sense of in, without. But we are not yet arrived at the origin of the word. The Arabic ٍ, p. 40, among other meanings, denotes the head of a family, which being rendered more general and abstract, gave birth to the Greek πρός, πρός, to the Latin præ, to frum in the Icelandic, Norfe, Danimith, Swedish, to se in Fretich, and from in Scottish. And thus the Arabic origin of the word accounts for the different forms of from, frum, fies, frum, in the Northern dialects, the first being derived through the medium of Greek and Latin; the others immediately from Ain. Mr. Tooke happens to be right in the meaning of from, merely because the Gothic corruption of frum has correctly retained the original sense of primus. He thus illustrates it signification. Figs came from Turkey; lamp falls from ciling; lamp hangs from ciling. Figs came, beginning Turkey, that is, Turkey the place of beginning to come. Lamp falls, beginning ciling; ciling the place of beginning to fall. Lamp hangs, beginning ceiling; ceiling the place of beginning to hang. This explanation is rational and just; but when he adds comes is a complex term for one species of motion; falls is a complex term for another species of motion; hangs is a complex term for a species of attachment, though very true, this is nothing to the purpose. Come, falls, hangs imply each motion or direction,
direction, and from points to the origin of the motion or direction in each, without any reference whatever to their peculiar meaning.

To the prepositions of and from, alludes the, till, and for. Mr. Tooke, in the latter, with equal propriety, does it from his own name, apply it from the Gothic tynos, to act, which is but the Greek ἀπό, to fabricate. Equally absurd is it to say that the Latin ad is from ambum. The parent word, as we have seen, is the Arabic نِن: نِن, to move to a thing. In Celtic, the word has preserved its original form (atta) in the exact sense of to. But in Persian, losing the initial vowel, it became taa; whereas, in Latin, retaining the first and dropping the last, it exists under the form of ad, and in English under that of at. To and at have a signification corresponding to their kindred origin, the former denoting the object of motion, and the latter coalescence with that object after its reaching it. “That till should be opposed to from, says he, only when we are talking of time, and upon no other occasion, is evident for this reason, viz. that till is a word compounded of to and while, i.e. time. And yet, for the life of me, I can discover no signification of these two words, while, took place in the language long before the present wanton and superfluous use of the article the, which, by the prevailing custom of modern speech, is now interpolated. So that when we say, “From morn till night,” it is no more than if we said, “From morn to time night.” When we say, “From morn to night,” the word time is omitted as unnecessary. So we might say, “From Turkey to the place called England, or to place England,” p. 365. But while, or, as it is in the Anglo-Saxon, beo, does not mean time but a period, or revolution of time, such as a day, week, &c. and is derived from the Hebrew תב, sunt, or geel, to revolve, and year, or, as our ancestors spelled it, gear, is derived from תב, sunt, or in Greek γείς. The Hungarian geel is also the parent of our sneak. To points to a final object either in place or time, while, in strict propriety, is applied to time only, and is derived from velo, to rise, and was at first expressive of the rising sun. Thus, “I will wait till morning,” i.e. I will wait the rising sun. As till denotes time, rising, or alternation of time, the word is always understood to be followed by some change implied in the context, but never expressed; thus, “We are always infinable of a bleeding, till (or until) we lose it,” then “we are infinable of it,” is a change implied. They will stay till morning; and they will then depart, is to be understood. Till exists in the Cymric language, and this is an additional proof, that the uncouth compound to sneak is a mere fiction of Mr. Tooke.

Mr. Tooke takes for to signify cause, as opposed to of, signifying consequence, from the Gothic subjunctive forma, a cause, p. 367. He thus illustrates them, I am sick of my husband, and for my gallant. Love makes her sick of and sick for. Here of and for seem almost placed in opposition. At least their effects in the sentence are most evidently different. With the help of these two prepositions alone, and without the affinities of any other words, the expresses the two contrary affections of loving and desiring. Her gallant was the offspring of her husband, proceeded from her husband. Her gallant was the cause of her love. But if her gallant proceeded from her husband, he was the cause of her gallant: and of and for, instead of being opposed to each other, as they certainly are, mean just the same thing, namely, cause, and not cause and consequence. But in truth, the matter is just the reverse of what our grammarians represent. Of means cause or origin, and for means consequence or end. She is sick of her husband—he is sick, her husband is the source of—she is sick for her gallant, and the object to which he looks with desire is her gallant. Accordingly, for always supposes the attention not directed backward, as to the cause, but forwards, as to some end; and its etymology is this, περι, to pass over, περιο, or per, the medium of passing to an object; the French pour, for, the object or end to which passage is made. Johnson gives for forty-five different meanings. But there is not one instance in which it does not bear a final describable from its primary signification of end or object. Thus, Christ died for us; Christ did us (i.e. our redemption) being the end or object of his death. To fight for the public good—fight, the public good being the end or object of fighting. He does all things for the love of virtue. He does all things, the love of virtue being the end or motive of all his actions, and to in all other instances.

By (in the Anglo-Saxon bia, be, big) is the imperative of byld of the Anglo-Saxon verb bread, to be. And our ancestors wrote it indifferently be or by. So then, according to this, our auxiliary be and the preposition by are of the same origin and what analogy in the name of common feasts is there between them, excepting the accidental resemblance of sound. Let us apply this etymology to the solution of some cases. "He was slain by the sword," i.e. he was slain be a sword, or, "Let a sword be." We might ask let a sword be what? Mr. Tooke has anticipated the question by saying this preposition is frequently, but not always, used with an abbreviation of construction: subauditor, instrument, cause, agent, &c. Really it appears to us surprising, that a man of taste and understanding should write thus. In Hebrew אָב, ba, is to pass, and is the parent of θαι in Greek. In Arabic and Persian it became a preposition, signifying the medium of motion. In this sense it gave birth also to the Latin via and to the English way, by, and also to the Anglo-Saxon preposition bi or be, and the English by, which was used by our old writers to signify the interval of time during which motion is continued; as, “By fo long a time,” i.e. for so long a time—By his life, i.e. during his life.

Then it came to signify the medium or instrument by which any action in general was performed. He was slain by the sword—He was slain, the sword being the medium or instrument of his slaughter. The derivation of with from wychan is no less absurd. What has with to do with wych, or, as we have it, were? The parent of this verb, which signifies to with, is the Hebrew יָכָה, wychan, light, air, the medium of existence. The Greek μέτα, denoting connection, connexion, instrumentality, has passed into the Anglo-Saxon in the form of mid, where it is corrupted into with, and exists in the same sense in both forms. The letters m, v, w, are of the same origin, and often change one for another. Many Greek words are borrowed from the Hebrew, by changing μ into β, as παντίν, μαθάν, is βαςονιν, to rule; and all the Welsh words borrowed from Latin have or corrupted into wy, arma arw; more wcr; me wo. Inflections of this species of corruption occur in Anglo-Saxon and Gothic. Thus, the Gothic wids is the Greek μέτα; and hence the Anglo-Saxon, and the English ear. Even wychan, from which Mr. Tooke also derives with, is only the Latin mittus, to send, to put. And not wychan, as he says, but γυνίς signifies to join or put together.

“"The English preposition through, says our author, is no other than the Gothic subjunctive durch, or the Teutonic subjunctive durub, and like them means derv, get, passage, p. 334.” And he adds in the next passage, “After having been in what manner the subjunctive bowe became a preposition in the French, you will not wonder to see derv become a preposition in the English; and though in the first instance it was more exy for you to see the nature of the French bowe, because having no preposition corresponding to it in English; yet I am persuaded you will not charge this to me as a fanciful
tactical or far-fetched etymology, when I have placed before you at one view the words employed to dignify the fame idea in those languages to which our's has the nearest affinity."

After doing this, he adds, "Though it is not in Asia or its confines that we are to seek for the origin of this part of our language, yet is it worth noticing here, that the Greek, to which the Gothic has in many particulars a considerable resemblance, employs the word αυτος for "door." All this is very exquisite, and being confidently advanced, it has the air of truth, though it be misrepresentation. The preposition through exists, as Mr. Tooke has shown, in all the collateral languages; and it may be observed, what he has not, that there is a guttural annexed to the word in all. Thus in English through, Anglo-Saxon thurh or thurh, Gothic thurh, German durch, Teutonic durar or durub, &c. This uniformity in retaining a guttural, shows that a guttural was an original part of the word. And it is no other than the Hebrew י"ע, dark, road, passage, which has given birth not only to this preposition, but to a multitude of other words in all languages.

He came through Greece, he came, Greece being the road, a passage of his coming. The genial fun warms through the air; the genial fun warms; the medium or passage by which it does this, is the air. We shall only add on this subject, that the prepositions over, above, beneath, exist in the Arabic, with little or no variation, and in the same sense; while among is the Persian معین, in the middle, the name with the Celtic mecen.

In the Hindoostanic it is founded with a nasal guttural, as if written meng, and by the same analogy that mid became amid; bee, above; bow, about; meng became among. The corresponding word in Hebrew is י"ע, bin or ben, which means separation, distinction, an idea the very reverse of that contained in megar, to mix, from which Mr. Tooke derives it. From signifying separation, it came to signify the interval between two things separated, and hence the Hebrew bin (or written with the vocalization bin) is the parent of the Anglo-Saxon between, between, within. The Greek μετεξαιρε, to overturn, is in Latin revert, to turn, which the Anglo-Saxons have further corrupted into rcover-an, to turn to. Hence, in the form of cound it came to signify the object to which the attention is directed; as estegserd, i.e. cast up. We add only the etymology of over, Anglo-Saxon ofer; Greek εικος; Hebrew י"ע, ober, to pass over.

"We have already observed, that Mr. Tooke's description of the nature and use of prepositions belongs more properly to the conjunctions. But we ought rather to lay it down that it belongs to neither. Prepositions express the relation of things, and those relations are the same, whether things or the complex names of things are few or many; and the necessity of prepositions arises not from the impossibility of having a distinct complex term for each different collection of ideas, but from the necessity of those ideas we have of things and their operations. It is therefore utterly erroneous to say, that the preposition is employed to supply the place of complex terms. On the other hand, the conjunctions serve to propede or to compare our ideas, to combine or to separate them; and this use is entirely independent of the number or variety of complex terms. If the complex term of a language be few, they cannot be so few as not to need being separated; and if they be ever so numerous, they cannot be so numerous as not to need being joined in conjunction. Indeed what Mr. Tooke says on this subject is indistinct, inappropriate, and even nugatory; though some subsequent grammarians have gravely copied his reasoning as oracular wisdom.

The prepositions and conjunctions in English exist in the Anglo-Saxon and Gothic. But this circumstance Mr. Tooke has kept out of sight. He knew it would appear strange to&C. these words of this kind from verbs and nouns in the parent tongue, while the very same words existed in that tongue coeval, and in many infinities antecedent to the nouns and verbs represented to be their origin. But whence came those conjunctions and prepositions to the northern language? We have anticipated this question by proofs from fact. Those branches of the northern tongue, as the northern tongue itself, has done, originated in the oriental languages. The structure of those languages is such, that the verb is the leading part of speech, and not only the subjunctive parts, but even the noun is derived from it. This doctrine is inculcated and supported by the most extensive and obvious analogies, and taught in the popular grammar, so that no learner, who has made any progress in them, can be ignorant of the true origin whence these particles including adverbs, prepositions, and conjunctions, are derived. The verbs, from signifying in the Asiatic dialects the actions of things, degenerated to express the relations and connections of those things; and with some necessary variations incidental to sounds, passed into Greek, Latin, and other tongues, in the form of prepositions and conjunctions; and they were hence propagated, with still further corruptions, into the Gothic, Anglo-Saxon, and other European dialects. Losing much of their primary forms, and changed in signification, European grammarians soon considered them as distinct parts of speech. And much uncertainty, confusion, and obscurity, hung for ages on the subject, till Mr. Tooke rose and dismantled the mist, by ascertaining their true origin to be nouns and verbs. This he acknowledges, or rather boasts to have been a mere conjecture at first; and it has this singular fate, that, while the conjecture itself is perfectly just, almost every inference alleged to support it is erroneous and futile. Having no acquaintance with the oriental tongues, and seemingly little acquaintance with Greek and Latin, but endowed with a powerful mind, as we conceive, under some wrong bibles, and actuated by a desire of opening new paths of speculation, he boldly imputes the dignity of an ancient and independent language to oral corruptions, chiefly made by barbarous people, so late as the dark ages. On some of these corruptions he lays his hands, and holds them forth to the public as the parents of those words which long existed antecedently to those corruptions. This we believe to be a just representation of the question, and our readers will hence be able to appreciate the merits of his system. The following is the table of genealogy, which he gives of the leading conjunctions.

</table>

We will briefly examine these. Skinner, before Mr. H. Tooke, has derived gif from the Anglo-Saxon gifan, dare; and perhaps this very word is the foundation of his theory, though he has not mentioned (and he may have forgotten) the circumstance which gave birth to his conjecture. It is, however, important to observe, that the use of gif as a preposition, is not of a late origin: for the Anglo-Saxons used it in that sense, and derived it in common with the verb gifan from the Hebrew, Arabic, and Persian word כפ, kaph, the palm
Now the action of the hand is two-fold, to give or to receive. In the latter sense it has passed into Latin, and produced capio, capi
ci, and even cabes, meaning to hold; in the former it has given birth to the Anglo-Saxon verb *Žj$, which signifies the action of the hand in imparting. Our word *keep* is apparently of the same origin, meaning to hold. Mr. Tooke observes, that *gin* is used in our Northern coun-
tries, and by the Scotch in the sense of *if*, and he justly says, that it is only a contraction of the participle green.

*An* used by old authors, means *if*, as in the following lines, quoted by Johnson:

"An honest mind and plain: he must speak truth An they will take it fo; if not, he’s plain."

That is, *if* they will take it so. This Mr. Tooke derives from *aan*, to grant, which is only the Latin *am***an*, to *affertain to*; whereas *an* is the Arabic particle; *N*, as, which is pronounced as if written *in*, when meaning *if*. We borrowed it from the Gothic, where it is employed, as it is also in Latin, to mark an interrogation. The derivation of *unlefs*, or, as it was formerly written, *olfs*, *on-lefs*, *of-lefs*, signifies at first sight not to be disputed. The application of the Anglo-Saxon *olfs* does not appear forced; *as*, Troy will be taken, *olfs* the palladium be preferred, *i.e.* Troy will be taken, *olfs* that the palladium be preferred, or, *olfs* that circumstances, namely, the preservation of the palladium, and Troy will be taken. And yet we are perfuaded that this is not the true interpretation of *unlefs*. Mr. Tooke is not fair in explaining the words from which he would derive this and other particles; but, in order to answer his own purpose, gives them a meaning which they really do not bear. *On-lefs* is interpreted by *ly*, *un-lefs* *le*, *un-lefs*, *fleves*, and it has no other meaning; and in this sense it is incapable of solving the difficulty. —"Troy will be taken, *unlefs* the palladium be preferred," which is hardly pereu. Mr. Tooke acknowledges that the Anglo-Saxon writers have not given us instances of *olfs* in a conjunctive sense: —"but, instead of it," adds he, "they frequently employ *nyme* or *nemhe*, which is evidently the imperative *nym* or *new* of *nymhe* or *neman*, to which is subjoined the, *i.e.* that; and *nyme*, take away that, may very well supply the place of *olfs* the, expressed or understood, *difmifs* that. But *nymhe* signifies not merely to take, but to take counsel, it being derived from the Greek *nymel*, to consult or deliberate; while the Latin *nomen* is named by *be*, by *rite*, by *rit*, *rity*, truly *lefs* is a security by law, and *ullfs* we conceive is a corruption of *unlefs*, *i.e.* unpreferred, unfeared. Thus, *Troy* will be taken, *ullfs* the palladium be preferred, *i.e.* it being unpro
duced, or it being not provided, that the palladium be preferred; or, provided that the palladium be not preferred, *Troy* will be taken. This author adds: *lefs* the imperative of *lefs*, which has the same meaning with *en-lefs*, is like
twife used by old writers instead of *ullfs*; as, "But will not bide there *lefs* yourself do bring him." To this he subjoins, in a note, p. 173, "It is this same imperative *lefs*, placed at the end of nouns, and coalescing with them, which has been given to our language such adjectives as *hoplefs*, *rifelfs*, *deathlefs*, *motionlefs*, &c. *i.e.* *difmifs* hope, red, death, motion." But *lefs*, we think, which, though not in a comparative form, conveys a comparative idea, is the offspring of the *lefs* *lefs* *lefs* (as little is of *tare*); both signifying small, ferner. From denoting something minute, it came, as the Latin *minus*, to express negation. On this principle, a *liefs*

ufual, though in time it came to convey absolutely a negative idea. *Hoplefs* without hope; *bottomlefs*, having no bottom; and we appeal to our readers, whether this explanation be not more simple and natural than *difmifs* the bottom. If this derivation be just, *lefs* or *lefs* is not the past participle *lef* *lefs*, to difmiss, but a contraction of *lefs*, the analogical imperfective of *lefs*, and it means the least degree of some con
cquence that follows the preceding clause; as, "Let those who fland take heed they fall," which means, let those who fland take heed; if not, they will fall, and that is the least that may happen.

*Els*, and, in the Latin *ar*, is ultimately derived from the Greek *ekso*, or as it is in Latin *auges*, to increase, though it may come more immediately from *caten*, the Anglo-Saxon offsping of *egio*. An observation of Mr. Tooke goes cer
tainly to prove the latter, if we can depend on its correctness. "In each language," says he, "where this impre
cative is used conjunctively, the conjunction varies just as the verb does. In Danish, the conjunction is *eg*, and the verb *ager*. In Swedish, the conjunction is *eb*, and the verb *eka*. In Dutch, the conjunction is *ek*, from the verb *ecken*. In German, the conjunction is *eb*, from the verb *ecken*. In Gothic, the conjunction is *ek*, and the verb is *akkan*." This example serves to shew how nearly allied these languages are one to another, and how a large portion of them is derived from the Greek and Latin.

*Lef* is affurled the Anglo-Saxon *get*, or *gu*, *olfs*, *stem*, though Mr. Tooke has referred it to the verb *to get*. This grammian seems not to have sufficiently studied those analogies by which the genius of a language is formed. The Anglo-Saxon, delighting in gutturals, forms many of its words by prefixing the particle *ge*, or the letter *g*. Thus, *getef*, *predeum*, is only the Greek *πηγε*, with *gie*; and *gen-

sage* is our among. This peculiarity gave birth to the German mode of prefixing *ge* to the perfect participle, and is the principle on which the Greek *αν*, in Anglo-Saxon is corrupted into *geta*, *get*, or *gut*. The Anglo-Saxon *fellen*, the German *fellen*, the Swedish *fella*, the Danish *felle*, originated in the Greek *φελλα*, which denoted first to lay down the fail of a ship. Hence in the above mentioned modern tongues, it came to signify, to place, *compens*, or *adjut*; but the general consequence of putting down the fail is to give *fillefs* or tranquility to the ship. Hence *ek* *ek* gave birth *alo* to the Anglo-Saxon *fellen*, and the English to *fell*, and to the conjunction *fells*. The Anglo-

Saxon and Gothic used it conjunctively in the forms of *fille* or *felle*, and its immediate parent undoubtedly is *fellen*, and not *fellen*, as Mr. Tooke would have us believe.

*Els*, with no lefs certainty, is the Anglo-Saxon *eles*, the Latin *alter*, and the Greek *αλλα*, and has nothing to do with *alfean*, to *difmiss*, and it means not *excepere* or *dismis*, but a change or difference in the consequence, or in the condition of what is expressed in the preceding clause. Thus, let the derivation be just, *else* it will not be received, *i.e.* otherwise it will not be received: let the derivation be just; if otherwise than just, it will not be received. On Mr.

Tooke’s principle the solution stands thus: let the derivation be just, *difmiss* it will not be received, an interpretation at once unnatural and unmeaning; and in order to give it the appearance of sense and coherence, he is forced to sup
po*se a clause understood*. Let the derivation be just, *difmiss* the derivation being just, or *difmiss* that circumstance, it will not be received: see his resolution of such examples in vol. i. p. 247. The conjunction *αλλα*, like *αλλω*, is a mo
dification of the pronoun *άλλος*, *another*; and may be re
solved in the same way as *else* in English.

GRAMMAR.

**On the conjunction although, or though,** we quote the following remark from the learned Dr. Jamieson, in his Etym. Dictionary. "Mr. Tooke derives though from the Anglo-Saxon *thuban,* or *thefgan,* to allow. But there is not the same evidence here, as with respect to other conjunctions illustrated by this acute and ingenious writer. It is not incredible to suppose that this word had some connection with the adjective *thuban,* which means *hardly,* and the verb *to allow,* or *to be allowed,* and the use of the word as an adverb, or conjunction, is but one of the possible modes of using this verb."

Mr. Tooke derives *but* from two different words, *butan,* to *but,* and *buten,* or *beten,* *bet,* or *bet,* and *to except,* and accordingly assigns the word two different senses, as it is taken from the one or the other. In opposition to this, we maintain that *but* is the Anglo-Saxon *buten,* or *butan,* and has the sense which it bears in that language of *except,* without, and no other but this, or one reducible into this. We further maintain, that the Anglo-Saxon *buten* is the Arabic and Hebrew הָלַע, *to cut,* which, as it exists in the former with the termination, is *butun,* and the principal idea implied in it is *separation,* with *but* has flowed from the same source; *bit,* a mark; *bit,* to separate with the teeth. Let us apply the word thus explained. I saw none but two plants—two plants being separated I saw none, or two plants being excepted or taken away, I saw none.

In such infinities as these, the negative is often omitted for the sake of brevity; but it must be supplied before the sentence can be explained. Again, "I have much to say on this subject, but I must proceed to another." Mr. Locke observed, that in such infinities, *but* intimates a stop of the mind, in the course it was going. But, says our grammarian, the truth is, *but* itself is the foot of any word in the language from intimating a stop. On the contrary, it intimates something more, something to follow. And, therefore, whenever any one in dicing finds in his words with *but,* the question always follows, but what? p. 205. Now, we hesitate not to say that Locke, though not right, is nearer the truth than Mr. H. Tooke. "I have much to say on this subject, let that however be separated, or that being separated or laid aside, I proceed to another." Here then *but* denotes the removal of the thing which already occupied the mind, and the succeeding word or words mark that which is introduced to fill its place. On such a removal the mind naturally looks forward to the introduction of something else; and its expectation in this respect forms no part of the meaning expressed by *but,* but is a habit formed by experience or affection. It might having remarked, that the Churches prayed, *conferred* places, and consulted the originals; Chillingworth replies, "you pray, but it is not that God would bring you to the true religion, but that he would confirm you in your own. You confer places, but it is that you may confirm or colour ever with plausible disguises your erroneous doctrines; not that you may judge of them and for sake them, if there be reason for it. You confit the originals, but you regard them not, when they make against your doctrine or translation." In all these places, *but* does not, as Mr. Tooke affirms, direct something to be *added* or *supplied,* but *denotes* a separation or removal of something that ought not to be separated or removed. You pray not that God would bring you to the true religion; you pray, motive being apart, that he should confirm you in your own. You confer places, the right object is separated, and you confer them that you may confirm, &c. You consult the originals, and regard them when they make for your doctrine; this regard is separated when they make against your doctrine or translation. Thus, whatever endings may be ascribed to *but,* they are all reducible into one original signification. Nor have we need with this celebrated grammarian to trace it into two distinct verbs, a thing in itself very improbable and contrary to all analogy, nor would he have adopted so unlikely an hypothesis, if it were not necessary for supporting his syllaon, in this passage, I came not to destroy, but to fulfill—I came not to destroy, another thing, (i.e. I came for another thing,) I came to fulfill.

Mr. Tooke derives *but* from two different words, *butan,* to *lot,* and *butan,* or *beten,* to *not,* or to *except,* and accordingly assigns the word two different senses, as it is taken from the one or the other. In opposition to this, we maintain that *but* is the Anglo-Saxon *buten,* or *butan,* and has the sense which it bears in that language of *except,* without, and no other but this, or one reducible into this. We further maintain, that the Anglo-Saxon *buten* is the Arabic and Hebrew הָלַע, *to cut,* which, as it exists in the former with the termination, is *butun,* and the principal idea implied in it is *separation,* with *but* has flowed from the same source; *bit,* a mark; *bit,* to separate with the teeth. Let us apply the word thus explained. I saw none but two plants—two plants being separated I saw none, or two plants being excepted or taken away, I saw none.

In such infinities as these, the negative is often omitted for the sake of brevity; but it must be supplied before the sentence can be explained. Again, "I have much to say on this subject, but I must proceed to another." Mr. Locke observed, that in such infinities, *but* intimates a stop of the mind, in the course it was going. But, says our grammarian, the truth is, *but* itself is the foot of any word in the language from intimating a stop. On the contrary, it intimates something more, something to follow. And, therefore, whenever any one in dicing finds in his words with *but,* the question always follows, but what? p. 205. Now, we hesitate not to say that Locke, though not right, is nearer the truth than Mr. H. Tooke. "I have much to say on this subject, let that however be separated, or that being separated or laid aside, I proceed to another." Here then *but* denotes the removal of the thing which already occupied the mind, and the succeeding word or words mark that which is introduced to fill its place. On such a removal the mind naturally looks forward to the introduction of something else; and its expectation in this respect forms no part of the meaning expressed by *but,* but is a habit formed by experience or affection. It might having remarked, that the Churches prayed, *conferred* places, and consulted the originals; Chillingworth replies, "you pray, but it is not that God would bring you to the true religion, but that he would confirm you in your own. You confer places, but it is that you may confirm or colour ever with plausible disguises your erroneous doctrines; not that you may judge of them and for sake them, if there be reason for it. You confit the originals, but you regard them not, when they make against your doctrine or translation." In all these places, *but* does not, as Mr. Tooke affirms, direct something to be *added* or *supplied,* but *denotes* a separation or removal of something that ought not to be separated or removed. You pray not that God would bring you to the true religion; you pray, motive being apart, that he should confirm you in your own. You confer places, the right object is separated, and you confer them that you may confirm, &c. You consult the originals, and regard them when they make for your doctrine; this regard is separated when they make against your doctrine or translation. Thus, whatever endings may be ascribed to *but,* they are all reducible into one original signification. Nor have we need with this celebrated grammarian to trace it into two distinct verbs, a thing in itself very improbable and contrary to all analogy, nor would he have adopted so unlikely an hypothesis, if it were not necessary for supporting his syllaon.
this union, or co-operation, is the copulative and; but when a
perion or thing opposes or counteracts another, or, in the
form of and, is combined with another word to express again or
in return; as and upon, a word in return for a word, i.e.
an answer; and against the sun, see Hicks's Anglo-Saxon
Grammar, p. 87. When objects act upon the organs of
sense, the mind is supposed in return to act upon the
impressions of those objects in order to perceive them, and
the perception so acquired is called in Greek ἀναπληραμα.
Hence, in Anglo-Saxon anaply, if we attend to the com-
position of the word, means that sense which the mind acts
or acquires by a reciprocal action on its own organs.

The conjunction, according to Mr. Harris and other
grammarians, connects not words but sentences, so as out of
two to make one sentence. Thus, you and I and Peter
rode to London, is one sentence made of three. But this
notion Mr. Tooke refutes by the following example; two
and two are four; A and B and C and D form a triangle.
John and Jane are a hand-ome pair. Does A B form a
triangle, B C form a triangle? Is John a couple? Is Jane
a couple? Are two four? p. 221. In truth, conjunctions
as well as prepositions affect words and not sentences,
and their office is to combine the words succeeding to the
words going before them, i.e. to combine a word coming
after with a preceding word; a noun coming after with a
preceding noun, an adjective coming after with a pre-
ceding adjective, &c.

Mr. Tooke has not given the etymology of than, though it
exists only in Anglo-Saxon under the form of thanne, and in
Gothic under that of thana. But in order to come at its
origin, we must attend to the effect which certain objects
produce on the organs of sense. When two qualities, un-
equal in degree, are compared, that which exceeds appears
to receive by means of the contral an immediate augmen-
tation; while on the other hand, the less seems to diminish.
This being the case, and human nature being the same in
all ages and countries, the same form of expressing the
degrees of comparison has obtained in all languages.
Thus in Hebrew tab min beryuth, good from gold, i.e. bet-
er than gold. The Arabs borrowed the Hebrew min to
express their comparative; and the Persians denote it by
az, a word of the same import. The Latin tongue in
this instance is founded on the same general principle —
Clarior folis, brighter from the sun. The French de and
the Italian di are derived from the Latin de; and as the use
of cafes in these languages has for the most part given way
to prepositions, they express their degrees of comparison
by these particles in the sense of from. In our own tongue
the mode of expressing the comparative seems alone un-
telligible. But by tracing than to its root the mystery
vanishes; and we recognize the same great principle of
nature. The imperative of the Hebrew גַּדִּל, גַּדִּל, which has given birth to corresponding verbs in all other
languages, is גַּדִּל than, which is precisely our English than,
retaining not only its original sound, but moreover its
original sense of give, put, place. Thus, his face was brighter
than the fun. Put the fun (namely by the side) his face
was brighter. Lighter than gold. Pat gold, it is lighter.
From the juxtaposition of gold it becomes lighter; or
as in other languages lighter from gold. I shall only add that
בָּשׁ, בָּשׁ, of the German, is a corruption of the He-
brew גַּדִּל, min or המ, b, v, being interchangeable
letters. Accordingly the Germans say in the superlative, der
belle von feinen brudern, the best from his brothers, the
bath of his brothers.

It still remains that we notice the adverbs and interjunc-
tions, but as we have already occupied too much of our readers at-
tention in discussing the other parts of speech, we shall dis-
patch these by one or two general remarks. Adverbs, or as
Mr. Harris designates them, attributes of a secondary kind,
are corruptions from nouns, adjectives, pronouns, and verbs.
The name of adverbs given to such corruptions is not, if it
should be observed, descriptive of their nature, as different
parts of speech, but of their use in modifying the verb or
adjective to which they are annexed. An adverb is often a
substitute for a whole clause, as here, for in this place; then,
for at that lime. In this view, adverbs are the only words
which properly come under the denomination of abbreviations,
a term of which Mr. Tooke is so fond, and to which he so
improperly refers several other parts of speech. As to in-
terjections, it may be questioned whether or not they can be
considered as articulate sounds, though they have been
usually honoured with a distinct department in language.
One consideration, however, is calculated to leave them in
polemic of their hitherto enjoyed honours. Interjections, it is true,
are not distinct names of our feelings and passion, and there-
fore they have no, like other words, derived articulation
from the association of sense with sound; notwithstanding
that certain expressions or cries, which in form of sound, in
nature, are as well calculated to recall to our minds ideas of
certain emotions, as if, like other words, they had been by
common consent made the signs of those emotions.

GRAMMAR is also used for a book concerning the rules
of grammar, which obtain in any language. See Lan-
Guage.

The ancient grammars are: for the Hebrew, that of rab-
bi Juda Ching, which is commonly held the first Hebrew
grammar that appeared; though it is certain, rabbi Saahas-
Haggam, who lived before rabbi Juda, composed two works
of the same kind: one expressly of grammar; and the other
of the elegancies of the Hebrew tongue.

For the Greek, the oldest grammar is that of Gaza: the
Latin ones are the works of Martianus Capella, Prifcin,
and Acofus Pedanius.

The modern grammars are: 1. For the Hebrew, that of
Pagninns, the edition of Hen. Stephens, or le Preux, at
Geneva, in 1592; that of Petrus Martinius at Rochel
1592; that of Buxtorf; that of Ludovicius Deus, in three
languages; that of Ssiximus Amoma, which is a collectio
from Martinius and Buxtorf; that of Bellarmin, with the
notes of Muis; the of F. Sgianther, of W. Schickard,
and of Vict. Bytlimer, to the latter of which is annexed a
brief account of the Chaldee, are useful for beginners; and
those of Gronovius, Schultens, Schroader, Bayly, Bennet,
Robertson, &c.; and for the Hebrew, without the Mafforetic
points, the excellent grammar of Mafiel, to the second edi-
tion of which, published at Paris in 1745, are annexed Chal-
dee, Syriac, and Samaritan grammars; those of Sharp,
Wilson, Bates, Parkhurt, &c. 2. For the Chaldean, the
belt are those of Martimiis, Buxtorf, and Lud. Deus, in three
languages. 3. For the Syriac, those of Amd, Myricans,
Water, and Beveridge; with the Chaldee and Syriac ones
of Buxtorf, of Lud. Deus in three languages, and that of
Lanc-
den. 4. For the Coptic, the Prodomon Coptas, and Lingua
Egypitaca Refituta of Kircher. 5. For the Arabic, that of
Erpenius, and that of Golus, which is only Erpanius’s a little
augmented. 6. For the Ethiopic, that of J. Ludolphus.
7. For the Persian, that of Lud. Deus, and that of Sir
William Jones. 8. For the Sancrit, that of Wlkins and
Carey. 9. For the Armenian, that of Schroder and
Galanus. 10. For the Greek, that of Mart.
Rahandis Syiburgius, F Moquet, Volnus, Gaza, Her-
man, Bahly, Port Royal, Manutius, Bell, Milner, Moore,
Parkhurt, Valpy, Jones, &c. 11. For the Latin, those of
Diogenes, Defianter, the Minerva of Santtius, those of
Volnus, Ward, Clark, and Sprat; that of Port Royal, which

6
is only a collection from the rest; those of Lowe, of Etow, of Jones, &c. 12. For the Italian, those of Berger, Lanfre-
dini, Port Royal, and Veneroni, Baretti, &c. 13. For the Span-
ish, those of Salazar, Port Royal, the abbot de Vairac, &c. 14. For the Portu-
guese, that of Pereira. 15. For the French, those of the abbe Regnier, and F. Baffier, &c. 16. For the High Dutch, those of Claius, Hertzbergus-
en, Schetkelius, Boedichier, and Steinbach. 17. For the Ger-
mans, that of Wendeoro, &c. 18. For the English, those of
Wallis, Brightland, Greenwood, Lovth, Priestley, Mur-
ray, Cromeby, &c.

Grammar is also used in the same sense with elements;
as geographical grammar.

Grammar, Philosophical, is that which, without regard-
ing the several idioms of particular languages, only reflects
those principles that are essential to them all. One of this
kind was proposed by lord Bacon; not upon the analogy of
words, but such as should diligently examine the analogy or
relation between words and things. He disapproves too cu-
rious an inquiry about the original imposition and etymolo-
gy of names. This he thinks an elegant, and, as it were, a
waxed subject, that may be handomely wrought and twisted,
but is attended with little truth and advantage. But, says
he, it would be a noble kind of grammar, if any one well
versed in languages, both the learned and the vulgar, should
think of their various properties, shewing wherein each of
them excel and fall short; for thus languages might be en-
riched by mutual commerce, and one beautiful image of
speech, or one grand model of language, for justly express-
ing the sense of mankind, he formed like the Venus of
Apelles, from the excellencies of several. And thus, at the
same time, we should have some considerable marks of the
genius and manners of people and nations, from their respec-
tive languages. See Bacon's Doctrine of Delivery, § 7;
and De Augm. Scient. vi. 1.

The object of philosophical or universal grammar is speech
or language, as divided into its constituent parts, as a statute
may be divided into its several limbs; or elicit, as resolved
into its matter and form, as the same statute may be resolved
into its marble and figure; and thus it is distinguished from
the art of logic, which considers speech as combined or com-
posed, so that by this synthetic, simple terms are com-
bined to produce a truth, and two truths are com-
bined to produce a third, &c. In this kind of grammar,
the design is to point out the several powers and modes of
expression which sounds are capable of, to trace their
connections with, or relation to the ideas they represent;
and to show the actual variety of the external expressions
of the same mental conceptions which different languages
exhibit. By this comparison we shall be enabled to judge
which is the most adequate and convenient method of ex-
pression, what is defective and what is redundant in the
structure of any particular language, and direct to the most
proper method of supplying the defect, or effacing the in-
conveniences arising from the superfluity. (See Lan-
guage.) See an excellent and well-known work of this
kind, by the ingenious and learned Mr. Harris, called the
Hermes, or a Philosophical Enquiry concerning Universal
Grammar, 2d ed. 1765. See also Troke's Diversions of
Purley, and the preceding article Grammar.

GRAMMAR, Character in. See Character.

GRAMMARIAN, Grammaticus, a person well versed
in grammar; or who teaches grammar.

The denomination grammarian is, like that of critic, fre-
quently, though unjustly, used as a term of reproach; a mere
grammarian; a dry, plodding grammarian, &c. The gram-
marian is conceived as a person wholly attentive to the minute
of language; industriously employed about words and phrases;
and incapable of perceiving the beauties, the delicacy, finenesse,
extent, &c. of a sentiment.

Scaliger, however, considered grammarians in another light.
"Utinam elixam," says he, "bonum grammaticus? fulleit
enigmaticum, qui noites anchores probe vult intelligentia, effic
grammaticum.

The title grammarian, it is certain, was anciently a title of
honor; being given not only to such as applied themselves
to grammar, or excelled in philology; but to all who were
reputed learned in any art or faculty whatever, as is shown

The word was properly a title of literature and erudition,
and was frequently given to persons who excelled in all, or
many arts, called into polyhistori.

Thus, Philoponus, a famous philosopher in Justinian's
time, remarkable for the extent and variety of his know-
ledge, was furnamed Grammaticus, as appears from Photius's
Bibliotheca.

So Saxo, the Danish historian, in the 13th century, got
the appellation grammaticus; and as late as the year 1580,
Thomas D'Avisa, a celebrated Neapolitan lawyer, was fur-
mained the Grammarian.

The title grammarian was anciently bestowed on those
now called critics, men of learning, erudition, letters, &c.
and particularly such as wrote well, and politely, in every
kind.

It is in this sense that Suetonius intitiles his book which
he wrote on the first Latin authors, "Of the celebrated
Grammarians: ; and that Cornelius Nepos calls the com-
mentators on the orators and poets, grammarians; and
lately, it is in this sense the appellation is attributed by the
ancients to Apion, Philoponus, and Solinus.

The most celebrated grammarians of the second century
were Aper, Pollio, Eutychius, Proculus, Athenæus,
Julius Pollux, Macrobius, and Aulus Gellius: the works
of these last authors are an assemblage of abundance of
very different things, and subjects relating to the criticism
of the ancient writers, and the polite literature.

If the name have lost its ancient honor', it is through the
fault of those who have abused it; by their treating of
grammar in a low, pedantic, dogmatic manner; reducing it
to words and syllables; and dwelling altogether on tritris
puerile remarks and confusions: whereas its ancien office was
to make an accurate and thoroughexamun of an author;
to enter into all his views; to point out the beauties, and
the defects thereof; to dilate upon the true beauties from
the false; and the genuine productions of an author, from
the figments; that is, a grammarian was then, what we
call a critic now.

Those who only taught to read, understand, and explain
authors, were called grammatici, grammaticæ; in contra-
distinction from grammatici; though, in course of time, the
grammatici have risen in the place of grammatici, who are
now preferred to that of critics.

GRAMMATICAL, something relating to gram-
mar.

We say, grammatical construction; grammatical signifi-
cation, &c. Idioms, as Angulifins, Latinifins, Grecifins,
Gallicifins, &c. deviate from grammatical strictures. Such
a phrase is not grammatically just; it is an idiom.

GRAMMATICAL Criticism. See Criticism.

GRAMME, in the new weights of France, is the weight
of a centimetre of distilled water at its maximum of density,
= 18.8247 French grams = 15.444 English grams =
.022045 English avoirdupois pounds.

This weight is the standard, or unit, of the new systerm
of weights; 100, 1000, and 10,000 times its weight,
beeing expressed by the prefixes, den, kilo, mile, and myria,
respectively.
respectively; and γ, 6th, η, 7th, and ω, 8th, by the prefixes dein, centi, and mill. Thus, hectogramme signifies 100 grammes, and centigramme signifies the 100th part of a gramme.

GRAMMELOUCh, in Natural History, the name of an East Indian shrub, very common in the woods and forests. It grows to five or six feet high; its leaves are very long and narrow, and terminate in a point; they are of a lively green; the fruit is carried in a bag of a triangular shape, of the size of a hazel-nut, but something longer; on opening this there appear three cells, in each of which is contained one fruit, resembling the seed of the palma Chirili, but covered with a transparent pellicle, and a black one under that; the inside of the fruit is white, and is of a sharp and pungent taste. It is a very violent medicine, operating both by food and vomit, and that often, so as to endanger the life of the person who has taken it. They alay its operation by eating betel. Mem. Acad. Par. 1629.

GRAMMICA, in Botany, from γραμμα, a line, aligning to its slender thread-like form. Locurie. Cuchinie. 1769, appears evidently by his description to be a species of Cufetia, or Dodder. See CUSCUTA CHINEA, n. 6, which is probably the very plant.

Esch. Ch. Cotyleds in straight feattred lines. Cover none.

This genus differs from Polypodium, in having its capilile disposed in straight continued lines, instead of round dots. The involucrum is wanting in both. Dr. Swartz defines twelve certain species. Of these such as have a simple undivided frond, like G. lanceolata, Swartz. t. 1. f. 5, form the most natural affemblage. The genus has, however, the advantage of admitting some forms, which preceding writers did not well know how to dispose of, as G. Ceterach, (Afpplenium Ceterach; Linn. Sp. Pl. 1538. Scolopendrium Ceterach; Sm. Pl. Brit. 1171. Eng. Bot. t. 1244) and G. laeppophyllum, Swartz. t. 1. f. 6, which Linnæus and other botanists had hesitated whether to reckon a Polypodium or an Afpplenium.

Dr. Swartz mentions two doubtful species; the Polypodium graminum of Linnæus, perhaps his own Grammitis linearis; and the Afpplenium subfine, of Cavanilles lectures, n. 627, a native of the Philippine islands.

GRAMMONT, in Geography, a town of France, in the department of the Scheld; and chief place of a canton, in the district of Audenarde, built at the foot of a mountain by the Goth, and thence called "Gotteghem." When Baldwin de Mons, count of Flanders and Hainaut, purchased the lordship of one Gerard, in 1068, he built a town, calling it after the name of the former lord, Gerardmont; and hence, by corruption, Grammont. It is partly situated on a hill; and the river Dender, which runs through it, divides it into the Higher and Lower Town; 20 miles W. of Brussels. The place contains 50,080, and the canton 16,000 inhabitants, on a territory of 92,4 kilometres, in 17 communes.

GRAMMUM, a town of Hindooslan, in Myfory; 44 miles N. of Serinapatam.

GRAMPINE HILLS, a range of mountains, extending from E. to W. through almost the whole breadth of the kingdom, from Loch Lomond to Stonehaven, and deriving their name from one of them, the "Mons Grampis" of Tacitus, where Galgæus waited the approach of Agricola, and where was fought the battle so fatal to the brave Caledonians. This chain of hills forms the southern boundary of the Highlands; though four or five counties on the N.E. of that chain have, in their eastern and northern parts, the name of Lowlands. The transition to the Grampians is gradual; the first chain, according to general Roy, consisting of the Sadley-hills on the E., the Ochils in the middle, and Campy-hills on the W. To the Grampian chain belong Ben Lomond, 3262 feet high; Ben Ledy, 3009; Ben More, 3503; Ben Lawers, the chief summit, 4015; Scheallien, 3564; Ben Verlich, 3300; and other less considerable elevations on the cafl.

GRAMPONK, a small borough and market town, in the hundred of Powder, and county of Cornwall, East England, is situated on the banks of the river Fal or Fale, in the parishes of Creed and St. Probus, the eastern part of the borough being in the former parish, and the wester in the latter. Grampound is fuppoted, by Bolkafe, to fand on the feite of the Volba of Piolemy. Extensive privileges were conferred on this town by king Edward I., particularly a freedom from toll throughout Cornwall; and the remains of a Caedufa, or Pion, granted with all the lands in it by this monarch, are still extant. The right of holding a market was a grant from John of Elizaun, earl of Cornwall, and brother to Edward III., who, after the death of earl John, confirmed the first charter, and made the town a borough; but no representatives were returned to parliament till the reign of Edward VI. Two members are now elected by the magistrates and inhabitants paying foot and lot; but the whole number of voters is only 25. The corporation consists of a mayor, eight magistrates, a recorder, and a town-clerk. The church is about half a mile from the town, in the parish of Creed; but a small chapel of ease stands near the centre of the borough. Grampound is 263 miles S.W. from London; has three annual fairs, and a weekly market on Saturdays. In the return under the late act, the inhabitants amounted to 5355; the houses to 864; Polwehle's History, &c. of Cornwall.

GRAMPUS, in Lichnology, the Delphin us erra of Linneus; which see.

GRAMZOW, in Geography, a town of Brandenburg, in the Ucker Mark; 8 miles S.E. of Preilow.

GRAN, or Esztergorn, or Strigæun, a town of Hungary, situated near the conflus of the rivers Gran and Danube; the fee of an archbishop; 55 miles S.E. of Preilow. N. lat. 47 44'. E. long. 18'.

GRAN, a small island on the W. side of the gulf of Botnium. N. lat. 62 1'. E. long. 17 22'.

GRANA, a sea-port of Spain, in Galicia; 2 miles W. of Ferrol. N. lat. 43 20'. W. long. 8 15'.

GRANA Figlia, in the Materia Medica, the fruit of a species of richius.

GRANA Paradisi, or Greater Cardamons, are the seeds of the amomum of Linneus.

GRANA Regia, the seeds of the common richius, called by some palma Chrilli.

GRANADA, or GRANADA, sometimes called Upper Andalusia, in Geography, a kingdom or province of Spain, occupying half of the eastern extremity; and all the southern part of Andalusia as far as the straits of Gibralter, has the form of a pyramid with its base to the east, on the kingdom of Murcia, and its apex to the south-west towards the Straits. Its length is 38 leagues from the E. to the S. E.; the breadth at its apex seven from the S.W. to the N.E., and at its base 28 from S. to N. To the E. and N.E., it is bounded by the kingdom of Murcia; to the S. and S.E. by the Mediterranean; to the W., by the kingdom of Seville; to the W. and N.W. by that of Cordova; and
GRANADA.

and to the N.W. and N., by that of Jaen. It lies between 36° 20' and 38° N. lat. and between 5° 4' and 1° 30' W. long.; and contains about 650,000 inhabitants. This province has three fronts on the Mediterranean, viz. that of Amunecar, defended by three forts of little importance; that of Almeria, which was celebrated under the Arabs; and that of Malaga, the most flourishing and most frequented. Its principal towns are Granada, the capital, Malaga, Almeria, Guadix, Motril, Marbella, Velez-Malaga, Baza, Vera, Ronda, Loja, Santa Fé, Huefca, Antequera, and Alhama. Its rivers are the Verde, Xeril, Las Feguas, Guadalemén, Guadavil, Guadameche, Rio de Almeria, Rio Frío, Guadixmerina, Darro, Andaray, Guadix, Bravata, Marhán, Almancora, Aguas, Culebras, and Guadalete. This province is very mountainous; its chief mountains being the following, viz. the Sierra Verdet, or Vernejal, i.e. red mountain, so called from the colour of the soil, the Sierra de Blanquilla, the Sierra de Bajo, the Sierra Blancaquilla, or white mountain, denominated from its appearance at a distance, and the Sierra de Javal-Cohol. The Sierra Nevada is a grand and beautiful mountain situated nearly in the centre of the province; it takes its name from the snow that remains on it through the year. It is very lofty, can be seen at a very great distance, and is well known to mariners, who discover it far out at sea. The Sierra Alpujara, likewise in this province, is formed by the contiguity of several lofty mountains, and generally called the Alpuxarés. These afforded a retreat to a considerable number of Moors driven from Granada, who remained there 120 years, till their total expulsion from Spain. The Sierra de Ronda lies on the southern and eastern part of the province of Granada; stretching N. and E. in that of Seville, and running S. towards the straits of Gibraltar. Granada, although mountainous, contains plains of considerable extent, and pleasant valleys abounding in springs.

Granada, as a part of Andalusia, was first known to the Physicians and then to the Carthaginians, who were expelled by the Romans; and they also were expelled, in the fifth century of the Christian era, by the Vandals; and the Goths, led by Euric, afterwards took possession of the country. The Arabs entered Spain by Andalucia in the year 711; and after the battle of Xeres, which decided its fate, as well as that of Spain, it belonged to the caliphs of Damascus, and then to those of Bagdad; till at length Abdalrahman, or Abderrame, a prince of the blood-royal of the Ommites or Almohades, feized on the throne of Spain in 755. In the year 1027 the empire of the Moors in Spain was dismembered; and in 1221 the kingdom of Granada was dissolved. Soon after this period, viz. in 1236, Mahommed Alamir, or Alhamar, founder anew the kingdom of Granada; and his descendants preferred for about 2½ centuries the throne, which he transmitted to them. It was reserved for Ferdinand V. and Isabella his queen, to give the last blow to the power of the Moors, by depriving them of the kingdom of Granada at the end of the 13th century. The capture of Malaga, Aug. 18th 1487, facilitated the siege of Granada, the capital of the province, into which the Moors had collected their whole force. They were attacked in 1491, and after a siege of upwards of a year, the town was obliged to surrender to the Catholic armies; and thus in 1492 the Moorish empire in Spain terminated. The extent of Granada at this time was 70 leagues long and 30 broad; it contained, as is said, 32 great towns, 97 smaller ones, upwards of 3000 boroughs and villages, and 5,000,000 of inhabitants. The revenue derived from it amounted annually to 700,000 ducats; and gold and silver abound more in this kingdom than in any other country of Europe. But the astonishing fertility and wealth of this country passed away with its old inhabitants, and were succeeded by a deplorable degree of indolence, poverty, and misery.

GRANADA, or Granada, the capital of the province above described, and an archbishop's see, is a large city, which was entirely built by the Moors in the tenth century; and in 1235, after having previously belonged to the dominions of the kings of Cordova, it became the capital of a new empire, and soon acquired great celebrity in the Moorish annals. This town, which in a short time became important for its extent, population, wealth, and power, and the magnificence of its buildings, became, in process of time, the ultimate refuge and last bulwark of the authority of the Moors in Spain. We have already given an account of its surrender to the Catholic kings. At that period it was three leagues in circumference; its ramparts were defended by 1030 towers; its walls included 70,000 houses, and a population of 400,000 inhabitants. It had an army of 60,000 men; and the number that defended its ramparts in 1491 and 1492 amounted to 100,000. It was protected by two fortresses, each of which was large enough to contain 40,000 men.

This town stands on two hills, at the end of the plain called Vega de Granada, near the Sierra Nevada, on the banks of the Darro which runs through it, and of the Xeril which bathes its walls. The two fortresses just mentioned are on the summits of the hills on either side, thus commanding the town, which itself commands the beautiful adjacent country ten leagues round; and its situation is delightful. The plain, at the extremity of which it stands, is somewhat sloping; its diameter is from nine to ten leagues, and its circumference 30; on the N. it is bounded by the Sierra Nevada and the mountains of Elvira, and on the other sides by succeffive and varied amphitheatres of hills agreeably planted with vines, olives, mulberry, lemon, and orange trees, &c.; it is watered by five rivers, intersected by various canals, supplied from limpid rivulets with a number of springs; and it is covered with meadows, forests of oak, woods of orange-trees, orchards, sugar-canes, corn, flax, and in short all kinds of fruits and vegetables.

Granada was formerly divided into four quarters, viz. Granada, Albambra, Albayzin, and Antiquera. Of these, the first, or Granada, is the handomest, most important, most agreeable, best built, and best inhabited part of the town. It occupies the commencement of the plain, and a part of the valley between the two mountains; it is embellished with a number of fountains, large gardens, handomé squares, and fine buildings; it is inhabited by the nobility, clergy, magistracy, and the richest of the citizens; and the principal markets are situated in it. The quarter of Albambra, properly speaking, is only a great fortess, situated on a mountain, called Sierra del Sol, or mountain of the sun; it was the residence of the kings, whose palace still preserves great beauties. (See the description of it under ALHAMBRA.) The quarter of Albayzin resembles a faubourg raised on a hill, where was formerly a fort, which commanded and protected the town, from which it is separated by a rampart. It contains about 400 houses. Antiquera has the appearance of another faubourg built upon the plain; it was peopled by settlers from Antequera, and is at presente chiefly inhabited by dyers and silk weavers. Among the numerous squares of Granada we may specify as the handomest, El Campo, in which is a hospital; the Plaza Mayor, which is spacious, and used for public shows, particularly the bull-fights; and the Divarat-mia, embellished by a beautiful Jasper fountain, and by the two fine edifices of the Alhambra, which was used by the Moors.
Moors as a bazaar, and still appropriated to the purpose of a market-place, and containing about 200 shops; and the palace of the chancery. To these two buildings we may add an ancient mosque, now a parish-church, the cathedral, two hospitals, and the two palaces of the Alhambra. The cathedral is not large, but has a handsomely done, reeling on twelve arches, supported by many large pilasters; the vault is full of paintings and richly gilt, and two rows of gilded balconies run round it over the arcades. Statues of the twelve apostles in bronze, gilt, and as large as life, are placed against the twelve columns. The vault of the church of the Charterux is covered with fine paintings in fresco, by Antonio Palamino. In many of the houses are found remains of baths, constructed by the Moors; and most of the houses are embellished with fountains, which supply water not only for domestic purposes, but for moderating by its coolness the heat of a climate extremely warm in summer.

Granada is an archbishopric, worth 25,000 l. a year, containing a cathedral chapter, six collegiate chapters, and 194 parish churches. This city is the seat of a royal chancery, divided into six chambers, and composed of a president, twenty-five counsellors, two solicitors, and one alguazil mayor. The intendent of the province resides here; and the town has a criminal judge, two alcaldes mayors for the administration of justice, a municipality composed of a certain number of regidores, a war auditor, and a tribunal of the inquisition. The Alhambra has a jurisdiction peculiar to itself. The city is divided into twenty-three parishes, with forty convents, three beatarias, seventeen hermitas or chapels, nine hospitals, and eight colleges. Granada has an university, founded A. D. 1531; and an academy for painting, sculpture, and architecture, conducted at the king's expense, and free for all. The extent of Granada is nearly the same as it was under the Moors; but its population is very much diminished. In 1614, at the period of the total expulsion of the Moors from Spain, a very considerable number of the families of that people left it. The town, which had counted 400,000 individuals within its walls, and which had armed 100,000 warriors in its defence, is now reduced, according to the government returns dated by Mr. Townend, (Travels in Spain, vol. iii.) to 52,352 souls; although, upon good authority, he says, they may be reckoned 80,000. Under the Moors, Granada carried on a great trade, and was famous for its own productions; it manufactured cloths, various kinds of wooden utensils, and a great quantity of silk. Indeed, it is not possible to think of manufactures in Granada, without calling to mind the expulsion of the Moors, and pausing to examine the policy of that strong measure. They were numerous, and, in consequence of their industry, accompanied with frugality, they had acquired opulence and power. It is said, (see Townend, ubi supra,) that of 100,000, condemned by the inquisition for apostatizing from the Christian faith, 4000 had been burnt without any good effect. Philip III., in the year 1569, banished to Africa 140,000 out of the kingdom of Valencia; and in the three years following, 620,000 from Seville, Murcia, and Granada. If to these we add the multitudes that perished by famine, and by the sword, we shall be inclined to rate the loss to Spain at one million of its most active subjects. This loss, added to what the country had sustained by the previous expulsion of 800,000 Jews, with all their wealth, in the reign of Ferdinand and Isabella, was, under such a government as that of Spain, irreparable. The Moors are acknowledged by the skilled Spanish writers to have excelled in agriculture, particularly in watering their lands, in the cultivation of mulberry trees, the sugar-cane, rice and cotton, all introduced by them; in their peculiar breed of horses; and in the manufactures of silk, of paper, and of gunpowder, first brought into Europe by them. The manufactures of Granada, however, continued to be somewhat flourishing about the middle of the sixteenth century. Some regulations, favourable to them, were adopted and established in 1552. At that time great attention was paid to the production of silk in Andalucia, and the trade in it was prosperous. But, in process of time, as the consequence of the expulsion of the Moors, the privileges and immunities granted to the hidalgos or knights, bearing in the kingdom of Granada the proportion of 1797 to 63,490, the whole number of inhabitants, and various oppressive restrictions and burthens, agriculture languished, silk was neglected, the manufactures decayed, and in the seventeenth century few or none remained. Some attempts have been lately made to revive them; some new ones have been established, in which ribbons and silk fans are made; but they have not been very prosperous. Here is a manufacture of gunpowder on the king's account. In the production of nitre, at the salt-works near this town, about 100 men are employed in summer, and 26 in winter; and from these government obtains 30,000 quintals annually. In the vicinity of Granada are some considerable plantations of the sugarcane.

The environs of Granada are delightful; the public walks, of which the most frequent are those on the banks of the Xenil with cooling shade and refreshing fountains, and another, more wild and romantic, by the side of the Darro, are pleasant; and the country all round the city appears to be well cultivated. The market gardens appear like a wilderness of fruit trees, and yet are covered with the most luxuriant crops of all kinds of vegetables. Every cottage has a little court, or bower, formed by a lattice frame, and wholly shaded by the vine; under which, in the evening, the peasant assembles his family to take refreshment; whilst the nightingale from every tree is uttering his plaintive note. These gardens are all plentifully watered. Granada abounds in marbles, remarkable for their variety, and fountains of grain, beauty; and it has also a variety of alhambas, papayers, and other precious stones. Its mineral waters are also various and abundant.

Granada, a small town in the province of Nicaragua, seated at the S.E. extremity of the lake of Nicaragua, has considerable commerce in indigo, cochineal, hides, and sugar. In the year 1683, this town, and also Leon, the capital of the province, were pillaged by the buccaneers of America. N. lat. 11° 15', W. long. 86° 15'.

Granada, New, a viceroyalty of the dominions of Spain, in South America, extending from the river Tumbez to the Caribbean sea; that is, from S. lat. 3° 30', to N. lat. 12°, or about 930 geographical miles; its medial breadth may be rated at 4° or 240 geographical miles. This grand and opulent viceroyalty, though it dates its origin from the year 1718, was, after a long supplication, only established finally in 1742. It is sometimes called from its capital Santa Fé, and comprises the following provinces: viz. Juan de Braconnoros, Loja, Cuenca, Macas, Riobamba, Gayaquil,quito, Tacames, Paños, Barbacoas, Papayan, Rapuño, Novita, Antioquia, Santa Fé, San Juan de las Llanos, Merida, Santa Marta, Cattagena, Zinn, Choco, and the Tierra Firme, including the three districts of Darien, Panama or Tierra Firme proper, and Veragua. The ample provinces which form this viceroyalty were mostly discovered and annexed to the dominions of Spain about the year 1536, by Sebastian de Benalcazar, and Gonzalo Ximenes de Quevedo, two of the bravest officers employed
GRA

in the conquest of America. The former, who commanded at Quito, made an attack from the south, and the latter from Santa Marta on the north. As the original inhabitants of this region were farther advanced in improvement than any people of America, but the Mexicans and Peruvians, they defended themselves with great resolution and good conduct. The abilities and perseverance of these two officers ultimately prevailed, after encountering many dangers, and reduced the country into the form of a Spanish province. The kingdom of New Granada was at first governed by the royal audience founded in 1547, and by its president the captain-general. In 1728 this arrangement was changed, and the viceroyalty was established; but it was suppressed in 1744, and finally established in 1750. When the conquerors first took possession of this country, it was more populous than the generality of the other states; and its want of population at this time prevents its being rendered one of the richest in America. The government refashions that of the other vicerealties; with a royal audience at Santa Fé, the capital, a tribunal of accounts, a treasury, and a royal mint. The royal audience sits in the same hall for civil and criminal causes; there being five judges, a fiscal, a protector of the Indians, and other officers. The governments, comprehend in the royal audience, are Cartagena, Popayan, Santa Marta, Maracaibo, and Portobelo, with the district of the river Hacha; in the interior are Antioquia, Choco, Veraguas, Nueva Granada, Giron, Neiva, and the Llanos. There is also a royal audience at Quito, and a governor and president, who rules the southern provinces in subordination to the viceroy of New Granada. But Quito remains a bisho]pople while Santa Fé is an archiepiscopal, founded in 1562, with Popayan and Cartagena as suffragans. In 1783 the archbishop was named viceroy. There are also several millions in the country called Los Llanos, and on the Apari, Meta, and Cauca, with some little villages or flatlands. These on the Upper and Lower Orinoco, and river Negro, affixed to the Capuchins in 1769, belong to the government of Caraccas.

The population of this viceroyalty has not been accurately ascertained; but if the general population of Caraccas amounts to 728,000, it is probable, says Mr. Pinkerton, that rather more than one million may be allowed for that of Granada. Of the amount of its revenues we have no certain documents; but from the amount of the annual coinage at Santa Fé and Popayan, and allowing a tenth to the king for the expenses of government, they cannot be less than 220,000 pounds. The state of the military force is inconsiderable; nor would it be easy in these difficult provinces to collect an effective force of five or six thousand men. The capital of this viceroyalty is Bogota, or Santa Fé de Bogota, for an account of which see those articles. Of the other principal cities and towns notice is taken in the progress of this work. The commerce of this viceroyalty has very much suffered from the supression of the galleons; and though it has been encouraged by the freedom granted in 1775, it is not yet recovered. The contraband trade, carried on by the English on the Mufquito shore, and from the Portuguese settlements in Brazil, and the Caribbean sea, has impeded the exertions of the Spanish colonies. Its commerce is allowed to be very disproportioned to the distinguishing advantages of this territory. Its existence almost depends on the gold from the mines, a few manufactures, and some native products. The manufactures are carried on chiefly at Tunja, Socorro, Villa Rica, and other towns and villages towards the plains; and they consist of cotton cloths, carpets, counterpanes, and vessels of various descriptions, that support internal trade. The northern provinces produce excellent wood for the construction of ships; and the dyeing woods are superior to those of Campbeley. The frequency of Panama is exquisitely beautiful, and superior to all others. The chocolate from the banks of the Magdalena is esteemed equal to that of Caraccas; and vast harvests of cotton and tobacco might be gathered, while the navigable rivers Magdalena and Atrato, and the ports of Caraccas and Santa Marta, offer easy and commodious outlets to the European markets. Its intermediate part of Havanais presents another convenience to the traffic of this viceroyalty. The culture of coffee and chocolate is in a prosperous state in the province of Guayaquil. The salutary and useful vegetable productions of these extensive provinces are so numerous and diversified, that industry alone is wanting to open all the sources of commerce.

The climate of this extensive viceroyalty presents great variety; for though it lies under the equator, and in its vicinity, the enormous and sublime chain of the Andes, running N. and S. from the Table land of Quito and Cuenca to the Caribbean sea, and environs of Santa Marta, occasion every diversity from the snow and ice of the poles to the rain and heat of the tropics. The great rivers Magdalena and Atrato, and the lakes and terrains in this province. The animals are in general such as are common to the whole continent of S. America; and the inhabitants breed a number of horses and mules which they send to Peru. The mineralogy of New Granada cannot be reckoned unimportant; Alcudia, called by Pinkerton, obseiues, that gold is here more abundant than in any other part of America. The richest provinces in this respect are those of Choco and Antioquia; and they are easily accessible by the rivers Atrato and Guacarca, which enter the gulf of Darien, and are navigable for a considerable extent. Silver is also remarkably pure; and the mines of Marquetones, in the district of Pamplona are fo rich, that if they had a sufficient number of labourers, they might rival those of Potosi, as they sometimes yield eight marks of silver in the hundred weight. Copper and lead also abound, but they are not much valued; and the various kinds of precious stones are plentiful. Platina has been thought to be the peculiar product of Choco. Salt is obtained in great abundance. The natives use maize, or the Cassava root, instead of bread. Game is abundant; and the rivers and lakes furnish an ample supply of fish. The natives are tall, and wear thick, white, or variegated cloaks, which they tie round the waist with a thaf. They adorn their heads with filings of painted flowers very ingeniously made of cotton. Robertson's America, vol. iii. Pinkerton's Geog. vol iii.

GRANADIER, Grenadier, or Granadero, a foot-solder, who is armed with a firelock, bayonet, and in former services a flanger, and a cartridge-box that will hold 36 rounds. They wear a high cap, fronted with a piece of braos, on which the king's arms is generally represented, &c. and a piece of cloth upon their shoulders, called a wing. In former armies they have better pay than a common soldier. They were first established in France in 1647, and soon after formed into companies: they were first known in England in 1687.

Granadiers, or Grenadiers, Horde, called by the French grenadiers velins, or flying granadiers, are such as are mounted on horseback, but light on foot and on horsecap. They were first established in France by Lewis XIV, in 1676, and formed into squadrons.

Every battalion of foot has generally a company of granadiers belonging to it; which generally take the right of the battalion; and, being the tallest and stoutest men, frequently are the first in attacks.
We have had in England two troops of horse grenadier guards; the first raised in the year 1693, and the second in 1701.

GRANADILLA, in Botany, the diminutive of the Spanish name of the Pomegranate, Granado, used in the West Indies, and retained by Tournefort and Adanson, for the *Pajifera of Linneaus*. This appellation is particularly applied to the fruit of *Pajifera quadrangulifera*, much esteemed by West Indians, and sometimes ripened in England.

GRANADO, Granada, or Grenade, in the Military Art, a hollow ball or shell, of iron, brass, or even glabs, or potter's earth, filled with gun-powder, and fitted with a fuse to give it fire.

The name granado takes its rise hence, that it is filled with grains of powder, as a pomegranate is with kernels. Of these there are two kinds; the one large, the other small; the first are to be thrown at the enemy by a mortar, properly called bombs, or field. The latter to be cast with the hand, and thence denominated hand-granados.

The best way, Cafmir obsevers, to secure a man's fell from the effect of a granado, is, to lie flat down on the ground, before it burst.

The common, or hand granado, is a little, hollow ball of iron, tin, wood, pasteboard, or other matter, filled with strong powder, lighted with a fusee, and thus thrown by hand into places where men flaid thick; and particularly into trenches and lodgments. These are now firk into diff'e.

Their composition is the same with that of bombs; which bee. For fire, they are usually between two and three inches in diameter, about the bignets of a common iron bullet, and weigh about three pounds; as to dimensions, they are commonly in thickness one-eighth, one-ninth, or one-twelfth of their diameter; their aperture, or orifice, about onehalf, as prescribed by Cafmir, Thuanus obseruer, that the first time granados were used, was at the siege of Wachtendouch, a town near Gheldres; and that the inventor was an inhabitant of Veulo; who, in making an experiment of the effect thereof, occasioned two-thirds of that city to be burnt; the fire being kindled by the fall of a granado.

Bombs were known long before the invention of granados. The ancients had a fort of ollas, or fire-pots, somewhat of the fame nature with our granados, but they were much less perfect.

Cafmir mentions a fort of blind granados, without any aperture, or fusee, as not needing to be lighted; but being thrown with a mortar, they take fire of themselves whenever they fall on any hard solid object.

GRANARD, in Geography, a neat, new built market and poll town of Ireland, in the county of Longford. Adjoining is a remarkable hill or mount called the Ablad of Granard, thought to be artificial, and the site of a Druidil fort, which commands from its summit a most extensive prospect into fix or seven adjoining counties. It is 52 miles from Dublin, and 12 from Longford.

GRANARY, in Agriculture, a building contrived for laying up and storing corn, in order to preserve it for a length of time. They have, near Grand Cairo; magazines or granaries, called "Joseph's granaries," defended with wooden walls, in which vast quantities of grain are annually preserved; and many parts of Africa abound with granaries of this kind. They are frequently deep pits made in the solid rock, the descent into them being just large enough for a man to go down; but they grow larger as soon as the person is in, and are usually square, from thirty to forty feet in diameter. In those the great men of the country prefer their corn; they first cover over the floor with straw, then they lay on the corn, fill, as the heap rises, placing a thin bed of straw between the corn and the fides, as they did at the bottom. In this manner they proceed till the whole cavity is filled: when this is done they cover the mouth or entrance with a fort of hurdle of green boughs of trees, interwoven one with another. This they cover with about two feet thickets of mud, and over this a hill of earth, well beaten together, in order to throw off the rain and sun in both ways, that none may settle on the place and soak into the magazine. The corn thus stored up keeps three, four, or more years very good; and, not infrequently, the proprietor being taken off by the severity of the eastern governments, under which they live, the magazine is forgotten, and some accident discovering it many years afterwards, the corn is almost always found perfectly good in it. All the care they take, in regard to the grain, is to expose it two or three days to the sun's heat, to dry it thoroughly, before they carry it into the magazine.

It may be stated further, that in the duchy of Lithuania, and in the Ukraine, the people also preserve their corn in the same manner, in wells or pits made in dry places: but in these countries great care is to be taken in the opening of these floor-rooms: for, if people descend into them before they have had sufficient communication with the fresh air, they are often killed by the damps; this, however, is easily guarded against. By these, and numerous other infallibles of the practice of other countries, it appears evident that subterranean granaries may occasionally be highly useful for the purpose of preserving grain in particular situations and circumstances.

But the common granaries may, with proper care, be rendered much more useful than they are at present. The grand caution necessary to this purpose is, to guard against the too great humidity, which is often the case in places where there is a great number of doors and windows. A too free access of the external air is also to be guarded against; as this has not only a tendency to produce the above effect, but is liable to bring in with it the ova or eggs of a number of different insects, which prey upon and destroy the corn. A third caution is, when the corn is the produce of the country where it is preserved, not to fill the place with the crop of one place only, but to mix the harvests of two or more different provinces as may be, the one dry, the other moist, or otherwise differing as much as may be; thus the contrary qualities of the one may prevent the distillation of the other. These are the principal rules to prevent the corrupting of corn: but when the mischief once begins, it will be very difficult to stop it; all the care that can be employed should, of course, be taken in regard to these as speedily as possible.

It may be observed, that the chief points to be attended to concerning the erection of granaries are to make them sufficiently strong, and to give them such a situation as may afford them to the most drying winds. But in constructing a granary merely for the accommodation of a farm, it is unnecessary, Mr. Bateson observes, in the second volume of Communications to the Board of Agriculture, to attend to all those circumstances respecting situation, &c. which ought to be observed in building an extensive granary, where large quantities of grain are sometimes demanded. A farmer seldom wishes to have a great deal of his threshed corn on his hands at once; nevertheless there ought, on every farm, to be a place of security, capable of containing, at least, one-third or one-half the grain produced, if necessary.
duced annually on the farm. Where the practice of housing corn is followed, there is little or no room, he remarks, within the barn for a granary; but where this is not the practice, particularly where there is a threshing mill, the granary may be easily made over the barn; which, with proper tackle for hoisting the sacks from below, is, he thinks, the most convenient and least expensive place a farmer can have it in.

The ordering of the corn in many parts of England, after being separated from the chaff, dust, and other impurities, and well screened, is: after bringing it into the granaries, it is spread about half a foot thick, and turned from time to time, about twice in a week; once a week they also repeat the sifting. This sort of management is continued two months, and after that it is laid a foot thick for two months more, and during this time turned once a week, or twice, if the season be damp, and now and then again sifting over. After about five or six months, it is raised to five or six feet in thickness in the lofts, and then turned once or twice in a month, and sifting now and then. When it has lain two years, or more, it is only turned once in two months, and sifting once a quarter; but how long forever it is kept, the oftener the turning and sifting are repeated, the better the grain will be found to keep. It is proper to leave an area of yard wide on every side the heap of corn, and other empty spaces, into which it may be turned and toiled as often as there may be occasion.

ToKent they make two square holes at each end of the floor, and one round in the middle, by means of which they throw the corn out of the upper into the lower rooms, and so up again, to turn and air it the better. Their scones are made with two partitions, to separate the dust from the corn, which falls into a bag; and when sufficiently full, this being removed, the pure and good corn remains behind.

By these means corn has been kept in granaries thirty years; and it is asserted, that the longer it is kept the more flour it yields, in proportion to the corn, and the purer and whiter the bread is, the superfluous humidity only having been evaporated in the keeping. At Zurich, in Switzerland, it is said that corn has been kept eighty years, or longer, by the same methods of management.

It is stated that the public granaries at Danzick are seven, eight, or nine stories high, having a funnel in the midst of every floor, to let down the corn from one to another. They are built so securely, that, though every way surrounded with water, the corn contracts no damp, and the vessels have the convenience of coming up to the walls for their lading. The Russians prefer their corn in subterranean granaries, of the figure of a sugar-loaf, wide below and narrow at top; the loaves are well plastered, and the top covered with stones. They are very careful to have the corn well dried before it is laid into these storehouses, and often dry it by means of ovens, their summer dry weather being too short to effect it sufficiently for the purpose.

Different contrivances have been proposed by M. Du Hamel and Dr. Hales, for ventilating or blowing fresh air through corn laid up in granaries or ships, in order to preserve it sweet and dry, and to prevent its being devoured by weevils or other insects. This may be done by nailing wooden bars or laths on the floors of the granary, about an inch distant from each other, when they are covered with hair-cloth only; or at the distance of two or three inches, when coarse wire-work, or basketwork of oyster, is laid under the hair-cloth, or when an iron plate full of holes is laid upon them. These laths may be laid across other laths, nailed at the distance of fifteen inches, and two or more deep, that there may be a free passage for the air under them. The under laths must come about six inches short of the wall of the granary at one end of them, on which end a board is to be let edgewayes, and framing against the wall: by this disposition a large air-pipe is formed, which, having an open communication with all the interstices between and under the bars, will admit the passage of air below forcibly through a hole at the extremity of it, into all the corn of the granary, that will consequently carry off the moisture evolutions of the corn. The ventilators for supplying fresh air may be fixed against the wall, on the inside or outside of the granary, or under the floor, or in the ceiling; but wherever they are fixed, the handle of the lever that works them must be out of the granary; otherwise the person who works them will be in danger of suffocation when the corn is fumed with brimstone, as is sometimes done for destroying weevils. Small movable ventilators will answer the purpose for ventilating corn in large bins or in small granaries, and may be easily moved from one bin to another.

If the granary or corn-ship be very long, the main air-pipe may pass lengthwise along the middle of it, and convey air, on both sides, under the corn. In large granaries, large double ventilators laid on each other, may be fixed at the middle and near the top of the granary, that they may be worked by a wind-mill fixed on the roof of the building, or by a water-mill. The air is to be conveyed from the ventilators through a large trunk or trunks, reaching down through the several floors: to the bottom of the granary, with bunching trunks on each floor, by means of which the air may be made to pass into a large trunk along the adjoining cross walls: from these trunks several leffer trunks, about four inches wide, are to branch off, at the distance of three or four feet from each other, which are to reach through the whole length of the granary, and their farther ends to be closed: clamps of one-tenth or one-twelfth of an inch are however to be left open at the four joinings of the boards, where they are nailed together, that the air may pass through them into the corn. In some of these leffer trunks there may be flitting shutters, in order to flow the passage of the air through those trunks which are not covered with corn; or to ventilate one part of the granary more briskly than others, as there may be occasion. There must also be wooden shutters, hung on hinges, at their upper part, so as to shut close of themselves; these must be fixed to the openings in the walls of the granary on their outside: by these means they will readily open to give a free passage for the ventilating air, which ascends through the corn, to pass off, but will instantly shut when the ventilation ceases, and thereby prevent any dampness of the external air from entering: to prevent this more fully, the ventilation should be made only in the middle of dry days, unless the corn, when first put in, is cold and damp.

But in smaller granaries, where the ventilators must be worked by hand, if these granaries stand on ladders, so as to have their lower floor at some distance from the ground, the ventilators may be fixed under the lower floor, between the ladders, so as to be worked by men standing on the ground without or within the granary. A very commodious and cheap ventilator may be had for small granaries, by making the door of the granary serve the purpose, which may be easily done by making a circular screen, of the size of a quarter of a circle, behind it; but in order to this, the door must open not towards but outwards, of the granary, so that, as it falls back, it may be worked to and from in the screen; which must be exactly adapted to it in all parts of the circular side of the screen, as well as at the top and bottom.
GRANARY.

Bottom. But there must be a step at about eight or ten inches distance from the wall, to prevent the doors falling back farther, that there may be room for a valve in the screen to supply it with air: which air will be driven in by the door, through a hole made in the wall near the floor, into the main air-trunk, in which there must be another valve over the hole in the wall, to prevent the return of the air from within.

But with the view of facilitating the labour of frequently stirring and ventilating the grain, and of lessening the expense of such buildings, a member of the Society for the Encouragement of Arts, Manufactures, and Commerce, in a letter to Dr. Templeman, recommends a new-invented granary, of which the following description is given. It consists, he says, of seven stories of floors, and may be built of any dimensions, provided proper proportions are adhered to.

The form of it is square, supposing fourteen feet square, within the rooms or cells. The distance from the floor of one cell, to the floor of that above, is five feet; and the whole building should stand on strong posts, more or less in number, according to the dimensions, at the distance of six feet from the ground. The small staircases, or rather ladders, to go to the several cells, must be fixed on the outside of the building, with a leading rail, or rope, to prevent falling. The whole granary to be built of what is generally called brick noggin; that is, it is first framed in strong timber work, and the interlaces filled up with brick. The floors, beams, and joists, are to be made strong to bear the weight of the corn; and the inside of the cells well lined with dry oak-board, close jointed, and the outside weather-boarded, the boards being strongly nailed to the timberwork of the frame, and afterwards payed over with pitch. The floors of the cells are to be contrived, as to slide towards the middle, in which part is to be an aperture six inches square, to be opened or closed by means of a sliding shutter, which must have a long handle, reaching in a groove, without the granary. On three sides of the rooms there should be windows strongly latticed, covered with wire, to keep out large insects and birds, and with strong shutters, to defend the corn from the weather. On the fourth side is a door to each room, to open from without. The windows are to be small, and as close as possible to the sieving. Over the upper room or cell in a loft, on the outside of the door of which is fixed a crane, to be worked within by a winch and siefers. The use of the windows in the sides of the rooms, is to give the corn all the benefit it can receive from the wind and fresh air. The door, when the cell is empty, admits the workman to sweep, dust, and clean it. The method of managing corn in this fort of granary is as follows: when the wheat is properly cleaned, it is hoisted in sacks to the loft above, and emptied through a hole for that purpose in the floor. The apertures in the floors of the cells being all open (except the two undermost, which are closed by the latticing shutters), the grain falls through till it reaches the undermost cell but one: when this is filled to the height of about two feet, which may be seen through the windows, the aperture in the floor of the next cell above is shut by its slider. This being filled in the same manner, the next above it is also shut, and so on till the whole are filled, if required, except the undermost, which is left empty. In this condition the corn is left for a week or more, if it was got in very dry. When it is to be stired, the floor of the undermost cell is to be swept very clean, the door is again shut, and the slider in the floor above drawn back, which allows the corn to fall through into that cell. When the cell above is empty, the slider is again shut, the floor swept very clean, and the slider in the next floor over that is opened. In this manner they are all managed, till at last the uppermost cell remains empty; and the window having all been open while the corn was falling from one cell to another, renders great benefit thereto, by admitting a current of air to pass through. Under the aperture in the floor of the lower cell, a proper screen is fixed; at the end of this screen is fixed a conductor or spout, to which a sack is hung, its bottom resting on a Miller's hand-barrow; the slider is then drawn, and the corn let fall on the screen, from which it runs into the sack; when the sack is full, the slider is for a moment shut, till another sack, on another barrow, is put under the conductor; the workman then wheels the first sack to the outside of the granary, and, fastening the crane rope to it, it is drawn up by another workman in the loft. The same method is pursued till the lower cell is emptied. If it is necessary to screen all the corn at this time, a small screen is fixed under the aperture of the next cell to be emptied, so contrived, as to have a box at the back of it for receiving all the dust, feeds of wood, &c. that pass between the wires; and this screen is facefully fixed under every aperture as the cells are facefully emptied. After the first month the corn need be stirred in this manner only once a fortnight, and after the first six months, only once a month, unless the weather is foul, and prove in autumn very hot and damp. The advantages of this granary, as described by the inventor, are, that it is built at a small expense; that it contains a great deal of grain in a small compass; and that the grain is easily stirred and ventilated, without the tedious mode of turning it with freshels, or other similar means.

However, the plan of a granary, taken from one built on his own estate, by a very repectable and intelligent gentleman in Cheshire, who has found it to answer extremely well, it is conceived, by an able writer, will perhaps be preferable to the above, not only from its cheapness, but from its simplicity, and the easy mode by which the whole body of grain is stirred, and the air conveyed and circulated through every part of it, at whatever thickness or depth it is laid, and one floor only is necessary, however high the building may be.

There can be no doubt, but that a granary of this nature may be very useful and convenient in many cases.

This fort of granary is shown in Plate Granary on Agriculture, in which fig. 1. displays the front elevation of the building: a is the door into the lower part; b, the door into the loft above, to ascend to which a ladder is necessary; c, a crane for hoisting sacks up from below; d, d, d, are air-holes for ventilation. At fig. 2. is seen a section or view of the infide of the building: d, e, d, e, are wooden spoles, which reach from the air-holes on one side of the granary to thole on the other. These spoles are formed of inch deal, about six inches broad, and made with an angle simial to those spoles that are employed to convey off the rain water from the eafings of houfes. They are placed acrofs the granary with the angle upwards, as represented at fig. 3; b, b, b, are the ends of similar spoles, which crosses the others, and also reach to the air-holes on the other sides of the building, as seen at fig. 4; e, e, e, are half spoles, extending in the fame manner to air-holes on each side. It is necessary that the air-holes should decline outwards, in order to prevent the entrance of rain or snow in stormy weather; and they should likewise be secured from insects and vermin by wire cloth: d, d, the floor of the granary, which is three yards square, and divided each way into three hoppers, c, c, c, of one square yard each, making in the whole nine hoppers, as seen at fig. 5; f is a large hopper, that encompasses all the left, and has a slider at g for opening occasionally, as may be necessary in taking out the grain. And there is another smaller hopper h, which is supended to this by four iron halps.
HALPS, I, L, &c., that may be readily unfastened when required, from the square deal box a, e, fixed to the large hopper. Through the side of this box, the handle b of the lid must extend. This hopper is principally used for the convenience of taking out a small quantity of grain, but is removed when a large quantity is to be taken from the granary; as is a small loft, into which the sacks of grain are located, and emptied over the sides or rails m, n, from which it falls down, and passes through the hopper a, c, till f is filled (the sides g being closed); and as the corn continues to be emptied from the loft, the granary is gradually filled until it is up to the top if necessary. The spouts being all inverted, as noticed above, and open below, it is obvious that, although the granary is filled to the top, the corn will not, like a fluid, rise within the spouts above the level of their lower edges; and thus there will be a vacuum left within every spout, through which the air will freely pass. These spouts are placed three feet distant from each other, horizontally from angle to angle, and eighteen inches vertically; that is, from those in one tier, to those in another, which is the next, and crosses it. The holes in the bottoms of the hoppers a, c, f should be so proportioned, that one may not give vent to the grain faster than another; for which reason, the aperture of the middle one a, fig. 5, should be the smallest, because there is the least obstruction there. The apertures b, k, k, k, ought to be of somewhat larger, as the grain will meet with some little obstruction there by the sides of the large hopper; and the apertures or openings g, c, c, should be the largest, as the obstruction in the angles will be greater than in any other part of the work.

GRANASUOLA, in Geography, a town of Italy, in the department of the Amona; 6 miles N. of Faenza.

GRANATAN, a town of Saxony, in the circle of Erzgeburg; 12 miles N. E. of Freiberg.

GRANATARUS, in Middle Age Writers, an officer in monasteries who took care of the provisions.

GRANATE, popularly called garnet, in Natural History. See Garnet.

GRANATE Pegle. The counterfeit garnet in pails, is formed with three different proportions of the ingredients, which are these:

Take prepared crysall two ounces, common red-lead fix ounces, manganic hemten grains, zaffer three grains; mix all well together; and put them into a crucible; cover it with a lid, and let it in a potter's kiln for twenty-four hours.

Or, take crysall two ounces, minute five ounces and a half, manganic fifteen grains, zaffer four grains; mix them well together, and leave room for their swelling in the pot; bake them twenty-four hours in a potter's kiln.

The last method is this: take crysall prepared two ounces, minute five ounces; mix them, and add manganic fifty-two grains, zaffer fix grains; mix them well together, and let all be baked, in a pot well luted, in a potter's kiln for twenty-four hours.

The first of these makes a very hand some garnet of the common tinge; the second, a deep one, with something of a violet tinge, as many of the natural garnets have; but the third makes much the bright and brightest. Neri's Art of Glass, p. 134. See Glass and Paste.

GRANATINE, a name given by Kirwan to several triple compounds, properly of the granite kind; but as it includes also combinations that have no more than one external ingredient of granite (such as the combination of quartz, jade, and garnet), it is obvious, that many rocks, thus united into one class, are far from giving all the characters of granite compounds.
the year 1697. The leisure which his diplomatic functions allowed was employed in translations of Voyages and Travels from the Portuguese. In 1702 he accompanied the same minister in Spain, where he remained about two years as secretary. Soon after this the marquis de Torci, minister of state, took him into his service, and employed his pen in drawing up several memorials concerning the Spanish monarchy, and other political topics, in which he was of great use to his patron, and acquitted himself with great ability. As an author his last printed work was a treatise

"On the Succession to the Crown of France." This was given to the world in 1718, and is reckoned a curious and useful performance. He died at the age of 86 in the year 1713. He had been published of church preferment, and had held, for a time, the office of censor royal of books. Morei.

**Grand.** In Geography, is a denomination applied to a variety of places, as in the following instances.

**Grand Alps,** or Jura, a well-built town in the western part of the island of Hispaniola; the road of which is so bad, that vessels, in order to escape the wind, are compelled to take shelter behind Cape Donna Maria. N. lat. 18° 15'. W. long. 74° 5'.

**Grand Bay,** a bay on the S.W. coast of Newfoundland, somewhat S. of Cape Ray.

**Grand-Bourg-Saléguas,** a town of France, in the department of the Creuse, and chief place of a canton, in the district of Guéret. The place contains 2525, and the canton 7885 inhabitants, on a territory of 215,000 square feet, in eight communes.

**Grand Canal, in Ireland,** is an establishment of which we have given some account in our article **Canal,** and have here to correct an error which crept into that account, in stating that the canal terminates in the Shannon at Termonbarry, instead of Shannon-harbour, two miles above Banagher. The branch to the Barrow joins that river at Athy; with a collateral branch from Low-town near Mountain to Portarlington.

When the new part of the canal was finished in 1834, from Tullamore to the Shannon, a general repair and deepening of the old parts took place, in which 5000 men were employed for expedition, and the whole line was squared out, so that 60 ton boats might pass. At Tullamore there are wharfs and warehouses for goods, and also at Shannon-harbour, with inns and other accommodation for persons on business.

The Doonare and Boulavoune celleries in Queen's county, belonging to this company, were in February 1809 worked by 100 men, and they advertised for 200 more, in order to work 100 acres of a coal field three feet thick, which had then recently been laid dry: the canals and river navigations admitting of their being conveyed to Dublin, Limerick, Waterford, Athlone, &c.

Kildare aqueduct, eight miles from Dublin, is 100 feet high, according to M. De Luce, *Geology,* p. 320.

**Grand-Champ,** a town of France, in the department of Morbihan, and chief place of a canton, in the district of Vannes; seven miles N.N.W. of Vannes. The place contains 4139, and the canton 7850 inhabitants, on a territory of 205,000 square feet, in four communes.

**Grand-Couronne,** a town of France, in the department of the Lower Seine, and chief place of a canton, in the district of Rouen. The place contains 8000, and the canton 12,793 inhabitants, on a territory of 182,000 square feet, in 13 communes.

**Grand-Fathers,** several large detached mountains of America, in the S.E. corner of Tenefice, in which are the head-waters of French Broad, and Cataba rivers.

**Grand Fort, a town of Africa, on the Slave Coast.**

**Grande Iland,** an island in the Atlantic, on the coast of Brazil; 16 miles long and two broad. S. lat. 23° 15'.

**Grande Island,** an island of America, in Lake Superior, on the N. side of the lake. — Also, an island in Niagara river, about six miles long and three broad; its S. end is four miles N. of Fort Erie. — Also, an island at the mouth of lake Ontario, within the British territories; 20 miles long and at its greatest breadth four miles.

**Grande Isle,** a new county of America, in the N.W. corner of the state of Vermont, incorporated in 1825, and including the towns of North Middle and South Hero, Vineyard (late Isle Moree) and Alloette.

**Grande Ile,** two large islands in lake Champlain, each about eight or ten miles long, and forming a township belonging to Vermont.

**Grand Junction Canal.** To the full account which we gave of this very important inland navigation in our article **Canal,** we have here merely to add a few particulars which have occurred since that account was printed. The act of the 5th Geo. III. for the Grand Union canal provides, that a canal with locks is to be substituted for the railway-branch from Cayton to Northampton, in order to open a communication by water, from the head of the new navigation, the design for the continuation of the Leicester and Northampton Union canals further south than Market Harborough, where it now terminates, being dropped, in consequence of the adoption of the Grand Union above-mentioned, which will connect the above canal with the Grand Junction. The three aqueduct arches over the Ouse at Wolverton having been made flat elliptical, instead of the curves of equilibration, and the foundation also insufficient, they gave signs of great insecurity immediately on their centres being struck, and in February 1808 two of them actually fell in and emptied the canal, as far as the flupgates; fortunately, the old line of locks across the valley had not been disturbed, and the trade has suffered no interruption in consequence. A cast-iron aqueduct on brick and stone piers is now building for these three arches, under the direction of Mr. Benjamin Bevan, who is now the engineer to the company. In 1807 a new referror was completed near the side-ponds on the northern side of the Tring summit, for supplying water to the locks below the side-ponds in dry season.

In examining the strata and springs on the north side of the chalk summit, between Tring and Wendover, with a view to better supplying the Wendover branch and summit-level with water, Mr. Bevan discovered, that different water-tight beds in the lower canal held up springs a considerable height above the canal, owing to their dip to the southward; and in order to avail himself of this water, a Tough or tunnel was begun in the upper bank of the canal near Wendover, and has been driven about half a mile southward, intersecting different strata of chalk from beneath, and increasing in its supply of water as it proceeded; but observing that the principal vent of this water was in the winter and early spring months, when the other sources were more than sufficient for the supply of the canal, it occurred to that ingenious gentleman to place a strong and water-tight valve in the most favourable part of this tunnel, which, as soon as the autumn as the canal is amply supplied from its other feeders, is shut, and kept so, until thee begin again to slacken in their supply; the water in the immense plumes of these beds of chalk, in the mean time accumulating, as in a vast subterranean reservoir, the springs rise to the level which they originally did before this tunnel was begun, about 20 feet above the canal; and for many weeks after
after the opening of the valve, in the beginning of summer, they pour forth a most surprizing stream of water into the canal, which otherwise would have vested miles off in the chalk valleys, or slowly have made its way down through the joints and fissures in the strata to springs at the bottom of the chalk, which vent below the level of the canal.

In 1808 a twelve-horse single Bolton's steam-engine was erected near Nuth-mill, in Hertfordshire, to lift the water again, the rise of four locks, for better supplying the mills during seven or eight months of the year. The company, in 1806, caused boats to be fitted up for conveying fat sheep alive, in tiers one above another, from distant places in the county, to the London markets, instead of fatiguing them by driving along the roads, the scheme of thus bringing oxen having been previously tried, and found not to answer; but after a fair trial, the expenses were found to over-balance the advantages expected from this also; we are sorry to add, that the cattle-market at Paddington has failed, and that the pens erected for it by the company have been sold and removed.

The limited quantity of coals brought to Paddington, or within 20 miles of this canal by this, now pay a duty of 10c. 9d. per ton (of 20 cwt. 11 lb.), which is equivalent to the duty on Newcastle coals in the Thames: in consequence of this heavy and opprobrious duty, many waggons and carts are employed in fetching coals by land, from the next wharf beyond the limited distance, near Watford. The Grand Union canal above-mentioned is begun, and is to join this canal near the S. W. end of the Braunston tunnel. The design of a branch from near Tring, through Aylesbury and Thame, to the Thames and it's navigation and Wilts and Berks canal near Abingdon, has been again revived, and it seems probable, that an act for that purpose will pass in the ensuing session of parliament (1811). Towards supplying water to the inhabitants near Paddington, a transfer of the company's rights has been made to a separate water-company, which is expected to be confirmed by parliament in the ensuing session.

In November 1826, the company declared the first half yearly dividend of 1½ per cent, on the original shares, which has regularly increased to 3 per cent., half-yearly, exclusive of property tax. The affairs of the company seem now fast retrieving from the effects of their great mismanagement for many years after its establishment, and to be now in a very prosperous state; the shares (of 100l.) were, in September 1815, reported to be currently sold at 30l. each! although, at one period, the fame could with difficulty be disposed of at 65l. to 70l. each: such are the effects of good or bad management, and of abilities and integrity in those entrusted with the direction and management of an immense concern like this, in inspiring confidence in commercial men to enter into trade and speculations connected with the canal, and in capitalists to invest their money in the company's shares. A resolution of the general assembly of proprietors, on the 7th of June 1803, for appointing a general superintendent of their concerns, principally led to this beneficial change. On the 11th of June following, Charles Harvey, esq., was appointed to this office by the committee, and, after much opposition from certain powerful individuals, was, on the 11th of July, confirmed therein, by a general assembly called for the special purpose.

**Grand Key, a small island among the Bahamas.** N. lat. 26° 54'. W. long. 77° 48'.

**Grand Lacs, a lake of Louisiana.** N. lat. 32°. W. long. 93° 3'.

--- Also, a lake in the province of New Brunswick, near the river St. John's, said to be 30 miles long, eight or ten broad, and in some places 40 fathoms deep.

**Grand Luce, Le**, a town of France, in the department of the Sarthe, and chief place of a canton, in the district of Saint-Calais; 14 miles S.E. of Le Mans. The place contains 20,435, and the canton 10,493 inhabitants, on a territory of 2,717 kilometres, in 8 communes.

**Grand Menen Island,** an island of the Atlantic ocean; 6 miles S. by S.E. of Campo Bello island, opposite to Papanaquoddy bay on the eastern border of the United States.

**Grand Ridge,** is a term often used, (see our article CANAL,) for the water-head, or summit line, across an island or continent, from whence the rain waters fall by opposite courses to the ocean. It results from the admirable system of valleys, which the great Creator has spread over the whole face of the earth, having no part, perhaps, originally of the surface, without a decent and out-fall to the sea; that the ridges, or summit-lines, form a system not less beautiful and perfect than the valleys; and whence it happens, that, from any hill whatever, it is practicable to mark on a good map, and to travel to every other hill in the same island or continent, however large, without crossing any running water, however small, but constantly to pass along a ridge or waterhead; whence the waters on the surface fall opposite ways from your route. It seems surprizing, that no one has attempted to illustrate this subject by a good map, shewing all the connections and windings of these ridges in England, or even any local district, until of late, that Mr. Farley has prepared a square of map, including Derbyshire, shewing the ridges, and the situation of all the hills and principal eminences upon them, which is intended to accompany his report to the Board of Agriculture on that interesting district.

The triangular form of the British island, and the situation of the two principal rivers, the Thames and the Severn, (or rather the Bristol channel,) occasion the grand ridge of England to divide into two branches on the Chalk Downs, a few miles N.E. of Devizes; one of which, (the south-wester,) proceeds to Runway-how, and crosses the deep cutting of the Kennet and Avon canal, near to Devizes, near Elst Lavington, Warminster, Wincanton, Beamfnite, Crewkerne, Chard, &c. by a most circuitous route, passing almost to the north and to the south coasts alternately, until it reaches the Land's End in Cornwall; having, in this long route, probably deflected to no lower strata than the red ground or marl, of which we shall speak further presently.

The other, or south-eastern branch of the grand ridge, proceeds along the chalk and the clays and sands above it, across the deep-cutting of the Kennet and Avon canal, near Burbage, by High-clere, (near which it probably occupies the highest stratum in the whole British feries,) near to Alton and Haslemere, when it soon descends off the chalk into the great southern demudation, (see Philosophical Magazine, vol. xxxv. p. 130,) and pursues the under meanders, through the wealds of Sussex and Kent, by Alford, Leith-hill, Hands- crofts, (on the London and Brighton roads, being there on the lowest stratum but one which appears in that road,) by Turner-hill, Nutley, Crowborough, Rotterfield, Wadhurst, Tenter-den, Shadowshurll, Lyme (near Hythe), where it again ascends the edge of the chalk, and proceeds on it by Padlef- worth, Swiegfield, and Lydden, to the coast at King's Down, near Walmer castle.

From the point of branching, N.E. of Devizes, as above described, the grand ridge follows the chalk northward by White-horse hill, near Cherhill, &c. till within a few miles of...
of Swindon, when it turns to the N.W., and descends to the marle, and other strata below the chalk, crossing the Woburn sand flintstratum, not far from Wootton-Bailey; and passing to the Bath free-stone range, it crosses the Salperton tunnel, on the Thames and Severn canal, and proceeds near to the western edges of the fame strata, by Charlton-Kings, near Cheltenham, Stanway-hill, Broadway-hill, Lemington-hill, Long-Compton-hill, and Epwell; soon after which, the grand ridge begins to leave the free-stone, and take to the dark blue clays, &c. under it, except cropping some points of the flint, and traverses the Fenny-Compton tunnel, on the Oxford canal; thence by Holllidon, and near Daventry, it crosses the Braunton tunnel, on the Grand Junction canal, at Well-Haddon, and at Husband's-Bosworth, the tunnels of the Grand Union canal; when, turning north-west, the ridge paffes Gilnorton; and not far from Lutterworth it crosses the Lias clays and limestone strata, and descends to the red marle (above mentioned), and quickly, by a great fault, or sudden lift of the strata, is brought upon the coal-measures of the Bedworth-field, and crosses the deep cutting of the Coventry canal, through Bedworth town, across the late sir Roger Newdigate's canal, and sweeps round to the west, south-west, and south, to Kenilworth; when, having crossed another fault, and got again upon the red marle, it crosses the deep-cutting of the Warwick and Birmingham canal, near Baddesley-Clinton, and of the Stratford canal, near Hockley; thence by Ashby-heath, and crosses the Well-heath tunnel of the Worcestershire and Birmingham canal, and the Lapal tunnel of the Dudley canal; after which, the grand ridge crosses the bathatic hills between Rowley and Dudley, (which belong to the red marle strata,) and, descending to the coal-measures, crosses the Dudley tunnel N.W. of that town, and proceeds by Sedgley; then cropping an erect and demoted patch of the yellow lime-flint, it crosses the deep-cuttings of the Old Birmingham canal, the WVley and Ellington canal, and of the Staffordshire and Worcestershire canal, all near Wolverhampton town; then by Tatterhall, Wrottesley, Blnnhill, Cowley, Wootton, (near Eccleshall, Broughton, Ashley, Maer, Madeley-park, to Keele, (near Newcastle-under-line,) where it has again got upon coal-measures, by Bignole-hill, and across the Harcastle tunnel, on the Trent and Mersey canal, by Golden-hill, Wickinniton rocks, and, cropping an immense fault, descends to the lime-flint shale, (see Mr. Farey's section in Plate II, vol. xxxii. of the Philosophical Magazine,) on Biddulph Moor; thence paffes the top of the Great Rudyard revoir, to Gun-hill, and cropping to High Roches rocks, it there ascends the first grift; then crofes a small trough of the first coal-hall and second girt, and descends again to the first grift, or Ramshaw rocks, and still further, on the lime-flint shale, at the Royal Cottage, along which it proceeds to the N.W. side of Flash, and thence ascends the first grift again, on South-Axeedge-hill; it again descends to the lime-flint shale in crofing Middle and Great Axe-edge-hills; from whence it ascends across the first grift and first coal-hall, and ascends the second grift on Thatch Marsh; this it pursues to the north of the Macclesfield and Buxton road, and then turning N.E. again descends to the lime-flint shale, and follows it across the Mancheffer and Buxton road; soon after, it ascends the first grift and first coal-hall, on Combs's-mot, and again descends to the shale, paffes Sittinglow, (11 mile S.E. of Chapel-en-le-Frith,) when, turning eastward, it crofes the Great Lime-flint fault, (N. of Dove-holes,) and is found upon the third lime-flint, on which it crofes the quarries and rail-way of the Peak-Forest canal; soon after, it paffes over the bafliff-edge of the third coal-hall, and descends to the great fourth lime-flint in Peak-Forest, which is probably the leaffit flintstratum, to which the grand ridge paffes in its route through England; this lime-rock having been estimated to be four miles at leaff of perpendiculur thicknefs below the top of the chalk, from whence we commenced our defcription; much the greater part of this vaft series of flata having in this route along the grand ridge been loft suddenly by perpendicular lifts of the flata or faults, which, in proceeding to this point by more favourable routes, might have been seen baffling in effection. For about one and a half mile the ridge proceeds upon the fourth lime, then again paffes a point of the third coal-hall and third lime, to the village called Sparrow-pit, in the Mancheffer and Caflerton road, where it again crofes the great fault and descends to the lime-flint-hall on Rudhop-edge, whence it proceeds northward, and after crofing the Badele-road from Hayfield to Edale-chapel, it paffes the firt grift on Edale-rock, and proceeds across the moifes on Kinder-scout hills; thence it leaves at their N.W. corner, and crofes the moifes on the flade, and the ancient Badele-road called Doctor-Gate, from Glossop to Ashop Dale; it then paffes the firt grift again on shelf-flones, and follows the fame to Wain-flones and Blakele-low-flones, which seems to be the fift and land in Derbyshire, it then paffes N. E. by Round-hill, and descends to the firt coal-hall, crofes the Mancheffer and Penifone-road at Lady-crofs; where, turning N. W. it paffes the fcond grift rock, and proceeds by Dean and Brethand Edges, to crof the Glossop and Huddersfield road, on the bags upon this rock on Holme moifes; from hence the ridge, after fome dilance, again descends to the firt coal-hall, the firt grift, and to the lime-flint-hall, crofing the Stange tunnel on the Huddersfield canal near Marleton; the ridge then proceeds across Black-flone-edge, and crofes the deep-cutting of the Rochdale canal near the village of Hun dersfield, (which has improperly been laid in the population accounts of 1801, to be a town containing 1,671 perfons,) the ridge then paffes Holme on the Barley and Halifax road, whence it proceeds, and near Colne comes again upon coal-measures, which are, however, loft again at the great fault, in which part of the Fourfride tunnel on the Leeds and Liverpool canal was driven, and which occasioned the extraordinary trouble and expense attending that tunnel, which is mentioned in our article CANAL. From hence the grand ridge proceeds, by Barnoldwicke, West Marton, near the Cold-Combror, E. of Settleton lime-flone, over Pen nigator-hill, Snares-felt, Nine-Varlands, Kelton-fell, Lane forest, Scordal-head, Milburn-forcid, Aldinton-moor, (line), Hartide-crofs, Gelflake-forcid, Talkin, and crofes the Roman or Psits wall on the E. side of Upper Denton, and foon after it enters Roxburghshire in Scotland; through which it is much easier to trace this grand ridge than in England, it forming often the boundaries between the Scotch counties, to which this ridge and its collateral ridges are much better adapted than the rivers and brooks, which have generally been chosen as boundaries, both as being more permanent, and not liable to the changes which streams of water are undergoing in the bottoms of vales, and avoiding those disputes respecting, and the delay of making and improving bridges, fords, navigations, mills, &c. owing to the rivers being part in one county and part in another, and by which also many of the moft consider able towns are split into two or more counties, to the no small inconvenience of their inhabitants, in judicial and other county matters.

Grand River. See Ottawa and Ouse. — Alfa, a river of Africa which runs into the Indian sea. S. lat. 2° N. 41 —Alfa.
—Also, a river of Sicily, which runs into the Mediterranean on the N. side of the island, N. lat. 38° 3'. E. long. 14° 54'.
—Also, a river of America, which discharges itself into Lake Michigan, N. lat. 43° 25'. W. long. 82° 55'.—Also, a river of America, which runs into Lake Erie, N. lat. 41° 55'. W. long. 81° 8'.—Also, a river of Canada, which runs into the Detroit, N. lat. 42° 34'. W. long. 82° 32'.—Also, a river of Canada, which runs into the St. Lawrence, N. lat. 47° 3'.

**Grand River, or Rio grande, a river of Africa**, which runs into the Atlantic, near the Bificagos isles, N. lat. 14°, W. long. 14° 30'.

**Grande Soie, an Indiaman**, inhabiting a territory of the Miilion. and able to furnish 800 warriors.

**Grand Surry-Canal.** This canal is yet in the same state, nearly, as when our account of it in the article CANAL was written. In 1825, except that about two miles in length of it, at its N. E. end, has been brought into use, a work that the Croydon canal has been completed; and the dock for ships, at its entrance from the Thames, was completed and opened in June 1857, and has answered so well to the proprietors, that in the last session of parliament, they made an unsuccessful attempt to obtain power for a further extension of them. In February, 1859, this company determined on erecting a ten-horse steam engine on the banks of the canal, by the Deptford road, for supplying the neighbouring inhabitants with water, intending to let the surplus power of this engine to some manufacturers.

**Grand Traverse, a range of islands, consisting of huge rocks in lake Michigan.**

**Grand Trunk Canal.** A name commonly applied to the Trent and Mersey canal, which fee in our article CANAL.

**Grand Union Canal.** In the session of parliament, 1810. (50 Geo. III.) an act passed for making the Grand Union canal, the general direction of which is about S.W. 234 miles, in the counties of Leicestcr and Northampton, being considerably elevated, and crossing the grand ridge of the island twice, by tunnels, its middle part for about half its length skirting near to the ridge on its western side, and the two ends being on the eastern side of the ridge. Its objects are the completing of the long-defined water-communication between the Trent river and the many canals which connect therewith, in Derbyshire, Nottinghamshire, and Leicestershire, and the Grand Junction canal, and through it to the metropolis, without making the enormous circuit by Burton, Fradley-heath, near Litchfield, Tamworth, Atherstone, Nuneaton, and Braunstone, which at present goods, coming by water from Leicestershire, Nottinghamshire, and Derby must do; it is intended also to improve the necessary for the southern part of the Leicestershire and Northamptonshire Union canal, between Market-Harborough and Northampton, which on account of its difficulties has never been attempted; the present rail-way branch between the Grand Junction and Northampton is intended to be changed for a canal with locks, by which means the people of Northampton will have a water-communication with Market-Harborough, Leicestershire, &c. with only about 14 miles longer distance than the Leicestershire and Northampton Union would have been, if the same had been completed according to its original act. Market-Harborough and Daventry are the only considerable towns near the line of this canal, which commences in the Leicestershire and Northamptonshire Union canal near Gunley, and terminates in the Grand Junction canal near Buckby-wharf, near the S.E. end of the Braunstone tunnel. From Gunley 7 1/2 miles is a rise of 76 feet by 12 locks, and thence to Welford, 19 miles are level, then in 2 1/2 miles is a fall of 53 feet by eight locks, and thence to the Grand Junction canal about three miles are level; near Hubbard's Bosworth is a tunnel of about 1200 yards long, and near Crick another of about 900 yards long. Near Crick it is proposed to make a referrer of 66 acres above the canal, but below its level, so that the surplus water collected from other parts of the canal in rainy seasons can be here reserved, to be pumped up when wanted.

The width of the canal at top is 42 feet and 1/2 at bottom, and its depth of water five feet; the locks are 82 feet long and seven wide, calculated for 35 ton boats. This line was first surveyed by Mr. James Barnes in 1803, and by Mr. Benjamin Devan in 1809 and 1809, and the latter is appointed engineer for the execution of the work.

**Grand Western Canal.** To be denominated in an act which passed in the year 1796, as mentioned in our article CANAL, but under which no progress had then been made. In April 1812, it was reported, that a beginning had been made on the summit level, in Holcomb, Devon. A much larger canal, capable of conveying ships from the Bristol channel to the coast of France, has been some time in agitation, for avoiding the very circuitous and tedious navigation round the Land's End; which, however defensible, is scarcely practicable, we incline to think, for want of water.

**Grand Affife, in Laco. See ASSISE.**

**Grand Cape. See CAPE and ATTACHMENT.**

**Grand Centurion, E., an ancient book of very great authority, which contains the ducal customs of Normandy.**

**Grand Days. See Day, in Laco.**

**Grand Difuffs, dittrittio magna; a writ of difact, so called on account of its extent, which reaches to all the goods and chattels of the party within the county.**

This writ lies in two courts: either when the tenant or defendant is attached and appears not, but makes default; or where the tenant or defendant hath once appeared, and after makes default. On such occasions, this writ lies by common law, in lieu of a petit cape.

**Grand Elieir, grand, jury, bywret, prior, prior, of France, freemans. See ELIEIR, GUARD, &c.**

**Grand Guste, in Painting. See GUSTO.**

**Grande, in Geography, a town of Norway, in the diocese of Drammen; 21 miles N. W. of Drammen.**

**GRANDE is underlaid of a lord of the first rank or prime quality.**

In Spain, the term grandees is used absolutely to denote the prime lords of the court, to whom the king has once given leave to be covered in his presence: there are some grandees for life only; made by the king's favour simply, be covered. Others are grandees by descent; made by the king's favour, be covered for thyself and heirs. These last are reputed far above the former.

There are some who have three or four grandeeships in their family.

**GRAND-GOR.** A Scotch appellation for the venereal disease.

In the Philosophical Transactions, N 469. Sept. 5. we have a proclamation of king James the IVth of Scotland, ordering all who had this disease, or who had attended others under it, forthwith to repair to an island in the Firth of Forth. If the grand-gor was the posy, and this distemper came into Europe at the siege of Naples in 1494, it must have made a very
very quick progress to cause such an alarm at Edinburgh in
1492.
GRANDI, Enrico, in Biography, whom Vafari calls
Ercole da Ferrara, was a painter of the early ages in the
art after its revival. He was a disciple of Lorenzo Costa,
whom he afterwards surpassed in excellence, and at whose
death he was appointed to complete the work of the Crucifixion,
begun by the former for Domenico Garganelli, in
the church of St. Pietro in Bologna, by which he
achieved great reputation for the excellence of the colour, and the
truth and force of expression; although it is wrought in the
dry style of Mantegna and P. Perugino. When unhappily
the chapel was destroyed, that part of the picture
which was preferred was placed in the palace Tanara. His
peculiar style of manner made him many enemies in Bo-
logna. He therefore quitted it and went to Ferrara, where
he produced many works which are very scarce now. His
fondness for wine shortened his life, and he died at the age
of 40 in the year 1531.
GRANDI, Francis Lewis, who flourished in the latter
times of the 17th, and the commencement of the 18th
times, was born in 1671 at Cremone. He was dispossed to
a liberal life, and chose the profession of theology, in order
that he might freely indulge his inclination. He entered
into the religious order of Camaldolites, at Ravenna, at the
age of 16; and on this occasion he relinquished his own
Christian name, and received that of Guy. He became, in
the early progress of his studies, distinguished for his pro-
diciency in the different branches of literature and science,
and being dissatisfied with the Peripatetic philosophy of
the schools, he was ambitious of contributing to introduce a
more rational system. With this view he offered himself as
a candidate for the vacant professorship of philosophy in the
school of Florence, and obtained his object, though not
without the most determined opposition from the prejudiced
adherents to the old opinions. He now applied himself to
the introduction of the Cartesian philosophy, while, at the
same time, he became zealously attached to mathematical
studies. The works of the great Torricelli, of our country-
man Wallis, and of other celebrated mathematicians, were
his favourite companions, and the objects of his familiar
intercourse. He published a treatise to resolve the problems
of Viviani on the construction of arcs, which he dedicated
to the grand duke Cosmo III., who was so delighted with
the performance, that he appointed the author professor of
philosophy in the university of Pisa. From this time
Grandi pursued the higher branches of mathematics with the
utmost ardour, and had the honour of ranking the ablest
mathematicians among his friends and correspondents.
Of
the number may be named the illustrious Newton, Leibnitz,
and Bernouilli. By his life of St. Peter Damian, published
in 1702, and his examination of the legends of St. Romain,
he gave offence to the bigots of his community, and was
deposed from the dignity of abbot of St. Michael at Pià;
but the grand-duke had too liberal a mind to be offended;
and to shew the effusion in which he held the philosopher, he
immediately appointed him his professor of mathematics in
the university; which, perhaps, led to his re-instatement in
the abbacy. He now resolved some curious and difficult
problems for the improvement of acoustics, which had been
presented to the Royal Society in Dublin, and having ac-
complished his object, he transmitted the solutions, by
means of the British minister at the court of Florence, to the
Royal Society at London. The principal work of Le
Grandi was "A Treatise on Series and Infinitesimals." He
appeared likewise as the defender of Galileo's doctrine re-
specting the earth's motion, and obtained a complete victory
over those who opposed it. He was deeply versed in subjects
of political economy, and various disputes were referred to
his decision respecting the rights of estury, &c. He was
appointed commissioner from the grand-duke and the court
of Rome jointly, to settle differences between the in-
habits of Ferrara and Legnana, concerning the works
necessary to preserve their territories from the ravages of
invasion. For these and other important public services
he was liberally rewarded by his employers. Reverting to
his literary labours, Le Grandi engaged in a contest with
Le Ceva, on the subject of the philosophy of the ancients
and moderns. This diffusion was occasioned by a preface to
a Latin poem by Le Ceva, in which he maintained that
none but heretics would renounce the philosophy of Acri-
tote. The remainder of his life this great man spent in
mathematical pursuits, and in the publication of works of
science, which are too numerous to be recited here. He
died at the age of seventy-two in the year 1732.
GRANDIER, Urban, was born in the latter part of
the 17th century. His father, a notary-royal at Sable,
gave him a good education, and introduced him while young
among the Jesuits at Bourdeaux, to whose friendship he
recommended himself, as well by his natural genius and
understanding, as by his diligence and proficiency in his
studies. Conceiving highly of his talents, the fathers of
the college gave him the living of St. Peter, at Loudun,
of which they were the patrons, and procured him a prebend
in the church of the Holy Cross. These benefits rendered
him the object of jealousy with ecclesiastics, which was still
further heightened by the accomplishments of his person
and the elegance of his manners. With his friends he was easy,
facetious, and agreeable, but extremely haughty towards
those whom he regarded as his enemies. Some of his
brethren of the clergy he had exasperated, by the arrogance
with which he triumphed over them, upon gaining certain
suets in the ecclesiastical court, and he raised a host of foes
by his reported successful garrulities with the ladies, to the
great mortification of disappointed rivals, incensed fathers
and husbands. A league was formed with a view of driving
him entirely out of Loudun; a heavy charge of schismacy,
irreligion, and impiety was laid against him, in the bishops'
court of Poictiers, which produced, first, a sulpuration of
the priets' functions; and afterwards he was condemned to
relinquish his benefices, and to the practice of penance and
mortification. From a sentence to severe, Grandier appealed
to the archbishop of Bourdeaux, by whose means he was
acquitted, and even allowed to sue for the recovery of
damages, and the replevion of the profits of the benefices
during his sulpuration. The archbishop, a friend to peace,
carefully recommended him to change his residence, but he
was incapable of renouncing his favourite passion, revenge.
He returned to Loudun, bearing in his hand a branch of
laurel, and in his mind a fixed resolution of humbling his
enemies. They were equally bitter, and spurting under
the lash of the victor, they set about means to compass his
destruction. A priest, named Mignon, devised a plan, which
ultimately enabled them to gratify all their malice. He
trained up nuns in the Ursuline convent at Loudun, to act
the part of women puffed with evil spirits; these were
instructed to accuse, in their frantic fits, Grandier of
having seduced them to demonical influence. At first he
was indifferent to the reports, considering the calumnists as
a mere farce. It had, however, a mortal tragic conclusion.
Grandier, at length, finding, from the effects produced upon
the credulous devotees, that matters were taking a ferocious
turn, appealed to the magistrates, confessions of his own innocence,
and requesting them to take cognizance of the affair. They
began...
began the investigation, and were satisfied that the whole was the effect of trick, but when they attempted to interrogate their authority, and prohibit the continuance of such disgraceful proceedings, the priests who had patronized and instructed the women, and who were bent upon the destruction of Grandier, disowned their jurisdiction and defied their power. An application was made to the archbishop of Bourdeaux, who employed physicians to examine into the case, and by their report no doubts were left in the mind of the prelate, that the bufines was founded on the most gross and scandalous impudence. Upon this the archbishop issued an order, the necessity of which put the whole legion of devils to flight. After a time the scheme was renewed, and the authors of it contrived to engage cardinal Richelieu to favour their malignant designs. For this purpose the monks of Loudun wrote to father Joseph, one of their fraternity, informing him that Grandier was author of a farce, entitled "The Shoemaker's wife of Loudun," containing reflections on the cardinal's birth and person, which had excited in the bosom of the cardinal the sharpest tinges of resentment. Believing that the information was correct, he determined to make the farce feel the full weight of his vengeance. Grandier was arrested and brought to trial, and after a tedious proces, in which the farce of exorcising the possessed was several times repeated, and the judge's partiality and tyranny displayed in the most glaring light, upon the deposition of Altabruth, a devil of the order of Seraphim, and the chief of the possessing demons, and upon the deposition of the nuns, who pretended to be possessed of devils, the commissioners gave judgment, declaring Grandier duly attainted and convicted of the crime of magic, forcery, and possession, happening by his means in the persons of some of the Urfaline nuns, &c. for the reparation of which he was condemned to an amende honourable, and to be burnt alive with the magical characters." Grandier, innocent of the charge, heard the sentence without any emotion, and afterwards suffered the torture, ordinary and extraordinary, with unflinching fortitude, never suffering one repining exprefion against his enemies to escape him through the whole scene. The last words which he was heard to utter previously to the flames reaching his vital parts, were in supplication to God, to whose mercy he recommended himself. Such was the fate of Urban Grandier, whose pride and passions appear to have been causes of the conspiracy to which he fell a victim, and whose history exhibits a memorable example to the world. The judgment of God, the revenge of a minister, and the proclamation of a judge, may be wrought up. The relations of the case is given in "The History of the Devils of Loudun," first published at Amsterdam in 1654, and which has been frequently reprinted. As an author Grandier is known by a funeral oration for Serauella de St. Martha, which is highly commended for the masterly flakes of eloquence interpolated through it. Moreri.

GRANDINES, in Surgery, small tumours on the eyelids.

GRANDMONT, in Geography, a town of France, in the department of the Upper Vienne, near which was an abbey, suppressed in 1569; 15 miles N.E. of Limoges.

GRANDOLA, a mean town of Portugal, in the province of Evranda, containing 800 houses, situated between Caddan and the face of the sea. Behind it is the Sierra de Grandola, that proceeds in two ranges, one behind the other, from Seil to Seil; the town is 27 miles S.E. of Seil.

GRANDPRE', a town of France, in the department of the Ardennes, and chief place of a canton, in the district of Vouziers; 33 miles E. of Reims. The place contains 1350, and the canton 8617 inhabitants, on a territory of 2423 kilometres, in 14 communes.

GRANDRIEU, a town of France, in the department of the Lozere, and chief place of a canton, in the district of Mende; 10 miles N.W. of Langogne. The place contains 1657, and the canton 5880 inhabitants, on a territory of 233 kilometres, in 7 communes.

GRAND-SERRE, Le, a town of France, in the department of the Doubs, and chief place of a canton, in the district of Valencin. The place contains 1491, and the canton 6189 inhabitants, on a territory of 2324 kilometres, in 16 communes.

GRANDVILLE, or GRANVILLE, a town of France, in the department of the Chanel, and chief place of a canton, in the district of Arranches, 12 miles N.W. of it. The place contains 5454, and the canton 12,250 inhabitants, on a territory of 80 kilometres, in 8 communes. The harbour can receive only about 60 small vessels. The town is seated on a sharp rock, forming a peninsula of an oval form, and surrounded with walls; it has two gates, and two faubourgs. Near it is an oyster-fishery, and on the land side quay, and very hard stone. N. lat. 48° 50'. W. long. 1° 27'.

GRANDVILLIERS, a town of France, in the department of the Oise, and chief place of a canton, in the district of Beaulieu; 14 miles N.W. of Beauvais. The place contains 1635, and the canton 12,655 inhabitants, on a territory of 1671/2 kilometres, in 22 communes. N. lat. 49° 50'. E. long. 2° 7'.

GRANDWALDEN, or GRAN, a town of Norway, in the diocese of Christhiana; 26 miles S. of Chrisltiana. The town stands on an eminence in the midst of an extensive plain, looking down on several conical rocks, covered with firs, and remarkable for two churches in the same church-yard, called the "Two Sibers."

GRANGE, an ancient term for a barn, or place wherein to lay up and thresh corn.

The word is formed of the Latin granum; or of granum, grain, corn, &c. Hence also granger or granger, a grange-keeper or farmer.

Hence grange is a name which was formerly much applied to such farm-houses as were provided with large barns, granaries, and other similar offices, for the preservation of grain, &c.

Grange is also used, in a more extensive sense, for a whole farm, with all the appendages of fencing for horses, fields for cattle, &c. and for an inn.

Grange, Joseph de Chancel de la, in Biography, born in 1676 of an ancient French family, at Antwerp in Perigord, exhibited from his boyish days a singular passion for poetry and romance. He was educated among the Jesuits at Bourdeaux, and when he was only nine years old, he composed a comedy in three acts, which was represented by his school-fellows. His early talents seemed to have marked him out for distinction, and his mother took him to Paris, and obtained for him the place of page to the prince of Conti. Before he was sixteen, his tragedy of Jugurtha was represented in the capital, and was applauded as a most extraordinary effort of such a stripling. He continued to write pieces for the stage, which were productive of reputation and pecuniary advantages; but the work which rendered him famous, though it exposed him to much mortification and suffering, was entitled "Philippiques," a satire in verse, directed against Philip, the regent duke of Orleans. This appeared in 1748, and it charged the duke with the crime of poisoning several branches of the royal family. The
GRA

The author attempted to escape, but, falling into the hands of his pursuers, he was committed to the prison of St Margaret. It appears that he was not brought to trial, and that he contrived to effect an escape from prison and the country, but upon the death of the regent he returned to France, where he lived unmolested. He died at his family seat at Anto-
niat in 1738. His works were collected in five vols. 12mo.
and, with his own corrections, published the year after his de-
case. They consist chiefly of tragedies, operas, and miscel-
aneous poems. The tragedies are most esteemed: they are
said to be "artful in the contexture of the plot, and abounding
in interesting situations, but feebly written, and trite in lan-
guage and sentiment." In his latter years he employed his
time on a history of Portugal. In manners he had all the
fire and vanity of a Galton: he had few friends, and
seems to have been more feared on account of his satirical
powers, than beloved for his virtues.

**GRAVE, in Geography, a town in Sweden, in the pro-
vince of Dalecarlia.** 33 miles S.S.W. of Falun.

**GRAVE, Lat. a cape on the N. coast of the island of Hi-
paniola. N. lat. 19° 55'. W. long. 72° 30'. This cape, with
Point de Dunes, forms the mouth of the bay of Monte
Chirilli, in the county of Stirling.

**GRAVING POINT, a cape on the S. coast of the Isle of Wight.
N. lat. 50° 38'. W. long. 1° 15'.

**GRAVER RIVER, a river of Upper Canada, which em-
ties itself into a bay of the same name on the N. shore of
lake Superior, W. of the Cris. This river leads to Nip-
gan, a place which formerly furnished the belt beaver
and marting, and was the farthest advanced post of the French
traders, at the time when Great Britain conquered Canada.

Cliffs and order, Syngenia Poligyna-supercilia. Nat.

Gen Ch. Common calyx imbricated, spreading; its scales
oblong, obtuse. Cor. compound; the united florets of the disk
very numerous, tubular, five-cleft, regular; females fewer,
in the circumference, tubular, three-cleft. Stam. in the united
florets, filaments five, capillary, very short; anthers united
into a cylinder, with five teeth. Pijfl. Germin small; flye-
thread-shaped, the length of the filaments; stigma undivided
in the united florets, cloven in the female ones. Peric. none,
except the permanent calyx. Seed solitary to both kinds of
florets, oblate, compressed, crowned with a toothed bor-
der. Recept hemispherical, naked.

Eff. Ch. Receptacle hemispherical, naked. Seed-crown
membranous, toothed. Calyx imbricated, spreading. Flo-
rets of the radius three-cleft.

We have alluded to this genus under ETHYLLA, from
which it differs in having a crown to the head, florets of the
radius three-cleft, and scales of the calyx obtuse. It most
approaches Tanacetum in character, but is sufficiently distinct.
The following are the only species we have been certain
of to determine.

1. G. madraapatana. (Artemisia madraapatana; Linn.
Vind v. 3. 466. 88. Abhimutha madraapatnam, fane-
ciuncis incani folio, corymbis foliaribus in ramulis fulgi-
sio speciosis; Pluk. Amalhat. t. 533. f. 3. A. minus
coloratum (Octogonum, utique brunneum fasciculata folio-
rum alis; Pluk. Alm. 2. Phys. 1. f. 2. —Leaves finit-
med, somewhat lyrate, hairy. Flower-flasks elongated —Na-
tive of the East Indies. Resut annual, tapering, branched.
Stam. procumbent, a span or more in length, full-hooded,
kev, downy. Leaves alternate, feathery, deeply pinnate,
in a lyrate form, and finnate, clothed with soft whitish
hairs, their segments rather rounded. Flowers yellow,
almoist globular, near half an inch in diameter, on axillary,
solitary, simple, hairy flanks, half as long as the leaves. Lin-
neas in both editions of Sp. Pl. quotes Pluknet, t. 377.
f. 3. Adanson, his professed critics, seems to have an-
![GRA](https://via.placeholder.com/150)

Burm. Ind. 177. t. 58. f. 3.)—Leaves wedge-shaped, blunt-
toothed, smooth. Flowers nearly fcliee.—Native of China,
and the East Indies. We received it in 1803, from the
flw of the late right honourable Charles Greville at
Paddington, where it was preferred rather for its rarity and
regularity than for beauty. It is an annual plant, much
smaller in all its parts than the foregoing, smooth, prostrate,
of a light green colour. Flower the size of a small pea,
axillary, nearly feline, whitish, sometimes with a purple
tinge. Their structure is extremely minute.

We scruple to admit Ethylka decurjata into this genus,
though somewhat similar in habit, because of its naked
seed, and sharp calyx. See ETHYLLA.

**GRANGEMOUTH, in Geography, a village of Scot-
land, of considerable extent, bounded by its Lawrence Dun-
das, upon the angle formed by the junction of the river
Caron and the canal. It defers mention as a place of
considerable trade. Vessels bring into this port timber,
 hemp, flax, deals, iron, from the Baltic, Norway, and
Sweden, and grain from foreign markets, as well as from
the coasts of England and Scotland. The trade to Lon-
don is carried on by the Caron shipping company; 3 miles
E.N.E. of Falkirk.

**GRANGERIA, in Botany, so named by Commer-
cher in memory of Mr. Granger, a surgeon, who travelled
into Egypt and Judea between the years 1730 and 1736, from
whence he sent numerous seeds to enrich the botanical
garden at Paris. He published, in 1745, in 12mo. Relation du
voyage fait en Egypte en 1730, according to Haller, who
mentions him as "not a trilling man, though he touched
but slightly upon botany. He greatly depreciates the

Gen Ch. Cal. Perianth inferior, of one leaf, bell-shaped,
with five ovate, acute, persistent segments. Cor. Petals
five, roundish, scarcely longer than the calyx, inserted into
its rim. Stam. Filaments fifteen, oval-shaped, longer than
the petals, inserted into the calyx; anthers roundish. Pijfl.
Germin superior, obovate, woody; fylle one, thread-
shaped; stigma obtuse. Peric. Drupa obtuse, somewhat
triangular. Seed. Nut triangular, of one cell.

Eff. Ch. Calyx five cleft, inferior. Petals five. Germin
woolly. Drupa with a triangular nut.

1. G. basifolia.—A tree, native of the Ile de Bourbon,
where it is called Arbre de bois, or Box tree, from the finitude of its leaves to the Bure. These are about an inch long, ovate, acute, entire, smooth and even on both sides, nearly felid, with a pair of small awl-shaped, stipular. Flowers small, in terminal or axillary clusters. Fruit somewhat like that of an olive, but smaller, and rather angular.

GRANHULT, a town of Sweden, in the province of Smaland: 35 miles N. W. of Calmar.

GRANI, in our Ancient Writers, multilaches or whiffers of a beard.

The word seems formed from the ancient Britih or Irish, greann, a beard.

It is given for a reason why the cup is refus'd to the laity, "Quia barbati, & prolixos habent granos, dum peculium inter epulis fumant, priscis laique plus insigniunt, quam oris infundunt."

GRANIFEROUS, producing or bearing any sort of grain.

GRANIFEROUS Podis, a term signifying such pods as contain small seeds of the grain kinas.

GRANITE. Under this denomination Kirwan comprehends all varieties of granite that contain more than three ingredients, such as quartz, feldspar, mica, and garnet: such supernumerary ingredients, however, must be considered as accidental, and of too little importance to confar the distinction of a particular name on the granite in which they occur.

GRANINGE, in Geography, a town of Sweden, in Angermanland, on a lake; 42 miles N. W. of Hernfand.

GRANITE, an aggregate rock, the essential ingredients of which are feldspar, quartz, and mica, being the fame as those of gneifs, from which granite differs chiefly in the arrangement of the three component parts: their being mingled without order or regularity, produces a granular fracture, while that of gneifs is generally flaky. (See Gneiss.) It is, probably, this granular nature of the rock in question which has procured it its name; though some authors are of opinion that the word granite is nothing but a corruption of granites, a name mentioned by Pliny, as that of a flower of the colour of a flory's neck. The fact is, that the word granite, which is now adopted by almost all European nations, originated with Italian antiquaries, and Tournefort was not the first writer who makes mention of it.

The three constituent parts of granite vary with regard to their colour, size, relative quantity, form, and freshness.

The colour of this rock is generally more or less reddish, because the feldspar, usually the predominating part, is oftener of that than of any other colour. Sometimes the feldspar is greyish and yellowish-white, and so like the admixed quartz, that it can be distinguished only by its peculiar fracture and lustre. It has been observed that the red colour occurs more frequently in the newer, while the greyish-white appears to be more characteristic of the older formation of granite. Also long continued exposure of granite to the action of the atmosphere contributes to render its feldspath pale or grey. Yellow and green feldspar feldspar seldom occur, as ingredients of granite. — The colour of the quartz is usually greyish; sometimes this part is perfectly colourless and transparent, in which case, as the grains cannot be viewed by transmitted light, it appears deep grey or black. — The mica is much more frequently black or grey than brown or perfectly white.

The absolute size of the ingredients of granite is subject to considerable variation; they are seen from very large to very fine granular, the latter being more frequent in the newer formation. With regard to the relative size of its constituent parts, we distinguish equally mixed from unequally mixed granite; the former being that in which the magnitude of the three ingredients is nearly the same.

The quantity of these parts is equally various: so that sometimes one, sometimes two of them predominate: upon the whole it is the feldspar that is found in the greatest proportion, and the mica in the least. There are, indeed, some varieties of granite in which the quartz or mica are entirely wanting. Such binary aggregations of the granitic kind have received distinct appellations by some authors. Thole of quartz and feldspar, or feldspar and mica, were called simple granites by Wallerius; semi-granites by Blumenbach; and Kirwan propost to denote all these duplicates in general by the name granitcul, specifying, when necessary, the constituent peculiar parts of each. The aggregate of quartz and mica is called feyseflafl, or fellafin, by some of the older German writers; and that of feldspar and mica, especially when the latter is of a brown or brownish-red colour, and forms the predominant ingredient, has obtained the Finland name of Rapakivi. Such distinctions, however, are unnecessary and inapplicable, since often in one and the same granitic mass the proportion and number of the component parts are seen considerably to vary. Besides, there are many rocks enumerated by authors as granites, which cannot, with any propriety, be referred to granite compounds; such as feldspar with hornblende, with nephritic: stone, with garnet, and granite, or the same separately combined with quartz or mica.

There is but very little variety in the form of the component parts: they are almost always massive and indeterminately angular, and seldom occur in the form of regular crystals. The feldspar is found crystallized in Bohemia, at Schakkenwalde, near Carlbad; at Tafeld, in the Saar district; also near Holwenalde, in Upper Palatinate; at Orchenkom and Keisim, in the Eichtel-gebirge; at Schneeberg, in Saxony; in England; in the island of Arran, &c. The granite in which these feldspar crystals are seen, is often of such fine grain, and the quartz and the mica are so intimately united with each other, that they form, as it were, a matrix for the crystals: such granite is called parophyritic granite. Part of the pavement on Welminister and Blackfriars' bridge consists of this species of granite. Something like crystallization of the quartz is now and then observed in granite, but it is always irregular. In the variety, called graphic or Portrey granite, in which the feldspar constitutes by far the greatest part of the mass, and which contains mica in small groups, at great distances from each other, the quartz is disposed in such a manner, that when the rock is cut in a certain direction, it exhibits forms which bear some distant resemblance to written characters: whence it has obtained its name. But by some, neither the Portrey nor Siberian graphic stones are considered true granites. Also, the mica is now and then found crystallized in granite, such as in Siberia, at Waldheim, Metweda, Jo-georgenstadt, in Bohemia, &c. In a variety of granite of Mount St. Gotthard, all the three constituent parts are said to occur crystallized together.

The feldspar is also sometimes found in the shape of cuneiform concretions, representing on their fracture a surface comparable to the paws of fome animals, or to the petals of flowers: this singular variety comes from the neighborhood of Breitenbrunn, in the Upper Ertzgebirge.

With regard to the firmness or state of preservation which these three ingredients exhibit, we have to observe that the feldspar, which, in general, has a vitreous lustre and a perfectly foliated fracture, is also seen in various stages of decomposition; it occurs dull, earthy, friable, and even entirely disintegrated, in which state it is known by the name of porcelain sand. This disintegration takes place chiefly near the surface.
face of granitic mountains, and in the immediate vicinity of veins. Granite, with feldspar thus converted into an earthly flate, is found in Cornwall, on the Hartz, at Kurkardgie-n in Saxony, &c.; and it is probable to Mr. Emmer- 

lating that the giefs-tein. (Saxm fucraniun, Limn,) which on account of its loose texture, is made use of in the brafs foun-

of Switzerland. 1. Rock crystal. 2. Beryl; in the island of Alba, and perhaps also in Siberia. 7. White common opal, sometimes occurs in the granite of Lichtenfrock in Saxony. 8. Topaze is sometimes seen, together with tin-"tone, in the granite of Zinnwald. 9. Calcaceous fpar, very feldom. 10. Fluor-fpar, the fame; in Siberia, at Geier in Zinnwald. 11. Barytes, equally feldom; in Swit-

Switzerland.

Foreign beds are fels frequently met with in granite than in other rocks. The more remarkable ones are thole of tin-"tone, galena, and blende at Zinnwald on the Bohemian frontiers; the beds of mica, particularly in Silefia and Lufatia; of quartz, and rock crystal in Switzerland. AlsO beds of feldspar are felled to occur in it. The green feldspar, called Amazon fone, is found in large mafes in the granite of the Ural mountains of Siberia.

Stratification of Granite. — Though granite occurs frequently as widely-extended mafes, in which the eye is unable to discover any continued traces of parallel separation; yet there can be no longer any doubt that thofe geologists, who abfolutely denied the exifence of stratified granite, were either entirely unacquainted with the structure of many of the European granitic mountains, or too much influenced by the principles of their favourite theories, to allow the obferved traces of demarcation to be any thing but irregular and accidental rents and furrows. Pifi even endeavours, by mathematical figures, to prove the impoffibility of stratification in granite. Notwithstanding all this, the ob-

BUT in many cafes, it would appear that this ftratification is too definite to leave any doubt upon the mind of the ob-

servation of the moft eminent geologists appear to prove that fuch stratification, even in the ftrati{ed flate of the word, is not uncommon; but it is often a matter of great difficulty, for an eye, unaccustomed to viewing the ftructure of mountains on a large fcale, to diftinguish the parriiils, or to follow the obfcurly marked progres of the line of fe-

paration of the ftrata, efpecially when they are of confider-

able thicknefs.

whole group of mountains to which it belongs; for though he raw large tabular mafses, sometimes nearly vertical, sperea-rated by fissures, they appeared to him to be much too irr-e-ular, too little extended in length and height, and v Advisory too much in thickness, to be reckoned the effects of stratifica-tion. As in the third volume of Jameson’s “System of Mineralogy,” Arran is not mentioned among the localities where stratified granite occurs, it would appear as if that geognosin does not lay any stress upon his first remark on the nature of the above-mentioned mountain.

The relative age of the different varieties of granite has engaged the attention of several writers on geology; but it must be said, that most of the opinions that have been broached on this subject, and the various ideas entertained by theorists respecting what they call regeneration of gran-ite, are too vague, or at least too little founded on actual observa-tion, to be entitled to particular notice. Some geo-logists on the other hand have absolutely denied the exist-ence of a second and third granite-formation. The Wer-nerian school admits three distinct formations of granite. The third or oldest is that which, of all rocks we are acquaint-ed with, is sunk the deepest into the interior of the earth, and which therefore may with propriety be considered as the fundamental rock. This oldest granite also constitutes the highest parts of the surface of the earth, and, thus elevated, is generally surrounded, and, as it were, enveloped by other primitive rocks. It is frequently coarse-grained and porphyrithic. It occurs both stratified and unstratified; and it is the latter which is often seen in large globular distinct concave of considerable dimensions, such as in several parts of Bohemia, in the Fichtelgebirge, in the island of Arran, &c.

This formation is, of course, far more widely extended than those of a more recent origin. The second granite formation is considered as occurring only in veins which never reach any of the newer rocks, but are confined to the oldest formation. Such granite is marked with few regularity of structure, than what is observed in the older formation; at the same time that it surpasses the newest granite, both with regard to the regularity of arrangement, and superior firmness of the constituent parts. The third, or newest granite-formation, is always found superincumbent on older primitive rocks, often in an unconfomable and over-living position: it also occurs in veins, which have been seen to inter-sect or traverse veins of the second granite formation; as a certain criterion of the greater relative age of the latter. Its structure, according to the characteristic given of it by professor Jameson, is very irregular; it has a deep red colour, and contains sometimes grains of garnet, and often fragments of various primitive rocks of various magnitude. When it occurs in veins, there are, according to the same author, not connected with any rock beyond the flints which they traverse. Examples of this newest formation are, that at Greifenstein, a large group of deep rocks between Ehrenfriedersdorf and Geyer in the Saxon metallicous mountains, where the coarse-granular and irregularly aggregated granite, composed principally of feldspar, quartz, with but a small portion of mica, occurs rolling on mica flake, in an unconformable and over-living position: it contains nobs of quartz and feldspar, as also fragments of gneiss and mica flake, from the size of a cubic inch, to that of 100 cubic feet and upwards. Another instance of this formation we have in the tin flockwork at Geyer, where it is contained in a hollow of gneiss, and agrees in its characters with that of Greifenstein. Also her portion of the same formation, is that at Johanngeorgenfladl, Auerberg, and Eichenfladl, where, however, it occurs only in veins, which are from a foot to several fathoms wide, and are usually traversed by metallic-
erous and other veins. Mr. Mohs has given a very good characteristic of this newer granite. Freckens of the first kind occur also in Bohemia, Upper Lusatia, at Missella in the Alps, in the Shetland Islands, in Glen Morion, and in the Highlands.

The nature of the full mentioned granite veins is considered in a different light by Dr. Hutton, according to whom all veins, whether they are obviously connected, or whether they have no apparent connection, with any large mafses of granite, are coeval with, and constitute a part of the main body of what is called the oldest granite by the follow-ers of the Neptunian system. Mr. Playfair has given several examples of veins involutely connected with larger mafses; in those at the site of Coll, in the Hebrides, at Portfory, in Cornwall, in Glen Tilt ; and of such as are visibly connected with the main granite body, in those occurring in the island of Arran, in Galloway, in Inverness-shire, St. Michael’s Mount, Cornwall. Mr. Jameson, however, says that he has convinced himself, after a very careful examination of the rocks of the island of Arran and of Galloway, that they do not afford a single instance of granite veins, shooting from the oldest granite into the adjacent rocks, nor of veins traversing newer primitive rocks, as it has been intimated to be the case with the granite veins in Glen Tilt. The same author observes on this occasion, that veins of feldspar have been frequently confounded with granite veins, and be judicious some observations on this subject communicated by the late Dr. Mitchell, accord-ing to which there is a most palpable difference between fup-posed and genuine granite veins; the former being frequently narrower than one inch, and commonly much ruminated, and very tortuous; but they constantly adhere more firmly to the adjacent flints, and when they contain apparent fragments, the flaty structure of these is ever conformable to that of the contiguous rock; while genuine granite veins never fall short of some inches, are generally straight, seldom giving off branches; they have a distinct separation, and contain fragments of the adjacent rock, which lie promi-nently; the granite is uniformly uniform, containing the three ingredients equally mixed; and Dr. Mitchell has always found it small-grained. The supposed granite, accord-ing to him, consists of feldspar, of a very unequal grain, including sometimes spots of mica, and rarely specks of quartz. From all which this mineralogist concludes, that the last mentioned veins are nearly of contemporaneous origin with the rocks in which they are contained, and ought, therefore, to be considered as, and called, feldspar veins.

Although granite is the hardest, and one of the most durable rocks we are acquainted with, it is, nevertheless, subject to disintegration, which manifests itself not only in the crumbling of the surface of the exposed parts of granite beds, but likewise in the separation of vein mafses, which, being di united by the enlargement of the rents and fissures that generally traverse the granite mountains, or crosses the flints in a nearly vertical direction, are partly precipitated from their high situation, partly displaced in various manners, so as to produce the appearance of huge artificial structures, and of other objects to which the fancy of the beholder may compare them.

M. De Luce has been on the Riehenbirge, in Sileia, a number of pillars produced by such disintegration, both solitary and grouped together, in a straight line, and, at a distance, presenting the appearance of many high piles of girds.

The Adon-shola mountains in Dauria, which consist of granite, are, according to Pallas, in many parts broken into all manner of shapes, representing vast ruins, grottoes, and immense flat mafses piled on one another in all directions. Several
GRANITE.

Several of the mountains are, as it were, firewreathed with blocks of granite, which, at a distance, appear as numerous herds of cattle; and it is this circumstance which is said to have procured this name of Adon-glomo, a Mongol word, denoting herd-like mountains. All these detached rocks are fragments of the vast strata of granite that compose the greatest part of the Dauric mountains. The summits of the Gastein and other mountains of Arran have the appearance of huge walls composed of large granite masses. At Huelgoet, in Lower Brittany, we are informed by Monnet, as also in the Volges, enormous masses of granite are seen piled on one another, and forming most extraordinary scenes. The granite being divided into masses by fissures, which are filled up with granite and showing less solidity, this latter is sooner acted upon by atmospheric agency, whence, by its disintegration, the masses become perfectly detached, and adopt various positions. But besides the accidental groups formed by the rolling down of the rocks, there are other groups of granitic rocks at Huelgoet, that appear to be in their natural position, and many of them form an afflament of rock masses, which have a perfectly rhomboidal form, and are regularly joined to each other by means of their corresponding planes. One of the infolded rocks in a group at Huelgoet, is called Pierre brendante, or the rocking stone: it is 21 feet long, seven feet high, and eight feet wide, and its cubical content is 1160 feet; it is so accurately poised on the edge of another rock, which serves for its base, that the strength of a few men suffices to change its centre of gravity, and to communicate an oscillatory motion to it. The phenomenon of the rocking stone is not unknown in this country; the largest is that seen at the Land's End in Cornwall, where they are called Logan-formes. It weighs upwards of fifty tons, resting on another rock of granite of consider-able height close by the sea-shore. "The two stones," says Mr. Playfair, who avails himself of this phenomenon among others to explain the migration of flint masses, "touch but in a small spot, their surfaces being considerably convex towards one another. The uppermost is so nearly in an equilibrium, that it can be made to vibrate by the strength of a man, though to oververt it entirely would require a vast force. This arises from the centre of gravity of the stone being somewhat lower than the centre of curvature of that part of it on which it has a tendency to roll; the consequence of which is, that any motion impressed on the stone forces its centre of gravity to rise, (though not very considerably) by which means it returns whenever the force is removed, and vibrate backward and forward, till it is reduced to rest. Were it required to remove the stone from its place, it might be made easily done, by cutting off a part or blowing it away by gun-powder; the stone would then lose its balance, would tumble from its pedestal, and might roll to a considerable distance. Now, what art is here required to perform, nature herself is incapable of producing. If the wind acts on one side of this great mass, shall exceed that on the opposite in more than a certain proportion, and it is not likely that that proportion will be always maintained, the equilibrium of the Logan-forme will be subverted, never to return. Thus we perceive how motion may be produced by the combined action of the decomposition and gravitation of large masses of rock."

It was probably from seeing the fantatical and imitative forms produced by granitic cliffs, and by the disintegration of granite, that Mr. Vitre framed his unfortunate hypothesis respecting the pyramids of Egypt, and the ruins of Peripolis, Palmyra, and Balbec, all which, together with the temple of Jupiter at Girgentan, the palaces of the luecas in Peru, &c. &c. were considered by that antiquary as productions of nature.

Granite is much less metallic than gneiss, and other primitive mountains; but tin and iron abound in it. Besides these, several other metals occur in it in small proportions, viz. gold, though very rarely, in Peru; native silver, almost equally common, at Wittichen and Alt Wolfisch, in the Black Forest, near veins of silver and cobalt; copper; galena, for instance, at Schreberhausen, at the foot of the Schneekuppe, in Sildia; lithnium, zinc, cobalt, manganese, molybdenum, arsenic, tungsten, and wolfram, all which occur generally in small veins; but tin, galena, and blende are found in beds at Zinnwald in Saxony, and in Bohemia.

Notwithstanding the extent of granite over the world, it may be said that scarcely any country we are acquainted with is entirely destitute of that rock. In Asia we have the Uralian and Altai mountains with the Caucasus; in Africa, the Atlas, several mountains of Egypt, thole of the Cape of Good Hope; in North America, the mountains of New York, Pennsylvania, and Virginia; in South America, great part of the Andes, the mountains de los Marches in the Carracas, the Cordilleras of Paria, Sierra Nevada de Merida, &c.; in Europe, the Szwego mountains of Scandinavia, thole of Finland, the Carpathians, the Hartz, the Riesengebirge, the mountains of Upper Luflatia, a part of the Alpine metallic mountains, (especially Eibenstock, Johanneberg, Schwartzberg, Schneeberg, Ehrenfriedersdorf, Geier, Nauenfeld, Altenberg, and Zinnwald,) the Fichtelgebirge, the Odenwald and Schwartzwald, the Alps of Switzerland and Savoy, the Apennines, Pyrenees, the mountains of Cornwall, &c. all which have granite for their principal constituent rock.

The use of granite for architectural and economical purposes is perhaps nowhere more amply displayed than at Petersburg, where not only the imperial and other palaces, but even ordinary dwelling houses, have their lower parts lined with slabs of granite. The left bank of the great Neva, from the foundery to the Gulf of Cronstadt, and both banks of the Fontanka and of the Catherine canal, are lined by high walls constructed of such slabs of granite; as are many bridges over the Neva, balustrades, &c. The pillars, stairs, balconies, &c. in the palace of Cronstadt, are almost all of the finest kinds of granite. Those employed for ornamental architecture are cut and polished by lapidaries; but those intended for less delicate purposes, such as common slabs, steps, cylinders, troughs, &c. are worked by peasants, particularly by those of Oloven. The government towns, however, Molocow not excepted, are too distant from the chief granite mountains, to be enabled to make frequent use of that rock for the above purposes.

Granite has been more particularly applied, together with granite, for the purposes of architecture and statuary, by the ancients, especially by the Egyptians; and many very interesting monuments of their skill and patience are still existing in the collections of antiquities.

M. Brand has divided the different granites used in the arts after their predominant colours; the following are the principal varieties, in which, however, the black and white kind is not included, one of its ingredients being hornblende, which affixes it a place among the felsites. See Sienite.

Grey Granite of Cheifs, in the department of the Rhone; it consisted of white quartz and black mica, with large crystals of rose-coloured feldspar. The columns of the Eglise d'Lacce.
The grey granite of Thain.—It consists of grey quartz, black mica, and white feldspar crystals, which are sometimes from two to three inches long. The quarries of this granite are on the road from Lyons to Valence, on the right bank of the Rhone. It is very well adapted for the construction of large monuments. The granite of St. Peray, not far from Thain, is exactly like this, except that its feldspar crystals are of a rose-colour.

Grey Granite of Lavozi.—Found in the small island Lavozi, near Boniface, S. of Corfia, in the frants that separate this island from Sardinia. This granite is composed chiefly of small irregular crystals of feldspar, mixed with a little black mica, besides which it contains also feldspar crystals, of a milk-white colour. In the quarry of that island a large unmixed column is to be seen, which has been relinquished by the Roman workmen.

Grey Granite of Elba.—Its grain is pretty uniform; its colour sometimes approaches to light violet. There are four columns of this variety to be seen in the Muče Napoleon; they were taken out of the church which contained the tomb of Charles-magne, at Aix-la-Chapelle.

The grey granites are much more common than the green or greenish, of which the following deserve to be mentioned.

Antique green Granite.—Its predominant ingredient is white quartz, which contains here and there some light green feldspar. There is a column of it in the Villa Panthi, near Rome.

Fine granitic antique Granite.—(Bafalte verd ordinat.) The component parts of this work are so fine and intimately blended, that they can scarcely be distinguished by the naked eye. Its colour approaches to deep olive. It is very hard, and takes a fine polish. The Egyptians have much employed it for the construction of monuments; and several statues of it may be seen in the Capitol and the Villa Albani.

There is another variety with white spots, which is known at Rome under the name of Bafalto Orientale picechio; this is very rare, for there are but two columns of it in existence, namely, in the church of St. Pudentiana at Rome. Some varieties bearing that name are ilikenite.

Granite of St. Christopher.—Composed of violet quartz, white feldspar, and green mica. This magnificent rock is found at Ofans, in the department of the Ière.

Corsican orbicular Granite.—This beautiful rock (which probably belongs to the Bentine formation) was discovered by M. Barral, in the island from which it derives its name. Its composition is very extraordinary; it has a basis of ordinary grey granite, which, however, in most parts, exhibits a considerable portion of hornblende. But what more particularly characterizes it, is a number of balls, of from one to two inches in diameter, each composed of several concentric and perfectly parallel layers, the outermost of which, generally white, opaque, and two or three lines thick, is composed of quartz and feldspar, blended in various proportions, and exhibiting a chatoyant appearance, converging towards the centre of the ball. The second layer, which is of a greenish-black colour, and about one line thick, is composed of fine laminar hornblende; and this is succeeded by a white, generally transluicid quartz layer, of about four or five lines in thickness, inclusive of two or three thin layers of hornblende, that are generally seen within the fulness of this third principal layer. Each of these layers is generally of uniform thickness in the whole of its circumference. These three parts may be considered as the coating: the interior of each ball is less defined than the surrounding layers; it consists of a blackish and a whitish substance, the former surrounded by, and passing into the latter, the centre of which is usually a dark-grey spot.

The quarry of this rock is unknown, a single block only having been found in the gulf of Valinco, in Corfia: its weight was about 80 pounds; but it was soon broke into small fragments, which are now distributed among collectors. There is a beautiful valet of it, one foot six inches high, in the cabinet of M. Dedree. The granite of Corfia is figured by M. Faugas de St. Foud, in his "Eflai de Géologie," and in Mr. Sowerby's "Exotic Mineralogy."

Among the red granites, we have what is called red oriental granite, which, as usually containing hornblende, often in large separate patches, will be described under SiENITE.

The red Granite of Liguria.—This granite, says M. Patrin, is distinguished from others in this, that the feldspar, instead of being in grains, or parallelopid crystal, as in most other granites, coarsely appears in the shape of round or oval pieces of from half an inch to two inches in diameter. This granite takes a very fine polish, and in this state exhibits the feldspar in the shape of white, round, or oval chatoyant spots, in a reddish ground. The rock, which serves as a pedestal of the equinarian statue of Peter the Great, at St. Peterburg, is of this granite: the block was originally 32 feet long, 21 feet thick, and 17 feet long; but, in order to give it its present shape, imitative of a picturesque natural rock, it has been much diminished in size. This block was disengaged from a swamp, about forty versts from Peterburg: its weight was calculated to be above three millions of pounds. We have seen several fragments that were detached from the very block forming the pedestal of the statue; but in none of them did we observe the forms ascribed by Patrin to the feldspar.

The public summer promenade-garden at Peterburg is decorated with a superb colonade of this granite: the columns, which are sixty in number, are of the Tufcan order; their shafts, made of one piece, are about twenty feet high, and three feet in diameter. The island, called Kotlin-Oilrow, on which is the fortress of Cronstadt, is covered with blocks of this granite, the feldspar of which is sometimes of the kind called Labrador-iron.

Red Granite of the Voges Mountains.—This granite is composed of large laminé of rose-coloured feldspar, grey grains of quartz, and small scales of mica. It has fo strong a resemblance to the Egyptian red granite, that it is difficult to distinguish them. Its quarries are on the heights of Montaunier, near the Papean mountains, in the Voges.

Violet Granite of Elba.—The feldspar of this variety is in large violet crystals. The pedestal of the equinarian statue, in the Piazza della Santissima Annunziata at Florence, is made of it, as are also the fodes in the church of St. Lawrence in the same town.

Rose-coloured Granite of Bareno.—This beautiful granite consists of fine-coloured feldspar, white quartz, and some grains of black mica. Considerable quarries of it are found on the borders of the Lago Maggiore, which are worked, without intermission, for supplying Mian, and the whole of the neighbourling country, with this granite. It takes a very fine polish, and on it exhibits ribbands, or zones, of a grey colour, which are composed of the same ingredients as the rest of the mass, but reduced into very minute particles. Many columns, porticos, &c. are seen of it at Milan.

The name of graphic granite is given to those kinds in which the feldspar forms large cretations, intermixed with grey quartz-crystals, exhibiting, when cut transversely, axi-
G R A

granular figures, mostly shaped like a 7; while others are less regular, and bear a dimly resemblance to rude alphabetical writing. They are not considered to be genuine granite by some mineralogists.

Graphie Granite of Porphyry.—The fieldspar is of various tints of pale flesh-red; the quartz dark, but transparent, with now and then some small particles of mica. This rock is minutely described by Dr. Hutton.

Graphite Granite of Siberia.—Its fieldspar is of a yellowish-white, or reddish colour; the quartz, exhibiting figures similar to those of the quartz in the preceding foid, is of the variety called fimoaxy topaze. Mica occurs in it in small nebs, and black horn in acicular crystals.

Graphite Granite of Austria.—Of a pale rofe-colour; quartz crystals grey, very numerous. It is found in the neighbourhood of Austria, in the department of Saline-et-Loire, particularly at Marmagne. This, in M. Brand's opinion, is the most beautiful of all graphic granites. Another variety of this stone is found at the same place; its fieldspar is white; the quartz grey, in small crystals; it is susceptible of very fine polish.

Graphite Granite of Conflant.—Like-wise of a rofe-colour; but generally paler than that of Austria, from which it is also distinguishable, by its quartz-crystals being larger, and at greater distance from each other. It contains some faintly disseminated bronze-coloured mica. It takes a fine polish.

GRANVOROUS, an epithet or denomination given to fuch animals as feed upon corn, or any other grain or seeds.

Granivorous animals are chiefly of the bird kind. These have a peculiar provision for the digging of fo dry and hard a food.

GRANNA, in Geography, a town in Sweden, in the province of Smalnad; 18 miles N.E. of Jonköping.

GRANO, in Geography, a performer on the trumpet and German flute, and a composer of tunes for those instruments, which had their origin in the early part of the last century. He was a kind of mungrel dilettante, who during many years condescended to make concerts and give lessons, en professeur, always infinuating that it was merely for the pleasure of amusing the public and instructing individuals. Crano's trumpet march was long used by the Guards.

GRANON, in Geography, a small island on the W. side of the gulf of Bothnia. "N. lat. 61° 5'. E. long. 17° 5'.

GRANSEE, a town of the Middle Mark of Brandenburg; 30 miles N. N.W. of Berlin. N. lat. 52° 59'. E. long. 13° 13'.

GRANSO, an island in the Baltic, near the E. coast of Sweden. N. lat. 57° 45'. E. long. 16° 5'.

GRANSON, a town of Switzerland, in a bailliage of the same name, belonging to Bern and Friburg, situated between the lake of Neuchatel and mount Jura, and remarkable for the battle in which Charles the Bold, Duke of Burgundy, was defeated by the Swiss in 1476; 16 miles S. W. of Neuchatel. N. lat. 46° 50'. E. long. 6° 26'.

GRANT, Coxsoto, in Lasso, the regular method by the crown of transferring the property of incorporeal hereditaments, or such things of which no livery can be had. (Co. Litt. 9.) For which reason all corporeal hereditaments, as lands and houses, are said to lie in livery; and the others, as advowsons, commons, rents, revenues, &c., to lie in grant. (Ibid. 172.)

The reason is thus given by Bracton (I. ii. c. 18.): "traditio, or livery, nihil aliud est quam rei corporalis de personas in personas, de manu in manum, translatio aut in possessum induit; sed rei incorporeae, que sunt ipsum jus rei vel corporis invenietur, traditione non patiuntur." There, therefore, pass merely by the delivery of the deed. And in signories, or reversion of lands, such grant, together with the attornment of the tenant, (while attornments were requisite,) were held to be of equal notoriety with, and therefore equivalent to, a feoffment and livery of lands in immediate possession. It therefore differs but little from a feoffment, except in its subject-matter; for the operative words therein commonly used are "deeti et cuiue," "have given and granted." For the difference between gifts and grants, see the article GIFT. The king's grants are matter of public record. (See RECORD.) No freehold can be given to the king, nor derived from him, but by matter of record. To this end a variety of offices are erected, conferring in a regular subordination one with another, through which all the king's grants must pass, and be transcribed, and enrolled. That the same may be narrowly inspected by his officers, who will inform you any thing contained therein is improper, or unlawful to be pleaded. These grants, whether of lands, honours, liberties, franchises, orught besides, are contained in charters, or letters patent. (See PATENTS.) The manner of granting by the king does no more differ from that by a subject, than the constitution of his grants when made. 1. A grant made by the king, "at the suit of the grantees," shall be taken most beneficially for the king, and against the party; whereas the grant of a subject is confided most strongly against the grantor. It is therefore usual to infer in the king's grants, that they are made, not at the suit of the grantee, but "ex speciali gratia, certa scientia, et mero motu regis," and then they have a more liberal construction. 2. A subject's grant shall be construed to include many things, besides what are expressly, if necessary, for the operation of the grant. Thus, in a private grant of the profits of land for one year, free ingests, egrets, and regrets, to cut and carry away those profits are also inclusively granted. (Co. Litt. 55.) And if a feoffment of land was made by a lord to his vassal, this operated as a manumission (Litt. 565,) for he was otherwise unable to hold it. But the king's grant shall not extend to any other intent, than that which is precisely expressed in the grant. As, if he grants land to an alien, it operates nothing, for such grant shall not also enure to make him a denizen, that he may be capable of taking by grant. (Bro. Abr. tit. patent. 62. Finch. L. 110.) 3. When it appears, from the face of the grant, that the king is mistaken, or deceived, either in matter of fact or matter of law, as in case of false suggestion, misinformation, or misdirection of former grants; or if his own title to the thing granted be different from what he supposes; or if the grant be informal; or if he grants an esate contrary to the rules of law; in any of these cases the grant is absolutely void. (Frem 172. Finch. 101, 462.) To prevent deceits of the king, with regard to the value of the esate granted, it is particularly provided by the statute 1 Hen. IV. c. 6. that no grant of his shall be good, unless, in the grantees petition for them, profits annexed be made of the real value of the lands. Blacks. Com. vol. i. 261. 368.

GRANTHAM, in Geography, a township of Upper Canada, in the county of Lincoln, fronting lake Ontario.

GRANTHAM, a market and borough town in the foke, or wapentake, of the same name, in Kelleven division of the county of Lincoln, England, is situated on the side of the river Witham, on the ancient Roman road called Ermine street. The town comprises four principal streets. The church is an elegant stone structure, consisting of a nave and two spacious aisles, with large handsome pointed windows, and is celebrated for its lofty spire, which is 275 feet in height. The style of architecture appears to be that of the thirteenth century; though Mr. Gough observes that the church was endowed by Hugh, bishop of Lincoln, A.D. 1100.
Beneath the church is a chancel-house, filled with human skulls and other bones. Among several handiwork monuments in this edifice are, one to Sir Thomas Bury, chief baron there of exchequer in the time of George I, and one to Sir Dudley Ryder, chief justice of the King's Bench in the succeeding reign. The font exhibits a fine specimen of ancient sculpture.

Granville was incorporated under a charter granted by Edward IV, in 1463; when it first returned members to parliament; the representatives are chosen by the freemen of the borough. The civil government is vested in an alderman, a recorder, 12 common burgesses, a coroner, an echeator, and twelve second men, who are the common council. The jurisdiction of this corporation extends over the whole foke, comprehending twelve villages, and the alderman acts as sheriff of the town and foke, the sheriff of the county having no authority within the foke and district thereof. The guildhall was rebuilt under an act of parliament in 1787. A free-school was founded here by Richard Fox, bishop of Winchester, and further endowed by King Edward VI; this school attracts attention, from the circumstance of its having been a place of education to that luminary of science, Sir Isaac Newton. Near the south entrance of the church, on St. Peter's Hill, formerly stood an elegant cross, erected by King Edward I, in memory of Eleanor his queen, who died in 1290; this being one of the places where the corpse was laid in state in its way for interment in Westminster Abbey. Granville is distant from London 111 miles N., has a well supplied market on Saturdays, and five annual fairs. In the return under the late population act, the number of houses was 631, occupied by 3303 inhabitants.

A canal has been lately cut from Grantham to the river Trent, an extent of 25 miles. It is supplied with water by means of large reservoirs made for that purpose. The chief articles conveyed by this navigation are corn and coals. Turner's History of the Soke of Grantham, &c. Beauties of England and Wales, vol. 15.

Grantham Canal, is the parliamentary name of an inland navigation about 33 miles long, in the counties of Nottingham, Leicester, and Lincoln, of which we gave an account in our article Caxton, and nothing material has occurred to be added thereto.

Grantown, a town of Scotland, in the county of Inverness; 17 miles S. of Fores.

Granville, George, baron Landdown, in Biography, a nobleman chiefly remembered as a poet, born in 1667, was son of Barnard Greenville, one of the distinguished family of Greenville or Granville, the latter mode of spelling the name being introduced by the subj ect of this article, who is thereby separated from the rest of his house. He shewed very early talents, and was entered, in his twelfth year, at Trinity college, Cambridge. In the same year, he wrote a copy of verses on the duchess of York's visit to the university, and on the accostment of James II, he offered incense to the new prince in three short pieces, of which Dr. Johnson says, "the first is profane, and the two others such as a boy might be expected to produce." In 1688, when an invasion was threatened, he was desirous of devoting his life to the service of James, and requested his father to present him to the king for that purpose. The revolution succeeded, and being put on neither interest nor considerable fortune, he lived in literary retirement. During this period his dramatic works were chiefly composed and acted. The first of these was "The Gallants," said by himself, by way of apology, to have been written at an age when foolish are but beginning to spell. This was afterwards brought forward in a more correct form, under the title of "Once a Lover and always a Lover." His tragedy of "Heroic Love," founded on the fable of Homer's Iliad, was acted the same year with great applause from the wits and critics. On this occasion he was complimented in a copy of verses from the pen of Dryden. When queen Anne came to the crown, Mr. Granville emerged from the political obscurity in which he had lived: his fortune was increased by the death of his father, and that of his uncle, who left him an annuity. He was now elected a member of parliament for the borough of Fowey, and feeling the common ardour of his countrymen of all parties against the ambition of Lewis XIV., he joined other literary persons in a translation of the Philippics of Demosthenes, to oppose the nation to oppose the Philip of modern times. By the death of his elder brother Sir Devil Granville, in 1726, he succeeded to a good estate, and he continued to serve in parliament, sitting as knight of the shire for the county of Cornwall. On the change of administration in 1716, he was appointed secretary of war in the room of Sir Robert Walpole. He married in the same year Mary, the daughter of the earl of Jersey, then widow of Thomas Thynne, esq. Shortly after this he was introduced into the house of peers by the style and title of lord Landdown, baron of Biddeford, at the memorable creation of twelve peers, in one day, viz. December 31, 1711. The elevation, however, of lord Landdown was not one of those which appeared very extraordinary, as two peerages had become extinct in the Granville family. On account of his principles and conduct he stood high in favour of the queen, who made him a privy councillor, comptroller and treasurer of the household; but the accesion of George I put an end to the power of his party, and deprived him of his place. He remained steady to his former connections, protééting against measures which he deemed unconstitutional, and in consequence of his zeal he was regarded with a suspicious eye, and was reckoned by people in power as a disaffected man. Upon the breaking out of the rebellion in 1715, he was committed to the Tower, and kept confined in that fortress till February 1717, when he obtained his liberty and returned his seat in the house of lords. In 1719 he opposed with violence the proposed repeal of the bill to prevent occasional conformity; his speech on the subject he afterwards printed. Subsequently to this a derangement in his private affairs, owing to the want of economy, obliged him to spend some years on the continent. During his absence, the first volume of bishop Burnet's "History of his own Times," making its appearance, lord Landdown undertook the vindication of the duke of Albemarle and the earl of Bath, from some affronts thrown upon them in that work. He also took occasion to vindicate his great uncle, sir Richard Greenville, from the unfavourable representations of his conduct by lord Clarendon, and archdeacon Echard. On this occasion he published two tracts in 1732. In the same year he published a splendid edition of his works, leaving out a comedy, which, on account of its licentiousness, had been objected to, and he also omitted to insert his speech against occasional conformity. He now felt reconciled to the measures of government, and eloquent in prose and verse, he engaged in the futile and regard with horror. He went to court, and was graciously received by queen Caroline, to whom he presented his works, with some elegant lines written in a blank leaf. He died Jan. 30, 1735, in his 64th year. In private life, lord Landdown was amiable, polite, and candid. He was liberal in patronizing literary merit, and had the credit of being one of the first to recognize the rising powers of Pope, who repaid him for his kindness by his dedication of Windsor Forest.
Forst. His own talents, as a poet, were not of the first order, but his works are still read with pleasure. He is chiefly known as a writer of amatory pieces, most of which are addressed to Myra, the countess of Newburgh, the object of his youthful passion. These are not either highly poetical nor strongly expressive of feeling. Johnson characterizes his "Essay on natural Flights in Poetry," as professing didactic merit, and his "British Enchanters," as lively and pleasing. He seems to think favourably like- 

Granville, in Geography. See Granville.

Granville, a county of North Carolina, in Hillsborough district, S. of Virginia, containing 14,015 inhabitants, of whom 6106 are slaves. Its chief town is Williamsburg.

—Alfo, a township of the county of Annapolis, in Nova Scotia, N. of Annapolis river, on the bay of Fundy, 30 miles long; first settled from New England.—Alfo, a town-

ship of Hampshiire county, Massachusetts, about 14 miles W. of Springfield, incorporated in 1754, and containing 2300 inhabitants.—Alfo, a post-town in Washington county, New York, containing 3157 inhabitants.

Granville, or Greenville, a flourishing town in Muck-

lenburg county, Kentucky.

Granville's River, a river of the island of Egmont, or New Guernsey, which runs into the sea, S. lat. 1o° 42'.

E. long. 163° 58'.

Granulated Oil. See Oil.

Granulation, in Chemistry, an operation performed on metals, whereby they are reduced into small grains or globules.

It is done by melting them, and when in fusion, calling them from a certain height into cold water; in which they congeal into granules, as required, and are hereby rendered more easily to be diffused. The belt way is to pour the fluid metal through a cullender, or a new birchen bream, or to agitate the water with a bream, thus giving it a circular motion while the metal is poured in. Copper is granulated for making brats in a cylindrical wooden reevoir, four or five feet deep, in which a circular brat or copper bottom may be raised or lowered by means of a chain: The reevoir is covered with a copper lid, in the middle of which is a hole half a foot in diameter, intended to receive an iron ladle pierced with holes and coated with clay. The reevoir being filled with water, the melted copper is poured through the holes in the ladle into the water; where it is broken by its fall into smaller drops or grains, rendered solid by the cold water, and collected in the moveable bottom, which is raised by the annexed chain, that the granulated copper may be taken out. Macquer, Dict. Chem. Eng. edit. art Broil. See Brass.

Lead, tin, and brats, which are very brittle, when they are so hot as to be almost fused, may be granulated by pouring them, in a flate of fusion, into a box, the inner surface of which is rubbed with powdered chalk, and by shaking the box: the metals in the box are no sooner become solid, and consequently very brittle, than they are flivered, by being dashed against the sides of the vesel into a fine dust. Silver and gold, and the more tenacious metals, must be granulated in either of the first methods above-mentioned, with water. Cramer, Art of All, p. 79.

The term granulation is also applied to gun-powder: which fee.

The granulation of common boiling shot consists merely in causing the fused metal to fall in equal spherical drops into water. The lead is melted with the addition of a small proportion of arsenic, which being reduced to a metallic state, by means of grease floured in during the fusion, renders it less fluid. An oblong shallow vessel of iron, perhaps 10 inches wide, 14 long, and 2 deep, called a "Card," whose bottom is pierced with holes, proportionate to the size of the shot, is placed at the height of from one to three inches, over the surface of a tub of water, covered with a thin film of oil. The card is previously heated to the temperature of the metal, by immerging it in the caudron; and a quantity of soft drops or scoriæ, found on the surface of the fused alloy, is then placed on its perforated bottom, and being slightly prefled down with the ladle, forms a kind of filter, which partly chokes up the apertures, and prevents the metal from flowing through them in continuous streams. The fusled metal is then poured by ladle-fills into this vesel, and appears, notwithstanding, to run through it with considerable velocity; so that it seems difficult to believe, that it falls in separate drops, till one is convinced by taking up a quantity of shot from the bottom of the water. The imperfections to which this shot is subject, are remedied in the patent shot, the manufacture of which differs from that of the preceding kind, in the addition of a larger portion of arsenic, which varies according to the quantity of the lead, in dropping it from such a height, that it becomes solid before it enters the water, which is from 10 to 1500 feet. Besides, it is first dried and sifted. It is then boarded, which consists in fanning it on several polished slabs, or trays of hard wood, with rims in the form of a P, except that the sides converge towards the lower part, to which a slight inclination and alternate motion in their own planes are given by boys employed in the manufacture. The shot, whose form is imperfect, are detected by the fluggage of their motion, and remain behind, whilst the others roll off from the board. The last operation is the polishing; which is performed by agitating the shot with the addition of a very small quantity of black-lead, not exceeding two spoonfuls to a ton, in an iron vesel, turning on an horizontal axis, like a barrel churn. It does not appear that any higher degree of perfection than that which is thus attained remains to be desired. The argentum brilliany of the shot when newly made, the beautiful accuracy of its form, and the curious indiume of inanimate tastes which it preents when feattered on a plate, renders it even an agreeable object of contemplation. Nicholsoo's Journal, vol. 1. 406.

Granulation. In Surgery, granulations are the small eminences of new animal matter, with which the cavities of fores and wounds become filled up in the process of healing. Granulations, according to Mr. Hunter, are formed by an exudation of the coagulating lymph from the vesels, into which new substance the old vesels very probably extemate the same time that entirely new ones are generated in it. Hence granulations are exceedingly vateral, perhaps more than almost any other animal substance. Mr. Hunter informs us, that he noticed upon a fore a white substance, exactly similar in every visible respect to coagulating lymph. He did not attempt to wipe it off, and the next day of dressing he found this very substance vateral; for, on touching it with a probe, it bledd freely. He observed the same appearance on the surface of a bone that had been laid bare. He once scraped off some of the outside of one of the bones of the foot, in order to see if the surface would granulate. The following day he remarked, that the scraped part was covered with a whitish substance, having a tinge of blue. When he paffed his probe into it, he did not feel the bone bare; but only its resistancy. He conceived this substance was coagulating lymph, thrown out in consequence of in-
granulation, and that it would be forced off when suppuration came on; but on the succeeding day he found it vascular, having all the appearance of healthy granulations.

The vessels of granulations first pass to their basis from the original parts, whatever these may be, and then run in nearly parallel lines to their external surface, where they seem as if they ended.

The surface of the new fulbustace continues to have the same disposition for the secretion of pus, as the parts from which it itself was produced. Granulations are very convex, which is an appearance the very reverse of what happens in ulceration, or while a fur is increasing in size. They appear rough, in consequence of having a great many points or small eminences, and they are deemed the more healthy, the smaller such points are.

Healthy granulations are of a deep florid red colour, a circumstance which might lead one to suspect, that the colour was principally owing to the arterial blood; but Mr. Hunter was of opinion, that this appearance only denoted a brisk circulation in the new-formed fulbustace, the blood not having time to become dark.

When granulations are naturally of a livid red, they are commonly unhealthy, and have a languid circulation. Such appearances may often be induced by position, and we frequently see it take place on those of the leg, when the limb is not kept in a horizontal posture. In this circumstance, the new-formed vessels are incapable of supporting the increased column of blood, and of acting upon it. The flagrant allows the change of colour to happen, and the alteration, in all probability, takes place both in the arteries and veins. Here may be seen the reason why fore legs are frequently very backward in healing, when the patient is suffered to put his foot on the ground, or to walk about.

Healthy granulations, situated on an exposed or flat surface, rise nearly even with the surface of the surrounding skin, and often a little higher; and in this state they are always of a florid red colour. When they exceed this height, and assume a growing disposition, they are then unhealthy, and they become soft and spongy, without any disposition to form skin.

Granulations always have the same disposition as the parts upon which they are formed; and take on the same mode of action. If it is a diseased part, they are diseased; and if the disease be of any specific kind, they are also of the same nature, and, of course, produce matter of the same quality.

When granulations are healthy, they are always prone to unite with each other, the great force of which is to bring about the union of parts, somewhat like what is the result of union by the first intention. See WORXS.

The disposition which granulations have to unite with each other upon coming into contact, without the appearance of any intermediate animal substance, is perhaps effected, as Mr. Hunter conjectures, in the following manner. When two sound granulations approach together, the mouths of the secreting vessels of the one coming to oppose the mouths of similar vessels of the other, they are stimulated into action, which is mutual; so that a kind of sympathetic attraction takes place, and as they are solids, the attraction of cohesion is established between them. This has been termed inoculation. The vessels thus joined are altered from secreting to circulating. There are some other furnishes hazarded by Mr. Hunter respecting the rational of this minute process of nature; but the curious reader must refer for them to the author's own relation of the subject.

Mr. Hunter informs us, that he has seen two granulations on the head, viz. one from the dura mater after trepanning, and the other from the scalp, unite over the bare one, which was between them, so strongly in twenty-four hours, that some force was required to separate them, and when separated, they bled.

The inner surface of the skin, in cases of ulcers, not only does not readily granulate, but does not readily unite with the granulations underneath. Hence the frequent formation of fistulas and sinuses.

Unhealthy granulations have not an equal tendency to unite with each other; a smooth surface is formed, which continues to secrete matter. Thus, Mr. Hunter regarded the internal surface of a fistulous ulcer as, in some degree, similar to the inner surface of the urethra, when it is forming the discharge commonly called a gleet. Such fures have no disposition in their granulations to unite, and nothing can produce an union between them, but altering the disposition of these granulations, by exciting a considerable inflammatory and probably ulceration; so as to form new granulations, and by this means give them a chance of falling into a sound state.

It is also noticed by Mr. Hunter, that granulations are not furnished with so much power as parts puffed, which are originally formed. Hence they more readily ulcerate and slough. He states, that they not only draw the condition of the part in which they grow, or the condition in which they are themselves, but also, how the constitution is affected by many diseases.

The same author has made some observations respecting the longevity of granulations. He says, that they often seem to be formed with only dated periods of life, and those much shorter, than the life of the part, on which such granulations are situated. Their life, indeed, does not appear to be so short, when cicatization can be accomplished; but while a fur is in a granulating state, they frequently persist without any visible cause. Thus, says Mr. Hunter, a person may have on his leg a fur, which granulates well, the granulations have a healthy appearance, the skin is forming round the edges, and every thing promises well, when, all at once, the granulations become livid, lose their life, and immediately slough off. In some instances, they are destroyed, partly by ulceration, and partly by mortification. Then new granulations are frequently produced, and go through similar changes. Sometimes this happens three or four times in the same person. Mr. Hunter in vain tried various methods for rendering the granulations in such cases more durable.

Suppuration and granulation are essential for the cicatization and union of almost every wound, which has not been united by the first intention; a few small wounds and scratches, which heal under a scab, being the only exceptions.

Our author, in the following section of his treatise on the blood, notices, that cicatization seems to be in view immediately after the granulations are formed. The parts which had receded, in consequence of a breach being made in them, by their natural elasticity, and, probably, by muscular contraction, now begin to be brought together by this new fulbustace, which soon contracts. The contraction takes place in every joint, but principally from edge to edge, which brings the circumference of the fore towards the centre, so that the fore becomes smaller and smaller, although little or no new skin may be formed.

The tendency in the granulations to contract is, in some degree, proportioned to the general healing disposition of the fore, and the loofness of the parts, on which they are formed. When new skin cannot be produced, the granulations
do not fo readily contrast, and, therefore, Mr. Hunter infers, that their contraction and the production of skin are probably effects of one cause. The induration, occasioned by inflammation, retards the contraction of granulations, though Mr. Hunter was inclined to think, that the circumstance did not arise so much from a mechanical principle, as from the diminution of the disposition to the process occasioned by the inflammation itself. Granulations, however, as the same writer explains, are sometimes undoubtedly retarded in their contraction by mechanical causes, when formed on parts naturally fixed, such as a bone; for instance, on the skull, the femur, &c.

When, by reason of a loss of substance, there is a deep hollow fore, and the contraction of the granulations is considerably advanced, before they have had time to rise as high as the skin, the edges of the latter part are generally drawn down, and tucked in by it, in the direction of the excavated surface of the fore.

If it is a cavity or abscess, which is granulating, with only a small opening, as often happens when the surgeon has neglected to make a free aperture, the whole circumference contracts, like the bladder of urine, till little or no cavity remains; and if any cavity is left, when the granulations can contract no further, they unite with such as are opposite to them.

This contraction in the granulations, says Mr. Hunter, is continued till the whole of a fore is healed, or skinned over; but it happens in the greatest degree in the beginning, when there is least resilience in the surrounding parts.

The contraction of granulations may often be afflicted by art, namely, by using bandages, which tend to pull, draw, or keep the skin near to the fore which is healing.

Besides the contractile power of the granulations, there is a similar power in the surrounding edge of the cicatrizing skin, which affords the contraction of the granulations, and is even more considerable, drawing the mouth of the wound together like a purse, and sometimes, when the surface of the fore is high, grading the granulations.

The contractile power of the skin is chiefly confined to the very edge, where it is healing. The surrounding old skin either does not contract at all, or not much, as is evident from its being thrown into folds and plaits, while the new skin is smooth and shining. The original skin, having little or no power of contraction, is a reason why round fores cannot to readily heal as long ones.

Mr. Hunter has explained, that the uses, arising from the contraction of granulations, are various. It facilitates the healing of a fore, as there are two operations going on at the same time, viz. contraction and skinning. It avoids the formation of much new skin, an effect which is very evident in all fores which are healed, especially in found parts. When a thick thigh, seven or eight inches in diameter, has been amputated, the surface of the fore is of the same width; yet, in the end, the cicatrix will be no broader than a crow's-foot, in consequence of the old skin becoming drawn over, by the contractile power of the granulations. The advantage of this is considerable, since such parts as are originally formed are always much fitter for the purposes of life than those which are newly formed.

After all, a fore is covered with skin, the substance, which is the remains of the granulations on which the new skin is formed, till it continues to contract, till hardly any thing more is left than what the new skin stands upon. This is a very small part, in comparison with the first formed granulations, and, in time, it loses most of its apparent vessels, becoming white and limonaceous. All new-healed fores are at first redder than the common skin, but afterwards become much whiter.

As the granulations contract, the surrounding old skin is stretched to cover the part which is deprived of integuments. At first, the skin is brought little further than into the portion from which it had receded, on the occurrence of the wound; but afterwards it becomes drawn much more considerably, being stretched and elongated. See Hunter's Treatise on the Blood, Inflammation, &c. chap. 7.

GRANULES, in Geology, is a term which Mr. Whitehurst, ("Enquiry," 1st edit. p. 180) and others, employ to express the grains or minute lumps of flinty matter, composing the sand usually found on the surface of valleys, and which is formed by attrition and the grinding down of stones of different kinds.

GRANULOS. Roots, are those composed of smaller knobs than the grumose ones, and resembling so many grains of corn; of this sort is the white saxifrage.

GRANUM VIVIS, in Botany, a name given by some authors to the turpentine-tree. The fruit of this tree is reddish while unripe; but as it ripens, it becomes of a deep blueish-green colour, and hence the name.

GRANZA, in Geography, a town of Africa, in the country of Magadona.

GRANZOW, a town of the Ucker-Mark of Brandenburg; 8 miles S. E. of Prenzlow.

GRAO, a port of Spain, in Valencia, which carries on a coasting trade along the Mediterranean; on one side, on the coast of Catalonia, Roussillon, Languedoc, as far as Marselles; and on the other side, to Alicante, Cartagena, and Malaga; some vessels even pass the straits of Gibraltar, into the Atlantic, and go to Cadiz; and sometimes they go round Portugal as far as the ports of Galicia. The largest of these ships are from 50 to 60 tons, each having a crew not exceeding 11 men. They carry out wines, silk, wool, dry fruits, and kail; and return with linens, woollens, ironmongery, spices, and corn. Grao is pleasant in summer, on account of the feath-baths, which draw together a great number of people for health or amusement.

GRAPE, the fruit of the vine. See Vine and Wine. See also CURRANTS and Raisins.

GRAPE Hyacinth. See Hyacinth.

GRAPE, Muscros or sea-fade. See Coccus Lata.

GRAPE Wolf. See Lycozystyle.

GRAPES, gall, in Natural History, a name given by authors to a species of protuberances, resembling clusters of grapes, and when ripe of a reddish colour, which are found hanging from the oak at some seasons of the year. These are genuine galls, though of a peculiar kind, and owe their origin to a very small four-winged black fly. See Galls.

GRAPF-fruit, in Artificial, is a combination of small flat, put into a thick canvas bag, and corded strongly together, so as to form a kind of cylinder, whose diameter is equal to that of the ball adapted to the cannon. The number of shot in grape varies according to the service or size of the guns; in sea-service nine is always the number; but by land it is increased to any number or size, from one ounce and a quarter to weight to three or four pounds. In sea-service, the bottoms and pins are made of iron, whereas those used by land are of wood.

GRAPF-fruit, Botrites, is a sort of flagellates, which effervesc with acids, according to Dr. Grew, "Rarities of Gresham College," p. 304. It is also the name of certain botroidal flagellites, which are sometimes met with, pendant from the roofs of caverns in lime-flour districts.

GRAPEs, in the Muses, a term used to signify the arrows or many tumours that happen in a horse's legs. See Armbes. GRA-
GRAPHICA PERSPECTIVE, in Optics, is an instrument described by Mr. Martin, consisting of a tube containing two convex lenses, which are placed at twice their focal distance from each other; and in their common focus is another glass divided into equal parts with the point of a diamond. Though this instrument does not magnify any object, yet the angle under which an object is seen is easily known by it; and since this angle varies with the distance of objects, it is easily applied to the purpose of measuring inaccessible heights and distances; and since the field of view is divided into equal figures, it is useful in drawing the perspective appearance of objects. Moreover, as all foreign light is excluded by the tube in which these lenses are inclosed, pictures seen through it have a fine rehevo, on which account, and also because objects appear inverted through it, the images of a camera obscura are viewed with it to peculiar advantage. If a lens of a greater focal length be fixed at a proper distance from the centre of the tube, this instrument will be a telescope, and will magnify the prints which are looked at through it; and if a small lens be used, it will be a microscope, and the same micrometer will serve for them both. Martin’s Optics, chap. xvii. p. 260, &c.

GRAPHIDA, in Natural History, a name by which some authors have called the morchus, or French chalk.

GRAPHIS, in Botany, from γραφή, a name invented by Adamson, is pleased to label it grafe, and adopted by Ehrhart, for the various species comprehended under the Lichen scriptus of Linnaeus, and which constitute the very distinct genus of Ogeaphis in Acharus; see Eng. Bot. v. 25, 26 t. 1753, &c.

GRAPHICUS, in the Writings of the Ancients, a name given to an instrument used for extracting darts from wounds. It is said to have been the invention of Diocles, and is described by Cellus.

GRAPHITE. See Plumbago.

GRAPHOIDES, γραφίδοι, in Anatomy, an appendage of the bones of the temples, long, small, sharp, and a little crooked, like a cock’s spur; called also a syphoid.

The fame name is sometimes applied to the mucus of gratia.

Likewise an extension of the brain, resembling a writing pen.

GRAPHOMETER, a name which some authors, particularly the French, give to a surveying instrument, by us commonly called a semicircule; which see. Mr. Nicholson, in the fifth volume of his ‘Journal,’ 8vo. has described, and illustrated by appropriate figures, a subterranean graphometer, invented by M. Komarzowski, F. R. S., and presented to the National Institute of France. It is a simple construction of the common theodolite (which see), and is calculated to answer the author’s intentions in operations like those of mining, where great accuracy is not required. In vol. i. of the name ‘Journal,’ we have the description of an instrument resembling a graphometer, invented by C. Carangeot, for determining the mutual inclination of the faces of a crystal, or its prominent angles; it consists of two concentric, equal quadrants joined by a hinge; to which are applied compass-legs or radii, capable of being shortened to apply to small crystals, &c. See Graphometer. See also Plate VI. Crystallography, p. 95.

GRAPHNEL, or GRAPLING, or Ship-board, a kind of small anchor for boats or galleys to ride by. It differs from other anchors, as having four or five flukes and no flack, though there are some with three flukes, with which they use to sweep for lavers or small cables. In men of war also, the grapnels, or at least a lighter kind of them, whose flukes are furnished with strong bars on their points, are used to be thrown into an enemy’s ship, in order to catch hold of some of her gratings, rails, gun-wales, &c. This is done in order to board of her. They are particularly useful in fire-ships, and called fire-grapplings.

GRAAPPLE, in the Mercantile, a horse is said to grasp with one or both legs, when he catches or raves them more hastily and higher than ordinary, as if he were curvetting.

GRAPTOLITHI, in Natural History, are the petrificata fides of Limnaeus and others; as dendricus, landscape-marble, dendropotamites, &c., which, according to Mr. William Martin, ‘Outlines,’ p. 8, should be excluded from the list of extraneous fossils.

GRASS, Gramen, in Botany, See Gramina.

To enumerate all the species of grasses which are found growing naturally in England, would greatly exceed the bounds which can be allowed for this article; it will suffice, therefore, to mention a few species, which are either used in medicine, or cultivated as a pabulum for cattle; for there is scarcely a pasture in this country where great numbers of different species are not to be found intermixed. Mr. Ray has ranged them in the following order, viz. wheat-grasses, rye-grasses, dandel-grasses, panic-grasses, canary-grasses, fox-tail-grasses, cat’s-tail-grasses, hedgehog-grasses, crested-grasses, oat-grasses, cock’s-foot-grasses, buck-grasses, and millet-grasses. These and other grasses Limnaeus has arranged into distinct genera. See the following articles:

GRASS, Arrow-headed. See Triglochin.
GRASS, Bent. See Agrostis.
GRASS, Bird. See Bird-grasses.
GRASS, Canary. See Phalaris.
GRASS, Capon’s-tail. See Fenteca.
GRASS, Cat’s-tail. See Phylium.
GRASS, Clover. See Trefoil.
GRASS, Cock’s-tail. See Dactylis.
GRASS, Cotton. See Ereophorum.
GRASS, Couch. See Trifolium.
GRASS, Crested. See Dog’s-tail-grasses and Cynosurus.
GRASS, Dog’s-tail. See Trifolium and Agrostis.
GRASS, Zed-dog’s, a name sometimes given to the double spiked scaber, of Triticum. See Secale.
GRASS, Dog’s-tail. See Dog’s-tail-grasses and Cynosurus.
GRASS, Epeium. See Festuca.
GRASS, Fox-tail. See Alopecurus.
GRASS, Goose. See Asperugo.
GRASS, Hair. See Aria.
GRASS, Hard-tail. See Lagurus.
GRASS, Knot. See Polygus.
GRASS, Knot, German. See Sceletanthus.
GRASS, Knob, Mountain, and Verticillate. See Illecebrum.

GRASS, Love, or Quaking. See Briza.
GRASS, Meadow. See Poa.
GRASS, Hard meadow. See Cynosurus.
GRASS, Miller. See Milium.

GRASS, Oat, a name given to a species of the field. See also Avena.

GRASS, Panic. See Panicum.
GRASS of Parnassus. See Parnassia.
GRASS, Pepper. See Persicaria.
GRASS, Pudding. See Mentha.
GRASS, Quaking. See Briza.
GRASS, Rattle. See Peduncularis.
GRASS, Rush. See Spicibus.
GRASS, Rye, or Ray. See Lolium and Hordeum.

GRASS, Scorpon. See Scrophorus.
It is also asserted by Mr. Kent, that meadow and pasture-land is often neglected than ploughed ground, notwithstanding it generally admits of a much greater proportion of improvement. The best grazes cannot be collected at too great an expense; for he has seen a small spot of land, in the middle of a large piece, which was laid down twelve or fourteen years since, by the writer noticed above, upon an estate in Herefordshire, with some choice feeds, at the same time when the remainder of the field was laid down with common feeds; and that this spot is considerably better than the rest. From these experiments, and his own observations, he is clearly of opinion, that any person who has land calculated for grass may improve it, by this method of laying it down, to a much greater degree than he can in the common way. Dr. Anderson has likewise observed, in the second volume of his essays, that although it is probable, that none of the grazes that have been hitherto cultivated by the farmer are of the most proper kind for pasture; yet there is little reason to doubt but that many of the most valuable kinds for this purpose would admit of being cultivated with the same care as some of these are with which we are well acquainted, if they were properly separated from others, and cultivated with equal care. But so long as we shall remain ignorant of the peculiar qualities of each kind of grass, so as not to be able to distinguish the good from the bad, it is not surprising, that we should remain firmly persuaded that nature alone can provide valuable pastures, and that age is so essentially necessary for bringing them to their ultimate perfection. For, if we allow our fields to remain uncultivated, be it without having fowed them with any kind of grass-seeds, it must ever happen, that the seeds of such grasses as are brought by the wind, or otherwise, from the neighbouring fields, will there take root, and in time establish themselves. And as it may sometimes happen, that some of the most valuable pasture-grasses may there abound; the field, in these cases, will become filled with their seeds, and in due time may afford the most valuable pasture. But if bad kinds of grasses should abound in the neighbourhood more than the good, the field will as naturally become filled with the feeds of these useless plants. And as a number of these are hardy and abiding plants, if the field is once filled with them, the pasture will be, of consequence, always of little value, if it should be allowed to remain undisturbed for any length of time. Let the reader, therefore, consider how numerous the circumstances are that must accidentally concur together before it is possible to expect a very fine field of pasture-grasses, if left to nature; and then he will perceive how improbable it is that all these should concur to produce their full effect in any one field whatever. There must be roots of bad grasses, nor feeds of robust annuals, in the soil when it is left out from tillage; and the feeds of the most valuable kinds of grasses must be in the neighbourhood in such abundance as to fill the whole field sufficiently at once. Nor is this all. For as there is, no doubt, a considerable variety of valuable kinds of grasses, some of which are naturally fitted to grow to perfection on one kind of soil, or upon that soil when in certain circumstances, while others would thrive best upon another soil, or upon that soil only in certain peculiar circumstances; it must so happen, that these various plants which are best adapted to the soil in the state it may be in at the time, should be found in abundance in the neighbourhood of the field. Neither must there be found near that, any sort of robust quick-growing plant, the feeds of which, by being blown upon that field, might suddenly run up and suffocate in their infancy these tender and valuable plants. Nor must there be found any bad kinds of grass, that, by being established along with the good in

Vol. XVI.
any proportion, might tend to diminish the value of the
patture.

Now, let any one reflect on the infinite diversity these
few particulars may admit of, and think how utterly impos-
stable it is that all the favourable circumstances, without any
of those that are unfavourable, should concur in any one
ease, and he will acknowledge, that those who found their
hope of obtaining the most valuable pastures only upon the
fortuitous concurrence of all these circumstances, or who
imagine that every pasture which is old muid, on that ac-
count, of necessity be good, act in direct contradiction to the
plainest dictates of reason and common-fense. For, although it
should be allowed that the grasses hitherto cultivated are not of
the most proper fort for forming good pastures, and that
therefore, on some occasions, much better natural pastures
may be met with than could be formed by means of any of
those; yet it by no means follows from there, that if the
farmer were perfectly acquainted with the value and distin-
guishing qualities of each kind of natural grass, and knew
how to select and culture that best agreed with the local
soil and culture that best agreed with it, and every other particular relating to the
soil and culture there, he might not perhaps have it in his power
to form artificial pastures as much excelling the natural as
these last at present usually exceeded the farmer. For were
he possessed of the knowledge above supposed, he could at
once fill the void with the seeds of those valuable grasses
which he knew were best adapted to it, and thus effectually
exclude the admixture of every useless plant, or pernicious
kind of grass, that might be brought from the neighbouring
fields by the wind, or other accidental causes.

Let us, therefore, instead of contenting ourselves on all
occasions with such pastures or grass-lands as nature may af-
ford, rather study to improve those that are indifferent, by
endeavouring to obtain a knowledge of such plants as might
afford the most valuable pasture, and cultivating these with
affinity and care. The attention of the improving farmers
in Great Britain to this subject has been truly amazing.
But it is hoped the attempts that have been made by some
late writers may have the effect of turning their attention to a
subject of such great importance, with regard to which, they
all too doubtless make many valuable improve-
ments. I. is, however, to be feared, that till some attempt
shall be made to ascertained the particular qualities and pecu-
larities of the different kinds of grasses, the public will be
often imposed upon by specious accounts of new grasses,
which may be really polishe'd of few valuable qualities, and
may very much tend to discourage the inquirer. It is con-
fsequently necessary to sink all endeavours to discover
what are the particular purposes for which any one plant
would be deemed valuable, and in what respects it might be
looked upon as of no value at all: For, as there is no plant
that can be alike useful on all occasions, if we lose sight of
this most necessary definition, it may often happen, that we
may attempt to rear a particular plant for purge: which it
was never fitted to answer; and our want of success in these
trials may make it be entirely rejected, even in cases for which
it was extremely proper and beneficial.

It is flated that ray-grains continues to be the only grass
whose seeds can be purchased for the purpose of laying
down meadow and pasturage-land; and how inadequate that
grats is for such a purpose is known to every intelligent
farmer. Why indeed the loliun perenne (ray or eye-gras) should originally have been made use of in preference to all
the other grasses, cannot, perhaps, be satisfactorily account-
ed for: most probably it owes its introduction to accident, or
to its being a common graft whose seeds were easily collected,
rather than to its being preferred from any investigation of
its merits compared with the others. However this may be,
there appears to be no reason for excluding the others; for
it would appear exceedingly improbable, that of upwards of
a hundred grasses, taking the word grasses in its strictest
sense, that are growing wild in this country, the Author of nature
must have created only one as suitable to be cultivated for
patture or fodder. Since this period, however, most of
the natural grasses have been cultivated for the purpose of
affording feed, which may be procured genuine from many
feeders in most places. Taking it for granted then, that
there are other grasses superior in many respects to the ray-
grass, this question naturally arises—How comes it that they
have not found their way into general use? To this it may be
answered, improvements in any science, but more especially
in agriculture, are slow in their advances; and perhaps
no chefs of men adores more pertinaciously to old pre-
judices than that of farmers, and the difficulty of
distinguishing the grasses from each other has, too, no doubt,
proved one great obstacle: many of these plants are so
much alike, that the farmer in seeking out one of them is
to know some of them apart: is to, how easily may the
husbandman be deterred from the arduous task? There is
another cause also which may have operated against their
introduction: grasses, as well as other plants, have been
frequently recommended from a partial and limited obser-
vation of them, by persons who neither knew them well
as botanists or agriculturists, or who have recom-
manded them, merely to gain by the credulity of the
public. But, perhaps, the chief reason has been, that
persons who might be expected to make the improve-
ments, have not had the means fairly put into their hands to
make the experiment, there not having been any easy means
of obtaining such sorts of grass feeds as may be moll fit-
able for the purpose. It appears, however, that in the herbage
of good meadows, or grass lands, there should be a combina-
tion of produce, rateable land, and early growth. The first
is, in moss cafes, the agriculturist's grand object, and no
wonder, since it is the quantity chiefly which enables him
to pay his rent, and support his cattle; to obtain this, the
judicious husbandman has no expense in labour or manure.
But it does not follow that produce is to be attended to
solely, or that, for its sake, we are to cultivate rough cock's-
foot grasses, meadow-sweet, and such coarse plants. Grasses
which have been recommended for being remarkably grate-
ful to cattle, as the sheep's-fence grasses, or for the sweet-
ness of their foliage merely, if they are found to be defici-
ent in the grand article of produce, will never an'yer the
farmer's or grazier's purpose, since to be a good meadow it
must be productive. Cattle, in regard to food, doubtless
have their particular likings, though we cannot properly
judge of it, in which it may be necessary sometimes to indulge
them; but this practice must not be carried too far; for as
the farmer cannot afford to feed his ploughmen on pigs and
poultry, neither can he indulge his cattle in general with the
finer or more delicate hay or herbage. By the bye, we do
not know but that the most productive grasses may also be
the moSt nutritious, or that cattle will not as eagerly eat the
herbage or hay made of the meadow fox-tail gras, as of the
fine bent (agrostis capillaris), and proccum bent (trifolium prenchesium). Moreover, cattle are known fre-
quentiy to thrive on food to which they are habituated by
necessity, though at first they could scarcely be prevailed on
to touch it. Persons, in making experiments, are very apt,
as has been already observed, to conclude too hastily from
the appearance which a plant affumes on its being first planted
or sown; the molt insignificant vegetable will oft enc make a
great show, when its fibres have firsh earth to shoot into; but
but the trial comes when the object of our experiment has been in a meadow or pasture several years, when its fibres from long growth are matted together, and it meets with powerful neighbours to dispute every inch of ground with it; if it then continues to be productive, it must have merit. We see that lucern, when left to itself, is soon overpowered; if we sow broad-leaved clover, which is most undoubtedly a perennial, the first year we shall have a great crop of clover; let this field be left to itself, and the clover, like the lucern, will yearly diminish, not because it is a biennial, as some have supposed, but because plants harder or more congenial to the soil usurp its place; this flows, then, that at the fame time that we introduce a good plant, that plant must also be a powerful one, able to keep possession, and continue to be productive.

With regard to the second quality, or that of the cattle's thriving on the food they eat; this is, undoubtedly, of great consequence, and it is to be regretted that our knowledge of the most nutritive herbage is so limited; of those plants which have been cultivated, we are able to speak with some certainty; it is well known that clover, lucern, saintfoin, tares, and several other plants, have a tendency to fatten cattle; but what grasses, or other plants, which have not been subjected to a separate cultivation, have this particular tendency, remains to be ascertained by experiment. But as leguminous plants, in general, are found to agree with cattle, we may reasonably conclude that a certain quantity of them must be proper in pastures. Certain pastures are found to be more batable or feeding than others; but whether this springs from situation, or their particular produce, remains also to be discovered by further observation.

Respecting the third quality, or the early growth of plants, as the farmers and graziers unceasingly complain of the want of early herbage in the spring; those plants, therefore, which are found to put forth early foliage, and to be grateful to cattle, are deserving of great attention. As far as grasses are concerned, the sweet-scented vernal, the meadow fox-tail, the smooth and rough-stalked meadow-grasses, will effect all that can be expected from those of British growth: much, very much, however, will depend on seafsons: if the winter be very severe, or north-easterly winds prevail in the spring, grassy herbage will be backward: to counteract the bad effects of such seafons, our pastures should be warmly situated, not drains with moisture, sheltered by thick hedges, and divided into small enclosures: in short, a set of enclosures should be formed for this very purpose, where there is a prospect of its answering the designs of the cultivator. But where early pasturage is the deideratum, other plants, as well as grasses, may delver a place amongst them, as rib-wort, or rib-grasfs (plantago lanceolata), dandelion (arctium lappa), broad-leaved clover (trifolium pratense), with many others of the same kind. And as an early herbage, though it is valuable for pasturage, is no less so for hay; by the middle of May at thefeh, a meadow of this fort would be fit for mowing, and the second hay-making might commence by the time that hay-making usually takes place in the country. The writer has sometimes thought, but perhaps the idea is too speculative, that we ought to have two forts of meadows, one for hay, the other for pasture; that our hay-meadows should confit entirely of grasses, and chiefly for this reafon, that the hay would on that account be much sooner made; an object of consequence at all times, but more so when the proceds commencs in May. In June and July the more powerful heat of the sun is able to efticicate the thick leaves and stalks of the more succulent plants; but, in the neceffary prolongation of this benefice, the grasses must materially fuffer. But for the purpose of paflurage, the attention of the agriculturist should be chiefly directed to such forts of grasses as have the propensity of running to leaves, in preference to such as abound more in flower-flaks or items.

The fame writer states, that if we examine our meadows, pastures, and downs, we shall find them pretty much in a flate of nature, and, excepting those pastures which of later years have been fown with ray-grasfs and clover, full of an indiscriminate mixture of plants, some of which afford good, others bad food, some good crops, others fearely any crops at all; but that he may not be thought to speak at random on this subjece, he will flate a few facts to corroborate what he has allered. His worthy and much-efteemed friend, Thomas White, efq. with a view to ascertain the produce of several downs and commons fed on by sheep, procured, from each of those under-mentioned in Hampshire and Suffex, a turf, which, though not more than fix inches in diameter, and chosen indifferemtly, produced, on being planted in his garden, as follows:

**Different Turfs.**

**Turf from Selborne-Common.**—Plantago lanceolata, agrostis capillaris, avena flavecens, dactylis glomerata, felta du rincula, poa annua, cynodon crinitus, trifolium repens, crepis tectorum, achillea millefolium, galium verum, hypoch eris radicata, hieracium pilosella, thymus feryllum.

**Turf from Oakham.**—Trifolium repens, holcus lanatus, poa annua, agrostis capillaris, agrostis paludiris.

**Turf from Devon.**—Ranunculus repens, litorum perenne, holcus lanatus, prunella vulgaris, felta durincula, agrostis paludiris, trifolium repens, crepis tectorum, achillea mille folium.

**Turf from Glynd-llill.**—Medicago lupulina, achillea mil folum, poa pratensis.

**Turf from the fame.**—Avena flavecens, felta durinclula, felta ovina, hieracium pilosella, agrostis capillaris, trifiolium repens, thy us feryllum.

**Turf from Short-Heath.**—Feltula bromoides, aira pracoz, junceus campeliris, poa annua, agrostis capillaris.

**Turf from Mount Cabron.**—Rumex acetofa, daucus carota, medicago lupulina, potentirium fanguiforba, felta durincula, avena flavecens.

**Turf from Ringer-Dow.**—Liumnatharticum, sechio boa columnaria, ornithopus perpusillus, avena flavecens, felta durincula, trifolium repens, hypoch eris radicata, crepis tectorum, lotus corniculatus, junceus campeliris, hieracium pilosella, felta ovina, thymus feryllum, poa pratensis.

It is, perhaps, no small recommendation to the poa trivialis, that it is a principal grasp in that uncommonly productive meadow near Salisbury, mentioned by Stillingslees, and more particularly described in the first volume of the Memoirs of the Bath Agricultural Society. And that the account given of the extraordinary fertility of this meadow excited his curiosity, and induced him to request a gentleman residing near the spot to favour him with six small turfs, cut up in different parts of the said meadow, and which being planted in his garden, at Lambeth-Marl, produced as follows:

**Different Turfs.**

**Turf 1.**—Poa trivialis, ranunculus acri, triticiem repens, agrostis paludiris.

**Turf 2.**—Poa trivialis, alopecurus pratensis, triticiem repens.

**Turf 3.**—Poa trivialis, agrostis paludiris.

**Turf 4.**—Poa trivialis, triticiem repens, peucedanum filaus.

4 L 7

**Turf 5.**—
GRASS.

Thref 5.—Po a trivialis, alopecurus pratensis, agrisia paludis, avena clation, triticum repens.

This experience proves, in a great degree at least, what he long before suspected, that the extraordinary fertility of this meadow arose not from any new grases peculiar to it, but from several unusual circumstances concurring and favoring in an uncommon degree the growth of certain well-known grases, especially the poa trivialis and agrisia paludis; consequently, in the forming and improving of grases-lands, the most certain plan will be to cultivate the seeds of such grases as may be most adapted to them, and afterwards sow them at proper seasons upon the lands, when they have been put into a suitable condition for their reception.

The directions given are, that if a piece of ground can be had that is neither very moist nor very dry, it will answer for all the seeds; they may then be sown on one spot; but if such a piece cannot be obtained, they must be sown on separate spots, according to their respective qualities, no matter whether in a garden, a nursey, or a field, provided it be well secured and clean. Dig up the ground, level, and rake it; then sow each kind of seed thinly in a separate row, each row nine or twelve inches apart, and cover them over lightly with the earth; the latter end of August or beginning of September will be the most proper time for this business. If the weather be not uncommonly dry, the seeds will quickly vegetate; and the only attention they will require will be to be carefully weeded: in about a fortnight from their coming up, such of the plants as grow thickly together may be thinned, and those which are taken up transplanted, so as to make more rows of the same grases. If the winter should be very severe, though natives, as seedlings, they may receive injury; therefore it will not be amiss to protect them with mats, fern, or by some other contrivance. Advantage should also be taken of the first dry weather in the spring, to roll or tread them down, in order to flatten their roots in the earth, which the frost generally loosen; care must still be taken to keep them perfectly clear from weeds. As the spring advances, many of them will throw up their flowering stems, and some of them will continue to do so all the summer. As the seed in each spike or panicle ripens, it must be very carefully gathered, and sown in the autumn, at which time the roots of the original plants, which will now bear separating, should be divided and transplanted, so as to form more rows: the roots of the smooth-flaked meadow-grases in particular, creeping like couch-grases, may readily be increased in this way; and thus, by degrees, a large plantation of these grases may be formed, and much feed collected for the use of the agriculturist. But a more ready way, according to a late writer, is, for the farmer to notice that species of grases most affected by his soil, and carefully to gather the seed from a piece of old meadow, purposely left three or four weeks longer than common, or at least long enough to become sufficiently ripe. He should not scruple the trouble of selecting the heads as they lie in the swath; but they who desire not to be so particular, will thresh out the seed together, either in the field or before it shall have heated in the mow. And good seeds of different sorts of grases may now also be procured from different seedsmen in large towns and other places; but the collection under the title of hay-seeds should never be trusted in any respect. Mr. Curtis, from the numerous applications that were made to him by gentlemen for grases-seeds, was induced to select such as appeared to him the most useful, and thereby rendered the public an essential service. He wished at least to put it in their power to decide on a matter which had been long agitated, and from which he was far from being the only one that entertained the f Omnigene hopes of its proving a great national advantage. The grases he has recommended will, he is confident, do all that our natural grases can do: they are six of those which constitute the bulk of our best pastures; most of them are early, all of them are productive, and they are adapted to such soils and situations as are proper for meadows and pastures. But, let no one expect them to perform wonders; for after all they are but grases, and as such are liable to produce great or small crops, according to particular seasons, or to the fertility or barrenness of the soil on which they are sown and cultivated.

This lift comprehends the anthoxanthum odoratus, or sweet-scented vernal-grases; the alopecurus pratensis, or meadow fox-tail grases; the poa pratensis, or smooth-flaked meadow grases; the poa trivialis, or rough-flaked meadow grases; the fijlula pratensis, or meadow-foes grases; and the cynarum crepatus, or crested dog's-tail grases; of which representations may be seen at figs. 1, 2, 3, in Plate Grases, Agriculture, and figs. 1, 2, 3, in Plate Grases; but more full accounts of them may be found by referring to their different botanical titles, in different parts of the work.

But of the above grases, the meadow fox-tail and rough-flaked meadow grases are tift for moist land; the meadow-foes, or sweet-scented vernal, are the most proper for land either moist or moderately dry; and the smooth-flaked meadow-grases and crested dog's-tail are those that are best suited for dry pastures and other similar lands.

It is, however, supposed, that in the more southern parts of the kingdom we may in vain expect to clothe dry soils with the constant verdure of grases; they will not stand the drought of hot parching summers: in such seasons, they are only plants which send down roots to a great depth that can be expected to look green or be productive, as the lotus corniculatus, medicago falkata, and some others.

It is observed that many more grases might be added to this list, and those too which perhaps might be highly deserving of it; but he has his doubts, whether by recommending more he might not increase the difficulty of introducing grases-seeds without any adequate advantage in return.

But besides these, the fijlula ovina, or sheep-foe grases; the fijlula turgida, or hard-foe grases; the poa composita, or flat-meadow grases; the poa palustris, or marsh-meadow grases; the pheum nodosum, or knot-grases; and the holcus ferrugineus, or rye-grases, which is a useful grases in many cases; may all be employed with advantage. They may be seen at figs. 1, 2, 3, in Plate Grases, and at figs. 1, 2, 3, in Plate Grases.

And in the second volume of his Essays on Rural Affairs, Dr. Anderson has likewise given descriptions of many others, which, he conceives, may be beneficially employed in forming grases-lands, such as the alopecurus balticus, or buffalo fox-tail grases; the fijlula rubra, or purple foe-grases; the holcus mollis, or creeping foet grases; the plantago angelica and tenax, or narrow-leaved and small grases-graced plantain or rib-grases; and the poa procumbens, or creeping-meadow grases.

In a valuable "Essay on the Conversion of Grases-Land into Tillage," inserted in the Communications to the Board of Agriculture, vol. iii. part 1. the following detail of several plants of the grases kind is given, with the soils they
GRASS.

are most proper for, or on which they succeed to the greatest advantage.

"Ray-grass (Lolium perenne). This grass, which for many purposes is a very valuable one, is chiefly to be recommended for the two divisions of soil distinguished under the titles of loam and sand. It will flourish on any land, except stiff clay, and will grow even on that; but, upon rich lands and loams, it becomes not only a good spring-grass, but, if properly managed by due mixtures, turns out well as a permanent pasture-land; always, however, most valuable by being sheep-fed, for which it is singularly adapted. Mr. Pennec's two varieties of it are sold by

some persons who have tried them, to be superior to the common sort. Mr. Professor Martyn, he says, lates the Agrostis tenuis, poa nemoralis, bromus mollis, alopecurus, anthoxanthum, and poa pratensis, as all being earlier than the Lolium perenne, or ray. See Lolium Perenne.

"Yorkshire white (Bolus lanatus). This, he observes, flourishes well on any moisl foil, and grows very generally, except on the more dry and barren ones, where, however, it is also found. It should be taw chiefly with a view to beeping, for it is not equally good for other flock: many acres of it have been cultivated on his farm for sheep, and it has answered very well when kept clofè fed. Mr. Marigall, in his Midland Counties, mentions it as a good grass for cows and other cattle, but bad for horses. In his York Economy he, however, condemns it in toto; probably from not then having it clofèly remarked its qualities. See Holcus Lanatus.

"Meadow foxtail (Alpecurus pratensis). This is an excellent grass for good loams and clayey soils, and he has found it abounds largely on dry loams. He has laid down some parts of fields with it for comparison with other grasses on wet, sandy loams on a clay marle bottom, worth 14s. or 15s. an acre; but has found it giving way in four years to the plants more indigenous to the soil. He does not think there is any better grass for either hay or pasturage, and it yields feed in great abundance. He adds, that colonel St. Leger was, he believes, the first who entered largely into the culture of this grass; and Mr. Majendie, of Effex, revived it, and began with the Alopecurus. See Festuca Pratensis.

"Meadow foxtail (Alpecurus pratensis). He thinks that for moist loams and chays, there cannot be a better grass than this: it is very early, and it abides on his farm after nine or ten years on the soils upon which the meadow-foxtail gives way to others. It has also been found, by Mr. Majendie, harder against foils than the poa trivialis, the greatest objection to it being the difficulty of getting the seed in any degree of plenty; there is an infect that feeds on it, and occasions much disappointment. Mr. Professor Martyn, in his excellent "Flora Rustica," speaks, he observes, highly of this grass, and says the seeds may be collected without much difficulty; but he does not tincred advert to the infect which is so pernicious, as noticed by Mr. Majendie, and by the ingenious Mr. Swayne, in his "Gramina Palus.

In a field on his farm, where it is very well established, and the herbage thick, it produces very few foed-dawks." See Alopecurus Pratensis.

"Crested dog's-tail grass (Cynosurus cristatus). It is re-

marked, that to judge from the appearance of the bents of this grass in poor upland but moist pastures, a man would think it a very unpromising plant; but the rich marlines of Bridgewater and Bolton, the famous pastures of Pembton in Devonshire, and those close to Mr. Fuller's caile near Ulkeard in Cornwall, Mr. Thorne's bullock-grades, by linnet-ternes bottom near Tavilock, Miss Williams's at Little Malvern in Worcestershire, (which are among the richist

pastures in the kingdom), all abound, he afferts, very greatly in this grass; in some of them it is the predominant herbage. Mr. Marshall, in his York Economy, places it as the most prevailing plant in the best-grass meadows of the vale of Pickering, some of which will feed a large cow from May-day to Michaelmas. Very fortunately it abounds much with feed, so that he has had many buffels gathered in a feast on poor women and children, at one filling a pound, and laid down many acres with it successfully. At-
tention should be paid to its being ripe; for he once ordered eight buffels to be fown on eight acres, and it failed from deficiency in ripeness. See Cynosurus Cristatus.

"Roughed-dalked meadow-grass (Poa trivialis). It is observed that Mr. Boys, of Bethanger, in Kent, has been the largest cultivator of this grass in the kingdom, and sold large quantities of the feed, but gave it up for want of a demand. It is, he afferts, an excellent grass on good, found, and moist loams. It is accounted in Lombardy the queen of meadow plants (la regina dell'erba), whether for dry pastures or water meadows; multiplying itself much by seed, and little by the root; so that, if attention be not paid to permit some feed to fail, its quantity will febbly diminish. Excellent for all sorts of cattle.

"This hint concerning the feed is worth attention in England. Major Cartwright has found the poa pratensis to be an excellent grass on rich loams; and both succeeded well with Mr Williams, of Harleyford. See Poa Trivialis.

"Cock's foot (Dailya glomerata). This grass has been largely cultivated over the farm he now manages, and to his satisfaction on wet loams on a clay marle bottom, upon which the finer grasses are apt to give way in a few years to the indigenous produce. If suffered to rise high, it is very coicie; but, fed close, is a very valuable daff-pasture. Women and children make good earnings in gathering it as a buftel. He has now two buffels an acre, and the common red clover; and when the clover wears out, the grass fills the land, and abides well in it. It grows well in winter. It has been found highly useful as an early sheep feed."

It is rated in the Norfolk Report on Agriculture, that "for Mordaunt Martin, in 1788, observing, by an experiment, that this grass grew four inches in lefs than three days, determined to attend more particularly to it: he remarked, that when sheep were let out of a fold, they ran over every thing, to get at a bank that was full of it, and there ate it in preference to other grasses. In some parts of Norfolk it is called cows' grass, from their being very fond of it. He began to cultivate it in 1794. It grows at Midsummer, in a drought, when every thing else is burnt up. He fows it with nonch, instead of ray-grasfs, and finds it much more profitable." And "Mr. Overman, also, observing the cagerenfs with which sheep, when let into a fold at Bureham-market that had some cock's-foot grass in it, ran over ray-grasses, and every thing else, to get a bite of this plant, thought it worth cultivating, and loved about an acre, on the dry gravelly part of his farm, just above the marsh. This spot was the only one, in a large field, that did not burn in the severe drought of 1800, and convinced him of the excellence of the grass." He also flowed the writer "a beautiful crop of drilled wheat, which could scarcely be estimated at less than four quarters and a half per acre, pointed out a part of the field, inferior, if any thing, to the rest; and said it was an experiment on the cock's-foot grass; he had found it an excellent plant for sheep, but having examined the roots, perceived them to be so strong, that he had some fulfillment they might exhau-
the land, and therefore sowed this piece for a trial: the
result has satisfied him that all apprehension of the kind
was ill-founded, and he intends substituting it for ray-grafs.
The author has also "cultivated this grass on a large scale
for many years, and has found it of great use. It is a most
valuable plant when kept close fed." See Dactylis Glomera.

"Tall oat-grafs (avena elata). This is another coarse
grafs, profitable when kept close fed: the feed might be
had in any quantity from France, or gathered by hand in
England. In the Rev. Mr. Swayne's experiment, it
yielded a greater weight than any other grafts." See Avena Elata.

"Timothy grafts (phleum pratense). This grafts is repre-
sented by all travellers in America, he observes, as the
great support of cattle, &c. wherever Meadows are foun
and it is asserted to have considerable merit. He has several
times made the trial of keeping it close fed by sheep on a
moit loam, upon a clay marble bottom. The succes was
very encouraging: enough, he thinks, to prove that it is an
object, in this line of husbandry, which merits con-
iderable attention; and the more, as the meats are to be had,
very clean dressed, in any quantity from America, about
a guinea a bushel; which is sufficient, with other plants,
for four or five acres of land. He believes it is best adapted
to clay, moit loains, and espécially peat." See Phleum Pratense.

"Yarrow (achillea millefolium). This, he affests, is one
of the most common and most valuable plants that is to be
met with in England. On his farm the cultivation of it
has been carried on with succes as a sheep-paffure for some
years. It is found on moit loains almost equally with dry
burning sands, gravels, and chalks. It has a singular qua-
lity of refilling drought on the moit arid foids: to that,
if you fee at a distance a green spot on a burst-up, clofe-fed
paffure, twenty to one it is clothed with this plant.
It is found in the richef meadows and bullock-paffures.
Five fhillings per bushel are given for gathering the feed
in October: it is a plant deferving great attention Sheep
are very fond of it. It is faid to form a fourth-part of the
herbage of some of the fine meadows of Lombardy.
"Burnet (potentia fanguiforba). It is remarked that
there are large tracts of the meifl parts of the South Downs
upon which this plant forms half the indigenous pal turfage.
It abounds much alof on all other chalk downs; but it will
friifur on any foil, on fand, clay, fent, &c. Some writers
fpeak of it for cows: it has been cultivated on his farm
thefe five and twenty years for fheep, for which animal it is
very uful. The feed is to be bought almost everywhere," See Burnet.

And it is obferved in the Agricultural Survey of Nor-
fekfs, that this plant was "introduced at Stoke 35 years
ago, as the writer then related, with great succeds;
but it never made any progrefs, though it yielded luxu-
riant food for many horfes in February." However, "the
reputation of this plant attrafled the notice of Mr. Coke,
who formed an experiment at Holkham, to examine care-
fully its merits, and, with the spirit that characterizes his
husbandry, fowed 40 acres, mixing a fmall quanity of white
clover and rib-grafs with it. The refult was as defirable as
can be imagined; the field has been fully and incessantly
flocked with fheep, and was connantly pared as clofe to the
ground, as a favourite spot in a paffure is by horfes." And
in other refpects it is alfo uful, as "Mr. Bevan has
found it to be the moft wholesome food for fheep in a wet
spring, and a certain remedy for the flux." And he "is
never without twenty acres of it."

"White clover ( trifolium repens). It is afferted that this
plant has hitherto been the main dependence of thofe who
have laid down land to grafs; and though, for fheep, it has
not the fweetnefs of fome other plants, or of red clover, yet
upon the whole, it is one of the beft that can be relied on
for all rich or dry loains, fands, &c. and alfo for rich and
draincd clays and peats; but on poor wet loains and clays it
will not abide, but gives way to the water-grafs ( agrefis Taf-
lonfa) and noxious plants, or other indigenous grachts.
There is no better tell of good land, than its running fpon-
taneousity to this plant; from the fine loains on rock, upon
the Tamar, to the deep frabile ones of Leiceftershire, red-
clover, left unploughed, gives way to a thick covering of
this plant. Whatever feeds be fown, this clover fhould
form a part of the dependence for succeds. Mr. Bakewell,
Mr. Wright of Norfolk, and several other pratical farters,
made this obfervation, thatStock has been known to do
badly, though there was much food on the ground; per-
haps that is preficely the reafon; and that this plant, like fo
many others, demands very clofe feeding to difcover its
merit." See Clover.

"Trefoil ( medicago lupulina) . It is obferved that, though
only a biennial, it is fure to fheed fo much feed that it rarely
wears out of land. It is a good plant, not at all nice in fold,
and the feed cheap." See Trefoil.

"Cow-grafs ( trifolium medium). An exceilent plant for
ches and lrong loains. It is faid, in the Lincoln Report,
that Mr. Ancel got good crops on a rabbit land; the hint
is worth purfuing; but he has not been fecn it cultivated on
fuch foids. It is much more abiding than common clover. The
feed is always to be had: it is known also under the name of
marle grafs. Mr. Bakewell's method of laying down was,
by common red clover and ray grafs, being fure of plenty of
white clover and good graffes coming: but he prepared by
two crops of turnips in fucc elfion, and fowed with the barley
following. On fuch land as his, the practice is not to be
condemned, but on other foids it would fail entirely."

"Rib-grafs (plantago lanceolate). It is afferted that upon
rich lands and loains this plant gives a confiderable herbage,
and on poorer and drier foids it does well for fheep; but that
it is inferior to fome others. Mr. Mitchell obferves,
that it has flood the teft of years' eftablibhed practice
in Yorkfhire, and is in good eolution; though not well affec-
ted by horfes, and bad for hay, from retaining its fap. The
eminent Haller informs us, that the adornning richnefs of the
famous dairies of the Alps, decribed by Schenchez, is
attributed entirely to the plenty of this plant, and the alsbe-
illa vulgaris. The feed is always plentiful." See Plan-
tago.

"Lucern ( medicago fativa). This is more confined than
any of the other plants. A landlord fhould, he thinks, only
fipulate for it on very rich, deep, friable, dry, found, meadow,
loains, and fertile foids, worth 30s. an acre. Upon fuch
lands, he cannot do better than to encourage it among the
temantry, to be fown broad-cafl. 2ozs. an acre, and to re-
main while productive, which will be from twelve to fifteen
years. On fuch foids it will, he fays, support more cattle
than any other plant. See Lucern.

But more full accounts of thofe graffes will be found under
the different heads which are referred to.

With refpect to hay-feeds, it is flated that the only safe in
which these are admiffible, is when a perfon has a very clean
and valuable meadow or paffure which he faves with a view
for feed; drawing out the bad plants whilst the crop is on
the fowth, and threfhing the produce on a cloth, after fhed-
ing till the feeds be ripe. Thus managed, excellent feed
may
GRASS.

may be procured with ease, and be beneficially employed in the forming of grass-lands.

In regard to the arrangement of these different grasses, as they relate to, or are proper for different sorts of soil, it is fully shown in speaking of the methods of bringing land into the state of grass or fowrd. See Laying LAND down to Grasf.

But besides the plants that have been noticed above, it is remarked that there are many others, some of which have been tried under his direction, which deserve much attention; but he has not named them in the above-mentioned list, because the feed cannot be procured but with difficulty: some perennial vetches, clovers, mellcots, lotus, &c. &c. And several others are highly spoken of by some writers; yet as his own trials have not been equally successful, he is not authorized to recommend them. He never tried the viscum flaminum sufficiently, to give an opinion of it; but, by Mr. Swayne’s account, it deserves much attention.

However, in considering the modes of laying lands to the state of fowrd, lists containing the proportions or quantities of different sorts of grass-feeding suitable for different sorts of land, are offered to the attention of the cultivator. See Laying LAND down to Grasf.

It is remarked in a general way by the same writer “that if the land laid to grass be intended for sheep, it is not an object of very great consequence to sow only the finer grasses; as clove feeding after the first year will make any grasses named in the lists fine, sweet, and productive; but this effect depends altogether on its being constantly fed clove, that is, all feed-lets being prevented from riting. Every good farmer is sensible of the necessity of this with ray-grasfs; but most unaccountably does not extend a similar concern to other grasses. Above 200 acres under the author’s management have been laid down to grass, chiefly for sheep; and he has fenced the fields fo early in spring, and so thickly, as just to keep down the feed-lets; the cock’s-foot, oat-grass, and Yorkshire white, with the management, have proved sweet feeding grasses, not at all rejected, even in fields where the fock had a choice. Several writers seem to have been very sensible of the consequence of clove feeding. Mr. Davis, in the Wiltshire Report, says, “the sweetarts of the seeds on the downs of Wiltz depends much more on its being kept clove, and eaten as fast as it grows, than on any particular good quality of the grass itself; for there are many downs that, when clove fed, appear to be a very sweet pasture, but which, if sufficed to run a year or two without a full flock on them, will become so coarse, that sheep will almost as soon starve as eat the grass.”

And in the Survey of the County of Stirling in Scotland, it is stated, that, upon Bedemond, &c. the parturing of sheep has evidently in the course of twenty years improved the quality of the herbage so as to raise grasfs of a good species, and in very considerable abundance, where nothing formerly prevailed but bad kinds of grasfs, and thence in no great plenty; and the practice bids fair to banish heath from all the places that are partured by sheep.”

Further, Mr. Bell, who was the chief writer on husbandry we had for many ages, also remarks, “that there are poor soils which require a much longer time to grow a second inch than the first; and that consequently on such it is much more profitable to keep sheep than cattle.” The writer, on first reading this passage, made the experiment on land of 12s. and 15s. an acre, clipping the plants with scissors, and carefully measuring and weighing the produce, and comparing it with neighbouring plants left to perfect the feed-let; the superiority was proportioned to the times of cutting. Sheep-feeding not only, he says, ameliorates, by enriching the soil and fining the herbage, but also by destroying weeds. Ragwort, with which the bullock-grounds of Lanark, in Ireland, are overrun for want of sheep is, it is observed, much affected by them; and Mr. Marshall, in his York Economy, gives an instance of a meadow, foul in the extreme with knoobweed, cured by parturing it repeatedly in the spring with sheep. But here, a counter remark must be made, which is, that after a field has been partured long with sheep, and clove fed, it becomes unable to yield a growth of hay: the plants, by being constantly cropped down, acquire a dwarfish habit, however quick the growth in that early stage. There is a small field on the estate which he manages, which has been under grass, time immemorial, and kept fed for the last forty years at least, except one year in which it was mown, expecting a valuable crop; the leafe was very favorable, but he was utterly disappointed, for the produce was small. He has known the same thing happen on including an old common.

In Scotland, a similar remark has been made by Mr. Wight. “Two enclosures on the same field were laid down together with grass-feeding of the same kind; after two years’ hay, the one was surrendered to parturing; from the other a crop of hay was taken every other year. After seven years’ absence, the proprietor returned home, and wanting more hay, moved both, and that which had been partured gave the worst crop.” Something like the same thing has been observed in Switzerland, as stated in the Transactions of the Berne Society. It has occurred also in other instances.

With regard to the forming of grasfs or fowrd, the procuring of good feed has been found, from long experience in every part of the kingdom, to be of all other works the most executed by tenants: they sow the cheapest feed which can be procured, that is, common clover or ray, or the rubbish of their hay-lofts: the clover gives a crop the first year; but, as it wears out, all sorts of trumpery succeed, if the feed be not good enough to run spontaneously to white clover. Great care should therefore be taken by the owners of lands, which are to be brought into a state of grass, to have proper sorts of grass-feeding provided. About 25s. will purchase the seeds in most instances; the expense may be reckoned from 20s. to 25s. per acre; but depending on various circumstances, as the state of markets, and the price of labour. Of the seeds recommended, the following are to be bought in any quantity: cow-grass, Yorkshire white, Timothy from America, white clover, trefoil, ray, burnet, rib. And dog’s-tail and cock’s-foot are easily gathered by hand. Most of the grass-feeding that have been recommended as useful in forming good grass-lands may indeed, now, or in the future, prove of service to the different feeders in London, and other places, as already noticed.

And the best methods of preparing the land, sowing the seeds, and managing the new graz-lands, are considered in treating of the practice of restoring arable lands to grasfs. See Laying LAND down to Grasfs.
the course of cropping on arable land. In all well cultivated districts, they, however, form a considerable proportion of the crops. The first of the above is a most invaluable plant, whether it be mown and used green, patured, or made into hay. By its long tap-roots it resists the effect of excessive drought on the dry-stemmed plants, and increases the quantity of vegetable mould in all. It will grow on moat land, but is not equally productive; and whether it be mown and used as green, patured, or made into hay, it generally produces four or five times the quantity of fodder that the same land would have done with common grasses. Further, in good rotations, it frequently makes the second crop, in lieu of white corn mown once, and the after-grasses eaten off with horsetails, beets, or sheep, and the land then sown with wheat. In that case, two pecks of the bell-ray-grasses, mixed with fourteen pounds of the clover-feed, should be sown upon an acre, which not only increases the quantity, but also greatly improves the quality of the hay. If the clover is for fall-feeding, the ray-grasses should be omitted. But in poor light soils, the better way is to take two or three crops of corn, and then lay the land down three, four, five, or six years. In this case, it is advised by the farmer should sow the following seeds, in these proportions per acre:

"It is supposed, that by this management, the soil would acquire a vast increase of vegetable mould and, by the parterre maintaining one-fourth more stock than it did before, would be greatly charged with manure; by which means the land would be kept in perpetual good condition: and, when brought under tillage, produce one-fourth more corn than it did under other circumstances." And it is remarked, in the Norfolk Survey, that 'Mr. Puddiford was recommended by a friend, the management he had seen and approved, to sow his seeds at twice: half of each fort (white and red clover, and ray) at the time of sowing barley; and the other half before the rollers in going over the young crop: and this practice he intends to pursue in future. He thinks it will give them a better chance of succeeding. He has 6,000 acres of feeds: he lows the great quantity of 14 lb. an acre of white clover, 38 lb. of red, and one bushel of ray-grasses. The last he eateens much in spring; and, when an observation was made against it, said, that in April and May he had three thousand sheep that found the excellence of it." This should be attended to by the farmer. It was further stated, that "it was declared that, in 1754, in reverting the husbandry of that spirited cultivator of Holkham, it was remarked, that those who have been conversant in the husbandry of old improved countries, know that a common complaint is the failure of red-clover. It has been found to repeatedly, that the land is laid to be forfeited with it. In the same district it comes to nothing on the old improved lands, yet yields immense crops on any accidental spot, where never, or rarely, sown before. The observation is so common, that no doubt can remain of the fact; however, it may be attributed to certain methods in management pursued in this county. Peas and turnips had been tried as sublimates, but they are tillage-crops, and what they thin soils, harressed with the plough, want is, result. Mr. Coke, it is added, turned his views to a different and better quarter, to other artificial grasses, which would answer the same purpose as clover and ray-grasses. He had recommended to him, on a former occasion, trefoil, white clover, cow-grasses, rib-grasses, and burnet. Mr. Coke applied them with no inconsiderable facility to the present purpose, and, that the experiment might not be delusive, tried them spiritedly upon 50 acres in the middle of a large piece, laid with clover and ray-grasses. The quantities of feed he has found will vary according to circumstances; but, in general,

according to the price, and also the intended duration of the hay. The success of the first trial induced him to lay down a yet larger space the second year. And the third (with the barst of the last spring), no fewer than 225 acres; this, in truth, says the writer, doing justice to a new husbandry. Mr. Coke has found that those feeds fill the land completely with plants, which are abiding two and even three years; and how much longer they may last, is more than he can pronounce, as their appearance is just as good as ever. The author rode over all the pieces, and never saw a finer or more regular plant than they exhibited. And he has, on several occasions, remarked, that sheep give a preference to these grasses, whenever sown in the same field with clover and ray-grasses. And it is added, that "in regard to the continuance of these trials, some of the pastures now remain, and are as fine as the soil will yield: thick, clean, and sweet." And it is here remarked in regard to land being tired of this plant, that the observation he made, "during nine years that he was in the constant habit of viewing the farm of Mr. Arbutnot, in Surrey, merits some attention. When he began to farm, the land was sick of clover, infomuch, that it was almost sure to fail, from having been, perhaps for a century, sown every four or five years. His friend adopted the course 1 lb. of burnt wheat; 2 lb. of beans; 3 lb. of cow-crafs, in which it occurred once in three years, and the farmers predicted an absolute failure: he viewed three courses, and better crops, of pure red clover, were never gained. He began with ploughing treble the depth of that to which the land had been usually stirred, and he manured very amply for every crop of beans, partly with night-soil, from London. In what degree the success arose from depth of tillage, and what degree from a variation in manuring, cannot be ascertained; but the experiment proved that those agents were equal to the cure of the malady." It is also further noticed, that "some farmers in Norfolk have moved out of the common sphere, and ventured to plough deeper than their predecessors; nor have they found any inconvenience in so doing. It merits consideration, whether this practice will not prove in some measure a remedy to the failure of clover. As to manuring, and especially in great variations, the means are generally limited, and a change in this respect, however desirable, is rarely in their power."

But, "the only effective remedy hitherto practised, is that of omitting clover altogether, for one or two rounds, which points out the great importance of introducing as many new artificial grasses as possible." See Red Clover.

The red-cow clover is another plant of the clover kind, which has been found very useful as an artificial grass. According to Mr. Amos it is perennial, and grows naturally in high chalky fields, and in gravelly fields with clay beneath. In the most improved part of the country, where the land is
to red for some years, this feed is sown along with the white clover, as it continues in the ground much longer than the meadow-trefoil, and is nearly as productive, especially on chalyke and poor lands of fort. And that where a crop of any of these clovers is taken in lieu of a crop of corn, the grain should be sown first, but in quantity than if no feeds were sown with it; and, after the land has been made fine by harrowing and rolling them, fourteen pounds of clover-feed, and two pecks of bell-ray-grafs, should be sown upon an acre bush-harrowed the length-way, and roll the crofs way of the ridges; afterwards the whole must be well gripped or drained. Nothing more is necessary to be done, on account of the seeds, till the next spring, when the land should be well driefed with the swath-dresher or harrows, drawn with long bulky thorns, the latter end of March, or the beginning of April; then cleaned and rolled the crofs way again. In all these operations, the land should be neither too wet nor too dry, but in a rude medium with respect to both these extremes, as, under other circumstances, they do not succeed so well.

The time for cutting those two grasses is, when they are in full flower, and rather flewing evidences of declining or palling their maturity. See Clover.

Lucerne, in Mr. Wright's opinion, the sweetest grass for all sorts of flock yet known, and makes the cloefest fward, and is very productive of foliage. Hence it is, he conceives it most peculiarly adapted to laying down land to pasture. It flourishes most upon rich, dry, warm soils; yet it will accommodate itself to moist kinds. It is seldom sown alone, unlefs it be to raise the feed; nor should it ever be mown for hay. In laying down rich woods, which are intended to remain in pasture for many years, this feed should predominate in the composition that is made use of. But in the Agricultural Report of Norfolk it is stated, that "Mr. Wright, of Stanlow, does not like white clover; he thinks it a bitter food, and that sheep do not eat it kindly; so that while much food seems to be on the ground, flock do badly. This is an uncommon opinion, but the writer remembers Mr. Bakewell starting the same idea." See White Clover.

The protracted or hop-trefoil, is another plant of this fort, which is not very productive, and thrives best upon dryish gravelly fields, and pastures which have the same nature. They are both perennial. See Duglows.

Mr. Amos says, the bell crops upon light rich land; but it will thrive upon the thinnest fiftone, gravelly, and chalky soils, with great luxuriance, even where these are so poor as to afford a very scanty crop of any of the other sorts of grasses. It thrives best when sown alone, though it is frequently sown with barley and oats, by cultivators that have not much experience of it. And it is advised, that upon whatever soil it is sown, the land should be brought into a very fine and clean tilth by culture. And, that about the latter end of March, or the beginning of April, it should be ploughed, and if it is roughish, be harrowed once in a place; then upon every acre, sixteen pecks of fainfion feed should be sown; then harrowing the land well, and fowing eight pounds of common red-clover or trefoil, upon every acre afterwards, the land should be bush-harrowed and rolled. And, where weeds appear, they must be destroyed as they come up, by hand, or other means. It is recommended, that no flock be suffered to graze upon the feed, the first year; and, that in the second year, there is a crop of com, rape or bone-dall to an acre, about old Michaelmas, the plants are greatly invigorated and benefited by the application.

It is further stated, that, upon such lands as the above, it furnishes a crop of hay in summer of greater consideration than any other of the artificial grasses. The hay is excellent for all kinds of flock, and the after-math very good for cattle in autumn, and for sheep in winter, till Christmas. Hence, fainfion is a most valuable grass on lime-land, gravelly, and chalky folis; but it requires three years in coming to perfection; hence the propriety of sowing common red-clover or trefoil along with it. And it should be mown before it is in full blossom, otherwise there may be lods in that way. See Saintfoin.

Lucern is afflicted, by the above writer, to be the most productive, and that which comes into use sooner than any other of the artificial grasses. Horfes, beefs, sheep and pigs, are very fond of it, when it is mown and given them green, which is the most useful application of it. It is found to thrive best on rich, dry, loamy soils, which should be made deep, fine, and clean of weeds by culture. And, he advises, that about the middle of April, ten pounds of feed should be drilled on an acre, in rows of eighteen inches asfender, and one inch deep, with a row of common red-clover between each; then bush-harrowed and rolled. Nothing more is necessary to be done till weeds appear, when it should be hand-hoed well, and the weeds in the rows pulled out by the hand. And when as more weeds appear, it must be hand-hoed and hand-weeded a second time, and even a third time, if necessary; when this is done, great care should be taken not to tred upon the young lucern. And as soon as it begins to blossom it should be mown, carried off, and given to the flock green. By this mode of application, it will, he says, keep more flock than any of the other grasses.

But this plant also requires three years in coming to perfection; hence the propriety of sowing common red-clover along with it. After that time, it may be mown three, four, or five times in a season. But, between every mowing, it should be well hand-weeded, and made quite clean of weeds. And every third year it should have a covering of rotten dung, after the rate of eight or ten tons to the acre, applied over it about Martinmas. See Lucern.

Burnet is a grass of the artificial kind, of which there are several varieties; but the only one worth cultivation in this country is the common fort. This plant, though little cultivated, is highly valuable, either green or in hay for horfes and cattle, and is an excellent winter food for sheep. It thrives in a dry, clean, light and deep soil; but it will grow very well on poor, gravelly, and chalky soils, which must be made clean and fine by culture. And it is advised by Mr. Amos, that, "about the middle or latter end of July the land should be ploughed for the last time, and harrowed well; after these operations, four pecks of feed should be sown broad-call upon every acre, and then bush-harrowed and rolled. And it is suggested, that as the proper reason for sowing it is the latter end of July, it becomes an excellent succedaneum to turnips, when they have been destroyed by the fly, which is often the case." And it is stated, that "the most profitable way of cultivating burnet is by sowing it with other feeds, when the land is to be laid down in these proportions:

Vol. XVI.
GRASS.

The land should be bush-harrowed and rolled, and afterwards kept clean of luxuriant weeds. It is, however, remarked, that "much as this has been extolled, yet it is seldom found either alone, or with other grass-seeds, since the introduction of red and white clover; though its greatest excellence is for winter-pasture in the feeds of sheep, &c."

See Burnet.

Chicory is likewise a plant of this description, which may be found highly beneficial on many poor sandy or gravelly soils, where other sorts of grasses cannot establish themselves. It is asserted, in the Norfolk Report, that "Mr. Bevan sowed an acre of poor land, worth not more than 2s. 6d. rent, with chicory in 1793, and that the next year it produced 7l. 10s. in feed." And the writer says, that he has taken several opportunities of recommending this grass in that district. On large tracts of poor land, he is confident it would increase the produce tenfold; and it well merited trial, he thinks, on every soil in it. The objection which has been founded on its not being easily extirpated, is, he contends, of no importance, for tares should be sown after it on some soils, and turnips on others, in which system, its distinction is unquestioned. This hint should not slip the notice of cultivators in other districts.

This is a plant of the kind, which is much employed as summer herbage, either polluted or mown green, as foiling for horses, &c.; for hay, as a substitute for red clover (on land that has been tired of growing it); for manure to be buried in by the plough; and for feed; hence the reason for sowing the seed of this tare will depend upon the ufe it is intended for. When for summer herbage, &c., it matters not how early the feed is sown, provided it has not hard frost ensuing. The first sowing may be as early in February as the season and condition of the soil will allow, and to continue the sowing at due intervals through the months of March and April, which will give a good opportunity for succedion of them, to the great convenience of summer-feeding, but when for depasturing, it will be prudent to wait till the tares have gained a sufficient increase of haunch, before the flock are turned in upon them. And when for foiling horses, &c., they should be mown before they flower; and in no instance should the haunch be suffered to become rotten near the surface of the ground, which frequently happens on rich soils and moist situations. If for hay, the tares should be sown as early as March as circumstances will allow; but the time of mowing is more optional. Some mow them when the blossoms are fuller; others, just before they are quite ripe. But, in either case, the same caution is necessary, as in making fair thin and clover into hay; and that is, to avoid breaking off the leaves, in which a great part of their virtue resides. When they are intended for manure, the feed should be sown as early in February as the season and condition of the soil will permit, and at the rate of four bushels to the acre. For this use they should be ploughed in before they get too long in their growth. But whatever is the intended ufe in cultivating this tare, the preparation of the land is the same; and this plant delivers most in light sandy soils; and, in every cafe the land should be ploughed and harrowed once in a place, before the feed is sown; then sow the feed broadcast at the rate of three bushels an acre for the first and second ufe, harrow the land well afterwards, and then lay it dry.

Summer Tare.—The great objects in cultivating this tare are, 1st, spring-feeding and summer-herbage for cattle and sheep, especially ewes and lambs. 2d. Hay, as a substitute for red-clover. 3d. Manure, to be buried in by the plough. And 4th. Seed. But whatever is the intended ufe of this tare, Au-
gust and September is the prime season for sowing the feed of it. As soon, therefore, as the ground can be cleared of its crop, the land should be ploughed and harrowed once in a place before the feed is sown upon it. And it answers extremely well simply as a spring-food, when sown with rye, in the proportion of six pecks of each to the acre. See Tare.

Where they can be cultivated, crops of this tare should never be neglected. See Artificial Grajes.

GRASS-Ground, in Gardening, the parts of ornamented grounds which are kept in the state of lawn short grass or fward. Tho' these spaces which are extended in the fronts of the houses or habitations, and are termed lawns, are mostly kept in short-grass, which, by their compact verdure, summer and winter, and open rural appearances, exhibit a fine imitation of nature at all seasons, especially when the side boundaries terminate in rural plantations in various natural curves and bendings. This mode of laying out pleasure grounds prevails much at present. But besides these it is the practice to have rural short-grass openings continued between the plantations throughout the different districts of ground of this fort, separating and bounding the shrubbery clumps, borders, and other parts, in some places widely spreading, in others more contracted; but, in either case, extending to the boundaries of the several plantation compartments, in various bendings, sweeps, and curves; by which the whole is rendered Ruraly ornamental, and at the same time more agreeable and easy to walk on than gravel between the plantations, when the weather is dry and hot during the summer season. In the ancient style of gardening, it was much the custom to have straight short-grass walks, both for ornament and common walking upon; but for ornament, unless elegantly wide and spaces, they have a littleness in their general appearance, as may be seen where long rows of short-grass-ground are extended to some distance, in the way of walks; and for the latter purpose they are very improper in winter and all moist weather; and even in summer in the mornings and evenings, as being always damp and dewy. Walks of this kind should therefore be but sparingly introduced; and where any are made for variety, ornament, or summer's walking, they should be as spacious as the situation admits, not less than from ten to fifteen feet wide, and even twenty feet wide or more, when the walk is considerably extended in length.

The method of forming short-grass-ground work is either by sowing the parts with grass seeds, or by laying them with turf cut from a fine field, common, or down; the latter of which, where it can be obtained at a moderate expense, is greatly preferable, as it not only at once forms a complete fward, but is generally more clofe, even, and smooth, as well as less apt to run up to better grass, grow rank, or rife in tufts, than by the following method. The sowing method is, however, much less expensive.

Preparations.—In preparing the ground either for sowing grass-seeds upon or laying with turf, the whole must be broken up equally to a moderate spade's depth, clearing out all the roots of perennial weeds and other coarse materials. When this has been done, flakes or wooden pegs with notches, for making the level, according to the position of the ground, must be driven in; then proceed with line and spade to rough-level the ground according to the marks or place before the pegs, after which treading, rolling, or ramming the whole down equally, that it may nowhere sink in hollows afterwards. When this has been finished, the levels should be brought up more accurately, and the whole finished with a neat raking, clearing off all large stones, and making an

even
GRA S S.

even and smooth surface; in this state it may either be fown with grass seed, or laid down with turf.

For the first method the proper season for sowing are either February, March, and April, or in August or September in moist weather. In moist weal forests the former is probably the best, but in those of a dry gravelly nature, the latter. In this business it is of the utmost importance to procure good seeds; those from hay-fields or out of hay-lofts are often used, which may answer well, where the hay was the growth of some fine pasture free from weeds, and naturally afforded fine turf when grazed and mowed; but in other cases there is often a mixture of various sorts with weeds, by which the sward is rendered irregular and foul, and never makes handsome short grass-grounds. If you are not furnished with seeds of your own, they must be obtained from the seedman, and should be of those kinds which strike deep root, spread out laterally in their tops, are permanent, and capable of resisting the effects of heat; there are many of this kind. (See Laying Land down to Grass.)

The seed must be fown broad-cast, very thick and regular over the surface, and directly raked or harrowed in; and when the surface is dry it should be rolled with a wooden roller, to bury the seeds more effectually, and make a smooth surface: when the grass comes up, all weeds should be removed; and the same season, when the sward is become thick and green, an advanced some inches in growth, it should be mown, rolled it well afterwards, and continue mowing it and rolling two or three times the first summer, especially if it were fown in spring, as, the oftener it is mown and felled, the thicker and finer it will grow; and if it is intended to keep the grass tolerably fine, mowing will be requisite once a week or fortnight, according to the growth from April to October, and rolling once a week or fortnight in moderately dry weather, and occasionally in the winter season. In this way a good turf may be formed in a few years.

In the second method, which should always be employed where it can with convenience, the best turf is that of a fine pastured common or down, where the sward is fine and short, with considerable cloves.

The best season for laying the turf is from September till March or April, though it will grow at almost any time of the year, even, if there be occasion, in the summer months.

The turf for this ufe is mostly cut or played with an iron instrument called the surfacing iron; all the turfs being cut of an equal width, length, and thickness: the proper size is a foot wide, a yard long, and about an inch in thickness. They should be fird marked by a line the proper width, length, and depth, and then cut with a racer or cutter, firt longways a foot wide, then across in yard lengths, proceeding afterwards to cut them up; having particular regard to cut them level, and all of an equal thickness, otherwise it will be impossible to lay them level. As they are cut they should be rolled each up clofe and tight, the grafs fide inwards, and piled up by tens, especially if they are cut by the hundred, which is mostly the cafe. This is ufonally done at from about a fhillin to fifteen pence the hundred, according to the nature of the foil, as, whether soft and easy to cut, or hard and ftony. A man will cut from three to five, fix, or even hundred a day, with a perfon to trace them out and roll them up as they are cut from the surface.

The method of laying them is very easy: they are placed regularly turf and turf, unmolding them as they are laid, joining them up quite clofe edge to edge, and making good all deficiencies of broken parts as the work proceeds; and as soon as laid, they should be well beaten with broad heavy wooden beaters, as flat pieces of elm or oak plank two inches thick, fifteen or eighteen inches long, and a foot broad, having long handles fixed flating in the middles of the upper sides. With these beat the grafs regularly all over, and then roll it well with a heavy iron or stone roller, repeating these operations in moist weather as there may be occasion.

When very dry hot weather succeeds, so as to occasion the turf to shrink and open at the joints, a good watering is of much advantage to it.

The management of short grass-ground, after it has been thus laid down, is that of mowing it in summer frequently, to keep it short and fine, like a patured down; polishing occasionally with a long pole, to scatter the worm-calls, which greatly deface all short grafs, and rolling it frequently both to take up the scattered worm-calls to make the surface clean, and to render it smooth, firm, and even in its appearance.

Mowing once a week, ten days, or a fortnight, or, according to its general growth, during the summer, is necessary, especially for the principal home lawns, and other short grass-grounds, in the most coniposite parts; which parts should always be kept very clofe and fine, like the sward of a fine patured down or common: it is performed with a short grafs- scythe; and dewy mornings, or moist weather, must always be chosen for the work, as it will be impossible to mow short grafs properly in dry weather. Previous to mowing, it is of advantage sometimes to pole and roll the grafs the day before it is intended to mow. In performing the work of mowing, proper attention is necessary not to score or leave the marks of the frokes of the scythe, which has a very unightly appearance; to prevent which, as much as possible, the point of the scythe should be laid out rather wide, an inch or two beyond the measure of heed and point, especially for very short grafs, keeping the point rather out, and not drawing that part too falt inwards, gathering the grafs neatly to the left in a range; and after having moved thus to the end of the swarth, to mow it lightly back again, in order to trim off all scores, and other irregularities, unavoidably left the first time in executing the work.

After it has been all thus mown over, proceed to sweep up the mowings of each swarth regularly, by standing in the middle, sweeping it along alternately to the right and left, to the end of the swarth, forming all the grafs in a range, and each range; then heaped in large heaps, and carry the whole off directly in a wheel-barrow, large baffle, or other contrivance for the purpose.

The business of polishing is performed by a long, taper, pliable, a pone pole, fifteen or eighteen feet long, by passing it backwards and forwards, in rather dry weather, so as to break and scatter the worm-calls about. The grafs should be afterwards rolled with a wooden roller, when the surface is a little moist, but not too wet, by which the earth will all adhere to the roller, and render the surface perfectly clean, the work being repeated, as there may be occasion, the year round; and in mowing-time, if the surface is foul, it is particularly necessary to pole and roll on the day previous to mowing, by which a clean smooth surface will be provided, so as to be able to mow clofe, even, and more expeditiously. See Poling.

In the rolling of short grass-ground, it should be performed occasionally with a wooden roller, and a heavy iron or stone roller: the wooden roller is proper after polishing, to clean up the worm-calls and smooth the surface, being performed when the surface is not very wet, especially if full of worm-calls, as it would otherwise platter and daub.

4 M 2
the grass, and render it unhealthily; the heavy iron, or stone roller, should be used occasionally, when the surface is dry, to press down all inequalities, to clofe as to preserve a firm, even, smooth surface. And in fine-kept short grass-grounds, the rolling should be performed occasionally a day or two before mowing, to settle the surface firm and smooth, which greatly contributes to the easy and exact performance of the work: the buffets of rolling in small, or but moderately large short grass-grounds, is mostly performed by men; but in very extensive grounds, it is sometimes done by a horse or having a large roller for the purpose, with shafts like a cart, and the horse at the same time wearing a fort of leather shoes, very broad at bottom, made so as to lace on occasionally, like men's half-boots, to prevent his feet cutting the surface in holes, and rendering it uneven, and of a bad appearance.

Where short grass-grounds are defined by wild daisies, dandelion, or other weeds, the first may be removed by having the blade of an old broad-favred fixed in the end of a long pliable pole, which, as it cuts both ways, by sweeping it backwards and forwards, it will head down the daisies at a great pace; which may be repeated two or three times a-week, or as often as may be occasion for it.

The others should be extirpated by means of an iron for the purpose, made in the form of a small docking-iron.

In the autumnal finishing mowings, the grasses should be generally cut down as close and even as possible, that the fward may remain in a neat even surface over the winter seafon, and appear well in the early spring.

These directions for the management of short ornamental grass-grounds, regard only such as are required to be kept constantly short, close, and even in the surface, as is necessary in the principal lawns, past, walks, and other divisions, situated within the limits of the main pleasure-ground. In the outward considerably extended districts, continued into fields, parks, &c. it is not necessary to have them cut so frequently; two or three common mowings in a summer, with occasional rollings afterwards, may be sufficient.

Grass-beth, in our Countrys, grazing, or turning up the earth with a plough. Hence the customary service for the inferior tenants of the manor of Amered in Oxfordshire, to bring their ploughs to do one day's work for their lord, was called grass-beth, or grass-burt.

Grass Husbands, that fort of husbandry which has a relation to the management of grass-land, or such as are under the condition of fward. This, in a great measure, conffit in the proper clearing, manuring, pâturing, or feeding down, futting up, cutting or moving, and the preparation of the crops. This fort of management is far from being perfectly understood in many parts of the kingdom, and consequently the grass-land is frequently in the moft coarse and wretched state, being over-run with various kinds of coarse and aquatic plants, as well as thofe of the grass, and other defcriptions. See Husbandry, Grass, Meadow, and Pasture.

Grass-land, that fort, or defcription of land, which is mostly preferred in a state of barbage or fward. The forts of land that are the moft adapted for this purpose are, according to fome late writers,

1st. Such as are fitated near large populous towns, where manure is cheap and plentiful, and where the produce of grass-land is constantly on demand, and, of course, dear.

2dly. Such lands as are placed on the banks of rivers and brooks, that may be improved by irrigation to a much higher value than can possibly be done under any other method of cultivation.

3dly. Such lands as lie in valies of mountainsous countries, especially chalky soils, where old meadow-land is

fearce and valuable, and the greater part of the arable land is
of that nature and quality, that it is impossible to convert it to good fward-land. And

4thly. All fuch cold strong ground of the grass kind, which, if ploughed up, would not be applicable to the purposes of the turnup-husbandry, or those of modern farming, and which, under the belt practice of wheat-husbandry, may not be fo valuable as they are at present in the condition of fward.

The forming of grass-land is effected with different degrees of difficulty in different climates; in some parts of the inland it is accomplished, in general, with great care and facility, the foil having a natural tendency to the production of grass herbage, when left in an unploughed state, reverting to pasture without labour, expence, or even the fowing of feed; while, in other cafes, all the art of man has been found ineffectual, to make good grass-land. Even after 20 years fruitless expectation and expence, the man-holders have often been obliged to restore the ground again to a state of tillage-husbandry.

It is remarked, that confequently the great difficulty in this husbanfy is to difcern what fort of land is fuitable and proper for grases, and that which is improper for the purpose. The belt meadow-land does not always make the belt tilage-land, nor does the belt arable-land always make the belt pasture, but frequently the reverse. To make this determination, it is necessary to consider well the pro-
cese of nature in propagating and perpetuating grases. The great object of nature is to perpetuate all her fpecies; but upon the plants created for the support of animals intended for the food and use of man, he seems to have bestowed more than ordinary care. Different kinds of animals propagate in different modes, some oviparously and some viviparously. Plants having no locomotive motion are endowed with a power of propagating in both modes. In trees and shrubs, and many kinds of plants, the afittance of man is required to obtain viviparous production, by grafting, budding, &c. But, in grases, nature does her own work, and that in both modes. We have only to attend to her examples, and we shall seldom err. In trees and shrubs, the bud is the viviparous production; in grases, the root performs the fame office. Grases are as much the offspring of roots as of seeds. Every new root contains the germ of a future plant; and, as the feed-talks of grases muft necessarily be frequently cropped by animals, nature makes up the deficiency by an increase from the roots. Most of the belt grases are, in their nature, biennial; but nature, by giving them the power of propagating by the root, has in effect made them perennial; a much more certain mode of propagation than by feed, as being increased instead of being injured by the biting and treating of animals, and by the produce being perfect in one year instead of waiting two, as in the production by feed. But this process does not go on successfully. unless the land is peculiarly apt for the production of grases. If it is too wet, the grases will be injured in the winter by rain and frost, and will soon be superceded by rushes and other aquatic plants; if too dry, they will be killed by the summer's heat, and give place to moles, fenn, heath, &c. No land will it is conceived, a make good meadow, unless it is deep enough to admit the roots of grases to run down out of the reach of the summer's heat, and that it be retentive enough to hold water just so long as to produce fermentation, with such an aborbent under-litatum as will drain it before putrefaction takes place.

Some proportion of grass-land should always be attached to every farm, in order that a proper and suitable supply of winter and summer feed may be provided for such animals as may

GRASS.
GRASS.

may be requisite in managing them, and also that adequate proportions of good manures may be raised; as, where this is not the case, it is impossible that farms can be well managed. And on all sorts of grass-lands, it is of much consequence to keep them as clear and free as possible from the growth of all sorts of coarse plants, those of the aquatic kind being removed by suitable drainage, and the application of different substances of the absorbent description to the surface of the land. They should likewise be carefully eradicated from the hedge-rows of grass-fields annually, and by that means be prevented from spreading themselves over the ground by their seeds. By this practice, the hedge-plants would also be greatly benefited. These sorts of lands should also be kept as clear as the nature of their application will admit, of all kinds of obstacles that impede the production of perfect sward, such as the growth of moss on their surfaces, and the continuance of cattle dung-hills, ant and mole hills, as well as thoe of ticks, flies, and other similar substances. The proper methods of removing these are noticed under their particular heads, and in speaking of meadow-lands, and pastures.

According to the Agricultural Survey of the County of Herts, in an experiment made by the Duke of Grafton, it was found to destroy moths, no. The material has been well turned up. It is advised that manure should be laid on at the same time: but that where ashes are spread out over the surface without harrowing, the moss plant is destroyed, and the grass greatly improved. And in other cases, much advantage has likewise been experienced from the application of fine sand over the sward, in an even but not too thick a manner. But the dung of animals should never be suffered to remain any length of time in heaps upon the surface of grass-lands, without being burnt small, and dispersed over the surface; as, wherever that is the case, the sward in the places becomes tender, and the grass comes up coarse and in tufts, which are not eaten by cattle flock, and of course much injury sustained.

In respect to the prevention of the rising of ant-hills on grass-lands, they may be in a great measure, if not wholly, guarded against, by having recourse to frequent heavy rolling; as in the rolling down of ant-hills, instead of cutting them up, in an experiment made by the Duke of Grafton, it was found to be attended with complete success, on a large pasture which had been very much infested with ants, and which they had almost covered with hills. But in such cases the rollings should be performed both in the autumn and spring seasons, when the lands are in such states of moisture as just to admit the impression of the roller without receiving injury from the feet of the horses; as, where such operations are executed when the grounds are in a state of considerable dryness, the benefits are comparatively small. The beneficial effects that are produced in this way depend much upon the degree of conflagination that is effected; as it is only by this means that the insects can be prevented from carrying on their operations; a certain flame of lightness as well as flashed in the mould being essential to the execution of their labours in a perfect manner. But besides these attempts have been made in other ways to prevent the formation of these hills. For as it has been seen that "the economy of the ant requires the situation and soil to be dry, light, and friable, in order to carry on their works, it is probable that, in lands that will admit of the practice, it may be an easy and convenient method of destroying them, and preventing the bad consequences which their labours produce on the surface sward, to conduct water over them; and thus, at the same time, exterminate the colonies of ants, and irritate the ground; by which two improvements may be effected at once,—the land being cleared from ant-hills, while its fertility is considerably increased." And the use of night-soil, in combination with various sorts of earthy matters, has been advised with the intention of destroying such insects; but this is probably a practice that can only be depended upon in slight cases. See Ant-hill.

Upon still yellow clays, a Hertfordshire farmer has found the practice of draining, according to the Effex mode of carrying off the surface-water, useful, though this practice is totally unsafe by his neighbours in the same parish. Experience has convinced him, that drefling a cold tenacious clay not previously drained is an absurd waste of time, money, labour, and every thing most valuable. Having obtained a tolerably dry surface, his next object (with meadow-land) is to deepen the staple of the soil, and this he does by every kind of compost carried on it for two or three years together, which he finds establishes a better sort of grass than drefling once in three years on the surface.

It is suggested that the culture of feeding the first year, instead of mowing, is a practice that must be preferable or most according to the nature of the soil, and the object of converting it into grass-land. With respect to the former, he has found, that if he was to allow even the tendering of sheep the first year after the grass-feed is sown, he should fill the surface with receptacles for water, and should have very little, if any, grass of a coarse quality, notwithstanding his drains, because the sheep or cattle would press the clay so close, that the water could not penetrate into them; whereas, if he shuts up his field, suffering the grass to stand till it theds the feeds, he finds the following reason that he is enabled, by giving only a flight drefling, to cut a good crop of hay from it. And in cases of old worn out thin patches or moisy grass-lands, the practice of scarifying or cutting the surface sward, in different directions, by implements for the purpose, has been lately advised as very beneficial in promoting their improvement, especially where they are afterwards manured, and have suitable gras-feeding fowl over the thin or patchy parts, as in this way the grass-plants become more strong and vigorous. In performing this business Mr. Amos has adopted the use of a machine for scarifying and drefling grass-land, whether it is to be mown or depuffled with animals. And he conceives that the bell time of performing this operation, is from the middle of February to the middle of April. And that, in general, drefling the land one way is sufficient; but, if the sward be very moisy or adhesive, it should, be thinks, be drefled length and crofs ways, cleaned, and then rolled, the cutters of the implement being occasionally cleaned from the rubbish. It is also suggested, that if the sward be thin, it may be thickened very much by laying eight or ten tons of rotten dung upon it, and fowing seven pounds of white clover, four pounds of wild or cow-clover, four pounds of trefoil, four pounds of rib-gras, and one peck of bell rye-gras seeds, per acre, previous to its being drefled or bath-harrowed, and then cleaned and rolled. It is supposed that by drefling land in this way, mofs is torn up, ant and mole hills levelled and destroyed, the roots of the grass cut and horfe-hoed, which causes them to throw out fifth lateral shoots or floets, the sward thickened, and the surface made so clean as to put on the appearance of a perpetual spring when clofe fed down. And that, by such management, and grazing as much lock as will keep the gras in a young succulent state, and labbbing or mowing all the tufts and weeds three times in the course of the summer, the grazier will be enabled to receive every benefit from his land, and likewise
GRASS.

Statement of Expense.

In 1822 this method answered very greatly: the meads were then not capable of irrigation, but one meadow had since been watered, and the water has taken much greater effect on account of the funding, than if that operation had not been performed. The land has all been laid on the most boggy meadows. This hint should not escape the notice of the practical farmer in other districts, as there are many where it may be had recourse to, with the greatest advantage and success. There is likewise a similar method of improving old rough and boggy meadow-land described, with a plate, by a writer, under the title of Agricola Norfolkensis, in the first volume of the Fervet of the Agricultural Magazine, as practised by Mr. Rix, of the same county:—

"This meadow was situated at Clifton, near Fakenham, in the occupation of the above, and the property of T. W. Coke, esq," of Holkham. It is noticed that this meadow, from the neglect of former tenants, and want of judgment in cutting what few open drains or ditches were attempted, had become very wooded in many places, and at least three parts of the four so over-run with hedge and bushes, that its utmost annual value could scarcely be estimated at more than eight shillings per acre. The lands contiguous to it are of a light friable nature, inclining to sand, by spots, and fall with a gentle declivity towards it from each side; the meadow being the basin and receiver of the numerous springs which rise in the upper fields, and which, in course of time, had rendered some parts of it utterly impassable for an horse, and fearfully safe for a man at certain leasons. It is observed that the first repe the present occupier took was, as soon after Michaelmas as he could, to cut the drains, as he has shewn in the plan; all of which are provided, except the main drain, and forty of the ditches. These latter are cut both wide and deep, and are the chief outlet drains to the springs above. And as soon as the weather permitted, he next set the teams to work (which were enabled to enter, even upon the most unfound parts, very shortly after the first process was concluded), to level the hills, fill up the hollows, and to cart all the superfluous mould he could collect within the boundary of the meadow, (such as came out of the new-cut ditches and main drain principally), to the amount of 1000 loads, over the surface of the whole. About the last week of March he drilled; and where the roller could not work, from little inequalities of ground, he dibbled the feeds mentioned in the annexed statement, harrowing the small feeds in afterwards; and, in July last, he cut and stacked the produce, which the writer has seen, and can witness to be excellent hay. It is added that the present appearance of the meadow, after being fed down very close by more than fifteen score of sheep, exhibits, notwithstanding the very wet season we experienced, one uniformly dry, firm, and smooth surface, completely covered with a short turf, confiding of ray-gras, Dutch-clover, and good natural grasses. There are certainly some rushes yet, but far less numerous and strong than heretofore, and which it may justly be expected a few sweepings with the sythe, and hard l flocking with sheep, will in time wholly destroy. But though there may not be much

And it is likewise observed, that "Mr. Bevan's tractable land at Riddlesworth, joining to his low boggy meadows, gave him the power of carting sand down hill at an early expense; and thus he improved some parts of those meadows to great effect; from 100 to 150 loads an acre were spread at the expence of 4l. or 5l."
much novelty in the scheme of draining, the writer is of opinion, that very great merit is due to Mr. Salter, for the introduction of vetches, which he apprehends was never before tried on pasture-grounds, or indeed on any ground whatever unbroken by the plough. It certainly answers several admirable purposes, one is, that it gives a prospect every year of a bulky crop of hay, which otherwise must have been very scanty. And being sown with oats, the vetches afford that hovering kind of shade and protection to the young gramineae in which they most delight. The eddih is of course also worth more.

But he is not a little sure, whether Mr. Salter's experiment gave rise to the following practice, which, he is informed daily gains ground. Where the clover plants fall partially, or by spots, on a new layer, spring vetches are often drill-rolled upon the surface, not ploughed. The few clover-plants are thus left to grow with the vetches, and both together, in due season, form nearly as good a sward, as if the clover had not died away. Mr. Rix is so thoroughly convinced of the utility and advantage of the method he has pursued, that he is now preparing a second meadow, lying at the foot of the one just improved, for a similar process of improvement.

In cases where pasture-land can be spared for mowing, Mr. Rix seems to be of opinion, that vetches may be profitably employed, even a second year, upon new improved meadows. He has had some experience of such a repeated trial, and the writer believes he thinks favourable of it. He dibbles the feed upon the unbroken surface, after feeding it down as close as he can with sheep or other stock.

I t is stated that the above meadow of Mr. Rix's cannot be over-rated, if it be said that it is, at this moment, more worth thirty shillings per acre to a tenant, than, in its former state, it was eight shillings the acre.

"Debtor and Creditor Accounts of Mr. Rix's Meadow, ending at Michaelmas."

Total expense | 65 | 7 | 0

It is also necessary that care be taken to keep grass-lands in a proper state of production, by the judicious use of top-dressing, and by observing suitable methods of mowing and feeding them down by flock, and it becomes of course requisite in the view of keeping such lands in the most proper condition for the production of plentiful crops, as well as that of altering and improving the nature of the herbage, to have recourse to the occasional application of manures; as by this means the slope and depth of the vegetable mould are not only much increased, but the land brought into such a state of fertility, as it may afterwards be kept up with much less expense and trouble than before.

A late writer has stated, that "it is a circumstance well known to graziers in the belt cultivated districts, that when lands of this sort are suffered to get much out of condition, it is a much more difficult business to restore them to the proper state of productiveness, than to preserve them in it. From the constant decomposition and decay of various vegetable materials on the surface of grass-lands, new portions of vegetable mould are constantly added, that improve the quality of the lands, and at the same time afford a more suitable and fertile bed for the establishment of the different kinds of grass-lands. It is chiefly, perhaps, on these accounts that old grass-lands are superior to new ones, and it explains the reason of the greater utility of earthy composts, with dung in the latter than the former cases. However, with respect to the nature of the materials being made in such circumstances, there is much difference of opinion; but it should, probably, be regulated by circumstances; such as the rate of the land in regard to dryness, its situation, the heat of the season, and its nature and condition in respect to soil and fertility. Where the land is such as not to admit the dung-cart in the early spring-months, without the danger of injuring the surface by poaching on breaking the texture of the sward, the most proper period would seem to be in the beginning of the autumn, before the heavy rains fall; at this period the draughting may be laid on with the greatest convenience and safety; and from the after-grasses being chiefly confounded with the least loss in that particular. It is, however, recommended to be performed by some immediately after the land has been mown and cleared from the hay, in which method there may be an advantage in some cases, as the growth of the after-grasses may thereby be rendered more abundant." But, in other respects, it has been observed by the author of Practical Agriculture, that, "it must often be not only inconvenient, but un economical, as from its happening at a season when much other business is to be performed, it can seldom be attended to in such a manner as is necessary; and when the season at this period is hot, and there is much sun, as is generally the case, there must be considerable loss sustained in the evaporation and diffipation of the finer and more enriching particles, such as become more immediately the food of plants, from their being in a condition nearly suitable for being absorbed and taken up by the roots of the grasses. The extent of the loss incurred in this way is much more considerable than is commonly supposed, as much appear evident from the great evaporation and constant evaporation that is often kept up for many days, or even weeks.
weeks, as the very offensive smell that issues from Profes.
In this district, where we have occasionally witnissed the practice, with some of the less intelligent farmers, the moisture of the manure has been so much forced off and dissipated, especially when there is much wind, as to leave the materials apparently a perfectly dry flate. The sudden drying up of large ponds, at such feasons, shews in a more striking manner the extent of the injury that the farmer sustains in choosing this season for the application of his manure upon his grass-lands. And, it still further states, that "there is another way in which a vast loss of manure may take place when applied at either of the periods that have been just noticed, especially where the lands lie in sloping directions, as is frequently the case, which is by the heavy rains in the autumnal feason carrying down the more fine and rich parts of the manure, in a state of solution, into the ditches and runlets on the fides or other parts of the fields. Of the great waste of manure occasioned in this way any one may convince himself, by attending to the flate of the water as it drains off from the higher grounds into these places, after the land has been previouly dried, as it will be found highly coloured, and loaded with the enriching carbonaceous particles of the manure." And "after frosts, when sudden thaws occur, the fame thing happens," in a still more extensive degree than in the other fases.

In fases where the natural dryness and open texture of the soil admit of the manure being applied in the early spring months, there will be less danger of waste in the above manner, and at the fame time greater advantage obtained in the growth of the produce; as, from the moderate heat and quickness of the vegetation at this period, the grass will soon over-shade and conceal the dung, where laid on in a suitable state of reduction or fineness, without suffering much exhalation to take place; and the enriching material be conveyed to the roots of the grafs-plants at the time in which it may be the moft useful in promoting their growth. Where the principal object of the farmer is a large produce, and the nature of the foil will admit of the manure's being applied without injury, this is unquestionably the most fuitable as well as moft beneficial time of putting the dung upon grafs-lands. The eafier, however, it can be performed the better. See Manure.

But it has been flatled by fome, that manure produces the strongest effects upon the land when applied early in the autumn, or in meadows as soon as possible after they have had the hay taken off from them. And others suppose this last as the moft proper fason for laying the bullfines performed in of any.

In regard to the kinds of manure that are most proper, there is scarcely any fort that will not be beneficial when laid upon grafs-lands; in general, however, the more rich animal kinds will be the moft fuitable for the older forts of fward-land; and dung, in combination with fresh earthly materials, the more proper on the new lays or grafs-lands, as by this means a fine early bed will be prepared for the roots of the grafs-plants to shoot and freqoad themselves into, and a better fward formed in confequence of such applications. See Layering Land down to Grass.

It is the practice of the fett farmers in the hay-diétricfs of Middlesex to ufe the richest dung they can procure, without mixing it with any fort of curdy material, as they find it anowver boil in the quantity of produce, which is the principal object. The lands on which this fystem is pursued, are mostly such as have been long under fward, and where the soils are chiefly of the more tenacious, loamy, or clayey kinds. It cannot, however, be doubted, but that earthly compoifs in the proportion of a third or fourth of such materials may, in many fases, according to the nature and circumftances of the land, be had recourse to with great and beneficial effects, both in rendering the land more productive, and in bringing the herbage into a finer flate, as well as in bettering the surface for the purpofe of mowing. See Manure.

It may be obferved, that whatever the nature of the material may be that is employed in combination with dung, or the fort of manure that is ufed, it fhould invariably be brought into a rather fine flate. It is the practice, in the diftricts mentioned above, to turn over the dung that is brought from London in a flate of tolerable rottennesfs once, chopping it well down in the operation, fo as to be in a middling flate of fneness when put upon the land. It is neceufary, however, that it fhould be in a more rotten and reduced flate when applied in the spring, than when the autumn is the time of putting it upon the land.

In refpect to the proportion of manure made ufe of at one time, it fhould be, in order to be dealt, in a tolerable flate of cultivation, but, in general, fuch as to afford a good even covering to the surface of the ground. Where the manure is of a very good and enriching quality, the quantity may be from four or five to fix orfew loads on the acre, of fuch as are drawn by three or four horses. But where the manure is of an inferior quality, a much larger proportion may be requisite and proper.

The frequency of dressing grafs-lands, in fo far as it respects the foil, fhould confantly be performed at fuch diftances of time, as that the fertility of the lands may not be suffered to decline, but be preferred in an equal or increafed flate of heart; in which the manner and frequency of cutting, or otherwife confuming the produce, muft be confidered; as, where crops are more frequently taken off, the land muft be prevented from being injured, by the great fofs of fertility that must arise in this way, by the dressings being applied at shorter intervals, or in larger quantities at a time; but the fhirf is by much the bell method, as injury may often be done by too great a dressing being given at once. But, in general, where fuch lands are in a tolerable flate of cultivation, every third year may be fufficient; while on fuch as are of inferior value, it may be a better practice to do it every second year, as by this frequent application of manure, the lands may attain a gradual improvement; whereas, in the contrary cafe, they would be on the decline, and in time become poor and worn out to the great injury of the farmer. It is too common practice, in diftricts where grafs-husuandry is imperfectly understood, to almost wholly neglect the manuring of fward-lands, in order to employ it on thofe which are under the plough; but this is obviously bad management; as it is only by the raifing of full crops of grafs for being converted into hay, and of proper kinds of green food, that a full flock of cattle can be kept, and the largest poftible proportions of manure provided for the land. It may be noted there are a few articles made ufe of as top-dressings to grafs-lands, which cannot, it is faid, be frequently repeated with either safety or advantage, fuch as chalk, marle, chopped woollen rags, and some others. It is flatled, that "the lin of these kinds, especially when of a soft, uncohesive nature, fo as to readily fall down in the flate of solution to the roots of the grafs-plants, is found to produce the moft benefical effects, in rendering the lands more fertile and productive, and improving the quality of the herbage. It cannot, however, be often repeated in its fimple flate with advantage, as it is some time in producing its full effects; but in that of compoifs, it may be applied with succefs at shorter intervals. Marle is likewise a fubftance, especially when it is of the rich, foapy kind,
GRASS.

kind, that may be made use of with much advantage as a top-dressing on grass-lands; but as its operation is slow, it cannot be repeated at short intervals, except when employed in the state of a compost with dung-woollen rags, which, rendered small by being chopped into pieces, may be laid on land in the state of fward; but as they require a considerable length of time to sink down and become mixed with the foil, so as to be well covered by the grass, they cannot be repeated at short intervals. After they have been fully incorporated with the land, their beneficial effects are considerable, as have been fully shown in the trials of different grass-farmers; and there are various other matters that are occasionally applied as top-dressings on grass-lands; such as lime in combination with rich vegetable earth or peat, the ashes derived from the combustion of peaty substances, coal-silks, malt, dust, and foot. Most of these have been made use of with good effects when thinly spread out over the surface of lands in the state of grass. The three last have been found to produce the best effects in being dispersed over the new layers of the artificial grass kinds. All applications of this sort should be applied in February, being spread over the surface as evenly as possible. "If it can be done before a shower of rain, it will be the better, as it is of advantage to have them carried down to the roots of the grasses as soon as possible after they are laid upon the land." But some advise, in the management of purchased manures, that experiments should be formed for a year or two, before the practice is extended, to see which, at a given price, will suit the land best. Without this precaution, a farmer may probably expend large sums of money to little purpose. Nor should it be trusted to the mere appearance of the effect soon after the manuring; for some of them, particularly foot and mud-dust, will stay themselves after the first heavy showers, in a finer green than the rest of the field; but the proof of the effect does not arise from fine greens, but from weight of hay; for it has been found from experience, that the latter is not always an attendant on the former. Contiguous half-acres, or roods, should be marked out, the prices of the manures calculated, and on each piece a separate one spread, all to the amount of 20s. an acre, for instance. At hay-time, the crops should be weighed. It will then be known which manure, at the given prices, suits the foil best. This knowledge will prove true experience, and a very different guide from general ideas.

And here is still another circumstance necessary to be attended to in putting manure upon lands of this kind, which is not to suffer too much to be placed out in any of the heaps, but to have them set out as much as possible in moderate fixed portions, and "at regular distances from heap to heap; as, where the contrary is the case, it not only takes up more time, and causes much more trouble to the labourer in spreading them, but does not admit of the work being performed in so regular or so exact a manner. Besides, when the heaps are set out too large, much injury is done to the grazips-plants on the surface where they flood, if not from spread out, which should always be the case, in the quickest manner."

It is also of much consequence, in the execution of this business, to have convenient carts for the purpose, which, in general, are those of the single-horse kind. Some care is likewise necessary in the scaling or spreading-out all sorts of top-dressings on grass-lands, to see that the work be performed in an exact and even manner, and that all the clods and lumps be well broken down and perfectly reduced by beating with the fork or floovel. If possible, a dry season should be chosen for this sort of business, as, under such circumstances, it can be executed in the most regular and exact manner; as when the weather is wet, it is an operation that can never be well performed, as the materials clog up the feet and implements of the workman, and can never be effectually separated or divided so as to be spread out with the necessary degree of evenness."

It has been already noticed, that after the heaps have been set out, they should not be suffered to remain so long, as is often the case, before they are spread out, as the plants underneath them become blanched and tender, and great injury is done to the sward in such cafes, all of which may be easily avoided by spreading as soon as possible after the manure is taken out. Inconveniences of this kind may likewise be avoided by spreading the manure from the carts, as is the practice in the midland and some other districts; but in this method it is suspected the work can neither be executed in so exact a manner, or with so much economy of time or labour. In this way hill-reads will not be formed, and, of course, the disadvantage of their getting too large a proportion of the manure prevented; as Mr. Marshall has well observed in his Economy of the Midland Counties of the Kingdom.

The usual practice, as soon as "the whole has been spread out, and remained in that state for a fortnight or three weeks, or longer, according to circumstances, and is become in some degree dry and powdery, to apply a bulr-harrow over the surface once or twice in a place, in order to reduce the manure into a finer state, and bring it more fully to the roots of the grasses. But this sort of work, as that of spreading, should never be attempted when the season is wet, and the manure in a sandy, adherent state. As soon as this work has been executed, all the rubbish of every kind should be carefully picked off, in order that the ground may receive the action of the roller," which should be passed over it as frequently as may be thought necessary, when the land is in a suitable condition for receiving it. (See Rolling.) This is the principal business which is requisite in the management of grass-lands in general.

In Hertfordshire, "a mode of managing found meadows and pastures has lately been tried, and attended with great increase of produce. The grass is mown as soon as it is in blossom, and, consequently previous to the formation of seed. The after-grass is not grazed until it begins to contract a yellow appearance, in the latter end of October or the beginning of November. In this case the ground remains covered during the winter with a portion of dead herbage, through which the young grass springs with the greatest vigour. Mr. Knight contends, that the sap in all plants ascends through the abundant vessels of the root, and is diffused over the leaf, whence it is returned to form new roots and buds, and to prepare them for vegetation. According to this theory, if the leaves be eaten off on moving ground, as soon as they are reproduced, the roots are deprived of their nutriment, and the plants in consequence vegetate weakly in the succeeding spring. Whether this hypothesis be well or ill founded, it is certain that the ground which is left with this portion of the leaves of grass in the one season, is much more productive, and more early in the next; and close grazing will ever be found to decrease the quantity, although it should improve the quality, of the following crops." It is evident that there is some truth in this, from its having been found that the crops are more early and abundant in different cafes, where the after-grass is not fed down much in the autumnal season with live stock. See MOWING AND GRAZING.

Cooperative Quantity of Food from Grass and Tillage Land.

With respect to the difference in the proportion of human food raised from grass and tillage land, the first circumstance necessary to be attended to, according to a late writer, is that commonly...
GRASS.

However, in the cheese counties, the products vary a good deal: in Cheshire 4 cwt. per cow; in Shropshire 2½ cwt.; in Gloucestershire about 2½ cwt.; in Wilts 4 cwt.; in Somersetshire 3¼ cwt. The average of all these is 3½ cwt. and at three acres per cow, 1 cwt. and a small fraction per acre; and as these counties are richer than those applied to the produce of butter, meal may be constituted 1½ lbs. and pork 20 lbs.; in all £4.7s. per acre, or thereabouts. But as to meat, authorities are not very ample: in the midland counties there is a very general notion, that an acre of grass, at 42s. rent, will give 200 lbs. of mutton. By an experiment made on land of an inferior quality, which is mentioned in the Annals of Agriculture, land of 16s. rent, gave 80 lbs.; and he has heard, on good authority, that in Cambridgeshire some observations, carefully made, confirmed this proportion of produce in land fed both with bullocks and sheep; and the produce of beef, &c., in the Lincolnshire marshes, goes even further than this ratio or proportion to the acre.

With respect to the butter dairies, they are on land of about 16s. an acre rent; and if the produce be 97 lbs., the proportion will be 68 lbs. to every shilling rent. The cheese dairies, at 25½ rent, yielding 145 lbs. are also at about 68 lbs. per shilling rent. The meat is 58 lbs. per shilling. It is easy then to decide, that dairy counties are more advantageous than grazing ones in weight of produce; but their superiority is far greater in another point of view; their produce comes much more into the consumption of the poor; for, where one poor person eats meat, there are probably forty that consume butter and cheese. How to compare these products with those of arable land is very difficult; and yet the inquiry is too interesting entirely to be omitted: a long train of investigation might enable one to difentangle difficulties, but it would require much time to go deeply into such a variety of subjects. The produce of a good loamy soil, under the course, 1. Turnips. 2. Barley. 3. Clover. 4. Wheat, may, it is supposed, be calculated in this manner.

No. 1. Arable dry Land at 16s. an Acre Rent, Five Acres each Crop; twenty Acres in all, in a Course of four Years' Husbandry.

<table>
<thead>
<tr>
<th>Crop</th>
<th>Time</th>
<th>Persons</th>
<th>Weeks</th>
<th>Per acre</th>
<th>Per week</th>
</tr>
</thead>
</table>
| Turnips | 1 & 5 | 2 | 1 | 8 months | 4 lbs. | 100 lbs. | 200 lbs.
| Barley and oats | 6 months | 2 | 6 | 4 months | 1 lb. | 60 lbs. | 120 lbs.
| Clover | 7 months | 2 | 7 | 6 months | 1 lb. | 75 lbs. | 150 lbs.

In practice, the produce at these rates would vary according to the quality of the land and the management of the farm.

In the above accounts, the produce of each acre is calculated to maintain a family of five persons.
GRASS.

The same land, if in grazfs, would give 80lbs. of mutton per acre, 400lbs. per annum, and for four years 1600lbs. sufficient at 3lb. a day to support eight persons one year and thirty-six days.

Hence, "to make the deduction, before alluded to, of the farmer's family, and his labourers; supposed he farms an hundred acres, which is, probably, above the average size of farms of the kingdom, here are five persons to that extent, or one to twenty acres. If we reckon all forts of labour at 21lbs. an acre, we shall, he supposed, not be far from the fact: the pay of a labourer may be reckoned on an average at 2s. which we shall call the food of five persons; setting the earnings of the wife and children against rent, clothes, and other articles; this makes food 5s. a head; for every 5s. therefore that the farmer pays in labour, we may safely, he supposed, reckon that one person is fed from the produce of his farm before it reaches the market: the labour in the twenty acres in the above inferred climate being 21lbs. he calls four persons', and the farmer's family, making five, to be deducted from the acreable amount of the farm."
GRASS.

But if the barley and oats be brought into the account 
26 human food, the account will then stand in this way.

Deduct for farmer and labour | 6 | 1 | 2 |

Remain | 26 | 1 | 2 |

It is consequently stated, that in one case, the grass has the advantage as fifteen to six; in the other, the arable as twenty-six to fifteen.

**No. 111. Poor Soil or Heath — Rent 5s.; five Acres each Crop; thirty Acres in all.**

1. Turnips; four sheep an acre, to the increase of 6s. each, or 24s.; in mutton 48lbs.; and for five acres 240lbs.; sufficient, at 4l. per diem, for one person one year sixteen weeks and four days.

2. Barley and oats; one horse to thirty acres, which demands 2 1/2 acres of oats, at three quarters (feed deducted); the remainder therefore 2 1/2 acres for barley, at 25 quarters per acre, being sixteen bushels (feed deducted), and for 2 1/2 acres forty bushels remain for malt; but enough in bread, at nine bushels a head for 3 1/2 persons a year, minus one bushel.

4. Ditto.

5. Ditto.

The whole, without any horse account, would feed, 1 1/2 years, three sheep per acre, 26 weeks.

2. Two ditto ditto to the improvement (or the value in keeping) of 40s., and for five acres in each to 10s.; hence it appears that to keep one horse would almost equal the whole amount.

6. Rye: 1 1/4 quarter; twelve bushels; feed deducted, ten; sufficient to support one person fifteen months; and for five acres six persons one year and eight weeks.

Within a small fraction equal to

The same land in wheat would feed, but not fitton, to the value of 10s. per acre; call this 20lbs. of mutton; 120lbs. for five acres, and 60lbs. in six years; sufficient, at 4lb. per person, for three persons a year and thirty-six days.

Brought forward, arable account — 8 1 0

Deduct, as farms on this soil are large, only half a person for thirty acres for the farmer; and reckoning labour at 8s. an acre, it is 12l. for thirty acres, or 21 persons; in all three — 3 1 0

Remain for market — 5 1 0

Grass for ditto — 3 1 5

Consequently the arable is therefore superior as nearly three to one. Upon the whole of these comparisons it is sufficiently clear, that the arable land is, and in every case may be, (by eating barley and oats,) far superior to grassland in the article of feeding not only the people at large, but also in feeding a surplus to market. He cannot, however, let his papers go from his hands without requiring them to be read with candour. He prefers to offer them as rough sketches, that may approximate to truth, but cannot reach exactness; they may afford hints useful to future inquirers, and the subject is interesting enough to answer well a very careful examination. One observation that goes generally to all is too material to be omitted; the production of meat in England is, it is supposed, of small importance compared with that of corn, because the poor do not live on the farmer; meat is the consumption, generally speaking, of those who are in very easy circumstances, compared with the great consumers of corn; nor would the times be much complained of, whatever the price of meat might be, provided corn were at a reasonable price. This is a circumstance which should be considered as decisive of the inquiry; and sufficient to prove, that the great interests of the public demand every possible encouragement to tillage so given, as shall prefer corn at a fair price, neither too high for the poor, nor too low as to discourage the cultivation of it by the farmer.

With regard to what ought to be the proportion between the grass and arable land of a farm, errors are, it is observed, extremely common among landlords, and not left to with farmers; in general, however, they both look to their own interest; the land to keep much in grass, and the latter to plough all they can: with short hanks, and bad covenants, we are not to be surprised at either. One acre of moderate corn, says Adam Smith, in his Wealth of Nations, yields a greater net profit than an acre of the best pasture. And experience, Mr. Davis of Longleat observes, sufficiently evinces the extreme difficulty of persuading tenants to believe that they get more, generally speaking, by feeding their lands than by ploughing them; yet it requires
very few arguments to convince a landlord, that is cold wet lands especially, the less ploughed land you have, the less you put it in a tenant’s power to ruin your estate. That a tenant of 60s instead of 40s, per annum in a dairy-farm will get money, while a corn-farm will marve its occupier (though, perhaps, the former gives 15s an acre for his land, and the other but 10s), is felt-evident. Perhaps, says Mr. Billingley, in the third volume of the Bath Memoirs, there cannot be a stronger proof of the inferiority of the plough, with respect to profit, than the superior punctuality of the dairy-farmer in the payment of his rent. He never met with the reward of a manor devoted partly to corn and partly to dairy-farms, who controverted this statement.

Grass.—Upon this soil, with tenancies and not easily drained, a larger portion should, it is observed, be kept in grass than perhaps on any other; and for this reason,—green winter food is not to be gained at all, or, if gained, not without great difficulty and expense; consequently, the team, and whatever cattle may be kept for continuing draw and making dung, must depend in a larger measure on meadow hay, than upon fields which admit turnips, cabbage, &c. Clover will do on clay, but it is more hazardous and liable to failure; in which case, without a certain recourse in the hay of natural grass, the farmer would often find great inconveniences. He has examined many farms with this object in view, and found that, when half the land has been grass, they have been more profitably conducted than with a less proportion; but on no account with less than one-third.

Lamb.—It is stated that “one-third or one-fourth in grass is a proportion found suitable to various loams; the more they tend to wetness, the larger the portion. It is not, however, essential on these soils, not only because clover and other artificial grasses are less apt to fail; but likewise by reason of their admitting profitably the alternate husbandry of grass and arable.”

Sand.—It is contended “that some rich lands are of so happy a texture, that they do very well in permanent grass, and without burning in flight droughts; but, in general, it may be observed, that land in its several varieties is, of all other soils, that which pays best in tillage; it is easily worked; expences are light; it manures itself by agreeing well with sheep; and, as the result of the whole, farmers are usually rich upon it. In respect of the proportion, it is best managed, perhaps, when the whole is under the plough; for, by means of cultivated grasses of proper sorts, all the rock of the farm may be profitably supported, and the land reaped sufficiently, for ensuring a perpetual production of corn. But, contrary to this maxim, and most unprofitably, large tracts are commonly tied up from the plough, by covenants of leaves, under the name of sheep-walk, henth, &c., which would, by alternate tillage and red, produce more corn, and keep more sheep; than in the present state; this is particularly the case in Norfolk, Suffolk, Nottinghamshire, and some other counties.”

Chalk and Limestone Soils.—“Nearly the same observation is to be made on this clays; they are more productive under the plough than in grass. But landlords tie up their tenants from ploughing down in Sussex, Hampshire, Dorsetshire, and Wiltshire; but in Gloucestershire, the East Riding of Yorkshire, and Lincolnshire, they have, on the whole, been less tenacious; still, however, large tracts remain, which would be ploughed were tillage permitted. Rules may be carried too far, and this among the rest. Dorsetshire has its own leaves, which, in many cases, ought not to be touched; and fine fowet downs, which by very attentive management have been brought to a considerable degree of fertility, are so useful to sheep in winter, that exceptions must occur. Another motive for ploughing is the peculiar advantage derived on this soil from its formation, one of the most useful grasses that we owe to the bounty of Providence, but attainable only by tillage.”

Peat.—Imenous regions of moors spread widely through all the northern counties, and even in the most southern, as Devonshire and Somersetshire, Cambridgeshire and Wales; also fedgy bottoms are found every where. They admit and call for a much greater improvement than any other soil, comprehending the larger part of the waste lands of the kingdom. These soils are very rarely brought into the flate they are capable of, without tillage, and consequently, to prohibit it, is to pass a decree of perpetual fertility. The obstacle, however, most common on moors is, the rights of commonage, which do not come within the scope of the present inquiries. When improved, they are commonly much more adapted to grazes than to tillage, not however without numerous exceptions, as we fee by the general practice in the farms of Cambridgeshire and Lincolnshire. The alternate husbandry does well upon them; it is safe, however, to be too busy with the plough; for, when good grass is gained, it is the wiser way to continue it in a productive state. But it is further stated, that the subject of the proportion between grasses and arable requires a word or two, viewed in another light, besides the relation to soil. This is the prevalent application of the land. In the midland counties, where grazing very widely extends, it is common to fee entire farms of grass—land, and the tenant prohibited from breaking up an acre; in such cases there is a motive for ploughing not immediately connected with soil. To till a part would be right, whatever the soil may be; it varies in such a country not to be hasty, and the convenience and profit of having some is no inconvenient object; it would be carefully used as litter, and the manure arising would improve a portion of the land. Some cabbages, or Swedish turnip, or common turnip, might be raised (which to a certain extent, and for certain objects on such farms, would be highly valuable to the grazier), to so as to outweigh large expenses in procuring them on soils not quite adapted to their culture. There is not a question but a farmer in such cases could afford to pay more rent for liberty to plough a portion of his land than under the present covenants. This would, it is supposed, extend to a fourth of the farms in soil rather unfavourable to the plough; and to a large proportion in others. But even three or four small fields, though no more than one-fifth, one-sixth, or one-tenth, would be highly advantageous to himself and the public, and not at all injurious to the landlord or owner. And to dairy-farms, when entirely in grass, as many are in Wiltshire, Gloucestershire, and other counties, this remark is yet more applicable, as the produce of tillage, byre, or maize, &c. is yet more necessary than in a more fattening system. In this case, and indeed in most others, the quantity might be partly regulated by the tenant; a dairy-farmer, who keeps four horses to draw his butter or cheese to fairs, &c. ought, without question, to have tillage enough to employ those horses; and it is no difficult matter to ascertain that quantity. If the various works be examined carefully, it will be found, that a horse to twenty acres of tillage is a fair proportion, which will leave time for carting hay in summer, and the products of the farm in winter. He is not speaking here of tillage farms on sands, &c. or with rotations of crops, in which the soil reds for several years, on such the proportion varies; but merely on grass farms, where some horses must be kept, and are at present
unemployed a large part of the year. But meadow farms, properly so called, are never, to his knowledge, met with but in the vicinity of great cities, where the demand for hay is great and uniform; horses on such are kept only for the purpose of carrying hay to market, bringing dung back, carting the hay to the stack, and the manure to the fields. Straw is wanting for litter and for thatch; but it is questionable whether it is profitable to plough for this object only in any case; a scattering of tillage is in some places found, but not by any certain rule; the necessity is small, and straw usually to be purchased. Such different, being highly improved, demand very little attention, it is supposed. See This. See Rotation of Crops, and Pasture.

Grass-Leafs, in Agriculture, a term frequently applied to such ward lands as are appropriated to the purposes of grazing, or the fattening of neat cattle and sheep.

Grass-Seeds, a term often used to signify the several different feeds of grasses that are employed in laying down land to the flate of turf. It was, however, formerly, mostly made use of to denote the mixture of all sorts of rubbish that was scraped up from the hay lofts, or collected in the cribs or boxes below the racks in the stables. But in the improved method of forming new grass lands, the practice of using such mixtures of feeds is almost wholly laid aside, and only such as are really useful and proper, had recourse to, by which the lands are found to be much more valuable and productive. See Laying Lands down to Grass.

Grass-Field, in Rural Economy, a name applied to such fods or turfs as are parred off from the surface of old stward lands, whether they be intended for the purpose of burning on the land, for fuel, or for being laid down in order to form a lawn, or even spot of fine even turf. In the former intentions they are generally pared off by ploughing, or spades, contrived for the purpose; but in the litter almos constant with great regularity and exactness, by a turf spade for the purpose. A tool of the plough kind feems, however, capable of being employed in this way also with advantage. See the next article.

Grass-Cutting Plough, the name of a tool of the plough kind, which was invented on the continent by count Van Mattzen, and which has been highly useful in cutting grass-fods in a cheap and expeditious manner. It can also be hired recourse to with great advantage in paring the twards off old grass lands, walls, and commons, previously to their being burnt and brought into the flate of tillage-hubandtry. It is likewise capable of being converted to the purpose of forming walks in grounds where they may be wanted, as well as in paring the bottoms and sides of them, and of such as have been already made, by which means the gardener will only have the simple busineses of raking and rolling them to perform.

By some slight alterations in the manner of placing the coulters, grass-fods are likewise capable of being cut in a very ready manner, and in any form that may be required, so as to be employed in the construction of banks, fortifications, dunes, and other works of a similar kind. It would seem, consequently, to be a very useful tool in the expensive busineses of constructing embankments against the sea, or other large waters.

The inventor was led to the construction of this plough, in conquence of the want of a more cheap and expeditious method of performing the work than the usual one of the spade, in cutting turf for forming grass-plats, &c.

It may be observed that in forming the tool, the beam, or fore part of any common plough will answer the purpose; this part is consequently not reprepresented in the figure, the hind or operative parts being simply flown. The tool is capable of being managed by any person who is able to direct a common plough.

This plough may be seen at fig. 7, in the Plate on Grassing, in which the nine holes shown by A, A, in the beam, serve, as in the common plough, to regulate the length of the beam merely by placing the pin C forwards or backwards, and thereby to make the cutting-iron to work to greater or less depth. The two coulters, E, E, which are placed on each side of it, in front of the cutting-iron D, serve to guide the sde cut, preparatory to the separation of the turf or clods. The cutting-iron D may, by means of the screws G, G, be raised or lowered at discretion. And, in order to keep it in its place properly, the two supports H, are made, and provided with several holes for the purpose at I, formed in the cutting-iron D. The two handles are displayed at 

A certain degree of practical experience is necessary, in order to use this plough, for to form the turfs with exactness; and in the commencement of the work care should be particularly taken that the workman does not cut the turfs too deep, and that the plough be not injured by his inattention. In a very short time, he will, however, become accustomed to the business as to perform with great exactness. In setting out the work, a breadth equal to the width of the two cutters should be previously cut out, as by that means the cutting-iron takes the sde at proper depth, and executes the work, as soon as the draught commences, in the manner of the performance of the work, and are recommended as preferable to horfes, from their drawing more steadily, and being more readily managed on stiff lands; but we apprehend that this will not, in general, be found to hold good, and horse-teams are far more expeditions. See Team.

Grass, in Mining, signifies the natural surface of the earth over a mine; sometimes also it is called the "day," or the top; and a mineral vein appearing on the surface, is said to come, or appear to grass, or to the day. Coals and other stratiified minerals, when they come to the surface, are said to beafet, crop, hurl-out, go-out, want-cover, to run-out, to out-hurl, to head-out, to run-out, &c.

Grass River, in Geography, a river of America, in the N.W. part of the state of New York, which rises near the main branch of Black river, and runs N.N.W. about 50 miles, then N.E. 40 miles, and is lost in the river St. Lawrence. N. lat. 45° 12'; W. long. 74° 49'. It is a rapid river, affords many small-rafts, and near the mouth, its banks produce great quantities of hay.

Grasse, a town of France, and principal place of a diociph, in the department of the Var. The place contains 12,571, and the canton 13,554 inhabitants, on a territory of 100 kilometres, in four communes. The principal trade of the town consists in dry fruit, olives, oil, perfumes, and tanned leather —9 miles W.N.W. of Antibes. N. lat. 43° 39'. E. long. 6° 59'.

Grasse, Lyr; a town of France, in the department of the Aude, and chief place of a canton, in the district of Carcassonne; 20 miles S.W. of Narbonne. The place contains 1123, and the canton 4544 inhabitants, on a territory of 2023 kilometres, in 18 communes. N. lat. 43° 5'. E. long. 2° 42'.

Grasses, Petrified. Mr. Whitehall, in his "Inquiry concerning the Earth," vol. ii. p. 169, mentions grasses among the vegetable remains in the coal-measures of Derbyshire: but the late Mr. William Martin, who was perhaps better acquainted with these strata, says, "Outline," p. 85, that
that the graminis of these orchilaceous flarae are of unknown species in the recent flate, and appear rather allied to the canes and reeds of the Indies, than to grases properly so called. Mr. Farey also, in his laborious researches among these carboniferous flarae, has seen nothing refembling grases imbedded in them. See REEDS.

In peat districts, which are of modern or recent accumulation, and within the range of flooded rivers, it is not uncommon to meet with preferred grases, probably belonging to many of the recent species, at considerable depths below the surface of, or even at the bottom of the peat, or muddy deposits; but such peat foilles should on all occasions be distinguished carefully from stratified, or real foilles remains, as remarked in our article Coal.

**GRASSHOPPER, in Entomology, a species of Gryllus;** which fee.

**GRASSHOPPER, in Ornithology, a name given to the Alula tricolor;** which fee.

GRASSI, Cecilia, in Biography, afterwards Mrs. Bach, who performed the first woman's part for several succeeding years at the opera with Guisardi and Guadagni, was inanimate on the stage, and far from beautiful in her person; but there was a truth of intonation, with a plaintive sweetness of voice, and innocence of expression, that gave great pleasure to all hearers who did not expect or want to be surprised. Her performance of the part of Euridice, in Gluck's "Orfeo," with Guadagni, was perfect in all respects, and gave universal satisfaction.

GRASSWINKEL, Theodore, a learned lawyer and writer, who flourished in the 17th century, was a native of Delft. He wrote various works upon legal and political subjects, by which he acquired a considerable reputation, and was regarded by the government as a proper person to fill some office in the State; he was accordingly made a member of the Chamber of Holland, and secretary of the bapitist chamber upon the part of the State. He died in 1666, at Mechlin, and was buried in the great church at the Hague. His works were numerous; of these the following may be noticed, "Libertas Veneta, seu Venetorum in se et suis imperandis Juris." This was published in 1634, and in 1641, he defended the republic of Venice, in a dispute with the Duke of Savoy concerning precedence. For these services, that republic created him a knight of St. Mark. Previously to the publication of the last of the two above-mentioned works, he attempted to confute the popular maxims of Buchan, in a treatise, entitled "De Jure Majestatis." This was dedicated to Christina, Queen of Sweden, who was known to be a great affector of regal privileges. Grasswinkel defended the liberty of the seas against a native of Genoa, in his work "Maris Liberi Vindiciæ." He was author, likewise, of a treatise in two volumes 4to. "On the Sovereignty of the States of Holland." He was at all times a defender of particular states; but a violent oppressor of the rights of the people. Morel. Barke.

**GRATAROLUS, William, was born at Bergamo, in Italy, in the year 1510.** He was educated at Padua, where he took the degree of doctor of physic, and afterwards became professor of the same science, and gained considerable distinction. But having embraced the Calvinist doctrines, on the persuasion of Peter Vermilli, he fled from Italy, through fear of the inquisition, and retired to Marburg, where he taught medicine for a year. But he was compelled to leave that place also, and repaired to Bâle, in the hope of a better fortune, and where, in fact, he taught and practised his profession with success, until May 1562, when he died, at the age of 52. He was author of a great number of works, some of which are honourable to his talents, and evince a large share of knowledge; but in others he shews an attachment to the absurdities of the alchemists, much superflition, and opinions which do not imply a sound judgment. Eloy. Dict. Hist.

**GRATCHE, in Geography, a town of Ruffia, in the country of the Cossacks; 20 miles N.W. of Tzaritsen.**

**GRATIAN, in Biography, a Roman emperor, son of Valentinian I.** He was born at Sirmium, in 359. He was appointed by his father to a share in the empire when he was but eight years old. He was in his seventeenth year when Valentinian died. At this time Gratian was keeping his court at Treves, and was ignorant of what had happened till he was informed that the officers of the army had appointed as his partner in the throne Valentinian II. the younger son of the late emperor, by his second wife Juliana. Gratian, though hurt at the assumption of authority on the part of the army, readily ratified the election, and even treated his brother with affection and tenderness. The Western empire was nominally divided between them, but the superior age of Gratian gave him all the power. One of his first acts was to recall his mother to court, who had been divorced and banished; and this act of justice was followed by the punishment of certain officers in the state, who had abused their power, by cruelty and injustice. While the emperor was praised for these deeds, he has not escaped blame, and a high degree of censure, for putting to death the renowned general Theodosius, who fell a victim to the jealousy of some rival courtiers. History has also censured him for the indulgence which he afforded to the clergy, and for his severity against those who were denominated heretics, for the gratification of the orthodox. At the head of the Eastern empire was his uncle Valens, who was in 378 attacked by the Goths. Gratian, active and courageous, put himself at the head of an army, and marched to his assistance. He obtained a decisive victory in Alcane, and, pursuing his successes, crossed the Rhine, and penetrated into the heart of the enemy's country, in order to join the forces of Valens. Before, however, he could reach him, that emperor had been defeated and slain at the battle of Adrianople. Gratian now felt that he must take the most vigorous measures against their common enemy, and immediately called from his retreat Theodosius, son of the general who had suffered under his hasty displeasure, and placed him at the head of a separate army, with which he was enabled to destroy a large body of Sarmanians, who were on their march to join the Goths. Gratian himself proceeded to Constantinople, where he recalled those orthodox bishops who had been banished by Valens, and he also inflicted some edicts relative to the exercise of religion. As Valens had left no male heir, his nephew, disregarding the suggestions of personal ambition, filled the vacant throne to the satisfaction of all, by raising Theodosius to a station, for which his talents were peculiarly adapted. This was in the year 379, after which Gratian returned to Italy, and in his journey he had an opportunity of being benefited by the instructions of the celebrated Ambrose, at Milan, which proved beneficial to the orthodox, but occasioned new restrictions upon those who were regarded as sectaries. After this he continued for some length of time to attend to the defence and concerns of the empire, and is highly applauded for almost all the amiable qualities which have decorated the life of sovereigns. Still it was feared that his good principles were rather the effect of able and virtuous advisers, than the spontaneous result of fixed habits. What the best friends to their country feared, proved to be the real fact: he suddenly fell into inces of unmanly pleasures, spent much of his time in indolence or
frivolous amusements, which proved not only injurious to his subjects, but, in the end, ruinous to himself. Hunting became his favourite pastime: to enjoy the pursuits of the chase, he neglected the duties incumbent upon him, as the sovereign of a great people, and those only became his favourites who were skilful in hunting. He offended the more sober part of his subjects, by appearing in the garb of a Scythian warrior, armed with a bow and quivers, and drenched in the very point of emulating themselves into a furious shape, when a revolt took place among the legions of Britain, who, without hesitation, invested Maximus with the imperial diadem. Gratian attempted an opposition; but his own efforts were feeble, and these even counteracted by the treachery of some of his officers. He had no sooner unfurled his banners, and put himself in a warlike posture, than he was defeated by his handful troops. He had now no hope, and immediately fled with about 300 faithful troops towards the Alps. All the cities on his road manifested evident signs of disloyalty; they even refused him a shelter or admission into their towns, till he arrived at Lyons. Here, indeed, the gates were opened for his reception, but the hearts of the people were estranged to his cause, and upon the arrival of the cavalry of Maximus, the governor of the city betrayed the deposed emperor into the hands of the commander, who caused him to be put to death, as he rose from his supper. This was in the year 383, after Gratian had been on the throne nearly eight years. Gibbon. Univer. Hist.

Gratian, a Benedictine monk, who flourished in the twelfth century, was a native of Chiusi, in Tuscany, and embraced the monastic life at Bologna. Before his time, there had been many collections of canons and laws of the church, but they were so defective in matter and form, that they could not be conveniently explained, or even made use of as fylkemes of ecclesiastical policy. Gratian undertook the task of compiling such a system, and after more than twenty years' labour he produced, in 1151, an abridgment of canon law, drawn from the letters of the pontiffs, the decrees of the councils, and the writings of the ancient doctors, which he entitled "Concordantia Discordantium Canonum," or as it has been translated, "The Coalition of jarring Canons." In a new edition of this work, it was called "Decretum Gratiani," or "Gratian's Decretal." By this name it is generally known. Upon the first appearance of the work, it received the laud of approbation from pope Eugenius III., who declared himself so satisfied with its execution, that he commanded it to be publicly read in the schools. The professors of Bologna were the first who unanimously adopted it as a text-book in their public lectures, and their example was soon followed by the professors of Paris, and, in short, by those of almost all the European colleges. It is, however, said to be full of errors, and in other respects extremely defective, but as it was calculated to support depotism, and to extend the authority of the Roman pontiffs, it was for four centuries appealed to as the standard of ecclesiastical law, and even in ages preceding that dark period, it has occasionally been quoted with a degree of veneration and authority, to which it has no just title. It was used in MS. till 1570, when it was printed at Mentz; this edition was followed by imitations at Venice in 1576, and Paris in 1580. Another edition was printed at Rome under the auspices of pope Gregory XIII. in four vols. fol., on which a large portion of labour was bestowed in correcting its numerous imperfections. Anthony Auguflin, archbishop of Tarragona, in Spain, published a valuable treatise, "De Emendatione Gratiani," of which the best edition is that published at Paris in 1673.

Morn. Gen.

Gratification, a term some writers use for the dividing a draught or design into squares, in order to the reducing it thereby.

Gratins, in a Ship, are small ledges of sawed plank, framed one into another like a lattice or prison grate, lying on the upper deck, between the main-mast and fore-mast, serving for a defence in a close fight, and also for the coolness, light, and convenience of the ship's company.

Gratiola, in Botany, the diminutive of gratia, a grace or favour, the herb to which it is applied having been called, by the earlier botanical or medical writers among the moderns, Gratia Dei, the favour of God, because of its eminent virtues, which however are of a violent and cathartic nature. It is one of the plants which have been conjectured to yield the tincture called Aqua Medicinalis, so famous at present as a cure for fits of the gout; but this opinion, it seems, is contradicted by the proprietor of the secret. —Linn. Gen. 17. Schelch. 17. Willd. Sp. Pl. v. 132. Willd. Enum. v. 1. 88. Mart. Mill Dict. v. 2. Ait. Hort. Kew. ed. 2. v. 1. 42. Brown. Nov. Holl. v. 1. 457. Jaff. 121. Lamarck. Illust. t. 16. Gaertn. t. 53.—Cliffs and order, Diandria Monogynia. Nat. Ord. Perisoneae, Linn. Scrophulariae, Jaff.

Gen. Ch. 1. Col. Porianth inferior, in five deep, awl-shaped or ovate, upright, permanent segments. Cor. of one petal, tubular, unequal; tube longer than the calyx, angular; limb small, in five deep segments, of which the uppermost is broadest, emarginate and reflexed, the rest straight and equal. Stam. Filaments four or five, awl-shaped, shorter than the corolla, the two or three lowermost short and barren, the two uppermost attached to the tube of the corolla; anthers roundish. Pet. German superior, conical; style straight, awl-shaped; stigma with two lips, closed after impregnation. Peric. Capsule ovate, pointed, of two cells and four valves, the partition from the infixed margins at two opposite sides. Seeds numerous, small, flat. Ch. Corolla irregular, reverved. Two lamens bare."—Capsula superfloria, of two cells and four valves. Calyx in five deep segments. Stigma with two lips. Linnicinus's gratiola, in the first edition of Sp. Pl. 18, chiefly depended on the original and primary species, the officinalis, for of the three others there defined, dubia is Caperonia graticoloides of the second edition, and Lindernia pevidoria of his Mantilla 251: virginius, though in his poliation, was made a Gratiola chiefly on Gronovius's authority, and peruviana, though a genuine Gratiola, had then probably never been seen by Linnicinus at all, but was adopted from Peltier. In the second edition G. Monticellia takes place of the dubia, and a wrong East Indian synonym is annexed to virginius, but no further species are added. In the second Mantilla two new ones are described, rotundifolia and hypopappidae, both from the East Indies, so that six species in all are enumerated in Sp. V. V. ed. 14. To these Willdow has added eight more, chiefly East Indian, prudently declining to adopt three unclean ones from Walter's Flora Carolina. Willd has far outshone his predecessors, giving 31 species in all. Unfortunately a great share of these were derived from dried specimes, their genus determined chiefly by habit, and their flowers or fruit not sufficiently investigated. Indeed several of them evidently differ from the original genus in various respects. Mr. R. Brown, a more critical investigator, has greatly reduced the genus in question, though he has described three...
GRA

entirely new species from New Holland. We shall confine
ourselves to an account of such as are certain, with
compunctions remarks on a few of the rest.

106.)—Leaves ovate-lanceolate, serrated, five-ribbed,
smooth, somewhat longer than the flower-stalks.—Native
of moist places in D. mark, Germany, Switzerland, France,
and Greece, flowering in June. The roots are perennial,
rather creeping. Whole herb smooth. Stem annual, wi-
cending or erect, twelve or eighteen inches high, leafy,
round, pale and very fleck, generally single. Leaves nu-
orous, opposite, fiddle, dotted, above an inch long, ovato-
lanceolate, bluish, with many fiddle tooth-like leaves
in the upper part, and five, rarely seven, parallel ribs, of
which the middle one is the most considerable. Segments
none. Flowers pale blue, with an orange tube, hundred-
lessly an inch long, on simple, solitary, axillary stalks,
which are generally about half the length of the leaves,
ofen more, and bear a pair of bracteoles close to the flower,
by some taken for additional parts of the calyx; these are
spreading and a little toothed.—This species, a stranger
to Britain, is the original one, celebrated for its purgative
virtues, whence the French call it Poorman's herb, on
account of its cheapness and efficacy. Indeed its use
requires great caution, and a plentiful administration of warm
water, butter, or oil, at the same time. A serpule of the
dried herb is mentioned as a sufficient dose, but its uncer-
ainty, and its energetic properties, have justly brought this
medicine into disfavour; there being so many more unexpe-
tionable drugs for the same purpose. Its flavour is nau-
feous and intensely bitter.

(G. peruvian; Wall. Carol. 62.)—Leaves ovate, crenate,
airy as well as the stem. Flowers axillary, nearly fiddle.—
Native of moist places in South Carolina, flowering in May.
Stem simple or branched, near a foot high, square, leafy,
very hairy. Leaves ovate, not an inch long, somewhat
heart-shaped and clasping the stem with their bases, bluntish,
with two or three different teeth on each side, fringed, dotted,
and hairy. Flowers nearly fiddle, white, with a pair of
spreading bracts, which are fringed like the calyx.

albo; Peull. Peruv. v. 3. 28. t. 16.)—Leaves ovate oblong,
toothed, downy, obscurely five-ribbed. Flowers axillary,
fiddle.—Native of Peru, Mexico, and the Brazils. The
whole herb is more or less downy. Stem a foot high, un-
iform, softly hairy. Leaves oblong, somewhat ovate,
various in breadth, bluntish, obscurely five-ribbed, the
margin furnished with double teeth. Flowers white, nearly
or quite fiddle, shorter than the leaves, with a pair of brac-
toes very long, and about it equal to the calyx, strongly con-
temning the idea of their being properly calyx-leaves.

4. G. bifolia. Brown n. 1.—Smooth. Leaves ovate,
dotted, obscurely crenate or entire. Flowers fiddle.—
Native of the neighbourhood of Port Jackson, New South
Wales, and of Van Diemen's land.

5. G. palearum. Brown n. 2.—Clothed with glandular
hairs. Leaves lanceolate, toothed. Flowers nearly fiddle.—
Native of Port Jackson, the south coast of New Holland,
and Van Diemen's land.

6. G. denticulata. Brown n. 3.—Clothed with pow-
dery down. Leaves lanceolate, toothed in their forepart,
scarce longer than the flower-stalk.—Native of Port
Jackson.

Mr. Brown announces the existence of a few unpublislled
Vot. XVI.

species, natives of North America, of which we know
nothing further. He mentions the Linnaean G. hypolepis
and rotundifolia as species of Lindenia with two barren
flowers, undoubtedly a variable circumstance in this tribe,
and constituting no generic distinction. G. Morniera is his
Herpestis, and has the appearance of a good genus.

With respect to some other species.

G. bipinnata. Vahl. n. 4. (Digitalis biansfolia paulus-
burgiana; Tour. Int. 165.)—Leaves linear, entire. Flower-
stalks axillary, the length of the leaves.—Native of Port-
tugal. This forms an unquestionable Gratiola, near the
 officinalis, with which it agrees in qualities, but differs in
leaves, and in the flowers not being more than one-third the
size of that species.

G. obtusifolia of Retzuis, Vahl. n. 10, has neither the
habit, calyx, nor bracteoles of this genus.

G. trifila. Wild. n. 9, seems to agree in all these points
with Mr. Brown's Linnaeophila, the Hortenio indica of Lin-
nex.

G. lutea. Vahl. n. 17. (Gentiana curviflora of Linnaeus),
is referred by Mr. Brown to Toronia, a genus lithuerto
not much understood.

G. GRATIOSA. Officinalis. Hildeburgiana, in the Materia
Medica, is a plant to which various medical virtues have
been ascribed. The first account of its cultivation in Britain,
is that given by Turner in 1568, though it is said that the first
botanist who mentioned it was Matthiolus. It has a strong
bitter nauseous taste, with but little or no odour; and its
virtues are extracted more perfectly by aqueous than by
spirritus menstrua. It resembles Digitalis both in the
shape of its flowers, and in its medicinal effects, and hence
has been called Digitalis minimissima. It is certainly a powerful
and active cathartic, and operates more violently as generally
to induce vomiting; and on this account, Chamel thought
it to be a medicine adapted only to the more vigorous and
rebellious stomachs. Many others, however, recommend
it as a safe and useful purgative. But as its effects are
uncertain, it should be administered with the precaution of a
gradual increase of its dose. This plant has been communi-
cated in hydroelectrical cures; and in moderate doses it is said
not only to set as a hydrophone, but also to produce a diuretic
effect; and influences of its good effects in affiles and
anaerac are related by many respectable practical writers.
Gefner and Burgiss found a clew of the powder to be a
sufficient dose, as in this case it frequently excited nausea or
vomiting; others have given it to half a dram, two fer-
uples, a dram, and even more. The extract is said to be
more efficacious than the plant itself, and exhibited in the
dose of half a dram or a dram in dyseferensis, produces the
best effects. Kollesewits informs us, that in the hospitals
at Vienna, three manial patients were perfectly recovered
by its use; and in the most confirmed cases of inflamma-
tion, it effected a complete cure. It usually acted by
increasing the urinary function, or sialiferous discharges.

G. GRATIOSA. In Geography, one of the smallest Canadi
nrlands, N. lat. 29 15'. W. long. 13 17'.—Also, one of the
Amer. islands, about 10 miles long and eight broad.
It takes its name from its beautiful appearance, and fertility
in corn, fruit, pasture, and cattle, with which it supplies
Tercera, and several of the other islands. It is well peopled,
and has a number of villages; and the coast is defended by
forts. The chief place is La Plata. N. lat. 39 2'. W.
long. 27 56'.

GRATITUDE, in Ethics, a virtue disposing the mind
to an inward benevolent and outward acknowledgments of bene-

40
GRA

fits received. This is a virtue in which the Egyptians pretended to excel all the rest of mankind. See Egypt.

GRATUS, in Biography, a Roman poet, a native of Opia, a town of the place of his birth Fulculus, was of contemporary of Virgil. He has been mentioned by Ovid in a single dilithus. The work by which this author is known, and for which he is chiefly a short notice, is entitled "Cynegeticum," or the Art of Hunting with Dogs. It was entirely unknown to the moderns till it was brought to light by Paul Mantius in 1534. This learned editor printed it from a MS. copy brought by Sampiero from France. It is said to be written with a purity and elegance of the Augustan age. The bell edition was that of Lejoie 1659, 4to. with notes. It has been printed in the collection of "Rei Venaticae Scriptores," 1728, and in Mattaire's "Corpus Posthurnum." Gen. Biol.

GRATTAN, in Agriculture, a term applied provincially in some situations to such arable lands as are managed under a commonable rate. But in other places, as in Cornwall, it is regarded as signifying the moving of grasses the first year, after the ground has been manured with len sand; which is an operation that they denominate moving grattan. The stumps of common fields are also frequently called grattans.

GRATZ, or Gravz, in Geography, a town of the duchy of Stiria, on the river Murz; containing several churches and convents, an arsenal, a castle on a rock, and an inn, founded in 1532. In this town is held the assembly of the dates; and in 1784, it was erected into an archbishopric on the supposition of that of Goritz. It is surrounded by walls. The French took it in 1797; 70 miles S.S.W. of Vienna. N. lat. 47 10'. E. long. 15 16'. Also, a town of Sicilia, called also Headz, in the principality of Troppau, situated on the Mor; four miles S. of Troppau. N. lat. 49 47', E. long. 17 52'.

GRAZEN, in Geography, a town of Bohemia, in the circle of Bechin; 37 miles S.S.E. of Bechin. N. lat. 48 47'. E. long. 14 43'.

GRAVA SEA, a town of Naples, in the Basilicate; 15 miles E. of Venus.

GRAVATTEN, a town of Prussia, on the Curilis Neung; 20 miles S. of Memel.

GRAUDENTZ, a town of Prussia, in the palatinate of Culm, on an island near the Niltena; anciently called Gradec; 14 miles N.E. of Culm. N. lat. 53 28'. E. long. 18 28'.

GRAVE, in Grammar, a species of accent opposite to acute. The grave accent is expressed thus (') and shows that the voice is to be depressed, and the syllable over which it is placed pronounced in a low, deep tone.

GRAVE, in Music, is applied to a sound which is in a low or deep tone. The thicker the chord or string, the more grave the tone or note, and the smaller the accent.

Notes are supposed to be the more grave, in proportion as the vibrations of the chord are less quick. See Grave, in Music.

Grave is also an ingredient in the composition of divers terms in history and policy. Thus we say "land-grave, burg-grave, marg-grave, polity;" &c.

The word, in this sense, is formed of the German grafs, signifying content, count; called in the barbarous Latin gravis and graphio.

Grave is also used for a tomb, wherein a person defunct is interred.

Grave, Ital. (pronounced gravatey) an adverb applied to flow movements in the first degree, more quick than adagio, and more slow than largé. In adagio movements, the time is usually counted by quavers, in grave, by crotchetts. Grave, Ital. and groundment, French, not only imply a slow time, but a certain gravity in the execution.

GRAVE, in Geography, a strong town of Brabant, belonging to Holland, situated in a sandy country, on the S. side of the Meuse, 14 miles S.E. of Utrecht. N. lat. 51 40'. E. long. 5° 41'.

GRAVE Creek, a creek on the Ohio in Virginia, 12 miles from Wheeling. N. lat. 39 46'; W. long. 80 55'. Near this creek is a mound of earth, evidently the work of art, called an Indian grave. Although no tradition remains, that the Indians buried their dead in this manner, these mounds, on examination, have been found to contain a chalky substance, supposed to be bones of the human kind.

GRAVE Harmonic, in Music, is a phenomenon thus described by the late Dr. Robinet: "The reinforcements of found, which are called beats, are noises. If any noise whatever be repeated with sufficient frequency, at equal intervals, it becomes a musical note of a certain determinate pitch. If it recur 60 times in a second, it becomes the note C-flat, or the double octave below the middle C of our harpsichord, or the rate of an open pipe eight feet long. Now there is a similar (we may call it the very same) reinforcement produced in every complete cycle. When the two sounds found of the concord intersect the pulse of the other, the two sounds are more uniformly spread; but where they coincide, or almost coincide, the condensation of one undulation combines with that of the other, and there comes on the ear a stronger condensation, and a louder sound. This may be called a noise; and the equal and frequent recurrence of this noise should produce a musical note. If, for instance, C and E are found together; there is this noise at every third pulse of C, and every fifth pulse of E; that is, 80 times in a second. This should produce a note which is a 15th below C and a 17th below E; that is, the double octave below C, which makes 320 vibrations in a second. That is to say, along with the two notes C and E of the concord, and the compound found which we call the concord of the 17th, we should hear a third note FF in the bass. Now this is known to be a fact, and it is the grave harmonic observed by Rameau and Tartini about the year 1754, and verified by all musicians since that time." Mr. John Gough gives the following account of grave harmonics: "Where the two sounds found in concord are vibrations producing them are arranged in cycles, no one of which continues for a longer or shorter time than the rest; and their effect is perceived by the ear, which becomes fatigued of their presence. For when each cycle of a series, separately considered, exceeds the twelfth part of a second, the sense of hearing recognizes each point of division made by the coincidence of the vibrations which separate the contiguous cycles; this circumstance enables the sense to contemplate these periods apart, and comprehend their origin. On the contrary, when the duration of a cycle belonging to a compound series does not exceed the twelfth part of a second, the interval proves too small to be measured by the ear; it therefore escapes notice in a separate rate; for the points of division recur too frequently to be observed. When the auditory organ finds itself in circumstances answering to the preceding description, it has but one method to pursue; which is, to treat these derivative intervals in the same manner it treats all periods, which are found too small for its comprehension; it therefore reduces them to a simple musical sound, corresponding in pitch to a string which vibrates once in the time of each successive cycle. A grave harmonic is on this account always a lower note.
14. Find the number of vibrations made in one second of time by each of the given sounds: which, supposing C as the principal sound, to make two hundred and forty complete vibrations, is obtained, by multiplying this number by the larger term of the ratio of the given sounds to C, and dividing the product by the smaller term of that ratio, if the given sounds be above C, or the reverse if below it.

2d. Having thus obtained the vibrations of the given confonance, divide the larger number of them, by the larger term of the given confonance, and the smaller number by the smaller term, each of which, if the operation be rightly performed, will give the same result, and shew the number of coincidences of the pulses of the two given sounds in one second, and also the vibrations in that same period, of the grave harmonic sought.

3d. Compare the number of vibrations last found with each of the vibrations of the given confonance, and reduce their ratios to the lowest terms, which will then express the intervals or distances of the grave harmonic, below each of the given sounds.

By way of examples of these rules, we subjoin the following table, shewing the grave harmonic, and several other useful particulars, of the principal confonances in the octave, above C as the principal sound.

Note than any of its constituents, seeing the time of a cycle exceeds the greatest vibration that enters into the composition of it. The strength of a grave harmonic is also weak, when compared with the notes composing it, because these sounds form a kind of harmony, in the same manner as the notes of a sonata. The grave harmonic always keep the direction of the ears, so that the position of the head be changed as often as you please, resembling this to be a united sensation of the auditory duct, because it differs from external sounds, in having no fixed direction. The grave harmonics agree with the ringing of the ears in this remarkable particular; which is a strong proof that their immediate cause is seated in the second part of the nature of things, that this cause originates in the mind." Nicholson's Journal, 8vo. vol. iv. p. 2.

We have been thus particular in quoting from two very able writers on the subject of the grave harmonics, or Tartini's founds, in order to shew the foundation of the rules which we shall here give, for determining the grave harmonic of any given perfect confonance, viz.
but in page 350, lays down an inapplicable and false rule for calculating the place of the harmonic, or implied found, as he calls it; viz. "when two different founds are heard together, their combination always either really produces, or coloriously implies, a third found, whose vibrations are equal to the difference of the vibrations of the two founds in the same time." Thus C 240, heard together with G 360, produces 120; which is an octave below C, &c. Now it is observable, that this empirical rule will give the false results as ours above, only in such cases where the least terms of the ratio (in column 3) differs by unity; which is the case in eight of Tartini's examples out of the ten, but not with the VI or the 6th: which, according to Holden's rule, stands thus, 400 - 240 = 160, and \( \frac{240}{160} = \frac{3}{2} \), or the fifth below the key, instead of the X11th (as Dr. Robison and we have calculated it above); also, 384 - 240 = 144, and \( \frac{240}{144} = \frac{5}{3} \), or the octave and fourth, or eleventh, below the upper note, instead of the XXII. It is not a little surprising that Mr. H. should have overlooked these glaring incon- sequencies of his rule, with Tartini's experiments, on which he professes to have grounded it; acknowledging, however, (p. 354) that he is unable to discover any philosophical principles on which these phenomena can be explained, and can come unacquainted with the writings of the two authors, from whence we have extracted as above. We should not perhaps have thus adverted to Mr. Holden's essay, had it not been in other respects a most respectable work, and one through which these errors are likely to be widely disseminated among musicians, and were not the fanciful system of harmony, which he builds solely upon them, calculated to bewildcr still further the musical student, who may happen to have but a slight knowledge of mathematics.

Among the novelties of Mr. Holden's system, he pretends to prove, by means of the implied founds, (calculated by his rule,) that the minor third, \( \frac{2}{3} \), is a "superimposed third," and not the fundamental less third of the scale, which he lays is expressed by the ratio \( \frac{2}{3} \); (though conceived properly, as he lays, p. 571, by the ratio \( \frac{3}{4} \),) on which account we have introduced this comma deficient minor third into our table, and when its harmonic is shown to be \( \frac{2}{3} \), free octave below the upper note of the comma, instead of \( \frac{240}{160} \), or \( \frac{3}{2} \), which expresses \( \frac{2}{3} \) + 6th, or \( \frac{5}{3} \) and twenty first notes below the upper note, as Mr. H.'s rule would have given it; whereas, had he used the true method of affigining the place of the harmonic or implied found, his supposed fundamental less third, (besides proving less agreeable to the ear on trial, p. 354, than \( \frac{3}{4} \),) might have been degraded from the rank of concords, as having an implied found more than three octaves below the lowest of its notes, which is one of the essential properties of concords, according to their new conceptions.

Another result of these false principles in the essay is, the addition of the integer 7 among harmonic ratios (though to the exclusion of \( \frac{5}{3} \), \( \frac{7}{5} \), &c. \( \frac{2}{3} \), \( \frac{2^{\times 7}}{3} \), &c. page 341, and also of page 350; although \( \frac{7}{11} \), \( \frac{15}{19} \), &c. have real places in the false notes of the trumpet, horn, &c.), and the consequent introduction of what the author calls a grave fourth (see that article), in his descending scale, page 316. According to which also, the acute or comma-redundant major fifth \( \frac{3}{5} \), belongs essentially to the scale, instead of the true concord \( \frac{3}{5} \). We trust that we shall have performed an acceptable piece of service to the well-informed to the harmonic science, by pointing out the source of such incongruous stipulations as the above; and hope, that in a future edition of this useful work nearly all which follows page 349 will be expunged, and configned to its merited oblivion.

The grave harmonics found by the rules and table above, are occasioned by the coincidences of the vibrations of perfect concordances, or the beats of Mr. Sauveur, but since the beats of Dr. Robert Smith also, or those made by imperfect concords, when they occur oftener than 12 or 13 in a second, occasion a grave harmonic note to be perceived, and no theorems for calculating such beats, except that of Dr. Smith from the fractions of a comma of temperament, and Mr. Emerson's from the lengths of strings, having to our knowledge been published, we shall here supply that defect in our article Beats, and give theorems for calculating the beats made by imperfect or tempered concords whole vibrations per second are given, viz.

Let N and M be the number of complete vibrations made in one second, by the grave and acute notes respectively, of the tempered concord whose perfect ratio is \( \frac{n}{m} \) (being the least term, in its lowest number), and let \( \beta \) be the number of beats in one second of time.

Then, if the temperament be sharp, \( \beta = \frac{n - m}{N - M} \), the beats required.

Or, if the temperament be flat, \( \beta = \frac{n - m}{N - M} \), the beats required.

Take for example, the 3d in our table above, and we have \( N = 240 \), \( M = 384 \), \( n = 3 \), and \( m = 4 \); and by the second theorem above \( 6 \times 240 - 5 \times 284 = 172 \); the beats in one second: which are, it will be observed, just double the vibrations in column five of the table, and therefore the grave harmonic thus occasioned, is four octaves below the upper note of this comma deficient minor third. The above theorems for beats will be found of like ease application, in almost every instance of musical calculation.

Grave Intervals is a term applied by Mr. Maxwell and several other correct writers, to such consonances as are flattened or lowered by a major Comma (see article) and it is usual with them to distinguish such intervals by the grave accent thus, \( \mathrm{II} ' \), \( \mathrm{III} ' \), \( \mathrm{IV} ' \), \( \mathrm{V} ' \), \( \mathrm{VI} ' \), \&c.; and on the contrary, to apply the acute accent to such as are sharpened or raised a major comma, as \( \mathrm{II} - \), \( \mathrm{III} - \), \&c. and to call such acute intervals or comma redundant intervals, while those as much flattened are called comma deficient intervals. Which, according to Mr. Holden, a miscalculation, applied this term to intervals lowered by what he calls a bearing, whose ratio is \( \frac{240}{160} = \frac{3}{2} = 11 \frac{47}{69} \) + m. See Grave fourth, &c.

Grave fourth, according to Mr. Holden's system lately published, is an interval less than a perfect fourth, by what he calls a bearing (which is \( \frac{240}{160} = 11 \frac{47}{69} \) + m) having the ratio of \( \frac{240}{160} = 1 = \frac{3}{2} + 1 \) m in Mr. Fairey's new notation; its common logarithm is 881906, 8792, its Euler's logarithm or decimal value of the octave is 3923175, and it contains 2185650 major consonances.

Grave proper femitones, is an interval in Mr. Holden's System of Music, whose ratio is \( \frac{240}{160} = \frac{3}{2} = 43.65201 + 4 \) + m; its common logarithm is 9788109, and Euler's logarithm is 9788109, and the number of major consonances 3922754 which it contains.

GRAVEO, in Medicine, a Latin term, derived from grave, heavy, signifies that species of catarrh, which is usually called a cold in the head; and in which, together with a swelling of the naffles, and breathing of the voice, there is a feeling of fulness and weight in the forehead. It is, according to Celsus, nearly synonymous with the ρυγώδες of the Greeks. See Catarrh. Celsus, de Med. lib iv cap. 2.

GRAVEDONA, or GRAVIGNA, in Geography, a town of Italy, in the department of the Lario, on the lake Como; 42 miles N. of Milan.
GRAVEL.

GRAVEL, in Agriculture, a term frequently applied to a well known material of the small stone kind, the sizes of the particles of which vary from those of very small pebbles to cobbles, and sometimes larger. They are often intermixed with other materials, such as sand, clay, loam, flints, pebbles, iron ocre, &c. Hence there are sandy, clayey, loamy, flinty, pebbly, orty, or ferruginous gravels, &c.

GRAVEL, in Gardening, is a small stone subsistance made use of for the purpose of constructing roads, walks and paths. Walks formed of this material are great ornaments to gardens and pleasure-grounds, as well as useful for common walking upon.

The best gravel for these purposes is that which is naturally composed of irregular pebbles and flints, having a moderate proportion of a yellowish or brownish sandy loam, to make it bind, and give colour. It is obtained in fields and commons, in many parts, at from one, to three or four feet under the surface, though not equally good in all parts, in respect to quality and colour, some having a greater or less proportion of pebbles, a larger or smaller proportion of loam, which is more or less sandy or clayey: it is the colour of the loam, or oxvd of iron, principally, which confinutes the beauty of gravel walks; that of a deepish yellow or reddish colour being the most eligible, as when formed into well-laid walks and rolled, it has an exceedingly beautiful and ornamental effect. Where such gravel can be procured within a moderate distance, and easy expense, it is preferable to all others in some parts. Gravel is of an iron-mould colour, or of a dusty brown hue, which may nevertheless be of a proper quality for walks where the colour is disfigured.

Whatever colour the gravel may have, its proper quality for walks is, a due proportion of moderate, light, sandy loam, to make it bind close and firm at all seasons; but not so redundant, or so clayey, as to be clammy and stick to the feet in wet weather, or so sharp and sandy as to become open and loose in dry weather.

In some places, no other gravel is met with but such as is very loose, sandy, or pebbly, and which has scarcely any binding materials amongst it; which kind never of itself binds, but always remains open and loose, being at all times difagreeable to walk upon; this may, however, be mended by a mixture of light sandy loam, where practicable, adding about one load to every two or three of gravel, call- ing them together, and turning them over two or three times, that they may be well blended and incorparated; and this, when formed into a walk, will often bind close, firm, and smooth at all seasons of the year.

In preparing the gravel for walks, it should not by any means be finely screened, as is often the practice: as it is dug out of the pit, it is only necessary to cast it up in a heap, or long ridge, all such large rough pebbles only as roll down being cleared away; as it screened from the fines, it partakes too much of the loam, so as always to stick to the feet at every flail of rain.

In purchasing gravel for walks, it is mostlly from about two to five or six shilling or more per cart-load for three horf's, though the price differs greatly in different parts, and having regard to the nature of the gravel, as well as the goodheuds of it colour.

In respect to the distribution of gravel-walks in pleasure-grounds, for ornament or use, large ones are necessary to proceed parallel to the house, extending each way towards the side districts of the garden and ornamented grounds: according to the former style of gardening, a large walk of this kind was usually extended in a straight line from the front of the habitation along the middle of the pleasure ground, sometimes having grains plate continued on each side, and sometimes spacious borders furnished with curious shrubs and flowers. But in modern designs these middle walks are rarely admitted, especially in spacious grounds, having nothing in front beyond the parallel habitation walk, but an open rural grass lawn, free from all interferences of walks, &c. However, a good walk closely parallel to the house is indispensably necessary, both for ornament and convenience, and from this side-walks should branch off, communicating with the other parts of the pleasure or garden-grounds; one in particular to be extended in a serpentine manner quite round the ground, others leading in the same manner through the interior parts, so as to have dry firm walking at all times to every part of the ground or garden, without coming upon the grails.

The dimensions for gravel-walks must be regulated according to the extent of the grounds or gardens, as from five to twenty feet or more in width; but all principal walks should be at least eight or ten feet wide; and in large grounds or gardens leading directly from the house; they should be ten, fifteen, or twenty feet wide at least. When the houses and gardens are very large, the main walks continuous to the mansion are sometimes made thirty or forty feet wide; the boundaries on each side being sometimes in grass widely extended, and sometimes in borders for flowers and other curious plants, having either narrow verges of grass, or edgings of dwarf box, or thistle, on the sides of the walks.

In forming walks of this sort, they should be first flaked out to the proper width, and then the boundaries formed, each side of equal level, corresponding to the adjacent ground; the cavity of the walk for the reception of the gravel being afterwards made, the whole space being dug out at least twelve inches deep, to allow for a proper depth of gravel, both to prevent weeds coming from the ground below, and worms from calling up the earth; as also to allow of a proper depth for turning the gravel occasionally when the surface becomes foul; the earth dug out to form the cavity of the walk may be used to raise and form the ground on each side, if necessary, which, and the edgings, should always be completed before the gravel is begun to be laid down into the cavity formed for it.

When the cavity has been thus prepared, any hard rubbing materials may be laid in the bottom, several inches thick; such as coarse gravel or ballast, rough stone dust, brick, or other rubbish, which will greatly prevent worms, and help to drain the moisture from the top of the walk in wet weather, and in winter prevent a dry surface: the proper gravel is then to be laid fix or eight inches thick; in laying, raising the middle higher than the sides, in a gradual rounding form; which is not only necessary to throw off the wet, but also to give the walk a more ornamental appearance; the proportion to be observed in this is, for a walk of five or six feet width, an inch and a half of rite in the middle; for one of ten or twelve feet, two and a half inches; and for one of twenty feet, from three to four or five inches; the same proportion being regarded in other walks.

At every turn or shift for as the walk advances in laying, it is proper to tread, rake, and roll the gravel down, as it always rolls more firm and smooth whilst fresh firered; it is also necessary, for fear of rain, especially in loamy gravel; for which reason, more or less should always be laid in one day than can be finished off, except the rough laying. The treading should be performed regularly with the feet prettily close, taking short steps, so as to render every part equally firm, and not to sink in holes made by the feet, in the work of raking and rolling. The raking should be performed regularly lengthways of the walk; and in the finishing
off or smooth raking, a wooden-headed rake without teeth is most eligible, or the back of any common rake; as by any of these, the surface may be rendered more regular and even, without drawing off the requisite proportion of top pebbles, or raking them into holes or heaps; as the art of smooth-raking is to leave all the proper-sized top stones equally dispersed over the surface. As soon as any part is thus laid and raked, it should be well rolled both across and lengthways; and when the whole is laid, a good rolling should be given the whole length, repeating it till the surface is rendered perfectly compact, firm, and smooth; and after the first shower of rain, another good rolling should be given, so as to make it bind like a rock. This method should be practised with all walks made with these materials invariably.

The management afterwards is, occasional weeding, sweeping, and good rolling, once or twice a week, especially in the advanced part of spring, and all summer; and also occasionally in winter, in dry open weather; and when the surface become very foul, or over-run with small weeds or moss, as is often the case, they must be broken up in spring, and turned the surface to the bottom, and the bottom to the top, by which the weeds and moss will not only be buried, but the walks appear as fresh as when new laid. The custom of breaking up gravel-walks in the beginning of winter, and laying them up in rough ridges, to destroy weeds and moss, is not eligible for general practice, or only occasionally, where any walk is exceedingly overrun; it is mortly more advisable to permit all the principal gravel-walks to remain undisturbed, at least till the spring, when, if it appear necessary, the whole may be broken up, regularly turned, and re-laid in a neat manner.

The turning of gravel is a fort of flight digging, the foul surface being turned down, and the fresh up; some have it performed regularly once a year in the spring, in order to preserve the colour. In these cases, the laying, raking, and rolling, are performed the same as in the first contracting the walks.

The rolling should be performed once a week at least in summer, and if two or three times the more beautiful the walks will appear, and it will tend greatly to destroy weeds and moss; it is mortly a rule among gardeners to sweep and roll every Saturday. During the summer, it is of much advantage to give a good rolling after rain, which affords a compact smooth surface, and preserves the walks in good order.

Gravel, in Geology, is a term properly applied to those fabulous soils, or alluvial deposits of gravel, which are found scattered on the surface of the earth, in almost all situations. It is an essential character of gravel, that it shall contain rounded stones extraneous to the place where they are found, otherwise the breccia, rubble, and broken rocks and gravel near the surface, owing to the action of air, water, and frosts, &c. will be confounded with it, as too often has happened, in the descriptions of countries. The earthly and smaller matters found among gravels, vary in different situations, in all degrees from clay to sand; and yet, if such alluvial mixtures contain rounded stones, and fragments with evident marks of attrition on them, they differ, in describing such soils, to be denominated gravel, adding other words to distinguish the nature and quantity of their earthy mixtures: where rounded stones only are found, with little clay among them, as on the f.a. Beach, and in some gravel-pits, such may be denominated very clean gravel; if a small admixture of sand, loam, (a mixture of sand and clay,) or clay, be found among the stones, such may be denominated clean sandy, clean loamy, or clean clayey gravel: where a considerable portion of the mass is sand, loam, or clay, such should be called sandy, loamy, or clayey gravel; and lastly, where the earths greatly predominate, the terms very sandy, very loamy, or very clayey gravel should be used; or in place of these last, in extreme cases, alluvial sand, alluvial loam, or alluvial clay may be subtilized: the last of which terms would apply to the horizontal earthy deposits or meadow foils, by the sides of rivers, the mud of lakes, &c. We have here made use of the term alluvial, in its strict and proper sense, as denoting matters worn, moved, dispersed, mixed, and deposited in water, in distinction from the regular or undisturbed matters of the terrestrial strata; which, though they shew evident marks of having been deposited in a fluid, the perfect homogeneity of each lamina of the strata, and their vast extension, without rude or accidental mixtures, shew that the laws which governed the two kinds of terrestrial deposit, were not less difficult and marked, than are the processes of the precipitation of matters before mechanically mixed and suspended in a fluid, and the crystallization of substances from a medium super-saturated therewith. During the deposition of the strata, all was tranquil and quiet, except the movements of animated beings, which occupied successively the vast subaqueous plains of strata: during the formation and deposition of the gravels, all descriptions, all was violence and confusion, and apparently so continued for a long period of time.

No problem is of more practical and theoretical importance in geology, than whether gravel is any where found under regular and undisturbed strata? Were the decision of this question to be referred to the opinions of writers on geology, mineralogy, &c. there would be little room to doubt, from their description, that such is sometimes, and frequently, the case; but Mr. William Smith, from having devoted great part of twenty years to the accurate discrimination of stratified and alluvial matters, on the principles above, and after examining the results of the deepest and most extensive wells, shafts, mines, quarries, &c. and converging with quarrymen, miners, &c. who collectively have made an almost infinite number of observations, is decidedly of opinion, that no such cafe can be pointed out in England. It is true, that sandy, loamy, and clayey matters occur, with a very few rounded or broken and mixed flinty fragments among them, so that the nicest discriminations are necessary to distinguish such, in some places, from stratified sand, loam, (or natural brick-earth,) or clay; and under great thicknesses of such doubtful matters, beds of rounded and mixed stones are found, sometimes at very considerable depths, but in all such instances, the doubtful character has continued from the very surface downward, to such gravel-beds, and no where are regular strata of stone, clay, or sand found upon even these doubtful matters, when due caution is used in making and extending the observations. It is true also, that there are, in various parts of the British series of strata, siliceous, or grit-flint beds, and rocks, composed of distinct grains of flint, or crystallized quartz, of all sizes, from such as require a glass for viewing them, to others the size of a man's fist; and in several instances, contrary to the more common cafe, of small and sizeable, or uniform grains, which distinguishing most of our grit-stones, there are beds in which grains, as fine as possible, are mixed with the largest mentioned above, and have, in the cliffs and places where these confine bed-foils, or loose blocks of them, are seen exposed, so exactly the appearance, at first sight, of gravel-rock, or indurated sandy gravel, that it is no wonder they should have been to generally clasped with the gravels. These, however,
who, like Mr. Smith, and the writer of this article, will be
at the pains to trace the blocks of coarse flint alluded to,
to their natural bed, and to examine the newly cut, or broken
faces of them, and their beds and accompanying strata, and
of comparing them with the heterogenous mixtures and uncer-
tain and irregular stratification of the real gravel-rocks,
of which there are great tracts in Nottinghamshire, Derby-
shire, Leicestershire, Staffordshire, Cheshire, and others
of the midland counties, in some places of immense thicknefs,
will see abundant cause for distinguishing even the coarfed
and most irregular of our grit-flinted strata, from the super-
fi Совial gravel-rocks above-mentioned, and, indeed, from allu-
val, or water-worn mixtures of any kind. And such ob-
servers will be struck with surprize, that such a regular and
constant law, as seems to have regulated the formation of
grains of files, of all the flaxes mentioned, should not have
been observed and referred to, for explaining the formation of
coarse as well as fine grit-flints, and have guarded against
our confounding them with the water-worn gravels. Accu-
cumulations of gravel are to be distinguished into native and
foreign, according as the pebbles and earth and extraneous
bodies among them, can be referred to known and adja-
cent strata, or confils of flones and earths not elsewhere
found, or but in very diftant countries. For it will be found,
that except on the sea shore, where the waves continually
carry away, and again throw up the flones, which fall from,
or are washed out of the marine clifts, that the gravel of no
spot corresponds with the strata on which it is lodged, and
if in any situations in land this should seem to be the cafe, it
will probably be found, that those strata extend far to the
east or south-east of the place where their alluvial remains
are lodged, and the circumstances appear to be explainable,
on the principle of a general moving of native alluvia from
the south-east quarter towards the north-west quarter, as
It is a remarkable fact, that all the very coarse, and irregular
grit-flone strata, which have been noticed by the writer of
this article in England, precede or occur beneath a series of
carboniferous strata, or coal-measures; the lowest being
found in the first and third grit rocks of the great Darby-
shire demulcent, and the others occur, both above and below
the grey lime rock, which forms the floor and border of
the great South-Wales coal-field (Phil. Trans. 1861), also
the floor and edges of the forest of Dean coal-basin, and
the western edge of the Somerset and Gloucester, or Bath
coal-field, the northern edge of the Newcastle-under-
line, or pottery coal-field, &c. And which fact it seems to be
that Mr. Kirwan alludes to, under the name of semipor-
tolite in some of the cases mentioned pages 237, 293, 300,
307, 312, and 336, of his "Geological Essays": it is plain,
however, that these coarfe grit-flines, under our coals, do
not indicate the near approach of the fundamental rock of
granite, as Mr. Kirwan would have us believe. We cannot
close this article, without again advertimg to the importance
of accurately discriminating the alluvia found on different
parts of every country, and of tracing their connection with
the regular and continuous strata of flone on which they reside,
and from whence they have been torn. Much information
on the alluvia and strata of the midland counties of England
will be found in Mr. Yarce's Report on Derbyshire.

Gravel Rock, signifies a concreted or indurated mass of
fandy Gravel, (fee that article,) and is carefully to be distin-
guished from the coarfe grit-flone strata, which it often
closely resembles.

Gravel, is a term applied to such relics, or
extraneous follies, as are found in a rounded or worn flate, or
lodged among gravel, or alluvial mixtures, the ruins of
abraded and worn flata. See our article Coal, where the
distinctions between this and other classes of extraneous
follos are explained.

Gravel, in Medicine, the popular term for the disorder
occasioned by the formation of small calculi, or sand-like
concretions in the kidneys and bladder. It is the Nephralgia
arumofa of Sauvage; (see his Nofol. Method. Chas VII.
Genus XV. fpec. 2.) and to be distinguished from the
nephralgia calciforma of the same nosology, in which larger
calculi, or flones, are formed and impacted in the kidneys,
ureters, or bladder.

The symptoms which indicate the presence of gravel in
the kidneys, or in the passages from the kidneys to the
bladder, called the ureters, are chiefly a severe pain in the
loins, which is often accompanied by a fense of numbnefs,
extending down the thighs of the side affected, with a re-
traction of the telficle in the male, and with a fickness of the
fomach, often amounting to vomiting. During the passage
of the small calculi through the canal of the ureter, the
diffenion and irritation occasioned by the calculus, es-
pecially if its surface should be rugged and uneven, excite
thefe symptoms in a more or lefs severe degree, or for a
longer or shorter duration, according to its fize and form;
and they suddenly ceafe when it has entered the bladder.
Pain is again excited in the urinary organs, when the cal-
culus either lies over the aperture, or enters the canal of the
urethra, and a pain and difficulty of passing the urine is
excited. Thefe symptoms, attending the transit of a small
flone from the kidney, or its expulsion from the bladder,
constitute what is ufually called a fit of the gravel. The
more common forms of the diffece, however, confift in the
formation of a fort of fandy matter, of a red colour, which
impedes the free passage of the urine, and occafions consider-
able pain in the attempt, as well as an aching pain in the
loins, through the fymphyfis of the kidneys with the bladder.
A white nodous matter is fometimes discharged with the
urine, under both thefe forms of the diffece, probably
from the irritation excited in the secreting vessels, that open
on the internal surface of the bladder: the passage of the
small calculi occasionally causes a laceration of the small
blood-vessels, and bloody urine is therefore discharged.

The little calculi, excited in those cafes, are fometimes of
a bright red colour, and confift, as well as the red sand which
passes with the urine, or is deposited from it, of the uric or
lithic acid in a concrete flate.

The gravel is a diffece chiefly of advanced life. It is
common in gouty habits, in which it often alternates with the
paroxysms of gout. It has been observed, too, that it
defends by hereditary transmission, like that diffece; and
that of the children of gouty parents fonce have been attack-
ed with the gravel, while others have had the gout. It is
a curious fact, also, that the concretion, called chalk-
flones, which are deposited in the joints in the greut, con-
form of the fame fubstance as the gravelly concretions, viz.
the uric acid. It is to be distinguished from the rheumatic
affection of the bones, called lumbago, by the fickness which
attends the one, and which ceafs in the impace of the other.
and retraction of the telficle, as well as by the nodous or
bloody urine, the pain and difficulty of passing it, and the
appearance of the fandy fquadnent in it.

Chemistry has enabled the physician to administer great
relief to the fufferings occasioned by gravel. The discovery,
by chemical experiments, that the fubfance of these calculi
and nodous concretions is an acid, and therefore capa-
bile of folution in or combination with alkaline fubstances,
led to the administration of the alkalis internally, as reme-
dies for the diffece: and, although it has not been found,
that
that the larger stones of the bladder are dissolved or diminished by the action of alkaline medicines, yet the smaller concretions appear to be prevented from forming, and great relief from the pain and irritation, under all the varieties of concretion, is produced by the use of them. Perry's solvant, Mrs. Stephens' medicines, and Clittuck's R-cipt for the stone, are all of the alkaline class. It is probable that these alkaline medicines operate principally on the fluids in the first passages, by neutralizing the acids occasioned by indigestion, rather than by passing in the circulation, and combining with the uric acid in the kidneys or bladder. This would appear, partly from the fact, that the carbonated alkalies are equally or even more beneficial than the pure or caustic alkalies, in relieving the symptoms of stone or gravel; but it is principally proved by a circumstance, recently ascertained by the experiments of Mr. Home and Mr. Brades, that the absorbent earths, especially magnesia, are considerably more efficacious in relieving those symptoms, and in diminishing the quantity of uric acid in the urine, than the alkalies themselves. The magnesia is to be given in moderately large doses, two or three times a day, and if it proves purgative to the bowels, a few drops of the mixture of opium may be added to it. (See Philosoph. Transact. part i. for 1812.)

Were the alkalines used, it would appear that the potatoes are, on the whole, more beneficial in their complaints than the soda: the pure or caustic potatoes may be given freely, beginning with doses of fifteen or twenty drops, and gradually increasing it, well diluted with any thin drink; and it may be continued for a considerable time with perfect safety. But the carbonate of potash is not less useful, and, especially when dissolved in water saturated with carbonic acid gas, it is not disagreeable, and probably more efficacious. The efficacy of these acidulous alkaline waters was at first indeed attributed to the carbonic acid which they contain, and not to the alkali. (See Lord Medical Commentary on Fixed Air, by Dr. Dobson.) The soda water acidulated by the same gas operates in a similar way, and is another agreeable mode of taking these medicines. Lime-water is likewise pollicled of some remedial powers, but is less efficacious than the alkaline water.

All the aqueous liquors operate in some measure, perhaps, upon another principle, that of increasing the quantity of fluids which pass through the urinary organs, and thus of diluting the irritating uric salts, and consequently diminishing the distress which they occasion; and they may likewise operate negatively, by rendering the patient unable to drink the usual quantity of wine or other strong liquors. Other matters, which tend to increase the flow of urine, form to relieve the symptoms of gravel, upon the principle of dilution; especially small doses of the nitrous acid, or spirits asher nitro, of the pharmacopoeia.

When extreme pain is excited, either by the passing of a small concretion along the canal of the ureter or of the urethra, opiates will afford a temporary relief to the sufferings of the patient, and will perhaps aid in relaxing any spasmatic contraction that may take place in these passages, and thus expedite the passage of the calculi. The same object may be promoted by the use of the warm bath, by fomentations to the loins and pubes, and by warm glycerins.

For the modes of relieving the symptoms, connected with the presence of the larger calculi of the bladder, and of extracting these concretions by surgical means, see STONE:—for all Nephritic and Nephrite.

GRAVELVNAS, in Geography, a town on the S.W. coast of the island of Negroponts, on the fertile of the ancient Eretria; 15 miles S. E. of Negroponte.
point in engraving; after which, if a new edge be made by whetting the graver, it will be frequently found very good without any other alteration. Handmaid to the Arts, vol. ii. p. 56.

The other end is fitted into a wooden handle.

Besides engravers, the seal-cutters, lock-smiths, gunsmiths, gold-smiths, armourers, spursriers, &c. likewise make use of gravers.

GRAVEROL, Francis, in Biography, was born at Nîmes in 1635. He was educated for the profession of the law, and practised, as an advocate, in the parliament of Toulouse, and in the prebifdial chamber of Nîmes, and as director and secretary of the academy in the latter place. He was not only well versed in the studies connected with his profession, but deeply read in objects of general literature, and particularly distinguished for his knowledge of medals and inscriptions. In religion he adhered strictly to Calvinistic principles, which impeded his advancement in life, and at length involved him in persecution. To avoid the huf of cruel laws he retired to Orange, but, not thinking himself safe there, he attempted to pafs into Switzerland. In his journey he was apprehended by the officers of the civil power, and thrown into prison in the citadel of Montpellier. He was, after a long confinement, liberated, and died in the year 1694.

His works consist of several differtations on particular medals, and other monuments of antiquity. His "Observations on the Arrets of the Parliament of Toulouse," in 4to, were much eluced. He was well known to all the learned in Europe, and was admitted a member of the Rivcrvat at Padua.

At his death he had in hand some other literary works. Morei.

S'GRAVESAND, William James le, in Biography, was born at Bois-le-Duc in the year 1628. Having recourse to the examples of learned men, especially that of Boyle, he was sent to Leyden to study the civil law, but he soon exhibited a decided taste for philosophical and mathematical studies, which he determined to pursue in preference to the learning of the courts. He produced, when he was only eighteen years old, an excellent "Essay on Perspicacity," which gave him a considerable reputation among the mathematicians of the age in which he flourished. In 1679 he took his doctor's degree, quitted the university, and settled at the Hague, where he practified at the bar, and cultivated an acquaintance with learned men. He joined some other persons in conducting a periodical work, entitled "Le Journal Litteraire," which was continued without interruption from the year 1713 to 1722. S'Gravesand contributed to it the original differtations relating chiefly to geometry and physics. Among the difficulties most worthy of notice, and which were original pieces of his own composition, were the following, "Remarks on the Construction of Pneumatical Engines;" and "An Essay on the Collisio of Bodies," which was attacked by Dr. Clarke and other learned men, on account of its opposing the principles of the Newtonian philosophy. In 1715 the States General sent an embassy to England, to congratulate George I. on his accession to the throne of Great Britain. S'Gravesand was on this occasion appointed secretary to the persons composing this body, and during his stay in London, he became intimately acquainted with Sir Isaac Newton, and was, upon the recommendation of that great man, admitted a member of the Royal Society. Upon his return to Holland, he was appointed professor of mathematics and astronomy at the university at Leyden. He immediately undertook to teach and illustrate the Newtonian philosophy to the students of the university, and in 1734 he had the additional professorship of philosophy conferred upon him.

Vol. XVI.

So great were his exertions in the several duties of his office, and in preparing for publication his several works on the sciences, that he injured his constitution, and finally sunk under his labours in 1742, when he was only fifty-four years of age. His principal publications were: (1) "Physicae Elementa Mathematicae, Experimentis Confertam," five introductio ad philosophiam Newtonianam, which consists of the author's lectures; (2) "Matheseos Universalis Elementa," containing a syllabus of algebra for the use of students, with a commentary on Newton's Universal Arithmetic; (3) "Philosophiae Newtonianae Institutiones," which is an abridgment of his Elements of Physics; (4) "Introductio ad Philosophiam, Metaphysicam, et Logiam continens." His mathematical and philosophical works, excepting the first article, were collected and published at Amsterdam, in 2 vols. 4to, with an account of the life and writings of the author. The private character of S'Gravesand was highly respectable and amiable: his morals were exemplary, and he was beloved for his generosity, benevolence, and obliging manners. He was consulted by the ministers of the republic on all matters of finance, and he was of great service to them in deciphering and detecting the secret correspondence of their enemies.

GRAVESANDE, in Geography, a town of Holland, distant about four miles from the fea, six miles W.S.W. of Delft.

GRAVESEND, a town in the hundred of Tolting-tou, in the county of Kent, England, consists of several streets, built on a declivity leading to the Thames; and is particularly known in the parish of Milton, which adjoins to that of Gravesend on the south side. The early prosperity of this town received a considerable check in the reign of Richard II., when the French and Spaniards failed up the Thames in a body, burnt and burned many of the houses, and took a great number of the inhabitants prisoners. To alleviate the loss, the king was induced to give the townspeople a legal claim to the water-passage to London, by a grant to the abbey of St. Mary le Gracie. In the tenth of queen Elizabeth the parishes of Gravesend and Milton were incorporated by her letters patent: but the principal charter was granted by Charles I. in the year 1642. The chief officer, who had before this time been called the portrewe, was by this charter constituted mayor; and in him twelve jurors, twenty-four common councilmen, a fenechall or high steward, and other inferior officers, the government of the town is now vested. The liberty of holding two additional weekly markets on Wednesdays and Saturdays, and an annual fair of four days, was also granted at the same time, together with a full confirmation of the exclusive privilege, conferred by king Richard, of conveying passengers and goods by water to the metropolis. In August 1727 the greater part of the town was destroyed by a fire, which commenced in a barn-yard adjoining to the church, and consumed that fabric, with about 120 houses, besides outbuildings, stables, &c. The present church, which is dedicated to St. George, was erected on the old site in the year 1732, under an act of the fourth of George II., which appropriated 5000l. for that purpose, from the duties on coals and culm, levied under the acts of the ninth and tenth of queen Anne, for building fifty new churches in or near London.

Gravefand has been greatly improved since the year 1764, when a new town-hall, having an area beneath the poultry market is kept, was erected by the corporation. In 1767 a new wharf, crane, and wharfage, were made, the expense of keeping which in repair is defrayed by small tolls for cranage and wharfage. The increase of the trade, 4 P. population,
population, and buildings has been particularly rapid since
the middle of the last century. Under the late act, the
number of inhabitants was returned at 24,813, and that of
houses at 4,125; yet these numbers are very incorrect, and the
population can scarcely amount to less than 40,000, nor the
number of houses between 7,000. Most of the inhabi-
tants are engaged in maritime pursuits or employments.

A small manufactury for cables and ropes is carried on here;
and about the year 1780, a yard for ship-building, which
had long been diffused, was hired by a quaker, named Cle-
very, and several men of war and frigates, besides smaller
vessels, have been built here. About eighteen or twenty
smacks find employment in the cod and haddock fishery;
and most of the Dutch turbot vessels lie off this town, and
send their cargoes to the London markets in small boats.

Most of the East and West India trade, and, indeed, of
the outward-bound ships in general, are supplied with live
and dead stock at Gravesend; and also with vegetables;
about eighty acres of ground in the two parishes being cul-
tivated for that purpose, and for supplying the London
markets with asparagus, which is remarkable for its fine
flavour. Gravesend is situated 22 miles E. from Lon-
don. Haifeld's History of Kent, vol i. 800. Beauties
of England and Wales, vol vii.

GRAVINA, a township and village of America, in Long
Island, New York, seven miles from the city, containing
483 inhabitants.

GRAVIMETER. See HYDROMETER.

GRAVINA, Domenico DA, in Biography, who flour-
rished in the fourteenth century, was a native of Gravina,
in the kingdom of Naples. He was by profession a notary,
but in literature an historian. He seems to have taken an
active part in the civil wars which agitated his country at
that period, and on account of the side which he espoused,
he was deprived of all his property, and driven into exile
with his wife and children. He wrote a history of Naples
in the Latin language, and likewise a history of the trans-
actions in that part of Italy during his own times, from 1350
to 1355. A fragment of this work only is in existence,
the beginning and end being lost; it is, however, reckoned
a valuable document for the fidelity of the narration,
and is to be found in Muratori's collection of Italian his-
torians.

GRAVINA, John Vincent, was born in 1664 at Rogiana,
a castle in Calabria. He enjoyed all the advantages of a
very liberal education, and became well versed in the learned
languages; geometry, physics, history, and antiquities.
He also made himself acquainted with the principles of
theology. Having thus attained to a general knowledge
of the learning of the times, he went to Naples to study
the civil and canon law. After this he returned to Rome,
and lived with Paul Coordo of Turin. He was one of
the original founders of the academy of Arcadi, and had
the charge of drawing up their laws in the style of the
Roman tables. He arrogated to himself the merit of hav-
ing devised these laws, a circumstance which involved him
in a quarrel with the other members, particularly with
Creccembini, the founder of the society, to that these two
learned men were for several years at the head of two
factions which divided the body. In 1698, he was nomi-
nated professor of civil law at the college of Sapienza, and,
in five years after, he succeeded to the chair of the canon-
law. His method of instruction was excellent; he avoided
trifling verbal disputes, and mere scholastic speculations,
and entered into the spirit of the laws, illustrating their theory
by observations drawn from ancient writers, and by a cri-
ticism founded on his extensive erudition. This mode of

GRAVING, the art or act of cutting lines, figures,
or other delineations on metals; more properly called
engraving; which see.

GRAVING-dock, or Dry Dock, is a place from which
the water can be let out or pumped, after ships and boats
are floated into it to be cleared or repaired; sometimes, grav-
ing-docks are above the level of the water, and boats are
dropped upon inclined planes into the same. By the sides of tidal
rivers or harbours these are constructed with strong cleve
gates meeting in an angle to shut out the tide; which gates

or is about to leave the dock at such time. See Docks, and CANAL.

GRAVISKOI, in Geography, a fortress of Russia, in the government of Kolivan, on the Irilich; 219 miles S. S. W. of Kolivan. N. lat. 52° 15'. E. long. 73° 14'.

GRAVITAS, Rogers, in the Ancient Muses, was used to signify a sound produced by the remission or filling of the voice. Gravitas differs from immissio, as the effect from the cause.

Gravitas is also used to denote the state of a woman going with child. See PREGNANCY.

Gravitation, the exercise of gravity, or the action which a body exerts on another body by the power of gravity. It is sometimes distinguished from gravity. Thus, Manpertuis takes gravity for that force by which a body would fall to the earth supposed at rest; and gravitation for the same but diminished by the centrifugal force. See figure of the earth. determin. p. 256 of Mr. Mardoch's translation.

It is only gravitation, or gravity thus blended with the centrifugal force, that we can measure by our experiments. However, methods have been found to distinguish what remains of primitive gravity, and what has been destroyed by the centrifugal force.

It is one of the laws of nature, discovered by Sir Isaac Newton, and now received by all philosophers, that every particle of matter in nature gravitates towards every other particle; which law is the hinge on which the whole Newtonian philosophy turns. See Newtonian Philosophy.

What we call gravitation, with respect to the gravitating body, is properly called attraction with respect to the body towards which the other gravitates.

The planets, both primary and secondary, and also the comets, do all gravitate towards the sun, and towards each other; and the sun towards them; and that in proportion to the quantity of matter in each.

The Peripatetics, etc. hold, that bodies only gravitate when out of their natural places, and that gravitation ceases when they are restored to the same, the intention of nature being then fulfilled. The final cause of this faculty, as they maintain, is only to bring elementary bodies to their proper place, where they may rest. But the moderns shew, that bodies exercise gravity even when at rest and in their proper places.

This is particularly shewn of fluids; and it is one of the laws of hydrostatics demonstrated by Mr. Boyle and others, that fluids gravitate in proprio loco, the upper parts preffing on the lower, &c.

For the laws of gravitation of bodies in fluids specifically lighter, or heavier than themselves, see Specific Gravity, Fluid, &c.

Gravitation, Theory of Universal. Newton is very justly considered as the author of this great hypothesis, though several preceding and contemporaneous writers seem to have formed conjectures on the subject that did not differ very widely from the truth. From the time of Kepler it had ever day become more and more evident, that some mechanical cause had a very material influence on the laws of the planetary motions. The problems which the discoveries of that great astronomer left for future ages to solve were these: Why do the planets and satellites describe elliptic orbits, the former round the sun, the latter round their primary planet? Why is the centre of motion in the focus rather than in the centre of the ellipse? Why are equal areas described in equal times about the centre; and what can be the cause of that remarkable law that is found constantly to subsist between the distances of the planets from the sun and the times of their revolution?

Des Cartes first attempted a solution of these difficulties, by supposing a simple mechanical cause. He supposed the existence of a subtle fluid, which, though imperceptible to the senses, was in constant motion round the sun, and that it involved the planets in its powerful agency. This theory, on its first enunciation, does not seem deficient in plausibility, but upon more careful examination, it is found incapable of explaining any one astronomical phenomenon correctly, and indeed the action of such a fluid would produce effects in many cases exactly the reverse of what it was intended to explain. The spirit of rational enquiry that now began to be exerted on all philosophical subjects, rendered this theory of short duration.

Kepler at a much earlier period had formed more correct opinions on this subject than Des Cartes; indeed he seems to have had a very distinct idea of the existence of gravitation, though he never could have been aware of its agency being so extensive, or that it would ever extend in so satisfactory a manner as it has done since his own great discoveries. Gravity, he says, in his "Commentary on Mars," is only a mutual and corporeal affection between similar bodies. Heavy bodies do not tend to the centre of the world, but to that of the round body of which they form a part: and if the earth were not spherical, heavy bodies would not fall towards its centre, but towards different points. This conjecture has been fully verified by theory and observation; the earth appears not to be a perfect sphere, and accordingly a plumb-line does not tend to the exact centre of gravity of the whole earth, but to a point considerably remote from it, as has been explained under Degree, Earth, figure of, &c.

Kepler likewise strongly suspected that the attraction of the moon was the cause of the tides, and that the lunar irregularities arose from the action of the earth and sun. Perhaps, from the earliest times, some indistinct conceptions are to be occasionally traced in different authors concerning the existence of this universal principle.

Fermat, who preceded Kepler, affirmed, that the weight of a body was the sum of the tendencies of all its particles to all the particles of the earth; and Kepler was of opinion that two bodies left alone in free space would approach each other with velocities inversely proportional to their masses or quantities of matter.

A short time previous to the great discovery of Newton, Dr. Hooke made a still nearer approach to the truth. At a meeting of the Royal Society, May 3, 1668, he expressed himself in the following manner: "I will explain a system of the world very different from any yet received, and it is founded on the three following positions:

1. That all the heavenly bodies have not only a gravitation of their parts to their own proper centres, but that they also mutually attract each other within their spheres of action.
2. That all bodies having a simple motion will continue to move in a straight line, unless continually deflected from it by some extraneous force, causing them to describe a circle, an ellipse, or some other curve.
3. That this attraction is so much the greater as the bodies are nearer. As to the proportion in which those forces diminish by an increase of distance, I own I have not yet discovered it, although I have made some experiments to this purpose. I leave this to others who have time and knowledge sufficient for the task."

This is a very precise enunciation of a proper philosophical theory. The phenomenon, the change of motion, is considered
G R A V I T A T I O N.

fidered as the mark and measure of a change of force, and his audience is referred to experience for the nature of this force. He had before exhibited to the society a very pretty experiment contrived to show the nature of this force. A ball, suspended by a long thread from the ceiling, was made to swing round another ball, laid on a table immediately below the point of suspension. When the impulse given to the pendulum was nicely adjusted to its deviation from the perpendicular, it described a perfect circle round the ball on the table; but when the impulse was very great, or very small, it described an ellipse, having the other ball in its centre.

Hooke showed that this was the operation of a deflecting force proportioned to the distance from the other ball. He added, that although this illustrated the planetary motions in some degree, yet it was not suitable to their case: for the planets describe ellipses, having the sun not in their centre but in their focus. Therefore they are not retained by a force proportional to the distance from the sun.

The exalted genius of Newton can suffer no diminution by the enumeration of that above observations, for though the idea of such a principle as gravitation was not suggested first by Newton, yet so very obscure were the notions of even the most enlightened philosophers on this subject, that it had never been successfully applied to the explanation of a single astronomical phenomenon.

So intimately connected is this great discovery with the history of the human mind, that every known circumstance relating to it has been recorded with the greatest care. Dr. Pemberton relates that Newton, in the year 1666, having retired from Cambridge to the country; on account of the plague, was there led to meditate on the probable cause of the planetary motions, and upon the nature of that central force that retained them in their orbits. It then occurred to him that possibly the same force, or some modification of the same force which caused with us a heavy body to descend with a certain velocity to the earth, might likewise retain the moon in her orbit by causing a constant deflection from a rectilinear path. Before, however, this conjecture could be put to the test of calculation, it was necessary that Newton should have formed some conditional hypothesis relative to the modification of the force with respect to the distance.

That any agency emanating from a central point should decrease as the square of the distance from that point increases, is an hypothesis so natural, that we cannot be surprised that Newton should have selected it; but whether or not he had previously tried any other, or whether he had even at this time deduced it from the nature of the planetary orbits, does not now appear. The calculation which it was necessary to institute, we shall give with great minuteness in its proper place; it is therefore only necessary to remark at present, that it requires that the proportion between the radius of the earth and the lunar orbit should be exactly known. When Newton first attempted to verify this hypothesis, the requisite data had not been exactly determined, and a slight discordance between the results of the calculation and the supposable fact, induced him for a time to abandon his hypothesis. This circumstance has, with great propriety, been recorded as a striking instance of the cool and dispassionate frame of mind which this great philosopher possessed; at a moment when he had flattered himself with the hope of having discovered one of the most important secrets of nature.

Some few years afterwards he was again tempted to renew these calculations, as in this interval a degree of the meridian had been measured in France by Picard. This second attempt succeeded. It is related, that towards the end of the calculation he became so much agitated, as to be obliged to request a friend to assist him in finishing it; and certainly a moment of greater importance in philosophy will never be recorded in the annals of science.

The computation which was made by Newton to determine the identity of the force of terrestrial gravity, with that which retains the moon in her orbit, is still a subject of great interest to astronomers, as they now reverse the process; and taking the theory of gravitation as admitted, they deduce from the same computation the distance of the moon from the earth. We shall give it in the words of Leibnitz.

The force which at every instant deflects the moon from the tangent of her orbit, causes it to describe, in one second, a space equal to the vered line of the arc which it describes in that time; since this line is the quantity that the moon at the end of a second deviates from the direction it had at the beginning. This quantity may be determined by the distance of the earth, inferred from the lunar parallax in parts of the terrestrial radius; but to obtain a result independent of the inequalities of the moon, we must take for the mean parallax that part of it which is independent of these inequalities. This part is, according to observation, 52° 54'.9, relatively to the radius drawn from the centre of gravity of the earth, to the parallel, of which the square of the sine of the latitude is equal to 3. We select this parallel because the attraction of the earth, on the points corresponding to its surface, is at the distance of the moon, very nearly equal to the mass of the earth divided by the square of the distance from its centre of gravity. The radius drawn from a point of this parallel to the centre of gravity of the earth is 6369374 metres, from whence it may be computed the force which solicits the moon towards the earth causes it to fall 8.00101727 in one second of time. It will be shown hereafter, that the action of the sun diminishes the lunar gravity; the part. The preceding height must therefore be augmented /4th part, to render it independent of the action of the sun; it then becomes 8.00101201. But in its relative motion round the earth, the moon is solicited by a force equal to the mass of the earth and moon divided by the square of their mutual distance; therefore to obtain the height which the moon would fall through in one second, by the action of the earth alone, the preceding space must be diminished in the ratio of the mass of the earth to the sun, and of the masses of the earth and moon: but by the phenomena of the tides, it appears that the masses of the moon is equal to 1/4 of that of the earth, multiplying therefore this space by 1/4, we have 8.001003000 for the height which the moon falls through in one second by the action of the earth.

Let us now compare this height with that which results from observations made on the pendulum. Under the parallel above-mentioned the length of the pendulum vibrating seconds is equal to 8.65706: but on this parallel the attraction of the earth is less than the force of gravity by 3 of the centrifugal force due to the motion or rotation of the earth at the equator; and this force is 4th part of that of gravity; the preceding space must therefore be augmented 4th part, to get the space due to the action of terrestrial gravity alone, which on this parallel is equal to the mass divided by the square of the terrestrial radius; we shall therefore have 8.66553 for this space. At the distance of the moon it should be diminished in the ratio of the square of the radius of the terrestrial sphere to the square of the distance of the moon: for this purpose it is sufficient to multiply it by the square of the tangent of the lunar parallax, or 56° 55½, this will give 8.00100483 for
for the height which the moon should fall through in one second by the attraction of the earth. This quantity, derived from experiments on the pendulum, differs very little from that which results from direct observation of the lunar parallax; to make them coincide, it is sufficient to diminish the parallax $2\frac{1}{2}$, and to reduce it to $56^\circ 53^\prime 3$. This is the parallax resulting from the theory of gravity, differing only $\frac{1}{2}$, through part from that derived from actual observation, to which La Place thinks it preferable, considering the exactness of the elements from which it is computed. It would be sufficient to diminish a little the masses of the moon to obtain, by this theory of gravity, the same parallax that is given by observation; but all the phenomena of the tides concur in giving this satellite a mass more considerable, and very nearly such as has been used in the above computation. But however that may be, the small difference between the two parallaxes is within the limits of the errors of observation, and of the elements employed in the calculation. It is then certain that the force which retains the moon in its orbit, is the terrestrial gravity diminished in proportion to the square of the distance.

Having thus shown how the nature of the force which retains the moon in its orbit is investigated, it next remains to inquire if the same force of gravity pervades the roll of the solar system. The same great mathematician, above quoted, observes, that "of all the phenomena of the solar system, the elliptic motion of the planets, and of the comets, seems the most proper to conduct us to the general law of the forces by which they are animated."

Observation has shown, that the areas described by the radii vectores of the planets and comets about the sun are proportional to the times. Now we see, in the article Central Forces, that, for this to take place, the force which deflects the path of these bodies from a right line must constantly be directed towards the origin of their radii vectores. The tendency of the planets and comets to the sun is therefore a necessary consequence of the proportionality of these areas to the times in which they are described. To determine the law of this tendency, let us suppose that the planets move in circular orbits, which supposition does not greatly differ from the truth. The squares of their real velocities will then be proportional to the squares of the radii of those orbits, divided by the squares of the times of their revolutions. But, by the law of Kepler, the squares of these times are to each other as the cubes of their radii; the squares of the velocities are therefore as the radii. It has been shown, that the central forces of bodies, moving in circular orbits, are as the squares of the velocities, divided by the radii of the circumferences described; the tendency, therefore, of the planets to the sun, is reciprocally as the squares of the radii of their orbits, supposed circular. This hypothesis, it is true, is not rigorously exact; but the constant relation of the squares of the times to the cubes of the greater axes of their orbits being independent of their eccentricities, it is natural to think it would subsist also in the case of the orbits being circular. Thus, the law of gravity towards the sun, varying reciprocally as the square of the distance, is clearly indicated by this relation: analogies would lead us to suppose that this law, which extends from one planet to another, should subsist equally for the same planet at its different distances from the sun; and its elliptic motion confirms this beyond a doubt. To comprehend this, let us attend to this motion, beginning at the departure from its perihelion. Its velocity is then at its maximum, and its tendency to recede from the sun surpassing its gravity towards it, its radius vector augments, and forms an obtuse angle with the direction of its motion. The force of gravity towards the sun, decomposed according to this direction, continually diminishes the velocity till it arrives at the aphelion; at this point the radius vector becoming perpendicular to the curve, its velocity is a minimum; and its tendency to recede from the sun being less than its gravity towards it, the planet will approach it while describing the second part of its ellipse. In this part, the gravity towards the sun increases its velocity in the same manner as it before decreased it; and the planet will arrive at its perihelion with its primitive velocity, and recommences a new revolution, similar to the first. Now the curve of the ellipse at the aphelion and perihelion being the same, the radii of curvature are the same, and, consequently, the centrifugal forces of these two points are as the squares of the velocities. The vectors described in the same time being equal, the aphelion and perihelion velocities are reciprocally as the corresponding distances of the planet from the sun; the squares of these velocities are therefore reciprocally as the squares of these distances; but at the perihelion and aphelion distances, the centrifugal forces in the osculatory circumferences are evidently equal to the gravity of the planet towards the sun, which is therefore in the inverse proportion to the squares of these distances. Thus the theorems of Huygens on the centrifugal force were sufficient to demonstrate the tendency of the planets towards the sun: for it is highly probable that this law, which extends from one planet to another, and which is verified in the same planet, at its aphelion and perihelion, extends also to every part of the planetary orbits, and at the same time to every distance from the sun. But to establish it in an incontrovertible manner, it was requisite to determine the general expression of the force which, directed towards the focus of an ellipse, would oblige the projectile to describe that curve. And it was Newton who demonstrated that this force was reciprocally as the square of the radius vector. It was essential also to demonstrate rigorously that the force of gravity towards the sun only varies in one planet from the same force in another, according to their different distances from it.

This great geometrical scheme, that this followed necessarily from the law of the squares of the periodic times being reciprocally as the cubes of the distances; supposing therefore all the planets at rest at the same distance from the sun, and abandoned to their gravity towards its centre, would descend from the same height in equal times: this result should also extend to the comets, notwithstanding the greater axes of their orbits are unknown; for we have been in the second book, that the magnitude of the areas described by their radii vectores, supposes the law of the squares of the periodic times proportional to the cubes of their axes.

A general analysis, which embraces every possible result from a given law, shews us that not only an ellipse, but any other conic section, may be described by virtue of the force which retains the planets in their orbits; a comet may therefore move in a hyperbola, but then it would be only once visible, and after its apparition would recede from the limits of the solar system, to approach other funs, which it would again abandon, thus visiting the different systems that are scattered in the immensity of the heavens. It is probable, considering the infinite variety of nature, that such bodies exist. Their apparition should be a very rare occurrence; the comets, we shall observe, are those which, having closed orbits, return, at the end of intervals more or less considerable, into the regions of space that are in the vicinity of the fun. The satellites tend also perpetually to the fun. If the moon was not subject to its action, instead of describing an orbit almost circular round the earth, it would soon abandon...
GRAVITATION.

don it; and if this satellite, and those of Jupiter, were not solicited towards the sun, according to the same law as the planets, perceptible inequalities would result in their motions which have not been recognized by observation.

The planets, comets, and satellites are therefore subject to the same law of gravity towards the sun. At the same time that the satellites move round their planet, the whole system of the planet and its satellites is carried by a common motion, and retained by the same force, round the sun. Thus the relative motion of the planet and its satellites is nearly the same as if the planet was at rest, and not acted upon by any external force.

We are thus conducted, without the aid of hypothesis, by a necessary consequence of the laws of the celestial motions, to consider the sun as the centre of a force, which, extending infinitely into space, diminishes as the square of the distance increases, and which attracts all bodies that are within the sphere of its activity. Every one of the laws of Kepler discovers a property of this attractive force. The law of the proportionality of the area to the times shows us, that it is constantly directed towards the centre of the sun. The elliptic orbits of the planets show that this force diminishes as the distance increases; finally, the law of the proportionality of the squares of the periodic times to the cubes of the distances demonstrates, that the gravity of all the planets towards the sun is the same at equal distances. This gravity may be called the solar attraction when it is considered as relative to the centre of the sun, towards which it is directed; for without knowing the cause, we may by one of those suppositions, common among geometers, imagine an attractive power residing in the centre of the sun.

The errors to which observations are liable, and the small alterations in the elliptic motions of the planets, leave a little uncertainty in the results deduced from the laws of motion; and it may be doubted if the solar attraction diminishes exactly in the inverse ratio of the square of the distance. But a very small variation in this law would produce a very perceptible difference in the motions of the planetary orbs. The period of the terrestrial orbit would have an annual motion of 1 1/25 if we only increased by one ten thousandth part the power of the distance to which the solar orbit is reciprocally proportional; this motion is only 11.6 according to observation, and of this we shall hereafter see the cause. The law of the square of the distance is then, at least, extremely near, and its extreme simplicity should induce us to adopt it, as long as observations do not compel us to abandon it. At the same time we must not measure the simplicity of the laws of nature by our facility of conception, but when those which appear to us the most simple accord perfectly with observations of the phenomena, we are justified in supposing them rigorously exact.

The gravity of the satellites towards the centre of their planet, is the necessary consequence of the proportionality of the areas described by their radii vectors to the times, and the law of the diminution of this force, according to the square of the distance, is indicated by the ellipticity of their orbits. But this ellipticity is hardly to be perceived in the orbits of the satellites of Jupiter, Saturn, and Uranus, which renders the law of the diminution of the force difficult to ascertain by the motion of any one single satellite; but the constant ratio of the squares of the times of their revolutions to the cubes of their distances, indicates it beyond a doubt, by demonstrating, that from one satellite to another, the gravity towards the planet is reciprocally as the square of the distance from its centre.

This proof is wanting for the earth, it having but one satellite, but it may be supplied from the following considerations:

The force of gravity extends to the summits of the highest mountains, and the small diminution which it there experiences, leaves no doubt but that this force would be perceptible at much greater altitudes. Is it not natural to extend this to the moon, and to suppose that the force which retains it in its orbit, is its gravity towards the earth, in the same manner as the solar gravity retains the planets in their orbits round the sun? for, in fact, these two forces seem to be of the same nature; they both of them penetrate the most intimate parts of matter, animating them with the same velocities; for we have seen that the solar gravity solicits equally all bodies placed at equal distances from the sun, and that the terrestrial gravity also causes all bodies to fall through the same height in equal times.

A heavy body, projected with force horizontally from a great height, falls on the earth at a considerable distance, describing a curve, which is apparently parabolic; it will fall still further, if the force is greater, and supposing it about seven thousand metres in a second, it would not fall to the earth, but would circulate round it like a satellite, setting aside the resistance of the air: for it has been fully shown above, that, to form a moon of this projectile, it must be taken to the height of that body, and there receive the same motion of projection; and the identity of the moon's tendency to the earth, has been already demonstrated, by shewing that to obtain this tendency, it is sufficient to diminish the terrestrial gravity according to the general law of the variation of the attractive force of the celestial bodies; and we have seen, that the law of the diminution of gravity, which in planets, accompanied by several satellites, is proved by a comparison of their periodic times, with their distances, is demonstrated for the moon, by comparing its motion with that of projectiles, at the surface of the earth.

The observations of the pendulum made at the summits of mountains, had already indicated this diminution of the terrestrial gravity; but they were insufficient to discover the law, because of the small height of the most elevated mountains, compared with the radius of the earth: it was requisite to find a body very remote from us, as the moon, to render the law perceptible, and to convince us, that the force of gravity on the earth is only a particular case of a law that pervades the whole universe.

Every phenomenon throws new light on, and confirms the laws of nature. Thus the comparison of experiments on gravity with the lunar motion shews us, that the origin of the distances of the fun and planets, in the calculation of their attractive forces, should be placed in their centres of gravity; for it is evident, that this takes place on the earth, whose attractive force is of the same nature as that of the sun and planets.

The fun, and those planets which are accompanied by satellites, being thus proved to be endowed with an attractive force, varying inversely as the square of the distance, a strong analogy leads us to attribute the same property to the other planets. The spherical figure common to all these bodies, indicates that their particles are united round their centres of gravity by a force which, at equal distances, equally solicits them towards these points; but the following considerations leave no doubt upon this subject.

We have seen, that if the planets and comets were placed at the same distance from the sun, their gravity towards it would be in proportion to their masses: now, it is a general law in nature, that action and re-action are equal and contrary; all these bodies, therefore, re-act on the fun, and attract in proportion to their masses: they are therefore endowed
dowed with an attractive force proportional to their masses, and varying inversely as the square of the distance. By the same principle, the satellites attract the planets and the sun, according to the same law. This attractive property, then, is common to all the celestial bodies; it does not disturb the elliptic motion round the sun, when we confide only their mutual action; for the relative motion of the bodies of a system are not changed by giving them a common velocity; by impressing, therefore, in a contrary direction to the fun and to the planet, the motion of the first of these two bodies, and the action which it experiences on the part of the second, the fun may be considered as immoveable, but the planet will be solicited towards it with a force varying reciprocallly as the square of the distance, and proportional to the fun of the masses; its motion round the sun will therefore be elliptic. And we fee by the same reasoning, that it would be so if the planet and fun were carried through space with a motion common to each of them. It is equally evident that the elliptic motion of a satellite is not disturbed by the motion of translation of its planet, nor would it be by the action of the fun, if it was always exactly the same on the satellite and the planet.

Verthief, the action of the planet on the fun influences the length of its revolution as diminished as the mafs of the planet is more consideral; so that the relation of the square of its periodic time, to the cube of the major axis of its orbit, depends on its mafs. But since this relation is nearly the same for all the planets, their maffles must evidently be very small compared with that of the fun, which is equally free for the satellites with respect to their principal planets.

This we may readily suppute from their smallness.

The attractive property of the heavenly bodies not only belongs to them in a mafs, but to each of their particles. If the fun only acted on the centre of the earth without attracting particularly every one of its particles, oscillations would arise in the ocean, infinitely more considerable and very different from those which we observe. The gravity of the earth to the fun, therefore, is the refult of the gravity of all its particles, which consequently attracts the fun in proportion to their respective masses; besides, each body on the earth tends towards its centre proportionally to its mass, it reacts thereon, which is in the fame ratio. If that was not the case, and if any part of the earth, however small, attracted another part without being attracted by it, the centre of gravity would move in space, in virtue of the force of gravity, which is impossible.

The celestial phenomena, compared with the laws of motion, conduct us therefore to this great principle of nature, namely, that all the particles of matter attract each other in proportion to their masses, and inversely as the squares of their distance.

Already we may perceive in this universal gravitation, the caufe of the perturbations to which the heavenly bodies are subject; for the planets and comets being subject to the action of each other, they must deviate a little from the laws of the elliptic motion, which they would otherwise exactly follow, if they only obeyed the action of the fun. The satellites also, engaged in their motions round their planets by their mutual action, and that of the fun, deviate a little from these laws.

We perceive then that the particles of the heavenly bodies, united by their attraction, should form a mafs nearly spherical; and that the reful of their action at the surface of the body should produce all the phenomena of gravitation.

We fee moreover that the motion of rotation of the celestial bodies should slightly alter their spherical figure, and flatten them at the poles; and then the reful of all their mutual actions not passing through their centres of gravity, should produce in their axes or rotation similar motions to those discovered by observation. Finally, we may percei've why the parts of the ocean, unequally acted on by the sun and moon, should have oscillations similar to the ebbing and flowing of the tides. But these different effects of the principle of gravitation must be particularly developed, to give it all the certainty of which physical truth is susceptible.

It is in the universal application of this theory to all the known celestial phenomena, that the modern science of physical astronomy consists, a science which owes its origin to Newton, and which has been cultivated by every eminent mathematician, from the time of that great philosopher to the present day. It is to La Place that the merit must be given of having completed this theory, by showing that there remains not a single phenomenon that it is not capable of explaining; he justly observes, that there is no question here of vague causes, which cannot be submitted to analysis, and which the imagination modifies at pleasure, to accommodate them to the phenomena. The law of universal gravitation has this incomming advantage, that it may be reduced to calculation, and by a comparison of its results with observation, it presents the most certain method of verifying its existence; and so far are we from having to fear that new observations will disprove this theory, we may be assured before hand that they will only confirm it more and more, and that its consequences are equally certain as if they had actually been observed.

The astrononmical phenomena produced by the mutual gravitation of the heavenly bodies, will be found in the different parts of this work. As each subject will be particularly treated under its appropriate article, see Figure of the Earth; Preceding of the Equinoxes; Motion of he Earth's axis; Perturbation of the Planets, Moon, and Satellite; Tides, Libration of the Moon, &c.

But as the investigation of laws by which particles of matter gravitate to spheres and other solids cannot with propriety be referred to any other article, and as it forms to very essential a part of physical astronomy, we shall enter on the subject very fully. The more simple and easy investigations of astronomy suppose the action to be confined to simple gravitating points; now as such points exist in nature, it becomes requisite to consider the effect which an assemblage of these points will produce when arranged in different forms. Newton, who first entered upon these speculations, investigated almost all the cases which from applicable to physical astronomy, but professor Playfair has lately extended these researches, and has presented a paper on the subject to the Philosopbical Society of Edinburgh, which would reflect honour on the first mathematicians of Europe. A few of the leading propositions of this excellent memoir, will follow the investigation of the law of gravitation to a sphere.

Of the gravitation of particles of matter to spheres, and other mathematical figures.

1. A particle of matter placed within a sphere of uniform density, remains in equilibrium.

Let A L B M, a l b m, (Plate XV. Astronom:, fig. 12.) be two spherical surfaces, of which C is the common centre, and let the space between them be filled with gravitating matter, uniformly dense. Let p be a particle placed any where within this spherical shell; to every particle of which it gravitates with a force inversely as the square of its distance from it. This particle will have no tendency to move in any direction, because
its gravitation in any one direction is exactly balanced by an equal gravitation in the opposite direction.

Draw through $p$ the two straight lines $dp, pe$, making a very small angle at $p$. This may represent the section of a very slender double cone $dpe, ep$, having $p$ for the common vertex, and $de$ is for the diameter of the circular bases. The gravitation of $p$ to the matter in the base $de$ is equal to its gravitation to the matter in the base $e$. For the number of particles in $de$ is to the number in $e$, as the surface of the base $de$ to that of the base $e$, that is, as $de^2$ to $e^2$, that is, as $pd$ to $pe$, that is, as the gravitation to a particle in $de$ to the gravitation to a particle in $e$. Therefore the whole gravitation to the matter in $de$, is the same with the whole gravitation to the matter in $e$; since it is also in the opposite direction, the particle $p$ is in equilibrio. The same thing may be demonstrated of the gravitation to the matter in $q$, and $st$, and in a similar manner, of the gravitation to the matter in the sections of the cones $dp, ep$, by any other concentric surface. Consequently, the gravitation to the whole matter contained in the solid $dp, ep$, is equal to the gravitation to the whole matter in the solid $de, e$, and the particle $p$ is in equilibrio.

Now since the lines $dp, ep$, may be drawn in any direction, and thus be made to occupy the whole sphere, it is evident that the gravitation of $p$ is balanced in every direction, and therefore it has no tendency to move in any direction, in consequence of this gravitation to the spherical shell of matter comprehended between the surfaces $A L B M$ and $albn$.

It is also evident, that this holds true with respect to all the matter comprehended between $A L B M$, and the concentric surface $p n$ passing through $p$; in short $p$ is in equilibrio in its gravitation, to all the matter more remote than itself from the centre of the sphere, and appears as if it did not gravitate at all to any matter more remote from the centre.

We have suppos'd the spherical shell to be uniformly dense. But $p$ will still be in equilibrio, although the shell be made up of concentric strata of different densities, provided that each stratum be uniformly dense.

For if we suppos'd, that in the space comprehended between $A L B M$ and $p n$, there occurs a surface $albn$ of a different density from all the rest, the gravitation to the intercepted portions $gr$ and $st$ are equal, because those portions are of equal density, and are proportional to $pd^2$ and $pe^2$ inversely. The proposition may therefore be expressed in the following very general terms, "a particle placed any where within a spherical shell of gravitating matter, of equal density, at all equal distances from the centre, will be in equilibrio, and will have no tendency to move in any direction."

The equality of the gravitation to the surface $ed$, and to the surface $es$ is affirmed, because the numbers of particles in the two surfaces are inversely as the gravitations towards one in each.

For the very same reason, the gravitations towards the surfaces $ed$ and $qr$ and $ts$ are all equal. Hence may be derived an elementary proposition, which is of great use in all enquiries of this kind, namely,

If a cone, or pyramid $dp$, of uniform gravitating matter, be divided by parallel sections $de, qr, st$, &c. the gravitation of a particle $p$ in the vertex, to each of those sections, is the same, and the gravitations to the solids $pg, pd, qd, d$, &c. are proportional to their lengths $pg, pd, qd, d$, &c. the first part of this proposition is already demonstrated. Now, conceive the cone to be thus divided into innumerable slices of equal thickness: it is plain that the gravitation to each of these is the same; and, therefore, the gravitation to the solid $gr$, is to the gravitation to the solid $gd$, as the number of slices in the first, to the number of slices in the second, that is, as $pg$, the length of the first, to $qd$, the length of the second. The cone $dp$ was supposed extremely slender. This was not necessary for the demonstration of the particular case where all the sections were parallel; but in this elementary proposition, the angle at $p$ is supposed smaller than any alligned angle, that the cone or pyramid may be considered as one of the elements into which we may resolve a body of any form. In this resolution, the bases are supposed, if not otherwise expressly stated, to be parallel, and perpendicular to the axes; indeed, they are supposed to be portions $xy$, $yz$, $zx$, of spherical surfaces, having their centres in $p$: the small portions $xyz$, $xzy$, $yzx$, &c. are held as in insignificant, vanishing in the ultimate ratios of the whole.

It is easy, also, to see that the equilibrium of $p$ is not limited to the case of a spherical shell, but will hold true of any body composed of parallel strata, or strata formed, that the lines $p d$, $p e$, are cut in the same proportion by the sections $de$, $qr$, &c. In a spheroidal shell, for instance, whole inner and outer surfaces are similar, and similarly poited spheroids, the particle $p$ will be in equilibrio any where within it; because, in this case, the lines $pd$ and $ne$ are equal; so are the lines $p s$ and $od$, the lines $st$ and $rs$, the lines $qd$ and $dc$. In short, there is but one situation of the particle $p$ that injures this equilibrium.

But we may at the same time infer this very useful proposition,

2. If there be two solids, perfectly similar, and of the same uniform density, the gravitation to each of these solids, by a particle placed on or in each, is proportional to any homologous lines of the solids.

For, the solids being similar, they may be resolved into the same number of similar pyramids similarly placed in the solids. The gravitations to each of any corresponding pair of pyramids are proportional to the lengths of those pyramids. These lengths have the same proportion in every corresponding pair. Therefore, the absolute gravitations to the whole pyramids of one solid have the same ratio to the absolute gravitation to the whole pyramids of the other solid. And since the solids are similar, and the particles are at the similarly poited vertices of all the similar and similarly placed pyramids, the gravitation compounded of the absolute gravitations to the pyramids of one solid, has the same ratio to the gravitation similarly compounded of the absolute gravitations to the pyramids of the other.

3. The gravitation of an external particle to a spheroidal surface, strata, or entire sphere, which is equally dense at all equal distances from the centre, is the same as if the whole matter were collected in its centre.

Let $A L B M$ (fig. 124) represent such a sphere, and let $P$ be the external particle. Draw $P A C B$ through $C$, the centre of the sphere, and crost it by $L C M$ at right angles. Draw two right lines $PD$, $PE$, containing a very small angle at $P$, and cutting the great circle $A L B M$, in $D$, $E$, $F$, $G$. About $P$, as a centre with the distance $P C$, describe the arc $Cd m$, cutting $DP$ in $d$, and $EP$ in $e$. About the same centre describe the arc $DO$. Draw $d F$, $e G$, parallel to $AB$, and cutting $L C$ in $f$ and $g$. Draw $C K$ perpendicular to $PD$, and $H D, D S$, and $F E$, perpendicular to $AB$. Join $CD$ and $C F$.

Now, let the figure be suppos'd to turn round the axis $P B$. The semi-circumference $A L B$ will generate a complete spherical surface; the arc $CD$ will generate another spherical surface, having $P$ for the centre; the small
Gravitation.

Arcs \(DE, dE, FG\), will generate rings, or zones, of those spherical surfaces; \(DO\) will also generate a zone of a surface having \(P\) for its centre; \(fG\) and \(FI\) will generate zones of flat circular surfaces.

It is evident that the zones generated by \(DE\) and \(DO\), (which we may call the zones \(DE, DO\),) having the same radius \(D\), are to each other as their respective breadths \(DE, DO\). In like manner, the zones generated by \(de, fG, FI, FG\), being all at the same distance from the axis \(AB\), are as their respective breadths \(de, fG, FI, FG\).

But the zone \(DO\) is to the zone \(de\), as \(PD^2\) to \(PD^2\); for \(DO\) is to \(de\), as \(PD\) to \(PD\), and the radius of rotation \(D\) is to the radius \(dH\), also as \(PD\) to \(PD\). The circumstances, described by \(DO\) and \(de\), are, therefore, in the same proportion as \(PD^2\) to \(PD^2\); therefore the zones being as their breadths, and as their circumstances jointly, are as \(PD^2\) and \(PD^2\).

\(C\) and \(dH\), being the lines of the same arc \(CD\), are equal; therefore \(KD\) and \(fF\), the halves of chords equally distant from the centre, are also equal; therefore the triangles \(CDK\) and \(CFF\) are equal and similar. But \(CDK\) is similar to \(EDO\), for the right angles \(PDO\) and \(CDE\) are equal. Taking away the common angle \(CDO\), the remainders \(CDK\) and \(EDO\) are equal. In like manner, \(CFF\) and \(GF\) are similar; and, therefore, (since \(CD\) and \(CF\) are similar,) the elementary triangles \(EDO\) and \(GF\) are similar, and \(DO\) to \(DE\) is \(FI\) to \(GF\). The absolute gravitation, or tendency of \(P\), to the zone \(DO\), is equal to its absolute gravitation to the zone \(de\), because the number of particles in the first, is to the particles in the last, as \(PD^2\) to \(PD^2\); that is, as the gravitation to a particle in the first, to the gravitation to a particle in the last; therefore let \(e\) represent the circumference of a circle, whose radius is 1. The surface of the zone generated by \(DO\), will be \(DO \times \epsilon \times D^2\), and the gravitation to it will be \(DO \times \epsilon \times D^2\), to which \(\frac{d\epsilon \times \epsilon \times dH}{PD^2}\), or \(\frac{d\epsilon \times \epsilon \times dH}{PC^2}\), is equal. This expresses the absolute gravitation of the zone generated by \(DO\), this gravitation being exerted in the direction \(PD\).

But it is evident that the tendency of \(P\), arising from its gravitation to every particle in the zone, must be in the direction \(PC\). The oblique gravitation must, therefore, be estimated in the direction \(PC\), and must be reduced in the proportion of \(PD\) to \(PH\). It is plain that \(PD\) to \(PH\) is as \(de\) to \(fG\), because \(de\) and \(fG\) are perpendicular to \(PD\) and \(PH\); therefore the reduced, or central gravitation of \(P\) to the zone generated by \(DO\), will be expressed by \(fG \times \epsilon \times dH\).

But the gravitation to the zone generated by \(DO\), is to the gravitation to the zone generated by \(DE\), as \(DO\) to \(DE\), that is, as \(FI\) (or \(fG\)) to \(FG\). Therefore the central gravitation to the zone generated by \(DE\), will be expressed by \(\frac{FG \times \epsilon \times dH}{PC^2}\). Now, \(FG \times \epsilon \times dH\) is the value of the surface of the zone generated by \(FG\); and if all this matter were collected in \(C\), the gravitation of \(P\) to it would be \(\frac{FG \times \epsilon \times dH}{PC^2}\), and it would be in the direction \(PC\). Hence it follows, that the central gravitation of \(P\) to the zone generated by \(DE\), is the same as its gravitation to all the matter in the zone generated by \(FG\), if that matter were placed in \(C\).

What has been demonstrated respecting the arc \(DE\), is true of every portion of the circumference. Each has a substitute \(FG\), which being placed in the centre \(C\), the gravitation of \(P\) is the same. If \(PT\) touch the sphere in \(T\), every portion of the arc \(TL\) will have its substitute in the quadrant \(LB\), and every part of the arc \(AT\) has its substitute in the quadrant \(ATL\), as is easily seen. And hence it follows, that the gravitation of a particle, \(P\), to a spherical surface, \(ALBM\), is the same as if all the matter of that surface were collected in its centre.

We see also that the gravitation to the surface generated by the rotation of \(AT\) round \(AB\) is equal to the gravitation to the surface generated by \(TLB\), which is much larger but more remote.

What we have now demonstrated with respect to the surface generated by the semicircle \(ALB\), is equally true with regard to the surface generated by any concentric semicircle, such as \(a\). It is true, therefore, with regard to the shell comprehended between those two surfaces; for this shell may be resolved into innumerable concentric strata, and the proposition may be affirmed with respect to each of them, and therefore with respect to the whole. And this will be still true if the whole sphere be thus occupied.

Lastly, it follows that the proposition is still true, although these strata should differ in density, provided that each stratum is uniformly dense in every part.

It may, therefore, be affirmed in the most general terms, that a particle, \(P\), placed without a spherical surface, shell, or entire sphere, equally dense at equal distances from the centre, tends to the centre with the same force, as if the whole matter of the surface, shell, or sphere were collected there.

This will be found to be a very important proposition.

4. The gravitation of an external particle to a spherical surface, shell, or entire sphere, of uniform density at equal distances from the centre, is as the quantity of matter in that body directly; and as the square of the distance from its centre inversely.

For, if all the matter were collected in its centre, the gravitation would be the same, and it would then vary in the inverse duplicate ratio of the distance.

Cor. 1.—Particles placed on the surfaces of spheres of equal density, gravitate to the centres of those spheres with forces proportional to the radii of the spheres.

For the quantities of matter are as the cubes of the radii.

Therefore the gravitation \(g\) is as \(\frac{d^3}{d^2}\), that is, as \(a\).

Cor. 2.—The same thing holds true if the distance of the external particles from the centres of the spheres are as the diameters or radii of the spheres.

Cor. 3.—If a particle be placed within the surface of a sphere of uniform density, its gravitation at different distances from the centre will be as those distances. For, it will not be affected by any matter of the sphere that is more remote from the centre, and its gravitation to what is less remote, is as its distance from the centre by the half Cor.

5. The mutual gravitation of two spheres of uniform density in their concentric strata, is in the inverse duplicate ratio of the distance between their centres.

For the gravitation of each particle in the sphere \(A\), is to the sphere \(B\), the same as if all the matter in \(B\) were collected at its centre. Suppose it so placed:

The gravitation of \(B\) to \(A\) will be the same as if all the matter in \(A\) were collected at its centre. Therefore it will be as \(d^3\) inversely. But the gravitation of \(A\) to \(B\) is equal to that of \(B\) to \(A\). Therefore, \&c.

The absolute gravitation of two spheres whose quantities:
of matter are A and B, and the distance of their centres, is \( \frac{AB}{d} \). For the tendency of one particle of A to B, being the aggregate of its tendencies to every particle of B, is \( \frac{A \times B}{d^2} \). Therefore, the tendency of the whole of A to B must be \( \frac{AB}{d^2} \). And the tendency of B to A is equal to that of A to B.

6. But if the centripetal forces which tend to the different points of spheres are proportional to the simple distances from the attracting bodies, then the compound force with which two spheres attract each other mutually, is as the distance between the centres of the spheres.

Cafe 1.—Let A E B F (fig. 125.) be a sphere; S its centre; P a particle attracted; P A S B the axis of the sphere passing through the centre of the particle; E F, e f, two planes cutting the sphere and perpendicular to the axis, and equidistant one on one side, the other on the other, from the centre of the sphere; G and g the intersections of the planes and the axis; and H any point in the plane E F. The centripetal force of the point H on the particle P, exerted in the direction of the line P H, is as the distance P H; and the same exerted in the direction of the line P G, or towards the centre S, is as the length P G. Therefore, the force of all the points in the plane E F, (that is, of the whole plane) by which the particle P is attracted towards the centre S, is as the distance P G multiplied by the number of those points, that is, as the whole contained under that plane E F, and the distance P G. And, in like manner, the force of the plane e f, by which the particle P is attracted towards the centre S, is as that plane multiplied into its distance P g; or as the equal plane E F multiplied into that distance P g; and the sum of the forces of both planes is as the plane E F, multiplied into the sum of the distances P G + P g, that is, as that plane multiplied into twice the distance P S of the centre and the particle; that is, as twice the plane E F, multiplied into the distance P S, or as the sum of the equal planes E F + e f multiplied into the same distance. And by a similar train of reasoning, the forces of all the planes in the whole sphere, equidistant on each side from the centre of the sphere, are as the sum of those planes, multiplied into the distance P S, that is, as the whole sphere, and the distance P S jointly.

Cafe 2.—Let the particle P now attract the sphere A E B F, and, by the same reasoning, it will appear that the force with which the sphere is attracted is as the distance P S.

Cafe 3.—If another sphere be now composed of innumerable particles P, and because the force with which every particle is attracted is as the distance of the particle from the centre of the first sphere, and as the square of the distance conjugately, and is therefore the same as if the whole proceeded from a single particle situated in the centre of the sphere; the entire force with which all the particles in the second sphere are attracted, is that of which the whole sphere is attracted, will be the same as if that sphere were attracted by a force proceeding from a single particle in the centre of the first sphere, and is therefore proportional to the distance between the centres of the spheres.

Cafe 4.—Let the spheres attract each other mutually, and the force will be doubled, but the proportion will remain the same.

Cafe 5.—Let the particle P be placed within the sphere A E B F, (fig. 126.) and because the force of the plane e f, upon the particle, is as the solid contained under that plane and the distance p g; and the contrary force of the plane E F, is as the solid contained under that plane and the distance p G; the force compounded of both will be as the difference of the solids, that is, as the sum of the equal planes multiplied into half the difference of the distances; that is, as that sum multiplied into p S, the distance of the particle from the centre of the sphere. And, by a similar train of reasoning, the attraction of all the planes E F, e f, throughout the sphere, that is, the attraction of the whole sphere is conjointly as the sum of all the planes or as the whole sphere, and as p S the distance of the particle from the centre of the sphere.

Cafe 6.—And if a new sphere be now composed of innumerable particles, such as p, situated within the first sphere A E B F, it may be proved, as before, that the attraction, whether single of one sphere towards the other, or mutual of both towards each other, will be as the distance p S of the centres.

7. If the figures of the spheres be dissimilar and unequal, proceeding directly from the centre towards the circumference, but similar and equal throughout every circumference, at equal distances from the centres, and if the attractive force be as the distance of the attracted body, then the entire force with which two spheres of this kind attract each other mutually is proportional to the distance between the centres of the spheres. This is demonstrated from the preceding proposition.

The above investigations relate to the principal cases of attraction, namely, when the centripetal forces decrease in a duplicate ratio, or increase in the simple ratio of the distance. And it is remarkable that both these suppositions cause bodies to revolve in conic sections, and compose spheric bodies, whole centripetal forces observe the same law of increase or decrease, in the recedes from the centre, as the forces of the particles themselves do.

8. If a circle A E B (fig. 127.) be described round the centre S, and two circles E F, e f, be also described round the centre P, intersecting the former in E and e, and the line P S in F and f; and if E D, e d, be drawn perpendicular to P S; then if the distance of the arcs E F, e f, is supposed to be infinitely diminished, the limiting ratio of the evanescent line D d to the evanescent line F f is the same as that of the line P E to the line P S.

For if the line P E intersect the arc E F in q, and the right line E q, which coincides with the evanescent arc E q, be produced and meet the right line P S in T; and the perpendicular S G be drawn from S to P E, because the triangles D T E, d T e, D E S, are similar, D J will be to E e as D T to T E, or D S to E S; and because the triangles E q E, E S G, are similar, E e will be to e q or F F as E S to S G; and ex aequo D d is to F f as D E to S G; that is, (because the triangles P D E, P G S, are similar) as P E to P S.

9. If a superficiei, as E F f e (fig. 128.) be supposed to have its breadth infinitely diminished, and that by its revolution round the axis P S it describes a spheric concavo-convex solid to the several equal particles of which equal centripetal forces tend; then the force with which that solid attracts a particle placed at P is in a ratio compounded of the ratio of the solid D E' \times F f, and the ratio of the force with which the given particle in the place F f would attract the same particle.

For if the force be first considered of the spheric superfiicies F E, which is generated by the revolution of the arc F E, and is intersected any where, as in r, by the line d s, the annular part of the superficies generated by the revolution
GRAVITATION.

revolution of the arc \( r E \) will be as the small line \( D d \), the radius of the sphere remaining the same; as Archimedes has demonstrated in his book on the sphere and cylinder.

And the force of this superficies exerted in the direction of the lines \( P E \) or \( P r \) situated all round in the conical superficies, will be as this annular superficies itself; that is, as the line \( D d \) or, which is the same, as the rectangle under the given radius \( P E \) of the sphere, and the line \( D d \); but that force, exerted in the direction of the line \( P S \), tending to the centre \( S \), will be in the ratio of \( P D \) to \( P E \), and therefore will be as \( P D \times D d \).

If the line \( D F \) be now considered as divided into innumerable equal particles, each of which may be called \( D d \), then the superficies \( F E \) will be divided into so many equal annuli, whose forces will be as the sum of all the rectangles \( P D \times D d \); that is, as \( \frac{1}{2} P F^2 \times \frac{1}{2} P D \) and therefore as \( D E' \).

Let now the superficies \( F E \) be multiplied into the altitude \( F f \), and the force of the solid \( E F f \) exerted upon the particle \( P \) will be as \( D E' \times F f \); that is, if the force be given which any given particle, as \( F f \), exerts upon the particle \( P \) at the distance \( P F \). But if that force be not given, the force of the solid \( E F f \) will be as the solid \( D E' \times F f \); and that force not given conjointly.

10. If to the several equal parts of a sphere \( A B E \), fig. 125,) described about the centre \( S \), there tend equal centripetal forces; and from the several points \( D \), perpendicular \( D E \), drawn to the axis of the sphere \( A B \), in which a particle \( P \) is placed, moving in the sphere in \( E \); and if in these perpendiculars the length \( D N \), be taken as the quantity \( D E' \times PS \), and as the force which a particle of the sphere

situated in the axis exerts at the distance \( P E \) upon the particle

situated conjointly, then the whole force with which the particle \( P \) is attracted towards the sphere is as the area \( ANB \), comprehended under the axis of the sphere \( A B \), and the curve line \( ANB \), the locus of the point \( N \).

For supposing the construction in the last lemma, and theorem to remain, let the axis of the sphere \( A B \) be supposed to be divided into innumerable equal particles \( D d \), and the whole sphere to be divided into so many spherical conico-convex laminae \( E F f \), and let the perpendicular \( d n \) be drawn.

By the last theorem the force with which the lamina \( E F f \) attracts the particle \( P \), is as \( D E' \times F f \), and the force of one particle exerted at the distance \( P E \) or \( P F \) conjointly.

But (by the last lemma) \( D d \) is to \( F f \) as \( P E \) to \( P S \), and therefore \( F f \) is equal to \( D d \times \frac{D E' \times PS}{P E} \); and \( D E' \times F f \) is equal to \( D d \times \frac{D E' \times PS}{P E} \); and therefore the force of the lamina \( E F f \), is as \( D d \times \frac{D E' \times PS}{P E} \); and the force of a particle exerted at the distance \( P F \) conjointly; that is, by the supposition, as \( D N \times D d \), or as the evanescent area \( D N \times d \).

Therefore the forces of all the laminae exerted upon the particle \( P \) are as the areas \( D N d \), that is, the sphere will be as the whole area \( ANB \).

Cor. 1.—Hence if the centripetal force tending to the several particles remain always the same at all distances, and \( DN \) be made as \( \frac{D E' \times PS}{P E} \), the whole force with which the particle is attracted by the sphere is as the area \( ANB \).

Cor. 2.—If the centripetal force of the particles vary reciprocally as the distance of the particle attracted by \( A \), and

\[ \text{DN be made as } \frac{D E' \times PS}{P E}, \] the force with which the particle \( P \) is attracted by the whole sphere will be as the area \( ANB \).

Cor. 3.—If the centripetal force of the particles vary reciprocally as the cube of the distance of the particle attracted by it, and \( DN \) be made as \( \frac{D E' \times PS}{P E} \), the force with which the particle is attracted by the whole sphere will be as the area \( ANB \).

Cor. 4.—And universally of the centripetal force tending to the several particles of the sphere be supposed to be reciprocally as the quantity \( V \); and \( DN \) be made as \( \frac{D E' \times PS}{P E} \), the force with which a particle is attracted by the whole sphere will be as the area \( ANB \).

11. Supposing everything to remain as above, it is required to measure the area \( ANB \).

From the point \( P \) let the right line \( PH \) be drawn touching the sphere in \( H \); and having drawn \( HI \) perpendicular to the axis \( P A B \), bisect \( PI \) in \( L \), and \( PE' \) will be equal to \( PS' \times SE' \times 2 PSD \). But because the triangles \( SHP, SHI \), are similar, \( SE' \parallel SH' \) is equal to the rectangle \( PSI \).

Therefore \( PE' \) is equal to the rectangle contained under \( PS \) and \( PS \times SI \times 2 SD \); that is, under \( PS \) and \( 2 LS \times 2 LD \); that is, under \( PS \) and \( 2 LD \).

Moreover \( DE' \) is equal to \( SE'-SD' \), or \( SE'-LS'+2SLD-\frac{1}{2}LD \); that is, \( 2SLD-\frac{1}{2}LD \) ALB.

For \( LS'-SE' \), or \( LS'-SA' \), is equal to the rectangle \( ALB \).

Therefore if instead of \( DE' \) we write \( 2SLD-\frac{1}{2}LD \) ALB, the quantity \( DE' \times PS \) which is as the length of the ordinate \( DN \), will now resolve itself into three parts, \( \frac{2SLD \times PS}{PE \times V} \) \( \frac{PE \times V}{PE \times V} \) \( \frac{ALB \times PS}{PE \times V} \); where, if instead of \( V \) we write the inverse ratio of the centripetal force, and instead of \( PE \), the mean proportion between \( PS \) and \( 2 LD \), those parts will become the ordinates of so many curve lines, whose areas may be found by the common methods.

Ex. 1.—If the centripetal force tending to the several particles of the sphere be reciprocally as the distance, instead of \( V \) write \( PE \) the distance, then \( 2PS \times LD \) for \( PE' \); and \( DN \) will become as \( SL-\frac{1}{2}LD \) ALD.

Suppose \( DN \) equal to the double \( 2SL \times LD \) ALB.

and \( 2SL \) the given part of the ordinate drawn into the length \( AB \) will describe the rectangular area \( 2SL \times AB \); and the indefinite part \( LD \) drawn perpendicularly into the same length with a continued motion, according to such a law that its motion in each direction may, by increasing or decreas-

ing, remain always equal to the length \( LD \), will describe the area \( \frac{1}{2}LB - \frac{1}{2}LA \times \frac{1}{2}LD \), that is the area \( SL \times AB \); which taken from the former area \( 2SL \times AB \), leaves the area \( SL \times AB \). But the third part \( \frac{1}{2}LD \), drawn in a similar manner with a continued motion perpendicularly into the same length, will describe the area \( SL \times AB \); which subtracted from the area \( SL \times AB \) will leave \( AB \) the area sought. Whence this conclusion of the problem arises. At the points \( L, A, B \), (fig. 131.) erect the
the perpendiculars $L'$, $A'$, $B'$; making $A'$ equal to $L'B'$, and $B'$ equal to $A'L$. Making $L'$ and $L'B'$ asymptotes, describe through the points $a'$, $b'$, the hyperbolic curve $a'b'$; and the chord $a'b'$ being drawn, will enclose the area $a'b'$ equal to the area required $A'B'$.

Example 2.—If the centripetal force tending to the several particles of the sphere be reciprocally as the cube of the distance, or, (which is the same thing,) as that cube applied to any given plane; substitute $\frac{PE^3}{AS}$ for $V$, and $2PS \times LD$ for $PE'$; and $DN$ will become as $SL \times AS - AS^2 - ALB \times AS^2 - 2PS \times LD$; that is, (because $PS, AS, SI$ are continually proportional,) as $\frac{SLI}{LD} - \frac{1}{2} SI = \frac{ALB \times SI}{2LD}$. If these three parts be then drawn into the length $AB$, the first, $\frac{SLI}{LD}$, will generate the area of an hyperbola; the second, $\frac{1}{2} SI$, the area $\frac{1}{2} AB \times SI$; the third, $\frac{ALB \times SI}{2LD}$, the area $\frac{ALB \times SI}{2L'A'}$, that is, $\frac{1}{2} A'B \times SI$: from the first subtract the sum of the second and third, and there will remain $A'B$, the area sought. Whence arises this construction of the problem. At the points $L, A, S, B,$ (fig. 132) erect the perpendiculars $L', A', S', B'$, of which suppose $S'$ equal $SI$; and through the point $s$, to the asymptotes $L', L'B'$, describe the hyperbola $a'b'$, meeting the perpendiculars $A'a, B'b$, in $a$ and $b$, and the rectangle $2A'SI$, subtracted from the hyperbolic area $A'a \times b'B'$, will leave $A'B$, the area required.

Example 3.—If the centripetal force, tending to the several particles of the sphere, decrease in a quadruplicate ratio of the distance from the particles, substitute $\frac{PE^4}{2AS^3}$ for $V$, then $\sqrt[4]{2PS + LD}$ for $PE$, and $DN$ will become $\frac{SI' \times SL}{\sqrt{2S'I} \times \sqrt{2S'I}} - \frac{1}{\sqrt{2} \times \sqrt{2} SI} \times \frac{1}{\sqrt{2} \times \sqrt{2} LD} - \frac{SI' \times ALB}{2 \sqrt{2} S'I} = \frac{1}{\sqrt{2}} SI' - \sqrt{2} SI$. These three parts, drawn into the length $AB$, produce as many areas, namely, $\frac{2S'I \times SL}{\sqrt{2S'I}}$, and $\frac{SI' \times ALB}{\sqrt{2} S'I}$, into $\frac{1}{\sqrt{2}} LA = \sqrt{LB - \sqrt{LA}}$, and $\frac{1}{\sqrt{2}} S'I \times ALB$ into $\frac{1}{\sqrt{2}} LA - \frac{1}{\sqrt{2}} LB'$; and these, after the proper reduction, become $\frac{2S'I \times SL}{LI}, SI', and \frac{2S'I}{3LI}$: and these, by substracting the latter terms from the former, become $\frac{4S'I}{3LI}$; therefore the entire force with which the particle $P$ is attracted towards the centre of the sphere, is as $\frac{S'I}{PI}$, that is, reciprocally as $PS \times PL$.

The attraction of a particle, situated within the sphere, may be determined by the same method; but more expeditiously by the following theorem.

12. If $SI$, $SA$, $SP$, (fig. 133.) be taken continually proportional, in a sphere described round the centre $S$, with the radius $SA$, then the attraction of a particle within the sphere, in any place $P$, is to its attraction, without the sphere, in a place $P'$, in a ratio compounded of the sub-duplicate ratio of $IS$, $PS$, the distances from the centre, and the sub-duplicate ratio of the centripetal forces tending to the centre in those places, $P$ and $I$.

As, if the centripetal forces of the particles of the sphere be reciprocally as the distances of the particle attracted by them, the force with which the particle situated at $I$ is attracted by the entire sphere, will be to the force with which it is attracted at $P$, in a ratio compounded of the sub-duplicate ratio of the distance $SI$ to the distance $SP$, and the sub-duplicate ratio of the centripetal force in the place $I$, arising from any particle in the centre to the centripetal force in the place $P$, arising from the same particle in the centre; that is, in the sub-duplicate ratio of the distances $SI$, $SP$, to each other reciprocally. These two sub-duplicate ratios compose the ratio of equality; and, therefore, the attractions in $I$ and $P$, produced by the whole sphere, are equal. By a similar calculation, if the forces of the particles of the sphere are reciprocally in a duplicate ratio of the distance, it will be found that the attraction in $I$ is to the attraction in $P$, as the distance $SP$ to the semi-diameter $SA$ of the sphere. If those forces are reciprocally in a triplicate ratio of the distances, the attractions in $I$ and $P$ will be to each other as $SP^3$ to $SA^3$; if in a quadruplicate ratio, as $SP^4$ to $SA^4$. Therefore, since the attraction in $P$, in this last case, was found to be reciprocally as $PS^3 \times PI$, the attraction in $I$ will be reciprocally as $SA^3$ into $PI$; that is, because $SA^3$ is given reciprocally as $PI$; and the progression is the same indefinitely. The demonstration of this theorem is as follows:

Retaining the same construction as above, and a particle being in any place $P$, the ordinate $DN$ was found to be as $DE^4 \times IS \over TE \times V$; therefore, if $IE$ be drawn, that ordinate for any other place of the particle, as $I$, will become (substituting $PS$ and $PE$ for $IS$ and $IE$) as $DE^4 \times IS \over TE \times V$.

Suppose the centripetal forces proceeding from any point of the sphere, as $E$, to be to each other at the distances $IE$ and $PE$, as $PE$ to $IE$ (where the number $n$ denotes the index of the powers of $PE$ and $IE$); and those ordinates will become as $PE^4 \times IS \over PE^4 \times PS \times PE^n = IS \times IE^n$. Suppose the centripetal forces proceeding from any point of the sphere, as $E$, to be to each other at the distances $IE$ and $PE$, as $PE$ to $IE$ (where the number $n$ denotes the index of the powers of $PE$ and $IE$); and those ordinates will become as $PE^4 \times IS \over PE^4 \times PS \times PE^n = IS \times IE^n$. Because $S$, $I$, $E$, $SP$, are continually proportional, the triangles $SPE$, $SEI$, are alike; and hence $IE$ is to $PE$, as $IS$ to $SE$, or $SA$. Substitute the ratio of $IS$ to $SA$ for the ratio of $IE$ to $PE$, and the ratio of the ordinates becomes that of $PS \times IE^n$ to $SA \times PE^n$. But the ratio of $PS$ to $SA$ is sub-duplicate of that of the distances $PS$, $SI$, and the ratio of $IE^n$ to $PE^n$, (because $IE$ is to $PE$ as $IS$ to $SA$) is sub-duplicate of that of the forces at the distances $PS$, $IS$; therefore the ordinates, and consequently the areas which the ordinates describe, and the attractions proportional to them, are in a ratio compounded of those sub-duplicate ratios.

13. To find the force with which a particle, placed in the
GRAVITATION.

centre of a sphere, is attracted towards any segment of that sphere.

Let P (fig. 134.) be a particle in the centre of a sphere, and R B S D a segment thereof contained between the plane R D S, and spherical superficies R B S. Let D B be intersected in F by a spherical superficies E F G, described from the centre P, and let the segment be divided into the parts P F E G, P E D G; let that surface be supposed not purely mathematical, but phytical, leaving some but a very inconsiderable thickness; let that thickneff be called O, and (by what Archimedes has demonstrated) that superficies will be as P F x O; let us suppose besides, the attractive forces of the particles of the sphere, to be reciprocally as that power of the distances which n is the index; and the force with which the superficies

E F G attracts the body P will be

\[
\frac{2 \text{DE} \times \text{O}}{\text{PF}^{n+1}} - \frac{\text{DF}^2 \times \text{O}}{\text{PF}^n}
\]

Let the perpendicular F N, drawn into O, be proportional to this quantity, and the curvilinear area D B I, which the ordinate F N, drawn through the length D B, with a continued motion defcribes, will be as the whole force with which the whole segment R B S D attracts the body P.

14. To find the force with which a particle, placed without the centre of a sphere, in the axis of any segment, is attracted by that segment.

Let the body P, placed in the axis A D B, of the segment E B K (fig. 135.) be attracted by that segment: round the centre P, with the radius P E, let the spherical surface E F K be described; and let it divide the segment into two parts E B K F and E F K D E. Let the force of the former part be found by Prop. 11. and, the force of the latter part by Prop. 13. and the sum of the forces will be the force of the whole segment E B K D E.

These are the principal propositions by which Newton has investigated the nature of the attraction exercised by spherical bodies. In the thirteenth fection of the Principia, the author shews the manner in which the law of attraction is investigated for other bodies; the most interefting refults are contained in the following propofitions.

Of the attractive forces of bodies which are not of a spherical figure.

15. If a body be attracted by another, and its attraction be considerably stronger when it is contiguous to the attracting body, than when they are separated from one another by a very small interval; the forces of the particles of the attracting body decrease, as the attracted body recedes, in more than a duplicate ratio of the particles attracted.

16. If the forces of the particles, of which an attracting body is composed, decrease as the attracted body recedes, in a trinfec, or more than trinfec ratio of the distance from the particles, the attraction will be considerably stronger in the place of contact, than when the attracting and attracted bodies are separated from each, though by the moft minute interval.

17. If two bodies, similar to each other, and consisting of matter equally attracfive, attract separately two particles, proportional to those bodies, and in a similar situation to them; the accelerative attractions of the particles towards the entire bodies will be as the accelerative attractions of the particles towards particles of the bodies proportional to the whole, and similarly situated in them.

18. If the attractive forces of the equal particles of any body be as the distance of the places from the particles, the force of the whole body will tend to its centre of gravity; and will be the fame with the force of a globe, consisting of similar and equal matter, and having its centre in the centre of gravity.

19. If there be several bodies, consisting of equal particles, whose forces are as the distances of the places from each, the force compounded of all the forces by which any particle is attracted, will tend to the common centre of gravity of the attracting bodies; and will be the fame as if these attracting bodies, preserving their common centre of gravity, should unite therewith, and be formed into a globe.

20. If a solid be plane on one side, and infinitely extended on all other sides, and consist of equal particles equally attractive, whose forces decrease, as they recede from the solid in the ratio of any power greater than the square of the distances; and a particle placed towards either part of the plane is attracted by the force of the whole solid; then the attractive force of the whole solid, as it recedes from its plane superfaces, will decrease in the ratio of a power whose base is the distance of a particle from the plane, and is indeed lefs by three than the index of the power of the distances.

Though the above propositions are fufficient for all atmo-"
GRAVITATION.

\[ A \times \times A E ; \text{ and as this equation is sufficient to determine the nature of the curve to which it belongs, therefore all the sections of the solid, by planes that pass through } A \text{, are similar and equal curves;} \text{ and the fold, in consequence, may be conceived to be generated by the revolution of } A C B, \text{ any one of those curves, about } A \text{ as an axis.}

The solid so generated may be called the solid of greatest attraction, and the line } A C B \text{ the curve of equal attraction.

11. To find the equation between the coördinates of } A C B, \text{ the curve of equal attraction.}

From } C \text{ (fig. 136.), } \text{ draw } C E \text{ perpendicular to } A B \text{; let } A B = a, \ A E = x, \ E C = y. \text{ It has been found that } A B^2 \times A E = A C^3 \text{, that is}

\[ a^2 x = (x^2 + y^2) \text{, or } a^2 x = (x^2 + y^2)^2 \text{, which is an equation to a line of the fifth order.}

To obtain } y \text{ in terms of } x, x^2 + y^2 = a^2 x^\frac{3}{2} - x^2 \text{ and } y = x^\frac{3}{2} - x^2. \text{ Hence } y = \frac{3}{2} x^\frac{3}{2} - x^2, \text{ that is, } x = \frac{a}{3} \frac{3}{2} \sqrt{7}, \text{ or } 3 x^\frac{3}{2} = a. \text{ If } x \text{ be supposed greater than } a, \text{ it is impossible. No part of the curve, therefore, lies beyond } B.

The parts of the curve on opposite sides of the line } A B \text{ are similar and equal, because the positive and negative values of } y \text{ are equal. There is also another part of the curve on the side of } A \text{, opposite to } B, \text{ similar and equal to } A C B \text{; for the values of } y \text{ are the same, whether } x \text{ be positive or negative.

111. The curve may be easily confuted without having recourse to the value of } y \text{ just obtained. Let } A B = a \text{ (fig. 136.), } A C = z, \text{ and the angle } B A C = \frac{\pi}{2}. \text{ Then } A E = A C \times \cos \frac{\pi}{2} = a \cos \frac{\pi}{2}, \text{ and so}

\[ a \cos \frac{\pi}{2} \cdot \cos \pi = z, \text{ or } a \cos \pi = z. \text{ Hence } z = a \sqrt{2} r.

From this formula a value of } A C \text{ or } z \text{ may be found, or the angle } B A C \text{ be given; and if it be required to find } z \text{ in numbers, it may be conveniently calculated from this expression. A geometrical construction may also be easily derived from it. For if with the radius } A B, \text{ a circle } B F H \text{ be described from the centre } A \text{; if } A C \text{ be produced to meet the circumference in } F, \text{ and if } F G \text{ be drawn at right angles to } A B \text{, then}

\[ \frac{AG}{AB} = \cos \frac{\pi}{2} \text{, and so } z = a \times

\[ \sqrt{A B \times AG} = A C. \text{ Hence, if from the centre } A \text{, with the distance } A B, \text{ a circle } B F H \text{ be described, and if a circle be also described on the diameter } A B \text{ as } A K B \text{, then drawing any line } A F \text{ from } A \text{, meeting the circle } B F H \text{ in } F, \text{ and from } F \text{ letting fall } F G \text{ the perpendicular on } A B \text{, intersecting the semicircle } A K B \text{ in } K \text{, and if } A K \text{ be joined, and } A C \text{ made equal to } A K \text{, the point } C \text{ is on the curve.}

For } A K = \sqrt{A B \times AG} \text{, from the nature of the semicircle, and therefore } A C = \sqrt{A B \times AG} \text{, which has been shown to be a property of the curve. In this way a number of points of the curve may be determined; and the field of greatest attraction will be described, as already explained, by the revolution of this curve about the axis } A B.

IV. To find the area of the curve } A C B.

1. Let } A C E, A F G \text{ (fig. 135.) be two radii indefinitely near to one another, meeting the curve } A C B \text{ in } C \text{ and } F, \text{ and the circle described with the radius } A B \text{ in } E \text{ and } G. \text{ Let } A C = z \text{ as before, the angle } B A C = \pi, \text{ and } A B = a. \text{ Then } G E = a \sqrt{2}, \text{ and the area } A G E = \frac{1}{2}

\[ a^2 \frac{1}{2} z^2, \text{ and since } A E : A C : : \text{ sec } A E : \text{ sec } A E f. \text{ The sector } A C F = \frac{1}{2} z^2 \pi. \text{ But } z^2 = a^2 \cos \frac{\pi}{2}, \text{ whence the sector } A C F = \frac{1}{2} \pi a^2. \text{ But } z^2 = a^2 \cos \frac{\pi}{2} \text{, (III.) the sector } A C F \text{, or the fluxion of the area } A B C = \frac{1}{2} a^2 \frac{1}{2} \pi \cos \frac{\pi}{2}, \text{ and consequently the area } A B C = \frac{1}{2} a^2 \text{, fin. } z, \text{ to which no constant quantity need be added, because it vanishes when } z = 0 \text{, or when the area } A B C \text{ vanishes.}

The whole area of the curve therefore is } \frac{1}{2} a^2 \text{, or } \frac{1}{2} A B^2 \text{; for when } z \text{ is a right angle fin. } = 1. \text{ Hence the area of the curve on both sides of } A B \text{ is equal to the square of } A B.

2. The value of } x, \text{ or } x \text{, is a maximum, is easily found. For when } y \text{, and therefore } a^2 \text{, is a maximum, } \frac{1}{2} a^2 x - x = 0, \text{ or } x^2 = a. \text{ Hence } x = a \sqrt{2}, \text{ and therefore } a : b = \sqrt{2} : 2, \text{ or as } 1: 1: 1 \text{ nearly.

3. It is material to observe, that the radius of curvature } A \text{ is infinite: for since } y = a^2 x - x, x^2 = \frac{a^2}{x} - x, \text{ when } x \text{ be very small, or } y \text{ indefinitely near to } A, \text{ the circle becomes the diameter of the circle, having the same curvature with } A C B \text{ at } A; \text{ and when } A \text{ vanishes, this value of } y \text{, or}

\[ y = \frac{1}{2} x^2 - x \text{ becomes infinite, because of the divisor } a \text{ being in that case } = 0. \text{ The diameter, therefore, and the radius of curvature at } A \text{, are infinite. In other words, no circle, having its centre in } A B \text{ produced, and passing through } A, \text{ can be described with so great a radius, but that at the point } A \text{ it will be within the curve of equal attraction.

The field of greatest attraction then, at the extremity of its axis, where the attracted particle is placed, is exceedingly flat, approaching more nearly to a plane than the superficies of any sphere can do, however great its radius.

4. To find the radius of curvature at } B \text{, the other extremity of the axis, since } y = a^2 x - x, \text{ if we divide by}

\[ a - x, \text{ we have } y = \frac{a^2 x - x}{a - x} \text{ and so}

\[ \frac{a^2}{3} \frac{x}{a} \frac{1}{3} \frac{2}{3}. \text{ Hence the equation to the curve becomes in this case, } y = a^2 x - x, \text{ or } x = a \frac{1}{2} x^3 \text{, then we have } y = (a - x) \frac{1}{2} (a - x)^3.

But when } x \text{ is extremely small, its powers higher than the third may be rejected; and therefore } (a - x)^3 = a^3 \frac{1}{3} (1 - \frac{2}{3} x) \frac{1}{3}. \text{ Therefore the equation to the curve becomes in this case, } y = a^2 x - x, \text{ or } x = a^2 \frac{1}{2} a^2 - a^2 x + 2 x a x = a^2 \frac{1}{2} a^2 - a^2 x + 2 x a = \frac{1}{2} a^2 - a^2 x + a x.

Hence
GRAVITATION.

Hence \[ \frac{d^2}{dz^2}, \text{or the radius of curvature at } B = \frac{3}{2} a. \] The curve therefore at B falls wholly without the circle B K A, described on the diameter A B, as its radius of curvature is greater. This is also evident from the construction.

V. To find the force with which the solid above defined attracts the particle A in the direction A B.

Let B (fig. 137), be a point indefinitely near to B, and let the curve A c b be described similar to A C B; through C draw C D perpendicular to A B, and suppose the figure thus constructed to revolve about A B; then each of the curves A C B, A c b, will generate a solid of greatest attraction; and the excess of the one of these solids above the other, will be an indefinitely thin shell, the attraction of which is the variation of the attraction of the solid A C B when it changes into A c b.

Again, by the line D C, when it revolves along with the rest of the figure about A B, a circle will be described; and by the part C c, a circular ring, on which, if we suppose a solid of indefinitely small altitude to be constituted, it will make the element of the solid shell A C c. Now the attraction exerted by this circular ring upon A will be the same as if all the matter of it were united in the point C, and the same, therefore, as if it were all united in B.

But the circular ring generated by C c is \( \frac{\pi}{D} (D C - D c) = 2 \pi D C \times C c. \)

Now, \( 2 D C \times C c \) is the variation of \( y^2 \), or \( D C \), while \( D C \) passes into \( D c \), and the curve B C A into the curve b c A; that is, \( 2 D C \times C c \) is the fluxion of \( y^2 \), or of \( a^2 \); taken on the supposition that \( x \) is constant and \( y \) variable, namely \( \frac{1}{3} a^2 d x \). Therefore the space generated by \( C c = \frac{4 \pi}{3} a^2 d x. \)

If this expression be multiplied by \( x \), we have the element of the shell \( = \frac{4 \pi}{3} a^2 x d \).

In order to have the solidity of the shell A C B c, the above expression must be integrated relatively to \( x \), that is, supposing only \( x \) variable, and it is then \( \frac{1}{3} x \times \frac{4 \pi}{3} a^2 x d + C. \)

But \( C = C \), because the fluent vanishes when \( x \) vanishes, therefore the portion of the shell A C c = \( \frac{1}{3} x \times a^2 d \), and when \( x = a \) the whole shell \( = \frac{4 \pi}{3} a^2 d \).

Now, if the whole quantity of matter in the shell were united at B, its attractive force exerted on A would be the same with that of the shell, therefore the whole force of the shell \( = \frac{4 \pi}{3} a^2 d. \) The same is true for every other indefinitely thin shell, into which the solid may be supposed to be divided; and therefore, the whole attraction of the solid is equal to \( \int \frac{4 \pi}{3} a^2 d \), supposing a variable, that is, \( = \frac{4 \pi}{3} a^2 d. \)

Hence we may compare the attraction of this solid with that of a sphere of which the axis is A B, for the attraction of that sphere \( = \frac{\pi}{6} a^3 \times \frac{1}{3} a^2 = \frac{2 \pi}{3} a^5 \times a : \) the attraction of the solid ADBH (fig. 136), is therefore, to that of the sphere on the same axis as \( \frac{4 \pi}{3} a^2 \) to \( \frac{2 \pi}{3} a \), or as 6 to 5.

VI. To find the content of the solid ADBH, we need only integrate the fluxionary expression for the content of the shell, namely \( \frac{4 \pi}{3} a^2 d. \) We have then \( \frac{4 \pi}{15} a^2 \) = the content of the solid ADBH. Since the solidity of the sphere on the axis A is \( \frac{\pi}{6} a^3 \); the content of the solid ADBH is to that of the sphere on the same axis as \( \frac{4 \pi}{15} a^2 \) to \( \frac{\pi}{6} a^3 \); that is, as \( \frac{4 \pi}{15} \) to \( \frac{\pi}{6} \), or as 8 to 5.

VII. Lastly, to compare the attraction of this solid with the attraction of a sphere of equal bulk. Let \( m = \) any given mass of matter formed into the solid ADBH; then for determining A B, we have this equation \( \frac{4 \pi}{5} m^2 = \frac{\pi}{15} a^2 \); and, therefore, also, the attraction of the solid, \( \left( \text{which is } \frac{4 \pi}{5} a^2 \right) \) = \( \frac{4 \pi}{5} m^2 \sqrt{\frac{15}{4 \pi}} = m \left( \frac{4 \cdot 5^2 \cdot 3 \pi^2}{4 \cdot 5^5} \right) \)

= \( m \left( \frac{4 \cdot 5^2 \cdot 3 \pi^2}{4 \cdot 5^5} \right) \times \left( \frac{1 \cdot 4 \cdot 4 \cdot 5^4 \pi}{25} \right) \).

Again, if \( m \) be formed into a sphere, the radius of that sphere \( = \frac{\sqrt{3}}{4 \pi} \), and the attraction of it on a particle at its surface \( = \frac{m \left( \frac{16 \pi}{9} \right)}{m^2 \left( \frac{3}{4 \pi} \right)^2} \).

Hence the attraction of the solid ADBH is to that of a sphere equal to it, as \( m \left( \frac{16 \pi}{9} \right) \) to \( m \left( \frac{16 \pi}{9} \right)^2 \); that is, as \( (27)^2 \) to \( (25)^2 \), or as 3 to the cube root of 25.

The ratio of 3 to \( \frac{1}{25} \), is nearly that of 3 to \( \frac{3 - \frac{2}{27}}{3} \) or of 81 to 79; and this is therefore also nearly equal to the ratio of the attraction of the solid ADBH to that of a sphere of equal magnitude.

VIII. — It has been supposed in the preceding investigation, that the particle on which the solid of great attraction exerts its force, is in contact with that solid. Let it now be supposed, that the distance between the solid and the particle is given; the solid being in one of the plane of the plane and the particle at a given distance from the same plane on the opposite side. The mass of matter which is to compose the solid being given, it is required to construct the solid.

Let the particle to be attracted be at A (fig. 137), from A draw A A' perpendicular to the given plane, and let E F be any straight line in that plane drawn through the point A', it is evident that the axis of the solid required must be in A A' produced. Let B be the vertex of the solid, then it will be demonstrated as has been done above, that this solid is generated by the revolution of the curve of equal attraction, that of which the equation is \( y = a^2 x - x^2 \) about the axis of which one extremity is at A, and of which the length must be found from the quantity of matter in the solid.

The solid required then is a segment of the solid of great attraction, having B for its vertex, and a circle of which A E or A' F is the radius, for its base.

To find the solid content of such a segment, CD being \( y \), and A C = \( x \), we have \( y^2 = a^2 x^2 - x^2 \) and \( a^2 x^2 = \pi a^2 x^2 = \pi a^2 \times x^2 = \pi a^2 \times x^2 \) is the cylinder, which is the element of the solid segment.

Therefore \( \pi y^2 \), or the solid segment intercepted between B and D, must be \( \pi a^2 x^2 = \frac{\pi}{3} a^2 x^2 + C. \) This null vanishes when \( x = a \), or when C comes to B, and therefore
GRAVITATION.

fore \( C = \frac{4\pi}{15} a' \). The segment therefore intercepted between \( B \) and \( C \), the line \( A \) being \( x' \), is \( \frac{4\pi}{15} a' - \frac{3\pi}{5} \).

This also gives \( \frac{4\pi}{15} a' \), for the content of the whole solid,

when \( x = c \), the same value that was found by another method at \( VI \).

Now, if we suppose \( x \) to be \( = A A' \), and to be given \( = b \),

the solid content of the segment becomes \( \frac{4\pi}{15} a' - \frac{3\pi}{5} \).

\[ + \frac{\pi}{3} b \]  which must be made equal to the given solidity, which

we shall suppose \( m ^{3} \), and from this equation \( a' \), which is yet unknown, is to be determined. If then for \( a \) we put \( u \), we have \( \frac{\pi}{3} \) \( + 3 \) \( b \) \( u' - 3 \frac{1}{2} \) \( b \) \( u' - \frac{1}{2} b \) \( u' = \frac{m^{3}}{\pi} - \frac{b}{2} \), and \( u' = \frac{m^{3}}{\pi} - \frac{b}{2} \).

The simplest way of solving this equation would be by the rule of false position. In some particular cases it may be resolved more easily; thus, if \( \frac{15 m^{3}}{\pi} - \frac{b}{2} = c \), and \( a' = \frac{2}{3} b \), that is \( a'' = \frac{2}{3} b \), or \( a = b \times (\frac{2}{3}) \).

\[ \sqrt{\frac{729}{64}} \]

IX.—1. If it be required to find the equation to the superficies of the solid of greatest attraction, and also to the sections of its parallel to any plane passing through the axis; this can readily be done by help of what has been demonstrated above.

Let \( A H B \) (fig. 138), be a section of the solid, by a plane passing through \( A B \) its axis. Let \( G \) be any point in the superficies of the solid, \( F \) a perpendicular from \( G \) on the plane \( A H B \), and \( E F \) a perpendicular from \( F \) on the axis.

Let \( A E = x, \ E F = x, \ G F = x, \) then \( x, x, x, \) and \( x \) are the three co-ordinates by which the superficies is to be defined.

Let \( A B = a, \ E H = y, \) then from the nature of the curve \( A H B, y' = a^{2} x' - x'^{2} \). But, because the plane G H E is at right angles to \( A B, G \) and \( H \) are in the circumference of a circle of which \( E \) is the centre; so that \( G E = E H = y \).

Therefore \( E F^{2} + F G^{2} = E H^{2} \), that is \( x'^{2} + y'^{2} = a^{2} \), and by substitution for \( x'^{2} \) in the former equation, \( x'^{2} + y'^{2} = a^{2} x' - x'^{2} \), or \( a^{2} x' = x'^{2} \) which is the equation to the superficies of the solid of greatest attraction.

2. If we suppose \( E F \), that is \( e \), to be given \( = b \), and the solid to be cut by a plane through \( F \) and \( C \) being parallel to \( A B \) making on the surface of the solid the section \( D G C \); and if \( A K \) is drawn at right angles to \( A B \), meeting \( D C \) in \( K \), then we have, by writing \( b \) for \( e \) in either of the preceding equations, \( b^{2} + b' = a^{2} x' - x'^{2} \), and \( a^{2} = x'^{2} - x'^{2} = b^{2} \), for the equation to the curve \( D G C \), the co-ordinates being \( G F \) and \( F K \), because \( F K \) is equal to \( A L \) or \( a \).

This equation also belongs to a curve of equal attraction; the plane in which that curve is being parallel to \( A B \), the line in which the attraction is constant, and distant from it by the space \( b \).

Instead of reckoning the abscissa from \( K \), it may be made to begin at \( C \). If \( A E \) or \( C K = b \), then the value of \( b \) is determined from the equation \( b^{2} = a^{2} b^{2} - b' \), and if \( u = b + u \), \( b \) being put for \( C F \), \( u' = a^{2} (b + u)^{2} - b' \), or \( u' = (b + u)^{2} + b' = a^{2} (b + u)^{2} \), or \( (u' + b' + b') = a^{2} (b + u)^{2} \).

When \( b \) is equal to the maximum value of the ordinate \( E H \) (IV. 2) the curve \( C D G \) goes away into a point; and if \( b \) be supposed greater than this, the equation to the curve is impossible.

X.—The solid of greatest attraction may be found, and its properties investigated, in the same way that has now been exemplified, whatever be the law of the attractive force. It will be sufficient in any case to find the equation of the generating curve, or the curve of equal attraction.

Thus, if the attraction, which the particle \( C \) (fig. 136) exerts on the given particle at \( A \), be inversely as the \( m \) power of the distance, or as \( \frac{1}{A C} \), then the attraction in the direction \( A E \) will be \( \frac{A E}{A C + r} \), and if we make this \( = 1 \), we have \( \frac{A E}{A C + r} = \frac{1}{A B} m \), or making \( A E = x, L C = y \), and \( A B = a \), as before \( \frac{a}{a^{2} + x^{2} + y^{2} + \cdots} \).

If \( m = 1 \), or \( m + 1 = 2 \), this equation becomes \( y^{2} = a x - x^{2} \), being that of a circle of which the diameter is \( A B \).

If, therefore, the attracting force were inversely as the distance, the solid of greatest attraction would be a sphere.

If the force be inversely as the cube of the distance, or \( m = 3 \), and \( m + 1 = 4 \); the equation is \( y^{2} = a x - x^{3} \), which belongs to a line of the fourth order.

If \( m = 4 \), and \( m + 1 = 5 \); the equation is \( y^{2} = a x - x^{4} \), which belongs to a line of the tenth order.

In general, if \( m \) be an even number, the order of the curve is \( m + 1 \times 2 \); but if \( m \) be an odd number, it is \( m + 1 \) simply.

In the same manner that the solid of greatest attraction has been found, may a great class of similar problems be resolved. Whenever the property that is to exist in the greatest or least degree belongs to all the points of a plane figure, or to all the points of a solid, given in magnitude, the question is reduced to the determination of the locus of a certain equation, as in the preceding example.

Let \( s \), for instance, be required to find a solid given in magnitude, such, that from all the points in it, slant lines being drawn to any number of given points, the sum of the squares of the lines so drawn shall be a minimum. It will be found, by reasoning, as in the case of the solid of greatest attraction, that the superficies bounding the required solid must be such, that the sum of the squares of the lines drawn from any point in it, to all the given points, must always be of the same magnitude. Now, the sum of the squares of the lines drawn from any point, to all the given points, may be shown by plane geometry, to be equal to the square of the line drawn to the centre of gravity of those given points, multiplied by the number of points together with a given space.

The line, therefore, drawn from any point in the required superficies, to the centre of gravity of the given points, is given in magnitude, and therefore the superficies is that of a sphere,
GRA

sphere, having for its centre the centre of gravity of the given points.

The magnitude of the sphere is next determined from the condition that its solidity is given.

In general, if $x, y$ and $z$ are three rectangular co-ordinates, that determine the position of any point of a solid given in magnitude, and if the value of a certain function $z$ of $x, y, z$ be computed for each point of the solid, and if the sum of all these values of $z$ added together be a maximum or a minimum, the solid is bounded by a superficies, in which the function $z$ is everywhere of the same magnitude. That is, if the triple integral $\int \int \int z$ be the greatest or least possible, the superficies bounding the solid is such, that $z = A$, a constant quantity.

The same holds of plane figures. The proposition is then more simple, as there are only two co-ordinates, so that $\int x \int z$ is the quantity that is to be a maximum or minimum, and the line bounding the figure is defined by the equation $z = A$.

All the questions therefore that come under this description, though they belong to an order of problems, which requires in general the application of one of the most refined inventions of new geometry, the calculus variationium, form a particular division, admitting of solution by much more simple means, and directly reducible to the construction of loci.

In these problems also, the synthetical demonstration will be found extremely simple. In the instance of the solid of greatest attraction, this holds remarkably. Thus it is obvious, that $f(x, y, z)$ any particle of matter placed within the curve $A B C H$, will attract the particle at A in the direction $A B$, less than any of the particles in that curve, and that any particle of matter within the curve will attract the particle at A more than any particle in the curve, and more, $a fortiori$, than any particle without the curve. The same is true of the whole superficies of the solid. Now if the figure of the solid be any how changed while its quantity of matter remains the same, as much matter must be expelled from within the surface, at some place C, as is accumulated without the surface, at some other point H. But the action of any quantity of matter within the superficies $A B C H$ on A is greater than the action of the same without the superficies $A B C H$. The solid $A B C H$ therefore by any change of its figure must lose more attraction than it gains. Thus is its attraction not distinguished by every such change, and therefore it is itself the solid of greatest attraction.

Among a number of propositions which the limits of our work do not permit us to notice, it is proposed, "to determine the oblate spheroid of a given solidity, which shall attract a particle at its pole with the greatest force." And it appears that the gravitation at the pole of an oblate spheroid is not a maximum, until the excentricity of the generating ellipse vanish, and the spheroid passes into a sphere. When a sphere passes into an oblate spheroid its attraction varies at first exceeding slowly, and continues to do so till its oblateness, or excentricity, becomes very great.

The cone of greatest attraction has the radius of its base nearly double that of its altitude, and the attraction of the cone, when a maximum, is about $\frac{1}{2}$ the attraction of a sphere of equal solidity.

Of all the cylinders given in masts or quantity of matter, that which attracts a particle at the extremity of its axis with the greatest force is when the radius of the base of the cylinder is to the altitude as five to eight nearly, and it appears that the attraction of the cylinder, even when its form is the most advantageous, does not exceed that of a sphere of the fame solid content, by more than a hundred and eighty-third part.

A semi-cylinder given in magnitude, attracts a particle situated in the centre of its base, with the greatest possible, in the direction of a line biseecting the base, when the altitude of the semi-cylinder is to the radius of its base as 125 to 216.

GRAVITY, Centre of. See CENTER.

GRAVITY, Line of. See LINE.

GRAVITY, Plane of. See PLANE.

GRAVITY, Terrestrial is that force by which all bodies are continually urged towards the centre of the earth.

It is in consequence of this force that a body cannot remain at rest on the surface of the earth, without exercising a preasure either on some intermediate body, or on that portion of the surface of the earth which supports it; and the intensity of this force is measured by the degree of preasure, produced by a given mass. The tension of a string, by which a weight is suspended, arises from the force of gravity. The spring feel-yard, an instrument fold at the loops for weighing, is extremely well adapted to illustrate the effect of the force of gravity; the infufed fulbance draws out a scale by overcoming the refistance of the spring. These machines are not capable of great exactnecfs, but if an instrument of this kind could be made with sufficient accuracy, the alteration of the scale, (the weight remaining the same,) would shew any change in the force of gravity; and we might, by taking this apparatus to the summit of a high mountain, observe whether any change took place in the force of gravity by such an operation.

We measure likewise the force of gravity by the time which a body, suffered to descend freely from a state of rest, employs to fall through a given space, or (as has been explained under Dynamics) by the velocity which a body, thus falling, acquires at the end of a given time. Thus a body, falling freely, during the interval of one second, acquires a velocity of $52\frac{2}{3}$, that is, it would strike an obstacle with the same force as another body of the same mass, which was moving uniformly with the velocity of $52\frac{2}{3}$ per second.

The density of the earth being about $2\frac{1}{2}$ that of water, we infer that the force of gravity of a sphere, 8000 miles in diameter, and whose specific gravity is twice and a half that of water, would attract a particle of matter placed jut without its surface, in such a manner as to cause it to move towards its centre, $16\frac{2}{3}$ feet in one second.

It is, however, to be observed, that it is only at the pole that the whole force of the earth's gravity is actually exerted on a particle of matter; at every other part of the earth's surface, the force of gravity is diminished by the motion of rotation, which producing a centrifugal force, opposite in its tendency to that of the force of gravity, diminishes the effect of the latter as we recede from the pole and approach the equator. But, besides this, there is another cause which contributes in a very remarkable manner to modify the force of gravity at different points of the earth's surface, which is the elliptic figure of the earth.

The equatorial regions being more elevated than the polar, are more removed from the influence of the central attraction. Both these circumstances, and their effects, must be attended to when we propose to make any very accurate computation of the force of terrestrial gravity.

The diminution of gravity arising from the elliptic figure is nearly equal to the product of the $\frac{1}{15}$th part of the force of gravity, by the square of the cosine of the latitude. The centrifugal force diminishes the force of gravity in the same proportion; thus by the combination of these two causes, the diminution of gravity from the pole to the equator

Vol. XVI.
equator is equal to 0.0694 multiplied by the square of the cosine of the latitude, the force of gravity at the equator being taken as unity.

The most exact instrument we possess, for measuring the intensity of the force, is the pendulum, whose oscillations are immediately accelerated or retarded by the slightest alteration in the force of gravity, and it is only by means of this instrument that we are enabled to infer with precision, the exact space that a heavy body falls through in one second of time.

**Gravity. The Nature of.**—Of the nature of gravitation, or the force of gravity, nothing more is known, than that it is apparently an essential property of matter, or, at least, of all matter that hitherto has become the object of human investigation, for Newton was not disposed to believe that that matter might exist which was not endowed with this property, and suggests the supposition that it is caused by the agency of an elastic medium pervading all space. This medium, he supposes, to be much rarer within the dense bodies of the sun, the stars, the planets, and the comets, than in the empty celestial spaces between them, and to grow more and more dense at greater distances from them, so that all these bodies are naturally forced towards each other by the excess of pressure. Upon this supposition, Dr. Young remarks, in his Lectures, that the effects of gravitation might be produced by a medium thus constituted, if its particles were repelled by all material substances with a force decreasing like other repulsive forces, simply as the distances increase; its density would then be every where such as to produce the appearance of an attraction, varying like that of gravitation. Such an ethereal medium would, therefore, have the advantage of simplicity, in the original law of its action, since the repulsive force, which is known to belong to all matter, would be sufficient, when thus modified, to account for the principal phenomena of attraction.

It may be questioned whether a medium, capable of producing the effects of gravitation in this manner, would also be equally susceptible of those modifications which have been supposed necessary to the transmission of light. In either case, it must be supposed to pass through the apparent substance of all material bodies with the most perfect freedom, and there would, therefore, be no occasion to apprehend any difficulty from a retardation of the celestial motion; the ultimate impenetrable particles of matter being, perhaps, scattered as thinly through its external form as stars are scattered in a nebula, which has still the distant appearance of an uniform light; and there seems no reason to doubt the possibility of the propagation of an undulation through the Newtonian medium, with the actual velocity of light.

It must be remembered, that the difference of its pressure is not to be estimated from the actual bulk of the earth, or any other planet alone, but from the effect of the sphere of repulsion of which that planet is the centre; and we may thus deduce the force of gravitation from a medium of no very enormous density.

Dr. Young observes, that a similar combination of a simple pressure with a variable repulsion is also observable in the force of cohesion, and supposes that if two particles of matter, floating in such an elastic medium, capable of producing gravitation, were to approach each other, their mutual attraction would at once be changed from gravitation to cohesion, upon the exclusion of the portion of the medium interceding between them. The well-known experiment of the two exhausted hemispheres of Magdeburg affords an illustration of this hypothesis, where we see apparent cohesion derived from atmospheric pressure, and if we place between them a thick ring of elastic gum, we may represent the natural equilibrium between the forces of cohesion and repulsion, for the ring would resist any small additional pressure with the same force as would be required for separating the hemispheres so far as to allow it to expand in an equal degree; and at a certain point the ring would expand no more; the air would be admitted and the cohesion destroyed, as when a fold of any kind is torn asunder. These suppositions, however, are directly opposite to the hypothesis which affirms to the elastic medium the power of passing freely through all the interstices of the ultimate atoms of matter, since it could never pass between two atoms cohering in this manner; we cannot, therefore, at present assert the identity of the forces gravitation and cohesion so strongly as theory would allow us to do if established. In short, the whole of our enquiries respecting the intimate nature of forces must be considered as merely speculative amusements, which are of no farther utility than as they make our views more general, and affird our experimental investigations.

La Place, after having shown how the law of gravitation is deduced from the phenomena of the solar system, concludes his reflections on this subject by enquiring whether the principle of gravitation is a primordial law of nature, or if it may not be the general effect of some unknown cause? Here, he observes, we are stopped by our ignorance of the nature of the intimate properties of matter, and deprived of every hope of answering this question in a satisfactory manner. Indeed, says this great author, of forming hypotheses on this subject, let us content ourselves with examining more particularly the manner in which this principle has been employed by philosophers.

They have admitted the five following suppositions:

1. That gravitation takes place between the most minute particles of bodies.
2. That it is proportional to the masses.
3. That it varies inversely as the square of the distance.
4. That it is transmitted instantaneously from one body to another.
5. And that it equally acts on bodies in a state of repose, and on those which by their motion in the direction of its action should seem likely to avoid a part of its influence.

The first of these propositions is, as we have seen, a necessary result of the equality which exists between action and reaction, every particle of the earth attracting it as the particle itself is attracted; this supposition is confirmed by the measures of the degrees of the meridian, and by experiments on pendulums; for amidst all the irregularities of the measured degrees, we may perceive the traces of a regular figure, which is conformable to the theory. The great influence that the comparison of Jupiter has upon the nodes and perigees of the orbits of its satellites, proves to us that the attraction of this planet is composed of the attractions of all its particles. The proportionality of the attractive force to the masses is demonstrated in the earth by experiments on pendulums, the oscillations of which are of the same length of whatever substance they are composed. It is proved in the celestial regions by the constant relation which exists between the squares of the periodic times of bodies revolving about a common focus, to the cubes of the greater axes of their orbits.

We have seen with what precision the almost absolute state of repose of the perihelia of the planetary orbits indicate that the force of gravity varies according to the inverse square of the distance; and now that we know the cause of the motions of these perihelia, we may regard this law as rigorously exact. It is the same with all emulations which proceed from a centre, such as light;
GRAVITY.

light; it seems as if all forces whose action could be perceived at sensible distances obeyed this law. It has lately been observed, that the attractions and repulsions of electricity and magnetism decrease in proportion to the squares of the distances. A remarkable property of this law is, that if the dimensions of all the bodies of the universe, their mutual distances and velocities were to be augmented or diminished proportionally, they would describe curves entirely similar to those described at present, and their appearances would be entirely the same. For the forces which animate them being entirely the result of attractions proportional to the masses divided by the squares of the distances, they would be augmented and diminished proportionally to the dimensions of this imaginary universe. It may be remarked at the same time that this property can only belong to the law of nature. Thus the apparent motions are independent of its absolute dimensions, as they are likewise of the motions it may have in space, and we can only observe and recognize relative phenomena.

It is this law which gives to spheres the property of attracting each other mutually, as if their whole masses were united at their respective centres. It determines also the orbits and the figures of the celestial bodies by lines and surfaces of the second order, at least if we neglect their perturbations and suppose them fluid.

We have no method of measuring the length of time in which gravity is propagated, because the action of the sun having once reached the planets, it continues to act on them as if the attractive force was communicated instantaneously to the extremities of the system. We cannot, therefore, ascertain in how long a time it is transmitted to the earth, no more than we could measure the velocity of light, were it not for the aberration, and the eclipses of Jupiter’s satellites. But it is not the same with the small difference that may exist in the action of gravity upon bodies according to the direction of their velocity.

M. de la Place has found by analysis, that an acceleration should result in the mean motions of the planets round the sun, and in the mean motions of the satellites about their planets.

M. de la Place had assumed this method of explaining the secular equation of the moon, when he believed, with other geometers, that it was inexplicable on the principle of universal gravitation. He found that if it arose from the same cause, a variation should be made in the contrary direction of the moon, in order to release it entirely from its gravity towards the earth, at least six million times greater than that of light; the true cause of this equation being now known, we are certain that the action of gravity is much greater than this. This force, therefore, acts with a velocity which we may consider as infinite; and we may conclude, that the action of the sun is transmitted in an invisible instant to the extremities of the planetary system.

Do any other forces act on the heavenly bodies beside their mutual attractions?

We are unacquainted with any, and we may affirm that their effect is totally insensible. We may likewise be certain that these bodies experience no sensible resistance from the fluids through which they pass, as light, the tails of comets, or the zodiacal light.

The attractive force disappears between bodies of an inconsiderable magnitude, and re-appears in their elements under a variety of forms. The solidity of bodies, their crystallization, the refraction of light, the elevation and defension of fluids in capillary tubes, and all chemical combinations, generally are the results of attractive forces, the knowledge of which forms the principal object of natural philosophy.

Are these forces the same as that of the gravity observed in the celestial regions, and modified on the earth by the figures of the integrant particles? To admit this hypothesis we must suppose much more space empty than full in all bodies, so that the density of their particles must be incomparably greater than the mean density of their whole volume. A spherical particle of one hundred thousandth of a foot in diameter should have a density at least ten thousand million of times greater than the mean density of the earth, to exert at its surface an attraction equal to the terrestrial gravity. But the attractive forces of bodies greatly far surpass this gravity, since they reflect light, whose direction is not changed by the attraction of the earth. The density of these particles should, therefore, be to that of substances in a ratio which the imagination would fear to admit, if their affinities depended on the law of universal gravitation. The ratio of the intervals which separate the particles of bodies to their respective dimensions, would be of the same order as in flars which form a nebula, which in this point of view may be considered as an immeasurable body. There is no reason, however, which absolutely forbids us to consider all bodies in this manner. Many phenomena are favourable to the supposition, particularly the extreme facility with which light penetrates diaphanous substances in all directions. The affinities would then depend on the integrant particles, and we might, by the variety of these forms, explain all the variety of attractive forces, and reduce to one general law all the phenomena of astronomy and natural philosophy. But the impossibility of ascertaining these figures, renders this investigation useless to the advancement of science.

Some geometers, to account for these affinities, have added to the laws of attraction, inversely as the squares of the distances, new terms which are insensible at small distances; but these terms would be the expressions of as many different forces, and besides being complicated with the different figures of the particles, they would only complicate the explanation of the phenomena.

Amidst these uncertainties the wise plan seems to be, to endeavour to determine by numerous experiments the laws of affinities; and to effect this, the most simple method appears to be, by comparing these forces with the repulsive force of heat, which may be itself compared with that of gravity. Some experiments already made with this view, afford us reason to hope, that one day these laws will be perfectly known, and that then, by the application of analysis, the philosophy of terrestrial bodies may be brought to the same degree of perfection, which the discovery of universal gravitation has procured for astronomy.

GRAVITY, in Hydrostatics. The laws of bodies gravitating in fluids, make the business of hydrostatics.

Gravity is here divided into absolute and specific.

Gravity, absolute or true, is the whole force with which the body tends downward.

Gravity, specific, called also relative, comparative, and apparent gravity, is the excess of gravity in any body, above that of an equal quantity or bulk of another; and denotes that gravity, or weight, peculiar to each species, or kind of natural body; and whereby it is distinguished from all other kinds.

In this sense, a body is said to be specifically heavier than another, when under the same bulk it contains a greater weight than that other; and that other is said to be specifically lighter than the first. Thus, if there be two equal spheres, each a foot in diameter; the one wood, the other lead, since the leaden one is found heavier than the wooden
GRAVITY.

one, it is said to be specifically, or in specific, heavier: and the wooden one specifically lighter.

This kind of gravity some call relative; in opposition to absolute gravity, which increases in proportion to the quantity or mass of the body.

Gravity, law of the specific, and buoyancy of bodies.—I. If two bodies be equal in bulk, their specific gravities are to each other as their absolute gravities. Thus a body is said to be twice as heavy, specifically, as another, if it have twice its gravity under the same bulk.

Hence, the specific gravities of equal bodies are as their denfities.

II. If two bodies, compared together, be of the same specific gravity, their absolute weights will be as their magnitudes or bulks.

III. The specific gravities of bodies of the same weight are in the reciprocal ratio of their bulks. Hence the masses of two bodies of the same weight are in a reciprocal ratio of their bulks.

IV. The specific gravities of two bodies are in a ratio compounded of the direct ratio of the absolute gravities, and the reciprocal one of their bulks. Hence, again, the specific gravities are as the denfities.

V. The absolute gravities of two bodies will be in a compound ratio of their specific gravities and their bulks.

VI. The bulks of two bodies will be in a compound ratio of their absolute gravities directly, and their specific gravities inversely.

VII. A body specifically heavier than a fluid, lofs so much of its weight therein as is equal to the weight of a quantity of the fluid of the same bulk.

For, suppose a cubic inch of lead immersed in water; a cubic inch of water will, thereby, be expelled from its place: but the weight of this water was fulfilled by the refilance of the ambient water. Therefore, such a part of the weight of the leaden cube must be refilled by the refilance of the ambient water, as is equal to the weight of the water expelled. The gravity of the body immersed, therefore, must be diminished by so much.

Hence, 1. Since a fluid, specifically heavier, has a greater weight, in the same bulk, than a lighter; the same body will lose a greater part of its weight in a fluid, specifically heavier, than in a lighter: and therefore it weighs more in a lighter than a heavier.

2. Equal homogeneous bodies weighing equally in air, lofe their equilibrium if one of them be immersed in a heavier fluid; the other in a lighter.

3. Since the specific gravities are as the absolute gravities under the same bulk; the specific gravity of the fluid will be to the gravity of the body immersed, as part of the weight lost by the fluid, to the whole weight.

4. Two solids, equal in bulk, loose the same weight in the same fluid; but the weight of the specifically heavier body is greater than that of the specifically lighter; therefore, the specifically lighter lofs a greater part of its weight than the specifically heavier.

5. Since the bulks of bodies, equal in weight, are reciprocally as the specific gravities; the specifically lighter lofs more weight in the same fluid than the heavier; wherefore, if they be in equilibrium in one fluid, they will not be so in another; but the specifically heavier will preponderate, and that the more, as the fluid is denser.

6. The specific gravities of fluids are as the weights lost by the same body immersed in the same.

VIII. To find the specific gravity of a fluid.—On one arm of a balance suspend a leaden globe; and to the other, fallen a weight, which is in equilibrium therewith in air. Immerge the globe successively in the several fluids, while specific gravities are to be determined, and observe the weight which balances it in each. These several weights, subtrahend, severally, from the first weight, the remainders are the parts of the weight lost in each fluid. Whence the ratio of the specific gravity of the fluids is seen.

Hence, as the denfities are as the specific gravities, we find the ratio of the denfities of the fluids at the same time.

This problem is of the utmost use: as by it the degree of purity or goodness of fluids is easily found; a thing not only of service in natural philosophy, but also in common life, and in the practice of physic. See Hydrometer.

That the specific gravity may be found the more accurately, the weight of the thread not immersed in the fluid is to be subtracted from the weight of the solid in air; and the force necessary to make the thread subside (if it be specifically lighter) is to be added to the weight lost. But if the thread that sustains the solid be heavier than the fluid, the weight of the thread in the air is to be subtracted from the weight of the solid in air; and the weight the thread loses from the weight lost in the fluid. Indeed, this precaution may be spared, if, in examining the specific gravity of several fluids, care be taken that the same thread be immersed in the same depth in each.

IX. To determine the ratio which the specific gravity of a fluid has to the specific gravity of a solid that is specifically heavier than the fluid.

Weigh any mafs of the solid in a fluid, and note the just weight therein; the specific gravity of the fluid will be to that of the solid, as the part of the weight lost by the solid to its whole weight.

X. The specific gravities of equally heavy bodies are reciprocally as the quantities of weight lofte in the same fluid. Hence we find the ratio of the specific gravities of solids, by weighing masses thereof, that are equal in air, in the same fluid; and noting the weights lost by each.

XI. A body, specifically heavier, depends in a fluid specifically lighter, with a force equal to the excess of its weight, above that of an equal quantity of the fluid.

Hence, 1. The force which sustains a specifically heavier body in a fluid, is equal to the excess of the absolute gravity of the body, above that of the fluid, under the same bulk: e. gr. 47 lbs. of copper loses 5 lbs. of its weight in water; therefore a power of 42 lbs. is able to sustain it.

2. Since the excess of the weight of a solid over the weight of a fluid specifically heavier, is less than that over the weight of a specifically lighter fluid under the same bulk; it will descend with less force in a specifically heavier fluid than in a lighter; and, consequently, it will descend more slowly in the former than in the latter.

XII. A specifically lighter body sinks in a heavier fluid, till the weight of a quantity of the fluid, equal in bulk to the part immersed, be equal to the weight of the whole body.

Hence, 1. Since the specific gravities of bodies of the same weight are reciprocally as their bulks; and the bulks of fluids equal in weight, are as the parts of the same fluid immersed therein; the specific gravities of fluids are reciprocally as the parts of the same body immersed therein.

2. A solid, therefore, immerges deeper in a lighter fluid than in a heavier, and deeper, as the proportion of the specific gravity of the solid to that of the fluid is greater.

3. If a body be of the same specific gravity with a fluid,
the whole body will be immerged; and it will remain in any given place of the fluid.

4. If a specifically lighter body be wholly immersed in a fluid, it will be urged, by the collaterals of the fluid, to ascend with a force equal to the excess of the weight of the fluid, bulk for bulk, over the weight of the solid.

5. A body, therefore, specifically lighter, lying on the bottom of a vessel, will not be raised up, unless the heavier fluid rise above such a part as is equal in bulk to a quantity of the fluid of the fame weight with the whole solid.

XIII. The specific gravity of a solid is to the specific gravity of a lighter fluid, wherein it is immersed, as the bulk of the part immerged is to the whole bulk.

XIV. The specific gravities of equal solids are as their parts immerged in the same fluid.

XV. The weight and bulk of a specifically lighter body, and the weight of the specifically heavier fluid, being given, to find the force required, to keep the solid wholly immerged under the fluid.

As this force is equal to the excess of the weight of the fluid beyond that of an equal bulk of the solid; from the given bulk of the solid, and the weight of a cubic foot of water, find, by the rule of three, the weight of a bulk of water equal to that of the body. From this subtract the weight of the solid; the remainder is the force required.

E. g. Suppose the force necessary to detain a solid eight feet in bulk, and 100 pounds in weight, under water, required; since a cubic foot of water is found to weigh 70 pounds, the weight of water under the bulk of eight feet, is 560; whence, 100 pounds, the weight of the solid, being subtracted; the remainder 460 pounds is the force necessary to detain the solid under water.

Hence, since a specifically lighter body ascends in a heavier fluid, with the same force that would prevent its ascent; by the present problem, we can likewise find the force wherewith a specifically lighter body ascends in a heavier.

XVI. The weight of a vessel, to be made of a specifically heavier matter; and that of a specifically lighter fluid, being given: to determine the cavity the vessel must have to swim on the fluid.

The weight of a cubic foot of the fluid being given, the bulk of the fluid equal to the weight of the vessel is found by the rule of three. If, then, the cavity be made a little bigger than this, the vessel will have less weight under the same bulk than the fluid, and will therefore be specifically lighter than the same, and consequently it will swim.

XVII. The force employed to retain a specifically lighter solid, under a heavier fluid; and the weight lost by a heavier solid in a lighter fluid, are each added to the weight of the fluid, and weigh together with it.

The several theorems here delivered, are not only all demonstrable from the principles of mechanics, but are conformable to experiment. In effect, experience is here found to answer exactly to calculation, as is abundantly evident from the courses of philosophical experiments, now frequently exhibited; where the laws of specific gravitation are well illustrated. See Hydrostatical balance.

The specific gravity of any substance is the relative weight of a given volume of it, compared with the same volume of some other substance taken as a standard, and which is usually distilled water at some given temperature. The absolute gravity of a body is its entire weight, its specific gravity is the weight of a given portion, as a cubic foot or cubic inch. As it would be very difficult, and in many cases impossible, to measure the exact volume required to be weighed, a method of determining the specific gravity of solids has been devised, founded on a principle of Archimedes. It appears to have been known to the Ancients, that when a solid body, heavier than water, is plunged into that fluid, it loses as much of its weight as is equal to the weight of the fluid it has displaced.

By the application of this principle we are enabled, in a very easy manner, to determine the specific gravity of a body by first weighing it in air and afterwards in water. Then if the weight in air be divided by the weight lost, or the difference of the weights in water and air, the quotient will express the specific gravity of that body, or the relative weight of an equal volume of that substance, and of the water in which the experiment was made.

The specific gravity of two fluids may be determined by the same principle; for if we weigh a solid of any magnitude, as a ball of glass, first in water and then in any other fluid, the quantities of weight lost in each experiment will be in the same proportion as the specific gravity of the two fluids.

The specific gravities of any substances, and in particular of fluids, such as are lighter than water, may also be very conveniently determined by means of a common balance, employing a phial with a common ground stopple filling it first with water and then either with a given fluid, or with a portion of the fluid of which the weight has been ascertained, together with as much water as is sufficient to exclude the air.

It is necessary to attend to a great number of minute circumstances when we wish to determine the specific gravities of substances to a great degree of accuracy; these will be particularly noticed when describing the particular instruments that have been invented for the purpose. See Hydrostatic, Balance, Hydrometer, &c.

One mode of ascertaining the specific gravities of fluids, differing but little from each other in density, is to have a series of globules of glass so loaded, as to correspond to the specific gravities indicated by as many numbers, which are marked on them, and throwing several of them together into the fluid, and to observe which of them remains nearly stationary, without either rising to the surface or sinking. This method, though not expeditious, appears to be very secure from error, and is well adapted to determine the strength of spirituous liquors. But in all these experiments it is necessary to be aware that a considerable change of the joint bulk of two substances is often produced by their mixture, and that in general their dimensions are considerably contracted. Thus, 18 gallons of water and 18 gallons of alcohol, instead of 36 gallons, make only 35 gallons, consequently the specific gravity of the compound is one 35th greater than the mean of the specific gravities of the ingredients. And in some cases the whole dimension of a single substance may even be contracted by the addition of another substance; thus iron, by the addition of one-eighth of its bulk of platinum, becomes contracted one-fourth of that bulk.

For measuring the specific gravity of gasses, Mr. Leslie has devised a new method, which consists in observing the time employed in emptying a vessel through a small orifice, by means of the pressure of an equal column of water.

A Table of Specific Gravities.

Principally from Davies and Lavother. Davies’s table is compiled with great diligence from many different authors; Lavother’s is chiefly extracted from Drillon; it is carried.
GRAVITY.

to four places of decimals, but little dependence can be placed on the last.

Solution of pure ammonia

Gravity, in Mechanics, denotes the conatus or tendency of bodies towards the centre of the earth.

That part of mechanics which considers the motion of bodies arising from gravity, is peculiarly called Statics.

Gravity, in this view, is distinguished into absolute, and relative.

The former is that with which a body descends freely through an unresisting medium: the laws of which see under DESCENT of bodies, ACCELERATION, MOTION, INCLINED PLANE, &c.

The latter is that with which a body descends after having spent part of its weight in overcoming some resistance. Such is that with which a body descends along an inclined plane, where some part is employed in overcoming the resistance, or friction of the plane. The laws of relative gravity, see under INCLINED PLANE, DESCENT, FLUID, RESISTANCE, &c.

Gravity, Centre of. See CENTER of gravity.
Gravity, Diameter of. See DIAMETER of gravity.
Gravity, Paracentric acceleration. See PARACENTRIC.
Gravity, Plane of. See PLANE of gravity.
Gravity, Retardation from. See RETARDATION.
Gravity of the air. See WEIGHT of the Air, AIR and ATMOSPHERE.

Gravity, in Music, is an affection of sound by which it becomes denominated grave, low, or flat.

Gravity stands in opposition to acuteness, which is that affection of sound by which it is denominated acute, sharp, or high.

The relation of gravity and acuteness, is the principal property on which music depends, and it is the distinct, fixed, and determinate quality of this relation which entitles founds to the denomination of 'equable, harmonical or musical.'

Gravity is, therefore, that modification of sound by which it is considered as grave or low, with respect to, or compared with, other sounds, that are acute or high. See ACUTE.

The degrees of gravity, &c. depend on the nature of the sonorous body itself, and the particular figure and quantity thereof: though, in some cases, they likewise depend on the part of the body where it is struck. Thus, e.g., the founds of two bells of different metals, and the same shape and dimensions, being struck in the same place, will differ as to acuteness and gravity; and two bells of the same metal will differ in acuteness, if they differ in shape or magnitude, or be struck in different parts.

So in chords, all other things being equal, if they differ either in matter, or dimension, or tension, they will also differ in gravity.

Thus again, the found of a piece of gold is much graver than that of a piece of silver of the same shape and dimensions; and in this case the tones are, ceteris paribus, proportional to the specific gravities: so a fold sphere of brass, two feet in diameter, will sound graver than another of one foot diameter; and here the tones are proportional to the quantities of matter, or the absolute weights.

Vol. XVI.

But it must be observed, that acuteness and gravity, as also loudness and lowness, are but relative things. We commonly call a found grave and loud, in respect to another which is grave, or low with respect to the former; so that the same found may be both grave and acute, and also loud and low, in different comparisons.

The degrees of acuteness and gravity make the different tones or tunes, of voices, or found; so we say one found is in tune with another, when they are in the same degree of gravity.

The immediate cause or means of this diversity of tones lies very deep. Mathematicians express the proportion of found to found, by the ratio of numbers. The moderns fix it on the different velocity of the vibrations of the sonorous body: in which Sense gravity may be defined, a relative property of found, which, with respect to some other, is the effect of a lesser number of vibrations accomplished in the same time, or of vibrations of a longer duration. In which sense also, acuteness is the effect of a greater number of vibrations, or vibrations of a shorter duration.

If the vibrations be isochronous, the found is called musical, and is said to continue at the same pitch. See CHORD AND STRING, in Music.

If two or more founds be compared in the relation of gravity, &c. they are either equal, or unequal, in the degree of tension. Such as are equal, or produced by isochronous vibrations, are called unison.

The unequal, including, as it were, a distance between each other, constitute that we call an interval in music; which is properly the difference, in point of gravity, between two founds.

Upon this inequality, or difference, does the whole effect depend; and in respect of this it is, that these intervals are divided into concords and disconcord. See HARMONICS AND RATIO.

As the gravity of founds depends on the thickness, length, and tension, of the strings, or on the length and diameter of the pipes, and, in general, on the volume or mass of the sonorous bodies; the increase of any of these qualities (except tension) augments the gravity of found. But there is no absolute point of gravity in nature, and no found is grave or acute, but by comparison.

GRAULKET, in Geography, a town of France, in the department of the Tarn, and chief place of a canton, in the district of Lavaur; nine miles N.E. of Lavaur. The place contains 1,119, and the canton 7159 inhabitants, on a territory of 185,519 square, in fix communes.

GRAUN, Charles Henry, in Biography, chapelmaster to Frederick II, the late king of Prussia, was the favourite composer of that prince, from 1732 to the time of his decease, in 1759. On the accession of the prince of Prussia to the throne in 1740, his majesty, having determined to have an Italian lyric theatre in his capital, sent Graun to Italy to study the Italian language and taste in music, and to engage vocal performers. Graun remained two years in Italy, during which time the king, his royal master, had constructed, in spite of the Silevian war, one of the most magnificent, complete, and convenient theatres in Europe, for which Graun was the composer to the end of his life; and even after his decease little music but of his composition was ever performed in it for a long time.

The works of this master are very numerous: before his arrival at Berlin, he set three or four operas in the German language at Brunswick, but the words were bad, and it is not fair to judge of his genius by those early productions. He composed for the Berlin theatre, in the space of fourteen years, from 1742 to 1756, twenty-seven Italian operas; and
and for the church; a Te Deum, and a Paeifone, besides miscellaneous productions of less importance, as odes and cantatas, with the overture and recitatives of the pastoral opera of Galatea, of which his majesty, Quantz, and Nichelmus, set the fongs.

On the decease of this excellent composer, innumerable poems and panegyrics were written to his memory. Among the "Critical Letters concerning Music," published by M. Marpurg, there is an address to M. Fried. Wilhelm Zachari, the celebrated poet and musician of Brunswick, recommending the death of Graun to his muse. No great stress can be laid on panegyrics; however, there are few of Grauns admirers, who are not ready to burn with fire and faggot all those who dare to doubt of this author's veracity.

"Graun, the brightest ornament of the German muse, the noble master of sweet melody, is now no more! creator of his own taste, he spoke not, but to our hearts; tender, soft, compassionate, elevated, pompous, and terrible, by turns—he could force tears of admiration from us, at his pleasure; an artist, who made no other use of art, than to imitate nature, in the most pleasing and expressive manner; each stroke of his pencil was equally perfect, full of invention, and of new ideas, his genius was inexhaustible. The model of sacred music, and in the theatre inimitable! a man who commanded our affections, not only by his talents, but by his virtues, of friendship, probity, and patriotism; no man was ever so universally lamented by the whole nation, from the king, to the lowest of his subjects."  

Now, to reverie the medal; it is denied, by the other party, that Graun was the creator of his own taste, which is the taste of Vinc; they deny, that he is ever pompous or terrible, but say, that an even tenor runs through all his works, which never reach the fullline, though the tender and graceful are frequently found in them; they are equally unwilling to subscribe to his great invention, or the originality of his ideas; and think that full more perfect models of sacred music may be found in the choruses of Handel, and the airs and duos of Pergolesi and Jomelli: nor can they well comprehend, how that composer can be called inimitable, who is himself an imitator.

We have recently examined the scores of Graun's operas, and fee no reason for changing the opinion which we formed 30 years ago. He was certainly a great master, elegant in his melodies, and correct and regular in his harmony; but if any one of his operas were now to be revised, it would be thought in want of variety and fire.

During the life of his great and ill-fated patron, he was revered as much at Berlin as Handel in England; both great men, most affable; but much discrimination is necessary in drawing a parallel between them. Handel formed his style on the best models of the old school, at the time of its greatest perfection; such as Geminiani, Colono, Alceg. Scarlatti, Stenerson, and Corelli: Graun on that of the inventor of the new style, Vinci; who, though extremely and justly admired for the grace and elegance of his melodies, the simplicity of his accompagnement, and the facility and elegance of his style in general, has been far surpassed by Pergolesi, Jomelli, Piccini, Sacchini, and Pachelbel. German is perhaps more obliged to Graun for smoothing, simplifying, and polishing the coarse, laboured, and indecent style of their old masters, than to any Italians that have been employed at the imperial court or at Dresden, to set the dramas of Apollonio Zeno and Metastasio. Handel had more spirit and invention, and Graun more polish and refinement. Handel was wholly unrivalled in the country where he spent the greatest part of his life; but Graun had a rival in the Roman Catholic courts, in the celebrated Haffi, his countryman, whose compositions were as much in circulation and favour all over Europe, as those of Vinci and Per- golesi. Those of Graun seem wholly confined to Germany, and almost to the court of Berlin; nor do we ever remember to have heard Mara sing one of his airs in England, though during many years he performed the principal female parts in his operas at Berlin. His Te Deum was first appointed to be performed at the concert of ancient music in 1758, by the late duke of Leeds, then marquis of Caernarthen, and it has continued a fock piece ever since. Many of his duets, and his Eob Requiem are admirable compositions, and it certainly deserves to be ranked very high among the great masters of the last century.

GRAUN, John Cottolin, brother of the above composer, and concert-mafer to his late Prussian majesty, Frederick II. His admirers at Berlin, say that "he was one of the greatest performers on the violin of his time, and most assuredly, a composer of the first rank; his overtures and symphonies are majestic, and his concertos are master-pieces, particularly those for two violins, in which he has united the most agreeable melody with all the learning that the art of counterpoint can boast; he has likewise frequently set the Salve Regina, and composed masses, which are rendered grand and noble by simplicity and good melody, even in the most laboured parts."

But less quarter is granted to this master, by the admirers of more modern music, than to his brother; they often find his overtures and symphonies too like those of Lulli, and too full of notes to produce any other effect, when played at Berlin, than that of lulling the hearers: and in his concertos and church music, when that is not the cafe, the length of each movement is more immoderate, than Christian patience can endure.

Perhaps the truth may lie between these two opinions; and with respect to the chapel-mafer Graun, it should be remembered, that he was seldom allowed to follow the bent of his own genius.

GRAUNT, John, born April 23, 1662, was brought up to the trade of a haberdasher, but by his good fortune and integrity in business he acquired the esteem of his fellow citizens, so as to be elected into the common council of the city of London. The bills of mortality, which were annually laid before this body, led Mr. Graunt to turn his attention to the science of political arithmetic. From very small beginnings he collected a large body of materials, from which he composed a work entitled "Natural and Political Observations made upon the Bills of Mortality." This work was well received by the public, and passed through several editions; it obtained likewise for the author an admission into the Royal Society, upon the particular recommendation of the king, who gave it in particular charge to those concerned, that if they found any more such tracts, they should be sure to admit them. It is generally supposed that Mr. Graunt received valuable assistance from Sir W. Petty; but the style is such as might be expected from a plain citizen, and the tabular form, presenting at one view the general results of a number of important facts, was a thought essentially leading to all the conclusions which have since been established relative to these subjects. After his retiration from business, he was admitted a trustee for Sir William Hackhouse, into the management of the New River Company, which, with the unlucky circumstance of his being a convert to popery, gave occasion to the groundless calumny of his having had a hand in the great fire of London.
At length he retired from the University for a time. His studies were pursued in a hermitage, and in the interval between his periods of residence at Cambridge, he had maintained a correspondence with his friends. He was a great admirer of Pope, and his letters are full of eulogy on his genius and accomplish-ments. His first publication was a collection of poems, which he dedicated to the Duke of Ormond, and this was followed by a collection of odes and elegies, which he dedicated to the Duke of Devonshire. His next work was a collection of poems and essays, which he dedicated to the Duke of Richmond. These works were followed by a collection of essays and poems, which he dedicated to the Duke of York. His last work was a collection of poems and essays, which he dedicated to the Duke of Marlborough. These works were followed by a collection of poems and essays, which he dedicated to the Duke of Richmond. His last work was a collection of poems and essays, which he dedicated to the Duke of York. His last work was a collection of poems and essays, which he dedicated to the Duke of Marlborough. He died at the age of 84, in 1734.

Gray, Thomas, in Biography, a distinguished English poet, descended from very respectable citizens of London, was born in Corsiliil, December the 26th, 1716. His grandfather was a considerable merchant; but his father, Mr. Philip Gray, was of an indolent and refractory temper; and therefore dissatisfied rather than increasing his paternal fortune. He had many children, of whom Thomas, the subject of these memoirs, was the fifth; all of them except himself died in their infancy, and he is said to have narrowly escaped suffocating, owing to a too great fulness of blood, which destroyed the rest, and he would certainly have been cut off as early, had not his mother, with a courage remarkable for one of her sex, ventured to open a vein with her own hand, which instantly removed the paxyoxin. He was probably destined for a profession, and accordingly sent to Eton school to acquire the fundamental stock of classical literature. Here he was placed under the immediate care of Mr. Anstruther, his mother's brother, at that time one of the ablest masters, and likewise a fellow of St. Peter's college, Cambridge, to which place Mr. Gray removed, and was admitted a pensioner in the year 1734. Of his residence at Cambridge few memorials are recorded; he seems rather to have cultivated a literary taste in silence, than to have had any aim at public distinction. He never gives any account of the university congratulators of the prince of Wales's marriage, and his verses were admitted to be the chief of the academical collection. His letters, during this period, to Mr. Well, which are printed by Mr. Maffon, show that he had little reverence for the graver studies, or for the dignified periphrases of the place, and that he had acquired that exaltedand profound sense which was the permanent feature in his character. He quitted college in 1738, and occupied a seat of chambers in the Inner Temple, with the avowed intention of studying the law. A Latin ode, addressed upon this occasion to Mr. Well, who had the same purpose in view, exhibits in a striking manner the ascendency which the poet possessed in his mind over the ideal lawyer; and on the invitation which Mr. Walpole gave him to be the companion of his travels, he had an offer of this intention, and never after refused it. They set out in the spring, and his letters from the different stages of his progress, are a proof of the intelligent curiosity with which he viewed the striking objects of art and nature, and the manners and habits of mankind. Thus, in his letter from

Amiens, he describes everything that he saw on the road, paints in vivid colours what was remarkable in the several towns through which he passed; and he adds, that "on every hillock is a windmill, a crucifix, or a Virgin Mary dressed in flowers, and a fort et robe; one sees not many people or carriages on the road; now and then a trotting friar, a countryman with a great muff, or a woman riding astride on a little ass, with short petticoats, and a great head-dress of blue wool." They travelled through France, crossed the Alps, visited the principal towns of Italy as far as Pisa, returned to Rome, and in the spring of 1741 proceeded to Venice. Upon their way these two companions fell into a disagreement, which occasioned their separation. Of this unfortunate incident the biographer says, "Mr. Walpole enjoins me to charge himself with the chief blame in their quarrel; confessing that more attention and complaisance, more deference to a warm friend, superior judgment and prudence, might have prevented a rupture that gave much uneasiness to both, and a lasting concern to the survivor; though, in the year 1744, a reconciliation was effected between them." Mr. Gray, with his own very moderate resources, finished the rest of the tour, and arrived in England in September 1741, two months previously to the death of his father. He now returned to academic retirement at Cambridge. In the following year he had the misfortune to lose his friend Mr. Well, the confident of his sentiments and partner of his studies. The death of this hopeful young man left a vacancy in Mr. Gray's heart, which was never after filled. He had an ambition to excel in Latin poetry, but was convinced that nothing could only be acquired by works according to the general taste of his countrymen. He made many noble beginnings of poems, which, if he had possessed perseverance enough to have completed them, would have returned to his immortal honour. In the year 1742, he took the degree of bachelor of civil law, a circumstance which gave him every necessary privilege for improving an university residence, and he set down to a course of reading, which he pursued with the diligence of an exact critic. For several years his exulting learning and high poetic talents were known to but a very few of his most intimate friends. In 1747 he published his "Odes on the distant Prospect of Eton College," and in 1751 his "Elegy written in a Country Church-yard," was sent into the world without the author's name. Few poems were ever so popular; it has passed through an almost indefinite number of editions, and is at this moment one of the most favourite productions of the British muse. It has been translated into Latin and Greek verse. In 1753 Gray buried his mother, to whom he had always been devoted, but with true filial duty and affection, and on her tomb he wrote, "The tender mother of many children, one of whom alone had the misfortune to survive her." At college he was, on account of some peculiarity in his manners, subject to the boisterous tricks of a few riotous young men of fortune, who took a pleasure in disturbing and alarming him; he made remonstrances on the subject to the heads of the house, which not producing the effect which he anticipated, he removed his residence to Pembroke Hall in 1756, and in the succeeding year he was, on the death of Cibber, offered the post of poet laureat, which he declined. His motive for refusing this office could not have been through any doubt of his being adequate to its duties, for in the same year he showed what he was capable of doing as a lyric poet, by the publication of his two principal odes, entitled "On the Progress of Poetry," and "The Bard." It would indeed have been most lamentable, that any of his genius and independent mind should have been fettered by the obli-
gradation of producing periodical exhibitions of court incense. The odours just mentioned were much less popular than the elegy; many could not understand them, some ridiculed them, and in general they were more the objects of abomination than of rapturous feeling; nevertheless, among persons of real literary taste, they raised the author's poetical character to a level with that of the first poets of his country. 

In the year 1759, Mr. Gray varied the uniformity of his life by a residence, which continued three years, in lodgings near the British Museum, chiefly for the purpose of consulting curious books and manuscripts in that great national repository. In 1765, he took a journey into Scotland for his health, was introduced to several eminent literati in that country, and fed his imagination with those scenes of natural sublimity and beauty which no man was better qualified to write, and to improve. He had, previously to this, sought for the professorship of modern history at Cambridge, but either his application was too late, or the patron, Lord Bute, had other interests to serve; it was given to another candidate. A second vacancy occurred in 1768, when it was conferred upon him, unfolicted and unexpected, in the midst, however, of some defects in the former part of his life, as always been capable of doing noble things in a noble manner. The place was worth 1000 per annum. and Gray made a voluntary return for the favour by an "Ode to Madam," for the installation of that nobleman, as chancellor of the university in 1769. His new office laid him under an obligation to forse exertions; he might indeed have sheltered himself by the example of his predecessors, and received the emoluments without paying any regard to its duties, but the idea of retaining a perfect income did not accord with his temper; he immediately set about preparing for active forecoumtry an admirable plan for his inauguration speeches, in which, after enumerating the preparatory and auxiliary studies requisite, as ancient history, geography, chronology, &c. he defended to the authentic sources of the science, such as public treaties, state records, private correspondence of ambassadors, &c. He also drew up and laid before the duke of Grafton, three different schemes for regulating the method of choosing pupils privately to be instructed by him, which were highly approved, and if he had been accustomed, by general habits, to those exercises which he felt would have been beneficial to the improvement of his pupils, much might have been expected from his lectures, but with a mind replete with the stores of knowledge, ancient and modern, he was totally unable, through the handfull effects of habitual literary inattention, to bring his valetudinary to use on demand; and after many uneasy struggles, he proceeded no further than to sketch out a plan. His health was indeed rapidly on the decline; low spirits, "the hideous scholar's familiar malady," seized him; an irregular hereditary grain made more frequent attacks than usual on his feeble constitution; at length a sudden haunch, with which he was affected while dining in the College Hall, indicated that the disease had left the extremities and established itself in the bosom. He died July 30th 1771, in the fifty-sixth year of his age. He was sensible to the lift, and aware, through the whole of the disease, of its great danger, but expressed no visible concern at the thoughts of his approaching dissolution. With a warm imagination, Mr. Gray had cool application, and a calm sedate disposition. He was attentive to economy, yet wholly void of avarice; he was generous, even when his circumstances were the most narrow. He was careful of himself, and to timorous, that it was affected, some of the final views in a tour to the Lakes, etc. But when he did not wish to venture to those spots whence they were to be seen. This want of personal courage is a singular contrivance with the manly and martial strains of his poetry. In morals he was temperate, upright, and a constant friend to virtue. His religious opinions were not known, but he always abhorred the dissemination of scepticism and infidelity. Few men of his reputation have had such vanity, and he bore with good-humour and easy negligence all the criticisms upon his compositions. The learning of our poet was general and deep; it comprised almost every topic of human enquiry, excepting what belonged to the sciences properly so called. As a poet his muse was often devoted to the late potlister, at least, as long as there is taste enough left to feel and enjoy elegant writing. No one appears to have possessed more of that faculty of poetical perception which distinguishes among all the objects of art and nature what are fittest for the poet's use, together with the power of displaying them in their richest colours. According to a critic, Mr. Gray "did not excel in pure invention, neither is he highly pathetic or sublime, but he is splendid, lofty, and energetic; generally correct, and richly harmonious. Though lyric poetry is that in which he has chiefly exercised himself, he was capable of varying his manner to suit any species of composition. Perhaps he was best of all qualified for the moral and didactic, if we may judge from his noble fragment of "An Essay on the Alliance of Education and Government." As a writer of Latin verse he is perhaps surpassed by few in classic propriety. His letters are entertaining and instructive, free from all parade; they possess a fund of pleasantry, which will ever render them proper among those of his countrymen and are at all times in accord with the principles of literary taste. By a friend who has described his character it is said that "perhaps he was the most learned man in Europe; he was equally acquainted with the elegant and profound parts of science, and that not superficially but thoroughly. He knew every branch of history both natural and civil, and had read all the original historians of England, France, and Italy; and was a great antiquarian. Criticism, metaphysics, morals, and politics, made a principal part of his plan of study; voyages and travels of all sorts were his favourite amusement, and he had a fine taste in painting, prints, architecture, and gardening; with such a fund of knowledge, his conversation must have been equally instructive and entertaining; but he was also a good man, a well bred man, a man of virtue and humanity. There is no character without some speck, some imperfection; and I think the greatest defect in his, was an affection in delicacy, or rather effeminacy, and a visible fulfulness or contempt and disdain of his inferiority in science. He also had in some degree that weakness which perplexed Voltaire so much in Mr. Congreve; though he seemed to value others chiefly according to the prografs they had made in knowledge, yet he could not bear to be considered himself merely as a man of letters; and though without birth, or fortune, or lineage, his defile was to be looked upon as a private independent gentleman." Madon's Life and Letters of Gray, four vol. 80. 1778. Gray, or Grey, a mixed colour, partaking of the two extremes, black and white. In dyeing, many of the varieties of grey, iron-grey, slate colour, &c. are given by prococies, in general, similar to those for black, but with smaller quantities of the ingredients, and especially a shorter time of immersion. They are often finished with a weak bath of well, cochineal, Brazil-wood, and other livid colours to give some particular tints. In the Blanehe they make several sorts of grays: as the brandished or blackened grey, which has spots quite black, diffused here and there. The fuddled grey, which has spots
of a darker colour than the rest of the body. The light or silver grey, wherein there is but a small mixture of black hairs. The dark or iron grey, which has but a small mixture of white. And the brownish or sandy-coloured grey, where there are bay-coloured hairs mixed with the black.

Gray, in Zoology, a name given in some counties of England to the badger.

Gray is also used in some places for a species of wild-duck, more commonly known by the name of the gadwall.

See Deck.

Gray, in Geography, a town of France, and principal place of a district, in the department of the Upper Saône, seated on the Saône, which is navigable by boats to Lyons, whither the inhabitants fend grain and iron, the chief articles of their commerce. The place contains 5009, and the canton 13,823 inhabitants, on a territory of 213 square kilometres, in 26 communes. N. lat. 47° 27'. E. long. 53° 40'.

Gray, a port-town of America, in Cumberland county and state of Maine; 13 miles N.W. from Portland. The township was incorporated in 1778, and contains 987 inhabitants.

Gray's Bay, a bay on the N. side of the river Columbia, in New Georgia. N. lat. 46° 19'. W. long. 236° 22'.

Gray's Creek, a river of Virginia, which runs into James river. N. lat. 37° 3'. W. long. 76° 56'.

Gray's Harbour, a port or bay on the W. coast of North America, examined and described by Mr. Whitby. The surrounding shores are low and apparently swampy, with salt-marshes; the soil is a thin mixture of red and white sand over a bed of stones and pebbles. At a small distance from the water side, the country is covered with wood, chiefly pines of an inferior stature and growth. The number of Indians inhabiting this place were estimated at about 100, they spoke the Nootka language, though it did not seem to be their native tongue, and they appeared to vary in little or no respect from those people occasionally seen. N. lat. 47°. E. long. 236° 27'.

Grayling, or Umbur, the English name for the fish called by authors Thyminius, and Thymius, and by Arctedi a species of corregenous, and the Salmo Thyminius of Linnaeus, which fish, it is believed, is found in the fresh waters and clear rapid streams, chiefly in the mountainous counties of England, and in the like situations in other countries, and is one of the finest kinds of all the fresh-water fishes. It is common in Lapland, where the guts of it are used instead of remet to make cheese, which they get from the milk of the reindeer. It is a voracious fish, rises freely to the fly, and will very eagerly take a bait. It feeds on worms, and spawn in May.

Grayson, in Geography, a county of Virginia in the upper waters of the Great Kanawha. It contains 3742 square miles, and 170 villages. Its form is trapezoidal, the longest line being about 50 miles, and its greatest breadth 15 miles. It is mountainous, abounding with timber and iron ore; and two large iron-works are erected in it. About a fifth part is arable. The town house is in N. lat. 36° 35'. 250 miles S.W. of Richmond.

Grazelma, a town of Spain, about 13 miles from the borders of the province of Granada, built partly on the side, and partly on the top of a mountain. Most of the inhabitants are employed in the manufacture of woollen and cotton cloths, and also of crucibles. Their number is about 3000.

Graziani, Anton-Marie, in Biographie, a bishop and elegant writer, was born of a distinguished family at Borgo-Iu-Sepolcro, in Tuscany, about the year 1571. Having obtained a good knowledge of grammatical learning at Friuli under the celebrated Abolemio, he was sent to Padua to study the law. In 1590 he visited Rome, and was kindly patronized by commendone, afterwards cardinal. He accompanied this friend, between whom and himself there was an unalterable attachment, in all his journeys into Germany and Poland, and refuted to quit him, though solicitud with great promises by Henry of Valois, at that time king of the latter country. After the death of commendone in 1584, he was made secretary to pope Sixtus V., and took a considerable share in the election of Clement VIII., who, in 1592, in gratitude for his services, created him bishop of Amelia, and sent him as his munici to the Italian princes and states, in order to unite them in a league against the Turks. When at Venice, he prevailed that republic from declaring in favour of Cesar d'Este after the demise of Alphonso II., duke of Ferrara. In 1598 he retired to his see, where he remained, till his death in 1615, and abundantly employed in the duties of his high office.

As an author Graziani is known by the following works: "De Bello Cyprioe," lib. v. 410. 1624; "A History of the War of Cyprus;" "De Vita Commendonii, Cardinalis," which was intended as a tribute of gratitude and affection to his deceased friend and patron; "De Canibus adversis Vcruum illustribus," and a collection of synodal ordinances.

In 1734 the public were presented with a curious posthumous work of this author, entitled "De Scriptis Invitis Minervae, ad Aloysium Fratrem," lib. xx. in which he not only gives an account of his own life and writings, but that of his native town and family; of his brother's travels, and of the public affairs in which he was engaged.

Morei.

Graziano, D. Bonafico di Marino, maestro di cappella of the Jesuits' chapel and seminary at Rome, was a very voluminous composer of sacred music and cantatas, who flourished from the year 1650 to 1678. Padre Martini has given the following list of his ecclesiastical publications: three books of psalms for five voices, a due cori, or for two choirs; published at Rome 1652 and 1670. Masses at 5 Rome, 1671. Six books of motets, for 4, 3, 4, 5, and 6 voices, Rome, 1655. Responsoria della Settimana, Rome, 1663. Litaneias for 3, 4, 5, and 8 voices, Rome 1675. Sacred and moral compositions, for 1, 2, 3, and 4 voices, 1678. Of his cantatas, though none are mentioned in this list, yet the number of them, that have been preserved in MSS. collections of old music, is equal to those of Carilliini, Cesti, and Luigi Roffi, particularly in the British Museum; Dr. Aldridge's collection of music in the library of Chrift-church, Oxford; Dr. Burney's Collect. &c.

Grazieri, in Agriculture, a term commonly applied to such farmers as are engaged in the art and busines of fattening various sorts of live stock on paste and other grains. That this sort of business may be managed to the best possible advantage, the grazier should have a perfect knowledge of the nature, properties, and value of all sorts of cattle and sheep flock, as well as of the quality of the ground on which they are to be fed, and of the best proper methods of fating them to each other. And he should also be well informed concerning the nature and states of markets in general. It is obvious that upon these being well understood and properly regulated, much of the success of this sort of farming busines must depend; as thereby proper advantage may be taken, not only of fairs and markets, but a variety of other necessa rу circumstances.
The markets for the sale of fat stock, especially those of the next cattle and sheep kinds, are generally as high about the end of April as at any other period of the year, in consequence of the supply, at that season of the year, being only had from cured or corn-fed animals, not one farmer in a thousand having any of their winter green food remaining. On this account such beasts or sheep as are really fat at that time are sure to fetch a good price in the markets, and particularly at Smithfield. With the latter animals, however, the less, in some instances, it is rather different as to those farmers who are good providers: spring food is now beginning to be ready, though seldom in such plenty, from the number of bad managers, as to reduce the markets in any great degree. 

The inexperienced grazer should consequently fully weigh and consider the different modes in which he may be able to dispose of his fat stock to the greatest advantage. The first and principal place to which his attention will be directed, will probably be Smithfield market, especially for the more southern graziers. If he be situated in a district that is divided into small or middling fixed farms, and in which the farmers are not commonly in the regular practice of employing discount drovers, in whom proper confidence can be placed, be will of necessity be as safe as his neighbours, and may not have reason for any particular caution.

The mode is very common in the eastern part of the county of Norfolk. Where he occupies a very large farm, whatever the nature of it may be, whether an arable grazing one, as is customary in West Norfolk, or a grafs grazing one, as in the county of Lincoln, on a scale that enables him to tend many droves in a pretty regular manner to his fullman, he may safely trust to him; as the usual confidence and integrity of trade mostly take place in such cafes. But it must be observed, that it is seldom the cafe that the grazer who feeds occasionally or accidently a lot of fat beasts or sheep to Smithfield market, gets as fair a price for them as his great neighbour, who is in constant dealing, gets the same day, or his little one, whose flock took the same chance through the means of a confidential drover. The person who thus drops in a lot, out of the regular course of his business, is scarcely ever satisfied with the treatment he meets. And there is, without doubt, much truth in the remark, in consequence of the frequency of its being made by persons from different places.

On the other hand the inexperienced grazer should consider the circumstances well, and try the country butchers, in order to feel his way through the difficulty as well as he can, provided his farm be of such a size, and in such a situation, as to lay him open to its influence and effects.

In the case of grazing, great advantage may be derived, by those who have not had much experience, from the frequent weighing of the animals while alive; as by a comparison of the living with the dead weight, in such cafes, as when they are killed in their own neighbourhoods, they may soon become able to judge, with a tolerable degree of correctness, of the dead weight of any common fixed beast, of which they have ascertained the weight while in the living state. And where the living weight has been taken from tables of admeasurement, such as those composed of B wor, they may compare the result in a pretty exact way.

The work of ascertaining the living weight in sheep, calves, hogs, and other similar kinds of animals, may be effected in a simple and easy manner, merely by the contrivance of a sort of cage or large covered bulb, with a door at each end for their reception and discharges, to which is attached a pair of large flaxyards, so as to show the weight.

The frequent weighing of the fattening flock shews the grazer the different degrees of progress which the animals have made in different periods and situations, as well as what the effects of different sorts of food are upon them; what changes may be necessary in it, and when it may be the most proper to sell, provided the markets should be suitable. In short, a fort of confidence is in this way gained by the grazer, that could not be readily acquired in any other manner.

But affluence of this nature is not by any means necessary for such graziers as have been long accustomed to the handling and judging of the weights of animals, as they can in general form tolerably correct opinions by the eye and the feel, in consequence of such long experience; though it not unfrequently happens that they are deceived, the beasts turning much better and heavier than they had imagined. It has, indeed, been remarked that, let the grazer be as experienced as he may in buying and selling, as well as in judging by the hand and the eye, the butcher will beat him, from having been able to bring the live to the left of the dead weight, in such a variety of different instances, as must render his judgment perfect. The grazer, though he cannot therefore equal him, may, in a great measure, approximate to him by means of frequent careful weighing of the living animals.

It must of course appear evident that it is a matter of great consequence for the flock farmer, to make himself, as soon as possible, perfectly conversant with this part of his business, as without it he must be liable to be greatly deceived in his dealings.

GRAZING, the practice of feeding and pasturing down grazls-lands with different sorts of live stock, with the intention of improving and rendering them fit for the market. It is a fort of management that cannot be carried on to much advantage, except in those districts where the quantity of pasture land is considerable, and of a suitable quality for the purpose, or where the value of the produce of such land is but small in comparison with the flock which is fed upon.

There are particular districts in different parts of the kingdom that are much more in this system of farming than others, as is exemplified by those of the counties of Lincoln and Leicester, in the middle part of the island, Someret, Gloucester, &c. in the west, and Romney warth, &c. in the south.

But there are tracts of grazing ground of more or less extent in most of the counties of the kingdom.

It is well remarked that there are certain situations as well as descriptions of pasture ground on which this method of farming may be had recourse to with better profits, and more success than that of any branch of the dairying system. This must be the case in all those districts where the proportion of land in the state of tillage is very small in comparison to that of the pasture kind, consequently the price of produce of the grass fortrilling in comparison to that of the fat stock. In all such districts of the kingdom where the grazls-lands are of so fine and rich a quality, as to be capable of fattening large bullocks or other cattle, this system may be had recourse to with much success and profit, and is perhaps the best application to which the lands can be applied, as is fully shown by such districts being mostly under some management or other of this nature.

It may be observed that the art of grazing to advantage depends upon a variety of circumstances, such as those of the nature and quality of the grounds, the propriety of the management of them in respect to feeding down, changing, and shuffling them up; the properly adapting the flock to them.
them in quantity, size, and quality; the judgment of the grazier not only in feeding such as are most suitable for the purpose and most disposed to fatten, but in obtaining them, where they are to be purchased, at such prices as that they may pay well for keeping; and disposing of them, when fattened, at their full value and advantage.

It has been stated, by Mr. Kent, that the flocking of land with proper cattle is one of the nicest parts of the science of farming. Where nature is left to herself, she always produces animals suitable to her vegetation, from the smallest sheep on the Welsh mountains to the largest horned ox in the richest pastures in Somerfithur. But good husbandry admits of our increasing the value of the one in proportion to that of the other. Land improved enables us to keep a better flock of stock, which thaws the double return the earth makes for any judicious attention or labour we bestow upon it. The true wisdom of the occupier is best shown in preserving a due equilibrium between this improvement of his land and stock. They go hand in hand, and if he neglect the one, he cannot avail himself of the other. It should, therefore, be first considered what kind of cattle, or other sorts of stock, will answer the purpose best, on the particular description of land upon which they are to be grazed; and next, what sorts may pay the most in the consumption of the produce.

In general, it will probably be found, that upon strong florid pastures of the drier kinds, the large sorts of cattle, with some of the larger breeds of sheep, will be the most suitable stock; but that where the grasslands are neither so luxuriant nor so dry, and upon turnip-lands, the small English, Welsh, or Scotch cattle, with some of the small breeds of sheep, will be most profitable. Thus, as different sorts of grassland and different kinds of produce feed in point of profit to require different descriptions of animals to feed upon and confine their produce, it is of much importance to be at some pains to make the best and most suitable application. And in cases where the grazier breeds his own flock, he will have little difficulty in feeding such of the different kinds as are the most adapted to his views; but where the animals are to be purchased in, which must most frequently be the case, more care and circumspection will be necessary. It will be proper, though a difficult task, to make a choice of such as have been well kept and are in a thriving condition; as when they have been limited in their food, and have the contrary appearance, they seldom do so well for the uses of the grazier. It will likewise be of advantage to have them from situations in which the lands are inferior in point of richness. It is noticed by some, that many farmers have found great advantage in buying sheep from the poorer spots, as they generally thrive more when they come into a richer pasture, like trees which endure transplanting the better for coming from a poor nursery. They likewise think that they endure feeding and penning better than sheep which are bred on a more luxuriant soil. And they are certainly right, in these observations. But, with respect to the notion which farmers are apt to entertain, that all kinds of sheep will not endure penning, they labour under an error. It is believed that all lean or floc-shorn are the better for being flocked. They are generally more healthy; and, above all other advantages, this one is certainly obtained by it: when such sheep are put to fatten they thrive much better and fatter, as oxen do that have been moderately worked. But where the grazing-lands are very moist, sheep are not by any means a sort of flock to be depended upon, as they are extremely liable to become diseased.

In addition to these points, it is necessary to have consider-

able regard to the qualities or properties of the kinds of animals, whatever they may be, in the intention of grazing them with profit; those kinds, whether of cattle or sheep, which have the property of keeping themselves fat, or in tolerably full condition, by the least consumption or expenditure of food, being constantly preferred, whatever the size or breed may be, as that is evidently a quality of much greater importance to the grazier than that of mere size, considered in an abstract manner. It is flated, that where there are fine and rich pastures, the grazier may "choose his beasts as large as he can find them, provided they are of the right breed and shape; but let him always prefer shape to size; for it will assuredly pay him better;" and, that "those who are upon indifferent grass must take care to proportion the size of their beasts to the goodness of their pastures; their cattle had much better be too small than too large; as there are vast tracts of land that will answer in grazing, which are not good enough to support large breeds." And it is not improbable, but that the same thing may hold good in a greater degree in regard to sheep. But in all such cases, as where the flock is reared upon the land of the farm, which is often a good practice, there can be little difficulty, as has been seen, in fixing upon such animals as are the most proper in these different situations; but as it must often be necessary for the grazing farmer to purchase his live-stock at fairs and country markets and sells, and, consequently, with a less degree of care and attention, as well as knowledge, will be required for him to accomplish it in the most advantageous manner.

In a fyllem of Practical Agriculture, lately published, it is noticed to be "of great importance in this busines to provide such as have been kept in a proper manner, and are in a healthy, improving state; as, where the contrary is the case, they are difficult, and require much greater length of time to be brought into the slate proper for sale than would otherwise have been necessary. It is, perhaps, experience alone that can qualify the grazier to form a correct judgment in these respects; in general, however, he is led to the choice of stock by no fixed or scientific principles, but by the impression the appearances of the animals have upon him." And, it is stated on the authority of Mr. Marshall, "that the experienced grazier, who has been accustomed to attend fairs and markets, knows at a glance, or by the suffice of the slightest touch, whether the animals he is about to purchase will suit him. Their general form and looks please him. They are easy to work; their hides are fine and thick; their muscles are well formed; their countenances brisk; their skins alive, and their fleece mellow. On the whole, they have the resemblance of those which have been grazed before with success. Others are rejected, from the grazier not having found any such as they referable to have done well, but many to have turned out in an unprofitable manner. And the writer of the above work conceives, that there are certain "principles in this branch of the farmer's business which may be attended to with great advantage, as the animals have certain points or parts, the proper or improper forms of which denote them to be valuable, or the contrary, for this purpose. These are, that the legs should be fluted in proportion to the size of the animal; the back very straight, broad, and flat; the loin wide; the carcass deep round, or rather barrel-shaped below; the fore-quarters round, full, and spreading; the bones small; the flesh adhering an chalky feel; the skin thin, and a disposition to fatten well, and on the belt parts. Where these marks are predominant, the flesh is meltly fit for the purposes of the grazier." And, "that where the hair of the hide, in fattening cattle, is inclined to curl instead of being
GRAZING.

being flanked, they are most disposed to thrive. This has been found to be the case in practice in different parts of the kingdom," as has been shown in various publications on agriculture.

"In lean beaus also, when the hair of the hides is curled, they commonly keep themselves in better condition than where the contrary is the case. In all cases a disposition in the animals, of whatever fort they may be, to wildness, and not remaining quietly in their pastures, forms an inescapable objection in this system of management; as no animal ever fatten, well that has a tendency to ramble: it is quietness, feeding quickly, and lying much, that has the greatest tendency to make them become fat in a short time;" a fact which is fully confirmed by what happens in the new Leicesters or Duleby breed of sheep, which are so tame and quiet as scarcely to move over a common pasture. And, "from the result of actual experiment with four different beaus, in which the least possible difference could not be discovered on the most minute examination, it has been found that too much attention cannot be bestowed in the choice of the breed of fattening flock, as, though they were in every respect the same in appearance, two, from their superior disposition to fatten, were found to afford a profit in the proportion of fifteen shillings the week, while the other two did not yield more than about five shillings and ten-pence." This fact is recorded in the Annals of Agriculture, and clearly shows that too much attention cannot be paid by the grazing farmer to the discovery of this propensity in the flocking of his pasturage, or other grazings.

Notwithstanding it must often happen that the grazer cannot fully avail himself of this, from the impossibility or vast difficulty of procuring such animals, and is consequently under the necessity of buying in such as are more at hand, and ready for his use.

It is the usual custom in Leicestershire, and the neighbouring districts, to have commonly recourse to the improved long-horned breed of cattle, from the animals being bowld to fatten in a ready manner, and to afford good beef. And, in the adjoining county of Lincolnshire, a mixture of the large beaus, of both the long and short-horned breed, are said recourse to as grazing flock, besides those breed in the county, and such as are brought into it by the Scotch drovers.

On the contrary, in Somerfahlshire, the dark-red fort, or Devonshire breed, has been long much in esteem by the graziers, and have lately spread themselves much into the midland districts, as Leicesters, Oxfordshire, and Warwickshire, from the grazing farmers in those districts finding them to answer upon their pastures more perfectly. And in Suffolks, the prime breed is also held in considerable estimation by the farmers, as well as their own variety of it, as they are both bowld to fatten kindly, and with considerable expedition, upon their lands, and to have a ready sale in their markets and fairs.

However, in the more arable or tillage districts of Norfolk and Suffolk, where turnips and artificial grazings are more in use, the Kilc, Galway, and other small Scotch breeds, as well as those of the Welsh runt kind, are in preferable demand, from their answering better upon those forts of food, their more kindly disposition to fatten, and the excellent quality of their flesh, which never fails to have a ready sale in the London market, where the greatest part of their fat flock is sold. But the grazing farmers in the northern counties have mostly recourse to their own long-horned breed, raised on the farms, with the different Scotch breeds brought into the districts, their home fort being in their experience the leaf disposed to take on fat and become saleable. And the large Hereford fort, as well as that kind of Welsh cattle termed the Glamorgan, are allo very advantageous grazing flock in situations where the pastures are good, and they can be finished with other forts of food. Great numbers of the former of these forts are purchased by the graziers round the metropolis for being fattened or brought considerably forward on the rich grass lands, which have been mown for hay, and finished with other forts of food. Yet the small breeds of the Scotch, Welsh, or other finer kinds, may, in many cases of the inferior forts of grazing lands, be the most beneficial in affording profit to the farmer, as he can fatten them more to the nature and state of such lands, and they have more chance of becoming fat. But, if indeed it has been stated in the tenth volume of the Past Papers, on the experience of fifteen years, that the small animal has generally "a more natural disposition to fatten, and requires (proportionably to the large animal) less food to make it fat; consequently the greater quantity of meat for consumption can be made per acre." If this point was satisfactorily proved, there could be no doubt of small animals being preferable both on this description of grazing land, and that of a better quality; but, as an able and accurate observer has upon much experience been induced to think differently on this subject, the grazer should be cautious how he has recourse to small breeds upon lands that are capable of fattening large ones, until the question has been fully decided.

In respect to what relates to the fort of cattle that may be employed to the greatest advantage under this system, oxen, and fuch heifers as have been fayed, are in general considered, by the bel informed graziers, as the best fort of flock; as besids being more quiet, the latter have not only the property of fattening in a more expeditious manner, but with a less consumption of food. They are not, however, to ready provided by the grazer. The ox is of course the most commonly, as well as most extensively, employed for the purpose of the grazer, as having the advantage of being capable of being fattened, and of affording good beef, after he has been beneficially wrought in the team of the farmer. Cows, under different circumstances, are likewise often bought in by the grazing farmer for the purpose of being made fat, such as those that have become dry, have flipped the calf at an early period, or are becoming aged; but much caution is necessary in the purchase of this fort of grazing flock, as they frequently turn out less favourably than bullocks or heifers, though in some cafes they leave a good profit. When old, they rarely thrive well or get fat with any degree of expedition. Indeed it is, perhaps, the best way, in all cafes, for the grazer to have such flock as is not too far advanced in age, as young animals are invariably more disposed to get field, and become fat, than such as are old. In the grazing of such heifers and cows, they should be suffered to take the bull as soon as they have an inclination, and be ready for being fold off fat several months before the time they would have calved. Such cow or heifer flock as are in calf, may sometimes be purchased in at a cheap rate in the fairs in the autumnal season, and be fattened off in the early spring with a good profit. There is likewise another description of this fort of flock sometimes grazed, which is what are termed free martins, or cows that are barren; but they are said to feldom answer in this intention in any very advantageous manner.

In relation to the most proper sheep flock for the grazer, when the pastures are rich, and afford full keep, the improved, large long-wooll'd breeds, as the new Leicelters, may yield

GRAZING.

the best profit; but where the lands are less rich, and the feed of coarse-leaves plentiful, thefinal, improved, short-woollen breeds, as the South Downs, may leave a more ample profit to the farmer. Where wethers of the former kind can be procured, they well turn out well for the purpose. And in the contrary circumstances, perhaps the South Downs cannot be excelled by any of the short, or middle-woollen breeds. But in particular situations and circumstances of grazings, many other breeds may, however, be more profitable to the grazing farmer. It is stated, in the Agricultural Survey of Somersetshire, that the Dorsets, formerly so prevalent in that district, have lately given way to the polled, native breed of the lower part of the county; from their females of their giving a larger proportion of wool, and their fattening more expeditiously, and at the same time more fully, especially in the internal pastures. However, in the rich marshes in the southern parts of the island, the grazing farmers, who are mostly in extensive businesses, have constantly recourse to the polled, white-faced breed, and that of the South Down, which they find the most profitable forts on their lands that can be employed.

In the northern parts of the kingdom, the graziers have principally recourse to the native breeds, the heath and Cheviot, and find the former the quickest in getting fat, and the most hardy in their nature. The Cheviot breed, however, latey to have gained ground in the more elevated and hilly pastures.

Whatever the breeds of the animals may be that are made use of as grazing flocks, it has been found, from long experience, that it is a matter of much importance to procure them from districts, where the quality of the land is inferior to that on which they are to be fattened, as by such means they not only get fat in a more expeditious manner, but without suffering any check upon being sent upon the pastures.

It is a matter of much consequence in sheep grazing that they have a fine clothe pasture; and that they be prevented from going upon such grasing-lands as have been covered by water, and become sandy. As under such circumstances, they are liable to become diseased. And besides this, it may be beneficial in many cases for the farmer to be careful that horses are not turned upon the pastures along with them, as it has been found that the turf of long, rank grasses that rise about the dung-heaps, are apt to render them in a state of disease, except where frost has taken place, when the danger is for the most part removed; and it is supposed, that it is also dangerous to suffer sheep to browse upon such a pasture, especially that of barley, which hoofs up among the stubble, after the harvest is completed; and that the long grasses unfound are equally detrimental, whether the soil be light or strong. In the former situations, they frequently pull up the herbs by the roots, which they eat with the dirt adhering to them, which will inevitably give them the rot; and, if the long grass be strong land, and should not afford a sufficient supply of food, they are liable to the hunger-rot, from being compelled to eat the rank, unwholesome vegetables produced upon such grounds, especially the arrow-wort, and the marsh-penny-wort, both of which plants flourish in wet situations, and ought carefully to be eradicated wherever they are found. It is further advised, that in turning sheep into pastures, particularly water-meadows, and also into those pastures that are subject to rot, to purse the same precaution as with neat-cattle; which is previously to satisfy the craving of appetite, by giving them hay or cut straw, and after the dew has been evaporated by the rays of the sun, to drive them gently round the field for two or three hours before they are suffered to eat. But, whenever any fort of dry food is given, they ought to be supplied with pure water, particularly during the intense heat that usually prevails in the summer months, and which often renders the grass as dry as a fluff. For this purpose, clear, light-running water is always to be preferred, where it can be obtained; though, in general, whatever prevents itself is made use of. But where this necessity of life is found only in a tainted state, or overcharged with the juice of dung, it will be advisable to give them well-water in troughs or shallow tubs. This must be particularly attended to in the folds, so long as the sheep are confined there by the severity of the weather. It has been noticed, that "the watering of sheep is, on the Continent, regarded as a circumstance of the greatest moment, and accordingly, receives that attention which it requires. Thus, in Sweden, and at the national farm at Rambouillet in France, they are daily watered with running-water, or with that obtained from lakes or springs, fraught with most properly and rigorously prohibited. And in some of the Saxon sheep-farms, the sheep are watered in the cogs or folds during the winter, instead of taking them to watering-places. Spring or well-water is conducted by means of pipes into troughs, out of which the sheep drink at pleasure; they in consequence drink oftener, and each time take less water, which is favourable to their health. The ordinary mode of watering sheep in that, and we may add in many parts of our own country, is attended with many inconveniences. The animals refuse to drink water in the winter, if it be too cold; they hurry while drinking, and do not take enough when the weather is very windy, or hail, rain or snow falls. "Between which, they often disturb the water with their feet; this disgusts them, and at length one part of the flock completely prevents the other from approaching the watering-place." And it has been advised to fold them before the dew falls in summer and winter, and never remove them till it excites, letting them have hay or other dry food of some sort.

It is stated, that all grazing-land of rich quality ought to be felled with sheep, cattle, and horses, so that the grass may be eaten clean off; for, unless it is regularly depauperated, much damage ensues. Each of the above three kinds of animals prefers, as most palatable food, some grasses which the others reject; and none of them will bite near their own dung, though they may near that of others; and thus they conjointly contribute to keep the pasture level without much expense. Pastures or grazing-lands should be kept as level as a bowling-green, both for ornament and use; for, by one part being left higher than another, the long grasses increase in patches; and land where it grows may be considered as taken away from the pasture, as the cattle will almost sooner starve than eat it. By leaving the fort of grasses the animals refuse from year to year, the land incroaches in weeds, plants, and diminishes in useful ones; as the feed of such plants continually drops, and the useful ones are prevented feeding by the cattle eating them. If such pastures were mown in those places, it would give the useful plants room to grow. There are in this kingdom an infinite number of acres of rich and excellent land, which, from bad management, and from want of judgment in flocking, become of no more value than a barren soil. But such grazing land as is intended for the purpose of feeding cattle, a few sheep are conceived absolutely necessary to cut up the weeds. If any part of the pasture be getting into beets, or higher grass than it ought to be, and the animals begin to neglect it, you must mow it immediately, and as near the ground as possible; for the clover you cut down such coarse parts, the sweeter and the quicker will the grass spring up in the place. Could animals, by hunger, be driven

Vot. XVI.
driven to eat the long grasses, they would not fatten upon it; for, as the nearer the bone the fweeter the flesh, so the nearer the ground the sweeter the grass; it is not, he supposes, so much the quantity as the quality of the food that must be attended to. And in further proof of the advantage of hard focking, it is flated, that it is a common complaint, that the land is good in spring, but it goes off. Is this to be wondered at, when one-third, or perhaps one-half of the yield is become fo rank, that no one animal in the pasture will bite a mouthful of it? Suffer the very best piece of graves-land, entirely free from weeds, to be without either eating off the grass, or mowing it, and in a few years it will be over-run with weeds, have very little useful grasses in it, and in fact be little better than rubbish. Consequently, there can be little doubt of the beneficial consequences of hard or close focking on the older forts of grazing-land; but on the new keys it should probably be seldom attempted, as injury may be done to fuch lands without the flock being thereby adequately improved.

But in grazing farms, there are several different styles of management pursued, in respect to cattle as well as sheep. The practice with some graziers is, "to purchase their cattle in the fairs in the autumn, about October, or in the following month, supporting them through the winter, principally with straw, or sometimes, which is a much better practice, with a little hay mixed with it, till towards the beginning of March, continuing their fattering through that and the fucceeding month with some fort of succulent food, such as turnips, potatoes, or other fimilar kinds, until the grdfs be in a flate fit to be turned upon in May, on which they may be carried forward and completed, according to circumstances, about August, or in the following month."

And another practice "is to purchase their heifers lean, as soon as the grdfs-lands are in a flate fit to be turned upon in May, wholly completing their fattering on the grdfs about the latter end of October, or later in the autumn, according to their quickness in feeding. In this fystem of management, the smaller kinds of cattle flock may be found in general the most advantageous, especially where the lands are of the lefs fertile and luxuriant descriptions."

Another practice, sometimes had recourse to by grazing farmers, but which is, in general, perhaps less profitable then either of the above modes, is that of buying in flock at such periods, according to the difference in their prices, as that they may be ready to be fold off about April, or in the fucceeding month, a period at which they utually fetch high prices in the markets. It has been observed, that "in this fystem, with large oxen or other forts of beasts, it is sometimes the practice to keep them through two winters, giving them only one fummer's grdfs; being in the firit winter not fully fed, but kept in good grdfs in the fummer feaon, and forced on with the beet feeding in the second; but with the smaller forts of flock, one fummer's grdfs and a winter's feeding is the usual mode; the cattle being brought in as soon in the spring as the grdfs is rifen to a good bite."

It is in very few instances that the animals can pay for this length of keeping. And, "in some diacrtics, heifers are preferred to oxen; in which case, they buy them in about March or April, and after keeping them through the fummer, sell in October and November."

This method is thought, by some, a profitable fystem of management." By the author of the Modern System of Practical Agriculture, on these different styles of feeding, it is noticed that they may all "probably be practifed with advantage under diferent circumstances; but it is obvious that the first can only be had recourse to with propriety, where green winter food is raised in sufficient abundance, and the grazier has a flore of litter for being converted into manure. Under other circumstances, the second mode of management will be much more profitable. The two fift methods are the leat convenient, and, probably, on the whole, except in very favourable circumstances, the leat profitable, especially the former of them, as, from the great length of time which they are kept, much management and attention to food becomes necessary to render them advantageous; which, with common servants, is seldom sufficiently regarded."

But in addition to these several modes or plans of fattening next-cattle, there is a practice followed in some rich hay-diarcrics near large towns, and particularly by the hay-farmers in Middlesex, which is, that "of buying in small cattle in tolerable condition in the autumn, as soon as the after-grdfs is ready, in order to their being fattened out on the roans, and disposed of towards the latter end of October, or beginning of the following month."

And, regarding sheep flock, the same difference of systen takes place; as, in some cafes, where the lands are in a state of inclosure, it is the "practice to buy ewes in lamb in the latter end of summer or beginning of autumn, keeping them on the inferior forts of graves-lands, hedges, or falls, till the beginning of January; and then, by giving them turnips or cabbages, to keep them in good condition through the period of their lambing, and afterwards in the belt manner that can be contrived, in order that the lambs may become fit for the butcher sufficiently early to admit of their being afterwards fattened, and disposed of in the beginning of the autumn."

This, in many cafes, is found a profitable systen of management, but which requires much care and attention in directing it.

Another practice in this business is, to purchase wether flock about the beginning of May, at the age of two or three years, keeping them sparingly till some weeks after the grounds have been cleared from hay; then bringing them to good keep in the roans, afterwards fattening them by means of turnips or cabbages, so as not to have them ready sooner than the beginning of March, which is commonly the season in which they fetch the highest prices. In this systen of grazing management, a good profit is mostly afforded by farmers who pursue it in a judicious and ready manner.

And a further practice in fattening sheep is pursued in some cafes with great profit and success, which is that of buying in lambs of the wether, or other kinds, about the beginning of September, which are kept in different methods by different graziers, being by some brought forward with the greatest possible expedition by the best keep, so as to be ready to be fold off as soon as possible. But others have recourse to the contrary method, keeping them only in a middling way during the winter, till about the beginning of April, and then forcing them forward by good keep, so as to have them ready for the butcher in August, or continuing them in the following month; and then clearing the whole of the flock from the land. In this practice, large profits are often made by judicious graziers, especially when situated near large towns where the population is great.

Another systen of fattening, which can only be pursued to advantage in situations near large populous towns, is that of providing graves-lands for the markets as early as possible in the spring months, which pays the grazier well in many cafes. With this view, it is the practice to procure the more forward ewes, such as those of the Dorset breed, which drop their lambs in the beginning of January, if not before. In Middlesex, where this management is much attended to, in consequence of the great demand, it is the custom

Grazing.

for being converted into manure. Under other circumstances, the second mode of management will be much more profitable. The two last methods are the least convenient, and, probably, on the whole, except in very favourable circumstances, the least profitable, especially the former of them, as, from the great length of time which they are kept, much management and attention to food becomes necessary to render them advantageous; which, with common servants, is seldom sufficiently regarded."
tom to purchase this sort of ewes at Kingston, Weyhill, and other fairs in the neighbourhood. The ewes, in order that they may have a plentiful supply of milk, are extremely well kept on turnips, brewers' grains, and fine green sweet rooten hay, and the lambs thereby forced forward in such a rapid manner, as to be ready for the markets in the beginning of March or April. And the ewes, from their becoming dry so early, are capable of being fattened and disposed of towards Michaelmas, usually fetching the prices at which they were purchased in at; as the whole of the flock is in this system cleared within the year, the farmer has the opportunity of fully ascertaining its advantage or disadvantage.

The statement of which is thus given in the able Survey of the Agriculture of the County of Middx,:

It is hinted, that "in this management very much depends upon keeping the ewes perfectly well fed, and in dry warm enclosed pastures, as without such attention the ewes are apt to become thin and lean, in consequence of the greatness of the evaporation, and afterward to require a much longer time in being made fat," by which means much loss must be sustained. In the Economy of the Midland Counties, a notice in respect to fattening grafs-lambs, is suggested, which in particular cases may be beneficial; which is that of removing the lambs from the ewes when they decline much in milk, before they are perfectly fattened, in order to complete them on young clover, or other sorts of prime keep.

The chief object in this case is, that of the ewes becoming sooner ready for the butcher. Some, also, conceive, that after the first flush of milk is gone, and it begins to be scanty, the lambs thrive better "on grafs alone, away from the ewes," than when kept along with them, as the hankering after the little milk that is afforded prevents their feeding freely on the grafs. Hence it is supposed, that "where this method is followed, which can probably be with advantage only where the milk of the ewes is greatly deficient in supporting and bringing the lambs forward, much attention must be paid to having the keep early and in abundance. In this view, rye-graSs and white clover for early use, and broad clover at a later period, may be the most proper and useful crops. In this management the ewes should be carefully examined occasionally; and, where much deficiency in the milk is found, the lambs be immediately removed to the pastures."

In respect to the flocking of grafs-lands in the most advantageous manner for the grazer, it must depend materially on the richness of the lands, and the nature of the flock in respect to size, and other circumstances. But, according to Mr. Billingsley, the Somersetshire graziers, in flocking the rich and middling sorts of grafs-land, allow, to an ox from one acre to an acre and a half; and one and a half ox to each ewe. But, in Lincolnshire, they flock in much larger proportions; as is shewn in the Agricultural Survey of that district, where they are brought into a tabular form as below, for the more rich pasture land.

</table>

Average - 3 1/2 1 1/2 2

Upon this it is observed, that "considering the size of the sheep, which cannot be estimated at less than 200 lb. a quarter, on an average; and that the bullocks rise from 50 to 100 fl. (14 lb.), this rate of flocking is very great indeed. There are, on every acre, 360 lb. of mutton, and reckoning the bullocks at 20 fl. each, dead weight, there is also 376 lb. of beef; in all, 696 lb. of meat per acre, besides the winter produce, which is immense."

But, in the rich grazing counties in the more southern parts of the island, a large proportion of both sheep and cattle flock is admitted per acre: the exact proportion, however, differs with different graziers very greatly.

But the great and leading principle in this business is, however, never to flock in such a manner as to restrict the animals in the leaf; as it is by their being enabled to fill themselves quickly, and to lie down much, that the greatest progress and advancement in fattening are made, whether in flock of the cattle, sheep, or any other sort, when at grafs. But, on the inferior or weaker grafs-lands, a much smaller proportion of flock than on those of the rich and fertile kind only can be employed. It can frequently not be more than an ox and a sheep or two, to two acres, or two acres and a half. However, in flocking with west-cattle, for the purpose of fattening, it should constantly be such as the animals may have a full bite; but with sheep, such as to keep the pasture in a rather close state of feeding. Another circumstance is necessary to be attended to, in order to bring the grazing-flock properly forward in pastures, which is that of changing them more frequently than has generally been the case with grazing farmers. And it is, perhaps, on this principle, as well as those of their affording greater degrees
Grazing.

The same writer also adds, that "the manner of flocking a grazing farm in the marishes differs according to the nature of the land. In Romney Marsh, the views of the grazier are chiefly directed to the breeding and management of sheep; and in the Isle of Sheppey, both bullocks and sheep claim his attention, whilst in some parts the marsh land is wholly appropriated to the breeding of horned cattle and colts. Tho' grazing farms are most eligible, which admit of breeding and fattening on the same paiture. This is the case with Romney Marsh, a tract of land to eminently distinguished for a valuable breed of polled sheep, that it furnishes the graziers of Sheppey, and other places in this county, with an annual supply of lean-flock over and above what is reserved for feeding; so that it is evident the graziers here enjoy a double profit from his farm, though it is believed, since the increased value of lean-sheep, that the graziers in the Isle of Sheppey have many of them adopted the method of breeding their own flock." This is probably the most beneficial practice.

In the county of Wiltshire, the cattle bought in in September are wintered on the coarse pastures and in the ikra-yard. In May following the young ones are sent to the commons; and those of an older description turned upon the best pastures as soon as possible, according to the circumstances of the situation. But in the Agricultural Report of the North Riding of Yorkshire, it is said that "there the usual time of breaking the pastures is the 12th May, from which time they continue regularly flocked until about October, when, if the stock consists of milk-cows, or feeding cattle and sheep, they are removed to the grass pastures; the pastures, with the addition of the stubbles, remain flocked during the winter with more sheep or lean cattle; but the latter are, by many farmers, taken into the ikra-yard for the night. The herbage of the pastures is, however, it is thought, thus completely destroyed before winter, and the land thus left is harrowed, and the growth of moss greatly encouraged, to the almost certain ruin of the grass-land. An influence has not occurred in the course of the survey, of the practice of preferring a considerable part of the fanner's growth of grass upon the land, for spring feed, a practice well worthy of attention. This winter clothing, it is supposed, enriches the fowards, destroys the moss, and, by keeping the roots of the grass warm, causes an early vegetation in spring, when the scarcity of the herbage to much enhances the value of it. On farms, the foil of which is not adapted to turnips, this practice would, it is said, be peculiarly beneficial.

"In March, the land intended to be pastured the ensuing summer, is, or ought to be freed, and the stock put into the land intended to be mown, where they remain, until those pastures are broken up in the beginning of May.

"In the dales of the Moorlands, the lower lands only are adapted to meadow; consequently, the land cannot be changed alternately from meadow to pasture, as may be practised in many other parts of the Riding; though there, as before noticed, the practice is not sufficiently attended to. There are many instances of cow-pasture, which have been invariably fummer-fed during several generations." See Pasture-Lands.

"The bell farmers usually pasture their new laid ground the first two years, and that chiefly with sheep, as sheep improve grass more than any other kind of stock, both by their trading more lightly and uniformly, and by the dung and urine being more regularly dispersed over the land. But the practice of eating them very bare during the first autumn and winter after favours, and also moving them the first summer, is too prevalent; such practices are, it is observed,
Grazing.

erved, the ruin of seeds. Some, however, think that
patturing new laid ground is most excellent management;
the several grazings, by being frequently cropped, becom
not only firmer in nature, but much more numerous. Stock,
when patturing new lands, ought to be often changed; if
ever you over-cast, they will require some time to recover
their usual vigour. New laid-grounds sometimes give sheep
the rot, particularly three or four years laid, on indifferent
foils."

And the practice of shifting the stock from one paiture
to another, of mixing different kinds of flocks together in
a due proportion in the same pasture, and under flocking
with sheep, pastures deftined for feeding larger cattle, should
always be particularly attended to.

It is stated in the Survey of Lincolnshire, that “the rich
grazing lands are the glory of that county, and demand
a singular attention. The soil is a rich sandy clay, fome
very diff, but of uncommon fertility, as may be known
by various instances. Some of the grazing lands in Long
Sutton that were common, will carry five or six sheep an
acre, and four bullocks to ten acres. Mr. Scrope has
there four acres, which carry 45 sheep in summer, and must
be bobbed often to keep it down. And on the gras-lands in
Deeping Fen, improved by paring and burning; Mr. Graves
keeps five sheep an acre from Lady-day to Michaelmas, and
one and a half in winter, and a bullock of 60 stone to two
acres besides in summer.”

And from some trials which were made by T. Frydell,
eq, in the grazing of near cattle on the belt foirt of ground
in Lincolnshire, and which are given below, Mr. Young is
led to conclude, that 41. an acre is the highest rent he has
heard of in that county, and much higher than common,
even for the bell lands. This seems to confirm the idea he
has entertained, that the rich grazing lands of this district
are better rented than fuch or nearly fuch lands in other
parts of the kingdom. And further, that “the average
weight of the beasts was 70 stone, being of the York or
Lincoln breed; the sheep all Lincoln. The former bought
in April or May, and all gone by the 11th of December;
the sheep are bought in May; they are clipped twice, and
fold fat in April or in May following; that there is little
difference in feasons, except that, after a bad winter, the
sheep are not ready for market fo soon by a month as they
are after good winters. The losses in weight in driving to
Smithield is very little; the expense, beait 15. 9d. sheep
11. 9d. each. Mr. Frydell held for severai years a piece
of land in Skirbeck parish, which measured 21 acres, and
kept, communibus annuis, from Lady-day to Michaelmas, 19
heavy beasts, and a 100 sheep, and birtened fifty sheep.
And he now holds a paiture adjoining his garden, at Bolton,
of eight acres, which keeps in fummer ten oxen and forty
sheep, and winters thirty sheep. But the finest grazing
lands are at Bolton, Aldercruch, Foflyke, Sutherton, Kirton,
Frantun, Whiberton, and Skirbeck: these will carry, in fummer, a bullock to an acre and a half, besides
four sheep an acre; and two sheep an acre in the winter
season.”

It is stated that “the Rev. Mr. Berridge, of Aldercruch,
has near his house forty acres of the rich gras, upon which
the flock is upon an average 300 sheep; sixteen fattening
bullocks, three cows, four hurles, and carries through the
winter three sheep an acre. This land is valued at 40s. an
acre. It is a vail flock. He favoured him with these partic-
ulars in the presence of a dozen neighbours, and called in
his manager to confirm it; it wanted, therefore, no after-
corrections.” And “in the grazing lands at Swinehead, a
beast an acre of 40 to 70 stone, and two or three sheep; 150
two sheep an acre in winter. Mr. Tindal, at Ewerby, which
is on high-land, compared with Holland Fen, flocks a bul-
lock to two and a half acres, and three sheep per acre in
summer, and two sheep an acre in winter. And in the lord-
ships of Horbling, Billingborough, Berthorp, Semp-ling-
ham, Pointon, Dowby, Dunby, and Hackonby, there are
extensive tracts of rich grazing land applied to fattening
bullocks and sheep, carrying a bullock to two acres, and three
sheep per acre in fummer; and two sheep an acre in winter,
which lands are generally rented at 3s. per acre. Mr.
Eikington, of Howel, keeps one bullock and nine sheep to
three acres, and in the winter two sheep an acre.”

But “Hanworth, north of Lincoln, is chiefly grafs which is fed
by cows, calves, and young cattle. On the Law at Norton
Place, which is heath-land, two couples per acre in fummer;
but the foil not adapted to permanent grafs without great
exertion.” And “there is a tract of paiture-land, which is
of considerable extent north and south, but very narrow
east and west, which lies in the vale between the heath and
the Wolds. It viewed it from Norton Place going to Owerby, which is in it; the quality is good, but of the
second rate.” And further, that “the gras-land ele to
Gainsborough last at 4l. and 6l. an acre.” The marsh grafs
on the Trent and Knaiia, &c. 20s. to 30s. and produces
one and a half or two tons of hay an acre. The marshes on
the river are stocked from the 12th of April to the 12th
of May; this of late has, however, been omitted, as they
found the gras hurt by it. Clear the hay by Lammas, one
to one and a half ten an acre. Then turn in milch-cows,
and afterwards other-stock, till November. Rent 20s. but
measurc short. And at Garthorpe, in marsh-lands, some
rich grazing lands, which will carry a good bullock an acre,
but no sheep fed. This land is now let to break up at
3l. 15s. an acre for 14 years.” But that “Mr. Heffelden,
at Barton, has four acres near the town; levelled and ma-
ured it after the allotment, and this year it feeds four
cows; three of them joifted at 3l. a week, a produce of 12
guineas. At Immingham and Stallenborough, there are
some marsh-lands that will carry nine bullocks of 60 stone
upon 12 acres, and 12 sheep, and two flocks of bullocks in
winter; some has only one. But the same lords have, it is
remarked, clay pastures that will not do any thing like
this. And, at Thornton college, Mr. Uppeby has a few
clopes of extraordinary fine grazing-land, which will carry
the largest bullocks, and it is worth, he thinks, 50s. an acre
rent.

“ The marsh on the coast of Grainthorpe, Saltfleetby,
and Thedlethorpe, &c. is very good: it will keep three
sheep an acre, and an ox to three acres; and one sheep
and an half to an acre in winter. The hilly wold good paitures
on marl and chalk at Gayton, near Louth, will carry three
ewes and three lambs per acre, and a sprinkling of young
cattle, &c. besides; some only two ewes and lambs, besides
beasts, such land as is worth 15s. to 2zs. an acre. In the
marshes that are in the vicinity of Saltfleet and Sutton,
there is some defiance, which it will be proper to note by
particulars. In Northcots, the quality rather inferior, being
chiefly for breeding. There Chapel, better, but ill like
and for breeding also. In Granthorpe, a great deal very
good grazing land. Coultholm, low, swampy, and but
little good. Skidbrook, a great deal, and very good. South
Somercots, the same; but 1000 acres of 50s., or common
meadow. The three Saltfleetby's 5000 acres, and a great
deal very strong and good for feeding beasts. Some of the
late Mr. Chaplin's marshes here hold fo high as 75s. the
flute
In the Theddlethorpes, much very good; but some low, and not well drained. Marblemorton, very good. Sutton, remarkable good and strong feeding land.

"In these marsh parishes, the rich grazing ground of the first quality lies at about 40 sh. an acre, and the roll about 30s. Such as will not breed, but are used for hay, at 20s. to 25s. per acre, and this division of feeding and breeding is here also expressed by saying, that one part of marsh will feed sheep; but the other, keep them in holding order, will make them hold the flesh they have got, but not fatten profitably. If the stool of these lands is compared with the grazing districts of Boston and its vicinity, it was remarked to him, that these are more naturally good, and much better watered: they have at all times plenty of fresh water here, which is a great object; but for artificial fertility, locality to towns and markets, &c. the Boston lands are much superior. The mead at Boston, &c. is here said to be more than an acre; here left, not more than three roads, and the ing land still left. On ten acres, at Skidbrook, eight beafts and sixteen sheep have been summered, and the sheep wintered also. And, in general, the marsh that lies from 30s. to 40s. will carry a beaft to two acres, and two sheep an acre; but, perhaps, he says, more generally one and a half sheep."

With respect to the profit of grazing the beart land, it is stated in this manner:

The grofs interest rather better than 10s. per cent.

Mr. Parkinons, of Reefesby, observed, that the rich marhs were better managed, and in better order, twenty years ago, than they are at present; the wold farmers had not then got such possession of them, and they were in the hands of resident graziers, who attend more to holding, which kept them fine; for nothing hurts marsh land so much as letting it run coarse, from permitting the grazs to get a head. And he calculates an acre of rich marsh in Wrangle, &c. thus:

Or total interest 111. 5s. 6d. per cent.

In the hundred of Skirbeck, the pasture consists of three
forts in point of rent, &c; the highest at about 45s. being
from 32 to 50s. The second from 26s. to 32s. average
28s. The third, average 1s. 10d. Besides this a small
quantity of open meadow, called ingles, average about
18s. The best kind of pasture is chiefly stocked with
shearing wethers, bought at the spring market at Boston,
which, having yielded two fleeces of wool, are sold off
early in the next year; and by beasts in the summer, fold
in autumn; some kept on farther in eddibh, but all gone
in the winter. The second best is chiefly fed by young
beasts and hogs, kept on to shearings; these are well kept,
as their value materially depends on it; there are also
some few breeding sheep on this division of the pasture.
The third class is chiefly mown. But it is to be noted
that all these particulars relate to an acre larger than statute
measure, about 43 roods."

"The first division is stocked at the rate of three sheep
per acre, winter and summer, with the superlative of some
bought in the spring, and not cleared from the land till
some months later than the time at which they are bought.
The heaths are in proportion, on an average of seven to ten
acres, from 5s. to 10s. The second class winters
about five sheep to two acres, with not less than four
per acre in summer, with a few cows and young beasts; and
on both these there will be some few horses, too uncertain
for average. On the better land, they are chiefly horses making
up for fail; and, on the second quality, horses employed
in work, or young ones; it is not usual to keep any horses
in summer except on the pastures. The produce of hay
on the third may be about 35s. an acre; the eddibh eaten
by cattle from the other grounds; or by hams or hogs,
before they go to their winter keeping.

The writer hints that the profit upon this first class of
land is greater than upon the rest; and that the third
yields very little profit by grazing, and would pay much
better in tillage. There are many graziers there, who have
no other land than what is upon these flats, and some who
are supposed to have made by their business enough to have
realized
realized a comfortable subsistence. The grazing accounts of certain fields in the occupation of Mr. Loft, of Math Chapel, are stated in this way:

Grazing.

It is however stated, that very few fields will yield anything like this; he has but one close; and there are some expenses omitted. And "Mr. Tennison, of Lincoln, has 43 acres of marl at Grimby, that summer-feeding 14 bullocks; and carries 35 sheep the year through." But that "in the tract of marl-land on the sea-coast, they observe, that where most grasses is left in autumn, there the herbage is the coarsest and worst next year; the remark was made in answer to recommending eddiis for spring-feeding sheep, which would not do so on rich marl, though it might on uplands." It also shows, that the system of close feeding is proper, and would answer well in many districts where it is not the practice." And "in the hundred of Skirbeck, they like to have a tolerable head of grass in the spring, before turning in; and afterwards go to stock as to prevent its getting coarse by running away, so as to prevent the necessity of hobbling; which, however, must be done in a wet growing season."

But after the flock has been brought into a proper state for the market, there is in many situations much difficulty in Dispose of it to the best advantage. Mr. Marshall has remarked, that though it be attended with less difficulty than that of buying in the flock, it requires much knowledge, as well as experience, to execute it in the best manner, or with the least possible loss. A due consideration of the prospers of the flock while feeding; and of the length of time they have been upon the land; may afford some fort for guide in the business; but the most correct judgment may be formed by the young grazier, by the practice of frequent weights, and the accurate comparison of the living with the dead weight of such flock as are killed in his neighbourhood, as it is a much more certain method than the use of the eye and hand, as has been shown under the head Graziers. Having recourse to frequent weighing has also the advantage of showing the progress that is made by animals under different forts of keep or food. But besides this, the grazing farmer must be regulated in the sale of his flock by the nature of his situation. In most of the midland and southern parts of the kingdom, Smithfield is the place where the fat flock of the farmers are disposed of; while in other parts, they are frequently sold in the neighbourhood, or to the large towns which are at no great distance. In the former cases, especially on the less extensive farms, the Fat Flock are brought out to be sold, and the make it a bullocks, being employed by various graziers in the name vicinity, who have an entire confidence in them. With the more extensive graziers, who fend up frequent lots, the business is done by a salesman, in whom they have confidence. With little grazing farms, the computer is often to sell them to the butcher in the neighbourhood, which is frequently the best method. And the advantages of these different modes must depend greatly upon circumstances. Some, however, suppose that the London market is the best calculated only for those who give a weekly attendance, on account of the uncertainty of the supplies. The expenses being materially different, as with the salesman's commission, they are more than three or to five. Consequently, that fat flock-may in many cases, where only a few, or what are termed small lots, are to be disposed of, be sold at home with less expense than having them sent to distant markets; but that with large lots, the latter mode must be had recourse to, as more certain, expedients, and convenient. Upon the whole, the facts which have been stated fully shew that the advantages of the grazing system must be materially different under different circumstances, and be greatly influenced by those of a local kind. It has indeed been remarked by a Kentish grazier, that the profits of no two grazing farmers are exactly "alike on the same given quantity of land," nor even on the same land, as years, prices, as well as the exertions and talents of each individual, are different. In all cases, the superiority of the success must be a great measure depend upon the knowledge, exertion, and excellence of the method which is adopted by the particular farmer. Statements can of course only shew what are the general profits of the system. With meat-cattle, in the western and midland districts, they are given by Mr. Billingbye, and Mr. Young, in the Surveys under the direction of the Board of Agriculture. In this way, the former says, that a grazing farmer who has 250 acres of land, may fatten annually one hundred head of cattle, as oxen, with seven sheep and ten coals, which together may afford a comfortable but not exorbitant profit to him.

And on the rich grazing lands in Lincolnshire, according to the latter writer, the practice seems to afford a much greater advantage to the farmer; as the account, given by T. Pykell, esq. M. P. for twenty acres, in 1796,stands thus:

And that “the difference between the buying and selling price, los’s deducted, 200l. 8s., is the produce of the land, or 16l. 6s. per acre, which is very great indeed, and shows that this land would let at 5l. 2s. an acre, supposing this year to be an average one.”

“This difference of rent would deduct 44l. from the profit of 87l. and leave 43l., which, with 21l charged, make 65l. interest on the year’s advance of 546, or 11½ per cent.”

But in the system of grazing pursued in some of the southern rich marshy districts with sheep, as stated some time ago, the amount stands as below, according to Mr. Price; but at present the profit must be much higher, from the improved management of the Romney Marsh graziers in general.

It is remarked, "on the first of these statements, that the year was favourable for vegetation; and that such profits could not probably be made seven years together, which is the most accurate method of calculating profits on land. There being no affeles on the land, also, makes it more profitable." And further, that two modes in respect to the profits on fattening land are stated; the first used by the best graziers; the other, the most common: some take bullocks in to keep, others buy rents; the profits of which must depend on their judgment, but 3½ is the medium profit between the whole; 1½ each sheep is generally allowed as the gained profit by fattening. It is added that "it cannot be supposed that this profit will always amount to so much as the years differ; therefore dry fees will abate it, and a large tract of land cannot have the supply of flock to make it so great. There are losses to be taken out; but, upon the whole, it is very profitable, as the expenses are so moderate, that one servant-man can manage a thousand acres of pasture land. The value or rent of land is put too low, except for long leases unemployed, or where a large quantity of land is taken. The average price of rent is from 4½ to 5½ for fattening land, unless four or five hundred acres of breeding and fattening, perhaps about 3½; and some old leas 1½ breeding land."

It is stated that where sheep, in order to fatten them in a more expeditious manner, or to finish them in the field, where the grass is insufficient for the purpose, have the addition of turnips or other sorts of luxuriant green food, great care should be taken; by the grazier, that a due proportion of some sort of dry material be had recourse to at the same time; as without such precaution, not only mows but may be sustained by the death of some of the sheep in particular instances, but by their making less progress in becoming fat than would otherwise be the case. Hay, cut stuff, bran, or a few oats, answer the purpose very well. See Sowing.

It is necessary, in order that the consumption of these sorts of food may be conducted in the most economical manner, that proper troughs, racks, crib, or baskets, should be provided, and fixed in such a way, that they cannot be overturned. The graziers, in some parts of Lincolnshire, have a large sort of crib or wicker-work bucket, being eight or ten feet in circumference, and wattled to the height of one foot or a foot and a half, in a close manner, and then left open at about a foot and a half; after which it is closely wattled again for nearly a foot, being drawn in in a narrowing manner at the top, so as to have only proper room for introducing the food. The rails of the frames are placed about eight or ten inches apart, which admit of the sheep feeding in a distinct manner. It is described in the fourth volume of the third series of the Repertory of Arts, &c. and denominated a tumbrid. It may be seen at fig. 8, in the Plate on Granaries. This contrivance affords much advantage, both in the faving of food from being wasted, and in affording the leas sheep an opportunity of feeding without being disturbed or driven away by the strong ones, and consequently much injured.

In the Rural Economy of the Midland Counties, it is noticed in respect to the practice of grazing in such seasons as are very wet, that an incident of this sort that occurred to the writer in the very wet autumn of 1789 is interrelling. "The general complaint is, that grazing stock, though they have this year rolled in grass, have not done well; Mr. Henton, of Hoby in Leicester, being singular in laying it to the choice of his feeders, and done tolerably. Indeed his flock corrobates his assertion. He had a lot of cows at Loughborough, the 12th of August, the fattest in the show. "But his management is more remarkable than his success." He "foddered them with hay all the wet weather; that is, he mowed the broken grass for them, beginning under the hedges, and continuing to move the coarsest patches throughout the piece. "The first day (the day it was mown), the cattle feldom this touched it; but the second or third day; they fell to it freely, eating it "between whales," in preference to grass. In the morning, it was always the first thing they filled their bellies with. "The cattle having eaten up the more palatable parts of the herbage, the thistles, and other offal, were raked up, and carried off the ground: most excellent management! "This Stock committed of about fifty head. At first one man only was employed in moving, &c. But, before the rainy weather ceased, he set on another man. "What an admirable thought! that which other men suffered to stand waste in itself, an encumbrance to the ground, and a nursery of weeds, was converted to food, more nutritious, in a wet season, than the best of the standing herbage."

Mr. Parkinson of Lincolnshire, had made a practical obser-
ferration, which is, that "the less sheep are changed, the better." It demands the farmer's attention, as the saving of the injury of flocking in many cases. And it is noticed, that the grazing on rough land, Mr. Marshall remarks, that "the fairs at Birmingham are among the worst in the country for fat stock; the butchers giving the grazers no encouragement to drive their flock to them, preferring the toll of riding twenty, thirty, or perhaps forty, miles from home to pick up their "fat!"" paying a principal part of their time and their profits in an employment truly ridiculous. How convenient it would be to the grazer, as well as to the butcher, to have a weekly market, a Smithfield at or near Birmingham! to the grazer, in thereby having a constant and certain market whenever he wanted either keep or money; and, to the butcher, in saving time and travelling expenses. Yet the few animals which are taken there at present, are frequently driven out of bounds. But Thursday, which is the ordinary market-day, is improper. Monday or Tuesday would be a more suitable day; and Sutton, perhaps, the most suitable place. In performing the business of purchasing in flock, the nearfell fairs are always to be preferred, if it can be done there with propriety; as much injury and loss is frequently sustained by driving from a considerable distance.

And the business of grazing other kinds of animals may, in some cases, be a profitable concern, but must always be regulated by the nature of the land and circumstances of the farmer. Where he has a considerable extent of the more coarse part of the pastures, he may often find it advantageous to graze young horfes, especially where he has the convenience of breeding them likewise. But though it is a practice sometimes followed by grazing farmers, to admit horfes in the same pastures with the other flock, it should certainly be avoided as much as possible, as they are very injurious by teasing and driving the fattening cattle about, and preventing their feeding so much as is otherwise the case. It is a better method to let them follow this flock off flock. When the flocks are admitted upon the grazing lands in Somersetshire, it is seldom done in a larger proportion than that of one to twenty acres. But there is another animal which it has long been a practice in particular situations to graze. This is the hog, which, where the farmer has a piece of rich grafs, either of the artificial or natural kind, he may turn upon it with much advantage. With clover, and some other artificial grafs, the animals are found to succeed perfectly well in this sort of management; but it is objectionable as loosing a vast fourteenth of manure of an excellent kind. When the field is so stocked as that the hogs can return in the evenings to the well littered fities, it may, however, be a highly benefial fystem of practice. There can be no doubt but that this sort of management might be much more extensively employed with this animal, and that thereby much of the food of ilore pigs might be saved. See Hog.

GRAZIOSO, ItaL. Graziosifem Fr. graceful, are terms in Artists, addressed to the performer; but if the composition is devoid of grace, the term can convey no instruction to the performer. It is in vain for the composer to sit down with a resolution to compose a graceful movement; it must come unfeigned, and infenibly.

Marmontel has defined grace in poetry, grace in attitudes, grace in motion, grace in the arrangement of words in prose, of figures in painting, as a poling, a lacquer, a varnish, a gilding to every human action; without which we may be surprised and entertained, but never perfectly pleased.

No poet, perhaps, abounds in grace and facility so much as Metafilho; for examples, see his cantatas.

Among musical composers, perhaps, none have been more gifted with this charm than Pergolesi, Sacchini, and Cimarosa.

The time of a grazioso movement is nearly the same as andante; smooth, gentle, and inclined to piano; no coarse strokes of the bow on the violin, or dry cocs de ligne on the G flute, except, to vary the expression and effect, the composer indicates the contrary.

GRAZZANO, in Geography, a town of Italy; 15 miles N.S.W. of Verona.

GRAZZINI, Gio. Paolo, of Ferrara, in Biography, left the profession of goldsmith to become a painter at an advanced period of his life; his chief instructions he owed to the friendship of Carlo Bonone. The first specimen of his capacity was a picture of St. Eligio placed in the goldsmith's hall of Ferrara. Eight years which he had employed to finish the work were amply redeemed by the display of a master hand, and a tone of colour that pleased him near in rank to Porpora, and allommed all Ferrara, who had known Grazzini for half a century. He continued to produce works of less compass, but of equal taste, which are met with in private collections. He died in 1632. Rufii's Pilgritt.

GRAZZINI, Anthony Francis, surname Il Lofa, an Italian writer, was born at l Florence in 1553, and is known to posterity as a considerable writer in prose and verse. He is particularly remembered for his light and jocose poems, among which are many of the Cant Carminalefchi, or Carnival songs. Thefe, it is said, were first invented by Lorenzo de Medici, and a collection of them was published by Grazzini at Florence in 1559. His other works are as follows: "La Guerra de Molin, poema giocole," 1584. "Stanza," &c. "Comedie VII," "Il Lofa, Dialogo," &c.; "Lettera," "Orazione," &c. Rive, Novelle XI. The last was an extremely popular work, and as a novel it Grazzini was thought to be a worthy rival of Boccaccio in the elegance of his narration and purity of his style. He was one of the founders of the academy Della Crusca.

MORERI.

GREASE, among Furriers, &c. an inflammation and swelling of the heels about the fetlocks, and sometimes of the legs of a horse, as high as the knee or hock, with the seer of an oily matter, to which the disease owes its name. The matter discharged from the heels has a peculiar offensive smell, and the heels themselves are sometimes ulcerated. Heavy horfes, with round fliny legs, are the most subject to this disorder, and the white legs more than the rest. It is almost always found in the posterior extremities.

Grease is occasioned by sudden changes from a cold to a hot temperature, such as the removing of horfes from grafs into hot stables; from the too sudden change of a generous to an impoverishing diet; from neglect on the part of grooms in leaving the heels wet and full of sand; and from constitutional debility. On the approach of this disease, and for several days before any very considerable appearances of swelling and inflammation, the animal seems to feel much pain in the affected heel, which is indicated by his rating it frequently from the ground, and his not being able to rest upon it without uneasiness. At this early period, the disorder may in general he removed by a poultice of boiled bran and indeed powder constantly applied to the part, and kept moist with warm water; giving every night, or every second night, a mild diuretic. When the inflammation and swelling are consider-
GREASE.

able, the fore-mentioned poultice may be used, and a strong diuretic, or a purgative may be administered as long as the cafe seems to require it. When the swelling and inflammation have abated, which will commonly happen in three or four days, the poultice may be discontinued, and the following astringent lotion may be applied five or six times a day.

Forms of astringent lotion, viz. No. 1. Alum powdered, 1 oz., vitriolic acid, 1 dr., and water, 1 pint. No. 2. Alum powdered, 3 oz., vitriolated copper, 3 oz., and water, 3 pint. No. 3. Sugar of lead, 3 oz., vinegar, 6 oz., water, 1 quart. In each of these recipes mix the ingredients. Some alteration may be necessary, according to the strength of the lotion. If the inflammation and irritability of the part are considerable, they must be diluted with an equal quantity of water; but if the inflammation be subdued, and a swelling and ulceration remain, the astringent cannot be made too strong. If the heels be ulcerated, and especially if they appear foul and have an offensive smell, one or other of the following astringent ointments should be applied to the uces, viz. No. 1. Hog's lard, 4 oz., oil of turpentine, 2 dr., and water of acetated litharge, 8 oz. No. 2. Venice turpentine, 1 oz., hog's lard, 4 oz., and alum finely powdered, 1 oz. Mix the respective ingredients. If the ulcers be deep, and do not readily heal, they should be washed with the detergent lotion previously to each dressing. Regular exercise on clean and dry ground is of the highest importance. In flight cafes of grease, the astringent lotion and a few diuretic balls will generally effect a cure; but if the disease be of long standing, and more especially if the horse has had it before, it will be more difficult to remove it. In such cases an alternative, in the nature of a powder, compounded of powdered refined niter of each 4 ounces, mixed and divided into 8 doses, should be given in the corn every day, until it produces a considerable diuretic effect.

In very obilinate cafes, roves in the thigh have been found useful. Digitalis, or fox-glove, has been recommended in those swellings of the legs which are the consequences of grease; but as this is a violent medicine, and apt to injure the stomach, it should be cautiously administered; the dose is from half a dram to one dram. When a horse has suffered much from this disease, and appears to be weak and out of condition, a liberal allowance of corn will tend to recover him, especially if it be diluted by the astringent lotion, and careful grooming. In cases of this kind exercise is indispensable. When the disease depends upon debility it is obvious that a dose of physic would be improper; but considerable benefit has sometimes attended the exhibition every morning, till the bowels are moderately opened, of the following alternative; viz. ficcureine aces, 1 oz., calafe sop, 1 oz, powdered ginger and myrrh, of each 4 oz. Form these into a mass with sugar, and divide it into 5 balls. This remedy, though of an opening quality, will improve the horse's strength, and at the same time promote abstraction. Or the following preparation may be administered; viz. antimony, finely powdered, and flowers of sulphur, of each 6 oz.; lutein powder, 2 oz.; and honey sufficient to form a mass for 2 balls; one of which may be given once or twice a day.

Nothing tends so much to prevent grease and swelling of the legs as frequent hand-rubbing, and cleaning the heels carefully, as soon as a horse comes in from exercise. Initerate cafes of grease, where the disease appears to be in some degree habitual, a run at grafts is the only remedy. If a dry paddock can be procured where the horse may be sheltered in bad weather, it will be found very convenient; for thus circumstanced the horse may perform his usual labour, and be kept free from the complaint. In the earlier stages of the disease, the practice of turning the horse into a fatt-marsh is serviceable: and a few months' run on a salt-marsh has frequently eradicated the disorder, when other remedies have failed. Obstinate cafes of grease may very frequently be cured by withholding the horse's allowance of water for two days, or even a longer time, and then riding him into the sea or salt water, when his thirst will induce him to drink freely; and the salt water will act as an useful laxative and alterative. This process must be frequently repeated, whenever it does not appear to be injurious in any material respect. In a few obstinate cafes, Mr. White says (Treatise on Veterinary Medicine,) that he has often merited all service, giving one ball every morning, until the bowels are opened: it is formed of calcined, 4 dr., aces, 1 dr., Castile soap, 2 dr., and oil of Juniper, 30 drops, made into a ball with syrup for one dose. In the treatment of these ulcers, or "cracks," as they are often termed, which particularly occur in the back part of the patellas, and which are of difficult cure, cleanliness is of great importance; and when they appear inflamed and painful, it will be useful to apply a soft poultice, in which a little Goulard has been mixed, for two or three days. The following ointment, viz. fresh hog's lard, 4 oz. and white lead finely powdered, 1 oz. mixed, may then be applied, spread on tow, and fixed with a light thin bandage. If cracks or ulcers appear in the heels, without that general swelling of the legs and discharge of matter, which constitute the disease named grease, they may besoon cured by applying the astringent ointment, and giving a few doses of diuretic alteratives; but when these are accompanied by the grease, laxatives or purgatives are necessary, according to the condition of the horse. In obilinate cafes, the matter discharged is made of hog's lard, 4 oz. palm oil, 2 oz. and fine olive oil, 1 oz. melted by placing the pot which contains it in boiling water, and, when melted, stirring in 1 oz. of the water of acetated litharge, and continuing to stir it till the mixture is nearly cold. If the ulcers are deep, the horse should be kept in the stable till they are nearly healed, with a cooling opening diet; and his legs should be frequently and briskly rubbed with the hand; and a few of the diuretic alterative powders should be given. When proud flesh, as it is called, appears in the ulcers, it must be destroyed by cauteries, such as blue vitriol powdered, or distilled in warm water, or tannin cautery. When this is neglected, they function more to a large size, and become devoid of a firm consistence, in which state they are commonly named "grapes.

In recent cafes of grease, in which the heels are inflamed and swollen, and discharge a whitish-coloured matter, much benefit has resulted from fomenting them for a considerable time with warm water, in which a small quantity of Goulard has been mixed, and immediately applying the Goulard poultice. In obilinate cafes of grease, the matter discharged is very solid; the fomenting practice is useful; that is, a poultice of linseed meal, warm water, and yeal, which soon restores the offensive smell, and causes a dry scurfy matter to be formed. Powdered charcoal has also been recommended for the same purpose. In recent cafes the Goulard poultice and cold purgatives will soon reduce the inflammation considerably; and then the cure is easily accomplished by astringent lotions. For preventing a return of the complaint, exercise and good grooming are indispensably necessary; frequent hand rubbing of the legs, and a diuretic powder occasionally, are also useful. Horses with white binder legs, or such as are much exposed to swelling of the legs, should be bandaged for some time, particularly after hard work, keeping the bandage constantly moist with a solution of alum and water. In some cafes of grease the inflammation seems to extend to the cellular membrane under the skin, the consequence of which
which is a more severe pain and lamenefs than when it is superiour. The inflammation generally terminates in an abscess of the heel, which bursts and leaves a deep ill-looking ulcer. Although the general swelling of the legs subsides, the ulcer is extremely irritable, and healed with difficulty, particularly if the horse be exercised. By applying poultices and warm digestive ointment, and by keeping the horse at rest, the ulcer gradually heals. When ulcers of the heel do not appear disposed to heal, the adherent ointment above-mentioned should be changed for the following, which is more stimulant, and previously to its application, the foot should be washed with a solution of blue vitriol. The stimulating ointment is prepared by mixing ointment of yellow rhubarb, 4 oz. olive oil ½ oz. and red nitrate of silver in fine powder ½ oz. See White’s Treatise of Veterinary Medicine, vol. 1.

If the griece be an attendant of some other disease, it will be in vain to attempt the cure before the diseafe be removed, that is the original cause of it. Therefore, if it be a hectic, the yellows, or the feirin, &c. the directions given for those difeafes are to be followed, and in the mean time proper applications are to be used outwardly for the griece.

Grease, Molten, a difaife of the intellines, incident to hores, and generally dependent on some constitutional affection. Horses that have been well fed, without much exercise, are peculiarly subject to this complaint; although they appear sleek and fat, they are not fit for violent or long-continued exertion, unless they have been brought to it gradually; and therefore when they are put to work in this state, and violently exercised, a fever often ensues; and this fever commonly depends upon general inflammation or increased action of the whole arterial system. In this disease, nature makes an effort to remove it by a violent purging; and the mucus, formed on the inner surface of the bowels for the purposes of lubricating and protecting them from the action of any acrimonious matter that may happen to be passing through them, being now so abundant, appears somewhat like fat mixed with the dung. When blood is drawn from a horse in this state, a large quantity of inflammatory bruised lymph, or buff-coloured jelly, appears on its surface. Such is the account which Mr. White gives of this disease, and he explains the account of those veterinary writers who represent molten greece as consisting in a colliquation or general making of the fat of the body, great part of which is absorbed, and thrown upon the blood and upon the intellines, whence it is voided with the excrement. Nor does he approve of the description of this disease, given by Mr. Baving, in his Treatise on Veterinary Medicine, who considers it to be the same with the human dysentery. In the course of a ten years’ extensive practice, he says that he has never met with a single case that resembled the dysentery described by medical authors. “I have often observed,” says this writer, “during the progress of symptomatic fever, internal inflammation, mucus mixed with the dung, which had sometimes the appearance of part of one of those long white worms so often found in the horse’s bowels; at others it resembled a membrane. I have observed the same thing in horses of great bodily health, or after the operation of a violent physic. I have also seen many cases where there was tenesmus or considerable irritation in the rectum; the horse frequently voiding a small quantity of dung, and appearing in pain. But this was always a symptom of some more important complaint, and easily removed, or the effect of physic, and very unlike dysentery.” Molten greece, according to Mr. White, is not to be considered as a distinct disease, but merely as a symptom, sometimes appearing in general inflammation, but more frequently in fevers. In either of these cases some of the internal organs are more affected than others. When a difficulty of breathing occurs, indicated by an unusually quick motion of the flanks and expansion of the nostrils, it is a sign of an affection of the lungs. When molten greece appears, it shews that the mucous membrane of the bowels is more particularly affected; sometimes both these parts are affected at the same time. The principal remedy in this diseafe is copious bleeding, according to age, strength, and other circumstances of the case. It is often necessary to repeat the operation of bleeding; and if the disaife appears to be principally feated in the lungs, only laxatives should be administered and bowels infibted in the chest and belly; the fides also may be blifled, or the multbard embrocation rubbed on the fides and belly. In mole of greece, or when the bowels are affected, if a copious purging occurs, it should not be suppressed, but encouraged, by giving frequent decoctions of bath, gum arabic dissolved in water, flarch, or the powder of arrow root, and boiled in water. When the dung is voided sparingly, but frequently, and particularly when any worms are mixed with it, let a pint of calfer oil be given, which may be repeated, if necessary, about two days. In this case it will be proper to rub the multbard embrocation on the belly. If the diseafe con- tinue, and especifally if there be considerable irritation about the anus; the horse frequently ejecting a small quantity of excrement, and appearing to be in great pain, the following opiate clyfter may be given. viz. opium 1 dram, warm water 8 oz. mixed, to which add about a quart of flarch water, i. e. flarch boiled in water, of a proper confequence for a clyfter. If the exhibition of a clyfter seems rather to increase than alleviate the pain and irritation, the dofe of calfer oil must be repeated, and a clyfter thrown up only of water gruel or a little oil. As the gut in this case is very tender and irritable, the clyfter pipe should not be rough, and it should be introduced with caution; it should therefore be perfectly smooth, covered with oil or hard, and not protruded with violence. It is probable, says Mr. White, that a small, short tube of bone, about three times the bulk and length of the pipe used in human subject, would be preferable in this occasion to that which is commonly employed. White’s Treatise of Veterinary Medicine, vol. 1.

Grain, among Hunters, denotes the fat of a bear or hare.

Greasy, in Agriculture, a term provincially made use of to imply any thing foul, whether in animals or land. It is frequently used figuratively, in matters of mortality, &c. to signify any thing affected, diseased, peculiar, important, &c. Thus we say, Shakespeare was a great genius; queen Elizabeth had a great soul; Cromwell was a man of great designs; Da Vinci, a great painter; Galileo, a great philosopher; Buffon, a great critic, &c.

Great: a term of comparison, denoting a thing to have more extent than some other to which it is referred. Thus we say, a great space; a great distance; a great figure, a great body, &c. See Comparison.

Great’s likewise used figuratively, in matters of mortality, &c. to signify any thing large, elevated, extraordinary, important, &c. Thus we say, Shakespeare was a great genius; queen Elizabeth had a great soul; Cromwell was a man of great designs; Da Vinci, a great painter; Galileo, a great philosopher; Buffon, a great critic, &c.

Great is also a title or quality appropriated to certain princes, and other illustrious personages. Thus we say the great Turk; the great Mogul; the great Khan of Tartary; the great Duke of Florence, &c.

Great is also a surname bestowed on several kings and emperors. Thus we say, Alexander the great, Cyrus the great; Charles the great, or Charlemagne; Henry the great.
Great Britain

of France, &c. So the English frequently say, Edward the great, or the great Edward; William the great, meaning King William III. or the great William. The French say Louis the great, le grand, speaking of Louis XIV. of Paris says, Charlemagne first got the surname great from the tallness and eminence of his stature. Helgaud adds, that Hugh the great of France was thus denominated on account of his great pith, goodness, &c.

Great is also applied to several officers who have pre-eminence over others. Thus we say, the lord great chamberlain; the great marshal of Poland, &c.

Great Bank of Newfoundland, in Geography. See Bank.

It lies between 41 and 50° 24' N. lat., and between 49 45', and 54 45' W. long.

Great Barrington. See Barrington. The number of inhabitants by a late estimate is 1754.

Great Bay, a bay of North America, at the mouth of the Piscataqua river, between Portsmouth and Exeter, in the flate of New Hampshire.

Great Bear lake. See Bear lake.

Great Bear. See Ursus major.

Great Cape, in Geography, a Cape of Upper Canada, where lake Superior descends into the narrows of the fall St. Mary.

Great Diocletian. See Diocletian.

Great Egg Harbour, &c. in Geography. See Egg Harbour river.

Great Fanning, a river of America, in New York, which runs in the mountains near the source of the river Oneida, and runs N. W. by W. to lake Ontario.

Great Intervals, in Music, signify the fame, with Holden and some other writers, as greater and major do with the generality of musicians, and is applied to the intervals marked with Roman capitals, as II, III, V, VI, VII, &c. See Great.

Great Island, in Geography, a small island in the East Indian sea, near the N. coast of the island of Flores. S. lat. 7 59'. E. long. 120 54'.—Also, an island in the river Nicaragua, between lake Erie and lake Ontario. N. lat. 53'. W. long. 78° 59'.—Also, an island of Ireland, in the county of Cork, being the larges of the islands formed by the river Lee in Cork harbour; on it is the flourishing town of Cove.

—Also, an island in Piscataqua harbour, New Hampshire, in the United States.

Great Kanawha. See Kanawha.

Great Letters. See Capitals.

Great Maps. See Map.

Great Meca. See Mecatia.

Great Octave, in Music, is applied by the Germans, according to their tablature, or notation of musical notes, to the octave, or rather septave, beginning with C on the second fager line below the half flat, and ending with B on the second line, or B of Guido, and to which they exclusively apply the Roman capitals C, D, E, F, G, A, B. See Dr. Calle:ott's Musical Grammar, art. 34. See also Small Octave, Once-marked Octave, and Twice-marked Octave.

The object of this tablature is, to enable musical notes to be written or printed without eles or lines and spaces in a slaver.

Great Officer. See Officer.

Great Pelican Island. See Pelican.

Great Repeat. See Repeat.

Great Ridge, in Geography, one of the ridges of the Alleghany mountains, which separates the waters of the Savannah and Alatamaha. At the S. E. promontory of this ridge is that extraordinary place called Buffaloe lick, distant about 80 miles from Augusta. It occupies several acres of ground. A large cane swamp and meadows, forming an immense plain, lies S. E. of it, and in this swamp Mr. Bartram apprehends that the branches of the great Ogeechee take their rise. The lick is nearly level, and lies between the head of the cane swamp and the ascent of the ridge.

Great River, a river of Virginia, which runs into the Staunton river. N. lat. 36° 46'. W. long. 79° 12'.—Alfo, a river of Canada, which runs into the river St. Lawrence, 20 miles below Quebec.

Great River. See Rio Grande.

Great Scale, in Music. The late Sir Marmaduke Overend, after a life almost spent in researches into the nature and proportion of musical intervals, succeeded, to the satisfaction of Dr. Boyce, his intimate friend, to whom his labours were submitted, in unravelling the mysteries of the Greek scales of music, as they fays, in a paper on the great scale, in his quarto manuscripts, vol. ii. page 113 to 133, now in the library of the Royal Institution, which is thus entitled, viz. "All the Greek scales of music combined, with the diatonic intence, extended in the acumen and gravitas, with their reminiscences and intentions to double flats and double sharps in each; still refined, elucidated, and calculated, by Marmaduke Overend, Edwaford 1779." In pages 143 to 149 of the fame volume of MS. we find also the several ratios of this scale in their least terms, and the indices of the component primes, of one octave of the acumen and the gravitas with the fynemonens, the reminiscence, &c. This scale, which contains 86 notes within the octave, is a great musical curiosity, which we are sorry that our limits will not admit of inferring by the notice here taken of it, the curious may refer to the manuscripts themselves for further satisfaction. See Greek Scale.

Great Seal. See Seal.

Great Sixth, Redundant, in Music, or redundant great fifth, according to Holden, is the inversion of the deficient less third of his scales (.), and has a ratio of \( \frac{475}{54769} \times 9f + 41m \) in Farey's notation, its common logarithm being \( 0.76591678566 \), its Euler's log. or decimal of the octave \( -7.7765775 \), and it contains 43-3868 major commas. This interval does not belong to the received or diatonic system, having the number 7 in its ratio.

Great Sodus. See Sodus.

Great Third, in Music, probably according to Holden's new and fanciful system, is the ratio which the mind "probably" conceives (page 37 of his "Effay") as pertaining to the major third in the common chord minor, and to which he assigns the numbers \( \frac{7}{7} \), \( 260.2750822 + 4f + 18m \) in the new notation; its common logarithm is \( 0.8934235924 \) and that of Euler, \( 0.3378230 \); it also contains 15-20576 major commas; it is far removed from the received or diatonic system of intervals, as involving the prime number 19, and yet it is one of those which result from earl Stanhope's directions for tuning; it is the larger equal-feeding binaral third of his lordship, see Equal Tuning. Mr. Holden, at page 584 of his effay, relates an experiment in which this third proved an "intermediate discord," which is more than might be expected, from the temperament of rather more than 7,ths of a comma, which it has.

GREATER Hexarched. See HEXARCHY.
GREATER, in Music, is applied to distinguishing several intervals, whereof there are two of the same name, as greater, second-leather second; greater third, leather third; &c. Major interval is as often applied to these, and by some few writers they are called great intervals. The femtome or difference between the greater and the lesser intervals of the same names, are not equal, but of two different magnitudes, viz., the femtome minor \( \Phi = 37 \Sigma + f + 3 \), which occurs between the thirds and the sixths major and minor, and the femtome medius \( \Phi = 37 \Sigma + f + 4 \), which occurs between the seconds, fourths, fifths, and sevenths, major and minor: the difference of these femtomina being the major comm \( \Phi = 11 \Sigma + m. \)

GREATHAM Fleet, in Geography, a river of England, which rives in the county of Durham, and runs into the German sea, 5 miles S. of Hartlepool, N. lat. 54° 43'.

GREATMAN'S Bay, a bay of Ireland, on the N. coast of Galway bay; six miles N. from S. Arran isles.

GREAVES, John, in Biography, was born at Colmore, near Aldersford, in Hampshire, in the year 1622. He was educated in the churche, and in the other elementary parts of learning by his father, who was rector of the place, and the most celebrated school-maister in that country. When he was fifteen he went to Balliol college, Oxford, where he applied himself with great afflication to the studies of the place, and took his first degree in the year 1641. Three years after this he fled candidate for a fellowship of Merton college, when he was the first on the list of five who were then elected. In 1628 he took the degree of M.A., and more particularly directed his attention to the study of the mathematics and oriental learning, and became the friend of the most eminent scholars in the university, among whom were Mr. Briggs, Savilian professor of astronomy, and Mr. Peter Turner, professor of geometry in Gresham college, London. Had he wanted any motive to induce him to pursue his studies with vigour, the example of his contemporaries would have furnished that motive. Mr. Greaves read over all the writings of the most celebrated mathematicians of that and the preceding age, and he made himself familiar with the ancient Greek, Arabian, and Persian authors. In the year 1630, upon the resignation of Mr. Turner, he was elected professor of geometry at Gresham college, in consequence of the high reputation which he obtained in the university. At this period he was introduced to archbishop Laud, the chancellor of the university of Oxford, from whom he received several marks of favour. Soon after this, Mr. Greaves resolved to travel for improvement, and in 1635 we find him in Holland, attending the lectures of James Golius, professor of Arabic at Leyden; thence he proceeded to Paris; afterwards to Rome, Florence, and Padua, making exact observations upon everything deserving of notice. Upon his return he determined to take a voyage to Egypt, a design which met with the decided approbation of the archbishop. His object in this was not only to make himself acquainted with such remains of antiquity which that famous country possessed as might serve to illustrate ancient literature, but also to make astronomical and geographical observations; he therefore furnished himself with instruments of every kind for the purpose, and such printed Greek and Arabic books as he thought might be advantageously exchanged for MSS. and other objects worthy of collection. He embarked in the river Thames for Leghorn in the year 1635, accompanied by his friend Mr. Edward Pococke, and proceeded first to Italy, and thence to Constantinople, where they arrived about Michaelmas. Here he was received with great attention by Sir Peter Wych, to whom he brought out letters of recommendation from archbishop Laud. He was immediately introduced to Cyril Lucar, the Greek patriarch, who afforded him much valuable assistance in purchasing Greek MSS. The venerable patriarch promised to recommend him to the monks of mount Athos, in Macedonia, where, he said, "he would have had the liberty of entering all the libraries in that place, to have collected a catalogue of such books, as either were not printed, or else, by the help of some, there might have been more correctly set out." Thence, by dispelling with the anathemas which former patriarchs had lain upon all Greek libraries to preserve the books from the Latins, the patriarch proposed to have presented to the archbishop of Canterbury, for the better protection of his grace's designs in the edition of Greek authors, but the death of that patriarch frustrated Mr. Greaves' intention of visiting the celebrated mount, and occasioned his being a sufferer in another respect; for having procured from a Greek monastery some MSS. of the fathers, he was under the necessity of reforming them, and losing his money to avoid a greater inconvenience. Mr. Greaves, having lost his friend, determined to proceed to Egypt, but before his departure he had an opportunity of shewing his great attention to astronomical science; knowing that there would be an eclipse of the moon in the course of a few months, he furnished proper persons with convenient instruments for observing it at Constantinople, Bagdad, Smyrna, and Alexandria, and gave them necessary directions for the purpose. For his conduct in this respect Dr. Halley paid him the highest compliment by saying that a greater service could not be rendered to the science of astronomy than by taking the phases of the moon's eclipses at those places, in order to determine their longitudes, since in and near them were made all the observations by which the mean motions of the sun are limited. Mr. Greaves having finished his arrangements for this business, went by Rhodes to Egypt, and arrived there in the month of September 1638. This was the boundary of his intended journey, and here an immense field for the exercise of his inquisitive genius opened upon his view. He omitted no opportunity of examining whatever the heavens, the earth, or subterraneous parts offered him, that might be delaying of notice; but complains of having his astronomical observations frequently interrupted by the clouds and rain, which he found to be frequent, especially in the middle of winter. But what particularly engaged his attention, and employed his care, were the pyramids, of which, at that time, there was no satisfactory account before the public. This talk he undertook, and towards the close of the year 1538 he took a careful survey and measurement of them. Having gratified his curiosity, furnished his mind with a large flock of useful knowledge, and collected some Greek, Arabic, and Persian MSS., as well as ancient coins, and other varieties, he embarked at Alexandria in the month of April 1639, and arrived at Leghorn in June. He now made a second tour of Italy, which occupied him nine months. At Florence he was received with particular marks of respect by the grand-duke of Tuscany, Ferdinand II., to whom he addressed a Latin poem sent from Alexandria; and he also was permitted to

GRE
have free access to the Medicean library, which had been refused to him as a stranger when on his former tour. From Florence he went to Rome, whence he returned to Leghorn, and embarked on board a vessel for London, with a rich cargo of MSS., gems, coins, and other valuable antiquities. Upon his arrival in England he found his native country distracted by the conflicts between the king and parliament: he was, from principle, a friend to the royal party, and involved himself in much trouble by the zeal which he displayed in that cause of monarchy, and in his attachment to archbishop Laud. Having made a short stay at Gresham college, he went to Oxford to digest and prepare his papers for publication, in which he was assisted by archbishop Usher, who had long known and esteemed him, and to which he devoted himself with much diligence on theдей. Having proceeded to London, Mr. Greaves took his professorship at Gresham college, but he was almost at the same time chosen the Savilian professor of astronomy at Oxford, and obtained likewise a royal dispensation to hold his fellowship at Merton college, on account of the diminution in his stipend as professor, arising from the circumstances of the civil war. The labours of the professorship being suspended, he proceeded with his literary avocations, and in the year 1644 translated into Latin the "Lemnata of Archimedes," correcting the diagrams, and supplying what was frequently found defective in the demonstration itself. This piece was published by Mr. Samuel Peiter in his Miscellanies, or "Mathematical Lucubrations," 1659. Mr. Greaves, about the same time, compiled "A Perilian Lexicon," out of such words as could be met with in the evangelists, the psalms, and two or three Arabian and Perilian homilies. In 1643 he drew up a scheme for gradually introducing the new or Gregorian Rite, by omitting the intercalary day of the leap year for forty years, to which scheme he was highly inclined by the king and council, and would probably have been carried into execution had the times been favourable to the innovation. In 1646 he published his work entitled "Pyramidographia," or a description of the pyramids of Egypt, and soon after a "Difcourse on the Roman Foot and Denarius," from whence, as from a common standard, the measures and weights used by the ancients may be deduced. About the year 1648, Mr. Greaves found that he should be under the necessity of resigning his professorship; he accordingly, before his interest was entirely gone, introduced a successor, viz. Mr. Seth Ward, afterwards bishop of Salisbury. He then went to London, where he married, and living upon his patrimony, devoted his time to literary labours. He published many learned works, among which was "Elementa Linguae Pericae," 1646, to which the author subjoined "Anonymous Perica Sigilis Arabum et Perfarum Astronomic." In 1653 he published an astronomical work, to which he prefixed "A Short History of the Rise and Progress of Astronomy among the Arabs," and subjoined his " Britt Tabulae." But this work, published in other works, and had prepared many more for the press, when he was attacked by a disorder that proved fatal to him. He died in the fifth year of his age. Of his learning, ingenuity, diligence, and wonderful perseverance, there is abundant evidence. He was highly esteemed by many of his most eminent contemporaries both at home and abroad; steady in his principles, and in his friendships, and his death was lamented as a real loss to science and literature. Biog. Brit.
GREEK ACCENTS. See ACCENT.
GREEK BIBLE. See BIBLE.
GREEK CHURCH. See CHURCH.
GREEK CHURCH, MUSIC OF THE. The conflict between the Greek and Roman churches, which happened in the ninth century, prevented such changes as were made in the Roman ritual, after that period, from being adopted by the Greeks; and the notation used before seems long to have continued in the East. In Rufius, however, all the rituals were called in at the beginning of the last century, and a uniform liturgy was established, in which the modern method of writing music was received. But in the Greek ikes a notation peculiar to its inhabitants is still in use, which is not only as different from our as their alphabet, but totally unlike that in the ancient mss.

In examining the most ancient of these in the Vatican library, which were written in capitals, the first notation which we could discover, consisted chiefly of accents, and when small letters were afterwards used, their accents were only dimension heightened. In the tenth and eleventh centuries they very much resembled the characters to be found in contemporary Latin missals. However, the melodies in the lower ages became more elaborate, and the notes more numerous than in those of higher antiquity.

St. John Damascenus, who lived in the eighth century, is celebrated by the writers of his life, and by ecclesiastical historians, as the compiler and reformer of chants in the Greek church, in the same manner as St. Gregory in the Roman. And Leo Allatius (De Libris Eclef. Graecorum) under the title "Octoechos" (Octoëchos: eight tones), tells us they were composed by J. Damascenus. Zarzino goes still farther, and informs us (Inquir. Harm. 420. parte. cap. viii.) that in the first ages of Christianity the ancient Greek notation by letters having been thrown aside, John Damascenus invented new characters, which he accommodated to the Greek ecclesiastical tones; and that these characters did not, like ours, merely express single sounds, but all the intervals used in melody; as a femitone, third, minor, third major, &c. ascending and descending, with their different overtones. This resembles, we think, the modern, the notation in the ecclesiastical books of the Roman church, before the time-table, and characters in preface use were invented, or, as least, generally received.

The abate Martini of Venice (see "Preface State of Music in France and Italy") having visited the Greek siles in hopes of acquiring such a knowledge of the music practised there at present, as would enable him to judge whether any of the miraculous powers attributed to it by its ancients still remained, as well as to compare its excellence with that of his own country; and as this learned and sagacious enquirer confided to us his papers on that subject, we shall communicate to our readers a sketch of their contents.

The fyllem of modern Greek notation seems much more complicated and obscure than the ancient. The characters convey nothing to the mind either by their form or names, the greatest part of which cannot be confined; and the roll are confused to no purpose. Their signification, as words, does not point out their meaning as conical characters; and all that we can discover is, that some of them seem descriptive of gesticulations such as α ἂν, ἄν, which, perhaps, directed the priest to look up, or stretch his hands towards heaven. Βλέπω, which might direct him to make the sign of the cross, or to carry the cross. νέφελος, φλέκω, ραδιείν. Indeed, it is said in the papers, that some of these characters are for the Νυμφαίος, or Λαοδεκαια, and not

GREEK MUSIC. See Μουσική, for the voice. This is the more likely, as the Greek service abounds in gesticulations and manual dexterity.

The abate was informed, that though the oriental Greeks have signs for musical sounds equivalent to ours, they fix more by tradition than science. However, the distinctions for the duration of sounds, such as our time-table, &c., are still wanting. The abate procured an extract from a tract upon the music of the modern Greeks, written by Lampadarus; but he was, or when he lived, no one could inform him. In this it appears, that the characters amount to more than fifty; among which most of the names of those musical terms, given by Du Cange, from a MS. treatise on the ecclesiastical music of the Greeks, are to be found. (Grefi. Med. et inf. Graciatis.) Du Cange, who has so amply collected and explained the characters used by the modern Greeks in chemistry, botany, astronomy, and other arts and sciences, is silent as to their musical notation; nor have we been able to acquire any information on that subject, except that with which the abate Martin has supplied us. The title of the treatise by Lampadarus is the following: Τοῦ Θεοῦ Μουσίκης. The extract from it, which is in our possession, is too long for insertion here; nor would it be of much use, could we allow it room, as no equivalents to the Greek characters are to be found in our own notation. But with respect to the author, we find among the manuscripts, which we made in the king of Sardinia’s library at Turin, an account of a Greek MS. of the fifteenth century, N. 553. b. 1. 24, in which Lampadarus is often mentioned as author of the music to the hymns and prayers it contains. Fabricius, like-wise, 1 lb. Græc. vol. ii. p. 269, 564, and 586 speaks of a MS. in the Selden collection at Oxford, and another in the Bibliotheca Library at Louvain, in which there are explanations of the notes used by the modern Greeks, and musical compositions by several authors, particularly Lampadarus. In the patriarchal church of Constantinople there are four fingers, which are placed on the right and left side of the choir; the first on the right is called δέκα, the principal finger; the first on the left άκραπόμολος, Lampadarus; the two others which fall the principals are called δόροθεις. It is probable that Lampadarus, who flourished about the year 1300, either took his name from the office he filled; or, on account of his eminence in music, that his name was given to the office.

To infer here the musical characters still used in the rituals of the Greek church of out of Ruffin, and endeavour to explain them, will perhaps be conferring but a small favour on our readers; for from the scarcity of music written in such characters, one will be their opportunities of making use of any knowledge they may acquire by the study of them, that it would be like learning a dead language in which there are no books, or a living language without the hopes of either reading or converting it.

Those readers who may be disposed of gratifying themselves in matters of curiosity, may consult Dr. Burney’s History of Music, vol. ii. p. 56; for they will find the fourteen musical characters that occur in the Greek MSS of the Evangelists, written in capitals during the seventh, eighth, and ninth centuries, though at present they are wholly unintelligible, even to the Greeks themselves. It is observable that the more ancient the MSS, the fewer and more simple are the notes; the νοῖδες Αλεξανδρειαί, in the British Museum, has none; and the Evangelist MSS in the Harleian collection, 5785, 5987, both of the tenth century, have only such as these, which were copied in Greece by the abate Martini.
GREEK MUSIC.

The "Codex Ephraemi," in the king's library at Paris, of the fifth century, has likewise the same kind of musical notes, and it is signed as a reason for the "Codex Alexandrinus," not having them, that it was written for private use, not for the service of the church.

Kircher undertakes to give his reader an idea of modern Greek music and its characters; and has indeed collected a great number of notes and their names, but pretends not to furnish equivalents in the music of the modern world. And to infest such barbarous names, and more barbarous characters here without explanation, would no more help to initiate a student in the mysteries of Greek music, than the Hebrew or Chaldee alphabet. At the first glance they very much resemble the characters used in Chorography, an art invented about two hundred years ago to delineate the figures and steps of dances. They are too numerous and complicated to be infested and explained here; however, we have given the names and component notes in the History of Music, vol. ii. p. 51. 52; by the study of which the musical reader will be able to form some idea of the melody which they are intended to express.

There are eight ascending, and six descending characters, some for single sounds, and others for wider intervals, as thirds and sixths, such as Zarlino, in the passage mentioned above, had imagined were invented by J. Damacenus; and all these have their particular Chironomia, or signs for the gestures with which the priest is to accompany the inflections of voice.

The beginning, or first note of every chant, is called Ison, which is equivalent to the key or tone in which any melody is begun.

Kircher, to whom even Egyptian hieroglyphics are easy, has resolved the names of the Greek notes into Latin. Mufurgia, ubi supra.

The abate Martini heard the Greeks, in Paschall Week, sing several tropes or modes, which they now term sylis, in four parts, in the style of Palestira; and this kind of music they call Cretan, but why, is not only to divine, unless they heard counterpart while the Venetians were masters of the island.

The abate says that he often heard the common people of Greece sing in concert, and observed that they made frequent use of the fourth, "della consonanza che noi chiamiamo oggi quarta." By this he must mean that they used it as a concord in two parts, or if there were more than two parts, in positions where our harmony forbids the use of it; otherwise it would not have affected his ear as a singularity.

The fact is curious, and we find it confirmed by Zarlino, who observed the same practice in the Greek church at Venice. The fourth, we find, was in such favour during the time of Guido, as to be preferred in difficult to every other concord, and thought to constitute the most pleasing harmony. This partiality may probably have arisen from the importance of fourths in the ancient Greek Gymn, and the want of a temperament to render thirds and sixths more agreeable; but the improvements in harmony soon brought it into disfavour in Italy; while, from a contrary cause, it has kept its ground to the present time in Greece, at least among the people. And, indeed, even in Italy, it seems to have retained a part of its ancient privileges long after the time of Guido, and when harmony was thought to be in great perfection; for Zarlino says, that Juquin, and the other old Fiendish masters, used it frequently in their compositions: "in parte grave, denza aggangranche alto intervall." The present state of Greek music, indeed, does not confirm or favour the opinion of Dr. Brown, who allerts with his usual courage, that, "about four hundred years after Guido, the daubed art once more passed over into Italy from Greece: certain Greeks, who escaped from the taking of Constantinople, brought a refined and enervate species of music to Rome, &c." As many travellers assert that the modern Greeks have no music in parts, we may suppose, that in those places where it was heard by the abate Martini, it had been brought thither by the Venetians, during the time that they had posseffions in the Archipelago.

That the Greek music has undergone many alterations since the ancient treatises that are come down to us were written, is certain from the change and increase of its vocabulary. Bryennius has given, as names of intervals, a list of barbarous terms not to be found in any preceding writer within our knowledge; and in the Greek glossary of Du Cange, and the abate Martini's papers, a great number occur that are not to be found either in writers of high antiquity, or in Byzantium.

The technical language of the Greeks has always been copious, and in music perhaps its seeming redundance is more conspicuous than in any other art or science. But in other arts and sciences words are representative of things existing; whereas, in denomiinating the tones and inflections of voice, which, to realize, require new creation, there can be no correspondence between the type and substance. The colours, the forms, and objects, which a painter wishes to represent, are: in nature; and the poet, in all the embellishment of wild enthusiasm and fervid imagination, describes what he has seen and felt, or what is to be seen and felt, and for which common language must supply him with symbols. But it has never entered the thoughts of man to give names to all the minute shades of colour between black and white, or to the gradations by which light is propagated between the time of total darkness and the sun's meridian. And yet, in a race of founds, from the lowest musical note in the human voice to the highest, where octaves are not represented by similar signs and appellatives, the names and characters must be numerous. The lines and chiefs of the European music have certainly freed it from many perplexities with which it was embarrassed, even in the artifices times of canto fermo.

But however flowery the Greeks may have made their ecclesiastical melody, or however they have multiplied its characters, the desire of permanence in the heads of the western church, with respect to all sacred matters, long kept music in the plain and simple style in which it was left by pope Gregory the Great; for we do not find, till the invention of counterpoint, that it received any material change or improvement. Our own bible and liturgy, if they remain in their present state five or six hundred years, will, perhaps, be unintelligible to the vulgar, though written in the best language of the country when they were introduced into the church. And the Greek and Roman languages, which were so well understood by the primitive Christians, became dead and obliterated degrees, to all but the learned in after ages. The preciption of change or innovation in sacred concerns which has occasioned permanence, has likewise been the cause of inlegance and obscurity.

"Peter the Great, like his predecessors, had a particular partiality for the music of the church; maintained his own choir, or faylers for divine service, and read publicly in the church the epistles and the hours, which, in that country, is permitted to be done by any layman, who delights in such exercise, as well as by the priest." (King's Rites of the Greek Church.)

Many of the kings of France not only sung in the closet, but composed hymns for it, and set them to music. (Laborde.)
GREEK MUSIC.

(Plancke.) And we have heard his present majesty, at fix o'clock prayers in St. George's chapel at Windsor, officiate alone as clerk; repeating the refponses, and reading the psalms aloud for verses, with the minister, and uttering the amen in the clerical style.

Music has been very much cultivated at Peterburgh in the Imperial chapel and metropolitan church during the last century, as well as in the theatre. And though no instruments are admitted in the Greek church except in the Sistine or pontifical chapel at Rome, yet every vocal refinement, both in composition and performance, that can with propriety be allowed in ecclesiastical music, has been received in the church service at Peterburgh, in the Imperial chapel and cathedral of which capital, near a hundred voices are daily employed; and at Moscow, in several churches, when the sovereign is there, forty or fifty.

The music of the Hymnologia of the Russian ambassador's chapel in London, is sung to figurative music in three and four parts, distinct from the intonations or canto fermo. It consists of short, elegant, and simple strains or movements, in the Italian style, in plain counterpoint, composed to Slavonian words, by Bortinianki, who was sent to Italy, early in life, by the empress Catherine, to study composition.

The taste for good music palled from the theatre to the church. The plain chant of the modern Greeks is different from that of other Christian churches. It is more varied than the Gregorian chant; and that of the hymns rather refers to the figurative music of motets, than canto fermo. The empress Elizabeth, who was well acquainted with the kind of counterpoint a capella, and had great pleasure in uniting her voice with the choir, would never allow the Italian florid song to have admission in the sacred service; but says the Gotha Almanack, in an abridged history of the music of Russia, 1772, "Italian music has invaded even the Greek church as well as the Roman." This voice of complaint borders on croaking. We have taken considerable pains to obtain information on the subject, and have heard the service of the Greek church performed in several parts of Europe; and we have been favoured with a score of some of the music in present use in that service, composed by Bortinianki, a native of Peterburgh, and find that it is neither so bold and dry as canto fermo, nor so florid and flighty as that of the Italian theatre. It is plain counterpoint, non fugato, in which the words seem well accented, the parts moving all together; so that there is measure, clearness, tranquillity, and soothed air, pure harmony, and natural and simple modulation. Nothing vulgar occurs, nor any thing to remind us of the opera house, yet the strains are not without grace or gravity. It seems to excite attention by its sweetness and simplicity, more than by the art of fugue, or extraneous modulation.

GREEK MUSIC, ANCIENT. We shall here introduce some observations on the subject, extracted from a dissertation written several years ago.

Section I.—Of the Notation or Tablature of Ancient Music, including its Scales, Intervals, Systems, and Diagrams.

The music of the ancients, according to Euclid, Alypius, and Martianus Capella, was divided into seven constituent parts: these were sounds, intervals, systems, genera, modes, mutations, and melopoin, or the composition of melody. To these divisions, which comprehended only what was denominated harmonics, or the science of music, briefly so called, were added five other requisites, no less essential for a musician to know, than the preceding seven: and these were, rhythm, or the regulation of cadences in all kinds of movement; metre, or the measure of verses; organic or the instrumental art; hypocris, or gesture; and poetic, or the composition of verses. And all to these divisions, Aristides Quintilianus, and some other musical writers, added alexiwn, or the art of singing; which, indeed, seems of more importance to music, than either the organic or hypocris art.

In order to communicate to our readers all the information we are able, upon so dark and difficult a subject, we shall consider the music of the ancient Greeks under six heads only as absolutely concern music, according to our acceptance of the word; for it is plain that several of its ancient divisions more immediately belonged to poetry. Indeed these two arts were at first intimately connected, and so dependent on each other, that rules for poetry were, in general, rules for music, and the properties and effects of both were so much confounded together, that it is extremely difficult to disentangle them.

Leaving, therefore, for the present, all other divisions, divisions, and sub-divisions, with which ancient musical treatises abound, we shall proceed to fulfil the title of this section.

In the study of modern music, the first objects of inquiry are the names by which the several sounds in the scale are expressed; and, if we regard music as a language, the scale or gamut may be called its alphabet.

Plutarch says, that it is not sufficient for a musician to know what kind of music should be set to any particular poem; he should likewise know how to write it down in all the genera, that is to say, in the diatonic or natural scale, consisting of six tones and six semitones; and the chromatic, in which the scale was divided into semitones and minor thirds; and in the enharmonic genus moving by quarter tones, and major thirds, as will be explained hereafter.

It does not appear from history, that the Egyptians, Phoenicians, Hebrews, or any ancient people, who cultivated the arts, except the Greeks and Romans, had musical characters; and these had no other symbols of sound than the letters of their alphabet, which likewise served them for arithmetical numbers and chronological dates.

As the notation of the Greeks was imagined in the fancy of the art of music, when the flute had but few holes, and the lyre but few strings, the simplicity of expressing the octave of any sound by the same sign, as in modern music, was not thought of; the most ancient and constant boundary of musical tones being the diatessaron, or fourth, the extremes of which interval were fixed, though the intermediate sounds were mutable; and in the manner of tuning they confused the difference of intervals in the several genera.

The Greek scale, as in the time of Aristoxenus, the oldest writer upon music, whose works are come down to us, extended to two octaves, and was called septuaginta, maximum immutatrix; the great, the perfect, the immutable syllem; because its extremities formed a perfect consonance, including all the simple, double, direct, and inverted concords, with all the particular syllemis; and it was the opinion of the ancients that this disdiapason, or double octave, was the greatest interval which could be received in melody.

This whole syllem was composed of five tetradecachords, or different series of four sounds, and one note added at the bottom of the scale to complete the double octave; whence the figuring which produced this sound was called 

\[
\text{αναβαλλωμενος, or note suffixed to the scale; for though this}
\]

was constantly the lowest found in all the modes, it was not included in the tetrachords.

All these sounds had different denominations in the syllern, like our gamut, A re, B mi, C fa ut, &c. besides two different characters, one vocal, and the other instrumental, appropriated to each found in the several modes and genera, for the purpose of writing down melodies.

That the fourth was a favourite and important interval in
Greek Music.

The music of the ancients, is plain from the great system of two octaves having been composed of five of these tetrachords, in the same manner as the scale of Guido is of different hexachords.

The first tetrachord is called by the Greek musicians hypaton, or principal; the sounds of which are denominated:

1. Hypate hypaton, principal of principals;
2. Parypate hypaton, next the principal;
3. Hypate melos, or index of principals; from its being played with the index or fore-finger. This third sound of the first tetrachord in the diatonic genus was likewise called hypaton diatonic.
4. Hypate melos, or principal of the middle or mean tetrachord; for this sound not only served as the last or highest note of the first tetrachord, but as the first or lowest of the second; whence these two tetrachords were called conjoint, or connected. These four denominations of the sounds in the first tetrachord may be compared with the terms B mi, C fa ut, D fol re, and E la mi, in the Guido scale; or with the sounds

\[
\begin{align*}
\text{B} & \quad \text{mi} \\
\text{C} & \quad \text{fa} \\
\text{D} & \quad \text{fol} \\
\text{E} & \quad \text{la} \\
\text{F} & \quad \text{mi} \\
\end{align*}
\]

The sounds of the melos, or middle tetrachord, were placed in the following order:

Hypate melos, or principal of the mean tetrachord;
Parypate melos, next to the middle principal;
Lithuanus melos;
Melos, or melos, as this sound completes the second tetrachord, and is the centre of the whole system. The sounds of this tetrachord correspond with those which in the base of the scale of Guido are called E la mi, F fa ut, G fol re ut, and A la mi re, which are equivalent to

\[
\begin{align*}
\text{E} & \quad \text{la} \\
\text{F} & \quad \text{fa} \\
\text{G} & \quad \text{fol} \\
\text{A} & \quad \text{la} \\
\text{B} & \quad \text{mi} \\
\end{align*}
\]

This appears from the Greek tetrachords, as well as from this example, that neither the ancients nor the early moderns admitted the sharp seventh of a key into their scales.

The fourth tetrachord, ascending, is called diezeugmenon, disjunct, or separated, as it begins at B natural, which is not a note in common with any one in the other tetrachords. But though this system of four sounds is only an octave higher than that of the first tetrachord, and though the next is but a duplicate of the second, we shall present them to the reader, as the several sounds of which they are composed have in the Greek music different denominations.

The first found of the second octave, or series of eight sounds in the ancient great system, is melos, and the first of the fourth tetrachord begins with the note

Parameles, near the melos, or middle found; the next is called

Trite diezeugmenon, or third string of this tetrachord from the top; then follows the paranome diezeugmenon; and lastly, the

Note diezeugmenon, or final found of this tetrachord;

The melos in ancient music was of equal importance with the key note in modern music: being an octave above the prollambanomenos, which was the lowest found of the ancient modes, and a kind of key note to them all.

Euclid calls melos the found by which all other founds are regulated. And Aristotele, in his XXXVIth Problem, sect. 19, says that all the tones of a scale are accommodated, or tuned, to the melos. The same author likewise tells us, Problem XX, that all melody, whether it moves above or below the melos, has a natural tendency to that found.

The third tetrachord, beginning by the last note of the second, was then called synechmenon, or connected, tetrachord; the sounds of which proceed in the following order:

Melos;
Trite synechmenon, or third string of this tetrachord from the top;
Parameles synechmenon; penultimate of this tetrachord;
Note synechmenon, half of the synechmenon tetrachord; the four sounds of which correspond with those in the centre of our gamut, that are called A la mi re, B fa, C fol fa ut, and D la fol re, or

After ascending regularly thus far, up to D, by three conjoint tetrachords, the fourth tetrachord in the great system is begun by descending a minor third to B natural, the octave above the first found of the lowest tetrachord. Something of this kind is to be found in the scale of Guido, divided into hexachords; for, after ascending six notes regularly in the durum hexachord, it is necessary to descend a major third, if we would begin the natural hexachord; and when the natural hexachord is completed, if we would begin at the melos, it can only be done by a leap of a third below.

This will best appear by an example in notes:

\[
\begin{align*}
\text{Ut} & \quad \text{re} \quad \text{mi} \quad \text{fa} \quad \text{fol} \quad \text{la} \\
\text{Ut} & \quad \text{re} \quad \text{mi} \quad \text{fa} \quad \text{fol} \quad \text{la} \\
\end{align*}
\]

The last found of the fourth tetrachord is the first of the fifth, which is called the hyperbolos, or supreme tetrachord; the sounds of which ascend in the following order:

Note diezeugmenon, half of the diezeugmenon tetrachord;
Trite hyperbolos, third string of the hyperbolos tetrachord;
Parameles hyperbolos, penultimate of the supreme tetrachord;
Note hyperbolos, half of the supreme, or highest tetrachord, and of the great system, or diagram.

This last tetrachord, being added to the scale long after its first formation, was called hyperbolos, from its founds being more acute than the rest, and beyond the common bounds.
Greek Music.

The ancients used likewise four different monosyllables ending with different vowels, by way of embellishment, for the exercise of the voice in singing; like our mi, fa, sol, la.

The repetition of these monosyllables is a further proof that the fourth in the ancient music served as a boundary to a system of four sounds, in the same manner as a hexachord did in the Guido scale, and as an octave does for eight sounds in the more modern practice.

Any interval between the terms of which one or more sounds intervened, was by the ancients called a system; E G, for example, constituted a system of a third minor; E A, of a fourth; E B, of a fifth, &c.

Thee smaller systems were of different species; thus there were three kinds of tetrachords, that differed in melody by the position of the femitone, which was sometimes at the beginning, sometimes at the end, and sometimes in the middle; as in the following example, where the black notes are femitones, and the white, tones.

As the Greeks used all the four and twenty letters of their alphabet for musical characters, or symbols of sound; and as their most extensive system or scale did not exceed two octaves, or fifteen sounds, it should seem as if their simple alphabet was more than sufficient to express them; for their music being at first only a notation of their poetry, the rhythm, or air, must have been determined by the metre of the verse, without the assistance of figures of proportion peculiar to music. But supposing it was necessary for them to have different characters to express the different feelings of the verse, it is certain that vocal music was in no want of them; and instrumental being chiefly vocal music played by instruments, had likewise no need of them, when the words were written, or the player knew them by heart.

However, in order to multiply these characters, the letters of their alphabet were sometimes written in capitals, and sometimes small; some were entire, some mutilated, some doubled, and some lengthened; and besides these distinctions in the form of the letters, they had others of situation, sometimes turning them to the right, sometimes to the left; sometimes inverting, and sometimes placing them horizontally; for instance, the letter gamma, by these expedients, served to express seven different sounds: T L I F N E M. Some of the letters were also barred, or accented, in order to change their symbolical import; and these still not sufficient, they made the common grave and acute accents serve as specific musical notes.

It is a matter that has been long disputed among the learned, whether accents were originally musical characters, or marks of pronunciation. It is in vain to ask what the terms of the voice, which the proofs on both sides are so numerous. (See Gally and Spelman against accents, and Prin and Forster in defence of them.) Mr. West is firmly of opinion that accents were originally musical notes, fet over words to direct the several tones and inflections of the voice, requisite to give the whole sentence its proper harmony and cadence. (Pind. vol. ii.) And the abbé du Bos, who frequently by a peremptory decision cuts the knot of such difficulties as he is unable to untie, affirms, without sufficient proof, that-as poets originally set their own verses, they placed for this purpose a figure, or accent, over each syllable. So that, according to this writer, we are at present not only in possession of the poetry of Homer, Pindar, Anacreon, and Sappho, but their metre. Why then do we complain of the total loss of Greek music? (See Reflex. Critique, c. iii. p 85.) But as music had characters different from accents so early as the time of Terpander, to whom the invention is given by the Oxford Marbles, which place this event about six hundred and seventy years before Christ; and as accents for prose or poetry are likewise proved to be of high antiquity, it seems as if there could have been no necessity for the ancients to use one for the other.

But it has already been remarked that the letters of the alphabet, though turned, distorted, and mutilated, so many different ways, were insufficient to express the sounds of all the modes in the three genera; so that recourse was had to accents, as the scale became more extended, in order to augment the number of characters. And Alipius, in the enumeration of the notes in the enigmatic genus, tells us, that tetrachordon is represented by beta and the acute accent; and tetrachordon parthiac is represented by alpha and the grave accent.

This is a proof that the accents were known at the time of Alipius, and were then used chiefly for prose, not music, for which they were only called in occasionally. Indeed they are mentioned as accentual marks by writers of much higher antiquity than Alipius; for not only Cicero and Plutarch, but Aristotle and Plato, speak of them as merely regarding the elevation and depression of the voice in speech. However, in the early Greek and Roman mists, as will be shown hereafter, the musical characters used in canto fermo, seem to have been only heightened accents.

These various modifications of letters and accents in the Greek notation composed in all one hundred and twenty different characters, which were still considerably multiplied in practice; for each of these characters serving many purposes in the vocal as well as instrumental notation, or grammat, and being changed and varied according to the different modes and genera, as the names of our notes are changed by different clefs and keys, the one hundred and twenty Greek characters produced one thousand five hundred and twenty notes.

Two rows of these characters were usually placed over or under the words of a lyric poem; the upper row serving for the voice, and the lower for instruments.

If we had not the testimony of all the Greek writers who have mentioned these characters, for their use and formation, it would be natural to suppose that the double row of different letters placed over each other, and above the words of a poem, were intended to express different parts, with respect to harmony; as with us, in modern music, the treble notes are written over the base, and the first treble over the second; but Alipius, who is extremely minute in his instructions concerning the use of these characters, in all the modes, tells us, in express terms, that the upper line of the notes is for the words, and the lower for the lyre. (Eur. 13. 74.)
GREEK MUSIC.

We are told, not only by Alypius, but by Gaudentius, p. 23, that of the two rows of letters used for musical characters, the upper is for the words, that is, *to fingen*, and the under to be played. And he afterwards proves them to have been unison to each other, both by his definitions and by placing them opposite to the name found in all the scales.

In this author, the notes of the great system of the Lydian mode in the diont tonic genus are arranged in the following order:

Z τ RΦ CΡ M I σ γ Z E σ β μ I

And these he defines in such a manner as leaves no room to doubt of the identity of their significations.

It is somewhat strange that the notes for the voice in ancient music should be placed above those for the lyre, and consequently further from the words. Meibomius, in his preface, has, however, given a curious reason for this custom, from a fragment of Bacchius, senior: "The upper line of notes is for the poem, the lower for the lyre; because the mouth, which alone gives utterance to the words, is placed by nature above the hands, which produce tones from the instrument."

Z = Proflamabamos, an imperfect Zeta, and Tau placed horizontally.

Τ Η Hypate hypaton, an averted Gamma, and a Gamma direct.

R L Parhypate hypaton, an imperfect Beta, and a Gamma inverted.

Φ Hypaton diatonos, a Phi, and a Digamma.

C C Hypate micos, Sigma and Sigma.

Φ Φ Parhypate micos, Rho, and Sigma inverted.

M Μ Micos diatonos, Mu, and a lengthened Pi.

I < Μή, Iota, and a horizontal Lambda.

θ V Trite symmenon, Theta, and an inverted Lambda.

Γ Ν Symmenon diatonos, Gamma and Nu.

ζ Ζ Symmenon micos, an inverted Omega and a Zeta.

Z = Parameko, Zeta, and Pi placed horizontally.

Π Π Trite micos, Epiloa, and an inverted Pi.

υ Z Diezeugmenon micos, as Symmenon, which was the same fling in the lyre.

ι = Diezeugmenon, horizontal Phi, and a small Eta lengthened.

ι = Trite hyperboleon, an inverted Upilox, and an imperfect Alpha.

M Μ Μ Hyperboleon diatonos, Mu, and a lengthened Pi, accepted.

ι = Νετε hyperboleon, Iota, and an accepted Lambda, placed horizontally.

It is from the indefatigable labour of the learned Meibomius, in his Commentaries upon the ancient Greek musicians, particularly Alypius, that we are able to decipher these characters; which, before his time, had been so altered, corrupted, disfigured, and confounded, by the ignorance or negligence of the transcribers of ancient manuscripts, that they were rendered wholly unintelligible.

With our utmost study, reading, and contemplation, we could reduce the Greek notation to no order, nor ascertain whether it was to be read upwards or downwards. The neglect of these distinctions will introduce an universal scepticism concerning every part of ancient music.

Galle, Zardo, Bontemp, Tevo, M. Rouffeau, Dr. Brown, and others have attempted to dignify and lower had different acceptations among the ancients, from those in which they are understood by the moderns, without guarding, as they ought to have done, against such consequences, with respect to the situation of the scale, as it was natural for the reader to draw from that assertion.

At length, an infallible rule presented itself to us in the works of the great Euclid, who has been regarded for so many ages as the legislator of mathematicians, and whose writings have been their code. In his section of the Canon, p. 57, edit. Meibom, he represents *profloamabamos* by the whole firing: so that, if any thing concerning ancient music can be made certain, it is, that this whole firing represented the lowest found in the Greek scale, which, in the Hyperborean mode, was equivalent to the note A.

Half the firing, Mefo, its octave, a,

Third part, June diezeugmenon, fifth of the octave, c,

And the fourth part of the firing, Note hyperboleon, the double octave, a,

which include all the concords that the ancients admitted. Eight ninths of the firing are allotted to the sound Hypate bardia gravitas, which is B in the scale, one tone higher than profloamabamos, or A.

This representation of the whole firing and its divisions into harmonic and aliquot parts, must put an end to every doubt concerning the order of the scale, which may have arisen from the inverted application of the words *highb* and *low*, constantly occurring in all the more ancient and authentic Greek writers on music.

Sect. VIII.—Of the Art of composing music. See Melopoeia.

Sect. IX.—Whether the Ancients had counterpoint or music in parts.

This is a subject which has given birth to many learned disquisitions and disputes; and as it long remained a matter of opinion, those who believed, and those who denied the point in question, consequently treated each other with all due polemic ceremony. The champions for antiquity thought themselves involved in the controversy; and whether they were possessed of musical knowledge, or were fit to be admitted to the charms of harmony, or not, they determined to regard every man as an enemy to found literature, who did not subscribe to the articles of their faith.

A poem, called "Le Sicle de Louis le Grand," written by Charles Perrault, of the Academy of Sciences, and brother to Claude Perrault, the famous physician and architect, occasioned the long and acrimonious dispute between him and Boileau, and soon brought on a general war among the learned throughout Europe, concerning the superiority of the ancients or moderns, with respect to arts, sciences, and literature. This piece was first read by the author at the Academy of Sciences in 1688, and was soon followed by his "Parallel des Anciens et des Modernes." The notes to Boileau's translation of Longinus were intended as a reply to Perrault, and are full of bitter invective, not only
only against him, but the moderns in general. Racine, La Bruyère, and Fontenelle, took sides in the quarrel, which in France was kept alive, with great animosity, for near thirty years.

In England, the controversy between Sir William Temple and Mr. Wotton, Mr. Boyle and Dr. Bentley, and Swift's "Battle of the Books," were consequences of this quarrel.

Those who had written ex professo on music, had frequently differed in their opinions concerning counterpoint, having been known by the ancients, previous to the learned, in general, interfering themselves in the dispute, and before we give our own opinion, as an individual, it is incumbent on us, as a historian, to inform our readers, who were the principal champions on both sides. Would it not render our article too long, the reasons aligned by each for seizing his sword, that is, his pen, in the quarrel, should likewise have a place here. But our limits will only allow us to say, that the most eminent defenders of ancient harmony in our femile of the word, are Gaffurio Zarbo, Gio Battista Doni, Isaac Volfius, Zacharia Tevo, the abbe Fragier, and Mr. Sillingfleet, author of "Principles and Power of Harmony."

Their opponents are Gratianus, Salinas, the cavalier Hercules Botrigrifi of Bologna, Artusi, Cerone, Kepler, Mercurius, Marilisus Eneias, Kircher, Claude Perrault, and the late elegant and learned poet Mr. Medon, who had studied modern music, and has left his decided opinion against the ancient Greeks having cultivated counterpoint. (Hist. Mus. vol. i. p. 125.) To these we may add Montempi, the first Italian musical historian, the learned Dr. Wallis, M. Burette, who has explained the subject, and defended it in all its ramifications. Patiri Martini of Bologna, a learned dilettante, has given a specimen (Stori della Mus. i. p. 174.) of much meagre counterpoint as was likely to have been produced without the use of imperfect concords, which the Greeks termed discordes. The late throwed and penetrating critic J. J. Rousseau, is very explicit upon this subject in his "Musical Dictionary," at the article Counterpoint, which he terminates by saying, "It has long been disputed whether the ancients knew counterpoint; but it clearly appears from the remains of their music and writings, especially the rules of practice, in the third book of Aritoxenius, that they never had the least idea of it." After this list of the most respectable writers on both sides of this long disputed question, it now remains to tell the reader ingeniously our own sentiments; and to confess the truth, we will venture to say, that we do not believe the ancients ever did use fomalhymes harmony, that is, music in different parts; for without thirds and sixths it must have been imipid; and with them, the combination of many sounds and melodies moving by different intervals, and in different times, would have occasioned a confusion, which the ancient Greeks had for their language and poetry would not suffer them to tolerate.

Sect. IX.—Of the Dramatic Music of the Ancients. See Dramatic Music.

The Greek dramas confonded of soliloquy, dialogue, and chorus, and it has naturally been supposed, that these were sung to different kinds of music. Soliloquies full of sentiment and passion had probably a different, more elaborate, and refined melody, than the dialogues; but the chorus must necessarily be set to measured music, or the performers, if left ad libitum, could never have kept together.

Sect. X.—Of the effects attributed to the music of the ancients.

Materials for this part of our dissertation are so numerous, that if we were only to present the reader with all the theories that have been related by the most grave and respectable historians and philosophers of Greece and Rome, concerning the moral, medicinal, and supernatural powers of ancient music, this fction would be as full of the miracles of musicians, as the "Golden Legend" is of those operated by the saints. The credulous and exclusive admirers of antiquity have, however, so long read and reverenced all these narrations, that they are imprest by them with an extravagant idea of the excellence of ancient music, which they are very unwill ing to relinquish; and yet, after a most careful investigation of the subject, and a minute analysis of this music, by examining its constituent parts, we have not been able to discover that it was superior to the modern in any other respects than its simplicity, and slight adherence to metrical feet, when applied to poetry. For, as music, considered abstractedly, it appears to have been much inferior to the modern, in the two great and essential parts of the art, melody and harmony.

We have considered the marvellous effects ascribed to ancient music, under three several heads:

First, in softening the manners, promoting civilization, and humanizing men, naturally savage and barbarous: this, by its exciting, or repelling the passions:

And thirdly, its medicinal power, in curing diseases.

And we think, that the whole may be conduced into practical fables, allegories, and vulgar errors. Many fange stories of the power of music over man and beast have gained admission into books, even in this philosophical and unbelieving age, at which perversity will double the fable.

Greek Language, the language of the Greeks. Whether we consider the high antiquity of this tongue, its varied excellencies, the unrivalled models of composition which it contains, or the extensive influence which the study of it has produced on the more modern dialects of Europe, it claims, in an eminent degree, the attention of learned men, as a subject no less curious than useful. The advantages to be derived from the study of these authors who have written in this tongue, are too notorious to need description, and are recommended to us by the united testimony of the learned in every age and country. The Greeks have left the most durable monuments of human wisdom, fortitude, magnificence, and ingenuity, in their improvement of every art and science, and in the small writings upon every subject necessary, profitable, elegant, or entertaining. They have furnished the brightest examples of every virtue and accomplishment, natural or acquired, political, moral, or military; they excelled in mathematics and philosophy; in all the forms of government, in architecture, navigation, commerce, war; as orators, poets, and historians, they stand as yet unrivalled, and are likely to continue unrivalled for ever; nor are they left to be admired for the exercises and amusements they invented and brought to perfection, in the institution of their public games. Nor can we become sensible of these admired excellencies in any of the belles translations from the Greek. They may indeed communicate some knowledge of what the originals contain; they may present us with propitiosities, characters, and events; but allowing them to be more faithful, more accurate than they really are, or can well be, still they are no better than copies in which the spirit and lucre of the originals are in a great degree necissarily lost. The powers of the Greek are vastly beyond those of any other tongue. Whatever the Greek writers describe is always felt; and almost seen; motion and
The Greek tongue, as it was spoken in different provinces, was divided into different dialects, called the Attic, the Ionic, the Doric, and the Aeolic. The Attic is that which was used at Athens, and in the adjacent country; those who have particularly distinguished themselves in this dialect, are Thucydides, Aristophanes, Plato, Herocrates, Xenophon, and Demosthenes. The Ionic differed very little from the ancient Attic; but having afterwards made its way into some towns of Asia Minor, and into the adjacent islands which were colonies of the Athenians and Achaeans, (among which are reckoned Samos, Miletus, Ephesus, Smyrna, and some others,) it imitated a new tincture, and fell very far short of that decency to which the Athenians afterwards attained. The principal writers in this dialect were Hippocrates and Herodotus. The Doric first prevailed among the Lacedaemonians and the inhabitants of Argos. It travelled afterwards into Epirus, Sicily, Rhodes, and Crete. This dialect has been used by Archimedes and Theocritus, (both of Syracuse,) and Pindar. The Aeolic was spoken at first among the Ebaeians and their neighbours, and afterwards it passed into Ionia, a province of Asia Minor, between Ionia and Mytilus, which included ten cities, all Greek colonies. The chief writers in this dialect were Sappho and Alcaeus, of whose writings, little has survived the habit of ancient learning; but this idiom is occasionally blended with the use of the other dialects in the compositions of Homer, Theocritus, Pindar, and others. It may be remarked farther that the lapse of time which occasioned the difference of these dialects, as they arose from a common item, has moreover caused them to differ from themselves. For instance, in the Attic there is a wide distinction between the style of Demosthenes, and that of Thucydides. Nor has the Ionic dialect invariably continued the same, the people of Asia speaking it differently from the old Ioniens of Greece, who followed the ancient language of Athens, and the same observation holds in regard to the Dorians and Eolianis.

The ramification of the Greek tongue into its several dialects, while it forms one leading cause of its copiousness, occasions one of the most serious difficulties in the acquisition of it by learners. This difficulty, however, will be much diminished, if the dialects be reduced to those unavoidable changes, which are founded in the nature of language, and in the progress of speech. The changes we mean are such as flow from the fluctuation of the vowel sounds, from the different manner of combining, or of resolving any two consonant vowels, and lastly, from the substitution or interchange of the homonymous consonants, i.e. the consonants of the same organs.

Oriental grammarians, with much propriety, have divided the consonants into three classes, corresponding with the organs employed in producing them. Thus ร, ฎ, ฏ, being founded by the lips, are hence called bilabials. On the other hand, ง, งг, งгг, งงง, enunciated by a contact of the tongue with the extremities of the upper teeth, are, for a similar reason, labials ง. ง. ง, while ง, งг, งгг, uttered by a contraction of the lips, receive the name of gutturals. This distribution of the consonants, though here confined to the Greek alphabet, necessarily extends to any other system of letters, and well deserves the attention of him who would acquire a philosophical acquaintance with the origin and derivation of words. To the interchange of the homonymous consonants, it is chiefly owing that the proper language of men, at first rude and barbarous, became copious and refined (the same original term hence splitting into many), was afterwards diversified into distinct dialects, and at length into distinct languages. Nor is it, we conceive, beyond the reach of philosophical enquiries to prove that the simple terms of any one language have their kindred terms in all other languages, diversified indeed by the differences of character, termination, and meaning; and that they may be traced back through the several stages of social life, till they meet, like so many shoots, in one common root.

The Greek language is a very copious subject, and a full account of it would carry us beyond the limits necessarily preferred by our plan; we shall therefore content ourselves with some remarks calculated to ascertain its origin, and to unfold those analogies by which it grew from a few fertile roots to the copiousness and refinement which distinguishes it beyond most other tongues.

In enquiring into the origin of the Greek tongue, or in referring to it to a higher dialect, we of course mean its roots or primordial words, which were simple, few in number, and consisting of two, three, or at most four letters; while its compound terms, which are exceedingly numerous and diversified, must have been indigenous, the product of time, and of improvement in knowledge and the arts of life, long after the introduction of its more elementary parts into Greece. With this limitation we have no hesitation in saying, that the simple words of the Greek language are all derived from the Hebrew, Arabic, and Persian, and principally from the first of these tongues. And for the confirmation that the Greek is derived from the Hebrew, or that the Greek primitives are Hebrew radicals, we offer the following observations. Muses, in the tenth chapter of Genesis, the fountain head of universal history and geography, enumerates those heads of separate families by whom the earth was divided after the flood. He describes them by those names which the nations that sprang from them, or the countries they severally occupied, retained in his time. By those parts of the earth, which he calls גֶּנֶּשׁוֹת, or rather by Genesis and Javan, and their sons,—"In their lands every one after his tongue, after their families in their nations." This division must have been regularly conducted. It must have taken place in the time of the patriarchs here mentioned; for the act was theirs, and the nations retained their names to the time of Moses; may many of them long afterwards, for we find them recognized by history and geography. Javan is well known as the parent of the Greeks, the name Ionians being anciently applied to him to the several branches of that nation. But it appears from the sacred history that Javan spake the Hebrew tongue; and he, with the colony under him, must have introduced it with them, and made it the first language of Greece. The letters of the Greek tongue refer its origin to the same oriental source; for they are nearly the same with the Samarian when inverted, or written after the European manner, from left to right; and with little variation they have ever retained the names of the Samaritan or Hebrew alphabet. This is confirmed by Diidorus the Sicilian, lib. v. who gives it as the opinion of persons in his days, that letters were invented by the Syrians, from whom the Phœnicians first learnt their use, and then communicated them to the Greeks. Their Alphabets, Herodetus describes lib. iii. as the inhabitants of Jerusalem, to which he gives the name of Cadpius, the name it had of old, and ill continues to have in the East. The authority of Herodotus and Diodorus, Pliny, u

GREEK LANGUAGE.

These examples are sufficient to show how the Greek has been derived from Hebrew roots. Some thousands of Greek primitives owe their origin to the same source; and it is not too much to say that, if the Hebrew language had been preserved in its full extent in which it once flourished, not a Greek term could be named, which might not be traced to some one of its roots. But as its records are comparatively so scanty, many of the parent terms of Greek may more immediately be found in the kindred tongues of Syria, Chaldæa, Arabia, and even Persia, which lack, though different in structure from the Greek, contains a multitude of its radical terms. The conclusion that Greek originally flowed from the Hebrew tongue, ferves to explain many of the properties which distinguishes this celebrated language, and to correct many errors into which learned men have fallen in treating this subject.

"The eastern tongues, says Dr. Gillys (History of Greece, vol. i. p. 15.) are in general extremely deficient in vowels. It is, or rather was, much disputed, whether the ancient orientals used any characters to express them. Their language, therefore, must have had an inexplicable thickness of sound, extremely different from the vocal harmony of the Greek, which abounds not only in vowels, but in diphthongs. This circumstance denotes, in the Greeks, organs of perception more acute, elegant, and differing. They felt such faint variations of liquid sounds as escaped the dulness of Asiatic ears, and inverted marks to express them. They distinguished in this manner, not only their articulation, but their quantity, and afterwards their musical intonation. We do not think this observation altogether just, but think it rather founded in a misconception of the oriental languages. In these every consonant included in itself the vowel necessary to its pronunciation; and while they thus prefixed a series of consonants to the eye, each in pronunciation is accompanied with its appropriate vocal sound, which rendered every word just as many syllables as it had of consonants, and gave to the language an exact meaning of vowels and consonants. When the Hebrew tongue ceased to be a living language, its true pronunciation was of course lost; and with it was lost the sound and even the existence of the included vowel; and to supply this loss we invented the vowel points in Hebrew, Arabic, and the accents in Greek, which appear to be of kindred or rather of the same invention with the diacritical marks in the Asiatic tongues. The early Greeks, being unable of the included vowel in the parent tongue, gave it a separate existence, by annexing it to the consonant: and as this vowel, though originally the same and always short, was liable to fluctuation, and to perceptible difference of sound, it naturally gave birth to the several short vowels. In Homer the digamma, which was a labial consonant, interposed between two vowels, which otherwise would have formed a diphthong. And this circumstance might lead us to conclude that the early Greeks conform to the Asiatic tongues in rejecting the nse of diphthongs, and that the use of diphthongs prevailed only as the digamma was laid aside. In the more ancient languages of Asia, all the vowels were short, and every vowel that had no independent form was probably long: but short as well as long vowels came in time to have a separate existence; and the Shinfric, so far from being deficient in vowels, can boast of sixteen, a number more than the double of those in Greek.

We remark, in the second place, that the derivation of the Greek primitives from the oriental tongues will, in general, set aside as npository and erroneous the derivations of the ancient scholiasts, and of those modern lexicographers who have adopted their explanations. These scholiasts and grammarians are valuable as expounders of the Greek text; but as they were apparently ignorant of the oriental tongues, the account which they give of the words thence derived are often frivolous in the extreme. It is necessary to justify this affront by a few examples. Αγαλλια, a hedge or fence, occurs in Theocritus, Idyl, i. 47, and the scholiast derives it from αγαλος, blood; because those who pass through such a fence are made to bleed. This derivation, natory, as it appears, is adopted by Hederic in his lexicon: whereas its origin is the Hebrew סֵּפֶר, a book, to strengthen, to secure, and thence applied to a hedge, which by surrounding defends a place. On the same principle סֵפֶר, a garden, the origin of which neither Hederic nor any of the ancient scholiasts, we believe, have attempted to unfold, is borrowed from סֵפֶר, the garden, from סֵפֶר, to surround: hence the term denoted a place surrounded or secured as a garden is. Lennep indeed derives it from סֵפֶר, a book, a word quite foreign to the purpose. The word סֵפֶר, which occurs in Theocritus, Idyl, vi. 10, is thus explained by the scholiast: סֵפֶר, a book, a fountain in Cos, from the particle סָלַח, to flow, or because it resembles the nomina of סָלַח; whereas סָלַח is evidently the Hebrew סֵפֶר, a book, or סֵפֶר, a fountain. The Greek scholiast, annexed to every author, abound with such peculiarities as the above; nor is the "Etymologicum Magnum" to be excepted, though the Greek lexicographers have fought for no better or more rational guides in their enquiries after the origin of the words which they explain.

Hemsterhuis, Vulckenaer, Rubniken, Villoisson, Lennep, Scheid, are indeed justly celebrated among modern critics for their researches into the origin and meaning of the Greek tongue. Their theories contain many valuable observations on the analogy by which that language grew from comparatively few radicals to its present complicated form; but their jumble of etymologies appear to us, for the most part, fanciful and erroneous; because in no instance, or at least in very few instances, have they fought the Greek terms in the languages of the East, whence assuredly they had been derived. Hemsterhuis derives שֵׁס, Deus, from the verb שָׁש, to run, to dispise; while its real origin, in our opinion, is the Hebrew and Arabic שֵׁש, שֵׁש, pronounced in the latter language שֵׁש, to shine. The Chaldeans represented the Supreme God under the figure of light; and to this representation the facred writer seems to allude, when he says that God is light. The same writer deduces יִשְׂמָה, יִשָּׁמֹה, from יִשְּמִה; while its source is יִשָּׁמַה, שָׁמַר, to be strong. From the same origin the hepplie uses יִשָּׁמ, יִשֶּׁמ, יִשָּׁמ, שָׁמ, before, to have flowed, though it seems to point to the Hebrew שָׁמ, שָׁמ, which in Arabic means the head or root of a family, and hence it came to signify origin or priority in the form of יִשָּׁמ, hence prior or prates in Latin.

Scheid derives יִשָּׁמ, שָׁמ, שָׁמ, שָׁמ, д, д, a bird, diversion, which was taken from birds. The same writer will have יִשָּׁמ, יִשָּׁמ, יִשָּׁמ, יִשָּׁמ, יִשָּׁמ, to stretch, though far more naturally it points to the Persian س, س, س, س, a tooth: in, hence שָׁמ, שָׁמ, שָׁמ, Shema, primarily meant, to cut with the teeth. The Hebrew שָׁמ, שָׁמ, שָׁמ, שָׁמ, שָׁמ, שָׁמ, שָׁמ, to shine, to scourch, gave birth to שָׁמ, שָׁמ, שָׁמ, שָׁמ, שָׁמ, שָׁמ, but Villoisson foolishly derives it from שָׁמ, שָׁמ, radere. The same critic as wisely traces שָׁמ to the same root, because, says he, лимм, is ad radicum aptum. But its origin is evidently שָׁמ, שָׁמ, a grove, hence שָׁמ, wood, and by dropping the initial vowel שָׁמ, and by transposition שָׁמ, שָׁמ, שָׁמ, שָׁמ, שָׁמ.
Greek Language.

The passage of this folio is further a version: There exist apart in the plain, in the front of the city, namely Troy. This term is called Batheia; but the Immortals the tomb of for-laying Myriame.

The language of the Trojans, though a dialect of the Greek, was, we may suppose, from their situation, mixed with an influx of Italic terms. Of this class is Batheia, which in Hebrew is Ytt, and means an abode. In Isaiah, xiv. 18, and Joel, iii. 25, it signifies the last home of man. The term here occurs in the Greek form 

But is the rational of", which may for contrary, accessible by a circular arc.

This paragraph is a fair specimen of the manner in which these etymologists have, by certain analogies, founded on their own fancies rather than on the real structure of the Greek tongue, yoked together under one common root words the most foreign to each other. The verb 

Greek factum ex opes, but from 

the same origin are derived opes, opes, opes, opes, opes, opes, opes, opes, and opes, all of which are but different modifications of the same primitive words by different people who used the same tongue. On the other hand, opes, to come or go, originated in 

or 

to travel, prolong, extend. On the other hand, 

which means a row of plants, or the order in which anything is done, is from the Hebrew 

arranged, arrangement, measure, rhythm, came the verb 

or 

to the sounds of music in a dance or to the battle. The movements in a dance and in war have been regulated by the same measures; and hence dancers and warriors had the same names applied to them. 

Macbeth being called 

as the author of the Etymological writer, 

Hence, too, a leader, i.e., one who put the men in order of battle, was called 

and, moreover, 

which denoted a species of dance, came in Latin to signify præsum. Such learning, acuteness, and diligence as were possessed by Herder, and the celebrated men abovementioned of his school, however perversé, could not altogether have been misapplied. Their labours, therefore, must preface some imbecility of just etymology, but their fury, upon the whole, appears to us both fanciful and erroneous, and calculated more to perplex their readers than to furnish them with solid information.

Etymology, as it may serve to ascertain the primary sense of a word, to unfold a general principle in the formation of language, to exemplify the manner in which philosophical notions, political occurrences, and religious institutions influence the mind and give birth to new modes of speech, is a subject of rational and useful inquiry. In this enlightened view it blends itself with the history of philosophy, of politics, and of religion, with the structure of the human frame, and even with the theory of the human mind. Connected with any or with all of these purporses, none but the unimformed will neglect or decry this branch of philology as vain and useless; and without such connection none but pedants will pursue or extol it as worthy of attention. As the Greek originated in the Etruscan languages, a knowledge of these languages to a certain extent is absolutely necessary, to form a rational and competent etymology in the dialects of Greece: and many passages must exist in the Greek writers, especially the more ancient poets, which can be understood only by light reflected from the East. It will not be foreign to our purpose to illustrate this position by a few examples. The first we select occurs in Homer's Iliad, i. 815:

Or 

The next passage in which the use of the Oriental tongues serves to illustrate obscurities in Greek authors, we shall select from the Agamemnon of Aeschylus. On this paragraph much has been written, and written in vain by the critics. Clytemnestra, the lady Macbeth of ancient days, boasts of her fidelity, during the absence of her lord, and the joy with which she would receive him on his return.

Oeci ida xégal, exh xégal xegal.

Allei prox anlws kalado x xégal xégal.
Greek Language.

The lines are thus rendered in the elegant and poetical version of Mr. Potter:

Never knew I pleasure
In the blamed converse of another man,
More than the virgin metal in the mines
Knows an adulterate and debasing mixture.

On this passage the author has the following note: "I have honestly says, "all quid sed quid non intelligo." Mr. Heath disapproves the allusion, though he thinks it a proper expression, the grace of which is lost on our ignorance, and says, "quid non sed quid non videmus alies olim formian videmat."—In the old Persian called the Prid, the first principle of things was called 2N, and though supposed to be fire by the disciples of Zaroulia, the term is a modification of 2N, ad, water, which the Arabsians maintained to be the original element. With the notion that water is the primary matter, the early Greek philosophers appear to have borrowed the term. Hence Euan, to plunge, (which Leunpe ably deduces from 2N) hence to Euan, immerse; and the pirane 2N xi 5N is a metaphor for a flat or wound, it being produced by a weapon plunged into the body as into water. The sentiment which the words convey to the herald, whom Clytemnestra addressed, is to this effect, "I know no pleasure with any man, and feel no more the sting of calumnies, than the point of a spear. But the language is studiously equivocal, and in this peculiarity confined at once the skill and the obscurity of it. While the queen appeared to express the above meaning, the in reality expressed quite the reverse. I know no greater pleasure, though no report more disgraceful, than a spear plunged in him, (namely Agamemnon,) by another husband. This artful equivocation arises from the manner in which the clause ανα σητον αυτης απισταν is connected. If taken with παρα, the lines convey the spear; but with 2N xi 2N, they convey the light.

For this interpretation we have the best authority, namely that of the Chorus, who were present: who, perceiving that the herald was misled by the artful ambiguity of the words, hints at their true significancy as soon as the queen withdrew from the stage.

Autē me 1ooy xei μακάρισαν σατ 
Ταραξιζα ερεμον επικεφαλεια λογα.

Which may be thus rendered: "This woman hath told thee learning (the who hast yet to learn,) what see is, a tale which discerning interpreters perceive to be very learning,—well to become her character and views. Here 2N depend on πεποθας; and the Chorus intimate, that her words, understood, as they seem to have been by the herald, were false and unbecoming, but strictly true and appropriate in the sense in which they, who knew the woman better, had reason to regard them. Taken in the light sense, the metaphor 2N xi 2N is too violent for the simplicity of the foment; and the falsehood, moreover, is so glaring as to clash the queen with the bafed of deceivers, without a trait of that masculine intrepidity and elevated ardour with which she preferred to the object of her desire. In the latter it exactly suits the dark ambiguity of prophecic language: and the boldness of it is in unison with that vehemence and glow of pleasure, with which the anticipated the plunging of the weapon in the bosom of her husband. For these reasons the Chorus justly pronounce her language πεποθας, as at once expressive of her true feelings, her artifice, and her intrepidity.

Lycophron, who flourished under Ptolemy Philadephilus, is known to have studiously affected the use of hard and obscure terms, which, from their antiquity, must demand the attention of Asiatic scholars. In his Cofandria, the only remains of his voluminous productions, occur these lines:

They contain a prophetic address to Paris, now commencing his expedition for the rape of Helen, and may be literally rendered: —The ship and seat of Phereclus will bear thee to the two ports and coasts of Gythium, having in their fists to the rocks the crooked teeth of the pine, Hecules (i.e. singularity,) of the flood. Phereclus as an artist constructed the ship, and as a footsayer, confounded the gods, and endeavored to conciliate them to the projected expedition. As such, he was naturally led to give the vessel the name of τηρεμνος, which with the Greek termination is the Chaldian and Pharian term for the tutelary gods, Διηνυμος, ταρπαμ, or τραπαμ. The scholar says, it is the name of a foreign ship; and in this he is followed by Hefychis. It was certainly usual to carve the images of the gods on the ship, which they were suppofed to protect; and to them the sailors fled in scenes of danger. (See Hor. i. 14.) The figures, which at this day are often framed in the forpart of the ship, are but the remains of the same custom. The practice, no doubt, originated with the Pharian: and it was natural for them to call their ship by the name of these gods which were suppofed to preserve them. The rudders, the oars, the sails, by which the vessel was moved, are here affectingly called the τιρεμνος, he being the author of them. Of the derivation of the term the scholiast and Hefychis appear equally ignorant, and the whole of this passage is a striking instance how incompetent the ancient commentators were to explain in many places the terms of the Greek tongue.

The ancients had statues of their gods seated before their doors, and in the entrance of their harbours. These received the salutations of strangers and passengers. Lucian mentions this custom in his first book. Hence the doors and ports received the name of τηρεμνος, as being places where the gods were treated, from the Arabic Διινυμος, salutations. The account which the scholiast gives of this term is ridiculous: τηρεμνος περι το σον ελογιαν, τεριο δυν σολομ. The explanation of Hefychis is more rational, though not the true one: τηρεμνος, οι θεοι περι το σον θειον. This is a fair specimen of the manner in which the Greek words, derived from the East, are explained in the old glossaries. But farther, πεποθας, ταρπαμ, is the Hebrew אושד, falkh, or πλαγ, (the vowels being arbitrary, and not existing but as included in the consonants of the original,) and signifies to divide, and whence a noun any thing divided, such as portions of the land and sea. From the same original is derived πλαγιας, as serving to divide the earth into distinct territories: hence too, the Latin plagas, a chine or region. Finally, the unfruitful term πεποθας originated in the Persian πλονιας, an extremity or limit which, as the limits of a river came hence to signify its lands; as the limits of the sea its shores, or the rocks lining them. The limits of a door are its polis; and hence the Celtic word lyuncori, the door polls; and probably from the same source, on account of their remoteness, and probably has been derived the appellation alligned to the Canary Islands.

The attempts of Paris, under the auspices of Phereclus, to appease or conciliate the gods, are alluded to by Horace, lib. i. 15, who appears to have had the passage of Lycothron in his view. Phereclus, the first adviser, perhaps,
Greek Language.

of the expedition, is represented by Homer as properly punished; for he received an ignominious death from the hand of Merion. The poet adds, I. v. 65, ἐφησον ἱματικ, 

since he did not at all know the decrees of the gods. To say that Pherorchus did not possess this knowledge, appears not only a profane, but an unnecessary saying: for who is the man that is acquainted with the divine decrees, while yet unfallen? But when it is considered that Pherorchus had pretended to be so knowing, and probably predicted future success, while the event turned out very different from his predictions, there is much propriety and even point in the remark; since it holds forth the diver as a deceiver, who by his impurities brought ruin upon himself and his country. From this we may conclude, that the beauties of Homer, who confines himself beyond any other poet to general nature, yet in many instances depend upon circumstances unknown to, or unobserved by modern readers.

The prevailing taste for oriental literature promises to contribute much to the improvement of philology. And when clavish scholars shall engage with due attention in this pursuit, the more ancient Greek writings will share in the general benefit, by the light reflected upon them from the East. The derivation of the Greek from the oriental tongues, the frequent use of terms which Homer, Hesiod, Lycophron, and others have adopted in their primary significations, have occasioned difficulties which a critic, however able, but verified only in Greek and Roman authors, is hardly able to solve. These difficulties, instead of being explained, have been glossed over by the futile etymologies of the ancient scholiasts and lexicographers: and they can be properly felt and successfully removed only by those who have extended their study from the elegant language of the Greeks, to the no less polished languages of Persia, Arabia, and Judea. Of this position the examples above cited afford sufficient illustration: and they are, it is hoped, too curious, new, and solid, not to be undermining of a place in a dictionary of science.

In the last place, the derivation of the Greek from the ancient languages of the East, will account for the origin of the much disputed digamma. In these tongues gutturals abounded, which, like other consonants, contained in themselves the vowel necessary to their pronunciation. But it is the tendency of every guttural, when become habitual, to fall down, in the rapidity of utterance, into a mere aspirate, till it at length vanishes. Thus corvis has degenerated into hora; χωρ, into huna, earth, and into hona, a creature of earth, man. Thus also the Hebrew ה, which signifies life, soul, self, appeared in Greek in the form of γ, αγα. Moreover דד, kalad, a liver, gave birth to (πατωνι). This word retains an unquestionable mark of its derivation, for it has the form דד, kedos, or דד, kador; and this variation has been transferred into the Greek καδος and καδος. Hence we obtain the origin of the aspirate placed over a vowel. It was originally a guttural, which losing its power as a consonant left the included vowel behind, with an inverted comma above, to perpetuate that part of the letter which fell into diffus.

The guttural, when softened into an aspirate, is apt to be dilated into a long vowel. Hence the reason why γ, in the ancient Greek, seems to have been accompanied by an aspirate, as in ὑδέγειν. On the same principle that a guttural softens into an aspirate, the aspirate often melts into a gentle breathing, or becomes in pronunciation quite quick, as the Latin honora and honos become in English honour and honest, the b being mute. On the same principle the gh became silent in our tongue, as in taught, fought. So in the Greek ἡβης, (αυτος, a king, has degenerated into ωνος, which Homer pronounced ωνος. This leads us to remark, that the aspirate, instead of vanishing, was changed into a labial letter ων, ων, b, f, or c. Thus laugh, cough, which are still strong guttural sounds among our northern neighbours, are found left, c, among us. Thus also in Greek, what was at first written χαρπος, was pronounced χαρπος; and the words ωνος, ωνος, were found ωνος, ωνος, or fou, fou, fe.

But the digamma did not always originate in a guttural, but sometimes in consonants allied to our w or y. Thus from γ, 'y, is derived the Greek ἰδα, which in Homer is found with, because the original is yada, hence the Latin videt. So again from λιθος, y is taken, λιθος, founded winae: hence nations, and nation.

We have already observed, that in Hebrew every consonant contained in itself the vowel necessary to its pronunciation. This vowel the Greeks detached and gave it a separate existence, by subjoining it to the concomitant consonant. And as the Hebrews seem at first to have founded every consonant, thus dividing each word into as many syllables as it had of consonants; and as they further seem to have used vowels only in conjunction with consonants, and to have considered them as unfit to be employed alone and independent, so the Greeks, in imitation of them, used at first only short vowels; they next adopted the long or compound vowels a and e; but still avoided the diphthongs, and when any two vowels concurred, they converted the first of them into a labial consonant. Thus, διαφορετικος, was founded not lampetovoti, but lampetovoni, or lampetovit; and μουσας, pronounced μουσας, or μους; αυς, αυς.

This letter is called digamma, because it has the form of two gamma, one upon another like our capital F, and also called laphis, as supposed to belong exclusively to theIonic dialect. But this account of it proves, that it did not belong, as Dr. Bentley and others have supposed, to the Ionic dialect only, but to all the dialects of Greece, in their more ancient mode of pronunciation. It follows also that the universal opinion of the learned, who say that the digamma at first prevailed, and was afterwards succeeded by the aspirate, is the reverse of the truth. For the true state of the case is, that gutturals at first prevailed; these softened into mere aspirates; and these again were changed for a more easy and agreeable letter, which being simply a labial was diversified by different people into y, ι, ι, ι, ι, b, f or c. But the digamma, it will be laid, is to be found only in Homer, by far the most ancient writer of Greece, while the aspirate is in all the more recent authors. The answer is this: the use of the aspirate obtained in the written language, and was, therefore, less susceptible of corruption. On the other hand, that of the digamma prevailed in pronunciation, which was more liable to change, and to deviate from the original terms. Homer, we may naturally suppose, adopted the first in composing and writing his poems, and the last in reciting them to the people. The written form, we may presume, was at first used but little, but prevailed by degrees; while the peculiarities of pronunciation in their turn began to decline. The language, as written by Homer, at length became fashionable in the conversation of polished people, and the aspirate, being thus triumphant in the daily converse of learned men, would, of course, in their writings, triumph over oral and temporal corruptions.

The change of a guttural into an aspirate, or into a long vowel, or into a labial letter called the digamma, is not peculiar to any one language, but is founded on the structure of the organs of speech; and instances of it prevail in all languages, both ancient and modern.

The preservation of the aspirate in the written language of Homer,
GREEK LANGUAGE.

Homer, while the *digamma* was used in reciting them, is a proof (if a proof be wanting) that Homer did actually use a *caferian* language, and that his works were preferred by a written language; otherwise the *digamma* would have been left, and the *digamma* alone would have prevailed in all the Greek authors who succeeded that celebrated bard. If an editor of Homer in modern days would invert the *digamma*, he would corrupt the original orthography of Homer, and subliterate in the room of the original characters the corruptions of pronunciation.

We shall now make some observations on the leading parts of speech, which must serve to unfold the peculiar nature and amusing character of this language. As *gender* is the distinction of sex, there cannot in *trinernma* be in any language more than *two* genders, masculine and feminine; nouns expressing inanimate objects, or things without life, being in a philosophical *fem. siter* or *either* gender. But *neuter* nouns had by analogy assigned them the terminations of masculine and feminine nouns; and unfortunately for Greek, and the other European languages affected by it, the termination became fixed regarded as an index of the gender, without any reference to the meaning. Thus nouns designating females ended in -α or -έ; and for this reason the names of inanimate things, and also adjectives, having the same ending, are said to be *feminine*. For the same reason nouns in -ον or -ένον, though meaning things without life, are generally masculine, because these happened to be the predominant terminations of the names of males. There are, therefore, in this language two principles which regulate the gender of nouns, the *fugification* and the *termination*; the former ascertaining the gender of living things, or things whose sex it is of importance to distinguish, the latter that of inanimate objects. There is, however, a third principle, on which is founded the distinction of gender, we mean the analogy which inanimate objects sometimes have to living creatures. There are several terminations common to males and females, and these afford such analogy an opportunity to operate. Thus *άρξις* reason, though expressive of what is neither male nor female, is made masculine, as signifying the commanding and the most excellent faculty of the human mind; whereas *κάτα*, *άρχιτευκτικύ*, from its affinity to *κάτα*, the earth, or from the passive nature of its *fugification*, a characteristic more of the female than of the male, is made feminine. That this analogy is not fanciful might be proved by many instances. In Greek, *εικόνα* is masculine; but *Theocritus* (Idyl. i. 132.) in representing it as producing *violet*, makes it feminine. This affinity to the female sex is the reason why *άρσις*, with the specific names of trees in *άρσις*, is always feminine, though the termination is decidedly masculine. In cases where the termination absolutely belongs to the names of males or females, this principle of *analogy* necessarily gives way to the termination. Thus, because a *final* is invariably appropriate to feminine nouns, *άρσις, áρσις*, *ής* is feminine; on the other hand, *ένος*, *άρσις*, is masculine, from its termination as well as from analogy.

Nouns and verbs in Greek have a *dual number* to express two things, or such things as are in pairs, as hands, eyes, feet. The *fug* of the dual occurs frequently in the poets, though not peculiar to them, nor always observed by them, when speaking of two objects. The dual number is by no means necessary in language, although it may enable the Greek to express the number two or pairs with more elegance and precision. It was, therefore, rejected by the *Eolians* and by the Latin, who derived their tongue from the *Eolic* dialect. The seventy translators, moreover, have rejected the *fug* of the dual number, and in this they have been followed by the writers of the New Testament and the Greek fathers.

*Cases* have been defined by all modern grammarians to be changes in the termination of nouns; but the name *παράγον*, in Greek expressive of *cases*, clearly shows that this is not the primary meaning of a *case*. For *παράγον* means a *fall*, and, from signifying a *fall*, it came to signify the place in which a noun falls in a sentence. The ideas, then, which a *case* at first expressed is the *position* of a noun in a sentence, and by that position expressing the relation of one word to another. Thus, if a noun denoted the *direct* subject of a proposition or discourse, it is said to be in the *right* *case*, *πάραγον*, *πάραγον*, i.e. the *direct* or *straight* position; but if a noun expresses an object or quality *indirectly*, it is said to be in an *oblique* *position*, *πάραγον*, *πάραγον*, and this deviation from a *direct* to an *indirect* position, as the subject of discourse, is in the language of grammarians further called *cases*, *declension*. Further, *cases* express the relation of things in motion or action, and the relations necessary for the purposes of language are chiefly the following: the relation of *causa*, the relation of *effect*, the relation of *beginning*, the relation of *medium* or *instrument*, and the relation of end. A noun denoting the relation of *causa*, i.e. denoting the agent of an active or the subject of a neuter or connecting verb, is in the *nominaive*; that of effect in the *accusative*; that of beginning in the *genitive*; that of medium in the *instrumental*; and that of end in the *dative*. The *nominaive* above is called the *right* or direct *case*, the rest are all called *oblique* *cases*; though the *accusative*, as expressing a direct part of a proposition, might more properly be called a right, than an *oblique* *case*.

Moreover, the *relations of bodies in motion or action* were at first expressed by *prepositions*; and our ideas of relation arise from the things related, and which succeeded them in their formation, *prepositions* being, and probably, did, in the early life of language come after, instead of going before the nouns which they governed. In consequence of this arrangement, they combined into one word with the final syllables of the connected noun, and thus served to give a diversity of terminations. Hence the origin of *cases* in the *fug* in which cases have hitherto been described by modern grammarians. It is worthy of remark, before we quit this *subject*, that the *nominaive*, as expressing *causa*, has a close affinity to the *genitive*, which means *beginning*. But the former fixes the attention on the noun, as an *agent* or a *cause* in action: while the latter holds forth its noun as the *source* or *beginning* of motion. The *beginning* of a thing is often the author and owner of that thing: hence the *genitive* has the *secondary* *fug* of *possession*. On the other hand, the *accusative* is nearly allied in *fug* to the *dative*; but the former is not used in its strict and original *fugification*, unless it denotes an *effect*, or the thing in which *motion* terminates; while the latter, in strict propriety, marks the end to which *motion* points, and in which it terminates. The *genitive* *blends* opposed to the *dative*, as beginning to the end, like the opposite points of a right line; while the ablative expresses the *medium* or *instrumentality* of the *motion* by which that line is generated. The *ablative* therefore denotes one of the most important and distinct relations in language, and yet the Greek, with all its boasted copiousness and *preposition*, has not a distinct termination to express this *case*, but denotes it sometimes by the *genitive*, and at others by the *dative*, with or without a *preposition*. Finally inanimate things only move after they are put in motion, or act as they are acted upon. This is probably the reason why neuter nouns in Greek have no termination to express *causa*, distinct from that

GREEK LANGUAGE.

The second aorist is the same tense with the imperfect, and verbs of the imperfect differ from verbs of the second aorist, not because they express different modifications of past time, but because they come from different roots. Thus, from πηνον and τηνον are derived the imperfect πηνον and τηνον, while τηνον and τηνον, in the second aorist, have been deduced from the oblique πηνον and τηνον; as is the modification, so are the terminations the same in both. The puperfect has its personal terminations from the imperfect, by annexing the subjunctive in each person—σαν, σαν, &c. The characteristic of the first future is that it is not the first aorist, as is supposed by grammarians, but the first future, which is, indeed, proved by its signification, as well as by analogy: for, in all instances this tense expresses a future time, not absolutely so, but time future in regard to another verb connected with it in the sentence. The optative has its tenses, in general, derived from the corresponding tenses in the indicative, by changing into ιον: but the first person, as it has been observed, is derived from verbs in μον; as, if οένονον, οένονον, οένονον. The third plural, like the third singular, follows the analogy of verbs in μον, iron, contracted in the same manner as οένον becomes οένον.

The imperfect mood, originally in the first person, retained ον of the imperfect tense; as λέγον, let me receive. Hence, dropping the final ον, it has, in the common tongue, the first person in έτον. The pronoun γινε, which, in Persian, is to added in the form of τον, constitutes the second or third person—γινε. And γινε, contracted into γινε, forms the third plural—γινε, which, by dropping γινε, is again abridged into γινε, erroneously supposed to be the dual number. When a command is given, it is necessarily given in the present time, and it can be executed, not in the γινε, but in the future. It is impossible, therefore, in reason, that the imperative mood can have a γινε tense. Thus, γινε is the present imperative, or that of the second future; and γινε is the first future, not the first aorist. In some of the dialects, 2ον is substituted for the subjunctive vowel. On the other hand, the Lornians change γινε, or without its concomitant vowel, into 2ον. Thus, in the imperfect, for 2ον, or γινε, they used 2ον, I 2ον: for the present γινε, γινε, which the Attics contracted into γινε; and in the third person plural, of the passive form, for γινε, they write γινε, and for γινε, γινε. In the same manner γινε, which is used to be the first aorist, but which, in reality, is the first future, becomes, when γινε is added, not γινε, but 2ον. From the imperative thus principally ending in γινε, we obtain the third person plural in γινε—γινε, γινε, which are contractions of γινε, γινε, or γινε, and γινε for γινε. By the above Ionic analogy, we also obtain what is called the άοοις first aorist, γινε, which has the personal terminations of the first aorist indicative. It is thus changed from τον to 2ον, used for 2ον, in the same manner as δον is for δον.

The infinitive is formed by adopting γινε, or, as it is in Hebrew, γινε, into 2ον, and by subjoining 2ον, 2ον. In the perfect it has γινε, 2ον; but in the first aorist it is dropped—2ον, probably for τον, which, after the analogy of the perfect, would be γινε. In the Ionic and Attic dialects, the infinitive, however, is formed from verbs in μον, though oblique, τηνον, τηνον: as 2ον, or 2ον, which or 2ον, 2ον; or 2ον, 2ον. To these, after the analogy of the perfect, is added 2ον, 2ον, 2ον, 2ον, 2ον, 2ον, 2ον, 2ον.

The passive voice is formed by combining the subject of the passive with the personal pronoun in the dative case—μον, μον, or μον. Thus 2ον, μον, house for me; μον, μον, house for thee; μον, house for him. These combinations, which by a slight change become μον, μον, μον, μον, μον, μον, came to convey the idea, I have a house, thou hast a house, or I am housed, thou art housed. And this is the reason why the passive form in all authors have either an active or a passive signification, the context alone serving to ascertain the tense of the verb. The dual γινε is made passive by changing into 2ον, 2ον, and not τον, and it is worthy of remark, that in the first person plural it takes 2ον before it very frequently, as τον, for τον, and in the imperative 2ον for 2ον.

As the personal pronoun, combined with the radical word
word to form the passive voice, was μις, the primary form of the verb must have been τιτωτήξ, and not τιπτωτήξ; and in the imperfect τιπτωτήξ, and not τιπτωτήξ; and afterwards ἐπετίστη into ἐπετίστη, as in other numerous influences. Hence the passive form of verbs in -ία was originally the same with that of verbs in -ία; and this form had only two femes, μις for the present, and ὑπό for the past. The second person singular is formed in the common tongue by dropping ε and contracting the two succeeding vowels in every mood and tense. Thus τιπτω, τιπτω, τιπτω; imperfect τιπτω, τιπτω, τιπτω, -ότι, -ότι, -ότι, -ότι; first aorist middle τιπτω, τιπτω, τιπτω; optative τιπτω, τιπτω, τιπτω; -ότι, -ότι, -ότι, -ότι. The first future middle is derived from the first future active, by changing ε into ὑπο. The second future middle is derived from τιπτω, (which is from the obsolete τιπτω). This drops ε and is contracted—τιπτω, τιπτω, τιπτω. Hence what is called the second future is no other than the first future. The same obsoleto radical has given rise to the second future passive, which is no other than the first future—τιπτω, τιπτω, τιπτω. It preserves the future from the obsolete in τιπτω, τιπτω, τιπτω; while the first future is from the obsolete in τιπτω, τιπτω, τιπτω. What grammarians call the first aorist passive is from verbs in -ία as τιπτω, τιπτω, τιπτω; ἐπετίστη, ἐπετίστη, ἐπετίστη; ἐπετίστη, ἐπετίστη, ἐπετίστη. The third plural s is dropped—τιπτω, τιπτω, τιπτω. So in the active voice, τιπτω for τιπτω; τιπτω for τιπτω; τιπτω for τιπτω. In the infancy of language, while words were yet feeble, the mind, naturally war, whereby a writer or speaker might give an additional weight to his meaning, was to repeat such terms as he wished to render emphatic. The more ancient any language is, the more numerous appear the traces of such repetition; and, next to the Hebrew, they form a remarkable feature in the Greek tongue. Thus, μις, μις, I defile defile, blended into one word, became μις, and means I greatly defile; ἐπετίστη, ἐπετίστη, I walk walk; ἐπετίστη, I stride; and such words are numerous in this tongue; from which we may draw the following influences.

First, that the augment is only the remains of a verb δεσιλλιδ, in order to augment the viene. Secondly, this augment takes place in the present tense as well as in the imperfect as τιπτω, τιπτω; κλησι, κλησι; ἐπετίστη, τιπτω. Thirdly, that the augment of the imperfect, and of the aorist, is but a corruption, still more remote of the reduplication; and that the dialect, which presumes a consonant to the vowel like the perfect, such as τετοιανα, for στεπτερια, is the most ancient usage, and comes nearest to the primitive simplicity of the language. Fourthly, the augment is applied to the first and second futures; and the effect of it is to increase the figurative of the verb; τιπτω, τιπτω; ἐπετίστη, ἐπετίστη, τιπτω. I will cry loudly; τιπτω, τιπτω, ἐπετίστη, τιπτω, I will greatly rejoice. Fifthly, that the form called by grammarians πάλαξ γείταντα is not a distinct tense, but the first future middle augmented; τιπτω, τιπτω, τιπτω; τιπτω, τιπτω, τιπτω. Sixthly, that the augment of the perfect was more nearly to the original reduplication than that of any other tense, which is preserved still more distinctly in the augment of verbs beginning with vowels α, ω, ε, and the like.

The Ionians, who have observed, changed into τιπτω; and this analogy, perhaps, converted the imperfect form τιπτω, into τιπτω, of τιπτω. The third person plural would be then τιπτω, τιπτω, τιπτω. Hence the Boeotians used τιπτω, τιπτω, τιπτω. The Dorrians write τιπτω, which, in the common tongue, is softened into τιπτω. The simple and natural way of forming the perfect was to give it the characteristic of the present which it always implies, as an action, though past, still continuing in its effect; τιπτω, τιπτω, τιπτω. But from the facility by which letters of the same organs are changed for one another, τιπτω became τιπτω, and τιπτω, became τιπτω, τιπτω, τιπτω. Hence τιπτω and τιπτω, which are improperly called the perfect middle, seem to be the original perfect active, accidentally corrupted. And as there is no intention for the distinction of perfect active and perfect middle, the fact there is none in figurations. When, from whatever cause, a in longe verbs became the characteristic of the perfect, it prevailed in other verbs, which still retained the characteristic of the perfect—τιπτω, τιπτω, τιπτω. The distinction, therefore, of perfect active and perfect middle: a fiction of grammarians, founded on the interchange of similar conforims, or the blind impulse of analogy.

Propositions form the most difficult part of the Greek tongue, not only because they, for the most part, govern different cases, but because each has a great variety of significations. Yet the author of the Greek grammar, above mentioned, has laid down two observations, which tend greatly to simplify this branch of the Greek language. The primary meaning of a proposition, says he, is to be found in the root from whence it is derived, and the meaning is obtained, or one obviously connected with it, and flowing from it by analogy, it prefers in all cases whatever. A proposition combines with its own signifies the meaning of the case in which the dependent noun is used, and governs the genitive, the dative, or the accusative, as the writer wishes to fix the attention of his readers on the origin, the intramoreality, or the object of the govern noun.

We cannot forbear transcribing one infallence (which is the first that occurs) of his manner of explaining the propositions—υπο (from the Hebrew נ, ah, a stem or root; and as the root is underneath, the plant or tree springing from it, the primary seance of ὑπο is) under, ὑπο ὑπο, under a field. Further, the root of a tree is the cause of its growth; hence ὑπο denotes the cause or agent of the action specified in conjunction with it. "And they were baptized by him, ὑπο ὑπο, he being the cause of their baptism." Finally, as a root shoots upwards, so as to appear above the ground, ὑπο is sometimes to be rendered from under ὑπο ὑπο from under the yoke ὑπο, (from the same Hebrew origin with ὑπο; and as the root is the origin of a thing, it denotes beginning, cause, motive, and is rendered) from. As by the use of ὑπο, the attention is directed backward to the beginning of motion, its governed noun is an ὑπο, in the genitive. He was not able to see Jesus, ὑπο ὑπο ὑπο from the crowd, because he was standing the cause of his inability. From signifying beginning, ὑπο came to express the exact point of time at which motion begins. They went from slipper, ὑπο ὑπο, i.e. immediately after slipper. It expresses also the distance to which a thing has advanced, in consequence of moving, ὑπο ὑπο, the land. The consequent of distance in most cases is separation, or privation, ὑπο ὑπο ὑπο, from their arms, i.e. without them. Taken in this sense, ὑπο, abbreviated into ὑπο, in Latin ab, becomes ὑπο, and compounded with nouns, adjectives, and verbs, imparts to them a contrary signification: ὑπο ὑπο, υπο ὑπο, as in Latin-like. On the contrary, the effect of distance in some cases is increase, as a stream grows larger the farther...
it flows from its source, or as a tree becomes greater with its gradual expansion from the root. For this reason it is abbreviated, sometimes increases the signification of its compound.

The Greek surpasses almost all other languages in the number and variety of its terms; and the cases of its superior copiousness are, 

1. The many dialects which it comprehends, and which served to divide by accidental corruption the same primitive into many words;

2. The facility with which nouns combined with the personal pronouns in the formation of verbs, and the great variety of ways the noun may be converted into verbs, so as to form distinct verbs, yet allied in sense and found to each other;

3. The various ways in which verbs, adjectives, and participles have been changed into abstract nouns; and

4. The great multitude of compound terms, formed by the union of verbs or adjectives with nouns, and of propositions with verbs. The combination indeed of prepositions with simple verbs is the most fertile cause of the extent and comprehension of the language. The simple verb \( \phi_{\nu} \), thus combined, has given birth to no less than \( \phi_{\nu} \tau \phi_{\nu} \) compound verbs. This single instance sufficiently shows the genius of the language, and proves that, however few its simple primitive words may have been, its derived and compound words are in a high degree voluminous and varied, yet connected by an obvious and uniform analogy, both in regard to the formation and the meaning of each term.

But this language is not less remarkable for the harmony of its structure, than for the comprehension and variety of its terms. The perfection of its language, as well as of music, depends on the melody of its sounds; their measure or rhythm, their variety, and their fruitableness to the subject, which they are meant to describe or express. The circumstances of the Greeks in the earliest periods of their society, rendered them peculiarly attentive to all these objects. They lived continually in crowds; all matters of consequence were decided by the voice of the assembly, and, next to the force of his arms, every warrior felt himself indebted to the persuasive accents of his tongue. The perpetual necessity of employing the power of eloquence, during the infancy of their political state, made them retain the original tones and cadences, by which, as yet unpracticed in the use of arbitrary signs, had made known their affections and their wishes. These tones and cadences, imitating the language of action, (the first and most natural language of savages,) possessed a degree of energy and of warmth which can never be attained by the mere artifice of articulate sounds. By uniting them to these sounds, the Greeks gave all the force of a natural to an arbitrary sign. Music and action were incorporated in the fulness of their speech; and the descriptive power of words was extended to all those objects which can be characterized by sound and motion, or which the various modifications of those qualities can suggest to the mind of man. Gillies, Hist. of Greece, vol. ii. p. 233.

GREEK. \textit{moder} or \textit{vulgar}, is the language now spoken in Greece, and called \textit{Modern Greek}, from Constantinople being called \textit{Roma Nova}.

There have been few books written in this language, from the taking of Constantinople by the Turks; scarcely anything but some catechisms, and the like pieces, composed or translated into the vulgar Greek, by the Latin missionaries.

The native Greeks are contented to speak the language without cultivating it; the Turkish policy not allowing any of the subjects of their emirates to apply themselves to the arts and sciences.

GREEK. It is not easy to assign the precise difference between the \textit{vulgar} and the ancient Greek: it consists of the terminations of nouns, pronouns, verbs, and other parts of speech, which make a difference between those two languages much like that observed between some of the dialects of the Italian or Spanish: we inflect in these languages as being the most known; but we might have said the same thing of the Hebrew, Slavonic, &c. dialects. The modern Greek also curtails words, runs them into one another, and adds a fort of elocut 'c particles to the end of them; it confounds the vowels \( \varepsilon , \iota \), and the diphthongs \( \alpha \varepsilon \) and \( \varepsilon \iota \), which they pronounce and often write only \( \iota \). They likewise often confound cafes, moods, tenses, and particles. See Brehmwood's Inquiry concerning the Diversity of Languages, \&c. chap. 2.

Besides, the modern Greek has divers new words not in the ancient; particularly several participles which appear as expletives, and which are introduced to characterize certain tenses of verbs, and other expressions, which would have had the same meaning without such particles, had custom dispensed with them; divers names of dignities and offices unknown to the ancient Greeks; and abundance of words borrowed from the vulgar tongues of the neighbouring nations.

Accordingly one may distinguish three ages of the Greek tongue: the first ends at the time when Constantinople became the capital of the Roman empire; not but there were several books, especially of the fathers of the church, written with great purity after that time; but as religion, law, and policy both civil and military, began then to introduce new words into the language, it seems necessary to begin the second age of the Greek tongue from that epoch, which lasted to the taking of Constantinople by the Turks, when the last age commences.

GREEN, in \textit{Biography}, an organ-builder, on the model of Sancta, whom he succeeded, and has left behind him monuments of his skill and ingenuity in many of our churches and manorid of the nobility and gentry. To this modest and ingenious man, ever ready to adopt any hint tending to the perfection of his art, we are indebted for the improvement of the mechanism of the most noble and comprehensive of all instruments, having eafed the touch, voiced the pipe, and contrived a foot of the whole instrument, in a manner superior to any of his predecessors. He died when scarcely arrived at the middle of the period of mortal life.

GREEN, \textit{Matthew}, was born, probably in London, about the year 1696. He was educated among the diversers, and his learning extended to the knowledge of a little Latin. At this period, those who differed from the established church were rigid in their principles and gloomy in their manners. He appears to have been, on this account, dif-
gulled with those who were the associates of his youth, and to have completely abandoned the party. He speculated freely on religious subjects, and length adopted the system of outward compliance with established forms. At one time he appeared to be ready to join the quakers, but something occurred which prevented him from making an outward profession of their principles. His circumstances were very narrow, but he was fortunate enough to obtain a place of some trucl in the Custom house. He died at the age of forty-one, in the year 1735. His disposition was remarkably mild, and his conversation abounded with wit. He was subject to low spirits: as a cure for this, he composed the work by which, as an author, he is principally known, "The Spleen." This poem presents a picture of his mind and manners, which implies a practical philosophy of the sober and rational Epicurean call. The other works of Mr. Green consist of "The Grotto;" "Verdes on Bar- chay's Apology;" "The Seeker;" and some smaller pieces. In manner and subject," says the critic, "they are some of the most original pieces in the language: they rank among the easy and familiar, but are replete with uncommon thoughts, new and striking images of remote ideas by some unexpected latitude, in which wit principally confils. For poems which bear more repeated perusals; and with those which, full utter them, they do not fail to become favourites." Gen. B. G. E.

GREEN, one of the original colours of the rays of light. Grafs and herbs, and even all vegetables in places exposed to the open air, are green; and those in subterraneous places, or places inaccessible to the air, white and yellow. Thus when wheat or the like germinates under-ground it is white or yellow; and when it is in the open air, green; though this too is yellow before it be green.

GREENS, Artificial, are very rarely simple colours, but produced by mixture of yellow and blue.

Two powders, the one blue, and the other yellow, well mixed, appear perfectly green; though, when viewed with a microscope, we observe a chequer of blue and yellow.

The tincture of red roses with oil of tartar per deliquum, or with spirit of sul ammonia, produces green. The tincture of many red flowers is changed into green by an alkali. The tincture of red roses, and the yellow tincture of crocus, or the blue tincture of cyamus, and the white spirit of sul ammonia, produce green. The formation of verdigris becomes colourless by the affinity of the spirit of nitre, and by the affinity of the oil of tartar it becomes green again.

As no vegetable has yet been discovered, which is capable of giving to cloth of any kind a permanent green colour, the dye for this purpose is a compound colour, formed in dye-vats either by putting a yellow on a blue ground, or a blue on the yellow ground, or by mixing the blue and yellow materials, and dyeing with them as with a simple colour. The common and most permanent green is given to woollen cloth in the following manner. The cloth, being first dyed blue in the indigo vat (see Indigo), is then well scoured, and afterwards dyed in a bath of weld or any other yellow dye with alum and tartar, as in the mode of dyeing of simple yellows, except that the yellow materials are used in greater quantity than the yellow alone of equal body would require. Very deep greens are made to acquire a light brown or kind of burnish by adding to the bath small quantities of logwood and sulphat of iron. As for flax, they are first strongly scoured, then dyed yellow with weld, and afterwards mixed in the indigo vat. Silk, cotton, and linen are dyed green in the same general mode, but with considerable variations in the different processes. The most beautiful green hitherto known, and which perfectly well reлитs the action of light and air, is given by the composition of Prussian blue and yellow, but this colour is destroyed by soap and alkalies. To cotton this colour is given, by first treating it olive with weld, or any other yellow dye, and a compound mordant of alum and iron, and then raising the green by prussic acid. (See Prussian blue.) But all these works, that in the proews for this purpose there seems to be a mutual distribution of the mordants and colours, the Prussian colour taking the iron and becoming blue, whilst the alum and weld remaining in the olive form a faf yellow, and unite with the blue into a fine green.

The only simple green in common use is that of the carbamati oxide of copper precipitated from verdigris by an alkali. A solution of verdigris is made in vinegar, and a few hours before dyeing a solution of as much pears as verdigris is added to it, the mixture is heated, and the cotton, previously emulced, is passed through this bath. The colour then given is a soft apple-green. Aikin's Dict.

The dyers make divers shades, or calls of green, as light green, yellow green, grofs green, laurel green, sea green, dark green, parrot green, and columb green.

GREEN, Brunswick, is a pigment used by some of the German artists, which they prepare by adding to the folution of one part of muriated ammonia in cold water, three parts of copper chippings; and by covering the glads vessel that contains it with gaude fo as to keep out the duf, and placing it in a warm situation, so that the moisture may evaporate, which purpose will be effected in a few days. The muriated of ammonia foam begins to be decomposed by the copper, which is corroded and converted into a green oxysi. When the whole is evaporated to dryness, let it be digested in two or three successive portions of spirit of wine, as long as any green oxysi is taken up; then add the solutions together and expel the liquor by a gentle heat, the residue is a pure dark green sub-mariat of copper, known in the shops by the name of refined Brunswick green.

GREEN, Mountain, or Hungary green, is a fort of greenh powder found in little grains, like sand, among the mountains of Kermanent in Hungary, and thole of Moldavis. Though some hold, that this mountain green is fictitious, and the fame with that the ancients called fit utris, prepared by calling water, or rather wine, upon copper red-hot in the furnace, and catching the flames thereof on copper plates laid over for that purpose: or by dissolving copperplates in wine, much in making verdigris. The painters make use of this colour for grafs green. It is sometimes counterfeited by grading verdigris with ceruff.

GREEN, Cokined, and plain green. See Verdigris.

GREEN, Prussian. See the proews for making Prussian blue.

GREEN, Sup. See colours from Fruits, Buckthorn, and Sap-green.

GREEN, Saxan, an extremely beautiful green colour, so called because the blue part is given by the Saxan blue or sulphat of indigo; the proews of dyeing which is this; the cloth or silk is first to be dyed a Saxan blue, in the following manner. Having ground nine parts of indigo with twenty of red arceo into a fine powder, add forty-eight parts of strong spirit of vitriol; which mixture swells, grows hot, and emits a sulphurous smell. After standing in a moderate warmth of twenty-four hours, pour off the liquid part, which will be of an extremely deep blue. A small quantity of this liquor, drop into hot water, instantly spreads, tinges it of a fine light blue, and fits it for dyeing.
the prepared wood, cloth, or silk; and by increasing or diminishing the proportion of the blue composition, the colour may be rendered deeper or lighter. This, Dr. Lewis says, is the method used for preparing the blue composition by the dyers of Norwich, who purchased this secret from Saxony.

The cloth or silk, thus dyed blue, is next anamed, and then dipped in the yellow decoction of weld or suffolk, and the desired colour will be obtained.

Suffolk is commonly preferred as the yellow material, because it is less liable to be altered by the adhering acid of the sulphate of indigo than weld or the other yellows. To correct this effect of the acid, and enable quercetron to equal the Suffolk in this respect, (whilst its natural colour much exceeds it,) Dr. Bancroft advises, after the cloth has received the blue, to mix with the alum mordant, in order to neutralize the adhering acid, before the yellow is given.

For the fulling it may be dyed green at one operation, by boiling it for a little time in a mixture of the blue and yellow liquors. For this purpose the cloth is first anamed and well rinsed; and the cloth is then dyed in a strong decoction of fulling, to which, when cooled to a blood heat, is added sulphate of indigo. Dr. Bancroft recommends for dyeing a beautiful Saxon green, the following expediency proceeds, by using the compound alum and tin mordant; put into the boiler six or eight pounds of quercetron bark to every one hundred pounds of cloth boil with a sufficient quantity of water; then add six pounds of the nitro-sulphate of tin, (in preference to the nitro-muriate,) and four pounds of alum; when these have boiled five or six minutes, lower the heat with cold water to blood-warm, after which, add as much sulphate of indigo as may be thought necessary for the intended depth of colour, and then dye the cloth in this bath with proper care. Aikin's Dict.

By combining any blue and yellow dyes, in different proportions, all the shades of green may be produced, from the bluish green of the cabbage-leaf to the greenish-yellow of the cabbage-leaf.

GREEN, in Agriculture, a term provincially signifying grass-land, or such as is in the state of turf.

GREEN, in Geography, a county of America, in New York, taken from Ulster and Albany counties, bounded on the N. by Albany and Schoharie, E. by the river Hudson, S. by the county of Ulster, and W. by the county of Delaware; 30 miles in length from E. to W., and from 12 to 20 in breadth. The number of its inhabitants is 15,767, and its chief town is Catskill. — Allo, a county of Pennsylvania, bounded N. by Washington, S. and W. by Virginia, E. by Monongahela river; 33 miles long, and 18 broad. The number of its inhabitants is 865. — Allo, a county of Kentucky, extending from Ohio river on the N. to Tenessee state on the S., and bordering W. on the Mississipi river, and E. upon Hardin and Jeffferson counties. The number of its inhabitants is 6,025, of whom 816 are slaves. — Allo, a county of N. Carolina, in the district of Newbern, containing 4218 inhabitants, of whom 1406 are slaves. — Allo, a town in Kennebec county, and state of Maine, situated on the E. side of Androscoggin river, 164 miles N.E. from Boston; containing 933 inhabitants. — Allo, a post-town in Franklin county, Pennsylvania, situated near the Connequeague creek; 176 miles W. by S. from Philadelphia; containing about 83 houses, 2 German churches, and a Presbyterian church, and 884 inhabitants. — Allo, a township in Franklin county, and also a township in Washington county, in the same state. — Allo, a navigable river of Kentucky, which rises in Mercer county, has a gentle current, generally in a W. direction, and is navigable nearly 150 miles; at its confluence with the Ohio it is upwards of 200 yards wide. — Allo, a small river which rises in the town of Marlborough, in Vermont, and falls into Connecticut river, above Deerfield, in Massachusetts. — Allo, a river of New Brunswick, which runs into the St. John, N. lat. 47° 20', W. long. 67° 38'. — Allo, a river of Canada, which runs into the river St. Lawrence, 166 miles below Quebec.

GREEN Bank, one of the banks near the island of Newfoundland; 129 miles long, and 48 wide. N. lat. 45° 30' to 46° 50'; W. long. 53° 30' to 53° 50'.

GREEN Bay, a bay on the W. side of Lake Michigan, about 50 miles long, and 15, 20, or 30 broad in different parts, lying nearly from N. to S. At its entrance is a string of islands extending N. to S., called the "Grand Traverse." There are about 30 miles in length, and serve to facilitate the passage of canoes, as they afford them a shelter from the winds. The communication between Lake Michigan and the Green bay is sufficiently deep for a vessel of 60 tons, with a proportionable breadth; the land adjoining to the bottom of the bay is very fertile, the country generally level, and the views of it agreeable and extensive. The inhabitants of its coasts call this bay the Menominee bay. N. lat. 45° W. long. 87° 58'. — Allo, a bay on the E. coast of the island of Antigua, S. from Green island.

GREEN Briar, a large and fertile county of Virginia, surrounded by Bath, Randolph, Harrison, Kanawhaw, Botetourt, and Montgomery counties; about one hundred miles long and 45 broad; containing 3304 free inhabitants, and 271 slaves. The chief town is Lewisburg; 163 miles W. of Staunton. — Allo, a river of Virginia, which purifying a S.W. course, runs into the eastern side of the great Kanawhaw. N. lat. 37° 57'; W. long. 89° 58'.

GREEN Bug, in Agriculture, the name of a small insect, which is often found destructive to different plants in both fields and gardens. It also frequently proves destructive to hop crops. It is very difficult to destroy it in many places.

GREEN Chef., in Rural Economy, the name of that sort of chaff which is prepared with some kind of green vegetable juice, as that of cabbage and other similar plants.

GREEN Copperas. See COPPERAS, and Sulphate of Iron.

GREEN Creek, in Geography, a river of Pennsylvania, which runs into the Susquehanna. N. lat. 40° 58'; W. long. 76° 30'.

GREEN Crop, in Agriculture, that sort which is formed of some kind of green vegetable; such as that of some sort of artificial grass, the turnip, cabbage, tare, rape, &c., which are so termed in contradistinction to those of the grain description. The introduction of crops of this nature between those of the grain kind, has constified one of the most important improvements in modern agriculture. By this means, land has not only been prevented from being exhausted and worn out, but brought into the most proper condition for the growth of grain, without undergoing the injurious processes of naked or summer following. It has likewise had the effect of greatly increasing the number, and improving the quantity of all sorts of live stock, in consequence of their having more abundant supplies of food, and these at the same time of better qualities. There can therefore be no doubt of the great advantage of these crops, which should of course be grown as extensively as possible by the farmer, as by them he may be enabled to support much larger stocks of cattle and sheep than could otherwise be the case, and at the same time raise much larger quantities of good manure. See MANURE. Besides, new, great advantages might, in different instances of cattle-farms of the breeding kind, be derived
rived from the more extensive cultivation of such green crops as the winter support of the flock.

And crops of this nature have likewise been found of extensive utility in the breeding of milk-cows in winter dairying, as is fully shown in the various trials made by J. C. Curwen, esq. in a northern district of the kingdom, in the view of supplying the poor of a large town with milk. The value of which crops in this sort of application, on the supposition of their being sold to the cow-keeper, and the expenses of their cultivation, are stated in the following manner.

Green Crops.

Twenty-two acres of green crop, at 10d. per acre

Expenses of raising and cleaning.

Four acres of cabbages, at 12d. per acre

Two acres of Swedish turnips, at 5s. per acre

Six acres of common red turnips, at 4l. per acre

One acre of Kaldrabi

Nine acres of rape or cole, at 3l. per acre

---

118 10 0

Gain on crops £ 101 10 0

It is considered that the improvement of the land, and the value of the succeeding crops, are fully adequate to the rent and taxes.

This statement shews in the most clear point of view the vast benefit of this kind of crops even in this sort of application, and that they should not be disregarded by those engaged in the busines of husbandry. But in some other modes of application they will be found far more important and beneficial.

By some they have also been considered as of great utility when turned into the field by way of a manure, though others are wholly of a different opinion; probably in consequence of the trials having been made in very opposite descriptions of soils, and under very different circumstances of them. It is extremely probable, likewise, that the advantage of this practice will be much greater where the crops are turned in during the summer months than in other cases, in consequence of their running more quickly into the putrefactive state. It has been advised, that whatever may be the nature of the crops, they should be ploughed under by means of a skim-coultor plough, as constituting the only means of turning them in, in so complete a manner as wholly to conceal them. And that, in case of fowling the land with broad cast turnips, the work should be performed at least three weeks before the feed is put into the soil, and that it should be afterwards only very slightly harrowed in. See Turning in Green Crops.

Green Earth, in Mineralogy, Feldspars, Saff.; Chloride of Nitrate, Boiling; Argilla vermiculata, Weirm.; Graméens, Weirm.; Kali chlorate hygrophilus, Haüy; Ferra di Terrone, Ferra di Brenteria, Ita.; Veronef earth, an earthy substance belonging to the argillaceous genus. Its colour is indicated by its name, but there are several shades of it, the principal of which are verdigris, and celadon green, passing sometimes into black and mountain green, frequently with an admixture of grey; it has also been observed of a more or less pure olive green.

**G R E**

It occurs massive and disseminated, in rounded and angular fragments, and in globular concretions; likewise in grains mixed with sand, and as coating onagate balls, in the hollows of amygdaloid, (toad-stone,) &c. Internally it is dull, but on the riffs a fat-like lustre is sometimes observable.

Fracature fine-earthy, or more or less flat conchoidal, approaching to flaky. Divisible into indeterminately angular, blunt-edged, opaque fragments.

It feels rather greasy, is always more or less soft, mild, and easily frangible; streak rather thinning; adhesion to the tongue inconsiderable. Specific gravity about 2 1/2.

The chemical charaters of green-earth, derived from Klaproth's analysis of three varieties, viz. those from Monte Baldo, in the Veronese, from Cyprus, and from East Prussia, are the following:

The green-earth from Monte Baldo, when heated to redness, loses five per cent. of its weight, while its hardness is considerably increased. The fragments thus subjected to the fire become externally of a yellowish-brown colour, internally greyish-black and glintening. That of Cyprus, after ignition, loses eight parts of its weight; and its colour is converted into dirty brownish-yellow. Exposed to the fire of the porcelain furnace in the charcoal crucible, it fuses to a somewhat porous greenish glafs, externally of a dirty-green colour, internally of that of emerald; in the clay crucible it is converted into a greenish-grey flag. The green-earth of New East Prussia, when freed from the admixed sand by elution, and ignited, changes its green colour into light leather-brown; the conglomerated particles are converted into a hard mass, and thus lose nine per cent. of their weight. The acids do not act upon green-earth, and they leave its colour unaltered.

The results of the analyses of the above three varieties were:

Ibid. 100

The Prussian green-earth, by thus differing from the two others, particularly with regard to the alumina as a constituent part, appears to approach the nature of chlorite.

Green-earth occurs principally in amygdaloid, also as incrustation on the nodules of zeolite, &c. contained in the cavities; sometimes as coating the sides of these cavities, which are often partly filled with the earth. It is also, though less frequently, found in porphyry and basalt, as nodules in the newer sandstone, and even in the rocks belonging to the new flint-strap-formation, such as at Afshin in
in Bohemia, where calcareous tuff is seen alternating with narrow layers of a conglomerate, made up of grains of calcarceous spar, and blunt-edged fragments of the tuff to which the green earth serves as the cementing substance. But in the same place green-earth forms a flat-tz-layer of a foot in thickness, whose base consists of wacke-like clay and calcareous tuff; the roof of indurated marl. The green-earth of New East Prussia, consisting of earthy particles, mixed with a coarse sand, forms a considerable bed in the neighbourhood of the river Memel, between Loffofna and Sallowraye.

Among the localities, besides those of Monte Baldo in the Veronese, Cyprus, Prussia, and Bohemia, already pointed out, the following may be mentioned: Altenburg, and Planitz, in Saxony; Oberklein, in the Palatinate; Koenigstein, in Hungary; Pontauensiper, in Normandy; Scotland, Iceland, the Ferro-islands, and wherever true amygdaloid occurs.

This earth is used as a pigment, particularly for water-colour painting, and being very durable, and not too expensive, alo for house painting, &c.

The green-earth of Cyprus, according to Mariti, is sold at 4½ piasters for a measure of 100 cakes. It is carried from the pit in large baskets made of the palm-tree; three of these baskets generally contain the above mentioned quantity. A great deal was exported to Holland; often by way of ballast.

That of Bohemia, above mentioned, is sold, according as its colour is deeper and its grain finer, from two to four florins the cwt. Part of it is also burnt there in small kilns, and sold as a red pigment.

By the Italians green earth is called Verde di Brentonico, from the vicinity of Monte Balca to a place of that name.

Green fellow, in Agriculture, a term often applied to such arable land as is rendered clean and free from weeds, by means of green crops, without having recourse to the processes of naked or summer following. This constitutes one of the numerous improvements in modern husbandry. See FALLOWING OF LAND.

Green Finch, in Ornithology. See Loxia Chloris. See also Tanaagra Greaca, and Fringilla Lutyracea.

Green Fish. See Cod-Fishery.

Green Food, in Agriculture, that part of food which is employed in its green or succulent condition, in the feeding, foddering, and supporting of various kinds of live stock. This is a part of food that has, within these late years, been much more extensively employed than was formerly the case; yet its advantages are probably in general not so fully understood as they ought to be. Its importance and utility will, however, soon appear by the making of a few experiments in a proper manner.

Green Glass. See Glass.

Green Hare, or green-hog, in our Old Writers, the same with wart in foresets, &c.

Green Hides, are those not yet tanned, or dressed, but such as are taken off from the carcases. See Hide and CURVING.

Green Iron Earth. See Irox.

Green Island, in Geography, a small island among the Philippines, near the S. coast of the island of St. Lucia. N. lat. 13° 30'. E. long. 121° 2'.—Alfo, a small island in the East Indian Sea. S. lat. 6° 5'. E. long. 123° 30'.

Alfo, one of the smaller Bahama islands. N. lat. 21° 48'. W. long. 71. 5.—Alfo, one of the lefier Virgin islands, called Likewise "Serpent island," situated near the E. end of Porto Rico.—Alfo, a low woody island near the N. E. coast of New Holland; 12 miles E.N.E. of Cape Grattan. S. lat. 16° 48'. W. long. 214° 5'.—Alfo, an island in Hud-
This rock, with a view to the periods of its formation, is divided into primitive, transitory, and flint green-flone.

The primitive green-flone is generally distinguishable from the others by its highly crystalline structure. The hornblende, in which a tendency to crystallization is almost always observable, generally constitutes the predominant ingredient; but sometimes this is only apparently so, the feldspar being not seldom hidden by it in such a manner, that it bears the greatest resemblance to small laminae of hornblende. In this case the blow-pipe discloses the illusion by melting the hornblende; when the feldspar recovers its usual whitish colour, and is converted into a white glass.

Werner subdivides primitive green-flone into four varieties:
1. Common green-flone, in which the two ingredients, mixed in different proportions, form a granular mass.  
2. Porphyritic green-flone, being the common variety, including large crystals of feldspar.  
3. Green-flone porphyry, in which the granular basis, which is with difficulty distinguishable, includes crystals of feldspar.  
4. Green porphyry, in which the granular nature of the basis is no longer visible to the naked eye; it appears uniform and simple, with a blackish green or phænacol green colour, and includes crystals of compact feldspar. (Jamefon.)

There are to be referred the porfido nero, and porfido verde antico of Italian antiquaries, of which we shall say more hereafter. The third and fourth of these varieties might, we think, be safely united; at least the definition given of them does not indicate any difference, except in the shade of green.

This old green-flone appears sometimes stratified. Gneifs is the rock in which the different varieties first appear; the next rock in which they occur is mica-flate, but the beds of green-flone in either of them are scanty and inconsiderable; they are observed more numerous and of greater extent in clay flate in Scotland. According to Mr. Jamefon, the clay-flate and mica-flate, that form a great portion of the country extending from Loch Lomond, by Callander, Comrie, and Dunkeld, contain numerous beds of green-flone; and there, we are informed by this geognosian, as in all other countries, the clay flate contains more numerous and larger beds than the mica flate.

There is a vast number of varieties of primitive green-flone in Bohemia; but it is found in the Saxony district of that country, where it yields chiefly on green-flone. It occurs there also with quartz as a constituent part. The varieties mentioned by Reufc, as being found there within a narrow compass, are:
1. A small mixed grained mixture of velvet black hornblende, which exhibits a tendency to a prismatic crystalline form, with yellowish white feldspar, and greenish-white and smoke grey quartz. The hornblende is the predominant part; the quartz is here and there entirely wanting; the mixture pretty uniformly granular.
2. A variety in which the hornblende is seen in groups, distinct from those of the feldspar and quartz; so that the whole forms an interlacing of black and yellowish-white spots.
3. A variety in which the hornblende is so prevalent, that feldspar and quartz can with difficulty be distinguished by the examining glasses, which discovers these ingredients collected into small spots and flrips; it contains also here and there some sheets of mica.
4. Var. in which the hornblende is seen partly massive, in spots, flrips uniformly blended with the feldspar and quartz; partly in small circular crystals; they are divergingly aggregated, or crofs each other in all directions; feldspar tile and brownish feldspar; quartz only here and there in smoke grey grains.
5. Var. in which the hornblende shows a strong tendency to crystallization, and is much accumulated in some places; though, generally speaking, its proportion to the mixture of yellowish-white and reddish-grey feldspar and greyish-white quartz, is but small; it contains larger and more numerous flakes of silverly and yellowish-white mica. 6. Var. in which the texture becomes more thick-flaky; the smoke-grey quartz becomes predominant, the yellowish-white feldspar disappears almost entirely, and the hornblende is only thickly differentiated.
7. Var. in which the yellowish-white and reddish-grey feldspar predominates over the hornblende, which is seen partly massive and in fine granular concretions, partly in inflated and dispersed minute fix-seeded prisms, imbedded in the feldspar; while the quartz is entirely wanting. It is remarkable that in this district the primitive green-flone is seen, by flow gradation, to pass over into perfect gneifs. The more it approaches the latter, the more the granular texture becomes indistinct; the rock adopts a thick flaty texture, the hornblende is seen more and more to diminsh, while the mica increases both in quantity and size, until perfect gneifs stands confounded as the constituent rock.

This rock is common also in many other parts of Europe; but the accounts we possess of the green-flone of several countries is too imperfect to enable us to determine how much of it may be considerd primitive.

The transition green-flone is not easily distinguishable in specimens. It is characterized by Mr. Jamefon as being "a fine granular mixture of hornblende and feldspar; and sometimes the mixture is so intimate, that the constituent parts are not to be distinguished. Quartz sometimes traverses it in the form of veins, or is disseminated through it; a character which distinguishes it from flint green-flone, which rarely contains quartz. Sometimes it occurs in globular distinct concretions, and these again consist of curved lamellar concretions, forming the globular rock (kugelfels) of Voigland. Sometimes it is penetrated with reddish brown oxide of iron, which, combined with the dark-brown hornblende, gives the rock a liver-brown colour; hence it is denominated in Voigland, where it occurs, leber-fels, or liver rock. Beds of it occur in the upper part of Dunfrieshire, in the Hartz, Bohemia, &c."

Flake-green-flone. Prof. Jamefon, in his "Mineralogical Description of Dunfrieshire," has given a short account of the occurrence of green-flone in the independent coal-formations, and Mr. Filif has discovered beds of amygdaloid in the first or oldest flint-lime-flone; whereas the former author concedes himself entitled to introduce what he terms the flake-trap, which is distinct from the flint newer formation called the new float-trap by Werner. In the independent coal formation it occurs in beds from one foot to many fathoms in thickness; it contains imbedded olivine and augite, and is traversed by numerous veins of calc-fspar; it often also contains fussy cavities, which are lined with calc-fspar, quartz, barites, cubicite and prismatic; and the cavities are sometimes filled with water.

The green-flone of Werner's new float-trap formation is, upon the whole, distinguishable from the older formation, by its structure being of a less crystalline appearance, and by its distinct concretions approaching more to the coarse granular. Its colour usually inclines more or less to green. Certain varieties are reddish, and these are denominated sementic green-flone. When fresh and rather large granular, it usually exhibits a simple structure; when, on the contrary, it is disintegrated, and smaller granular, it occurs in globular, and there again in curved lamellar distinct concretions. Certain varieties approach to wacke, and these are usually vesicular, and form a kind of amygdaloid. It is sometimes very distinctly stratified, and frequently occurs in veins." Jamefon.

The use to which the common green-flone is applied are not
as a manifold. As it frequently contains a considerable portion of iron, and is sufficiently fusible, it serves for a flux in the iron work in Smolend. Of the porphyritic varieties of the primitive green-flone used for ornament, the following deserve to be mentioned:

Antique black porphyry (porfido nero antico). There are two or three varieties differing, with regard to the intensity of the colour, from greenish-black to brown-black; and likewise with regard to the size of the whitish feldspar-crytals: in one of them the crytals are very finely, and this is more frequently seen among the remains of antiquity than the others.

Mr. Graaf in his Miraculi of Allace, mentions a black porphyry as occurring at Pontmont; and also as rounded blocks in the river Ill.

In the black Corian porphyry, the feldspar-crytals have a slight tint of green, like those of the antique green porphyry. Similar to a Laridian black porphyry, and Sardinian of one found in the neighbourhood of Ceres, which, besides small prismatic crytals of feldspar, includes rounded grains of transparent colourless quartz. The latter addition is likewise observed in a variety of a blackish Sardinian porphyry, which is sometimes wrought for ornamental purposes.

Antique green porphyry (porfido verde antico). This is the ophite of the ancients; a name derived from some supposed resemblance of this rock, when polished, to the skin of a serpent; whence, in modern times, antiquaries have referred the porphyry in question to the magnumian stone called serpentine, a mixture of which, with primitive lime-flone, constitutes the rock called verde antico. When once considered as the same with the real serpentine, the name verde antico, of course, also was equally applied to the green porphyry; a circumstance which has been productive of great confusion. There are now few monuments of ancient art executed in this porphyry to be met with.

There are some varieties of green porphyry, much resembling the antique, still found in several parts of Europe. There is a quarry of it on Monte Vito, in Piedmont; which, besides the feldspar, contains reddish grains, supposed to be garnets.

The green Corian porphyry, found in the district of Niotto, in Coriana, has a deep bottle-green base, and fine white feldspar crytals another, which contains some dark red garnets, occurs in the district of Golfo in the same island.

Sardisia describes the green porphyry of Gavone, resembling the black porphyry above-mentioned, in the figure and colour of the feldspar and quartz, but differing in its base, which is light green and, in fragments, transluèd at the edges. Both this and the black take an excellent polish.

The green porphyry of the Pdfes has a dark green base, and contains numerous middle-sized feldspar-crytals of a pale green colour. It is found at La Chevetray, on the heights of Frede and Comte, and made use of for ornamental purposes. In another variety, found not far from this quarry, the feldspar-crytals are so preished against each other, that they are ill-formed, and conceal almost the whole of the base. They are manufactured into slabs for tables, chimney-pieces, &c. and sometimes past by the improper name of green granites.

There is abundance of the green porphyry in the Pyrenees, where it is known by the old appellation of ophite.

Green-flone base, a compound rock, which may be considered as a variety of the preceding, from which it differs in having a distinct flat structure: the feldspar, moreover, being generally more abundant than the hornblende. It ranks with the primitive trap, but, not occurring in rocks older than clay-flone, is considered as the newest of the first classes of the trap formation. It occurs in considerable beds, and in Sweden whole mountains are said to consist of it. Several mining districts are situated in this rock, such as those of Gerzold, in Saxony, of Radolfza, in Silesia, and of Adelfors, in Sweden.

Green Sward, in Agriculture, a name applied to the gras, turf, or sward, by which land is covered while in the state of pasture or under the scythe. Such land as has been long in this state, is most uniformly covered with a close compact sward; while in the contrary case, it is moity light, open, and thin. See Sward.

Green Turtle Bay, in Geography, a small island among the Bahamas. N. lat. 26° 40'. W. long. 77° 59'.

Green Weal is used where effluents are delivered to the fluence out of the exchequer, under the seal of that court, made in green wax, to be leaved in the several counties.

Green Weed. See Broom.

Green Winter. See Winter Green.

GREENAE, in Geography, a town of Denmark, in North Jutland, 28 miles N. E. of Aarhus.

GREENBURGH, a township of Well Cheller, in the slate of New York, containing 1581 inhabitants.

GREENBUSH, a township of Renifable county, New York, containing 3472 inhabitants.

GREENCLOTH, a board, or court of justice, held in the compting-house of the king's household, for the taking cognizance of all matters of government and justice within the king's court royal; and for correcting all the servants therein, that shall any way offend.

To this court also belonged the authority of maintaining the peace for twelve miles round the king's court, wherever it shall be, excepting at London.

The judge of this court was the lord reward, assisted by the treasurer, comptroller, coffler, clerks of the green-cloth, &c. It took its name, greencloth, from a greencloth spread over the board where they sat, whereas were the arms of the compting-house. The clerks of this court were officers who attended there, and had businesses assigned them by the board. All bills of comptrolments, relating to the office, were summed up, and allowed by the clerks comptrollers, and audited by the clerks of the green-cloth. They also appointed the king's, queen's, and household's diet, and kept all records, registers, and papers, relating thereto; made up bills, parcell, and debentures for salaries, &c. and provisions and necessaries for the officers of the pantry, burley, cellar, &c. They also waited upon foreign princes, when entertained by his majesty. This court has been abolished.

GREENE, MAURICE, Dr. in Biography, was the son of the Rev. Thomas Greene, vicar of St. Olave Jeney, in London, and nephew of John Greene, serjeant at law. He was brought up in the choir of St. Paul, and when his voice broke was bound apprentice to Brind, the organist of that cathedral. He was early noticed as an elegant organ player, and was appointed organist for the church, and obtained the place of organist of St. Dunstan in the Weil, before he was twenty years of age. In 1717, on the death of Daniel Pocock, he was likewise elected organist of St. Andrew's, Holborn; but the next year, his master Brind dying, Greene was appointed his successor by the dean and chapter of St. Paul's; upon which event, he quitted both the places he had previously obtained. In 1726, on the death of Dr. Crofts, he was appointed organist and composer to the Chapel Royal; and on the death of Exceis, 1735, master of his majesty's band. In 1730, he obtained the
the degree of doctor in music at Cambridge, and was appointed public music professor in the same university, in the room of Dr. Tudway. Greene was an intelligent man, a constant attendant at the opera, and an acute observer of the improvements in composition and performance, which Handel and the Italian fingers employed in his dramas, had introduced into this country. His melody is therefore more elegant, and harmony more pure, than those of his predecessors, though less nervous and original. Greene had the misfortune to live in the age and neighbourhood of a musical giant, with whom he was utterly unable to contend, but by cabal and alliance with his enemies. Handel was but too prone to treat inferior artists with contempt; what provocation he had received from Greene, after their first acquaintance, when our countryman had a due sense of his great powers, we know not; but for many years of his life, he never spoke of him without some injurious epithet. Greene's figure was below the common size, and he had the misfortune to be very much deformed; yet his address and exterior manners were those of a man of the world, mild, attentive, and well-bred. History has little to do with the infirmities of artists; who being men, in spite of uncommon gifts and inspirations, are subject to human frailties, which enthrall, proufe, and the love of fame, more frequently augment than diminish.

Greene had the honour, early in life, to teach the duchess of Newcastle, which, joined to his professional merit, and the propriety of his conduct, was the foundation of his favour with the prime minister, and the notice of the first people about the court. In 1730, when the duke of Newcastle was installed chancellor of the university of Cambridge, he was appointed to the ode, and then not only obtained his doctor's degree, but, on the death of Dr. Tudway, he was honoured with the title of professor of music in that university. As an exercise for his degree, he set Pope's ode for St. Cecilia's day; having first had interest sufficient to prevail on the author to make new arrangements in the poem to render it more fit for music, and even to add an entire new flanza, between the second and third, which had never appeared in any of the printed editions.

Greene had sense and knowledge sufficient, in his younger days, to value and respect the abilities of the two great musical champions, Handel and Bononcini, whose diffident talents occasioned as much discouragement in the capital as the factions of Whig and Tory. At the same time: as he was impressed with the highest reverence for Handel's great style of playing the organ, and the force of his geniuses for composition, he could not help listening with pleasure to Bononcini's performance on the violoncello, and to the grace and good taste of many of his opera songs; at which, perhaps, Handel took umbrage—for during these feuds, he broke off his acquaintance, and ever afterwards, regarding him as an enemy, never mentioned his name but with contempt. This treatment naturally rendered Greene a partisan on the side of Bononcini, and in 1728 he defended him, as long as he was able, from the charge of plagiarism, with respect to a cantata which had been introduced at the academy of ancient music as Bononcini's, and which was afterwards discovered to be the composition of Lotti, at Venice. See Bononcini.

Greene's merit and connections were such, that he soon arrived at the most honourable appointments in his profession; for besides being organist of St. Paul's, in 1727, on the death of Dr. Croft, he was appointed organist and composer to the Chapel Royal; and in 1735 he succeeded Eccles as composer to his majesty, and master of his band, in which station he held all the offices of the laureate, Colley Cibber, as long as he lived.

The compositions of Dr. Greene were very numerous, particularly for the church. Early in his career he set a Te Deum, and part of the Song of Deborah, which were never printed; but the anthems and services which he produced for St. Paul's and the King's Chapel, he collected and published in two vols. folio; and of these the merit is so various as to leave them open to much discrimination and fair criticism. Among the faults to be ascribed to this composer, none are so flagrant as the light divisions in which his solo anthems abound, and the repetition of passages a note higher or a note lower in what the Italians call ripieno, which are always dull, tiresome, and indications of a florid fancy. The opening of his second solo anthem, vol. 1. p. 26, is very solemn and pathetic, and the organ part judicious and pleasing; but, page 45, Santa Regina tells her bed six times, while one very short passage is finging. "Lord how long wilt thou be angry," alla Poldiriana, for five voices, though none of the subjects are new, seems to us the best full anthem of his composition. The style is clear, the answers are regular, and the modulation such as discovers a familiar acquaintance with the best ancient writers for the church. Of the full anthem; "O sing unto the Lord," for five voices, the fugue in the first movement is well worked, and has a good effect in performance; but the rest of the anthem is not equal in its subjects, or their treatment. "Lord how are they increased that trouble me," seems one of the most pleasing of Dr. Greene's solo anthems. The last anthem in the first volume, for two voices, has many pleasing passages, and rather more variety of subject than most of the others.

The first movement in the second volume seems calculated to display, in the performers, the power of making a shake upon short notice. A shake, judiciously applied, is a brilliant embellishment in a finger; but when lavished, improperly, is pert and unmeaning; nor is it ever more to than upon the first note of a movement. There are not fewer than seventeen or eighteen shakes distributed among the performers in the course of one page, which are more than in modern opera fings of judgment, told; and expression, would use in a month, were his shake ever to good; the rest of the anthem is on common subjects, which are commonly treated.

The two-part anthem, "Thou, O God, art praised," has repeatedly a passage on the word praised, which has to our ear the disagreeable effect of two fifths; and there is a point at "unto thee shall my voice be performed," for which he was manifestly obliged to the second movement of Handel's fourth organ concerto. The rest of the anthem consists of agreeable passages of the times, but nothing like originality appears in any one idea.

"The King shall rejoice," for three voices, is agreeable commonplace. Perhaps that is hardly enough to say of the second movement: "O Lord grant me a long life." "Let my complaint," a full anthem, is very solemn and solid composition.

The anthem for Christmas day has an air of cheerfulness, suitable to the occasion, which runs through the whole composition. "Hear my prayer, O God," has more merit of gravity and expression than most of the anthems in this volume. "O sing unto God," is agreeable music, but too secular in its melody, and return to the subject; "Have mercy upon me;" the two first movements of this anthem

Vol. XVI.
are sober and affecting; but the second and third have too many vulgar and worn-out divisions; the last chorus, however, is more ecclesiastical, and less common in melody and modulation. The solo anthem; "Hear, O Lord," for a bafe voice, is grave and pathetic, on the model of Handel's bel canto oratorio song. The name may be said of the next, for two voices; "I will seek unto God." "O God of my righteousness(; is superior in the dext movement, joined vere, and chorus, to any thing in the preceding part of this volume; this anthem rimes somewhat above mediocrity. "O give thanks," is wholly written with Corelli's and Handel's materials, though somewhat differently disposed; particularly page 85, where the whole harmony moves together, one note lower, their time, after a crockett left, to this base; E, D, G, E, D, A, G, C. "The Lord is my shepherd," has too many light song-passages in it, notwithstanding the white and squire notes which give it a venerable look on paper. "O how amiable are thy dwellings," is a very agreeable anthem, though the passages were not new at the time it was composed. The movement with an organ accompaniment, in the anthem; "My soul truly waiteth," is well conducted, and not common; the rest of the anthem has merit, particularly the chorus of the last movement. "The Lord, even the most mighty God," for a bafe voice, is set with great gravity and propriety; few anthems, indeed, for that species of voice, are more agreeable; the points, however, in the chorus, are very common. The anthem in eight parts, a due cori: "How long wilt thou forget me," is very well written, a capella, and good music. Indeed, the first movement of this anthem manifests greater abilities than any of his productions that we have seen, who is in general very correct in his harmony, but as to invention and design, he seldom soars above mediocrity. "O Lord give thine ear unto my prayer," for two voices, is very pleasing music, particularly the first movement. The last anthem of this volume is made up of common play-oue passages; the first movement is heavy and monotonous; the audite tiresome, by the repetitions of an old harpichord-lellon passage in the base; the chorus justifies Mr.Mahon's cenure of the author, (colected of the words of anthems) for his too long and frequent divisions; these are too vulgar and rietous for the church, and, indeed, would have no merit of novelty any where. The voices, page 151, upon which the last chorus is built, has more of the dancing minuet, or Vauxhall song, in it, than belong to that species of gravity and dignity which befits devotion. We think we could neither play nor hear this movement in a church, without feeling ashamed of its impropriety.

There is considerable merit of various kinds in the Collection of Catches, Canons, and two-part Songs, published by Dr. Greene; the composition is clear, correct, and masterly; the melodies, for the times when they were produced, are elegant, and designs intelligent and ingenious. It was facetiously said, during the life of this composer, that his peculiar music fault of the church, and his anthems of the theatre. The truth is, he produced but little peculiar music. His song of "Go rofe," was long in general favour, and some of his easy ballads, as "Buffy, curious, thirsty fly;" "Dear Chloe while thus beyond measure," &c. were the delight of ballad-singers fifty years ago. The collection of harpichord students, which he published late in his life, though they discovered no great powers of invention, or hand, had its day of favour, as a boarding-school book; for being neither to elaborate as those of Handel, nor so difficult as the lefions of Scarlatti, or the lessons of Albri, they gave but little trouble, either to the master or scholar. Indeed, as all the passages are so familiar and temporary, they seem to have been occasionally produced for idle pupils at different times, with whom facility was the first recommendation.

Dr. Greene, during the last years of his life, began to collect the services and anthems of our old church composers, from the single parts used in the several cathedrals of the kingdom, in order to correct and publish them in score; a plan which he did not live to accomplish; but bequeathing his papers to Dr. Day, it was afterwards executed in a very splendid and ample manner. Dr. Greene died in 1755, and was succeeded, as composer to the Chapel Royal and master of his majesty's band, by his worthy pupil, Dr. Day.

GREENE, in Geography, a county of Washington district in Tenefee, containing 7610 inhabitants, of whom 471 are slaves. Greeneville college has been established by law in this county. (See GREENVILLE.) — Also, a county in the upper district of Georgia, bounded W. by the upper part of Ocmee river, E. by Wilkes county, and S. by that of Washington, containing 10761 inhabitants, including 3647 slaves. The chief town is Greenborough — Also, a county in the state of Ohio, bounded N. on the Indian ocean, S. on Rofs and Warren, E. on Rof and Franklin, and W. on Montgomery county. Its extent from N. to S. is 58, and from E. to W. 21 miles. By the census of 1803 it contains 446 white males of 21 years and upwards.— Also, a township in Chenango county, New York, on the E. side of Chenango river, containing 655 inhabitants.

GREENFIELD, a handsome flourishing poft-town in Hampshire county, Massachusetts, about 104 miles W. by N. from Boston. This township lies on the W. banks of the Connecticut river; it was incorporated in 1753, and contains 1254 inhabitants — Also, a post-town in Saratoga county, New York, containing 3673 inhabitants. — Also, a town in Hillsborough county, New Hampshire, containing 934 inhabitants.

GREENHILL, John, in Biography, a painter of much promise, but whose disolute morals cut short his thread of life, at the early age of 20. He was born at Salisbury in 1649, and became a pupil of Leiby, whose manner of course he imitated, and with much success.

GREENHOUSE, in Gardening, a house of shelter in a garden; contrived for preserving the more tender and curious exotic plants, which will not bear the winter's cold abroad in our climate. Greenhouses, as they are now built, serve not only as conservatories, but likewise as ornaments of gardens; being usually large and beautiful structures, in form of galleries, wherein the plants are handomely ranged in cases for the purpose.

The greenhouse is a sort of building, framed and covered with glazed frames, designed for the purpose of preserving various sorts of exotic shrubs, &c. through the winter season; the aid of artificial heat is not here necessary, except in very intense cold weather. It is advisable, in constructing such houses, to erect flats to life occasionally, which may prove irrevocable, not only in severe frosts, but also in mild foggy weather, where a moderate fire will now and then dry up the damps, which would otherwise prove pernicious to many of the tender kinds of plants.

It differs from the conservatory chiefly in this circumstance, that the plants, trees, or shrubs, are in pots or tubs, and placed upon stands, frameworks, ftrasses, during the winter, to be removed to proper situations in the open air, in the hot summer season; while in that there are built, borders,
diers, and clumps, laid out in the ground plan, and made up with the hell earthy materials, to the depth of three or four feet, in which the shrubs, trees, &c. are regularly planted; the whole of the roof being removed during the summer to admit fresh air, and replaced on the approach of the autumn, to remain until the following summer renders it unnecessary.

The green-houses are at present mostly contrived to stand in the pleasure-ground, near to the house, if possible. They should be upon a somewhat elevated spot, full to the south, and where the sun has access from its rising to its setting: these buildings are commonly of brick or stone, having the fronts and tops almost wholly of glass-work; and ranging lengthways east and west. They are generally constructed upon some ornamental plan. As to the general dimensions in respect to length, width, and height, they may be from ten to fifty feet, or more in length, according to the number of plants to be contained; and in width, from ten to fifteen to twenty feet; but for middling-houses, fifteen or eighteen feet is a sufficient width; and in height in the clear, nearly in proportion to the width.

The walls on the backs and ends, particularly the former, should be carried up two bricks thick; and if more than fifteen feet high, two bricks and a half thick; at one end of the back wall on the outside, it is eligible to erect a furnace for burning fires occasionally, communicating with flues within, ranging in two or three regions along the back wall, having one flue running along the front and end walls, raised wholly above the floor of the house.

The fronts of the buildings should have as much glass as possible, and wide glass doors should be made in the middle, both for ornament and entrance, and for moving in and out the plants. It would also be convenient to have a smaller entrance door at one end; the width of the windows for the glass sash may be five or six feet; and the piers between the sashes may be either of timber, fixed, the, or ten, or inches wide, according to their height, or if of brick or stone-work, two feet wide at least, sloping both sides of each pier inward, but from taking off the angles, a free admission may be given to the rays of the sun. For the same reason, the bottoms of the sashes should reach within a foot of the floor of the house, and their tops almost as high as the roof; and if brick or stone piers two feet wide, flutters may be hung on the inside to fall back against each pier. The roof may be either wholly or only half glass-work, next the front; the other half, flat, or only half that of the two, or front piers are of timber; and the flutters to the top of the glass may be so contrived as to slide under the flat roof; where the piers are of brick or stone, it is common to have the roof entirely flat or tiled; but slating the most ornamental for a half or whole roof; and the ceiling within should be white; which, as well as the whole inside wall, must be well plastered and white-washed, so as to render it clean and neat.

But in green-houses of modern construction, in order to have as much glass as possible in front, the piers between the sashes are commonly of timber only, from six to eight to ten inches thick, according to the height, so as to admit as great a portion of light and heat of the sun as possible, and the roofs wholly of glazed frame-work.

The green-houses for large collections of plants have sometimes two wings of smaller dimensions, added to the main buildings, at each end, in a right line, separated sometimes from it by a glass partition, with sliding sashes for communication, and the front almost wholly of glass-work, and half or whole glass roofs. Thus, by these additional wings, the houses confit of three divisions, whereby the different qualities and temperatures of the various plants can be more easily fitted. The middle, or main division, may be for all the principal and more hardy, woody, or shrubby kinds, which require protection only from frost; one of the wings appropriated for the succulent tribe, and the other to the more tender kinds that require occasional heat in winter, but which can live without the heat of an office or hot-house.

On whatever plans green-houses are constructed, the whole of the inside walls should be neatly smitten off with plaster and white-wash, and the wood-work painted white; the bottom being painted with large square paving tiles, or some other similar material.

In the green-house there should be flanks, frames, or trellis, which may be moved in and out, upon which rows of planks may be fixed, so as to place the pots or tubs of plants, in regular rows, one above another; by which their heads may be so situated as to interfere with each other; the lowest rows of plants next the windows being placed above four feet from them, that there may be convenient breadth left to walk in front; and the rows of plants should rise gradually from the fire, in such a manner, that the heads of the second row be entirely advanced above the first, the items only being hid; and at the back of the house, a space allowed of at least five feet, for the convenience of watering the plants, and to admit a current of air around them, that the damp occasioned by their perspiration, may be the better dissipated; which by being pent in too closely often occasion a mouldiness upon the tender shoots and leaves, and, when the house is close shut up, this flattering, rainy vapour is often very destructive; for which reason they should never be crowded too close to each other, nor should succulent plants ever be placed among them.

In Plate Gardening, (Green-house) there is a ground plan and elevation of an improved green-house in which fig. 1. shows the front elevation, fig. 2. the ground plan, and fig. 3. a section of the same.

And at fig. 4. is another house of this kind upon another plan.

Green-house Plants, in Gardening, are such as require the protection of this sort of building during the winter or other season; the following are the principal of the different sorts that demand this kind of treatment.

Succulent Kind.

Agave, agave or American aloe; comprising common great American agave, with entire green leaves, and a branching flower-spike;—common agave with striped leaves;—Virginian agave, with narrower pale-green leaves.

Aloe, African aloe; containing mitre-shaped aloe-tree, or fword aloe,—aloë ferox,—fan aloe;—lococotine aloe;—foap aloe;—partridge-breast aloe;—tongue aloe;—warted-tongue aloe;—pearl-tongue aloe;—cobweb-aloe;—hedgehog aloe;—cushion aloe;—spiral aloe;—pentagonal spiral aloe;—triangular spiral aloe;—iris uvaria aloe.

Anthericum, spider-wort; containing shrubby flowered, onion-leaved anthericum;—aloë-leaved anthericum;—mock alphodel anthericum.

Calceus, foreign calex;—containing callosa floccid;—Kleina or Indian calceus;—anteumorphium calceus;—papillary calceus.

Cactus, melon-thistle; containing cactus opuntia, or common Indian fig.

Caydenon, navel-wort; containing round-leaved, long-leaved, hemispherical-leaved navel-wort.

Crassula, liver orpine; containing several species. Lophoria.
GREN-HOUSE PLANTS.

Euphorbia, euphorbium; containing most of the foids.
Myriophyllum, fig marigold; containing many curious
fpecies.
Sempervivum, tree-ever, or base-leek; containing tree-base
leek;—variegated tree-base-leek;—leifer canary tree-
base-leek.

Herbaceous Kind.
Anthology, Ethiopian corn-flag; containing ringent scarlet
anthology;—Ethiopian crimson antholyza;—cunonia, or
large lipped scarlet-flowered.
Antirrhinum, snap-dragon; containing variegated snap-dra-
gon;—Gibraltar spotted flowered linaria;—Dalmatian toe
flax.
Arifloehia, birthwort; containing evergreen arifloehia;
—pifloehia, or small birth-wort.
Bryonia, bryony; containing African tuberous-rooted
bryony.
Calia, calia; containing sweet calia, or Ethiopian
arum.
Campanula, bell-flower; containing American bell-flower.
Canaria, canaria; containing canary bell-flower.
Canna, Indian flowering reed; containing common Indian
flowering reed, and varieties;—glaucescent Indian reed.
Crinum, afphodel lily; containing African afphodel lily;
—broad-leaved afphodel lily.
Cyclamen, cyclamen; containing Perian cyclamen, and
several varieties.
Erodium, erodium; containing pentandrous geranium or
crane’s bill;—thick-leaved erodium;—upright dwarf erodi-
um.
Brythra, coral-tulip; containing herbaceous erythrina.
Ixia, ixiia; containing African weedy-headed ixia;—bulbi-
erous ixia;—flexuous ixiia;—corymbous spotted-flowered
ixia.
Leonurus, leon’s-tail; containing African scarlet leonurus;
—striped-leaved leonurus.
Ornithogalum, flar of Bethlehem; containing Cape ornitho-
galum.
Trapaolum, Indian creft; containing double Indian creft,
or natturtium.

Shrubby Kind.
Andromeda, andromeda; containing tree andromeda, or
Carolina forrel.
Anthophyllum, amber-tree; containing Ethiopian smooth
amber-tree;—ciliated amber-tree.
Antibasis, Jupiter’s beard, or barba Jovis;—common barba
jovis, or silver bunt;—Spanish ternate-leaved barba jovis;—
dwarf Portugaue barba jovis;—ceramace, or prickly an-
thyllis.
Arctitis, arctitis; containing rough-leaved arctitis;—
narrow-leaved arctitis;—sea rag-wort leaved arctitis;—
plantain-leaved arctitis.
Arrtenia, mugwort;—containing tree wormwood.
Asphaltilia, swallow-wort; containing shrub asphaltilia.
Asparagus; comprising white prickly asparagus;—deci-
nated bristly-leaved asparagus;—acute-leaved asparagus;—
retrofacted great prickly asparagus.
Asfer, flar-wort; containing shrubby African alter.
Asfragalis, milk-seatb, &c;—comprising the tragacanth, or
goat’s-thorn, and several varieties.
Atropa, deadly night-flinte; containing shrubby deadly
night-shade of Spain.
Baccharis, ploughman’s spike-ned; containing ivy-leaved,
baccharis;—olander-leaved baccharis;—halimus-leaved
baccharis.
Bofea, y ru-mor;—or shrubby golden-rod tree.
Bromia, bromia; containing knob-flowered, or imbricated-
leaved, woolly-heath leaved abrotanoides, or thyme-leaved
radiated bromia.
Bubon, Macedonion pasley; containing shrubby galban-
iferous bubon;—shrubby gummiferous bubon.
Buddleia, buddleia; comprising American long-spike, oc-
cidental American, globular-headed buddleia.
Buphthalmum, ox-eye; containing shrubby Jamaica ox-eye;
—maritime, or sea ox-eye.
Bupleurum, hare’s ear; containing shrubby Aethiopian
hare’s ear;—shrubby duftrm-leaved Cape hare’s ear.
Calendula, marigold; containing shrubby Cape marigold;
—shrubby grafs-leaved Aethiopian marigold.
Cepora, capper-bush; containing fomious capparis, or
tree capper shrub.
Callian, callian; containing Cape phillyrea;—Mausweema,
or Hotentot cherry.
Canthus, canthus; containing African canthus.
Celastrus, sleet-tree; containing pyracantha-leaved cela-
trus;—box-leaved;—myrtle-leaved celtatrus.
Ceratonia, carob-tree; comprising common eabro-tree, or
St. John’s beard.
Clammea, clammea; containing dwarf palm.
Chrysanthemum, chrysanthenum; containing shrubby canary
chrysanthenum;—shrubby floccular chrysanthenum.
Chryzoa, golden-leaves;—containing shrubby coma aurae,
or greater African golden-leaves;—shrubby nodding gold-
locks.
Ciftus, ciftus; containing bay-leaved ciftus;—sea purflane-
leaved ciftus;—and several other species.
Citrus, citron-tree; containing lemon-tree, and orange,
with all the varieties of each.
Cliffortia, cliffortia; containing sea-leaved cliffortia.
Chelista, alaternside chelista; containing purflane-leaved
chelista;—alateria or Indian clavelia.
Colocasia, colocasia; containing shrubby Aethiopian scarlet
colucata.
Convvolulus, convvolulus; comprising evergreen canary
convvolulus;—silverly convvolulus.
Coronilla, coronilla; containing valentine coronilla;—
glaucus coronilla;—silverly coronilla.
Datis, datis; containing catinus-leaved datis.
Digitalis, fox glove; containing shrubby canary fox-
glove.
Diosma, African fjoria; containing opposite-leaved, hairy-
leaved, red diosma, &c.
Ebenus, eby; containing eby of Crete.
Empita, broom; containing shrubby eban broom.
Geranium, geranium; containing all the shrubby kinds.
Gendonia, gendonia; containing lobolly bay.
Gerertia, gerertia; containing shrubby prickly-leaved
gerertia.
Grewia, grewia; containing occidental grewia.
Halleria, halleria; containing African-fly honeyfickle.
Heliotropium, turn-satle; containing shrubby Peruvian helio-
tropium.
Hermannia, hermannia; containing althea-leaved, alder-
leaved, lavender-leaved, goof-tree-leaved hermannia.
Hypericum, St. John’s wort; containing warted-leaved.
Minorca St. John’s wort;—Carolina St. John’s wort;—
China monogynous St. John’s wort.
Jasminum, Jasminum; containing Catalonian jasmine;—
African jasmine;—yellow Indian jasmine.
H P Y H E M , candy-tuft;—evergreen tree candy-tuft;—ever-green
striped-leaved candy-tuft;—ever-flowering tree candy-tuft.
Jupiter, Malabar nut-tree.

Santana,
GREEN-HOUSE PLANTS.

Laurus, bay-tree; containing Carolina blue-berry bay—red-berryed bay-tree—Indian bay-tree—cinnamon-tree—campire-tree—deciduous bay-tree.

lobelia, lobelia; containing shrubby, pine-leaved, blue lobelia.

Lycium, box-thorn; containing African box-thorn—Barbary box-thorn.

Malva, mallow; containing African shrub-mallow medicago—shrubby hoary medicago, or moon trefoil.

Melia, melia; containing the bead-tree.

Menisus, mint; containing tree-mint.

Morus, morus; containing calcinated-leaved moria—ruit-leaved moria.

Myrica, gall, sweet-mallow, and common berry myrtle; containing oak-leaved myrica—Ethiopian heart-leaved myrica.

Myrtus, myrtle-tree; containing common myrtle, which comprises many varieties.

Nerium, oleander, or rose-bay; comprising common oleander, with red flowers, scarlet flowers, white flowers, double flowers, rippled-leaved.

Olea, olive tree; containing European olive tree—Cape or African olive tree.

Ononis, rift barrow; shrubby Spanish ononis.

Oleaster, olearia; containing hard-leaved chrysantheme.

Othamna, ragwort; containing pectinated-leaved othamna—southernwood-leaved othamna.

Paeonia, floury-wort; shrubby African paeonia.

Pelargonium, African geranium; containing many shrubby species.

Pheumus, Jeraphon faze; containing yellow phlomis, and varieties—purple phlomis.

Phyllis, phyllis; containing alkekengi, or winter cherry—fomiferous winter cherry—flexuous winter cherry.

Pistacia, Pistacia mut, and mastic tree; two or three varieties.

Polycarpa, milk-wort; containing shrubby myrtle-leaved polycarpa.

Portulaca, portulaca; containing shrubby Cape portulaca tree.

Potomitan, burnet; containing shrubby prickly burnet.

Prasium, frutibx hedge wattle.

Protea, floury-tree; containing common silverly protea, or changing tree—coniferous protea.

Punica, pomegranate tree; containing dwarf pomegranate.

Rhus, fumich; containing African hoary fumich, and varieties—African narrow-leaved fumich, and varieties—flaming-leaved African fumich.

Regula, regula; containing African bladder-mut.

Rhamnus, dock; containing  tormentor dock.

Rutacea, kale-bolly; containing Alexandrian laurel—tongue-upon-tongue laurel.

Secubia, secubia; containing shrubby lecythus.

Senecio, groundfet; containing shrubby African groundfet.

Sideraulis, iron-wort; containing Canary iron-wort—Cretan iron-wort.

Soluranum, night-shade; containing amomum Plinii—baftard capuchin, or winter cherry—African jagged-leaved soluranum, or pomum amoris—American twin-fruited soluranum—thorny, downy night-shade.

Tinactum, tanfey; containing shrubby Aethiopian tanfey—under-shrubby lampa-leafed tanfey—tree tanfey.

Tarakbanus, tarakbanus; containing shrubby African fleabane.

Tetragoneia, tetragoneia; containing shrubby tetragoneia.

Tecuinion, germander; comprising Spanish tree-germander—broad-leaved tree-germander.

Vites, chestnut-tree; containing evergreen chestnut-tree.

Ulex, furze or alder; containing African berry-bearing furze.

Xranthemum, xenanthemum; containing broad-leaved xranthemum—narrow-leaved xranthemum—trailing xranthemum.

Yucca, Adam's needle; containing common Adam's needle—threaded-leaved Adam's needle—sloe-leaved yucca—dragon tree-leaved yucca.

Zygophyllum, bean caper; containing xelile-leaved bean caper—purfane-leaved been caper.

Under-shrubby Kind.

Dracocephalum, dracocephalum; containing Canary dracocephalum, or balm of Gilead.

Gnaphalium, gnaphalium; containing oriental gnaphalium, and varieties—sweet-scented gnaphalium.

Indura, inula.

Kegelaria, kegelaria; containing African kegelaria.

Lavatera, lavatera; containing Cape lavatera.

Lovendula, lavendula; containing cat-leaved Canary lavender.

Lotus, bird's-foot trefoil; containing Cretan silverly lotus—lotus Jacobus—upright lotus.

Mediola, mediola; containing climbing African mediola.

Organum, organy; containing dittany of Crete—dittany of mountain Sipylus—Cretan marjoram—organy of Smyrna.

Periploca, Virginian flax; containing African hoary-climbing periploca, and varieties.

Phyllis, baflard alaternus; containing box-leaved phyllica—health-leaved phyllica.

Phyllis, baflard hare's ear; or simpla nobla.

Polium, or mountain poli; containing marum, or Syrian malich.

Rhynnum, buckthorn; containing broad-leaved Indian rhynnum—zizyphus, or jujube.

Selagia, flaga; containing coremb flago.

Smilax, rough bind-weed; containing Chinese rough bind-weed, or China-root—laurel-leaved rough bind-weed, and several varieties of each.

Stabe, flabe; containing bashard elchrysum.

It may be observed, that these sorts of plants must constantly be kept in pots, and some large kinds in tubs, for moving into shelter in winter, and into the open air in summer; as, being all exotics from various warm parts of the world, they are of tender growth in this climate, and consequently not able to live in the open air in the winter months.

And the pots and tubs for containing them must be of different sizes, according to the size and nature of the plants, which, as they advance in growth, should have large pots, &c. provided for them accordingly; and when they become wholly too large for the pots, they must be shifted into tubs hooped with iron, with two iron handles to each at the top-part.

It is necessary in potting or planting the different sorts, care should be taken that the pots or tubs have holes at bottom for the discharge of redundant moisture, each hole bring.
GREEN-HOUSE PLANTS.

being covered with a piece of tile or oyster-shell before the mould is put in, to prevent their being flopped up, and the earth from being washed out below.

The best modes of propagating the different sorts, the nature of the earth in which they succeed best, and the season most proper for raising them, are fully explained under the cultivation of the respective kinds, and may be seen under their proper heads.

General Method of Management of Green-house Plants.—As most plants of this sort are capable of bearing the open air from the latter end of May till October; but the rest of the year demand the protection of the green-house, they, of course, require to be set out into it as soon as the weather begins to be suitable, in the spring and summer months: especially for such as all the several varieties of myrtles, geraniums, oleanders, cistuses, phloxines, shrubby alyssum, tree-wormwood, tree-candy-tuft, yellow Indian and Spanish jasmine, Indian bay, &c &c. And this should be done in the latter week in May, or first in June, according as the season proves more or less favourable for all the sorts; but it should not be attempted till the season is become perfectly settled, and there is a fair prospect of summer being arrived, as there are often very cold nights and frequently frosty mornings in May, and even in the beginning of June, which, if the plants were fully exposed, would pinch the ends of their young shoots and leaves, and greatly injure them. A mild warm day should be chosen for this work; and if a warm rain, it will be of much advantage, as it washes the leaves and branches from the dust they have contracted, and greatly refreshes the plants that are thus exposed to it.

Method of Setting out the Plants.—This is done in the more hardy sorts in thin pots about the middle of May.

When first brought out, it is proper to place them in some sheltered sunny place, for a fortnight, till they are inoculated to the open air; then to set them in any open exposure, where they are to remain for the summer. And as soon as they are brought out, they should be cleared from all dead leaves, and all dead wood; and the earth on the surface of the pots be stirred, taking a little of the old out, and adding some fresh mould in its stead, which will prove very beneficial; then give moderate watering, not only to the mould, but also over the heads of the plants, to make them effectually from all dirt and litter which they have contracted in the green-house during the winter.

In putting them out, they may be placed according to the fancy of the proprietor; four of the handomest plants being occasionally placed to adorn spacious fore-courts, or arranged on each side of large walks contiguous to the main habitations; and others near ornamental garden-buildings, they are also sometimes diversified in groups, or small clumps in the most conspicuous places, in different parts of the pleasure-ground; exhibiting different sorts in each group, in order to cause the greater variety and effect in such situations.

As soon as they have been thus placed out, their chief culture is, to supply them plentifully with water during the summer season, in hot dry weather: all the woody or shrubby kinds in particular; likewise the herbaceous kinds that are not very succulent, require it three times a week at least; and in a very hot dry weather every day. The succulent kinds must also have a moderate supply of water two or three times a week in dry weather; the proper time for watering all the sorts at this season is, either in the morning before nine o'clock, or in the afternoon at four or five; for, if performed in the middle of the day in summer weather, the sun would exhale a great part of the moisture before it effected its intended operation on the fibres of the plants; this bulk

nfs should be duly attended to in dry weather. As the mould roots, and fibres of the plants are circumcised within the narrow limits of a pot or tub, the earth, as well as the fibres, dries very fast in summer, and necessarily requires frequent refreshments of water, to preserve that degree of moisture which is requisite for the support of healthy vegetation in the different plants.

Even moderate rains should not prevent watering occasionally, especially such plants as have spreading heads, which prevent the rains, unless very heavy or continual, from falling in sufficient quantities on the earth of the pots, to moisten it properly. And in hot weather, if some mowing of short herbs are spread on the surface of the orange-tree tubs and others, it will greatly preserve the moisture. During this season, it will also be a good practice to loosen the surface of the earth now and then in such pots and tubs as have a tendency to bind or become stiff by time.

Manner of taking in the plants.—About the beginning of the autumn, as towards the latter end of September, the more tender kinds of these exotic plants must be removed into the hothouse; the succulent tribe, in particular, should be removed to shelter at the first approach of excessive wet and cold nights. The oranges, lemons, and all the other species should be moved into shelter in due time, either in the end of September or early in October; for, if they are permitted to remain in the open air till attacked by sharp weather, it changes the beautiful verdure of their leaves to a rufy yellow hue, which do not recover during winter; therefore, about the latter end of September, or beginning of October at least, the principal plants should be brought in; the succulent and others of a more tender temperature, as early in the former month as the cold weather begins to come on; and continue moving in all the others as the cold increases; and by the middle of October have the whole collection in the hothouse. As the time approaches for moving in the different sorts, clear them perfectly well from decayed leaves, &c. all the pots being well cleaned, loofening the surface of the earth in each pot, and adding a little fresh mould. As the different sorts are brought occasionally into the green-house, they may be placed promiscuously till the whole are in, and then be arranged regularly, as they are to remain for the winter; leaving all the windows quite open till that time. When the whole is brought in, they should be diffused in regular order, so as to appear to the belt advantage, both in respect to their general arrangement and variety; and for as each may have an equal portion of fun and air; the tallest plants being arranged in the back, the others in their several ranks, according to their degrees of height, gradually down to the lowest in front; and as there is a vast variety both in size, shape, and colour, of the foliage, they should be diffused so as to set off each other and give a pleasing variety to the whole; and if possible, they should stand clear of one another; by which each plant will be separately conspicuous, and the whole exhibit a greater air of freedom and variety, as well as admit an equal portion of fun, and a more free circulation of air among them.

When the plants have been thus collected in, their principal culture is the supplying them with fresh air at all opportunities in mild weather, and giving moderate waterings occasionally, picking off decayed leaves, cutting out canals decayed shoots, and making occasional moderate fires in fever weather, also, sometimes to diffuse great damps and noxious fogs from them.

With respect to giving air, it should be admitted every mild, calm day, by opening the windows more or less, according to the temperature of the weather. When the plants are
GREEN-HOUSE PLANTS.

are first housed, they should have as much free air as the nature of the season will admit, by opening the windows every mild day to their full extent; and if the air is quite temperate, they may remain open in the nights for the first week; but in cold nights they should be constantly shut; this work of admitting air must be constantly attended to all the winter; for, without a due portion of this essential article in mild weather, the plants soon lose their fine verdure and assume a sickly yellowish colour, become discoloured, and the young shoots, in many sorts, grow mouldy and rot off, and the leaves of the plants drop; therefore, never omit every mild day, when not very damp or foggy, to open one or all of the windows little or much, according as the air is more or less temperate; the proper time during winter for this, is from about eight, nine, or ten in the morning, till three, four, or five in the evening, according to the mildness of the day; but as the days lengthen and the warm weather increases, give more air in proportion, earlier and later in the day as may be judged proper, being careful always to shut all close in due time every evening, as soon as the sharp air approaches. In foggy weather, it is advisable to keep the windows quite close; for the great damp occasioned by fogs are very pernicious to these plants whilst they are confined in the houfe; also, when hoarice or cold cutting winds blow towards the front of the greenhouse, the whole should be kept shut; or only, if thought necessary, some of the upper glasses drawn down a little way at top, above the reach of the wind rushing immediately upon the plants, likewise, in all frosty weather, the house should be kept close, except the frost is moderate, and the middle of the day sunny and warm, when some of the windows may be opened a little, but shut close again if the sun is clouded, and at any rate before the air changes cold; in severe weather, the shutters, &c. should be shut every night, also, occasionally when the frost is extremely rigorous and no sun; and likewise, in such weather, the allowance of fire-heat as hereafter directed may be necessary. As the spring approaches, and the weather grows warmer, enlarge the portion of air accordingly; admitting it also both earlier in the morning and later in the evening as the days lengthen; for then the plants will assume a growing state, and a considerable portion of air is requisite every mild day, both to strengthen the new shoots and insure the plants by degrees to the air against the time for removing them fully into it again for the summer season.

And watering will also be necessary to most of the sorts, but must be afforded them as sparingly as possible during the winter months, and fearfully any should be given when the house is obliged to be shut close through the severity of the weather; there are no certain rules to be given for the application of this; some plants require only a little water once a week, or ten or twelve days in mild weather, such as the orange and lemon trees, myrtles, oleanders, shrubby geraniums, and other woody sorts; all that is necessary being just to preserve the earth very moderately moist; the pots and tubs must therefore be examined with proper attention, and water given to such only as are in want. The herbaceous kinds should be rather more sparingly watered than the shrubby sorts; and all the succulent tribe have water but seldom, some not oftener than once a fortnight or three weeks, and that always but very sparingly at each time; and some that are very succulent require but very little from November till March; indeed all the succulents should only have it now and then at this season, when the earth in the pots becomes very dry and hard.

In executing the business of watering in general, care should be particularly taken to do it with great moderation at the time the plants are in the greenhouse, as when once over-wet the earth at this season, it will continue in that state for a long time, and by chilling the tender fibres of the roots of the plants, often caufl the loss of the leaves of many of them, and even the death of some kinds. In a funny day, from about eleven o'clock to two, is the most proper time for having this sort of work done.

Soft water, if possible, should be used, or at least such as had been exposed to the air two or three days, as fresh spring water is much too cold; and during frothy weather great attention is requisite to keep all the windows close, night and day, unless when very moderate, as just observed, and the middle of the day is sunny and warm; when some part of the house may be opened a little for two or three hours, having particular regard to shutting all close in dark time in the afternoon, before the airs change to become sharply cold; but in very severe frosts it must be kept close night and day, and the shutters or other covers of canvass or mats be also used every night; also, occasionally in the day time, when the weather is intensely severe, and no sun appears, and there are no flues for fires to keep out the frost. The shutters, or other shelters, besides the glasses, should however be used as little as possible in the day-time, except in cases of particular necessity, as every opportunity ought to be taken for the admission of light and fresh air, as much as the temperature of the weather will permitly permit, as most of the plants only want protection from frost and the common shelter of the house, which, with shutting the fash clofe every night, will be sufficient for the purpose.

In cases where there are flues for fires, it will be admissible to make moderate ones at such times as the frost cannot be otherwise kept out, especially on nights; but this must by no means be continued longer than is necessary to guard against very severe frosts and the danger of the plants.

In very cold, foggy, damp weather, a moderate fire is now and then in the flues also proves very beneficial in expelling the damp unwholesome vapours, so pernicious to all plants of this nature. Whilst the plants are in the houfe, all decayed leaves, &c. should likewise be constantly picked off, being necessary both to preserve the beauty and health of the plants. The decayed leaves of the succulent kinds should be cut off close with a sharp knife; the plants in general should likewise be occasionally cleaned from any filth they may contract in the house, such as dust, cobwebs, &c.

General Method of Culture of the Plants.—These sorts of plants generally want shifting into larger pots and fresh earth as they advance in growth; such as are fall growers, as some of the shrubby geraniums, &c. annually, or every other year; and some plants in large pots, &c. once in two or three years, and others not so often, especially some large grown American aloes, orange and lemon-trees, and those in large tubs, having a considerable substance of earth about the roots. Sometimes these and other similar kinds, when not convenient to shift them, have the top earth, and a little down round the sides, loosened to some moderate depth in the spring, removing the loosened soil, and filling the space up with fresh compost. But as the plants in general increase considerably in proportion to their nature of growth, shifting into larger pots or tubs, with some fresh earth, should not be omitted occasionally as it may seem necessary, as it proves beneficial to most of the sorts. They may molt of them be shifted with the ball of earth about their roots entire; but others, that are weak and loply, require shifting into entire fresh earth prepared for the purpose.

The most proper time for shifting all the sorts is in April,
or before they are removed into the open air for the summer; but it may be occasionally done in autumn, as in August or the beginning of September, in time to strike fresh roots before winter. In the work of shifting, each plant should be drawn out of its pot or tub with the ball of earth about its roots entire, then all the dry-matted fibres round the outside of the ball pared off and cleared away, also, some of the old earth at the sides, bottoms, and tops: then having the new pots and fresh earth ready, the holes at the bottoms of the pots should be covered with pieces of tiles or oyster-shells, and some of the fresh earth put in; placing the plant in the pot, and filling up the vacancy all round with more fresh compost, bringing it an inch over the top of the ball, giving a good watering to settle the earth clods in every part: after this, it is necessary to place the plants to have shade from the mid-day sun for a week or fortnight, and sometimes longer.

All such plants as are become of a weak sickly nature should, at shifting, have all the earth taken clean from about their roots, having them washed, and then planted into entire fresh earth properly prepared for them.

And the larger sorts of plants, such as the orange-trees, lemons, citrons, American aches, and others of similar growth, should be shifted, when large, from pots into tubs hooped with iron, having two iron handles at top, as observed above, for the convenience of lifting them in and out of the greenhouse, as they sometimes grow to so large a size as to require two and sometimes three or four men to move them. But all such plants as are not shifted annually should, in spring, have the earth in the tops of the pots or tubs hooped to a little depth, also, a little way down round the fibres, taking the loofened earth out; and in its stead adding a quantity of fresh mould, giving it directly a little water to settle it clods. This should never be omitted when necessary. At any time when the surface of the earth is observed to be stiff, whether in the shifted or unshifted plants, it is of much service to stir it an inch in depth occasionally, and add a little fresh compost when necessary to the plants.

And the mould or compost into which the plants are to be shifted is of considerable importance. The best is obtained from commons where sheep and cattle pasture, particularly in low places, where the finest grass grows and the soil is deep. A foot of the top soil with the turf should be taken off, and, if a sandy or hazel loam, it will do alone; but if a strong loam, some sand and black peaty, boggy, or moorish soil should be added. Such soils should be laid in a heap fix winter months or more, and frequently turned over. Some plants, such as aloes, cacti, melichrysum, anthemists, ixias, and exotic hothouse plants in general, require a soil which is a degree lighter, and which does not retain the water, but lets it pass readily. A little coalashes at the bottom of each pot is useful in this view as well as others.

Most of the ericas, or heaths, and other beautiful plants from the Cape of Good Hope, from America, and Botany Bay, delight and flourish in this sort of earth, which comes nearest to their native soil: thus, the heaths like a black peat or moorish soil; and the others, that which is made a degree stronger, with loamy earth intermixed with it.

It is necessary to keep the heads and every part clean from dust and other filth, by occasionally washing with water all the forts, which in moist is done by waterings over their heads; but in others, when very foul, by washing their leaves with a sponge and water, especially in winter.

This is often necessary to the oranges and lemons, and other large-leafed kinds of plants that have been mentioned.

Where the heads of any of the thrubby kinds are become very irregular or flabby, the branches may be pruned shorter or longer, as necessary, in the early spring months.

And where any of the principal exotics assume a declining state, such as oranges, lemons, &c. or have thin, thrashing, weakly heads, or are apt to drop their leaves, it is proper either to shift them wholly, or apply some fresh earth to their roots, and then prune the heads moderately close in the early spring, plunging them in a bark-pit under glasses. The heat of the dark-bed greatly revives their growth, that they break forth into many strong new shoots, and form handsome renewed full heads in the summer fedon.

While in the greenhouse, some plants drop all their leaves, either by the effects of cold or over-watering, or sometimes by being kept too long in too dry a place, as frequently occurs in myrtles and geraniums, and sometimes oranges, lemons, and others; in which case it is proper in the spring to prune the heads, shortening the long strong shoots and branches and to shift them with balls into fresh earth, or, if not shifted, to loosen the earth in the tops and sides of the pots, drawing out the loofened mould, and suppling the place with fresh. They afterwards soon push forth into young shoots and leaves, and renew their heads with verdure. Sometimes myrtles, geraniums, &c. in this state, when headed, may, on being brought forth in the summer, be drawn out of the pots, and plunged in the ground in a sheltered situation, and watered in dry weather; when they will send their roots into the full earth and break forth strongly at top into young wood and foliage, and form full heads, being then re-potted with balls of earth to the roots.

But the heads of green-house plants should never be clipped with garden-scissors, nor, by any mode of pruning, trimmed into any formal figure, as sometimes practised; but every fort be let assume its own natural growth, only just using the knife to regulate any very irregular or rambling shoot or branch, or to trim out some where too much crowded, and to cut out the dead wood they may contain in any part of them.

GREENLAND, in Geography, comprehends a peninsula generally allowed to be attached to North America, and a number of detached islands, situated in high northern latitudes; the former is called West or Old Greenland, and the latter East or New Greenland, and more commonly Spitzbergen.

West or Old Greenland, is now generally believed to be a peninsula, connected in its north-western parts, hitherto unexplored, with America. The reason alleged for supposing that the N.W. side is contiguous to America, and actually attached to it are the following: Davis's Strait, or Baffin's bay, it is said, becomes narrower and narrower towards 78° N. lat.; the coast also, which in other places is very high towards the sea, gradually lowers northward; and the tides, which at Staten Hook, and even as far as Cockin's found, in the 65th degree, rises 18 feet at the new and full moon, descends so much in the north above Disko, that in the 75th degree it does not rise much above eight feet, and probably loses itself entirely at lat. Hence captain Baffin gave up all hopes of finding a passage into the South seas through Davis's straits, and consequently concluded, that Greenland joined with America. The Greenlanders report, though much dependence cannot be laid upon their information, that the strait at lat. becomes so narrow, that they can approach the other side so nearly, as to be able to call to the inhabitants, and strike a fish from
GREENLAND.

from both sides at once: but they affirm, that a strong current runs from the north into the strait, which prevents their coming to one another.

The name Greenland was given to the eait side of this territory many hundreds years ago by the Norwegians and Icelanders, who are said to have first discovered it, because its appearance was greater than that of Iceland. But this east side, sometimes called Old or Left Greenland, is now almost totally unknown, because ships cannot navigate this coast, on account of the great quantities of floating ice. West Greenland lies between the straits of Davis and Prohibition, and Iceland, and is bounded on the W. by Baffin's bay, on the S. by Davis's strait, and on the E. by the northern part of the Atlantic ocean; but its northern boundaries are unknown. It reaches from the southermost point of Cape Farewell, and Staten- hook, in the 55th degree, on the right side north-eaftward, towards Snaizbergen, to the 80th degree; and on the left side opposite to North America, N. W. and N. till about the 78th degree; the coasts having been so far discovered. Most of the Greenlanders live from Statenhook to the 62d degree, or, as the inhabitants say, in the south; but as no Europeans live there, these parts are imperfectly known. The interior of this dreary country is extremely mountainous, and some of the mountains are so high that they may be discerned at the distance of 40 or 50 leagues. This is particularly the case with that which is the highest mountain in the country, called "Horte-tak," or flag's-horn. It has three branches or points, the most lofty of which serves as a sea-mark to navigators, and also as a weather-gage, for when a horn is approaching from the south, the summit of this mountain is enveloped in a small misty cloud. The hills and rocks of this country are covered with perpetual snow; though the low lands on the sea-coast are clothed with verdure in the summer season. The ice and snow, like the glaciers of Switzerland, fill the elevated plains, and even many valleys. The coast is indented with many bays and clefts which extend far into the land; and it is encompassed with innumerable large and small islands, and both visible and imperceptible rocks. The shore, however, is in many places inaccessible on account of the floating mountains of ice. This country is said to have been discovered by some emigrants from Iceland: the distance, according to the best maps, being about 8° of longitude, in lat. 66°, or nearly 200 geographical miles, though some maps reduce it to 5°, or not more than 150 geographical miles. The discovery was accidentally made by Eric Raude, or the red-headed, who being exiled from Iceland on account of the murder of one of his chiefs, found this country; and, coasting along the S. W. border, wintered at an agreeable island near a found, which he called Eric's found. Having in the following year examined the main land, he returned in the third year to Iceland; and in order to induce the inhabitants of Iceland to accompany him he called it Greenland, expressing its verdant appearance, and represented it as abounding with pasturage, wood, and fish. The effect of his representation was such, that in the succeeding year he was followed by twenty-five ships full of colonists, who had furnished themselves richly with house- hold goods and cattle of all sorts; however, only fourteen of these ships arrived safe: but in process of time more colonies flocked to Greenland, both on the east and west side, from Norway as well as Iceland. Torfæus, a native of Iceland, in his "Greenlandia Antiquia," dates the discovery of Greenland in the year 822. But it has been inferred from a bull united by pope Gregory IV. in 855, commits the conversion of the northern nations, and in express words, of the Icelanders and Greenlanders, to the first northern apostle Ansgarius, (if this bull be indeed authentic,) that Greenland must have been discovered and planted about the year 830, by the Icelanders and Norwegians. Leif, the son of Eric Raude, is said to have made a voyage to Norway, A. D. 999, to give the king, Olaf Tryggefon, an account of the new colony in Greenland; and this king, having first renounced heathenism, converted Leif, and perfused him to be baptized, and to take with him to Greenland a priest, for the conversion of the inhabitants. Upon his return his father was induced to embrace Christianity, and the rest of the colony followed his example. In the year 1052 they chose Arnold, a Norwegian, for their bishop; and he fixed his episcopal residence at Greenland. In the year 1261, they, and the Icelanders, forsook themselves voluntarily under the Norwegian sceptre; and from that time they were governed by a king's deputy from Norway, according to the laws of Iceland; and when an archbishopric was erected at Drontheim in Norway, the Greenland bishops became suffragans to this metropolitan. The intercourse between this colony in Greenland and Norway continued, with little interruption, till the beginning of the 15th century: the last of 17 bishops being appointed in the year 1406. During this period the Greenland trade is said to have been very considerable; and it is very probable that they exported a large quantity of fish, butter, cheese, fish, train, and pelts, chiefly by means of foreign ships; for though the Norwegian settlers in Greenland, upon their first establishment, failed in their own vessels from Iceland and Norway to this country, they afterwards very much neglected navigation. After the period above-mentioned Greenland seems to have been little regarded, and its intercourse with other countries almost wholly ceased. In order to account for this sudden change of condition, it should be considered, that the first settlers were very much harassed by the natives, who were a barbarous and savage people, and who resented, in their customs, garb, and appearance, the Eskuiaux found about Hudson's bay. These people were denounced "Skraelings," or "Kornalt," an appellation assumed by the Eskimoa. The Danish Chronicle, a work written in verse, and, indeed, of doubtful authority, though cited by Torfæus, informs us, that certain Armenians were first driven hither by a Norm, and that from hence they peopled Norway and America, and that many tribes were found in Greenland, who were governed by different chiefs. The Skraelings, it is supposed, and not without some degree of probability, first came to Greenland in the 14th century, not from the east out of Europe, but from the west out of North America. But their origin is traced to the N. E. regions of Great Tartary, between the Icsea (mare glacie) and Mungolia. They first came into Tartary, after the great dispersion of the nations, and were driven on further and further by impetuous or more potent nations that followed them, till at last they were compelled to withdraw into the remotest corner of Tartary near Kam- skatka, and from hence they migrated to America; extending themselves round the S. E. part of Hudson's bay, or through Canada as far as the North sea: and here, it is supposed, they were first found by the Norwegians in the 11th century. Dreadful and wifling to avoid the molestation which they suffered from the other Indians, these fugitives retreated northwards, till, probably, in the 14th century, they either crossed Davis's straits in their boats, from Cape Wulfingham, in the 66th degree, to the South-bay in Greenland, which can be scarcely 60 leagues wide; or else they went higher up by Baffin's bay, and, if came down on the parts where the Norwegians formerly had their habitations, first on the west side, and then by degrees round to the east. These Skraelings are supposed to have exterminated the Ice-}
of a similar nature were repeated, but no permanent advantage resulted from them.

At length, in the year 1724, a pious clergyman of Norway, Hans Egede, having long lamented the wretched condition of the Greenlanders, through the want of religious instruction, as well as a variety of worldly comforts, and having projected, from the year 1728, schemes for their relief, without effect, determined to relinquish his church preferment, and to make a voyage to Greenland, with a view of accomplishing his benevolent intentions. After having collected a capital of about 2000l., by various subscriptions, and obtained from the king an appointment of missionary, with the yearly salary of 60l., besides a present of 40l. towards his equipment, Mr. Egede placed himself at the head of a colony of 40 persons, and sailed for Greenland. Thee adventurers, having sailed Statenburch, encountered many dangers from storms and ice, happily landed at Ball’s river, N. lat. 64°, on an island near Kangek, which they called after the name of the ship in which they had sailed, "Haa-bat-Ox,” i. e. Hope island. They were hospitably received by the natives, and Mr. Egede took great pains, by his cordiality, attention, and by the familiarity with which he communicated to them religious instruction, to conciliate their friendly attachment. He also took great pains to acquaint himself with the language of the country, and to discover the best places for hunting and fishing, so as most effectually to serve the convenience of the colony. He made repeated attempts for exploring the eastern side of the country, and for discovering Frobisher’s straits, but the wind and ice rendered his efforts unsuccessful. As a missionary, he discharged the truth which he had undertaken with singular fidelity, diligence, and zeal, and having continued in this indefatigable region till the year 1736, he returned to Denmark with a debilitated constitution. He was soon after appointed superintendent of the mission in Greenland, with a salary of 100l. per annum, and was ordered to found a seminary of students and orphans, whom he was to instruct in the Greenland language, and who were to supply a succession of missionaries and catechists. He spent his latter years in a retreat with his daughter, on the island of Falster, and there closed his life of service and honour, November 5th, 1758, in the 73d year of his age. To him and to his son, Paul Egede, we are indebted for the most ample and authentic account of modern Greenland. The example of Mr. Egede has been finely followed by several missionaries, particularly from among the Moravians, whose principal settlements were at Kangek, New Herrnhuth, and Lichtensfeld. From Mr. Egede we learn that the most practicable method of reaching the eastern part of Greenland will be to coast north about in small vessels, between the great flakes of ice and the shore; the Greenlanders having always declared, that the currents, which rush from the bays and inlets, and run south-westward along the shore, hinder the ice from adhering to the land, so that there is always a channel open, through which vessels of small burden may pass, especially if lodges were built at convenient distances on the shore, for the accommodation and direction of the adventurers. The part of the country that is now visited by the Danes and Norwegians, lies between the 64th and 68th degrees of N. latitude, and so far the climate is found to be temperate. We are told, however, that the country is inhabited as far as 76°; but the Danishes and Moravian settlements are chiefly in the south-west, though at one time there appears to have been a factory as far north as 73°.

In the summer, from the end of May to the middle of September, the weather is warm and comfortable, when the wind blows from the east; though violent storms then occur, and
and the fogs on the sea-coast are Indescribably. The land near the shore exhibits a pelting verdure, but the inland mountains are perpetually covered with ice and snow. Beyond the 68th degree of latitude the cold is very intense, so that the rocks often burst by the frosts; and towards the end of August, the whole coast is covered with ice, which never thaws till April or May, and sometimes not till the latter end of June. The prodigious mists of ice that surround the whole coast exhibit an appearance, in calm weather, no less dazzling than dreadful, by the reflection of the sunbeams in its variety of colours; but when the wind blows and the waves are lifted up in mountain billows, these mists of ice differing against one another occasion blocks that make the observer tremble. Thunder and lightning seldom occur in Greenland, but the Aurora Borealis has frequent, and brilliant appearances. At the time of new and full moon, the tide rises and falls upon this coast about three fathoms, and the springs and fountains on shore rise and fall with the flux and reflux of the ocean.

The soil of Greenland refembles that of other mountainous countries, the hills being barren, and the valleys and low grounds, especially near the sea, rich and fruitful. It is, for the most part, unfertile clay or sand. But whatever is said of the fertility of Greenland is applicable only to that part which lies between the 65th and 67th degrees of latitude. The most northern parts are totally deftitate of plants and this. The soil is faid to have formerly produced a great number of cattle, and to have exported considerable quantities of butter and cheese to Norway. Some parts of the country yielded excellent wheat, and the oats that grew in it were so large as to furnish acorns as big as apples. In its present state, however, though some oats remain, and the traces of ploughed land are perceivable, Greenland is defstitute both of corn and cattle; but its nature is good, and if the soil were properly cultivated, it would probably yield grain. It produces excellent turnips and coleworts. The fides of the mountains near the bays are clothed with wild thyme, of powerful fragrance. The country abounds also with many other plants, and among its fruits we may reckon juniper-berries, blueberries, bilberries, and Bramble-berries.

The animals which are most abundant, are rein-deer, dogs resembing wolves, (see Don.) arctic foxes, and white or polar bears. Hares of different colours are common, but they are smaller than thofe of Denmark and Norway. The walrus, and five kinds of seals, frequent the shores. Here are found also ravens in great numbers, eagles of a very large size, falcons, and other birds of prey, and likewise a limnet, which warbles very melodiously. Whales, sword-fish, porpoises, &c., abound on the coasts; and also halybat, turbat, cod, haddock, &c. The species of insects exceed 90. The more dubious animals, which are said to inhabit these seas, are the mermaids, sea-mermen, and krakens. The polar bear, seals, and manate, says Pennant, (Arctic Zoology,) were originally natives of these countries. The other quadrupeds found their way here from either Hudson's bay or Labrador, on the islands of ice. The arctic fox found the fame kind of conveyance from Greenland to Iceland as it did with the rein-deer to Spitzbergen. To the last was wafted, probably from Labrador, the common weasel, the red or common fox, and the mout, which miffed Greenland, but flucked Iceland; and the common bat, which was originally temped driven to the latter from Norway; the volevere and varying hare never reached farther than Greenland. This, says Pennant, seems the progres of quadrupeds in the frigid zone, as high as land is found.

Greenland is thought to contain many mines of metal. To the southward of the Danish colony are fome appear-

ances of a mine of copper; Mr. Egede once received a lump of ore from one of the natives, and here he found calamine of a yellow colour. Crantz observes, that the highest mountains of this country are on the west side, and the rocks are full of elefs, commonly perpendicular, and seldom wider than half a yard, filled with spar, quartz, tale, and garnets. The rocks are generally rather vertical or some what inclined, confifting of granite, with fome sand-tone and lapis oilarz. Crantz also mentions micaeous schistus, coarfs-

marble, and verquiterne; with albeftus and amanatus, cry-

tals, and black fchoot. It is said that duste of argyll, a new fubflance, has been recently found in Greenland; and this is perhaps the foft transparent (one of Crantz. The lapis oilaris is of singular utility in Greenland, and the north of America, as it is used for lumps and culinary utensils.

The prefent inhabitants of the western coast of Greenland, and who are the defendants of the ancient Skrælings, whom we have already mentioned, and who exterminated the Jeland colony, very much refembe the American Samoide and Laplanders in their perfons, complections, and way of life. They are without doubt a branch of the Equimauk of Labrador, who fed that country, and peopled Greenland. They are short, brawny, and inclined to corpulence; with broad faces, flat noses, thick lips, black hair and eyes, and a yellowish tawny complexion. They are for the mofi part vigorous and healthy, but very short-lived, few reaching the grand climacteric, and many dying in their infancy, and in the prime of their youth. The hardness of the wind, and the glare of the fnow, render them subject to a disorder of the eyes. They are also afflicted with the leprous; and those who inhabit the northern parts are miferably tormented with dyeritries, rheums and pulmonary disorders, boils, and epithelis. The small-pox in 1744 made dreadful havoc among these people, who have no aid from missionaries, and who depend merely on their "Angekoks," or con-

jurers. The Greenlanders, with regard to their confitutional temperament and disposition, are cold, phlegmatic, indolent, and dull of apprehension; but quiet, orderly, and good-humoured. They live peaceably together; have every thing in common, without strife and animosity; and strangers they are civil and hospitable. They never wash themselves with water, but lick their paws like the cat, and then rub their faces with them. They eat after their dogs without washing their dishes; devour the ice which devote them; and even lick the sweat, which they scrape off from their faces with their knives. The women wash themselves with their own urine, under a notion that it makes their hair to grow; and in the winter-time immediately expose themselves to the air, that the liquor may freeze upon their skin.

In their general habit and manner they are intolerably filthy. In times of scarcity they fubhxt on pieces of old skin, reeds, sea-weed, and a root called "tugboronet," dressed with train oil and fat. The dung of rein-deer taken from the interlines, the entrails of partridges, and all sorts of offals, are counted dainties among these savages; and of the scrapings of seal-fkins they make delicate pancakes. The Danifh provisions were at first tailed by them with disguft and abhorrence; but they are now become fond of bread and butter, though they still retain an averton to tobacco and spirituous liquors. The Greenlanders in common content themselves with one wife, who is condenmed to drudgery, and liable to be divorced at the pleasure of the husband. Persons of superior rank and qualities are, however, indulged with a plurality of wives. Their young women are generally chaffe and lavish; nevertheless, at some of their feasts the men retire with the wives of their neighbours for licentious amours. Their superstitious customs are innumerable; e.g. when
a woman is in labour, the goffips hold a chamber-pot over her head, as a charm to hallow the delivery, and when a child is a year old, the mother licks and flabbers it all over, to render it, as she imagines, more strong and hearty. Their cloaths are made of the skins of rein-deer, seals, and birds. The men wear their hair short, commonly hanging down from the crown of their head on every side, and squared off at their foreheads. Some cut it off as high as their poll. But it would be a reproach to a woman to cut off her hair, which is never done except in cases of the deepest mourning, or if they resolve never to marry. All the Greenlanders speak the same language, though different dialects prevail in different parts of the country. Some few words are probably the relics of the old Norwegian; but these excepted, their language seems to have no affinity to etymology, declension, or signification, with any of the Northern, Tartar, or Indian languages, as far as they are known to us; but we must except the language of the Eskimaux in Labrador, whom, we have already said, to be one people with the Greenlanders. Their great number of polyfylables, and of repeatedly combined words, make their language very intricate. Nevertheless, it abounds so much with words, that the Greenlanders, like the Cimbic Tartars, have a proper word for every object or art that requires the least distinction. Besides, their words are varied and declined with such different modifications, yet according to a fixed rule with few exceptions, and are attended with prelites and suffixes, far more than the Hebrew, that the language is not only graceful, but plain and unequivocal. Moreover, they join many words together, as we have already said, like the North Americans, so that they can express themselves very concisely and yet significantly. Some of our letters are wanting in their language, and they never begin a word with B, D, F, G, L, R, or Z. They seldom join many con- sonants together, and never at the beginning of a syllable. The accent, upon which much depends, must be laid upon the proper syllable, commonly the last; and the Greenlanders, especially the women, accompany many words, not only with a particular accent, but with a certain significant aspect, which is necessary to be regarded in order to ascertain their meaning. They have but few adjectives, and these are mostly participles; they are placed after the substantives, which always begins the sentence. Substantives, as well as verbs, have singular, dual, and plural numbers, but no gender and they resolve never to marry. The Greenlanders are formed according to the different termination of the word, with few exceptions. The declensions are easy; the genis- tive has at the end a, or if a vowel follows, an m, either by addition or change; and the rest of the cases have a pre- position affixed to them. The pronouns are not placed be- fore the word, but one or two of its letters are attached to it at the end, and in different ways according to the different numbers. They have only five prepositions, which are not set before the nouns, as in other languages, but at the end, and again are varied in declining. The verbs have been divided into five conjunctions, according to their termina- tions. They have three tenses, the present, the perfect, and future; and they have six moods, the indicative, imperative, permissive, conjunctive, and infinitive. The Greenlanders have no verbs deponent nor passive, but the latter are formed from the active by some adjunction. They have several classes of adverbs, like other nations; but their numerals are few, so that they can scarcely count five; but in order to arrive at 20, they count the fingers of both hands and the toes of both feet. If they want to proceed farther, they begin again with their fingers and toes. They tack their conjuctions to the end of a word, as the Latins do their give; and they do not want interjections. Their syntax is simple and natural; the capital word stands in the front, and the rest follow in order according to their importance. Their style or mode of speaking is not at all hyperbolical, pompous, or bombastic, like that of the oriental, but simple and natural; yet they are fond of similitudes and metaphors. Their poetry has neither rhyme nor measure; but it confits of short periods; which, however, are sung to a certain time and cadence.

The Greenlanders have no traditions of the most memorable events of their ancestors in heroic fongs, as other nations have; who poetics no written records. All they can say of their progenitors is, that they were brave seal-eatchers, and that they killed the old Norwegians. Yet in their factual fongs, to which they are much addicted, they are more acute. They are well versed in genealogy, and can often trace their pedigree as far back as ten of their progenitors, together with all the collateral branches. Their imperfect arithmetic we have already noticed. Of writing they have no conception. On their first acquaintance with Europeans, they were frightened by speaking paper. In chronology, they reckon their years by winters, and their days by nights. They are not learned enough to fix the equino- xes, but they can guess at the winter solstice, within a few days by the fun-beams upon the rocks; and then they celebrate their new year by a fun-feast. From hence they reckon three full moons to the spring, and then they move from their winter houses into tents. In the fourth moon, i.e. in April, they know that the small birds make their ap- pearance, and the ravens lay eggs. In the fifth their angmarket, and the seals with their young ones give joy to their coals by their revolutionary visit. In the fith the eider-fowls breed. When they lose the moon in the bright summer nights, they carry on their calendar partly by the growth of eider- fowls, and size and shape of the seals, and partly by the shining of the moon on the dial of the rocks and mountains; so that they exactly tell when the seals, fishes, and birds will arrive in flocks and fhalos here and there, and when it is time to repair to the winter-houses, in which they generally shaf- ter themselves soon after Michaelmas. They divide the day according to the chb and flood, and the night by the rising and setting of certain stars. They think the globe of the earth stands upon polls, which are so rotten with age, that they often crack; and that they would have funk long ago, if they had not been kept in constant repair by the Angle- koks, who sometimes bring back a piece of rotten wood as an evidence of their important service. Their astronomoy makes the firmament to rest on a lofty pointed hill in the north, and on that centre it performs its revolutions. But this specimen is sufficient. When it thunders, two women are flretching and flapping a dried seal-skin, and the thunder is occasioned by that rattle. The mystery of the Aurora Borealis is unravelled by the fous of the dead friaking at a dance or a foot-ball. The rains are the overflowings of the celestial reservoirs; and if the banks should break, the sky would fall down. Such is their meteorology! In medicine and surgery they are no less ignorant than in the other sciences.

When a Greenlander is in the conflicts of death, they ar- ray him in his bell cloaths and boots, and bend his legs up to his hips, probably that his grave may be the shorter. After death, they febiously bewail him for a short hour, and next prepare for his burial. The corpse, being wrapped and sewed up in the man's best seal or deer-skin, is laid in the burying place, covered with a skin, and also with some green fods, and finally with heaps of great broad fones to keep off the birds and foxes. Near the burying spot they deposit the
the kajak and darts of the departed, and the tools he daily used; or if the deceased was a woman, her knife and sewing implements, that they might not be defiled by them, or row too much on their account, or because they should want them in another world. After the interment, those who attended the procession, betake themselves to the house of mourning: then the men sit silent for some time with their elbows leaning upon their knees, and their heads between their hands; while the women lie prostrate upon their faces on the ground, and softly weep and sob. Then the nearest relation pronounces an eulogy, reciting the good qualities of the deceased, and at every period deploiring his loss with loud crying and weeping. After this mournful diry, the women continue their lamentations in a tremendous howl. This kind of mourning is continued for a week or a fortnight. The howling is after intervals renewed, and prolonged for some weeks, and in some cases for a whole year.

As for the religion, or rather the superlition of the ancient Greenlanders, they are reported to be such gross idolaters as to worship the fun, and sacrifice to the devil, that he might forward, or at least not hinder, their hunting and fishing. The first missionaries, however, conceived that the Greenlanders had no kind of religion or idolatrous worship; and that there was not any observable trace of their entertaining any conception of a Divine Being. Others, however, have thought, with greater reason, that a faint idea of the Divine Being lay concealed in the minds of these people, because they directly alluded without any objection to the doctrine of God and his attributes. Among the Greenlanders, different opinions are entertained concerning the soul of man; some supposing that it is material or corporeal, and others that it is a spiritual essence, different from the body, and all material substances, and capable of surviving after death. They seem to have some confused and indistinct notions of a future state: of the place which is to be the final abode of good men; and of the nature of their reward. The most stupid Greenlanders, it is said, conceive a horror at the thoughts of the entire annihilation of the soul. They place their hell in the subterranean regions, which are devoid of light and heat, and filled with perpetual terror and anxiety. The Greenlanders speak of other superior and inferior spirits, besides the soul of man, which bear some resemblance to the major and minor gods of the ancient heathens. Of the first rank there are only two; a good spirit and a bad one. Besides the great spirits to an audience with whom an Angekok only can be admitted, there are other lesser spirits in all the elements.

The Greenlanders believe in apparitions, of the ghosts of the deceased. The 'Angekoks' are their forefathers or diviners, to whom peculiar privileges and honors belong. Although the Greenlanders have neither religion nor government, they are free from many of the grogger vices, which may be found among persons much more enlightened than themselves.

The traffic of the Greenlanders is very simple and concise, and is carried on altogether by barter. They very rarely cheat, or take the advantage of one another, much less steal, which they reckon infamous; but they glory in over-reaching, or robbing an European, because they think it is a proof of their superior wit and ingenuity. Their traffic is carried partly among themselves, and partly with factors and seasoners. Wherever there is a great assembly, or rendezvous of Greenlanders, as at a dancing match, or the fun-feaft in winter, there are always some that expose their wares to view, and announce publicly what goods they want in exchange. As those in the south have no whales, and those

in the north no wood, many boats of the Greenlanders coast every summer out of the south, and even from the east side of the land, and proceed from two to four hundred leagues, as far as Dîko, with their kajaks and women's boats, and the tackle and implements belonging to them, and barter wood for the horns of the unicorn, their women's boats, and whale's bones, and whale's fins, and part of these they track on their return home. In these voyages they take with them their whole family and household, and sometimes form a new settlement in the course of their voyage. The Greenlanders vend their fox and seal-skins, and especially their blubber, to agents or factors, and receive in return iron points for their darts, knives, lock-faws, gimblets, chisels, and sewing needles; also, striped linen and cotton, kerseys, woollen stockings and caps, handkerchiefs, cloths or boxes, wooden dibles, pewter plates, copper kettles, looking-glasses, comb, ribbons, and all sorts of toys for children. They are fond of buying snuff, also guns, powder, and shot; tobacco, which they use only as snuff, serves instead of small money with them. Indeed, they expect a little tobacco for every service they perform.

The assembly for dancing, and the fun-feaft above-mentioned, are not religious acts or ceremonies, but mere sports and amusements. The fun-feaft is kept at the winter solstice, and is a joyous occasion, and the return of the fun, and the renewal of good hunting and fishing weather. These dances are performed all over the country in large parties, and treat one another in the best manner they are able. When they have gorged themselves with food, they rise up to play and to dance. The means of intoxication they do not poifols, and drink only water. Their only musical instrument is the drum, which is beaten to common musical time. The music and dancing are accompanied with a song in honour of seal-catching, and such kinds of exploits; the performer extols the noble deeds of his ancestors, and expresses his joy at the return of the fun in the hemisphere. Every stanza of his ode is accompanied by the auditory. The following is a specimen of a complete cantata; the second and fourth lines expounding the chorus:

"The welcome fun returns again,
Anna ajah, ajah, ah-hu!
And brings us weather fine and fair,
Anna ajah, ajah, ah-hu!"

Such dancing meetings are appointed at other seasons of the year, when they have leisure to attend them. It is somewhat singular, and deserves mention, that they decide their quarrels by singing and dancing, and they call this a "Singing Combat." A Greenlander, who conceives himself injured, composes a satirical poem, and repeats it often with singing and dancing, till his domestics, and particularly the women, are able to remember it. He then publishes a challenge that he will fight a duel with his antagonist, not with a sword but with a song.

The respondent appears in the appointed place; when the accuser begins to pronounce his fatre to the beat of the drum, and his party join with repeating "Anna ajah," which occasions laughter among the attendants.

The defendant then returns in the same manner, and the laugh changes fides; the plaintiff again renews the same kind of afflnt. The whole body of attendants constitute the jury, and cosfer the baud on the victor, and afterwards the two contending parties are the best friends.

The Greenlanders are employed throughout the whole year in fishing or hunting. At sea they pursue whales, morfs, seals, fih for food, and seas-fowl. On shore they hunt the rein-deer in different parts of the country. And they have
GREENLAND.

methods peculiar to themselves, and corresponding implements, for accomplishing their objects both by sea and land; which we shall not here detail. The Greenland canoe, or "kalaq," like that in Nova Zembla and Hudson's bay, is about three fathoms in length, pointed at both ends, and 3 of a yard in breadth. It is constructed of thin rafts fastened together with the skins of animals, and covered with dreidled seal skin, both above and below, so that only a circular hole is left in the middle, large enough to admit the body of one man. Into this the Greenlander thrusts himself up to the waist, and fastens the skin so tight about him that no water can enter. Thus secured, and armed with a paddle broad at both ends, he ventures out to sea in the most stormy weather to catch seals and sea-fowl; and if he is overcast, he can easily raise himself by means of his paddle. The "kone-boat" is made of the same materials, but more durable; and so large that it will contain 50 persons with all their tackle, baggage, and provisions. It is fitted with a mail, which carries a triangular sail made of the membranes and entrails of seals, and is managed without the help of braces and bowlines. These kones are flat-bottomed, and sometimes 60 feet in length. They are built by the men themselves, who are obliged to do all the drudgery, including even the building and repairing of their houses, while the men are wholly employed in preparing their hunting implements and fishing tackle.

Greenland is a country very thinly inhabited. In winter they live in hovels and in summer in tents. The hovels are constructed of stones, on a deep rock, with layers of earth and sods between them. On these walls they rest the beam, or connected beams, for the length of the hovel, being from 4 to 12 fathom; and over these they lay the rafters, with small wood between them; the whole is covered with bilberry-bushes, and then with turf, with fine earth on the top. Their hovels have neither door nor chimney; the use of both being supplied by a vaulted passage made of stone and earth, entering through the middle of the house. The walls are hung on the inside with old worn tent and boat skins, fastened with nails made of the ribs of seals; and the roof is covered with them on the outside. In these huts, so constructed, they are guarded from wind, damp, and cold. The floor is divided into several apartments, separated by skins, according to the number of families for which it is designed. On these floors they sleep on pelts; and they commonly fit them all day long, the women cooking and sewing, and the men carving their tackle and tools. On the front wall of the hovel are several square windows, about two feet in size, made of seal's guts and halibut's maws, and fewed so neat and tight, that the wind and snow are kept out, and the light let in. These huts are all well warmed with fires, and lighted by means of lamps filled with train oil, and furnished with masts instead of a wick, which burns so bright that the hovel is both lighted and warmed by it. Over the lamp is suspended a bollard-marble kettie, in which they boil all their meat; and over this again is a wooden rack, on which they lay their wet cloaths and boots to dry. On the outside of their dwelling-houle they have their little store-houses, in which they lay up their little flock of flicht, fish, train oil, and dried herrings; and close by their store-houses they lay their boots, with their bottoms upwards, under which they hang their hunting and fishing tackle and their skins. Their summer tents are made with poles, put together in a conical form, covered on the inside with reindeer skins, and on the outside with seal-skins, doubled, or so dreidled that the rain cannot penetrate them. Crantz's History of Greenland, vol. 1.

GREENLAND, Eofs, or SPITBERGEN, was formerly con-

sidered as part of the continent of West Greenland, but it is now known to be a collection or group of islands, varying in their extent, and lying between 76 46' N. lat, the latitude of the South Cape, and 80° 30', the northernmost point of the Seven islands, and between 9° and 23° E. long. Sir Hugh Willoughby, who first discovered land in this high northern latitude, A.D. 1553, called it Greenland; conceiving it to be part of the western continent. It was afterwards visited, A.D. 1595, by William Barentz and John Cornelius, two Dutchmen, who claimed the honour of the first discovery, and called the country "Spitbergen," or sharp mountains from the numerous sharp pointed and rocky mountains which they observed in it; and in order to ascertain their own claims, they pretended that this was not the country discovered by Sir Hugh Willoughby, which in the maps and charts delineated by the Hollanders was denominated Willoughby land, though no such land ever existed. It is moreover said, that before the voyage of the Dutchmen, an English navigator, whose name was Stephen Barrows, had coasted along a defolate country from 79° to 80' 11' N. lat. which mull have been Spitbergen; this coast being very minutely visited by different times by navigators, who were employed in exploring a passage to the East Indies by the north-pole; a project which was suggested and strongly recommended by Robert Thorne, a merchant of Bristol, as early as the year 1527. Bourne, in his "Regiment of the Sea," written about the year 1577, mentions this as one of the five ways to Cathay, and seems to admit the practicability of it from a mistaken notion of the mildness of the climate near the pole, owing to the constant prevalence of the sun during the summer. In 1607, a voyage was proposed by some London merchants, for the discovery of a passage by the north pole to Japan and China, and it was undertaken by Henry Hudson, who fell in with land to the westward in 73° N. lat.; and soon after he fell in with Spitbergen, where he met with much ice; and this navigator advanced to the latitude of 80° 35'; but he was prevented from proceeding farther by an ice. In 1609, Jonas Poole was appointed by the Muscovy company on the same service; and he with much difficulty made the north part of Spitbergen, afterwards failing along and founding the coast, giving names to several places, and making many very accurate observations. Having twice attempted in vain to get beyond 79° 30', he was obliged to relinquish his object and return home. A second attempt in the following year was equally unsuccessful. In the year 1614, another voyage was undertaken, in which Baffin and Fotherby were employed; and Fotherby made a second attempt in the following year; but their progress was obstructed by the ice. This country and the adjoining seas have since been frequently resorted to by ships employed in the whale fishery; but its situation was never accurately ascertained till Captain Phips (now lord Malgrev) undertook a voyage by order of his majesty George III. in the year 1775. He found that the land, which was formerly supposed to extend as far as 78° N. lat., terminated with the "Seven islands," the most northerly point of which does not exceed 80° 30' N. lat. He observed other lands lying eastward at a considerable distance; but Spitbergen was found to be encompassed by water and in no part of it to be contiguous to the continent of Asia. He explored, with a degree of resolution and perseverance that did honour to himself and his associates in this expedition, the northern and western coasts, though he was prevented by the ice from advancing so far northwards as he wished; and he ascertained by accurate observation the longitudes and latitudes of several points, capes, and bays, which he visited. On his approach to the land
land he picked up a piece of drift wood, which was found to be fir, and not worm-eaten; and upon standing close in with the land, the coast appeared to be neither habitable nor accessible; it was formed by high, barren, black rocks, without the least marks of vegetation; in many places bare and pointed, in other parts covered with snow, appearing even above the clouds; the valleys between the high hills were filled with snow or ice. "This prospect," he says, in his "Journal," printed in 1774, "would have suggested the idea of perpetual winter, not the mildness of the weather, the smooth water, bright sun-dine, and constant day-light, given a cheerfulness and novelty to the whole of this striking and romantic scene." The current on this coast was found, both by the common and Bouguer's log, to run north half a knot an hour. The height of one mountain, above the level of the sea, was found by measurement with the meganeter, to be 15,035 feet, but by M. de Luce's calculation from observations with the barometer it was found to be 1560.

Among the harbours in which captain Phipps anchored, we may mention a small bay to the southward of Magdalena Hook and Hamburgher's bay; the former in N. lat. 79° 34', the same as Fotherby observed it to be in 1614: the high-water in this bay full and change at half an hour past one, or with a S.S.W. moon, which agrees exactly with Baffin's observation in 1613, the flood coming from the southward. Another anchoring place was Vogel Sang, N. lat. 79° 50'. E. long. 10° 2' 30"; the north eastermost point being the Cleven cliff, 79° 55'. E. long. 9° 59' 30", a bare rock so called from the resemblance of its top to a cloven hoof, which appearance it has always exhibited, having been so named by some of the first Dutch navigators who frequented these seas. It is also nearly perpendicular, so that it is never disregarded by snow, and on these accounts it is one of the most remarkable points on the coast. The southermost land is a high bluff point, called by the Dutch Vogel Sang. This found, though open to the northward, is not liable to any inconvenience from that circumstance, the main body of ice lying so near as to prevent any great sea; nor are ships in any danger from the fothe ice setting in, as this road communicates with several others formed by different islets, between all which there are safe passages. To all the sounds and harbours formed by this knot of islands the old English navigators had given the general name of Fair Haven, of which Fotherby took a plot in 1614. In this situation Hackluyt's Head-laid was found to be in N. lat. 79° 47'. E. long. 9° 11' 30". The tide rose about four feet, and flowed at half an hour after one, full and change. The harbour of Smeerenberg, distant about 11 miles, N. lat. 79° 44'. E. long. 9° 50' 45", has good anchorage in 13 fathom, sandy bottom, not far from the shore; and it is well sheltered from all winds. The island close to the place where our navigators lay is called Amsterdam island, the westernmost point of which is Hackluyt's Head-laid; here the Dutch formerly used to boil their whale-oil, and the remains of some convenues erected by them for that purpose are still visible. They once attempted to make an establishment, and left some people to winter here, who all perished. Nevertheless, as they seem to have died not through the intensity of the cold, but in consequence of being attacked by the fearchy, and as others, both English and Russian sailors, have wintered here, a colony might be settled in this country, if such an establishment were likely to answer any good purpose. The Dutch ships still return to this place for the latter season of the whale fishery. The island found in this country was chiefly a kind of mable, which differed eaily in the marine acid. But our navigators perceived no marks of minerals of any kind, nor the least appearance of presents, or remains of former volcanos. Neither did they meet with insects or any species of reptiles; not even the common earth-worm. They saw no springs, or rivers; the water, which was found in great plenty, being altogether produced by the melting of the snow from the mountains. During their stay in these latitudes, they had no thunder or lightning. The sky was in general loaded with hard white clouds; so that neither the sun nor the horizon was wholly free from them even in the clearest weather. They could always perceive when they approached the ice, long before they saw it, by a light appearance near the horizon, which the pilots called "the blind of the ice." (See Blink.) One of the most remarkable phenomena which this country exhibited was the "iceberg." (See Iceberg.) Of the animals and plants of Spitzberg, captain Phipps has given an account in the appendix to his Journal. The animals are the arctic walrus, the common seal, the arctic fox, the polar bear, the reindeer, the common whale, the fin fish; and the birds the eider-duck, the puffin, the akeala, the fulmar, the colymbus-grylle and trolle, the northern diver, the larus rissa, the arctic gull, and larus eburneus, the greater term, the greater brabling, the sea-finial, the coal-fish, the prawn, the cancer-borens, or singular species of crab, and cancer nauxes, not before described, and also cancer amplus, and cancer pullex; several species of vermes, and shell-fish. Among the plants are a small species of agrotis, several species of fadragis, of bryum, of coelcheairs, and of lichen.

Greenland, a town of America, in Rockingham county, New Hampshire, near the sea, five miles souththerly from Portsmouth, incorporated in 1713, and containing 548 inhabitants.

Greenland Fishery. See Whale Fishery.

Greenland Company. A joint flock of 41,000, was by statute to be called by subscribers, who were incorporated for fourteen years from the first of October 1663, and the company to use the trade of catching whales, whaling, &c., into and from Greenland, and the Greenland feals; they may make bye-laws for government, and of the persons employed in their ships, &c. (Stat. 4 and 5 W. III. cap. 17.) This company was further encouraged by parliament in 1666; but partly by unskillful management, and partly by real losses, it was under a necessity of entirely breaking up, before the expiration of the term assigned to it, ending in 1707. But any person who will adventure to Greenland for whale-fishing, shall have all privileges granted to the Greenland company, by 1 Anne, cap. 16, and thus the trade was again laid open. Any subjects may import whale-fish and oil, &c, of fish caught in the Greenland seas, without paying any custom, &c., Stat. 15 Geo. I. cap. 16. And ships employed in the Greenland fishery are to be of such dimensions provided with boats, for many men, fishing-lines, harping-iron, &c., and he to be licensed to proceed; and on their return shall be paid 22s. per ton bounty, for whales, &c., imported. 6 Geo. II. cap. 53. See Whale Fishery.

Greenlaw, in Geography, a town of Scotland, which, though the county-town of Berwickshire, is an inconsiderable place, pleasantly situated in a plain, bathed by the Blackadder or Blackadder. The acclivities of the surrounding escumences are tolerably cultivated. In its vicinity, about midway between Greenlaw and Kelso, on a rising ground, is Herne castle, which commands a view of the greatest part of the Merse and Roxburghshire, and was celebrated during the contentions on the border. It was a noted place of defence, often besieged by the English, and demo-
GREENOCK.

lified by Cromwell. It is distant 37 miles S.E. from Edin-

burgh, and contains 1270 inhabitants.

GREENOCK, the principal sea-port town on the firth

of Clyde, situated on the south bank of the river, about

24 miles below the city of Glasgow. The town of

Greenock is pretty well situated for commercial purpo-

ses, but in other respects it is neither pleasant nor so

circum-

This

stanted as to afford the prospect of any great increase either

of

extent or population. Indeed the great number of young

men, who, from habits of imitation as in other sea port

towns, early attach themselves to a seafaring life, must

prevent of itself a great obstacle to the latter. The town of

Greenock is held under and is entirely surrounded by the

lands of Sir John Stewart of Blackhall, bart., who is feudal

superior, and no purchase or acquisition of ground, either

for the purposes of extension or improvement, can be had

from any other person. This must of itself render exten-

sion a matter of more difficulty than where there are many

landed proprietors, the lands of some of whom, from the

common casualties and vicissitudes of human affairs, must

be occasionally in the market.

The harbour of Greenock is divided into two compart-

cents, and is entirely surrounded by well-built and com-

modious quays of freestone. The entrance is narrow, and in

the centre opposite to the end of the tidal quay, which serves

as the division of the harbours. The eastern branch is

shallow, and is therefore mostly frequented by coasting

vessels, herring busses, fishing boats, and other small craft.

The west harbour, being considerably deeper, is the general

repos of West Indiamen, American traders, and other

vessels of greater burthen. In the west harbour is a very

capital dry or graving dock, with flood gates to exclude

the water, and capable of containing two large ships at the same

time. It has been long in contemplation to improve the

harbour of Greenock by the erection of wet docks, similar to

those of London, Liverpool, Hull, and Leith, but proba-

bly from the difficulty of engaging the joint conset

of the numerous interests concerned, and other causes, no

steps have been hitherto taken for carrying this

scheme into effect. The principal deficiency of the harbour

of Greenock, exclusive of the ships bottoms taking the

ground every cbi tide, arises from want of water, there

being never more than fourteen or eighteen feet in the har-

bour, even at spring tides. Hence large vessels are obliged

to discharge part of their cargoes into lighters in the roads

before they can come into the harbour at all. This is

of itself a consequence where the cargo is to be brought to

Glasgow, if the weather be mild, but it is very inconvenient

and expensive when the cargo is to be landed, and when

the weather be boisterous. The whole rife of the tide at

Greenock is only about twelve feet, whereas at Liverpool

it is thirty-six and at Bristol forty-two. This also forms an

additional disadvantage to the harbour of Greenock, and

prefents a very great obstacle to every plan of artificial

improvement. With all these disadvantages, however, it has

many advantages over the neighbouring harbour of port

Glasgow, situated about three miles farther up the river.

The chief obstacle to vessels of great burthen making any

of these ports, is an immense bank of sand, accumulated

for many ages in this embouchure of the Clyde by the current

of the river, and which is feebly though slowly increasing.

Indeed nearly opposite to port Glasgow, this bank is en-

tirely uncovered for miles at low water. Notwithstanding

these natural disadvantages, the favourable situation of the

Clyde for maritime intercourse with every part of the

western hemisphere and the south of Europe, the great

coasting trade with the western parts of England and Wales,

and with Ireland, and the extensive herring fishery, has raised

Greenock to a high rank among the commercial ports of

Britain, and has been productive of the acquisition of splen-
did fortunes to many of the principal inhabitants. As

Greenock is not the seat of any staple manufactory, this

carrying trade is her chief, and indeed may be fairly called

her only support. During the American war, when the

carrying trade was entirely suspended in some channels, and

greatly impeded in all the others, a number of ship-owners

fitted out their vessels as privateers, but in general these

speculations were not productive of gain to the adventurers,

and in some instances with furious loss. In the recent wars

no attempts at privateering have been made.

The town of Greenock is governed by two magistrates,
elected annually, and a council; besides whom, the baron

bailli, nominated by the superior, also presides at the judi-

criff court of the county of Renfrew is held at Paisley, to

which the inhabitants of Greenock are ame-

nable; the same as the rest of the county.

In the external appearance of Greenock there is little

elegance or splendour to be seen. In the centre of the town

there is a small square, immediately fronting the mid-quay,

which divides the harbour. In this square is a very hands-

tome church of modern architecture. The other buildings

are the inns, of which the chief, recently built upon a tone

tine scheme, like that of Glasgow, is a very spacious, and

even splendid house. There is also a small neat theatre, the

private property of Mr. Stephen Kemble, the manager, and

some dancing-halls for the occasional recreation of the

inhabitants and strangers, of whom, from the maritime

situation, there is, at certain feasons, particularly at the arrivals

of the West India fleets, a considerable influx.

The scenery of the Clyde around Greenock is picturesque

and sublime. The river is about seven miles broad to the

opposite shore, where the village of Helensburgh is erected upon

the property of sir James Colquhoun of Lüfs, bart. This

village is built in a very pleasant situation, upon a fine bay,

formed by two projecting promontories, viz. by the hill of

Ardmore, on the cafl, and by Rofeneath, the property, and

one of the splendid residences of the duke of Argyle, on

the west. Beyond this, to the westward, appear the lower-

ing mountains of Argyllshire, between which is the vall

arm of the sea, Lochlong, which is twenty-four miles in

length, and in some places faid to be unfeatablely deep. About

twenty miles to the west is a small village, called Gourouk,

situated on a very fair deep bay, well sheltered by project-

ing head-lands, with a very good bottom for anchorage.

It is the opinion of most professional men whether engineers

or seamen, that this situation affords by far the greatest

number of natural advantages for a large and commodious

sea-port upon the Clyde; and it is almost singular that

Greenock should have riven to its present commercial im-

portance, whilst Gourouk, situated within les than two

miles, and possessing every superiority of physical advan-

tage, should have remained an insignificant village. Howev-

er this may have originated, too much capital has now been

expended upon Greenock and Port Glasgow, to leave the

smaller room to fuppose that they will be in any respect

rivalled by a village which possesses nothing but natural

situation to recommend it. On the road from Greenock to

Gourouk are many very fine villas, belonging to the

opulent merchants of Greenock. At both Greenock and

Gourouk are extensive row-works, belonging to the fame

company of proprietors. A little below Gourouk is the

Clonch light-house, a very high and well-built tower, lighted

by reflectors, for the safety of vessels coming up, or going

down the channel during the night. Some miles below this
this is the island of Bute, belonging chiefly to the nobility. Bute is about seven miles long, and generally level and fertile. Mount Stewart, the residence of the noble proprietor, is situated near the middle of the island, on the south side, and is a superb and delightful place. Of the other proprietors, Lord Ban- 

nairne, one of the Scottish judges, is the most conspicuous. The chief, and, indeed, almost only town on the island, is Rothsay, from which his royal highness the prince of Wales derives one of his Scottish titles; is a handsome, clean, small town, and has a considerable cotton mill and manufactory by it, belonging to a company of manufacturers in Glasgow. There are also the ruins of an old castle, which appears to have been of great extent, and once belonged to the royal family of Scotland. The inhabitants of Rothsay are chiefly sea-faring people, and employ themselves much in the her- 

ring fishery during the season. Large quantities of fine cod- 

fish are also caught off the coasts of Bute, Arran, and 

Argyylehire, with which the markets of the west of Scotland 

are supplied, generally at a rate not exceeding two-pence per 

pound of 225 ounces. Contiguous to Bute is a small island, 
called Inch Marnock, which is level and cultivated. It is the 

residence only of those employed in its cultivation. The 

island of Arran is nearly thirty miles in length, and is very 

mountainous. The highest hill, called Cottifield, is seen from 
a great distance. The island of Arran is the property of the 

duke of Hamilton, who is earl of Arran, who has a fine 

house, called Brodieck castle, on the island, where his 

family sometimes reside, especially during the season for 

fishing grose or black game. Arran used to be much 

noted for a smuggling trade, both in contraband articles 
brought by the seamen employed in the vessels trading to the 

Clyde, and also in the distillation of whisky. The vigilance 
of the revenue cruisers in the Clyde has, in a great measure, 
checked the former, and that of the excise officers the latter. 

On Arran are found a number of fine stones, and it is some-
times visited by lapiaders, during the summer, for the pur-

pose of searching for them, or of purchasing those occasion-

ally picked up by the natives. On the island are only 
two small towns or villages, viz. Brodieck and Lamlash, the 

latter of which, being defended from the south winds by an 

island in the mouth of the bay, is reforted to as a shelter in 

stormy weather by the ships and vessels navigating the frith 
of Clyde.

Besides those already mentioned, there are a few smaller 
islands in the frith, viz. the Cumbraes, which are two small 
islands lying pretty close to the southern shore, near the 

Renfrewshire coast, opposite to the village of Largs, about 

16 miles below Greenock. The larger island is about two 
miles long, and on it is a very neat village, called Milport, 

chiefly inhabited by fishermen and seamen's families. The 

latter island is a mere rock, where a few persons reside, who 

take charge of the light-house, and sometimes perfuse in a 

frigate of infamy are boarded here by their relatives, on 

account of the purity of the air, and the retirement of the 

situation. Farther down, and near the Ayrshire coast, is the 

frequental rock, or crag of Ailfa, from which the proprietor, 

the earl of Caflus, derives his British title. Ailfa is a high 

abrupt and barren rock, totally uninhabited, and covered by 

myriads of sea-fowl, in search of which it is sometimes visited. 

Of the general trade of the Clyde notice has already been 
taken under the article Glasgow.

GREENMORE POINT, a cape of Ireland, in the county of 

Wexford, in the Irish sea. N. lat. 52° 16'. W. long. 6° 18'. from Greenwich.

GREENSBORO, a post-town of America, in Well-

Chellet county, New York; 264 miles from Washington. 

Vol. XVI.

GREENSBOROUGH, a post-town and chief town of 

Greene county in Georgia, 30 miles from Lexington: con-

taining 25 houses, a court-house, gaol, and Presbyterian 

meeting-house. Lands are appropriated for the establish-

ment of an academy in this town.—Also, a post-township 
in Orleans county, in Vermont, containing 280 inhabi-

GreeNSBURG, a post-town, and capital of Well-

morland county, in Pennsylvania, situated on a branch of 

Sewickly creek, which empties into Youghiogany river. 

It contains 100 dwelling houses, a German Calvinist church, 
a brick court house, a stone gaol, 270 miles W. by N. from 

Philadelphia.—Also, a post-town in Green county, Ken-

ucky; 875 miles W. by S. from Washington.

GREENSVILLE, a county of Virginia, encompassed 

by Brunswick, Southampton, and Suffolk counties, on the 

N. W. and E. and N. Carolina on the S. It is about 24 
miles long, and 20 broad, and contains 2611 free inhabitants, 

and 4116 slaves.

GREENVILLE, Sir Richard, in Biography, a gallant 

naval officer, son of Sir Roger, of an ancient family, in the 

GreeCE, England; was born about 1545. At the age of 

sixteen he obtained leave from queen Elizabeth, with others 

of his young countrymen, to serve in the imperial army in 

Hungary, against the Turks. Upon his return, he engaged 

with the troops employed for the reduction of Ireland, where 

he displayed to such courage and prudence, as to obtain 

the appointment of sheriff of the city of Cork. He sat in 

parliament in 1571, as knight of the shire for the county of 

Cornwall. He was afterwards high sheriff of the county, 

and received the honour of knighthood. Withstanding his 
civil employments, his attention was chiefly fixed upon plans 
of foreign discovery and settlement, proposed by his relation 

for Walter Raleigh. When the patents were made out for the 

purpose, sir Richard obtained the command of a squadron 

fitted out for the purpose, consisting of seven small vessels. 

With these he failed in the spring of 1585, and reaching 

the coast of Florida in June, he left there a colony of one 

hundred men, and then failed homewards. He made other 

voyages, but when the nation was threatened with the dangers 
of a Spanish invasion, he was appointed one of a council of 

war, to concert means of defence, and received the queen's 

commands not to quit the county of Cornwall, which prevented 

him from executing his intentions of making another 

voyage to the American coast. In 1591 he was appointed 

vice-admiral of a squadron, fitted out for the purpose of 

intercepting a rich Spanish fleet from the West Indies. This 

fleet, when it appeared, was conveyed by a very superior force, 

and Greenville was urged to tack about, but he preferred, and 

no doubt his sailors agreed with him, taking chance of 

breaking through the enemy's fleet, which almost immedi-

ately surrounded him. The Spanish admiral, with four 

other ships, began a close attack at three in the afternoon; 

the engagement lasted till break of day next morning, during 

which the Spaniards, notwithstanding their vast superiority, 

were driven off fifteen times. At length the greater part of 

the English crew being either killed or wounded, and the 

ship reduced to a wreck, no hope of escape remained. The 

brave commander had been wounded at the beginning of the 

action, but he cautioned his wounds to be dressed on deck, 

and refused to go down into the hold, and in that state he was shot through the body. He was now taken to the cabin, and 

while in the act of being dressed, the surgeon was killed by 
his side. The admiral still determined to hold out, willing 

rather to sink the ship than surrender, but the offers of 

quarter from the Spaniards induced the men to yield. Sir 

Richard was taken on board the Spanish ship, and honour-
ably treated, but he died of his wounds in less than three days. His last words were the temper of the hero, better than any eulogium that could be formed for him; they were spoken in the Spanish language. *Here die I, Richard Greenville, with a joyful and quiet mind; for that I have ended my life as a true soldier ought to do, fighting for his country, queen, religion, and honour; my soul departing from this body, leaving behind the lasting fame, of having behaved as every valiant soldier is in duty bound to do.*

This noble minded man has been blamed for rashness; but excess of bravery, if such it may be denominated, in a British than in a true soldier meets with a ready pardon, and such examples as Greenville and a Nelson, though not always to be justified on the score of prudence, have effected more advantages for this sea-girt island, than can be well described. 

Biog. Brit.

**GREENVILLE, Sir Bevil,** grandson of the preceding, was born in the year 1596. He was educated at Exeter college, Oxford, under the celebrated D. Prideaux, where he acquired a large stock of knowledge, and an ardent attachment to the established religion of his country. When he came to his estate he distinguished himself as a most respectable country gentleman, and fat, very often, in parliament, as knight of the shire for the county of Cornwall, and burgess of Lanceton. In 1638, he attended the king with a troop of horse, raised at his own expense, in an expedition to Scotland. For this service he received at the hands of his sovereign the honour of knighthood. He distinguished himself during the civil wars, and had a command in the battle of Stratton, gained by Hopton against the earl of Stamford, in May 1643. He was present, and made a considerable stand in other engagements, particularly in that which was fought at Landdown, near Bath, in which the parliament forces were commanded by Sir William Waller. In this action Sir Bevil, at the head of his Cornishmen, received a fatal blow with a pole-ax. His body was afterwards found, surrounded by the officers; and it was observed, to the honour of the gentlemen of England, that there were more officers and gentlemen, than common men, slain on the king's side. Sir Bevil was extremely lamented: his character was drawn by lord Clarendon: *That which would have clouded any victory, was the death of Sir Bevil Greenville. He was, indeed, an excellent person, whose activity, interest, and reputation was the foundation of what had been done in Cornwall, and his temper and affection for public, that no accident which happened could make any impression on him; and his example kept others from taking any thing ill, or at least seeming to do so: in a word, a brighter courage and gentler disposition were never married together, to make the most cheerful and innocent conversation.* A monument was erected to his memory on the spot on which he fell. 

Biog. Brit.

**GREENVILLE, in Geography, a county in Washington district, South Carolina; situated in the N.W. corner of the state; containing 11,504 inhabitants, of whom 1459 are slaves. This county is mountainous and hilly; but it is well watered, and the climate is pleasant and healthy.**—Allo, a poll-town of South Carolina, and chief town of Cheraws district; situated on the W. side of Great Pedee river, in Darlington county. It contains about 30 houses, a court-house, gaol, and academy; 55 miles E.N.E. from Camden.—Allo, a poll-town and capital of Pitt county, North Carolina, on the S. bank of Tar river, distant 23 miles from Washington, and containing about 50 houses, a court-house, a gaol, and a seminary, called the Pitt academy.—Allo, a poll-town of Mecklenburg county, Kentucky; 766 miles W. by S from Washington.—Allo, a poll-town in Jefferson county, Millip-

*pp.territory; 1217 miles from Washington.—Allo, a small poll-town in Green county, in the state of Tenneesee, situated on the W. side of the north-easternmost branch of Nolacheek river, about six miles N. by E. of Greenville college; 653 miles S.W. of Philadelphia.—Allo, a fort and settlement in the state of Ohio, on the S. side of a north-western branch of the Great Miami, six miles N.W. of fort Jefferson, on the same branch, about 23 miles S.E. of fort Recovery. It has ballons at each angle, and is capable of accommodating 2000 men.**

**GREENVILLE Bay, or La Bay, a town and port of entry on the E. or windward side of the island of Grenada. It has about 60 dwelling-houses, a church, and several rich flowers of Indian and European goods, and plantation utensils. Its situation is low and rather unhealthy.**

**GREENVILLE College, a college in Greenville county, in Tennessee, founded in 1794, by the first act of the first assembly of the south-western territory. It is situated between two small northern branches of Nolacheek river, not far from Greenville, (which fee) the county town. Its local situation conduces very much to its utility, for it is retired, healthy, cheap, and new public roads in all directions. It is under the management of 14 trustees, and possesses a library of between one and two thousand volumes, and philosophical apparatus, and a convenient building.**

**GREENWICH, a market-town and parish in the hundred of Blackheath, and county of Kent, England, is situated on the banks of the Thames, adjoining to Deptford, and 5½ miles distant from London. There are traces of a royal residence at Greenwich fo early as the reign of Edward I, A.D. 1300. Henry IV. dated his will in 1408 from this manor, which was granted by Henry V. to Thomas duke of Exeter, after which it was conferred on Humphrey duke of Gloucester, uncle to Henry VI., who, in 1433, gave the duke licence to fortify and embellish his manor-house, and to make a park of 200 acres; under this grant the duke rebuilt the palace, and included the park, in which he erected a moated tower. On the duke's death in 1447, the manor reverted to the crown; and was a favourite residence of Edward IV., who enlarged and furnished the palace. Henry VII. spent much of his time at Greenwich, where his two sons, Henry and Edmund, were born. Henry VIII. made considerable additions to the buildings, and during his reign Greenwich became one of the principal seats of that festivity for which his court was celebrated. Tournaments and revels were frequently held; and in 1513 the first masquerade ever seen in England was here introduced. Edward VI. kept his Christmas here in 1552, and died in this palace in July following. The queens, Mary and Elizabeth, were both born here, and the latter christened with peculiar state. She was particularly partial to this mansion, and made it her summer residence, passing the festive hours of that romantic period in various diversions and splendid exhibitions. This palace was frequently visited by James I. and Charles I; it was afterwards assigned by parliament to the Protector; and, after the restoration, again devoted, with the park and appendages, to the crown; when the king, finding the whole building in a ruinous state, ordered it to be pulled down, and commenced a magnificent palace of free-stone on its site, under the direction of Webb, the son-in-law of Inigo Jones, from whose papers the designs are said to have been made. One wing, however, was all that was completed, at the expense of 36,000£, in which the king occasionally resided; but no further progress was made in the building either in that or the succeeding reign. Soon after the accession of William and Mary, a project was formed for providing an asylum for aged and disabled lea-
GREENWICH.

and their majesties having resolved to carry it into execution, sir Christopher Wren recommended that the unfin
ished palace at Greenwich should be completed and enlarged for this purpose. His advice being adopted, he contributed
his time and abilities in the superintendence of the works for several years without any remuneration. Such was the origin
of Greenwich hospital, of which the foundation was laid June 3, 1696, and which has been gradually enlarged and
improved, till it arrived at its present height of magnificence. The hospital is a splendid and extensive structure, principally
built with Portland stone, and consists of four distinct quadrangular piles of buildings, distinguished by the names of
the respective sovereigns, in whose reigns they were founded or built. The grand front opens on a terrace, skirting the
northern bank of the Thames, and extends 865 feet in length, in the centre of which is a defect to the river, by a
double flight of steps. The ground plan of the whole edifice forms nearly a square; of which king Charles's building
occupies the north-west angle; queen Anne's, the north-east; king William's, the south-west; and queen Mary's, the
south-east. The interval between the two former buildings forms a square 270 feet wide, in the middle of which is a
statue of George II; sculptured by Rysbrach, out of a single block of white marble, which weighed eleven tons, and
was taken from the French by admiral sir George Rooke: this statue was given to the hospital by sir John Jennings,
who was governor from 1720 to 1744. The space between the two latter buildings which include the hall and chapel,
with their elegant domes, and the two colonnades, forms a lesser square, apparently terminated by the ranger's lodge
in the park. The two squares are interfected by a franeous avenue, leading from the town through the hospital.
The building, which immediately front the Thames have a general correspondence in style and arrangement. The north
and south fronts of each exhibit the appearance of a double pavilion, connected above by the continuation of an attic
order, with a balustrade, which surmounts the whole, but is separated below by an open portal: the centre of each pavilion
displays an elegant pediment, supported by four Corinthian columns, and the fides a double pilaster of the same order.
King Charles's building contains the apartments of the governor and lieutenant-governor, the council-room, and
anti-chamber; with fourteen wards, wherein 300 penitents may be accommodated. In the council-room are several por-
traits; in the anti-chamber two large figures, given to the hospital by Philip Harman, esq., representing the exploits of
his ancestor captain Thomas Harman of the Tyger frigate, in the reign of Charles II.; and a series of six small
pieces, descriptive of the loss of the Luxembourg galley, in the year 1737. Queen Anne's building contains several
apartments for inferior officers, with twenty-four wards, for four hundred and thirty-seven penitents. King William's
building stands to the south-west of the great square, and comprises the great hall, vaulted, and dome, designed and
erected by sir Christopher Wren, between the years 1698 and 1703. To the east of these adjoins a colonnade, three
hundred and forty-seven feet in length, supported by Doric columns, and pilasters twenty feet in height. The
great hall is one hundred and fifty feet in width, fifty-six in length, and fifty high: the cilding and fides are covered with
portraits and emblenctical figures, executed by sir James Thornhill, for which he was paid at the rate of 3l. per square
yard for the cilding, and 1l. for the fides, amounting in the whole to 2685l. The west front of King William's building,
which is of brick, was finished about 1725 by sir John Vanbrugh: the building contains eleven wards, wherein are
five hundred and fifty-one beds. The foundation of the eastern colonnade, which is similar to that on the west
side, was laid in 1699; but the cilding, and the other parts of
queen Mary's building which adjoin it, were not finished
until 1752. It corresponds with king William's, and is furnished
with one thousand and ninety-two beds, in thirteen wards.
The present chapel, one of the most elegant specimens of
Grecian architecture in this kingdom, was erected from the
classical designs of the late James Stuart, esq., better known,
perhaps, by the appellation of "Athenian Stuart," which he
acquired from the Attic elegance of his buildings, and his in-
teresting publication on the antiquities of Athens. The chapel
is one hundred and eleven feet in length, and fifty-two in width,
and is capable of accommodating one thousand penitents,
nurses, and boys, exclusive of the seats for the directors and
other officers. The portal consists of an architrave, frieze, and
corinstitute, of statuary marble: the folding-doors are of
mahogany, highly enriched by carving. The interior is
finis hed in an elegant style; and is adorned with many ap-
propriate paintings; the most distinguished of which is the
altar-piece, executed by Weil, and representing the prefer-
ence of St. Paul, on the throne of Melita; a subject peculiar-
ly adapted to this establishment. Without the walls of the
hospital lies the Infirmary, erected in 1762, after a design by Stuart: it forms an oblong quadrangle, one hundred and ninety-eight feet long, and one hundred and seventy-five broad; and consists of two stories for the reception respectively of those whose cases require
surgical aid, and of those who are in need only of medical asistance. It contains sixty-four rooms, each is fitted up for the accommodation of four patients. It also includes a chapel, hall, kitchen, and apartments for the
physician, surgeon, and apothecary; with hot and cold baths, and other necessary offices. The penitentiaries, who are the objects of this noble charity, must be fanned disabled by age, or maimed, either in the king's service, or in the mer-
chant service, if the wounds were received in defending or
taking any ship, or in fight again a pirate; foreigners who have served two years in the British navy, become entitled to the benefits of this institution in the same manner as
natives. The widows of familian are provided for, having the exclusive privilege of being nurses in the hospital. The number of penitentiaries is upwards of 2400, who are furnished with clothes, diet, and lodging, with a small allowance of
money. The nurses are 144, each of whom receives eight pounds per annum as wages, with every necessary of life.
The governors of the hospital are about 100, and consist of all the great officers of state, the archbishops, the
lord chancellor, the judges, the master and five senior breth-
ren of Trinity-houfe, the lord mayor, and three senior aldermen of London, with some of the principal officers of the
hospital. The annual average expense of each penitentiary, according to the report of the commissioners of naval
enquiry, was estimated at 27l. 10s. 6d. per man; and of the nurses, 29l. 15s. od. each; the total annual expense being 69,206l.
5s. The funds of the establishment are principally derived from a duty of sixpence per mouth, paid by every mariner,
either in the king's or merchant's service; the forfeited eftates of the earl of Devonwater; and various benefactions
from different sovereigns, from parliament, and from private
persons.

The old tower at Greenwich, built by duke Humphrey, temp. Henry VI., was pulled down in 1463, by order of
Charles II., who founded on its site the present Royal Ob-
servatory, for the purpose of ascertaining the motions of
the moon, and the places of the fixed stars, in order to
facilitate the attempts to discover the longitude at sea.

Mr. Flamsted, the first astronomer royal, began his ob-
ervations...
GREGGIES, a town in Algiers; 50 miles E.S.E. of Tiflis.

GREGARIOUS BIRDS, are such as do not live solitarily, but associate in flights or coveys, a great many together in company.

GREGARIOUS, in Greeke, is applied to such reliquia or extraneous fossils, found imbedded in the strata, as are congregated a great number of the same species together, which very commonly is the cafe, particularly in calcareous rocks.

GREGGIA, in Botany, so named by the late Dr. Sanders, in compliment to Mr. John Greg, a gentleman long resident in Dominica, the correspondent of Ellis, Garden, and other naturalists of his day. He sent many plants to Kew and other collections, and returned to England about the year 1784, dying some years afterwards, at his seat near Hampton Court. —Gartn. t. 33. (Myrtus Gregii; Swartz. Ind. Occ. 866. Ait. Hort. Kew. vol. ii. 159. Mart. Mill. Dict. v. iii.) See MYRTUS.

GREGOIE, or GREGOUC, in Geography, a small island of Africa, in the river Jaucque, about a league from the sea, on the Gold Coast, where the European nations have factories.

GREGORIAN CALENDAR. See CALENDAR.

GREGORIAN CHANT. See CHANT.

GREGORIAN CODE. See CODE.

GREGORIAN EPOCHA, is the epocha, or time, whence the Gregorian calendar or computation took place. The year 1816 is the 220th year of the Gregorian epocha.

GREGORIAN NOTES, in Ecclesiastical Music. In the Roman missals, breviaries, antiphonaries, and graduals, only four lines are used in the notation of the chants; with two clefs, the base and tenor, or those of F and C, which are removable; and two kinds of notes, the square and the lozenge; the first for long syllables, and the second for short. In some modern French missals a third species of note is used, generally at a close; this is square with a tail added to it, and is of longer duration than either of the other two. However, the Italians seldom use any other than square notes in their canto fermo, nor did the French, in their more ancient books.

These characters are not supposed to have been invented by St. Gregory, nor were they in use till many ages after his time; but since their invention, having been appropriated chiefly to the purpose of writing ecclesiastical chants in the antiphony of that pontiff, they obtained the appellation of Gregorian notes.

GREGORIAN YEAR. See YEAR.

GREGORIO DE PUERTO VIEJO, in Geography, a district and

Greenwood, a township in Cumberland county, Pennsylvania, having 724 inhabitants.—Allo, a township in Mifflin county, in the same state, containing 969 inhabitants.

Green woods, a large forest of fatly pines in Litchfield county, Connecticut, covering part of that county, and clothed in a green bearded mois, which gives to the whole a gloomy, wild, and whimical appearance.

GREENES, a river of Ireland, in the county of Kildare, which flows by the pretty town of Ballitore, and joins the Barrow; 6 miles S. from Athy.

GREENSA, a town in Algiers; 50 miles E.S.E. of Tiflis.

Greenwich, a township of America, in Hampshire county, Massachusetts, incorporated in 1754, and containing 1,460 inhabitants; 20 miles E from Northampton.—Allo, a township in Gloucester county, New Jersey, on the E. bank of Delaware river, opposite to Fort Mifflin; 6 miles S. E. of Philadelphia.—Allo, a township in Suffs county, New Jersey, on the E. side of Delaware river, in a mountainous country; 31 miles S. W. of Newton; it contained, in 1790, 2,257 inhabitants.—Allo, a town in Cumberland county, New Jersey, on the N.W. bank of Cananzy creek, about 3 miles from its mouth, in Delaware bay, containing about 80 houses and a Friends' meetinghouse; 66 miles S. by W. from Philadelphia.—Allo, a maritime and port-town in Fairfield county, Connecticut, 40 miles E. of New York, and containing 3,147 inhabitants.—Allo, a town in Washington county, New York, on the E. bank of Hudson's river. At the saw-mills of this town much buffecf is done.

Greenwich, East, a port-town, and the chief townshif of Kent county, Rhode island, distant 16 miles S. from Providence, and containing 1,775 inhabitants. It includes a meeting-house and a handsome court-house; and though its commerce is much reduced, it derives advantage from its fisheries, and sends some vessels to the West Indies. It is situated on the N.W. part of Narraganset bay. It is noted for its good cedar, and formerly raised tobacco for exportation.

Greenwood, a township in Cumberland county, Pennsylvania, having 724 inhabitants.—Allo, a township in Mifflin county, in the same state, containing 969 inhabitants.
and town of South America, in the audience of Quito, and jurisdiction of Guayaquil.

GREGORIO, St. a town of Naples, in Principato Citra; 8 miles N. W. of Cangiano.

St. GREGORIO de Ato, a town of New Mexico; 110 miles S. of Santa Fé.

GREGORIUS, in leibthology. See SALMO lavaretus.

GREGORY I. in Biographe, pope, furnaced the Great, and also dignified with the title of Saint, was a native of Rome, and born about 544 or 5. He was defended from one of the most illustrious families in that city, and was educated in a manner suitable to his rank. His proficiency in literary pursuits exceeded the most sanguine expectations of his friends; and it was said that none in Rome excelled him in grammar, rhetoric, and logic. Having left the usual routine of school learning, in the course of which he had imbued sentiments of deep piety, as well as the elementary principles of knowledge, he paid particular attention to the study of jurisprudence, which was necessary to persons who filled those stations, to which he was entitled by his birth. When he came under public notice, he discovered such abilities, integrity, and prudence, in the exercise of the different senatorial employments, that the younger Julian, who was emperor, appointed him to the honourable post of governor of Rome. In this office he acquitted himself to the satisfaction of the emperor, of the senate, and of the people. At the death of his father, he became possess of immense wealth, and being, probably from some disappointments, disillusioned with the world, he determined to embrace the religious life. He devoted the greater part of his property to the foundation of religious houses, and to charitable purposes. He founded six monasteries in Sicily, and one at Rome in his father's house, dedicated to St. Andrew, over which he constituted Valerius abbot, whom he had selected for that post from a country monastery, and to whose discipline he submitted himself. From the time of his taking the vows, he abandoned himself to meditation, devotion, and the most rigorous abstinence. He was, however, in the year 579 taken from his retreat, ordained deacon, and sent nuncio from the pope to the imperial court; the object of this mission was to apply for relief in behalf of the inhabitants of Italy, against the ravages of the Lombards. So ably did he conduct the business, that the emperor was entirely satisfied, and Gregory became one of his principal favourites: he was equally beloved by the principal courtiers, and even by the bishops, notwithstanding the jealousy which they usually entertained of a pope's nuncio. While he was at Constantinople, he had a dispute with the patriarch Eutychius, on the quiddion. Whether, after the re-erection, the bodies of the righteous would or would not be palpable. The argument was carried on in the presence of the emperor Tiberius; Gregory maintained the affirmative side of the question, to which the emperor gave his decided decision, at the same time, he ordered the patriarch to acquiesce in the judgment, and condemned to the flames a treatise of that prelate in support of the negative side of the question. In 583 Gregory was recalled to Rome, and appointed secretary to pope Pelagius, until he obtained permission to retire to his monastery. He was chosen abbot; and in that office exacted of his monks as strict an observance of rigorous abstinence and discipline, as he practiced himself. After a short exercise of the monastic virtues, he was dragged from the cloister to the papal throne, by the unanimous voice of the clergy, the senate, and the people. He alone refilled his own elevation; and his humble petition, that the emperor would be pleased to reject the choice of the Romans, could only serve to exalt his character in the eyes of the emperor and the public, and he not only confirmed the wishes of the people, but congratulated the Romans on the choice which they had made. When the mandate was proclaimed, Gregory solicited the aid of some friendly merchants to convey him in a bæcket beyond the gates of Rome, and he concealed himself a few days in the mountains, and among the woods, where he believed, or affected to believe, that he should be safe from discovery. Notwithstanding this precaution, he was in a few days found in a cave, and brought back in triumph by the people, who would not abandon their charge, till they had taken him to the church of St. Peter, where he was instantly ordained. The pontificate of Gregory the Great, which lasted rather more than six years and a half, is reckoned one of the most flourishing periods of the church; his virtues, and even his failings, were happily united to his faction, and to the temper of the times. His first step was to satisfy the bishops of the chief fees, as to the orthodoxy of his faith. For this purpose, he wrote to the patriarchs of Constantinople, Alexandria, Antioch, and Jerusalem, declaring that he received the first four councils as the four books of the holy gospel; that he reverenced the fifth, and that he condemned the three chapters. In his rival, the patriarch of Constantinople, he condemned the Anti-christian title of universal bishop, which the successor of St. Peter was too haughty to concede, and too feeble to assume; and the ecclesiastical jurisdiction of Gregory was confined to the triple character of bishop of Rome, primate of Italy, and apostle of the West. He frequently ascended the pulpit, and kindled by his eloquence the congenial passions of his audience: the language of the prophecies of the Old Testament he interpreted and applied, and he took the opportunity of improving the present calamities of the people, by directing their hopes and anxieties to the invisible word. His precepts and example defined the model of the Roman liturgy; the distribution of the parishes, the calendar of festivals, the order of procession, the service of the priests and deacons, the variety and change of sacerdotal garments. Till almost the last period of his life, he officiated in the canon of the mass, which continued above three hours at a time. Gregory was no friend to heretics; he spared no pains to arm the civil and ecclesiastical power against the Donatists in Africa, and all who favoured them. At first, he was defeated in his efforts to destroy the harmony that subsisted between the Catholic and Donatist parties in that country: he contrived to introduce invidious distinctions, which by degrees renewed the animosities by which they had been formerly distracted, and terminated in the ultimate triumph of the Catholic, which was the strongest party. Notwithstanding the zeal of pope Gregory against the heretics, he was favourable to the Jews, and protected them against some violent Chritians. In certain letters, which he wrote to the bishops who were for forcing them to embrace Christianity, he condemned perfection of all kinds in the strongest terms, though he enforced it in the instance of Chritians, who ventured to differ from the Catholic creed. On his accession to the papal throne, a general relaxation of discipline, as well as of piety and morals, prevailed in the clerical orders: he immediately set about the correction of these evils with the utmost diligence and perseverance. While Gregory was preoccupied with correction on the clergy, he set before them an example of the conduct which he prescribed. He was strictly attentive to the duties of piety: he was humble, mild, compassionate, hospitable, and disinterested, an enemy to all pomp, grandeur, and show, frequently abridging himself of the necessaries of life to relieve the indigent, and was most indefatigable in instructing his flock, both by preaching and writing.
all his humility, however, Gregory was a most zealous as- 
affor of the power and prerogatives which his predecessors 
had exercised, or at any time claimed. He would declare, 
and no one seemed to doubt the sincerity of his assertion, 
that he would rather lose his life, than suffer the fee of St. 
Peter to forfeit any of the privileges which it had ever 
 Enjoyed, or the prime apollon to be any ways injured, or rob- 
bed of his rights. In the year 593, the emperor Alitled an 
exed, forbidding any soldiers to quit the army, under the pre- 
tension of embracing a monastic life, till the time of their ser- 
vice was expired. The pope determined to remonstrate 
against this decree, being persuaded that the ecclesiastical road 
was more safe than any other to the attainment of a heavenly 
crown. For this and some other acts of interference, the 
emperor expressed his dissatisfaction with the displey taken by 
the pope, in strong and even abusive terms, and they proved 
the means of frustrating this application for a redress of 
grievances occasioned by the cruelty and avarice of the 
empire. The king of the Lombards threatened to lay siege to Rome, in order that he might avenge himself 
of some circumstance that had happened contrary to his 
dignity, but Gregory made friends with his favourites, who 
had themselves embraced the Catholic faith, and by their 
tercessions the prince was induced to draw off his troops. 
About this time the patriarch of Constantinople assumed 
the title of ‘Universal Patriarch,’ a mea sure which alarmed 
Gregory, who made every exertion to prevent him from 
making good his claims. All his entreaties were vain, the 
patriarch enforced his title, and entangled it on his suc- 
cessors. When Gregory was informed of this he denounced 
the patriarch’s commission, and condemned his conduct on 
the occasion as vain, ambitious, profane, impious, execra-
ble, anti-christian, blasphemous, informal, and diabolical. 
In the year 596, Aglulph, king of the Lombards, broke 
into the imperial territories, laying waste the Roman duke-
dom of Campania, and carrying away the inhabitants into 
captivity. On this occasion Gregory exercised the most 
unbounded charity, in relieving the poor, and redeeming 
great numbers of prisoners, not only applying the revenues 
of his fee to those benevolent purposes, but large sums which 
he obtained by his application to the bishops, and the great 
men who were his friends, both in the East and West. 
Under his reign the Arians of Italy and Spain were reconciled 
to the Catholic church, and the conquest of Britain reflects 
less glory on the name of Cæsar than on that of Greg-
ory I. Instead of six legions, forty monks were em-
barred for that dilant ifand, and the pontiff lamented the 
sufferers duties which forbade him to partake the perils 
of their spiritual warfare. In less than two years he could 
announce to the archbishop of Alexandria, that they had 
happened the king of Kent with ten thousand of his Anglo- 
Saxons, and the Roman missionaries, like those of the primiti-
ve church, were armed only with spiritual and super-
natural powers. The credulity or the prudence of Gregory 
was always dispoled to confirm the truths of religion by 
violence and pretended miracles, and he accordingly acquired 
a high reputation with his own and succeeding ages. The 
patriarch of Constantiople dying, he was succeeded by 
Cyricus, whose faith was deemed orthodox by the pope, 
but who perfidied in claiming the title ‘Universal Patri-
arch.’ Gregory still resisted, and in the course of the cor-
respondence which he maintained with the patriarchs of 
Antioch and Alexandria to interell them on his side of the 
dispute, the last mentioned prelate gave him the title of 
‘Universal Pope,’ in hopes thereby to terminate the 
difference between the contending parties. Gregory, how-
ever, rejected the title with great indignation, and by way 
of contrast to the patriarch’s conduct, he adopted the ap-
pellation of ‘Servant of Servants,’ which his successors 
have retained to this day, and affected to use it even when 
distinguished by the most flagitious exercise of pride and 
defeatism. In the year 601, at the request of Angulfus, 
the pope sent a small colony of monks into Britain, and with 
fine directions to that apostle of the Anglo-Saxons, as he 
 has been denominated, as have proved the means of intro-
ducing the gospel corrup tions and superstitions into the 
system of Christianity estab lished through his mission. 
During this same year Sereus, bishop of Maercoles, or-
dered all the images throughout his diocese to be cast out 
of the churches and destroyed; his conduct was not quite 
approved by Gregory, though he pretended to applaud 
Sereus’s zeal, in not suffering any thing to be worshipped 
that is made with hands. Nevertheless, he condemned his 
calling them out of the churches and dashing them to 
pieces, as the effect of an inconsiderate and indirect zeal, 
observing, that “though images were not set up in the 
churches to be worshipped, yet they serve to instruct the 
ignorant : and it is one thing to adorn an image, and an-
other to learn from an image what is to be adored.” During 
the year 662 a revolution took place at Constantinople, in 
consequence of the revolt of the army, at the instigation of 
Phocas, a centurion, who was proclaimed emperor, and 
obtained possession of the imperial city and throne. The 
first object of the new sovereign was to destroy the abdi-
cated prince, with his six sons and a number of his relations 
and friends, and then he got himself acknowledged lawful 
emperor in all parts of the empire. On this occasion, 
Gregory expressed his utmost satisfaction and joy at the 
change that had taken place, without hinting that he 
felt any sorrow at the means by which it had been ac-
complished. He immediately wrote letters to the new 
emperor, congratulating him on his accession to the imperial 
crown, which he said was effected by a particular pro-
vidence, to deliver the people from the oppressions under 
which they had so long groaned, and he even commended, 
flattered, and extolled the tyrant, for his justice, clemency, 
and piety, in the most fullsome terms. His object in this 
abject behaviour was that he might, by means of the in-
fluence of the emperor, defeat the attempt of the patriarch 
to assume the title of ‘Universal Bishop.’ This he plainly 
told to Leontia, the new empress, representing to her what 
bliss they might expect from St. Peter in heaven, pro-
vided they obeyed the patriarch to relinquish the title, which 
the pope considered derogatory to the honour, dignity, 
and interests of his fee. In this object he succeeded, for Phocas 
enacted a law, by which he prohibited the bishop of Constan-
tiople from flying himself ecclesiastical or general patriarch, 
declaring that this title belonged to none but the bishop of 
an ancient Rome. This was not the only instance in which 
Gregory condescended to flatter base and infamous char-
acters: he deemed equal or even greater complaisance to 
Bean haut, queen of France, who is described by Bayle as 
the most wretched woman upon earth, but as capable of 
winning over the clergy to her interest, because at the same 
time that she committed the most enormous crimes, she was 
excessively liberal to ecclesiastics, and founded temples and 
convents, not forgetting to use very devoutly for relics to 
the holy father. In all the letters which the pope wrote to 
him, he treated her with the most abject flattery, declaring 
that no nation in the world was so happy as the French, 
since it merited such a queen, endowed with virtues and fine 
qualities of every kind. In the year 684, Gregory was 
attacked with a severe fit of the gout, a disorder to which 
he had been accustomed, and which rendered him incapable
of performing the duties of his high office. Ambassadors were sent to him from the queen of the Lombards, announcing the birth and baptism of her son; he was unable to write an answer to her majesty, with regard to some difficulties which she wished to have solved, but he returned to her by her ambassador, a complimentary note, containing commendations of her zeal for the Catholic faith, and with presents to the new-born prince, of a crook to wear at his neck, in which was enclosed a piece of the true crocus, as he was pleased to affirm, together with the gospel, in a Persian box. This was one of the last acts of the pope. He died in the month of March 634. Such were the transactions of Gregory I. who, for his talents and merits, been surnamed the Great. There was, however, a strange mixture of inconsistencies in his character. In some respects he discovered a sound and penetrating judgment, but in others the most shameful and superflitious weakness. He was no friend to secular and polite learning; he has even been accused of having destroyed the noble monuments of the ancient magnificence of the Romans, left travellers and foreigners, who came to visit Rome on religious motives, by paying undue attention to them, should neglect the holy places. This accusation does not stand on undeniable evidence. It is doubted by Gibbon and other well-informed historians. "The writings of Gregory," says Mr. Gibbon, "reveal the implacable averton to the monuments of chiefe genius; and he points his fearful cenfure against the profane learning of a bishop, who taught the art of grammar, studied the Latin poets, and pronounced with the same voice the praises of Jupiter and those of Christ. But the evidence of his destructive rage is doubtful and recent; the temple of peace, and the theatre of Marcellus, have been demolished by the flow operation of ages, and a formal proscription would have multiplied the copies of Virgil and Livy in the countries which were subject to the ecclesiastical dictator." Gregory invented new offices for the services of the church, and the sacraments, in which he preferred a vast number of rites and ceremonies that were unknown before his time. He took great pains in reforming the psalms of the church, instituting an academy of choristers, whom he taught to chant, and for whose use he composed that music which goes by his name. He left more writings behind him than any other pope from the foundation of the see of Rome to the present period. These consist of twelve books of "Letters," amounting to upwards of eighty hundred in number. "A comment on the book of Job," generally known by the name of "Gregory's Morals on Job." "A Pastoral," or a treatise on the duties of a pastor. This work was held in such veneration by the Gallican church, that all the bishops were obliged, by the canons of that church, to be thoroughly acquainted with it, and punctually to observe the rules contained in it. He was author also of "Homilies" on the prophet Ezekiel; and on the gospels, and of four books of "Dialogues." His works have been printed over and over again, in almost all forms, and at different places on the continent, as Lyons, Paris, Rouen, Basle, Antwerp, Venice, and Rome. The best edition is that of Paris, in 1705, in four vols. folio. The charity and wealth of this pontiff have already been referred to: in the use of his abundant riches, he acted like a faithful steward of the church and poor. The voluminous accounts of his receipts and disbursements were kept above three hundred years in the Lateran as the model of Christian charity. On the four great festivals, he divided their quarterly allowance to the clergy, to his domestics, to the monasteries, to the churches, the places of burial, the alms-houses, and the hospitals of Rome, and the relief of the diocese. On the first day of every month he distributed to the poor, according to the season, their stated portion of corn, &c.; and his treasurers were continually summoned to satisfy in his name the extraordinary demands of indigence and merit. The diftries of the sick and helpless, of strangers and pilgrims, was relieved by the bounty of each day and of every hour, nor would the pontiff indulge himself in a frugal repast till he had sent the dinner from his own table to some objects deserving of his compassion. The misery of the times had reduced the nobles and matrons of Rome to accept, without a blush, the benevolence of the church. Three thousand virgins received their food and raiment from the hand of their benefactor, and many bishops of Italy escaped from the barbarians to the hospitable abode of the Vatican. Gregory might justly be styled the father of his country, and such was the extreme sensibility of his confidence, that, for the death of a beggar, who had perished in the streets, he interdicted himself during several days from the exercise of sacerdotal functions. Moreri. Gibbon. Lardner.

Ecclesiastical writers feem unanimous in allowing that it was the learned and active pope Gregory the Great, who collected the musical fragments of the ancient hymns and psalms as the first fathers of the church had approved, and recommended to the primitive Christians; and that he selected, methodized, and arranged them in the order which was long continued at Rome, and soon adopted by the chief part of the western church. The anonymous author of his life, published by Canius, speaks of this transaction in the following words: "This pontiff composed, arranged, and constituted the Antiphonarium and chants used in the morning and evening services." Fleury, in his Hist. Eccl. tom. vii. p. 150, gives a circumstantial account of the Sculae Centenum, instituted by St. Gregory. It subsisted 350 years after the death of that pontiff, which happened in 634, as we are informed by John Diaconus, author of his life. The original Antiphonarium of this pope was then sublimed; and the whip with which he used to threaten to scourge the boys; as well as the bed on which he reclined in the latter part of his life, when he visited the school in order to hear them praythe. Two colleges were appropriated to these studies; one near the church of St. Peter, and one near that of St. John Lateran; both of which were endowed with lands.

It has been imagined that St. Gregory was rather a compiler than a composer of ecclesiastical chants, as music had been established in the church long before his pontificate; and John Diaconus, in his life, (ib. i. cap. 6.) calls his collection "Antiphonarium Centenum," the groundwork of which was the ancient Greek chant, upon the principles of which it was formed. This is the opinion of the Abbé Lebon, (Traité Histoire et Pratique sur le Chant Ecclesiastique, chap. iii.) and of many others. The derivation is respectable; but if the Romans in the time of St. Ambrose had any music, it must have been composed upon the Greek system: all the arts at Rome, during the time of the emperors, were Greek, and chiefly cultivated by Greek artists; and we hear of no musical system in use among the Romans, or at least none is mentioned by their writers on the art, but that of the Greeks. Gregory II., pope, was a native of Rome, and educated from childhood, in the Lateran palace, under pope Sergius, who appointed him his sub-deacon, almoner, and librarian. He was afterwards raised to higher polls in the church, and was selected by pope Constantine, as the most learned man of his time, to accompany him when he went to Constantinople, in the year 710. In that city Gregory distinguished himself by answering certain difficulties proposed to him by the emperor Julianus, and solving his doubts with regard to some questions
GREGORY.

in which, it should seem, he was much interested, though what those difficulties were are not ascertained. Upon the death of Constantine, in 715, he was raised to the papal dignity, and almost immediately upon this event, the Lombards made an incursion into the imperial territories, and took by surprise the city of Cumae. Gregory, in his qualities of Holy Father, endeavoured to prevail on them to restore it, first by threatenings of the vengeance of heaven if they should prove so wicked as to retain it, and afterwards by the offer of a large sum of money, and the particular protection of St. Peter, provided they withdrew their troops, and abominated from all further hostilities. Finding that they were equally deaf to the threatenings and promises of the pope, he applied for the assistance of the king of Naples, who, for a stipulated sum, undertook to recover the place, and succeeded in the enterprise. In the year 717, the emperor Theodotius, having resigned the imperial dignity, and retired to a monastery, Leo, the lazaristan, was, by the Senate and army, raised to the throne, on which occasion he wrote a letter to the pope, accompanied with a confession of faith, and also with promises to maintain the Catholic doctrine, as defined by the five general councils and the fathers. Gregory, in return, congratulated the emperor, in warm expressions of respect and loyalty, upon his accession, and assured him, that he would not only receive him for his sovereign, but would use his influence to preserve peace and amity between him and all the Christian princes of the West. In 721, Gregory held a council at Rome, in which several important canons were enacted on the subject of unlawful marriages and other points relating to ecclesiastical discipline. While this council was sitting, Winifred, afterwards archbishop of Mentz, and known by the name of Boniface, arrived on a pilgrimage at Rome, where he was received with extraordinary marks of respect. A few years after this, Ina, king of the West Saxons, arrived at Rome, on a pilgrimage to the tomb of the Apostles, having resolved to renounce the world, and embrace the monastic life. During his stay in the city, he built a college for the education of youth, and the reception of such of his subjects as should undertake pilgrimages; for the support of which he imposed a tax on every house or family, known by the name of Rome-foot or Peter-pence. This tax, which, about the middle of the ninth century, was laid on the whole kingdom of England, was originally deigned solely to the charitable uses above-mentioned, but it was afterwards converted, by the popes, to their own use, and levied under the denomination of a tribute to St. Peter. Still Henry delivered the country of the burden. About the year 726, Leo, determined to restore the Christian worship to its primitive state, forbid all kinds of image-worship, and ceased the edict to be promulgated through the empire. He gave notice of the same to the pope, requesting his assistance in carrying the revolution into effect, but Gregory made no scruple of avowing his decided opposition to the measure, and threatened the emperor with the indignation of St. Peter, should he persist in his projected reform. The emperor was not to be intimidated: he published his edict in Italy, but the populace was seriously against the innovation, and insurrections were immediately excited, which thesoldiery could not suppress without much mischief and bloodshed. Lutrud, king of the Lombards, joined the popular cry, and taking advantage of the disturbances, made a rapid progress in Italy. Every where he declared his readiness to protect image-worship, and every where he was received by the people as one sent from heaven to defend the Catholic faith. These events went beyond the wishes of the pope, he was filled with the utmost consternation, well knowing that if the Lombards were suffered to make head in the Italian territories, he should feel the weight of their yoke. He applied for assistance to Ursus, the doge of Venice, which was readily granted, and which was effectual in rescuing the emperor's dominions from the power of the Lombards. Gregory purified his design, and urged Leo, by all the eloquence in his power, to abandon his plan with regard to image worship; but the determination of the emperor was inflexible, and he took measures to get possession of the person of Gregory, to prevent him from fomenting divisions, and even rebellion among the people. Gregory obtained timely notice of his intention, and frustrated the design: he immediately thundered out a sentence of excommunication against the emperor's exarch, for endeavouring to obey his master; and the people instantly took up arms, overpowered the garrison, pulled down the statues of the emperor, broke them in pieces, and openly declared that they renounced their allegiance to him as sovereign: not satisfied with this, they some time afterwards murdered all those who were adherents to the emperor's cause: and among others the exarch himself. Notwithstanding this opposition, the emperor in 730 held a council of the Senate, the great officers of the state, and the bishops who were at Constantinople, in which it was determined, that as it was found by experience that images could not be suffered to remain in churches, and idolatry prevented, they should all be pulled down and destroyed. This being effected, he made a new effort with regard to the churches in the West: he again solicited the pope, but Gregory's answer breathed a determined spirit of hostility, and was written in a style of arrogance and abuse which was unsuited. He went still further, he assembled a council at Rome, confining of all the neighbouring bishops, which ifused a decree, not only declarative of the lawfulness of worshipping images, but commanding them to be worshipped, and condemning, as heretics, all who did not worship them, or who should presume to teach that they were not to be worshipped. The emperor, indignant at this assumption of power, feizd on the rich patrimonies of the Roman church in Sicily and Calabria, tore from the Roman see the provinces of East Ilyrium, and subjected the whole to the patriarch of Constantinople. By this conduct he inflicted the most severe wound in the heart of the pope, but before he had time to ripen any schemes of revenge, he died in 731, after he had sat in the papal chair near seventeen years. From the details of his actions already given, it appears that Gregory had a zeal for exalting the power and dignity of his see; he was besides arrogant and supercilious. As an author there are fifteen of his "Letters," and a "Memorandum," transmitted to his legates in Bavaria, containing instructions for their guidance in managing the ecclesiastical affairs of that country. These are inserted in the sixth volume of the "Collectio Conciliorum;" he was also author also of a liturgy, which was printed, with a Greek version, at Paris in 1595. Moreri.

GREGORY III., pope, was a Syrian by birth, became a prebender of the Roman church, and was much celebrated for his learning and talents as an eloquent and impulsive preacher. Upon the death of Gregory II. he was unanimously chosen his successor by the Roman people and clergy. He seemed determined to follow the footsteps of his predecessor, and declared himself a determined supporter of the worship of images, and he had no sooner taken possession of his see, than he wrote a letter to the emperor Leo and his son Constantine, whom he had taken as a partner in the empire, exhorting them to renounce their error, and to return, like dutiful children, into the bosom of the church. This letter he sent by Gregory, a prebender of the Roman church, on whose zeal and firmness he thought he could depend, but when
Gregory.

When the presbyter arrived, he understood that the emperors not only maintained their ground, but were determined to extirpate image-worship, and those who presumed to justify it; he therefore thought it most prudent to return to Rome without acquainting them with the object of his mission. On his arrival, the pope was so exasperated at the presumptuous conduct of the emperors which he had shown, that he called a council to determine upon some exemplary punishment, but, upon his promise of going back and executing his mission, he was pardoned. He immediately set out, but as soon as he had landed in Sicily, in his way to the imperial court, he was arrested, his letter taken from him, and he himself sent into exile. In the year 732, Gregory held a council at Rome to revenge himself upon the emperor for sending him a legate to banishment, and he procured a decree to be passed, establishing the worship of images, and denouncing excommunication against all who should presume to pull down, destroy, profane, or blaspheme them: he even expended immense sums on the purchase of pictures and statues with which he filled the churches at Rome, and encouraged the people in the daily worship of them: he likewise caused relics to be brought from all parts to Rome, where he erected a magnificent building for their reception and worship, appointing them an appropriate service, and monks to perform it. He made another unsuccessful effort towards the conversion of the emperor, who, weary of his applications, prepared to reduce the pontiff, and the Romans who supported him, to obedience by force. Upon this event, the people of Rome, at the instigation of the pope, withdrew from all subjection to the emperor, and formed themselves into a kind of republic, in which they were governed by magistrates appointed by their own authority, under the pope, not as prince, but only as their head. After this they were involved in hostilities with Luitprand, king of the Lombards, who ravaged their whole country, and even laid siege to the city. In this extremity, Gregory applied for assistance to Charles Martel, who refused to interfere till proposals were made that the pope and Roman people should solemnly renounce their allegiance to the emperor, as an avowed heretic, and persecutor of the church, and that they should acknowledge Charles for their protector, and confer on him the confessor dignity; and, on the other hand, Charles was to engage to protect and defend the pope, the Roman church, and the people of Rome, against the Lombards, and likewise against the emperor, should they either be attacked or modelled. To these terms Charles readily acceded, and as soon as Luitprand heard of the treaty he abandoned the siege of Rome, and retired to his own dominions. Gregory did not live long to enjoy the fruits of this policy, which contributed materially to the separation of the Italian provinces from the Grecian empire. He died in 741, after a pontificate of between ten and eleven years. The only literary remains of this pope are “Seven Letters,” which are to be found in the fourth vol. of the “Collect. Concil.” Morel.

Gregory IV., pope, a native of Rome, succeeded to the high office on the death of Valentine, in the year 827. He is commended for his extraordinary piety, of which some of the strongest testimonies are repairing and adorning churches and monasteries, and instituting the festival of “All Souls’” day. When the quarrel took place between the emperor Louis le Debonnaire, and his sons, Lotharius per- furred the pope to accompany him into France, to mediate a reconciliation between him and his father. When the pope had served this purpose, he was permitted to return to Rome, where the best action performed by him that we read of, was his rebuilding and fortifying the city of Ollus, as a protection against the defences of the Saracens. This pope died in 844, having presided over the Roman church about 16 years. Three of his “Letters” are extant in the seventh vol. of the Collect. Concil. Morel.

Gregory V., pope, whose original name was Bruno, was a German by birth, and a relation of the emperor Otho. He was chosen bishop of Rome when he was but twenty-four years of age; at his ordination he assumed the name of Gregory; and in a very short time after he feally crowned Otho emperor, who had before been very ill, king. He held a council in the first year of his pontificate, at which the emperor was present, and, it has been said, the German electoral college was instituted, but it is more probable, from the evidence of history, that the origin of this college is to be referred to a later date. Upon the breaking up of the council, he returned to Germany, having first made the Romans swear allegiance to him, and obedience to the pope, but fearely had the Germans repaid the Alps, when Crefcentius, a man of considerable wealth and power, perjured them to revolt, renounce their allegiance to the emperor, and choose him for their head. These events obliged Gregory to fly from Rome, on which occasion Cref- centius declared the fee vacant, and caused a person named Philagathus to be raised to it, who took the name of John XVII. Gregory excommunicated the usurper, and also his patron, a sentence which was confirmed by all the bishops of Italy, France, and Germany. Soon after this Otho, urged by the intreaties of Gregory, returned to Italy, with a large army, and advanced with the pope towards Rome. At their approach, the anti-pope John took to flight, but, falling into the hands of friends of the pope’s friends, was deprived of his flight, and otherwise cruelly mutilated. Crefcentius was also taken, and, with his accomplices, ignominiously executed. Gregory was now restored to his fee, and one of his first acts was to convene a council to meet at Rome, in which the marriage of Robert, king of France, with Bertha, widow of Odo, count of Champagne, was declared incestuous and null. He died in the beginning of 999, having left behind him many honourable testimonies of the vigilance and fidelity which he had exhibited in his office. His reign was very short; there are four of his “Letters” extant, in the 9th vol. of the Collect. Concil. A fifth, concerning the privileges of the abbots of Monfs. Major, may be found in the 4th vol. of “Baluze’s Miscellanea.” Morel.

Gregory VI., pope, whose original name was John Gratian, was defended from one of the most opulent families of Rome, and elected pope in 1044, as successor to Benedict. Upon his accession, there were no fewer than three pretenders who were pretenders to the honour of being successors of St. Peter. In this state, Henry III., king of Germany, resolved to go to Italy himself, and to inquire on the spot into the conduct of the popes, and the state of the church. He assembled a council at Sutri, in 1046, and sent an invitation to Gregory to preside at this council; with which he readily complied, flattering himself that the king would acknowledge him for lawful pope. But when he made his appearance there, a charge was preferred against him of having purchased the pontifical dignity with a sum of money. He confessed himself guilty of the charge, and, quitting his chair, divested himself of his pontifical ornaments before the council, and, begging forgiveness, renounced all claim to the throne of St. Peter. After this abdication, Henry carried him prisoner into Germany, where he ended his days. During the short time that he was at the head of the church, he performed some very beneficial acts. Finding the lands and revenues of the fee greatly diminished by usurpations, the roads infested by robbers, and other disorders pre-
vailing in the government, Gregory acted with such vigour, that a powerful party was roused up against him by those who had been accustomed to live by plunder. Moreri.

Gregory VII. pope, who, by his talents, raised the Roman fee to the highest pitch of power, is said to have been the son of a carpenter, and to have been born at the small town of Soano, in Tuscany. His original name was Hildebrand, by which he is frequently known in history. He was educated at Rome, where he was highly esteemed by Benedict IX. and Gregory VI., on the latter of whom he attended, when he was sent prisoner to Germany. Upon the death of Gregory, Hildebrand embraced the monastic life in the monastery of Cluny, where he was raised to the post of prior. By Leo IX. he was created sub-deacon, and by Nicholas II., archdeacon of the Roman church; by these pontiffs, and by some others, he was successfully employed in several negotiations. Under the pontificate of Alexander II. he was made chancellor of the holy fee, and had the absolute administration of all affairs, both ecclesiastical and civil, as well as the entire disposal of the revenues of the church of Rome. Upon the death of pope Alexander, Hildebrand appointed a falt to be kept, and prayers to be offered up for three days together, before they should proceed to the election of a new pope. While they were performing the obsequies of Alexander in the Lateran church, on the day after his death, the assembled people tumultuously cried out with one voice, "Hildebrand is pope, St. Peter has chosen him!" upon which he was immediately laid hold of and placed by force upon the pontifical throne. This election was confirmed on the same day by the whole body of the clergy and people. His next object was to obtain the confirmation of the king of Germany, which was a matter of no great difficulty, and immediately he took the name of Gregory, out of respect to his friend, Gregory VI. He was the last pope, the decease of whose election was transmitted to the emperor, or king, before his consecration, or who was consecrated in the presence of the imperial envoy. Gregory began his reign by engaging in the most bold and daring schemes for extending the jurisdiction of the Roman fee, and enriching the patrimony of St. Peter. He conceived the design, not only of emancipating the church from all subjection to princes, but of subjecting all princes to the church, and the whole church to his fee; of constituting himself supreme judge and determiner of all affairs, both ecclesiastical and civil; of disposing not only of bishoprics and archbishoprics, and other ecclesiastical benefices, but of kingdoms and states, and the revenues of individuals; and, in fact, fole and despotic monarch of the earth in temporal as well as spiritual. Gregory was from embroiled in a dispute with Henry IV., and he omitted no measures which he thought likely to strengthen his party, and, aided as he was by the superstition of the times, as well as by the resentiment of several princes, whom Henry had dishonoured, or who wished to shake off his authority, he soon created a formidable body of confederates in his support. This confederacy encouraged the pope to think of raising some other person to the throne instead of Henry, and, without hesitation, he wrote a letter to the princes, bishop, and people of Germany, empowering them to choose another king, if Henry did not, by a sincere repentance, render himself worthy of being replaced on the throne, which he had forfeited by his disobedience to the apostolic see. Upon the receipt of this letter, the confederate princes and bishops held a diet at Tribur, near Mentz, and they declared the king suspended from his royal dignity, and added, that if he did not obtain abjuration before the anniversary of his excommunication, he should be excluded for ever from the throne. Henry submitted to the degradation of preparing to throw himself at the feet of the pontiff, to solicit abjuration. He set out for Italy with his wife and infant son, and, after sustaining uncommon hardships in the passage of the Alps, amidst the rigours of an extremely severe winter, he arrived in that country. He was there speedily attended by the counts and bishops of Lombardy, who encouraged him to revenge the treatment which he had received from the pope, and offered to assist him with men and money. Gregory had, in the mean time, proceeded as far as Lombardy accompanied by the countess Mathilda, whose close intimacy with Gregory afforded too much reason for propagating many scandalous reports. Upon hearing of the king's arrival, and of the reception he had met with from his Italian subjects, the pope retired to the strong hold of Canosa, in the diocese of Reggio. While remaining in these fortress, many German bishops, and others who had been excommunicated for taking part with the king, repaired to him barefooted, clothed in hair cloth, to pray for abjuration and forgiveness, which they did not obtain without submitting to severe penance and mortification. The pontiff enjoyed the malignant pleasure of seeing the king added to the number of his humiliated supplicants. It was some time before the pontiff would admit the monarch into his presence, and when the order was inflicted for the purpose, it was on the condition that he should enter at the outer gate of the fortress without attendants; and at the next gate he was required to divest himself of the ensigns of royalty, and put on a coarse woolen tunic, in which drew, and bare-footed, he was suffered to wander for three whole days at the third gate, exposed to the severity of the weather, fasting and imploring the mercy of God and the pope. At length the persons of distinction who were with Gregory, affected at the sufferings of the king, began to complain of the severity of his holiness, which they said was more becoming a tyrant than an apostolical father or judge. These reports were carried to the pope, who on the fourth day admitted the king, and after much difficulty granted him abjuration. When the Lombard lords heard of the treatment which the king had met with, and his opprobrious convention, they were highly incensed not only against the pope, but against Henry, whom they accused of cowardice and treachery, in submitting to beg abjuration of a man whom they were determined no longer to acknowledge as their spiritual head. They deemed, at first, determined to depose him, and place his infant son on the throne; but they appeased their resentment he broke the convention with the pope, refused his title and other marks of royalty which he had laid down, and putting himself at the head of his forces, he prepared to check the pope's immediate ambition. After various successes, in which the confounding armies were alternately victorious, Henry fumoned a council of German bishops to meet at Mentz, who adjourned their sessions to Brixen, where they were accompanied by many of the Italian bishops and German and Italian princes. In this council, Gregory was accused of overfleeting the hierarchy, and making himself the monarch of the church; encouraging faction and rebellion; perfuming, excommunicating, and depoing a peaceable king, and placing a rebel on the throne. For these crimes they resolved that he should be deposed, and another chosen in his stead. Notwithstanding these measures, Gregory was able to recover himself, but he was again embroiled in new difficulties, and the Romans became incensed against the pope whom they considered as the author of the many calamities which they had endured, that apprehensions were entertained of his safety at Rome, and he thought proper to place himself under the protection
without delay for the Holy Land. He wrote also to the emperor Frederic II. exhorting him to fulfill the solemn promises which he had made to embark a sufficient army for the relief of the Christians in the East, adding the severest menaces if he should decline the undertaking, declaring that he would exert the power which heaven had put into his hands, and proceed against him as guilty of the breach of his vows. Frederic was obedient to the order. On leaving having embarked with a large army, he returned in three days, alleging that the ill state of his health rendered him incapable of so great an exertion. His excuses were not deemed valid, the pope would hear of no apologies, and passed on him sentence of excommunication, till at length the emperor embarked for Palestine, but not having found for absolution before his departure, he was still the object of Gregory's resentment, who took every method to render his expedition fruitless, and to excite civil wars in his Italian dominions. Even after the emperor had, by treaty, secured possession of the city and kingdom of Jerusalem, and was preparing for his coronation there, by the patriarch he found that the prelate had been terrified by the pastoral epistles, from taking a part in the ceremony, and had also laid the city, and the church of the sepulchre, under an interdict, that no divine service might be performed in them during Frederic's stay. The German bishops, likewise, who attended the emperor, were so much attached to the patriarch's alarms, that they refused to perform any religious functions, even to be present at the coronation; so that Frederic was under the necessity of taking the crown from the altar, and placing it upon his head with his own hands. On the emperor's return in 1229, Gregory excommunicated him again; and new causes of complaint were continually occurring between Frederic and the pope, the former being desirous of acting for himself, and the latter being fully bent upon reducing him to the most abject slavery. In the year 1241, Gregory called a general council to meet at Rome, and had sent legates with letters to all the Christian princes, entreating them to oblige the prelates in their respective kingdoms to repair to it. At first Frederic contented to the holding of the council, and promised not to molest the bishops who should attend it. But afterwards, finding that the pope was resolutely bent on his ruin, and that he intended to make use of the proposed council for this purpose, and even to arm the whole Christian world against him, he revoked his promises, and published a manifesto, which was sent through the whole of Europe, declaratory of his determined opposition to the pope's project. Nevertheless, great numbers of the bishops attended at Genoa, in their road to Rome, who, with two cardinals and all their treasure, fell into the emperor's hands, and the holy men were sent prisoners to Naples. This disappointment, together with the approach of the emperor, and his victorious army, gave such a shock to the pope, that he was seized with an illness which put an end to his life in a few days. He had been at the head of the church nearly fifteen years, which were distinguished by the calamities in which Italy was involved, chiefly owing to his immediate ambition, injustice, arrogance, and obstinacy. Many of his letters are to be found in the eleventh vol. of the Collect. Concli. Moreri. Bower.

Gregory IX. pope, whose former name was Ugozlin, was created cardinal bishop of Olbia, by pope Innocent III, and was afterwards employed on different legations to Germany and elsewhere, chiefly to preach up the necessity of engaging in the crusades. He was elected pope upon the death of Honorius III. in the year 1227, when he took the name of Gregory IX. Immediately after his consecration he commanded the western bishops to exert their authority, and oblige such persons as had taken the cross, to set out
GREGORY.

Gregory XI. pope, son of the count de Beaumont, and nephew of pope Clement VI. was created cardinal before he had completed his seventeenth year, and even then had accumulated upon him a number of rich benefices for the support of his new dignity. He was honoured also with other high offices in the church, while he was thus young. At this time he could have made no great progress in literary acquirements, but it is much to his credit that after his election he devoted himself to the instruction of the learned Baldi and other eminent tutors, as to become one of the ablest civilians, canons, and divines of his time. Upon the death of pope Urban V. he was chosen his successor, and was consecrated at Avignon, which was then the seat of the papal residence, in the beginning of the year 1371, when he was about forty years old. Almost as soon as he was consecrated, he sent legates to mediate a peace between the kings of France and England, and wrote to these princes, pathetically exhorting them to spare the blood of their subjects, and to compose their differences in a Christian and amicable manner; but unfortunately without succees. In the same year he erected twelve cardinals at once, and upon the election of Sicily to Frederic of Arragon, Gregory erected that island into a kingdom, on condition that the kings should do him and his successors homage. In 1374, the Florentines, having entered into an alliance with the Viconti of Milan, invaded the territories of the church, making themselves masters of several cities, and encouraging the people to throw off the papal yoke, and to refuse their liberties. Gregory's remonstrances on this occasion being fruitless, he issued out a bull of excommunication against the Florentines, which prohibited all people and nations from any communication or commerce with them; declared their estates forfeited, and the lawful property of those who should seize them. To his bull Gregory added other and still more forcible arguments to convince the Florentines of their error. He raised an army of ten thousand men which he sent under the command of the cardinal of the twelve apostles; and which was successful in stopping the ravages of the enemy. The Florentines, whole existence almost depended on their commerce, finding their traffic entirely stopped by the pope's bull, thought it prudent to make an attempt at reconciliation with the apostolic see, but the terms to effect this could not be agreed on by both sides, and hostilities were carried on with ardour, and chiefly in favour of the invaders. Gregory had hitherto resided at Avignon, though he had frequently been invited to Rome. In 1377, he arrived in that city, where he was received with great marks of joy by persons of all ranks, but the magistrates, though anxious for his presence among them, refused to give up any part of their power. Gregory having no means of establishing his authority, thought it prudent, and becoming his dignity, to withdraw to Anagni; but before he left Rome, he wrote several letters to England, against Wickliff and his doctrines, commanding the imprisonment of that worthy reformer and the suppression of his opinions. Wickliff, however, was so much respected and beloved by the English nobility, and people at large, that the bishops, to whom the pope's letters were addressed, did not dare to attempt his arrest. Towards the close of the year, Gregory, having come to some terms with the citizens of Rome, returned to that city, where he continued to receive many mortifications, which led him to the resolution of removing the papal seat to Avignon. But before he could execute his resolution he was taken off by death in 1378, after a pontificate of little more than seven years. He left behind him many letters, of which the greater part have been published by Waddingus. He is praised by his biographers.
biographers for piety, benevolence, and humanity; he was a patron of men of letters, and was himself respectable for learning, particularly in civil and canon law. He was at all times partial to his own relations, and paid more regard to their recommendation in the disposal of preferments than to the merit of the persons whom they recommended. Bowes, Moreiri.

GREGORY XII. pope, whose original name was Angelo Corario, was a native of Venice, and was preferred to the bishopric of that city by pope Urban VI. By Boniface IV. he was made titular patriarch of Constantinople, and by Innocent VII. he was raised to the dignity of Cardinal in 1495. He was now eighty years of age, and upon the death of Innocent in the following year, Angelo Corario was raised to the chair of St. Peter, and at his consecration took the name of Gregory XII. Peter de Luna was a rival candidate for the supreme honour, and assumed the name of Benedict XIII. Upon the consecration of Gregory he wrote to Benedict, and the rival competitors agreed to hold a congress at Savona in the year 1497, accompanied by their respective cardinals, with a view of restoring order in the church. It is probable that neither of them was desirous of this interview, because it was determined to use every means in their power to retain their dignities. Gregory refused to repair to the congress, though the meeting had been proposed by himself, which gave his enemies great advantage over him, his cardinals, elighted at his conduct, defected him, and withdrew to Pisa, where they published a manifesto in justification of their procedure, and an appeal to a general council, of which they sent copies to all Christian princes and states. A council was held at Pisa in March 1499, which was attended by a numerous body of ecclesiastics, and ambassadors from the kings of France, England, Sicily, &c. and after fifteen sessions it passed sentence of deposition against Benedict and Gregory, who were declared guilty of heresy, perjury, and contumacy, and unworthy of the smallest tokens of honour or respect, and cut off from the communion of the church.

Alexander V. was elected in their stead. Gregory, after some fruitless refusals, formally renounced his resignation to the council of Constance, laying aside all marks of the pontifical dignity. The council was so well pleased with his resolution that they decreed civil authority to the degree of cardinal fo long as he lived; and that he should have the precedence among the cardinals, and the title of perpetual legate of the march of Ancona. He died at Recanati in 1417, when he was ninety-two years of age. Some of his letters are extant in the eleventh and twelfth volumes of the "Collect. Com." He never was a man of thinning parts; but at the time of his advancement to the head of the church, he was highly esteemed on account of his probity, but before his death he had so completely lost his character, that no credit whatever was paid to his declarations, though made in the most solemn manner. Bowes, Moreiri.

GREGORY XIII. pope, was born of a very respectable family at Bologna, in the year 1502. He was brought up to the study of the civil and canon law, made uncommon proficiency in the pursuit, and taught the science in his native city with uncommon reputation for more than eight years. When he was about twenty-eight years of age, he took his degree of doctor, and was afterwards appointed judge of the court of commerce at Bologna, erected for the trial of mercantile causes. He resided for some years in Rome, was admitted into the church, obtained considerable preferment, and on the death of Pius V. in 1572, he was unanimously elected his successor, and at his consecration he took the name of Gregory XIII. The most important event in the pontificate of Gregory, was the reformation of the calendar, according to a method suggested by Lewis Lilio, a Calabrian astronomer, which concluded his death was presented to the pope by his brother. This method, which is fully explained under the word Calendar, and referred to in diverse other articles in our work, was immediately adopted in all Catholic countries, but was rejected by the Protestants, and by the Greeks, who chose rather to remain in error, than be indebted to the pope for the knowledge of the truth. In 1584, Gregory incurred the suspicion of having encouraged the assassination of Elizabeth queen of England, by Parr, an English Catholic, who was detected in a conspiracy against the queen's life. There was, however, no direct proof of Gregory being at all privy to the scheme. This pope contributed greatly to correct and amend the calendar, and he enriched with learned notes. A short time before his death, he received ambassadors from the islands of Japan, where the labours of Xavier and other Jesuits were said to have been crowned with abundant success. The ambassadors had a most flattering reception given them, and great regaleings were ordered to be made in the name of the pope, in account of the person which he appointed to open, of triumphs to the Catholic faith in a rich and populous empire. In the midst of these rejoicings Gregory was seized with a quinsy, which carried him off in the 84th year of his age, and the 14th of his pontificate. Several of his "Letters," "Harangues," &c. are said to be in existence, and preferred in the cabinets of the curious. He was much beloved by the Romans on account of the mildness of his government, which, by degenerating into weakness, gave occasion to numerous irregularities, and an almost general corruption of manners in the ecclesiastical state. He was a zealous friend to the Jesuits, to whom he granted many privileges, and built for their use, and richly endowed, the Roman college, and nearly thirty other seminaries in different parts of the world. Bowes, Moreiri.
Gregory XV., pope, descended from a noble family at Bologna, and named before his election, Alexander Ludovisi, was born in the year 1554. He was educated among the Jesuits at Rome, and then returned to Bologna, where he studied the civil law, and took his degree of doctor in that faculty. Having attained this literary honour, he went back to Rome, where he acquired the friendship of three popes, viz. Gregory XIV., Clement VIII., and Paul V. of whom the last appointed him archbishop of Bologna, and put him out as nuncio to adjust some differences which had taken place between the Spaniards and the duke of Savoy. For his able conduct in this difficult business he was promoted to the rank of cardinal. On his return he refereed on his diocese till the death of his patron Paul, in 1621, when he went into concile with the other cardinals, and was almost unanimously chosen pope, and assumed the name of Gregory XV. Where his own particular sentiments were not immediately concerned, he was a man of mild manners and very human disposition, but the whole of his papacy was marked with a violent excess of zeal and bigotry against the Protestants. As the Hugonots of France had, by the violation of the edict of Nantes, been driven to take up arms in their own defence, he wrote to Lewis XIII., exhorting him, by every argument in his power, to destroy or extirpate them; and to prove the extent of his zeal, he accompanied the letter with a bull, intended to animate the Papists in their flagitious and savage undertaking. He next published a bull, preferring a new form in the election of a pope, by which the cardinals were allowed to give their suffrages freely, by way of suffrity, by which he intended to prevent the chiefs of parties from having so great an influence in future elections. As a politician, he supported, to the utmost of his power, the emperor Ferdinand II. and Maximilian, duke of Bavaria, against the elector palatine of the Rhine, fon-in-law of James I. of Great-Britain: by his aid they were enabled to obtain the palatinate, an event that gratified him as well by the injury which it did to the interests of the reformed religion in Germany, as by the share which it gave him in the spoils of the valuable library of Heidelberg, a part of which was transferred to the Vatican. He also attempted the destruction of Calvinism, by endeavouring to persuade Lewis XIII., to allow the duke of Savoy to feize upon Geneva, the nursery of that system; but in this object he was disappointed. He was likewise unsuccessful in an attempt which he made to re-instate the Jesuits at Venice, from whence they had been banished during the pontificate of Paul V. In 1622 the Turks invaded Poland with a formidable army; to re-secure their power, Gregory sent immense supplies of money to Sigismund, by which he was enabled to withstand the barbarian power, and finally to gain a signal victory over them. About the same time the pope instituted the famous college, "De propaganda fide," and endowed it with ample revenues for the maintenance of professors to be educated for foreign missions. Gregory endeavoured to turn his own purpose the intended marriage between the princess of Wales, son of James I., and the infanta of Spain; he refused to grant a dispensation for the marriage, but upon very severe conditions, to all which James seemed willing to submit, when the affair was suddenly stopped by the pope's death, which happened in 1623, after he had filled the papal see about two years and a half. He was the author of some literary productions, which have been lost, likewise of "Epilola ad Regem Perfarum Sech Abbas cum notis H. galfoni," and "The Decision of the Rota." He is highly commended for his piety and great learning, particularly in canon law, and for his charity to the sick and poor. He was, in a certain degree, the encourager and patron of learning, and when his nephew, cardinal Ludovisi, had formed a kind of literary academy in his palace, he was frequently present at their meetings, and did all in his power to promote the extension of science and useful learning. He was a great friend to the Jesuits, and canonized their founder, Francis Xavier, and by him the see of Paris was withdrawn from jurisdiction to that of Sens, and erected into an archbishopric. Morei. Univer. Hist. Bower. Gregory of Neo-Cæsarea, surnamed Thaumaturgus, or Wonder-worker, from the miracles which he pretended to perform, was born at Neo-Cæsarea, in Pontus, and flourished in the third century; he is usually styled a saint, and was, known, before his conversion to Christianity from Paganism, by the name of Theodosius. His father was a zealot for the principles in which he educated his son, but he caused him to be instructed in the elements of useful and ornamental learning. He provided for him the most able tutors, one of whom earnestly recommended to his pupil the study of the Roman law, as what might be highly advantageous to him in future life. With this advice he complied, and made himself master of the principles of the science. Having laid the foundation of learning at home, he set out upon his travels. In Phœnicia he endeavoured to improve his knowledge of law under the celebrated professors of that science who refided there. He had a filler married to a lawyer in high esteem with the governor of Palentia, and chosen by him to be one of his counsellors. This lady was sent for by her husband to Cæsarea, and as the officer who came to escort her brought with him a greater number of carriages than were sufficient for her and those who would attend her, Gregory was induced to make one of the party. At Berytus he attended a school of philosophy lately opened by the celebrated Origen. For five years Gregory and his brother were disciples of this great master, who instructed them in logic, physics, geometry, astronomy, and ethics. He encouraged them in reading all sorts of ancient authors, poets, and philosophers, whose tenets were not sceptical. He restrained them only from such as denied a deity, or a superintending providence. It was during their attendance upon Origen that they became enlightened and zealous Christians; he introduced them to a knowledge of the sacred scriptures, and explained to them the passages which to their minds might appear obscurer and difficult. About the year 239, Gregory returned home; he took leave of Origen with great regret, but not before he had pronounced before a numerous auditory a panegyrical oration in praise of his tutor, which is extolled by Dupin as one of the finest pieces of rhetoric in all antiquity, and which affords at once a proof of the writer's eminent abilities, and of Origen's excellent method of educating those who were placed under his tuition. The tutor was attached to his pupil, and after his return to Neo-Cæsarea, he wrote to him a letter, intending, no doubt, that he should make what use he pleased of it, commending his excellent parts, which, he said, qualified him either to become a Roman lawyer of the first rank, or a philosopher of eminence among the Greeks, but he could rather wish that he would employ his great talents in the service of the Christian religion, which might better advantageously serve his exertions. His celebrity led many to sollicit him to open a school of philosophy in his native city, but a difference in himself led him rather to withdraw from public notice. He was next urged to undertake the office of Christian bishop, an application which he refiled a long time, though, at length, he was induced to accept the charge, and was ordained, according to Dr. Lardner, by Phœbus, bishop of Amasea, about the year 245. He was recommended to give all his exertions to his native city, which was large and populous,
GREGORY.

populous, but immered in superficiality and idolatry, and contained but very few Christians. By his great zeal, united to much prudence, he made numerous converts to Christianity, and established a church which is said to have been truly apostolic, both with respect to doctrine and discipline, and to have retained its purity, long after surrounding churches had admitted novelties and innovations which were a departure from their religion, and infensibly led the way to the grossest corruptions and abuses. This church went on flourishing and increasing under his care till the Decian persecution, in the year 250, when he thought it prudent to withdraw into retirement till the storm was blown over. He afterwards returned to his flock, among whom, during the remainder of his life, he discharged the duties of a faithful and vigilant pastor, and was instrumental in bringing not only the whole city, but the dependent district into the profession of Christianity. He was present at the first council at Antioch, in 264, when the case of Paul of Samosata was the subject of enquiry, and Gregory, with others, exerted themselves in preventing any harsh measures from being adopted against him. He is thought not to have long survived the meeting of this council, and to have died some time in the year 265. Upon the whole he was a great and good man, eminent for purity and simplicity of manners, zealous for the interests of the Christian faith and profession, and anxious to preserve them undaunted with superficialities and practices. The only works of his that are extant, which are unquestionably genuine, are his "Oration in Praise of Origen," and "A Paraphrase on the Book of Ecclesiastes." "A Canonical Epistle," consisting of eleven canons, is ascribed to him by some authors, but it is rejected by other very able and learned critics, and is considered to have been added by some modern Greek. His pieces have been frequently printed; they were collected into one volume at Paris, in 1626; and Gerard Vosius published an edition of them at Mentz, in 1604, in 4to. Dr. Lardner says there are two things to be lamented, 1st. That no more of this excellent man's writings have come down to us. It is plain that some of his writings are lost; for Jerom speaks of his epistles, whereas there is only one remaining. And B Alf mentions an "Exposition of Faith," or a "Dialogue with a Gentle," which is not now in existence. 2dly. That we have no history of his life, written by some contemporary. It may be well supposed that this apostolical man was chiefly employed in increasing his church, or in building it up in knowledge and virtue, by oral instructions and works of goodness. His church continued itself in the faith after his death, and near the end of the fourth century the Neo-Cæsarians were all Christians, having been all along to that period blest with pastors who were men of true worth. As Gregory, therefore, was an honour and ornament to the churches in his time, so his church continued to be an ornament to him. Lardner's "Christian" vol. 2. p. 368.

GREGORY NAZIANZEN was born near Nazianzum, in Cappadocia, about the year 324. His father was not brought up a Christian, but, by marriage, became a convert to the true faith. His learning, piety, and many virtues, pointed him out as a proper person for filling the episcopal character, and he was accordingly ordained, and appointed to the see of Nazianzum, where he officiated as pastor for the space of forty-five years. Gregory afforded only proofs of excellent natural abilities, and a serious turn of mind, and having made great proficiency at home, he was sent, for farther improvement, to different public seminaries of learning. He was first placed at Caesarea, in Cappadocia, whence he removed to Caesarea, in Palestine; thence to Alexandria, and proceeded from that city to Athens, where he intended to finish his academical studies. At the last named city he became acquainted with Balfi, celebrated in the church, and likewise with Julian, who was afterwards emperor. With the former he entered into the frictious habits of friendship. They lived together in the same house, united in the same studies, and embraced the same tenets in religion. Having been a considerable time at Athens, he felt a strong desire to visit his friends at home, and set out for Constantinople, on his journey homewards. At that city, he met his brother, Caesarius, who had just returned from Alexandria, and here he was strongly urged to settle, but by the influence of Gregory he declined all the flattering offers made him, and returned with him to Nazianzum. Gregory, on his return, was baptized, being about thirty years of age, and from this period he seems to have chiefly devoted himself to a studious and ascetic life, prafticing the austerities of monstery, and mixing no further in the business of the world than was necessary for the management of his father's concerns. In the year 359, he visited Balfi, in his retirement among the mountains of Pontus, and subjected himself to the same severe discipline which he preferred. He had not long enjoyed the company of Balfi, when he was sent for in haste to allay a ferment that had occurred in the church of Nazianzum. He succeeded in reconciling the differences that had occasioned the discontent; entered into orders; and was ordained presbyter. Julian, the avowed and malignant enemy of the Christians, had now ascended the throne: he published a law intended to prevent the adherents to the gospel from being instructed in the arts and sciences, hoping to render the followers of Christ barbarians; but this effort was partly defeated by the two Appollonarii; and Gregory, who wrote a number of poems in all kinds of verse, on divers serious subjects, by which the lips of the Greek and Roman classics was in some degree compensated to Christian students, on account of their excellencies and beauties as compositions. Gregory officiated for some years as assistant to his father in the pastoral office. In this situation he was instrumental in promoting the election of his friend Balfi to the see of Caesarea, in the year 370, a circumstance, though well meant by Gregory, which had nearly occasioned a rupture between the two friends; and which determined Gregory to withdraw into retirement, where he hoped he might be allowed to spend his life in study and religious contemplation; but by his father's earnest entreaties he was induced to become his coadjutor in the episcopal office at Nazianzum, on the express condition, that after his father's death he should be perfectly free from all obligation to that charge. Accordingly when this event took place, in the year 374, he quitied Nazianzum, and retired to Sclencia, where he continued for a long time in a monastery before he returned to his native country. About the year 378 Gregory, among others, was deputed, on account of his great learning, to go to Constantinople to afford in defending the Catholic cause against the Arians, who were making head against them. When he arrived at the city he found the Catholic cause reduced to the lowest ebb, so that the Catholics themselves durst scarcely venture to avow their opinions. At first he only preached in a private manner at his lodgings, but in a short time the fame of his eloquence brought multitudes to hear him, and he converted the house in which he was into a church; to this he gave the name of Anastasia, or the Resurrection, because the Catholic cause seemed to have its resurrection in this particular spot. His discourses excited the jealousy of the Arian party, who instigated the populace to attack him and his friends with clubs and stones, both in the streets and at
his church. Gregory they dragged like a malefactor before the magistrates, accusing him of being the cause of tumult and sedition, but he was acquitted of all malice, and the persecution by which he experienced served only to increase the number of his followers. His great celebrity attracted difficulties from distant parts, among whom was St. Jeron, who frequently boasted of having had the honour and happiness of studying under such a master. The Catholics were now sufficiently strong in number to desire the re-establishment of the episcopal office among them, and expressed their unanimous wish that Gregory would undertake it. He met with a rival in Maximus, an Egyptian Cynic philosopher, whom he had himself baptized, and admitted to the lower orders of the church. This perfon contrived a scheme for supplanting him in the episcopal throne by intrigue and boldness, and engaged some of the Egyptian bishops to favour his views. Gregory, on account of ill health, was obliged to quit the city for the sake of the country air, and the confederates, unwilling to lose any time, during the first night of his absence broke into his church, and placed Maximus upon the throne. The great body of the people of all classes and parties in religion were indignant at this conduct; they assembled, and with the utmost fury drove the intruders out of the church, who were now obliged to consult their safety by flight. This attempt to supplant him produced much uneasiness in the breath of Gregory, and made him very desirous of retirement, and after a time he determined to resign a charge which involved him in increasing troubles. He accordingly announced his intention to his people in a farewell discourse, in the course of which he pathetically exhorted them to persevere in the orthodox faith which he had taught them, and to be mindful of the labours and sufferings which he had undergone for that cause. No sooner had he finished his exhortations, than he was surrounded by persons of all ages, sexes, and qualities, who were to earnest in their entreaties that he would remain, that, at length, he promised not to defect them till the eastern bishops, who were expected soon to assemble at Constantinople, should relieve him by choosing a more worthy person to occupy his place. About this period Theodorus the Great was created a partner in the imperial throne, and in a short time felt the support of the orthodox faith; he issued an edict, commanding all his subjects to receive the Catholic doctrine of the Trinity under the heavy penalty of being treated as heretics and infamous persons. In the year 380 he came to Constantinople, where he treated Gregory with the greatest kindness and respect, and told him that God had sent him to give him possession of the church, which he was ready to deliver up into his hands as a reward of his labours. A day was appointed for his installation, but, at Gregory's request, the ceremony was deferred for the present, and soon after having obtained the emperor's consent, he abdicated his episcopal throne, and retired to his paternal estate, near Nazianzum, with the resolution of spending the remainder of his days in studious retirement, and the exercises of devotion. In 382, however, Gregory was summoned to meet the eastern bishops at Constantinople, but he refused to attend, and told the fathers very plainly that experience had taught him how little good was to be expected from any such assemblies, in which pride and ambition chiefly predominated, and which were rather calculated to widen than to conclude differences among Christians. Upon his return to his native country he was strongly importuned to undertake the charge of the see of Nazianzum, which had continued vacant from the time of his father's death, but he could not be prevailed upon to quit his retirement, where he died in the year 389, supposed to be about the age of sixty-five years. He was, in many respects, a great and a good man, and an ornament to the age in which he lived. His piety was ardent and sincere, though not unaccompanied with superfluous, and his morals strict and regular, but partaking too much of the severity enjoined by monastic institutions. His benevolence and charity were boundless, and they led him to devote the whole of his income to the relief of the poor and afflicted. The works of this father consist of "Sermons," "Letters," and "Poems." They were first published at Basli in 1550 in Greek; but the best edition of them was published by Morel, in two volumes folio at Paris 1659. By Dupin he is clasped with the most perfect orators of Greece, yet he admits that his style had too many antitheses, similitudes, and other rhetorical embellishments, which sometimes render his oratory effeminate. Erasmus says that he was discouraged from attempting the translation of Nazianzen's works, on account of the acumen and fine parts of his style, the grandeur and sublimity of the matter, and the obscure allusions which are frequently intermixed among his writings. Moreri. Dupin.

Gregory, furnish'd Nymph, a faint and father of the church in the fourth century, was a younger brother of St. Basil, and born at Cappadocia about the year 322. He was originally intended for the ecclesiastical life, though for some time he practised as a professor and philander, with great success and applause. At the persuasion of Gregory Nazianzen, he was induced to relinquish his secular pursuits, and to apply with great diligence to the study of theology, and whatever was connected with it. As soon as he had taken orders he became so eminent in the pulpit as he had formerly been at the bar. About the year 372 he was ordained bishop of Nyssa, in Cappadocia, by his brother Basil. He became distinguished for his opposition to the Arian party, and on that account was banished by the emperor Valens two years after his ordination. On the death of that emperor, he was recalled by Gratian, and referred to the polliion of his episcopal see. In the year 378 he was present at the synod held at Antioch, and on his return he paid a visit to Jerusalem, in the hopes of gratifying his wishes in viewing the scenes of Christ's ministry, death and resurrection, and the sanctuaries which existed among Christians in that city. Instead, however, of finding the virtues which might have been expected from the inhabitants of the Holy Land, he found "the place to be a sink of iniquity and debauchery, the seat of envy, malice, adultery, robbery, idolatry, poisoning, and bloodshed, where men afflict each other for a trifling reward, so that in no place were murders so frequently and so easily committed." In 381 he was summoned to the council that met at Constantinople, and to him was confided the task of drawing up a creed, which was adopted, and is the same as that which has been received into the English liturgy, under the name of the Nicene Creed, excepting the words "and the Son," in the part relating to the Holy Ghost, which were added at a later period. He was engaged in other councils, and his name appears in the bills of the prelates who were present at the synod held at Constantinople in the year 544. It is not certain how long he lived after this period. He had entered into the marriage state early in life, and continued to live with his wife after he had been advanced to the episcopal rank. His works, which consist of commentaries on different parts of the scriptures; controversial treatises; sermons and funeral orations; biographies of distinguished persons, letters, &c. are many of them more like the treatises of Plato and Aristotle, than those of other Christians. Moreri.
GREGORY.

GREGORY, GEORGE FLORENCE, commonly known by the name of Gregory of Tours, was born about the year 544. He was educated for the ecclesiastical profession, was a proficient in the learning of the times, and acquired considerable reputation by his talents as a preacher. Being attacked by a dangerous illness, he paid a religious visit to the tomb of St. Martin at Tours, which procured the occasion of his dedication to the nobility, clergy, and other inhabitants of that city, whose good opinion was conciliated by his behaviour among them. So strong was his impression made in his favour, that on the death of Etupomis, bishop of Tours, in 573, he was unanimously elected his successor. In the year 594 he took a journey to Rome, to visit the tombs of the Apostles, and to pay his respects to pope Gregory the Great, who received him with extraordinary marks of esteem. He died soon after his return to his diocese, in 595, when he was in the fifty-second year of his age. He was author of "The History of Franks;" "The Lives of the Saints;" "Fragments of a Commentary on the Psalms," and other pieces. The style ad language of the history are harsh and indelicate, but it supplies the historian with facts which serve to fill up the chains in the annals of the dark ages, and which carry with them strong internal marks of authenticity. The best edition of Gregory's works is that published at Paris in 1669. Moreri. Du Plan.

GREGORY of Rimini, one of the most subtle schoolmen in the 14th century, was born in the city whence he took his surname. He became a monk of the order of the Hermits of St. Augustin, and taught with great applause in the university of Paris. He was made general of his order at Montpellier in 1357, and died in the following year at Vienna. As an author, he is known by "Commentaries on the Four Books of Sentences;" "Commentaries on the Epistles of St Paul;" and "On the Epistle of St. James," by "A Treatise on Ufurry;" "Sermone;" &c. Moreri. Bayle.

GREGORY St. Vincent, a Flemish mathematician, was born at Bruges in the year 1524. He studied mathematics under Clavius, and became a member of the society of Jesuits at Rome. He acquired a very high reputation in the sciences, was chosen to some high offices, and was elected by Philip II., king of Spain, to be mathematical tutor to his son, prince John of Austria. He died at Ghent in 1667, at the age of eighty-three. He is known as author of three learned mathematical works, of which the principal is entitled "Opus Geometricum Quadrature Circuli, et Seclution Coni, decem Libris comprehensum," 1647, in two vols. folio. In this work he shews, that if one asymptote of an hyperbola be divided into parts, in geometrical progression, and from the points of division ordinates be drawn parallel to the other asymptote, they will divide the space between the asymptote and curve into equal portions. Moreri.

GREGORY, JOHN, a learned English divine, was born at Agmonleham, Bucks, in the year 1667. He received a good education, and was placed in the quality of fervitor to Christ-church college, Oxford, in 1624, where he was under the tuition of Dr. George Morley, afterwards bishop of Winchester. In this college he took his degrees, and was appointed one of the chaplains. In the year 1634 he published a second edition in quarto, of Sir Thomas Ridley's "View of the Civil and Ecclesiastical Law," with notes: by this work he acquired a high degree of reputation, on account of his deep and extensive learning, and the skill which he shewed in ancient and modern languages, Oriental as well as European. He obtained some considerable pro- ferment in the church, particularly a prebendary in the see of Salisbury. This he did not long enjoy, owing to the civil wars, in which our author was an active partisan of the royalists. Being now much reduced in his means, he took up his abode at an obscure ale-house near Oxford, where he remained in great privacy, devoting all his time to literary pursuits. He died before he had arrived at his fortieth year; he led, however, attained to the favour and correspondence of many of the greatest men of his age. In 1646 he published "Notes and Observations on some Passages of Scripture," which were afterwards included in the "Critici Sacri." In the year 1650 a collection of his learned tracts was published in quarto, under the title of "Gregorii Potentulae;" he left behind him three translations from the Greek into Latin, which were published in 1665, by Edward Byde, esq. in his own name. They are entitled "Palladius de Gentibus Indice et Brachmanniis;" "S. Ambrosii de moribus Brachmannorum;" and "Anonymi de Brachmanniis." Biogr. Brit.

GREGORY, JAMES, one of the most eminent mathematicians of his age, was born at Aberdeen in the year 1648. He was educated at the grammar school of his native town, and went through the usual course of academical studies in the Marischal college, with credit and reputation. He soon discovered a great turn for mathematical pursuits, and began, at an early age, to make improvements in the science of optics. He published, in 1665, a work entitled "Optica Promota, seu abditata Rationem Reflexorum et Reractorum Mysteria, Geometrica emuncta," &c. quarto. This work, which gave an account of the invention of the reflecting telescope, which will be described in the article Telescope, immediately attracted the notice of mathematicians in all parts. About the year 1664 or 1665, Mr. Gregory came to London in order to get his instrument executed by some able hand; but being disapponted in his object, he laid aside his telescope, and went to Italy, where he resided some years. In 1667 he published at Padua "Vera Circuit et Hyperbolae Quadratura," &c. quarto, in which he announced another of his discoveries, that of an infinitely converging series for the areas of the circle and hyperbola, by which they may be computed to any degree of exactness. He sent home a copy of this work to Mr. John Collins, who communicated it to the Royal Society, where it met with much commendation. Another work, which he published in the following year, was entitled "Geometria Pars Universalis, infirmissum Quantitatum Curvarum Transformationi et Mensura," in which he shewed a method of the transformation of curves. These works procured the author the correspondence of Newton, Huygens, Halley, Wallis, and other most eminent mathematicians. Mr. Gregory was now chosen a member of the Royal Society, and upon his return from his travels he communicated to that learned body an account of the controversy carried on in Italy concerning the motion of the earth. About the year 1668 he was appointed professor of mathematics in the university of St. Andrew's, an office which he held for six years; and in 1674 he was called to Edinburgh, to fill the mathematical chair in that university; this situation he held but little more than a year, when, in the month of October 1675, being employed in shewing the satellites of Jupiter through a telescope, he was struck with a sudden and total blindness, and died in the course of a few days at the early age of thirty-seven. Mr. Gregory possessed an acute and penetrating genius; he was unambitious, and contented with the advantages of his situation as professor, which conduced to the only pecuniary reward of his eminent talents. Besides the discoveries already noticed, he invented and demonstrated geometrically, by the
help of an hyperbola, a converging series for making logarithms, which is recommended by Dr. Halley for practical purposes: he sent to Mr. Collins the solution of the famous Keplerian problem by an infinite series; he discovered a method of drawing tangents to curves geometrically, without any previous calculation, and many other things which shew that the most brilliant part of his character was that of his mathematical genius as an inventor.

Biog. Brit.

Gregory, David, nephew of the preceding, an able mathematician, was born at Aberdeen in the year 1661. He was the eldest son of Mr. David Gregory who had the singular fortune to see three of his four all professors of mathematics, at the same time, in three of the universities; one, David at Oxford, his second son James at Edinburgh, and his third son Charles at St. Andrews. David, the subject of this article, received the early part of his education at his native place, but completed his studies at Edinburgh, where he took his degree of A.M. and so greatly did he distinguish himself in scientific pursuits that he was elected professor of mathematics in that university, when he was only in his twenty-third year. About this period he published from his uncle's papers, with considerable additions of his own, "Exercitatio Geometrica de Dimensione Figurarum, five Specimen Methodi generalis diemiendi quaesis Figurarum." He soon received the excellence of the Newtonian philosophy, and was the first who had the merit of introducing it into the schools by his lectures at Edinburgh. In this city he remained as mathematical professor with distinguished honour and applause till the year 1691, when hearing of Dr. Bernard's intention to resign the Savilian professorship of astronomy at Oxford, he went to London, and was introduced to Sir Isaac Newton, who, perceiving highly of his talents, recommended him to be chosen a fellow of the Royal Society. Newton introduced him to the notice of Mr. Flamstead the astronomer royal, and with his recommendations he was elected Savilian professor, though Mr. Halley was a competitor. Their rivalry laid the foundation of a permanent friendship between these eminent men, and Halley afterwards was the colleague of Gregory, by obtaining the professorship of geometry in the same university. In 1695 he published the substance of his optical lectures which had been read at Edinburgh. This work was entitled "Catoptrice et Dioptrice Sphericae Elementa," 8vo. Dr. Gregory, in 1697, gave a demonstration of the Catenarian curve, or that curve which is formed by a chain fastened at each end. The paper on this curve was printed in the "Philosophical Transactions," and also in a work of much reputation, entitled "Miscellanea Curiosa," as one of the noblest discoveries that had at that time been presented to the Royal Society. The most celebrated work of this learned professor appeared in the year 1701, entitled "Afronomica Physicae et Geometricae Elementa." This was written chiefly with the design of explaining Sir Isaac Newton's geometry of the centripetal forces, as far as his discoveries in astronomy are built upon, and to throw the astronomical part of his Principia into a new and more intelligible form. It was afterwards translated into English, of which the second edition was published in 1726, in two volumes octavo, entitled "The Elements of Physical and Geometrical Astronomy, &c." This impression was revised and corrected by Mr. Stone. In 1703, our author published a splendid folio edition of the works of Euclid in Greek and Latin. He now began to prepare, in conjunction with Dr. Halley, a new edition of "Apollonius's Conics," but he had not proceeded very far in the undertaking before he was cut off by death in 1710, when only in the forty-ninth year of his age. Besides the works of Dr. Gregory printed in his lifetime, two others were published after his decease; one "A Short Treatise on the Nature, &c. of Logarithms," printed at the end of Dr. Keill's translation of Commandeur's Enchuf; and the other "A Treatise of Practical Geometry," published by Mr. Macaulin in 1745.

Gregory, James, brother of the preceding, rose to high eminence as a mathematician. He succeeded his brother in the professorship of mathematics at Edinburgh, which office he held thirty-three years with great reputation, and retiring in 1725, was succeeded by the celebrated Macaulin. Charles, the other brother, was created professor of mathematics at St. Andrews, by queen Anne in 1707. This office he held with great credit thirty-two years, when he resigned in favour of his son David, who succeeded him in 1739. He died in 1756. He published a compendium of arithmetic and algebra in Latin, entitled "Arithmetica et Algebra Compendium, in Usum Juventutis Academicarum," Edin, 1736. Biog. Brit.

Gregory, Dr. George, was a native of Ireland, but at the death of his father, who was a clergyman, and a very elegant scholar, the subject of this article was brought to Liverpool, by his mother, who was a native of Lancashire, where he received the elements of a learned education, which he completed at Edinburgh. He took orders in the church in 1778, and was made at Liverpool till the year 1782, when he removed to London, and obtained the curacy of Cripplegate. In 1785 he became known as the author of a volume of "Elia's," which had an extensive sale, and went through several editions; and in 1789 he published a translation of Lowth's lectures on "The Sacred Poetry of the Hebrews," which was well received by the public. In the year 1784 he was preferred, through the interest of lord Sidmouth, by his majesty, to the living of Wellham, in Essex; he had previously to this obtained marks of distinction from the bishop of London, which, however, were attended with very full portions of emolument. Dr. Gregory did not long live to enjoy the ease and independence which his noble friend intended, by the presentation of the living of Wellham; he died March 13, 1808. Besides, the works already mentioned, he was author of a volume of "Sermons," of the "Economy of Nature," in three volumes; of a "Letter on Literature," in two volumes, and was likewise the editorial superintendent of an "Encyclopaedia of Arts and Sciences," in two volumes. He was author of a Church History in two volumes, 8vo.; and of the life of Chatterton, for whose fate he felt the most sincere commiseration, and divers other works with and without his name. Monthly Magazine.

Gregory, John, an eminent physician, and professor of the practice of physic in the university of Edinburgh, was born in May, 1725. His father was professor of medicine in King's college, Aberdeen; and his grandfather was professor of mathematics, first at St. Andrews, and afterwards at Edinburgh. Thus Dr. Gregory was the third professor of his family in a legal descent; and distinguished to be reckoned, that, from his great-grandfather, David Gregory, esq. of Kimairly, he was the fifteenth descendant who had held a professorship in a British university: his son now fills the same chair at Edinburgh.

John Gregory began the study of medicine at Aberdeen, and afterwards proceeded at Edinburgh, Leyden, and Paris. In the 26th year of his age, he was elected professor of philosophy in King's college, Aberdeen, and had at the same time the degree of doctor of medicine conferred upon him. In the year 1756, upon the death of his brother, Dr. James Gregory, who had succeeded his father as professor
Professor of medicine, he was elected to that chair. But about the year 1755, he left Aberdeen, and went to Edinburgh. Soon after this he was appointed professor of the practice of medicine in the university there, in the room of Dr. Rutherford, who resigned in his favour. The year following, upon the death of Dr. White, he was nominated first physician to his majesty for Scotland. Thus at the time of his death, which took place on the 10th of February, 1773, besides very extensive practice, he enjoyed the highest and most important professional offices, which his native country could afford him.

His first publication, entitled "A comparative view of the state and faculties of men with those of the animal world," made its appearance in 1765. This production combines many just and original reflections, with a liberality of sentiment seldom equalled. It went through four editions in two years. In the year 1770, a second work of Dr. Gregory made its appearance; but without his consent, and even contrary to his inclination. This publication was made from a short-hand manuscript taken at his introductory lectures on the practice of physic, and was entitled "Observations on the duties and offices of a physician, and on the method of professing inquiries in phlebology." Although this production contained much valuable matter, that, had it appeared in a much worfe dress, it could have done him no different, yet he was disfurnished with its form; and, therefore, he soon after published an edition of it himself, in which his former sentiments were propounded with all the advantages of a correct and elegant style. His last publication, "Elements of the Practice of Physic," was intended as a syllabus to his lectures; but he only lived to complete his account of the diseases usually termed febile.

Gregory Bay, in Geography, a bay in the fruited of Magellan, on the S. coast of Patagonia.

Gregory's Island, four small islands in the Mergui Archipelago. N. lat. 10° 36'.

Gregory's Sound, a passage between two of the south isles of Arran, on the western coast of Ireland, being one of the passages into Galway bay.

Gregoire, a town of Africa, in the country of Whidah; found 8. S. of Sabi.

Greewillier, a town of France, in the department of Mont Tomine; seven miles N. of Creutzmarch.

Greifenberg, a town of Lower Carinthia, on the Drave; 25 miles W. of Villaco.

Greifen, a lake of Switzerland, in the canton of Zurich, five miles E. of Zurich. It is about six miles long and a mile broad; on one side the shores are flat or gently rising, on the other side are hills richly wooded. The village of Greifen is agreeably situated on a small promontory, embrowned in a wood.

Greifenberg, a town of Silezia, in the principality of Jauer; 32 miles W. of Jauer. N. lat. 50° 51'. E. long. 15° 30'.—Allo, a town of Hinder Pomerania; 28 miles N. of Stargard. N. lat. 52° 51'; E. long. 15° 12'.

Greifenburg, a town of Germany, in the Ucker Mark of Brandenburg, on the Sprei; 45 miles N.N.E. of Berlin. N. lat. 53° 34'; E. long. 14° 3'.

Greifenhagen, a town of Hinder Pomerania; 37 miles N of Cultheim. N. lat. 53° 20'; E. long. 14° 36'.

Greifenstein, a town of Germany, in the province of Solms Brabant; seven miles N.N.W. of Braunfels. N. lat. 50° 51'; E. long. 8° 25'.

Greifswald, or Gipswald, a seaport town of Anterior Pomerania, on the river Rik, which is navigable to the Baltic. This town has an university founded in 1456. It was formerly one of the Hanseatic towns; 15 miles S.E. of Stralsund. N. lat. 54° 41'; E. long. 13° 23'.

Greifswalde Osee, a small island in the Baltic, off the mouth of the Oder, near the S.E. coast of the island of Uedem. N. lat. 54° 13'; E. long. 14° 3'.

Grein, a town of Austria, on the N. side of the Danube; 62 miles W. of Vienna. N. lat. 48° 16'; E. long. 14° 45'.—Mio, a town of the Arabian Iraq, on the Euphrates; 36 miles N of Sura.

Greitz, or Greitz, a town of Saxony, in the Vogtland, situated on a river which runs into the Elbe. In this town there are some stuff manufactues. It contains about 450 houses; 12 miles S.W. of Zwickau. N. lat. 50° 35'; E. long. 12° 10'.

Greensaker, a town of Sweden, in the province of Vastmanland; 48 miles W. of Stureholm.

Greewa. See Græwia.

Grenada, Lamba de, in Geography, a Spanish Dominican island, in the sixteenth century, was born in the year 1524. He was probably intended for a civil life, and educated with that view, but embracing the ecclesiastical profession, he acquired a high character for sanctity and virtue, and was chosen to fill the most honourable post of his order. He was held in much estimation by the kings of Portugal and Castile, and was made confessor to queen Catherine or Portugual, fitter to the emperor Charles V, who was desirous of appointing him to the archbishopric of Braga, an honour which he resolutely declined: he uniformly refused all the offers of ecclesiastical preferment, and devoted his days to the austerities of monastic discipline, and the composition of pious and devotional treatises. He died in the year 1583. His works are theological, consisting of "A Catechism," in four volumes; "A Treatise on Prayer," in two volumes; "Sermons," in the Latin language, in six volumes; and other pious and practical pieces. The greater part of them has been translated from the Spanish and Latin into French by father Girard, and published in two volumes folio, and eight volumes 8vo.

Grenada, in Geography, an island in the West Indies, about 20 miles in extent from north to south, and about 10 miles in mediad breadth; the extremes gradually contracting northward and southward, and particularly towards the S.W. corner. It was discovered by Christopher Columbus in the year 1498, who found it inhabited by a numerous and warlike people, called Caribees or Caribbees, among whom the Spaniards do not seem to have ever attempted to force a settlement. These original inhabitants remained happy and peaceful until the year 1650, when the avarice and ambition of a redheads individual devoted them to destruction. This person was Du Parquet, the French governor of Martinico, who putting himself at the head of upwards of 200 hardy ruffians, wantonly attacked and determined to dispossess the unoffending natives. This atrocity act was perpetrated under the mask of religion, and with a mixture of fanaticism and knavery which no human mind can contemplate without indignation and horror. Notwithstanding the injustice of this invasion, the commanders administered the holy sacrament, in the most solemn manner, to all the soldiers on their embarkation; and again on their landing, Du Parquet, causing a cross to be erected, compelled them to kneel down before it, and join in this most solemn prayer to Almighty God for success to their wicked enterprise. Checked, however, in the progress of this accursed business by some fragments of
conscience, after he had been hospitably entertained by the natives, he pretended to open a treaty with the chief of the Caribees for the purchase of the country. Accordingly he gave the natives "some knives and hatchets, and a large quantity of glass beads, besides two bottles of brandy for the chief himself," and thus, says Du Tertre, was the island fairly ceded to the French nation by the natives themselves in lawful purchase! And their future refinance was considered as contumacy and rebellion. Du Parquet, having established a colony in Grenada, and built a fort for its protection, committed the government of the island to a knishman, named Le Côme, who engaged in a cruel and bloody war with the Caribees, and being reinforced with 300 men from Martinique, he proceeded to establish and maintain his authority by massacres and murders, the relation of which makes even the reader to tremble. By a series of such enormities, the whole race of Caribees that possessed Grenada in 1650 was speedily exterminated; and the French, having destroyed all the natives, proceeded in the next place to massacre each other. Du Parquet, in the conduct and execution of those measures by which he had gained possession Grenada, had so far impaired his fortune, that in 1666 he was under the necessity of transferring it to Count de Cerillac for the sum of 50,000 crowns. This new proprietor appointed a governor, who, with tapical and ra-pacious disposition compelled the most respectable of the settlers to quit the country; and those who remained, assuming the administration of justice, brought the governor to a public trial, and ordered him for execution. Cerillac, deriving little advantage from his purchase, conveyed all his rights and interest in Grenada, &c., to the French West India company; whose charter being abolished in 1672, the island from that time became vellied in the crown of France. The island, as we may naturally suppose, was very imperfectly cultivated during the progress of these revolutions and calamities; and even so late as the year 1700, if Raynal has been rightly informed, it contained no more than 251 whites and 525 blacks, who were employed in three plantations of sugar, and 52 of indigo. By subsequent intercourse of a smuggling nature with the Dutch, the circumstances of the planters were somewhat improved, so much so that when, in the year 1762, the fortune of war made the English masters of this and the other Caribean islands, Grenada and the Grenadines are said to have yielded annually, in clayed and mucovado sugar, a quantity equal to about 11,000 hogheads of mucovado of 15 cwt. each, and about 27,500 lbs. of indigo. Grenada, having surrendered on capitulation in February 1762, was finally ceded, together with its dependencies, to Great Britain by the definitive treaty of peace at Paris on the 10th of February 1763. The chief stipulations of this treaty were as follow: 1st. That as they would become by their surrender subjects of Great Britain, they should enjoy their property and privileges, and pay taxes, in like manner as those of his majesty's subjects of the other British Leeward islands. 2dly. With respect to religion, they were put on the same footing as the inhabitants of Canada; i.e. liberty was given them to exercise it according to the rites of the Roman church, as far as the laws of Great Britain permitted. 3dly. Of such the inhabitants of Grenada as chose to quit the island, should have liberty to do, and 18 months should be allowed them to dispose of their effects. The island and its dependencies being thus become a British colony, two proclamations were issued, and General Mclwike was appointed governor. The crown, conceiving itself entitled by the terms of the capitulation to the duty of 4/12 per cent. upon all produce exported from the newly ceded islands, ordered such duty to be levied in Grenada, in lieu of all customs and duties formerly paid to the French king. This order occasioned a great constitutional question, which after much agitation was referred to a solemn adjudication before the judges of the court of king's bench in England. The cause was elaborately argued in Westminster hall, and lord chief justice Mansfield, in 1774, pronounced judgment against the crown: and therefore the duty in question was abolished, not only in Grenada, but also in the ceded islands of Dominica, St. Vincent, and Tobago.

The first assembly of Grenada met in 1765; and in 1768 the governor received instructions from the crown to admit two of the Roman Catholic inhabitants into the council, and to declare others to be eligible into the assembly on taking the oaths of allegiance and supremacy. These instructions, and the measures which followed them, were productive of great commotions and party divisions in the colony. The king, however, refused to revoke his instructions; upon which the most zealous of the Protestant members of the assembly declined attendance, so that it was but seldom that a house could be formed. In this state of faction and perplexity the island continued until its recapture by the French under the count d'Eslang, in 1779. By the general pacification which took place in January 1783, Grenada and the Grenadines were restored to Great Britain.

Grenada contains about 80,000 acres of land; of which the quantity actually cultivated has never exceeded 50,000 acres. The face of the country is mountainous, but not inaccessible in any part, and it abounds with springs and rivulets. To the north and the east the soil is a brick mould; on the west side it is a rich black mould on a sub-stratum of yellow clay. To the south the land is in general poor, and of a reddish hue, which extends over a considerable part of the interior country. On the whole, however, Grenada appears to be in a high degree fertile, and by the variety, as well as excellence of its returns, seems adapted to every tropical production. The exports of the year 1776, from Grenada and its dependencies, were 14,012,157 pounds of mucovado, and 927,607 pounds of clayed sugar; 818,700 gallons of rum; 1,827,166 pounds of coffee; 457,195 pounds of cacao; 91,643 pounds of cotton; 27,635 pounds of indigo, and some smaller articles: the whole of which, on a moderate computation, could not be worth less, at the ports of shipping, than 600,000 sterling, excluding freight, duties, insurance, and other charges. The sugar was the produce of 106 plantations, wrought by 18,293 negroes, which is rather more than one hoghead of mucovado sugar, of 16 cwt. from the labour of each negro; a return, says Mr. B. Edwards, equalled by no other British island in the West Indies, St. Christopher's excepted. The exports of 1787 were 175,548 cwt. 9 lbs. of sugar; 670,900 gallons of rum; 4,350 gallons of molasses; 8,512 cwt. 2 qrs. 4 lbs. of coffee; 271,716 cwt. 3 qrs. 18 lbs. of cacao; 2,562,437 lbs. of cotton; 2,810 lbs. of indigo, and miscellaneous articles; such as hides, dyers' woad, &c., to the amount in value of 645,454l. 9s. 9d.; and the total value of all, according to the current prices in London, 641,668l. 9s. 3d.

This island is divided into five parishes, viz., St. George, St. David, St. Andrew, St. Patrick, St. Mark, and St. John; and its chief dependence, Caracou, forms a seventh parish. Since the restoration of Grenada to Great Britain in 1783, an island law has been obtained for the establishment of a Protestant clergy. This act, which passed in 1784, provided stipends of 332l. currency, and 60l. for house-rent per annum, for five clergymen, viz. one for the town and
and parish of St. George, three for the other five out-parishes of Grenada, and one for Caricaou. Besides these stipends, there are valuable glebe lands formerly appropriated to the Roman Catholic clergy, when that was the established religion of Grenada, which became vested in his majesty as public lands on the restoration of the island to the British government, and which, it is said, have been applied by the colonial legislature, with the consent of the crown, to the further support of the Protestant church, with some reference for the tolerated Romish clergy. The capital of Grenada, soon after the cession of the country to Great Britain by the peace of Paris, is called St. George, which fee. The other towns in Grenada are, properly speaking, inconsiderable villages or hamlets, which are generally situated at the bays or shipping places in the several out-parishes. The parish town of Caricaou is called Hillsborough. Grenada has two ports of entry, with separate establishments, and distinct revenue officers, independent of each other; one at St. George, and one at Grenville bay, a town and harbour on the east, or windward side of the island. The whole population of Grenada and the Grenadiers has decreased considerably since these islands first came into possession of the English. In the year 1771, the number of white inhabitants was somewhat more than 1000; in 1777, they had decreased to 1300, and at a later period they were supposed not to exceed 1000, of which about two-thirds are men able to bear arms, and incorporated into five regiments of militia, including a company of free blacks or mulattoes attached to each. There are likewise about 500 regular troops from Great Britain, which are supported on the British establishment. Besides the regular troops sent from Great Britain for the protection of Grenada, there are in its garrison three companies of king's negroes, which came from America, where they served in three capacities, as pioneers, artificers, and light dragoons. In Grenada they form a company of each, and are commanded by a lieutenant of the regulars, having the rank of captain. The negro slaves have also decreased. In 1779 they were flattered at 35,000, of which 5000 were in Caricaou and the smaller islands. In 1785 they amounted to no more than 25,000 in the whole. The free people of colour amounted in 1787 to 11,455. To prevent the too great increase of persons of this class, every manufactory is, by an act of the island, charged with a tax of ten per cent. currency, payable into the public treasury. The evidence of these people, whether born free or manumitted, is received in the courts of this island, on producing proof of their freedom; and they are tried on criminal charges in the same manner as whites. They are also allowed to possess and enjoy lands to any amount, provided they are native-born subjects or caputitants, and not aliens. The governor is, by virtue of his office, chancellor, ordinary, and vice-admiral; and presides solely in the courts of chancery and ordinary, as in Jamaica. His salary is 3200l. currency per annum, which is raised by a poll-tax on all slaves; but in all cases of absence beyond twelve months, the salary ceases and determines. N.B. The currency of Grenada, or rate of exchange, is commonly 6s. 8d. per cent. work silver. The council of Grenada consists of 12 members, and the assembly of 26. A freehold, or life-estate of 50 acres, is a qualification to fit as representative for the parishes, and a freehold or life-estate, in 50l. house-rent in St. George, qualifies a representative for the town. An estate of ten acres in fee, or for life, or a rent of 10l. in any of the out-towns, gives a vote for the representatives of each parish respectively; and a rent of 25l. per annum, arising out of any freehold or life-estate in the town of St. George, gives a vote for a representative of the town. The laws courts in Grenada, besides those of chancery and ordinary are the court of grand-jury of the peace held twice a year, viz., in March and September; the court of common-pleas, consisting of one chief and four assistant judges, whose commissions are during pleasure, the chief justice being usually appointed in England, with a salary of 600l. per annum, and the others being commonly appointed by the governor without any salary; the court of exchequer, lately grown into a diocese; the court of admiralty for the trial of all prize-causes of capture from enemies in war, and of revenue-seizures in peace or war, having one judge of admiralty and one surrogae; and a court of error, composed of the governor and council, for trying all appeals of error from the court of common-pleas. The common and statute-laws of England are considered as extending to Grenada in all applicable cases, not provided for by the laws of the island. N. lat. 10° 17' W. long. 61° 50'. Edwards's Hist. of the West Indies, vol. i.

GRENADE, or GRENADA. See GRANADA.

GRENADE. See GRANADO.

GRENADE, a town of France, in the department of the Landes, and chief place of a canton, in the district of Mont-de-Marin; seven miles E. of St. Saviour. The place contains 1530, and the canton 7563 inhabitants, on a territory of 195 square miles, in eleven communes. — Also, a town of France, in the department of the Upper Garonne, and chief place of a canton, in the district of Toulouse; 12 miles N. N. W. of Toulouse. The place contains 3500, and the canton 9142 inhabitants, on a territory of 232 square miles, in 13 communes.

GRENADIER. See GRANADIER.

GRENADIER, in Ornithology. See LOMA ORIX.

GRENADIN. See FRAGILLA GRANATINA.

GRENADINES, or GRENADILAS, in Geography, a cluster of islands in the West Indies, amounting in number to more than 20, situated between Grenada and St. Vincent, and producing cotton, coffee, indigo, and canes. Caricaou is the principal. These islands formerly appertained to the government of Grenada; but by an arrangement of the British administration, a line of demarcation in an east and west direction, between Caricaou and Grenada, is the term of these, and some smaller islands farther west, are all that are now comprised in the Grenada government: Union Island, with all the little islands adjoining, to the north, being annexed to the government of St. Vincent. See CARICAOU and RONDE.

GRENAILLE, a name given by the French writers to a preparation of copper, which the Chinese use as a red colour in some of their most intact china, particularly for that colour which is called ulered, or red in oil. The china-ware coloured with this is very dear. The manner in which they procure the preparation is thus: they have in China no such thing as silver-coined money, but they use in commerce bars or mests of silver; these they pay and receive in large bargains; and among a nation so fully of fraud as the Chinese, it is no wonder that these are often adulterated with too great an alloy of copper. They pay, however, in this state in the common payments. There are some occasions, however, such as the paying of the taxes and contributions, on which they must have their silver pure and fine; on such occasions they have recourse to certain people, whose how much it is to refine the silver, and separate it from the copper and the lead it contains. Thus they do in furnaces made for the purpose, and with very convenient vessels. While the copper is in fusion, they take a small brush, and dip the end of it into water; then striking the handle of the brush, they sprinkle the water by degrees upon
upon the melted copper; a fort of pellicle forms itself by this means on the surface of the matter, which they take off while hot with pincers of iron, and immediately throwing it into a large vessel of cold water, it forms that red powder, which is called the grenaille; they repeat the operation every time they in this manner separate the copper; and this furnishes them with as much of the grenaille as they have occasion for in their china works. Observations for les Costumes de l'Afrie, p. 359.

Grenahen, in Geography, a town of Switzerland, in the Valais; 25 miles E. of Sion.

Grenat, in Ornithology. See Trochilus auratus.

Grenier, in Geography, mountains of Hindooftan, in the country of Guzerat, near Junagur.

Grenna, a town of Sweden, in the province of Smaland; 10 miles N.N.E. of Jonkoping.

Grenoble, an ancient, large, and well-built city of France, and capital of the department of Isère, situated in a marshy but fruitful plain, at the foot of a hill, near the confluent of the river Isère. Before the revolution it was the capital of Dauphiny, the see of a bishop, and the seat of a parliament. It was the scene of many cruelties in the religious wars, A.D. 1562. It is divided by the river Isère into two unequal parts, the largest of which is regularly built. Its manufactures are cloths, hats, gloves, &c. The number of its inhabitants is 23,5000 in 3 cantons, on a territory of 265 kilometres, in 26 communes. To the north are the ruins of a chateau, an eminence, which commands an agreeable prospect of the town, the banks of the Isère, and several fertile valleys. In a rugged valley, watered by the rapid Drac, about 5 leagues S. of Grenoble, are the mineral springs of La Motte, highly esteemed as a remedy for fluxes and all disorders of the stomach, but little used on account of the difficult access to them. Four leagues N. of Grenoble is Le Grand Chartreusse, a famous Carthusian monastery, founded A.D. 1086, consisting of an excellent library, and many apartments, on an eminence enrobed by rugged precipices of difficult access. N. lat. 45° 11' 59'. E. long. 5° 43' 16'.

Grenouilles, I.e.s, a cluster of rocks in the West Indian ocean, about 36 miles S.E. from Point Morand, in the island of Jamaica. N. lat. 17° 32', E. long. 76° 32'.

Grenville, a town of Nova Scotia. See Granville.

Grenville, a county in Upper Canada, bounded on the E. by the county of Dundas, on the S. by the river St. Lawrence, and on the W. by the township of Elizabeth town, running N. 24° W. till it intersects the Ottawa or Grawal river, and thence defending that river until it meets the north and westermmost boundary of the county of Dundas. This county comprehends all the lands near to it in the river St. Lawrence.

Grenville's Canal, a channel of the N. Pacific ocean, which separates Pat's Archipelago from the coast of New Cornwall.

Grenzhausen, a town of Germany, in the county of Wied; 3 miles N.E. of Cochem.

Grenpoin, a town of Switzerland, in the canton of Lucerne; 5 miles E. of Lucerne.

Gres, Cape A1, a promontory on the E. side of the Milipluppi, in the N.W. territory, 3 leagues above the Illinois river, and the tract of country so called extends 5 leagues up that river.

Gresham, Sir Thomas, in Biography, an eminent London merchant, son of Sir Richard Gresham, who was raised to the high office of lord mayor of the city of London, was born in 1510. He received an academical education at Cambridge, but being designed to follow the commercial business of the family, he was bound apprentice to his uncle Sir John Gresham, and thus became a member of the Mercers' company. His father was agent of the king's money concerns at Antwerp, and Thomas expected to be his successor in this business, but the preference was given to another person, by whose mismanagement they were brought into a deplorable condition. Rose and was now paid to the subject of this article, who was hout over in 1532 by the regency in the minority of Edward VI., in order to retrieve them. In this affair he exerted so much talent, that in two years he was able to pay off the whole of a loan bearing enormous interest, and raised the king's credit to the most respectable rank. At the accession of Elizabeth, he was for a time deprived of his office, but it was restored to him again, and he continued in it as long as he lived. He also received at the hands of his sovereign the honour of knighthood. He transmitted many important pecuniary negotiations of that long and glorious reign, and was a most spirited promoter of the infant manufactures of the kingdom, those of small wares in particular being established chiefly through his means. His own property, derived by inheritance, with that acquired by his industry and talents, made him the richest subject in the metropolis, and he made use of his wealth to noble and extensively benevolical purposes. In 1564 he had the misfortune to lose his only son, and he fell upon the moans of diverting his grief on this melancholy occasion by public undertakings. The first design of building an exchange for merchants, in imitation of that of Antwerp, was entertained by his father. Sir Thomas carried the plan into effect, and completed the noble building in three years. (See Royal Exchange.) When the troubles in the Low Countries interrupted the accustomed loans to the crown from Antwerp, Sir Thomas advised the minister to apply to the merchants of his own country, and this may be considered as the commencement of the immense advances since made to the crown from the same body. Sir Thomas Gresham next determined to hew a part of his wealth in founding a college for the sciences in his native city. The principal people in the university of Cambridge endeavoured to diffuse him from thus establishing a rival institution; but his determination was fixed. He devised by will his house in Bishopsgate-street for the purpose of being converted into habitations and lecture-rooms for seven professors, or lecturers on the seven liberal sciences, who were each of them to receive a salary out of the revenues of the Royal Exchange. These lectures are still given in apartments in the Royal Exchange, whenever there are a sufficient number of auditors assembled to call for the exertions of the lecturer. The subjects of the lectures are divinity, logic, physics, grammar, geometry, music, and rhetoric. Sir Thomas endowed many public charities. He died suddenly in his own house in the year 1579, and was buried in a sumptuous manner in the church of St. Helen, Bishopsgate-street. He had expended large sums of money in erecting corn, oil, and paper-mills upon the stream of the Brent, near his favourite villa at Ottery-park. Biog. Brit.

Gresham College. See College.

Gresholm, in Geography, a small island of Denmark, in the Categat; 4 miles N.E. of Lufsoe.

Gresi, a town of Turkish Armenia; 28 miles S.E. of Rizh.

Gresley's Canal, an inland navigation in Staffordshire, near Newcastle-under-Lyme, made in pursuance of an act of 15 Geo. III. To the account given in our article CanaL
Canal we have here only to add, that in 1805 the Nantwich and Newcastle rail-way was proposed, to connect with this canal, at Dale's pool.

Gresling, in Ichthyology, a name given by the Germans to the gobius fluviatilis, or common gudgeon, which is very frequent in their smaller rivers.

Gresnich, in Biography, a modern German composer of the Italian school, who has composed several successful operas in Italy, and whose capital bravura airs were frequently sung in England by madame Mara, for whose abilities of execution we believe they were originally composed.

Gressen, in Geography, a town of Samogitia; 20 miles N.N.E. of Meshnik.

Gresset, John Baptist Lewis, in Biography, born at Amiens in the year 1709, was educated among the Jansenists, and from this retreat he sent forth some poems, which pleased all the taste and delicate pleasantry that could have been looked for from the pen of a man of the world. These were entitled "Ver Vert," a very pleasing tale; his epistles of "La Chartreufe," "Les Ombres," and many others. His reputation as a poet was the cause of his quitting the society, and fixing his residence in the metropolis. He now tried his powers in dramatic composition; in tragedy he had very little success, but his comedies were better received; and that entitled "Mechant," represented in 1747, raised him to the first rank of writers in this class. It was regarded as a masterpiece in that species of comedy which paints manners with truth and force, without being highly comic. Gresset was admitted a member of the French academy in the year 1748. He grew weary of a literary life, leaned to doubt of the propriety of theatrical exhibitions, and soon after announced the stage, by a letter, in which he displayed the dangers attending public spectacles. He returned to Amiens, where he obtained a post under government, married a lady with a good fortune, and passed the remainder of his life in a manner which required him the esteem and respect of his fellow citizens. In 1775 he revisited the metropolis, and had the honour, as director of the French academy, to compliment Lewis XVI. and his queen on their accession to the throne. His discourse on this occasion, which was printed, was a severe satire on the vices and follies of the metropolis. He died in June 1777, having received, some time previously to this, letters of nobility, and having been likewise appointed historiographer of the order of St. Lazare. Gresset is placed between Chauveau and Voltaire for the grace of light poetry; he is perhaps the first at the theatre for elegance of versification in comedy, and his morals were as pure as his style. Gen. Dig.

Gressin, in Geography, a town of Hinder Pomerania; 14 miles S.E. of Belgard.

Gresten, a town of Austria; 9 miles N.E. of Bavaria Waithaven.

Gretna, a village of Scotland, in the shire of Dumfries, 8 miles from Carlisle, and 82 from Edinburgh, at the S.E. extremity of the county, near the W. bank of the Sark, and bottom of Solway forth; famous for the clandestine marriage of parties from England, celebrated by persons who have no right to marry, or to exercise any part of the clerical function; because it is out of the jurisdiction of the marriage act.
