Sympathies of the glandular sytem—These may be divided into the passive and active. The glandular tisues is very readily influenced by various excitaments, either in the natural state, or in diseases, which constitute its passive sympathies. The cases in which the excitation of other organs augments glandular action, are particularly observable in the mucous system. Most of the excretory ducts open on surfaces of this nature; and examples of the observation occur in the flow of saliva determined by the presence of food in the mouth; in that of urine produced by catheters retained in the bladder; in the seminal excretion produced by irritation of the glans; the flow of tears from irritation of the conjunctiva or pituitary membrane; and in that of bile during the passage of the food into the small intestine.

The glandular system frequently exhibits passive sympathies in disease; the organic properties are brought into action under these circumstances, the animal sensibility being very seldom developed from to produce pain. The innumerable varieties in the quantity or quality of fluids separated by the glands under circumstances of disease arise principally from sympathetic influence. Thus the salivary apparatus moistens the mouth, or leaves it dry; fills it with a viscid or a thin fluid, &c. The mucous organs cover the tongue with matter of most varying consistence, thickness, and colour; and this occurs from sympathy with various states of the stomat. The liver, kidneys, and pancreas are influenced in very numerous ways; wherever any organ in the animal economy is affected, these are deranged; their secretion is increafed, diminished, or altered, and frequently even inflammation and suppression supervened. The affections of the liver from injuries of the head are well known; and the lacrymal secretion is variously modified in inflammatory and malignant fevers, fo as to produce various appearances of the eyes. Weeping in various mental affections is another example of sympathetic influence. The teficles and prostate exhibit fewer inftances of such sympathies, probably because their functions are so much more isolated. The relations which connect the breasts and uterus are remarkable, and frequently observed. In the fequel of considerable acute diseases, particularly fevers, the action of the glands is often conliderably affected, and copious evacuations, called critical, the nature of which is not yet clearly explained, take place.

The active sympathies are less frequent than those of the prece-
Gland.

The preceding clafs; but diseases exhibit instances of them. Inflamations of the liver, kidneys, salivary system, &c. shew various phenomena produced sympathetically in other systems.

Bichat, in his Anatomic Generale, gives the following view of the characters which distinguish the vital properties of the glandular system.

11. Peculiar vitality (via propria) of each gland.—The vitality of the glands, resulting from the preceding powers confedered in a state of action, is not uniform in the whole system; because the structure varies in every instance, and each tissue possesses a peculiar modification of vitality. Hence result many phenomena noticed by Bordet.

1. There are certain matters on which alone each gland can act in the natural state. Thus the salivary apparatus does not form bile, the liver does not separate urine, &c.; and on this principle the difference of the secretions is founded. In the same way causthides act particularly on the urinary organs; mercury on the salivary glands, &c. 2. Each gland has its particular mode of sympathy. Thus the liver acts especially on the brain, the kidney influences the stomatch, the uterus and breasts affect each other, &c. 3. Each glandular inflammation has a peculiar character; that of the kidney is different from that of the liver or testicle; the inflamed prostate has very different symptoms from the testis in such a condition. 4. Every gland has peculiar diseases, or tumeifs at least to which it is more exposed than others. Hydrothorax, which are very common in the liver, are never seen in the salivary glands or testicle. Sarcoccele is extremely common, while nothing is more uncommon than an enlarged parotid. The liver alone exhibits that peculiar alteration, which constitutes the fatty state; and is the most frequent finding. Physicians, who have not been conversant with the inspection of morbid cases, use the vague and insignificant terms of obtrusion and induration for every kind of glandular enlargement. The increase of size is the only common character of such affections, while the nature of the tumour is entirely different. 5. Every gland presents some peculiar modifications in what are called the critical evacuations, occasionally consequent on acute diseases. 6. The different vitality of the glands occasions them to act at very different intervals, in consequence of direct irritation, or sympathetic excitation. The lacrymal gland, for example, pours out suddenly an abundant secretion, when irritated; while the kidneys or pancreas can be excited only very slowly.

2d Character. Inactive state of the vital powers.—The glands are subject to habitual alternations of increased and diminished action. The animal functions are especially influenced by sleep, which completely suspends them. The action of the glands is only partially diminished at certain times, except in disease, when it is sometimes completely suspended. Bichat compares the sleep of the animal life to the intervals of intermittent fevers, where the apathy is complete; and the sleep of the glands to those of remittent fevers, where the symptoms are merely diminished in degree. Saliva flows into the mouth abundantly during malnutrition; it merely moistens the cavity at other times. The pancreas and liver pour out their secretions profusely, while the food is in the duodenum; they act much less intensely during the state of abstinence. The kidney is particularly exerted some little time after a meal. The intermissions in the action of the breasts are almost as complete as those of the organs of animal life. Every mucous gland has its particular period of secretion; it is, when the surface, on which the duct opens, is in contact with any substance either retained in the cavity, or passing through it. We must, therefore, form this notion of the office of the glands; that they constantly separate a fluid from the blood, but that they are more active at certain periods, and consequentlv furnish a more abundant supply.

This remittance of the glandular action, says Bichat, depends on a cause analogous to that of sleep, which arises, in the animal life, from the fatigue experienced by the organs of secretion and locomotion, after a continuance of action. The altitude, of which the glands are susceptible, is not generally marked by any painful feeling; yet there is in the breast, after long suckling, a kind of dragging sensation, and actual pain is felt in the testis after emolition has been repeated two or three times.

3d Character.—The vitality of the glands is never encroached on at the same time in the whole system. When one is in action, the others are in a state of remission. We might conceive, says Bichat, that there is only a determinate quantity of vital powers for the whole, and that one cannot be exerted unfailingly without a corresponding diminution in the rest. The digestive apparatus is accommodated to this law. At first the salivary system produces an abundant secretion; then the stomatch comes into action; thirdly, when the chyme enters the duodenum, the liver and pancreas are principally exerted; and lastly, the kidney exercises its peculiar office to evacuate the residue of the fluids. All the glands cannot act at once; as, in the external movements, certain muscles are always in a condition of repose, while others are contracted. The moat improper time for infection is during digestion, because the mucous, pancreatic, hepatic secretions, &c. milt then be performed at the same time with that of the testicles. In diseases, the secretion of one gland is increased at the expense of others. This character of the glandular system is only an example of the general character belonging to all the vital powers, by which, when increased at one point, they are proportionally diminished in some other situation. Hence large absceses, considerable tumours, and dropies are always attended with debility of the glandular action. On the same principle is founded the use of blister, foment, moxa, cauteries, &c. which do not act, as old physicians supposed, by evacuating any morbid matters, but by putting an end to the irritation in the diseased part, by means of that which they determine in some other organ.

4th Character.—Influence of climate and the seasons on the vitality of the glands. From the preceding character is derived another phenomenon, which may be considered peculiar to the glandular system; viz. that it is in general more active in winter than in summer, in cold than in warm climates. Warmth, by relaxing the integuments, increases the cutaneous discharge at the expense of that of the glands; while the action of cold is the inverse of the preceding. Hence the same fluid, introduced into the body, is expelled in summer by the skin, in winter by the kidneys.

5th Character.—Influence of sex on the vital properties of the glands. Is the vitality of these organs more active in the male than in the female? In those which are subservient to digestion, the lacrymal and urinary secretion, &c. the two sexes exhibit very little difference. In the generative system, the male possesses the addition of testicles and prostate, the female of mammary glands; so that here there is a compensation. But the influence of the former on the animal economy very much exceeds in its force that of the latter.

Development of the Glandular System.

1. State of this system in the fetus.—Although the secre-
G I A

GLANDS, considered as simple organs, have this peculiarity, that they contain no material substance in their unexcited state, but are in such a state as to yield, on excitation, a quantity of fluid or secretion, or even a gas. The glandular system consists of the following glands: the salivary (parotid and submaxillary), the sweat (or vellum), the sebaceous, the mammary, the prostate, the seminal vesicle, the seminal vesicle, the ovarian, and the testicular. These glands are arranged in a certain manner, and are situated in different parts of the body. The salivary glands are situated in the cheeks, and are responsible for the production of saliva. The sweat glands are scattered over the body, and are responsible for the production of sweat. The sebaceous glands are situated in the skin, and are responsible for the production of sebum. The mammary glands are situated in the breasts, and are responsible for the production of milk. The prostate gland is situated in the urethra, and is responsible for the production of seminal fluid. The seminal vesicles are situated in the pelvis, and are responsible for the production of seminal fluid. The ovarian glands are situated in the ovaries, and are responsible for the production of female sex hormones. The testicular glands are situated in the testes, and are responsible for the production of male sex hormones.

GLANDS, defined as complex organs, have this peculiarity, that they contain a material substance in their unexcited state, and that this substance is capable of being transformed into another substance by the action of the gland. The glandular system consists of the following glands: the liver, the stomach, the pancreas, the kidneys, the bladder, the heart, the lungs, the spleen, the thymus, the thyroid, the parathyroid, the adrenal, the gonads, the pituitary, the parathyroid, and the thymus. These glands are arranged in a certain manner, and are situated in different parts of the body. The liver is situated in the right upper quadrant of the abdomen, and is responsible for the production of bile and the detoxification of many substances. The stomach is situated in the upper left quadrant of the abdomen, and is responsible for the production of gastric juice and the digestion of food. The pancreas is situated behind the stomach, and is responsible for the production of pancreatic juice and the regulation of blood sugar levels. The kidneys are situated in the posterior part of the abdomen, and are responsible for the production of urine and the excretion of waste products. The bladder is situated in the lower pelvis, and is responsible for the storage and excretion of urine. The heart is situated in the left upper quadrant of the thorax, and is responsible for the circulation of blood. The lungs are situated in the thoracic cavity, and are responsible for the exchange of oxygen and carbon dioxide. The spleen is situated in the left upper quadrant of the abdomen, and is responsible for the production of red blood cells and the recycling of blood components. The thymus is situated in the posterior part of the thorax, and is responsible for the production of T cells and the regulation of immune responses. The thyroid is situated in the anterior part of the neck, and is responsible for the production of thyroid hormones and the regulation of metabolism. The parathyroid is situated in the posterior part of the neck, and is responsible for the production of parathyroid hormone and the regulation of calcium homeostasis. The adrenal is situated in the posterior part of the abdomen, and is responsible for the production of steroid hormones and the regulation of blood pressure and blood sugar levels. The gonads are situated in the pelvis, and are responsible for the production of sex hormones and the regulation of sexual function. The pituitary is situated in the sella turcica, and is responsible for the production of pituitary hormones and the regulation of endocrine function. The parathyroid is situated in the posterior part of the neck, and is responsible for the production of parathyroid hormone and the regulation of calcium homeostasis. The thymus is situated in the posterior part of the thorax, and is responsible for the production of T cells and the regulation of immune responses. The thyroid is situated in the anterior part of the neck, and is responsible for the production of thyroid hormones and the regulation of metabolism. The parathyroid is situated in the posterior part of the neck, and is responsible for the production of parathyroid hormone and the regulation of calcium homeostasis. The thymus is situated in the posterior part of the thorax, and is responsible for the production of T cells and the regulation of immune responses. The thyroid is situated in the anterior part of the neck, and is responsible for the production of thyroid hormones and the regulation of metabolism.
GLANDERS.

corrupt flamy matter, running from the nofe, of a different
colour, according to the degree of the malignity, or as
the inflammation has been of a shorter or longer continuance;
being white, yellow, green, or black, sometimes tinged with
blood.

Authors ascribe it to various causes: some to infection;
some to a disorder of the lungs; others to the spleen;
some to the liver; and others to the brain. After it has
been of a long standing, that the matter is of a blackish
colour, which is usually in its kit stage, they suppose it to
come from the spleen; and hence they call it the "measuring
of the chime."

Kernels and knots are usually felt under the euid in this
disorder; and as these grow bigger and more inflamed, so
the glands increase more. The progress of the disease is
extremely uncertain; as some horses will endure it for many
years, without any other obvious inconvenience than a slight
discharge and the enlargement of the glands under the jaws;
and inflances have occurred in which these symptoms have
disappeared for several weeks, and returned, perhaps, with
no augmented virulence. In most cases, however, the
course of the malady is more rapid; the bones and carti-
lages of the nose are speedily eroded by the malignity of
the ulcers, from which an absorption commences, and con-
veys the poison into the circulation, gradually and fatally
contaminating the whole frame. Neither the appetite nor
the condition of the glanderous horse suffers materially in
the early or mild stage of the complaint. When, however,
it has spread its dominion over the thoracic visera, forming ulcers
in the fibulence of the lungs and in the wind-pipe, great
pain and difficulty of respiration are experienced, the dis-
corder becomes more considerable, the appetite is injured,
and the body of the unfortunate animal exhibits a picture
of extreme distress; and unless the humanity of the owner
does not induce him to terminate his sufferings, the disease
will, by tardy steps, afford relief to the wretched animal by
diffusion.

M. La Folfe, farrier to the king of France, has taken
great pains, by repeated dilatations, to discover the source
and cause of this disorder, and to ascertain the proper and
efficient method of cure. He has distinguished seven diffe-
rer kind of glanders, four of which are incurable. The
firt proceeds from ulcerated lungs, the juridament matter
which comes up the trachea, and is discharged through the
nostrils, like a whitish liquor, appearing sometimes in lungs
and grunes: the second is a waiting humour, that usually
keeps horses at the denture of a disease caused by too hard
labour, and proceeds from the lungs: the third is a malign-
unt discharge, which sometimes attends the triangles,
falls upon the lungs, and is discharged at the nostrils: the
fourth is when an scarinous humour in the farcy isces
those parts: the fifth arises from a horse's taking cold: the
sixth is a discharge from the triangles, which sometimes
vent itself at the nostrils: the seventh, or real glanders, is
that above described.

M. La Folfe, after examining, by dilatation, the creafes
of glanderous horses, and making a strict scrutiny into the
state of the visera, affihed in his enquiry by ingenious
anatomists for the space of ten years, affirms this disease to
be altogether local, and that the true seat of it is in the
pituitary membrane which lies the partition along the
inside of the nose, the maxillary bones or cavities of the
check-bones on each side of the nose, and the frontal
sinus or cavities above the orbits of the eyes; that the
visera, as the liver, lungs, &c. of glanderous horses are,
in general, very found; and, therefore, that the seat of the
disorder is not in those parts, as many authors have af-
fected. He found these cavities more or less filled with a viscid
flamy matter; the membrane, which lines both them and the
nostrils, inflamed, thickened, and corroded with forbid ul-
cers, which, in some cases, had eat into the bones. He
observed, that, when glandered horses discharge matter from
both nostrils, both sides of the membrane and cavities were
affected; but when they ran at one nostril only, that side
only was found disfigurured; and if one gland only was af-
feft, the horse discharged from one nostril only: but if
both were affected, the discharge was from both. It has
been observed, that the glanders in horses very much refem-
bles a disorder in men, called asthma.

In this disease, if the matter sticks to the inside of
the nostrils, like glue or stiff paste; if the inside of the nose is
raw, and appears of a livid or leaden hue, and the matter
becomes bloody, ferial, and of an afid-colour; these symp-
toms are very unprevalent; but when only a limpid fluid is
first discharged, and afterwards a whitish matter, the gland
under the jaw does not much increase, and the disorder has
been of no long continuance, a speedy cure may be ex-
pected. The core of the milder kind of glanders may first
be attacked by injections and fumigations. When these
latter symptoms appear, the horse should first be bled, and
drawn in the common disorder of cold; and then, let an
emolient injection, to decoction of linseed, marsh-mallow, elder, chamomile flowers, and honey of roes, or such like, be thrown up as far as possible with a strong
fire, and repeated three times a day: if the running is not
lessened or removed in a fortnight by these means, a refrin-
rent injection may be prepared with tincture of roes, lime-
water, &c. and the nostrils fumigated with the powders of
frankincense, mastic, amber, and cinambrt, burnt on an
iron heated for that purpose, the fumes of which may easily
be conveyed through a tube into the nostrils. When the dis-
cede is inveterate, recourse must be had to the operation of
trepanning; which M. La Folfe performed on three horses,
two of which discharged from one nostril only, and the third
from both: he trepanned the two first on that side of the
head which was affected, and the other on both sides, and
found that the wound and perforation filled up with good
flesh in twenty-six days, and the horses suffered no incon-
venience from the operation. The method of performing this
operation will be understood by means of Plate XIX. After-
lay's, fig. 1, and the following explanation: B, B, are two lines
representing the bounds of the cerebellum, or back part of
the brain, which commences from the line D. C C is a line,
where the superior part of the fissus frontalis commences,
together with a view of the bottom of the fissus, terminating
between the lines D and E, where appears a fulness in the
form of a pear, which is the os ethmoides, or sieve-like bone
through which the olfactory nerves pass, communicating
feasibility to the pituitary membrane. E represents the be-
inning of the maxillary fissus, terminating at M: the fiened
space between these lines represents the great cavities. F is
a bony partition, separating this fissus into two parts that
have no communication: of which partitions there are some-
times two, represented by F and G. Some horses have ne-
ither of these. N shows the place of the cornets or horns;
O, the redounding; P, their middle part; Q, the lower part
of them; and M, the bony pipe or canal which guards the
maxillary nerve: A A is the septum parum, dividing the
nofe from top to bottom, and separating the two noftrils; L
shows the place where the trepan should be applied, when
there is reason to apprehend that the glands is fared into
the frontal fissus; L is the place where it should be applied

5
Glanders.

to cleanse the maxillary sinus, though the round spot between D and E is preferable, because one orifice in this place will serve to wash all the parts, both above and below, with one injection. If it shews the place where another perforation should be made, as a drain for discharging the foul matter washed away by the injection; and this hole, kept open by a hollow leaden pipe, would, in all recent cases, be sufficient. I represent the injection thrown in by the syringe, which flows out by the orifice and the nostril K; and, during this part of the operation, the nostrils should be laid close. If there should be two bones in the maxillary sinus, it is absolutely necessary to pierce through both, with a filletor or sharp-pointed tuck, as in the figure. The trepan should be directed towards the interior part of the nose, to prevent its being obstructed by the roots of the teeth. K is the trepan, S the handle which turns it, and T the saw-part to be applied to the bone. The surgeon's trephine will answer the purpose for this operation; but before the instrument is applied, a circular piece of the skin, of about the size of half a crown, should be first cut off with the membrane which covers the bone. The syringe should be large enough to contain half a pint of injection. The injection itself should be of a deterrive nature, as a decoction of birth-wort, gentian, and centaury, or a quart of which may be added to two ounces of guaiacum and tincture of myrrh; and when the discharge abates, and the matter becomes of a thick consistence and white co'orn, this injection may be changed for barley-water, honey of roses, and tincture of myrrh; and for completing the cure, Bates's alum-water, or a solution of coecothor, vitriol, lapis medicamentosus, and such like, in lime-water, will serve to dry up the moisture, and to remove the tone of the relaxed glands. For this purpose Dr. Bracken recommends the following mixture: Take of alum and white vitriol powdered, of each one ounce; calamine them in a crucible; when cold, powder the cals, and mix it with a gallon of lime-water and a quart of vinegar, and decant the mixture clear for use. The perforations that are made in this operation should be kept open, after the use of the injection, by fitting to the upper one a piece of cork waxed over, and a hollow leaden tent to the lower, through which there will be a constant drain of matter from the sinuses; and both may be secured by a proper bandage. The growth of the flesh should be also checked by rubbing with caustic medicines, or applying the actual medicine. The cure will be expedited, by giving every day a quart or three pints of a strong decoction of guaiacum chips, by purging at proper intervals, and putting a rowel into the horse's chest; and if these fail, mercurials may be administered with the physic, and the alterative powders with lime-water may be given and continued for some time.

The following remedy is said to have succeeded, in fifty cases out of sixty, for curing the glanders, without trepanning. Keep the horse a day or two with small quantities of choice hay, and fedded bran; then blow up his nostrils as much as will remain, in fine powder, as will lie on a six-pence, evening and morning, giving him for drink small lime-water, during four or five days; then boil two ounces of clecampane roots in a quart of drink, till they mix, and give it once a day during three or four days more; then boil two handfuls of the white roots that grow on oaken pales, in two quarts of milk, till one is consumed; drain it and give the more, and give the milk full warm; repeat this for four or five days. About an hour after the horse has had his drink each day, take a piece of sweet butter, about the size of an egg, and about half an ounce of brimstone finely powdered, and work them well together; then take two clean goose feathers, as long as they can be procured, and make a hole in each of the quill ends, in which fasten two long threads; then anoint the feathers well with the mixture, and roll them in dry flour of brimstone; open the horse's nostrils, and thrust the feathers up into his head, fadening the threads to the top of his head, to prevent their dropping out; ride him an hour or two attending it, and let him stand half an hour after he returns to the stable before the feathers are taken out; pursue this course eight or nine days, bathing his head with camphorated spirits of wine, and afterwards confining his head over a tub of hot grains, that he may breathe the steam. A rowel may prevent a relapse.

After all that has been said, it is now generally allowed, that no effectual remedy for the glanders has yet been discovered. The operation of trepanning has never been attended with permanent success; and whatever relief has been obtained from the use of various medicines, it has been merely temporary, and the disease has been pronounced incurable. But though all attempts for curing the glanders have hitherto proved ineffectual, the inquiry should be pursued, and efforts for this purpose should be renewed till the veterinary's ingenuity and perseverance are crowned with success. The analogy subsisting between the glanders and the venereal disease has led some practitioners to recur to the use of mercury, but it has proved very partial. Professor Coleman mentions a single case which occurred at the Veterinary College, in which the glanders yielded to the treatment employed, which was that of repeated and long continued doses of calomel, carried to the extent of salivation. This solitary case led to many trials of a similar nature, but, unhappily, without the success which was hoped for by the professor, who exerted his wonted ingenuity to improve the hint which this single instance afforded. Others have made similar efforts in this way, with only a temporary abatement of the symptoms, but without ultimate success. Some years ago, great expectations were formed, from the use of the mineral acids in the venereal disease; and trials were made with these in some cafes of glanders, which were ineffectual. The late professor of the Veterinary College, M. St. Bel, made a variety of experiments for ascertaining the nature of this disease, and for investigating an effectual remedy, while he was professor of the veterinary school at Lyons; he has recorded the cases that fell under his notice, with his method of treatment, which was very diversified and multifarious; but he concludes with observing, "notwithstanding my failures, I think that a remedy may be found for the glanders." Many circumstances convinced M. St. Bel, that the virus of the glanders has greater activity in southern than in northern countries; and that its progress is more rapid in the mule and the ass, than in the horse; but that the former are not so subject to receive it by infection or contact as the horse is. The use of verdigris having been recommended by a professor of the veterinary art, Mr. Lawton, surgeon to the Oxfordshire light dragoons, gave this medicine a trial in two cases, those of a horse and mare, beginning with one drachm daily, and gradually increasing it to one ounce. But no beneficial effect was produced. Deflection of the horse after three months' trial proved no disease in the brain, but it was altogether continued to the septum of the nose and nostrils.

As the glanders is a disease of such virulence, known to be contagious in a high degree, and hitherto found to be incurable, it is of importance to distinguish it from other diseases to which the horse is subject. A cold, which has been sometimes mistaken for the glanders, may be easily distinguished from them. In colds, there is generally a certain
certain degree of fever, the eyes appear dull or watery, the appetite is diminished, and there is almost always a cough. If the glands of the throat should swell, they are not to closely attached to the jaw-bone as in the glanders, but feel loose and moveable under the skin; they are also generally in a state of active inflammation, feeling hot, and softer than in the glanders. In colds, both nostrils are almost always affected; in the glanders it frequently happens that the discharge is only from one. In colds, the nostrils are not ulcerated; in glanders this always happens, though at different periods of the disease. The strangles have been sometimes mistaken for the glanders; but in this disease the inflamed glands very soon suppurate and burst, by which all the other symptoms are generally removed, whilst in the glanders the glands seldom or never suppurate. In order, however, to avoid all danger, it is advisable, as soon as a horse is perceived to have a discharge from his nose, to put him into a stable, where he can have no communication with other horses. If the glands of the throat be enlarged and inflamed, apply a large poultice to them, tear the head three or four times a day, let the horse be well clothed, and give a fever powder every day, or once in 12 hours. By these means, the disease, if it arise from a cold, will soon be removed. When considerable ulceration is perceived in the nose, with the other concomitant symptoms of the glancers, the sooner the horse is destroyed, the better.

The most effectual method of purifying stables in which glanedered horses have been kept, is to remove, or carelessly scrape, and afterwards scour with soap, sand, and boiling water, every thing on which the horses may have deposited any matter, and afterward to cover every part of the stable with a thick coat of lime and size. It is a common practice with the owners of horses, when they have had any one of them feized with the glangers, to bleed and purge the red, by way of prevention; but this method will serve rather to promote than prevent the disease, as it will considerably increase the action of the absorbent vessels, by which action the glanders are conveyed into the lymph.

GLANDIUM, in Surgery, a name sometimes given to an excrecence near the anus.

GLANDORE, in Geography, a harbour of the south of Ireland, in the county of Cork: it is a little to the west of Ros, and has the village of Myros at the extremity of it.

GLANDORP, Matthias Loutis, in Biographia, a physician, was born at Cologne in 1592. He studied first at Bremen, in Lower Saxony, whence his family originated, and afterwards returned to Cologne, where he commenced his medical pursuits; but, by the advice of his father's friends, he was soon sent to Padua, in order to reap the benefits of studying under the great masters, who at that time were so distinguished in medicine. He attached himself particularly to Fabricio and Spigelius; and he made such great progress in anatomy under the latter, that he was deemed qualified to give public demonstrations. Before returning to Germany, he received the degree of doctor in 1618. He determined to fix himself at Bremen, in which city he found every thing favourable to his views; and his successes in practice gained him so much reputation, that he was elevated to the most honourable offices. He was physician to the archbishop and to the republic, where he died in 1643. He left several works, adorned with plates, which contain many important observations on anatomy. These are

1. "Speculum Chirurgorum, in quo quid in unamque vulnere faciemur, quidem omittendum, praestat pars affecta anatomica explicature, observationibus ad unumquaque valvis pertinentibus adjectis, conspexitur ac protrahatur."

3. "Gazophylacium polyphili triumexculorum et feotonum referatur," ibid. 1653, 4to. — London 1653, 4to. — He made frequent use of the actual case in the treatment of the most common disorders. The whole of Glandorp's works were collected and printed in London, in 4to. in the year 1729, under the title of "Opera omnia, nunc simul collecta, et plurimum emendata." This collection includes also some curious tracts on Roman antiquities. Elov. Dict. Hist.

GLANDORP, John, a learned philologus, who flourished in the middle of the 17th century, was born at Munster. He studied under Melancthon, and became very distinguished for his critical knowledge. He was elected rector of the college at Hanover, but, upon some dispute, he quitted it in 1555, and retiring to Gollas, was followed by most of his scholars. In 1560, he was made professor of history at the university of Marburg. He died in 1564. His works are

GLANDULA, in Anatomy, the name of a gland. The word is a diminutive of the Latin glanis, acorn; and is here used on account of some external resemblance between the glands of the body and the fruit of the oak.

GLANDULA Guidonis, among Surgeons, is a tumor resembling a gland; soft, single, movable, with roots, and separate from the adjacent parts.

GLANDULE, in English, signifies a little gland. Thus the mygdalae, or almonds of ears, are by some called glandules.

GLANDULOUS, or GLANDULAR, something composed of glands, or that abounds with glands.

The breasts are glandulous bodies. The cortical substance of the brain is commonly reputed to be glandulous; though Ruych, from the discoveries made by his admirable injections, holds, that there is no such thing as a gland therein.

The ancients distinguished a particular kind of flesh, which they called caro glandulosa, or glandulous flesh.

GLANDULOSUS Dolor, glandulorum corpus, more particularly denotes the proflata.

GLANDULOSUS Rutos, among Botanists, such tuberose roots as are fastened together in large numbers by small fibres or threads.

GLANIS, in Ichthyology, a species of siturus, which see.

GLANOVENTA, in Ancient Geography, a place of Britain, in the 12th Iter of Antoninus, suppos'd by Horsey to be Lancaster, in the county of Durham.

GLANS, Acorn, in Natural History, a fruit contained within a smooth but hard bark, including a single seed; its hind-part being covered with a kind of cup, and the fore-part bare. See Acorn and Oak.

GLANS Marinus, a name given to a genus of shell-fish, more usually called balanus, and in English the centre shell.

GLAN Turgifera, a name given by Gfener, and some other writers, to a kind of figured foif, found usually among the trochita and entochia, and evidently appearing to have in some manner belonged to them. All the writers, who have themselves examined the places where the trochita are found, have mentioned these under the names of glades trochitifera, others under its determinate ones. Agricola:
calls them lapides inornes; and Lifter, after him, rude stones, having impreisions of the entrouci. See farther Philof. Trans. No. 100.

GLASS, P. in Anatomy, the rounded extremity of the organ. See Generation, organs of.

GLANSHAMMAR, in Geography, a town of Sweden, in the province of Nericia; seven miles N. E. of Oboce.

GLANVILL, Joseph, in Biography, was born at Plymington in the year 1656, where he probably received the early parts of his education; but he pursued his mature studies at Exeter college, Oxford. He took his first degree in the year 1677, and removing to Lincoln college, he gradually mander of arts in 1678, and was, about the same time, appointed chaplain to Francis Rouz, eqq. provost of Eton college. The death of his patron induced him, after a very short time, to return to Lincoln college, where he spent his time in literary and philosophical studies, till the restoration of king Charles II. He became acquainted with the writings of Richard Baxter, and was an ardent admirer of his preaching and religious principles. He is said to have been an eager republican in politics, but, whether this he the real fact, has been much doubted. Upon the re-establishment of monarchy and episcopacy, he conformed to the national church, a circumstance that did not in the least abate the esteem which Baxter had before manifested for him. He became a zealous convert to the principles of the philosophy, in opposition to the fyllem of Arilolote, and published a work in their justification, entitled "The Vanity of Dogmatizing or Confidence in Opinions." &c. This piece introduced him to the acquaintance of many of the person who afterwards formed the Royal Society. About this time Mr. Glanvill entered into orders, and was presented to the rectory of Wimbish, in the county of Essex, and in 1662 he was inducted into the vicarage of Fresno-Seldow, in Somersetshire. He published in the fame year, but anonymously, a discourse on the fundamental doctrine of the ancient Rhenish philosophers, which he endeavored to prove was not incompatible with revealed religion. It was entitled "Lux Orientalis; or an Enquiry into the opinion of the Eastern Sages concerning the Pre-existence of Souls; being a Key to unlock the grand Mysteries of Providence in relation to Men's Sin and Misery." Upon the establishment of the Royal Society, he published his former treatise, corrected and enlarged, under the title of "Scepsis Scientifica; or confessed Ignorance in the way of Science, in an Essay on the Vanity of Dogmatizing and confident Opinion." This work was dedicated to the Royal Society, and the author was almost immediately admitted one of its members. In 1665 he published his work, entitled "Some Philosophical Conclerations touching the being of Witches and Witchcraft." This performance, which is still regarded as a curiosity, though very little creditable to the judgment of the author, engaged Glanvill in a controversy which lasted as long as his life. He was now presented to the rectory of Bath, in which city he fixed his residence. Here he met with many opponents, who were apt to treat him but roughly, on account of his adherence to the new philosophy, which led him to draw up a small but elegant treatise, entitled "Plus Ultra; or the Progress and Advancement of Knowledge since the Days of Arilolote. In an account of some of the most remarkable late improvements of practicable useful learning, to encourage philosophical endeavours, &c." The author was violently attacked on this occasion, but he defended himself with spirit and success. His reputation was now firmly fixed, and he was frequently called upon to preach on public occasions. At a visitation of the diocese, he delivered a discourse which met with general approbation, and which was frequently re-printed: it was a defence of reason in the affairs of religion, against infidelity, scepticism, and fanaticism of all sorts. He next attempted to show the correspondence between religion and the new philosophy, in a discourse concerning the religious temper and tendency of the experimental philosophy which is prized by the Royal Society. "While," says one of his biographers, "he was entitling himself to the particular acknowledgments of the members of that body, by defending the reasonable tendencies and useful tendency of their pursuits, he also contributed to their collection of instructive and entertaining papers, some observations on the names in the Mendip hills, and on the natural history and springs of Bath, which were well received, and inferred in the Philosophical Transactions." In the year 1672, Mr. Glanvill exchanged his rectory of Frome for that of Strean, in the same county, with the chapel of Walton annexed; and about the same time was made one of the king's chaplains. In 1676, he published his "Essays on several important Subjects in Philosophy and Religion," consisting of the principal of his former pieces, revised and improved, with a treatise, entitled "Antinomian Theology and Free Philosophy." Two years after this, his "Essay concerning Preaching" came out; it was written for the purpose of diffusing the younger clergy from that affection of wit and fine speaking, which began to be fashionable in those times, and to recommend and enforce a plain and practical method of enforcing the moral duties of the gospel, as the true eloquence of the pulpit. The last work of this worthy divine, was entitled "The zealous and impartial Protestant, shewing some great but least needful Dangers of Popery." Mr. Glanvill died of a fever at the early age of forty-four, and Dr. Hornbeck published a quarto volume of Discourses, &c. after his death, to which is prefixed an account of the author. As a preacher, Mr. Glanvill was eloquent and pathetic: in private life he was truly amiable and praiseworthy. He was author of various other tracts besides those already noticed, the titles of which are given in the Biographia Britannica. To this work the reader is referred for further particulars.

GLAREANA, in Ornithology, the name of a bird described by Gellner from the figure, and specified to be of a grey change and black belly; a kind of lark, the Alauda campfisaris; which fee.

GLAREOLA, a species of Pringa; which see.

GLAREOLA, in Ornithology, a genus of the Grallae order, founded on the natural family called by Brillon "Perdix de Mer," and also Glareola. The character of this genus confisits in the bill being strong, short, straight, and turned down or hooked at the tip; nostrils linear, and placed in an oblique position at the base of the bill; gape of the mouth large; feet four-toed, the toes long, slender, and connected at the base by a membrane; tail furred, and containing twelve feathers. The number of species, according to Gmelin, are three, namely, Atraica, Senegalensis, and Norvis, the first of which, however, comprises several remote varieties. Linnaceus described this as a species of hirundo, the second kind is a tringa of the same author, and the third, a gallinula of Ray. Species.

AETRICA. Above grey-brown; cellar black; chin and throat white; breast and belly reddish-grey. Gmel. Hirundo marina, Aldr. Hirundo riparia, Merg. Pratincola, Kran. Gallinula erythropus minor, Gmel. Perdix de mer, Buff. Sen. fuscarellus of Aldrocanus, Will. The length of this bird is nine inches; the bill black; with the base red; upper wing-coverts white; quill and tail-
tail-feathers dusky, the outer side of the first tail-feathers white; and the legs and naked part of the thighs in general red. The species inhabits chiefly the south of Europe, and the milder parts of Asia; towards the north it becomes more rare, from diffusive, and is very rarely seen to remote from the southward as Britain. It abounds most in the plains of the defers towards the Caspian sea, in the neighbourhood of the rivers, its food consisting of aquatic insects and worms.

One of the varieties of this species is called by Brillon Guaraola torquata, and by Buffon, "Perdix de mer a collier." The plumage beneath is white; the front black, with a white spot on each side, and the collar brown. Its size is rather inferior to the former, and the legs blackish instead of red. This, like the other, is a noisy, restless bird, and frequents the banks of rivers, aquatic insects constituting its principal food. The eggs are oblong, and usually about seven in number in each nest.

The bird called "Perdix de mer" by Sonnerat is another variety of this species; the lower parts of the plumage, and also the rump, are white; and the chin streaked with black, and surrounded by a black curved line. This was caught in the open sea, in the latitude of the Maldives islands, and lived a month at sea, with its crop filled with water.

Two other varieties occur in the East Indies, on the coast of Coromandel, and are likewise described by Sonnerat; the first of these is brown, the under parts, with the rump and base of the tail white; in the second, the tail-feathers are brown, having the outer ones marked with a white band.

SeneGalenis. Entirely fuscous. Gmel. Glaraola Senegalensis. Tringa fusca, Linnaeus. Perdix de mer brunus, Buff. Senegal pratitulico. Scarcely exceeds the former in size, bearing nine inches and a half in length, and inhabits Senegal. The same variety is found also in Siberia.

Newia. Brown, spotted with white; lower part of the belly and vent reddish-white, with black spots; bill and legs black. Gmel. La perdex de mer tachetés, Buff. Galbula malanopus, Rothmuller, Ray. Glaraola, Buff. Spotted pratitulico.

Size of Glaraola auricata. This variety is met with in Germany.

GLARIANUS, Henricus, Loritus, in Geography, furnishes no Glarianus. from the town of Glaris, in Switzerland, where he was born in 1588. He rendered himself famous by his knowledge of music, and belles lettres; but he may more properly be ranked among dilettanti theorists in music, than a musician by profession; and his abilities, as a scholar and critic, have been much less disputed by the learned, than his knowledge of music, by musicians.

He studied at Cologne, Basle, and Paris; his predecessor in music was John Cochlaeus; and in literature, Erasmus, with whom he lived in sincere friendship, and by whom he was warmly recommended, in a letter still extant, to the archbishop of Paris. He is called by Walther a philosopher, mathematician, historian, geographer, theologian, and poet; indeed, he distinguished himself in most of these characters. Gerard Vossius calls him a man of great and universal learning; and for his poetry, the emperor Maximilian I. honoured him with the laurel crown.

His famous treatise on music, is entitled GLAIANA, which implies twelve modes; to which number he wished to augment the ecclesiastical tones which had never before exceeded (hitherto, from the time of St. Gregory. In this, and a few more, adopted the opinion of Glarianus, but soon relinquished it, on finding that they had made no converts. Indeed, the whole twelve modes of Glarianus contain no other intervals than those to be found in the key of C and A natural, or in the different species of octave, in those two keys; and though his augmentation extends the compass of sounds used in the modes, it offers no new arrangement of intervals, as may be seen by his title-page, when it tells us that the authentic modes are D, E, F, G, A, and the plagal A, B, C, D, E, G; where we perceive that A, C, E, G, are repeated, by being made both authentic and plagal.

If, instead of twelve modes, Glarianus had augmented the eight to twenty-four, by affixing two to each semitone in the octave, he would have done real service to the music of his time; but his contemporaries were not yet ready for such an innovation, being still held too fast in the tramels of the church to dare use any other sounds than those which time had consecrated, and authority admitted within its path.

His book, however, contains many curious anecdotes and compositions of the greatest musicians of his time, which were excellent studies for his countrymen and contemporaries, and, if forced, would be still very instructive and useful to young contrapuntists. Glarianus died 1613, aged 74.

GLARIUS, or GLARUS, in Geography, a canton in Switzerland, formerly subject to the abbots of the convent of St. Gall, in Swabia, but possessing a democratic form of government, under a mayor, appointed by the abbots, but chosen by the inhabitants; till towards the latter end of the thirteenth century, the emperor Rudolph I. obtained the exclusive administration of justice; and soon afterwards his son Albert purchased the mayoralty, which had become hereditary, and reunited in his own person the whole civil and judicial authority. The government of Albert, and of his descendants the dukes of Austria, was arbitrary and oppressive; and therefore, in 1530, Switzerland, afflicted by Zuric, Lucerne, Uri, and Unterwalden, expelled the Austrians from the canton of Glarus, and re-established the democracy. Glarus then entered into a perpetual alliance with its deliverers, and was received into the Helvetic confederacy, with some restrictions, which were not abolished till 1550.

It was then the 6th canton, but afterwards became last in rank of the eight ancient cantons, as they were called. The people of Glarus enjoyed their liberties un molested till 1588, when the Austrians made an irruption into the canton, and pillaged the country and all the inhabitants. At this time 750 troops of Glarus, afflicted by the Swabians, compelled the whole strength of the Austrian army, and compelled them to retire. In the 16th century the reformation was introduced into this canton; but the Protestants and Catholics have been accustomed to live together on terms of mutual toleration and friendship: of late the number of Protestants has very much increased; and their industry in every branch of commerce is observed to be far superior to that of the Catholics. The government of this canton, previously to the French revolution, was entirely democratical; every person at the age of 16 had a vote in the "Landsgemeinde," or general assembly, which was annually held in an open plain. This assembly ratified new laws, had contributions, entered into alliances, declared war, and made peace. The "Landammann" was the chief of the republic, and was chosen alternately from the two sects; with this difference, that the Protestant remained three years in office and the Catholic two. The other great offices of state, and the bailiffs, were taken by lot from a certain number of candidates proposed by the people. The executive powers were vested in the council of regency, composed of 43 Protestants and 15 Catholics; and each set had its particular court of justice. This canton comprehends 336 square miles; and its population is estimated
estimated at 16,000 persons; its contingent to the army, under the old government, was 400 men. According to the division of Switzerland into 18 departments or cantons, in 1798, the canton of Glarus, together with the bailiages of Wallenstadt, formed the canton of Linth; but according to the constitution of the 29th of May 1801, Glarus, together with the bailiages of Sargans, Werdenberg, Gullen, Uznac, and Rappenfchwil, forms the eighth canton, and deputes five representatives to the diet.

This canton is entirely enclosed by the Alps, except towards the north; and there is no entrance but through this opening, which lies between the lake of Wallenstadt and the mountains separating this canton from that of Schwytz. At this entrance, the canton reaches from the banks of the Linth to the farthest extremity of its Alps, about 50 miles; forming a valley, which becomes narrower as you advance, and is fearfully more than a market shot in breadth at the burg of Glarus. It afterwards opens by degrees, and, about a league from this burg, is divided by the Freyberg mountains; at the point of this division, the two rivers, Linth and Serfi, unite. The hillocks of the Peak in Derbyshire, says Mr. Coke, are mere mole-hills to the Alps of Glarus. These stupendous chains of rocks are absolutely perpendicular, approach one another so near, and are so high, that the fun may be said to let, even in summer, at four in the afternoon. On each side are a number of waterfalls, which excite attention. The valley terminates in an amphitheatre of mountains, and the glaciers of the canton close the view. (See Linth.) All the houses in this canton, like those of Appenzel, are built of wood; large, solid and compact. with great pent-house roofs, that hang very low, and extend beyond the area of the foundation. The police in this democratical state is well regulated; nor does liberty often degenerate into licentiousness. Cattle, cheese, and butter constitute the principal commerce of the canton. The cattle are fed in summer upon the Alps; it is computed that 15,000 head of large cattle, and 4000 sheep, are fattened during that season upon the mountains belonging to the canton. The inhabitants also manufacture linen and mufkins. Among the exports, a confiderable article is slate, with which the canton abounds; the principal quarry being in the valley of Serfi, where large plates are dug up that serve for tables. These quarries once furnished Great Britain with plates for writing; but this branch of trade has been superseded by the great slate quarries in Caernarvonshire. The great part of this canton conflides of mountains, rocks, inaccessible forests, and barren heaths, covered with snow; and it is subject to frequent inundations, and to the devastations occasioned by tempests and falling rocks.

GLARNISH, a mountain of Switzerland; 7 miles W.S.W. of Glarus.

GLARUS, or GLARES, the capital of the above-described canton, situated upon the Linth. The town is large and populous; and the town-hall is a landfame frumace; 52 miles L. of Lucerne. N. lat. 26° 58'. E. long. 9° 3'.

GLASENDORF, a town of Bohemia, in the circle of Koeniggratz; 6 miles N.N.W. of Trutnov.—Also, a town of Sofia, in the province of Neiße; 11 miles S.W. of Potschau.

GLASGOW, a very populous, landfame, and regularly built city, is the county of Lanark, in Scotland; situated on the north bank of the river Clyde, which is navigable for vessels of 100 tons and upwards. In ancient times, and during the prevalence of the Roman Catholic religion, Glasgow was chiefly distinguished as an archbishop's see, and was of course principally under the influence of the archbishop and his inferior clergy. Their power seems in these days to have been civil as well as ecclesiastical; for the charters of the most ancient corporate bodies are held by this tenure, the civil magistrates being only noticed as of subordinate rank and authority, and the freedom fines, and other emoluments are expressly appropriated to ecclesiastical purpofes. The revenue of the diocese of Glasgow, if it may be estimated by the extent of lands subject to the payment of tythes, or (as they are called in Scotland) teinds, must have been very great; for those burthens extended over almost the whole of the counties of Lanark, Renfrew, Dumbarton, Ayr, Dumfries, and Galloway, comprehending the whole south-west district of Scotland, and perhaps a moiety of the most fertile land in the whole kingdom. Of this enormous revenue, since the reformation a small part, but now of great value, has been appropriated for the support of the university of Glasgow, a part of the payment of the parochial stipends, and a great part has reverted to the freeholders or their dependants, and these are constantly fluctuating as in other parts of the kingdom. The insurrections and civil wars, which devastated Scotland subjequently to the reformation, and previous to the revolution, having diverted Glasgow from all that attraction which it had acquired as the archbishop's see, and occasionally as the royal residence, it appears to have been only remarkable as the occasional scene of those sangunsary and ferocious contests for which the age was conspicuous. It fell into the hands of the regent upon the defeat and flight of the unfortunate Mary Stewart at the battle of Langfield, two miles south of the city. It was long afterwards battered and taken by Cromwell's army, and it was the refuge of the defeated party, after the battle of Bothwell bridge, fought between the regent (afterwards James II.) and the Covenanters. After the revolution it seems for many years to have been a place of little importance, polishing neither a sufficient degree of wealth or refinement to render it conspicuous for elegance or luxury, nor rich security or strength as to make it definable or important as a military poit. At the time of the Union with England, its whole population was estimated at only 14,000, a fact stated in the house of commons by Mr. Secretary Dundas, (now lord Melville,) in one of the debates when the Irish Union was in contemplation. Subsequently to the Union, the rife of Glasgow in commercial importance, even under the lucrative checks of the two civil wars in 1715 and 1745, of the vastly greater commercial embarrassment, occasioned by the supplantation of its colonial trade during the American contests, and all the subsequent hof
tilities produced by the French revolution, has been perhaps unequalled by any other place in the empire, or perhaps in the world. Its population, under the act of 1794, including its numerous suburbs, was returned at 94,000, and from the concealment which was practiced from the idle fears of ignorant people, many of whom foolishly imagined that cefus to be the precursor of a military conflagration, that number is supposed to be at least 30,000 short of the actual amount.

Different histories of Glasgow have been published. Of these, one published many years ago by Mr. McUre, one of the city clerks, was much esteemed, but is now considered as obsolete. Others have subsequently been written by Mr. Gibson, about 1774, and recently by Mr. Denholm, about 1796.

The limits of this article necessarily preclude the possibility of entering much into detail, nor would it be either amusing or instructive to the general reader. We shall therefore infer what remains concerning the present state of this
this great commercial and manufacturing city under the following general heads.

1. Situation and general state of the adjacent country.—

Glasgow is situated on the north bank of the river Clyde, in N. lat. 55° 52' and W. long. from the meridian of Greenwich 4° 30'. The extreme length from E. to W., including two suburbs, is nearly two miles, and its breadth from the cathedral or high church to the river about one mile. The central part of the city, that part which is upon the southern declivity of a hill. Perhaps no other town in Europe is, upon the whole, more regularly planned; for all the principal streets are either parallel or at right angles to each other. The chief streets are better paved than those of London, and generally wider; all the front buildings are of fine free-stone, which is found in great abundance in the immediate neighbourhood. The granite, or cobble-stone, for paving the carriage ways, is also very plentiful close by the town. The houses are very large and lofty, being more generally upon the French plan, where every floor forms a separate lodging, accessible by a common staircase, than upon the English, where one person occupies the whole premises. The more wealthy inhabitants, however, have almost universally adopted the English taste in building. In the old part of the town it is indeed much to be regretted that there are too few public streets, so that an immense number of buildings are crowded together, many of which are accessible only by narrow passages, which are very ill calculated either for free circulation of air, admission of light, or domestic cleanliness. In the modern buildings these inconveniences are avoided, and whatever inconvenience may remain, must rather be attributed to the habits or negligence of the occupants, than to want of facilities on the part of the architects.

There are many very fine public buildings in Glasgow, the most prominent of which we shall very briefly enumerate.

Churches.—The cathedral or high church is perhaps the finest specimen in Scotland of that species of architecture, generally denominated Gothic. It was founded in the year 1123, and consecrated in the presence of King David I. in 1136. This building is more similar to that of Litchfield, than to any other of the English cathedrals, but it does not appear to have ever been completely finished, and certainly until lately little care has been used for its preservation. After the reformation it is said to have narrowly escaped demolition from the misguided zeal of the people, who confounded the building itself with the religious or superstitious ceremonies which they had produced. It now contains two churches adapted to the Presbyterian form of worship, and the choir is used as a place of interment.

The burying vaults, or cemetery, were formerly occupied as another place of worship for the barony or country parish of Glasgow; but lately a new church has been erected for this purpose at the opposite extremity of the church-yard. The great aisle is very lofty, and in some degree resembles that of Salisbury. The church was dedicated to St. Mungo, or Kentigern, whose burying-place in one of the vaults is still shown.

The remaining churches possess in general little claim to architectural encomium or description. They are six in number, viz. the college, St. Andrew's, North Well, Iron, St. Enoch's, and St. George's.

St. Andrew's church is a handsome modern building, of Corinthian architecture, and is very familiar in appearance to the church of St. Martin in the Fields, Westminster.

St. Enoch's and St. George's are also handsome modern buildings. Besides the established or parochial churches, there are many dissenting chapels and meeting houses, some of which are very handsome and commodious.

Prison.—This is a large and very strong building, situated in the centre of the city, adjoining to the Exchange. The lower part is occupied by the council-chambers, and rooms for the magistrates and the city clergymen; the middle part of the building contains the close or lock-up rooms for those imprisoned upon criminal charges; and the two upper floors are allotted for the reception of civil debtors. The roofs are lofty, the apartments airy, and the building, upon the whole, commodious; but it is in compliance with an act of the legislature that the prisoners may have the benefit of fresh air and exercise, from which they are at present precluded.

Bridewell.—This is a large building which serves as a place of confinement, or penitentiary house, for persons of depraved habits convicted of petty offences. It is very well regulated, and every means of encouragement afforded for reclaiming the prisoners from their vices, and promoting habits of industry. Many, at the period of their confinement, have thus acquired and received considerable sums, besides the expense of their subsistence, which is deducted from their earnings.

Town Hospital,—for the reception of poor persons unable to maintain themselves. The expense of this establishment is defrayed by a tax or assessment on the inhabitants, and by the proceeds of the labour of those admitted, who are supplied with work suited to their respective abilities. The inmates are aged and infirm persons and destitute children; the latter are well educated, and when arrived at a proper age, the boys are apprenticed to trades and the girls sent to service. The economy of the house is superintended weekly by gentlemen who act in rotation. The whole is very well managed.

Royal Infirmary—a very fine modern building, from a plan of Mellis, Adams'. From 90 to 120 patients are generally under cure, but the house contains accommodation for a much larger number when required. It is supported by donations, legacies, and annual subscriptions; the funds at present amount to 10,000l. or 12,000l., besides what has been annually expended; the annual disbursement is about 800l. or 1000l.; the direction is vested in the lord provost, the dean of guild, convener of the trades, professors of medicine and anatomy, president of the faculty of physicians, member for the city, and eighteen directors, ten of whom are elected by the contributors, and the others by various public bodies. The directors elected by public bodies are, one by the council, one by the merchants, one by the trades, one by the university, one by the ministers of Glasgow, and three by the faculty of physicians and surgeons. The medical attendance is afforded gratuitously.

Theatre Royal.—This superb house was erected a few years ago by voluntary subscriptions, upon transferable shares of 25l. each. The total cost was upwards of 15,000l., part of which remains as a debt upon the property, the whole annual rent being appropriated for its gradual liquidation. The direction of the property is in sixteen directors, four of whom go out annually, in rotation, but may be re-elected. It is unquestionably the largest and most magnificent provincial theatre in Britain. The managers are merely lessees, and the lease is always given for a short period, seldom exceeding two or three years.

Concert and Assembly Rooms.—These rooms are also very splendid, and, like the theatre, were erected by voluntary subscription, upon transferable shares.

University.—The buildings of the university have been erected at various times, and in very different styles, cannot
be appreciated by any precise scale of architectural taste; but the whole has certainly an air of imposing grandeur, and is very well adapted in every respect to the purposes for which it is designed. It consists of four distinct courts, which communicate with each other, and is accessible from the high street by three gateways. Behind is a large garden laid out in lawns and shrubbery, with very fine walks; it is divided into three parts, of which one is appropriated as a botanical garden, another is open as a place of exercise and recreation for the students, and the third, in which the astronomical observatory is situated, is generally reserved as a place of retirement, for the professors, or of ammonium for their families and friends.

The university of Glasgow was founded in the year 1451, by William Turnbull, bishop of the diocese, and then confounded of a chancellor, a dean of faculty, a principal, who was also professor of theology, and three professors of philosophy.

The professors and lectures are now as follow:

The funds for the support of the university are in a very flourishing and prosperous state. Independently of the endowments derived from the students, salaries and commissidious hours are allotted to every professor, and these expenses are defrayed from the funds at various times granted to the university; of these, the funds or tythes of the parish of Govan, form a very prominent part. The students of the five junior classes, viz. natural philosophy, moral philosophy, logic, Greek and Latin, are distinguished by wearing gowns of scarlet frock; the students of the senior classes have no particular distinction of drest. The resident members of the university claim an exemption from all civil burthens and services, and generally from the jurisdiction of the city magistracy, but acknowledge that of the sheriff of the county, and of the supreme courts of Scotland.

The internal government of the university is vested in the principal and professors, who, in their juridical capacity, assume the title of regents. Their supreme court is a general assembly of the whole faculty, who, at a remote period, assumed the power even of capital punishment. The most severe sentence, however, which has been passed for many years, is that of expulsion, and even this has been very rarely exercised. An inferior court is the "Jurisdiction ordinaria," consisting of at least three regents, who determine offences against the general order and peace of the university, and punish by a pecuniary fine. Each professor also possesses the power of levying small fines in his own chapel for negligence, contumacy, or irregularity.

The number of students in the university was estimated at 500 thirty years ago, and this number is now greatly increased. The professors and students, when assembled for the election of a rector or any other general purpose, are divided into four nations, according to the places of their respective births, viz.

- Scoti—comprehending the natives of Scotland, and of the adjacent districts of Scotland south of the Forth.
- Transforti—natives of Scotland, on the north of the Forth.
- Rothi—natives of the west highlands of Scotland and of Ireland.
- Laudon—natives of the eastern districts of Scotland, of England, America, and the colonies. The votes of these nations are decided by a majority, and the majority of nations decides the question. In cafes of parity the decision is in the regents.

The university of Glasgow has recently received a most valuable acquisition, by the bequest of the museum of the late Dr. William Hunter, of London. For the reception of this valuable legacy, a very handsome building has been erected, where it is now arranged. The museum consists of a valuable collection of paintings, chiefly original; a very fine collection of anatomical preparations; a cabinet of medals, and a fine library. The medals are accounted of such value, that the trustees of the British museum are said to have offered 25,000l. for them, besides furnishing such duplicates as they possessed, and defraying the expense of an application to parliament for an act, to far to dissolve the teator's will. This liberal offer, however, was declined.

The public library of the university is also a collection of uncommon value. It consists of upwards of 6000 volumes, and many very rare and valuable manuscripts. In the faculty hall are some valuable paintings, particularly one of the "Martyrdom of St Catharine."

Among the celebrated literary characters, which have belonged to this university, the names of Dr. Cullen, Dr. Adam Smith, and the late professor Miller, are most recently conspicuous.

There are many other public buildings in Glasgow, of which it will be necessary to confine ourselves to very brief notices.

The Trades-hall is a fine modern building from a plan of Mr. Adams. It is used for the general meetings of the fourteen incorporated trades, and is also occasionally occupied for concerts, balls, and other public amusements.

The Merchant's Hall is an old building, remarkable for nothing but the spire, which is a very fine one. It is used by the body to which it belongs, in the same manner as the Trades-hall.

The Public Markets are very commodious, and consist of square-paved courts, surrounded by the stalls where the meat is exposed for sale. No cattle are slaughtered here, and they are kept very clean and regularly inspected.

The Barracks are situated in a large area walled round, and consist of three very large buildings, one of which is appropriated for officers, and two for non-commissioned officers and privates. Their complement is 1072 men, but they will lodge on emergency 4 or 500 more.

Town—
GLASGOW.

Town-House—a fine old building adjoining to the prison. Only one hall is retained by the body corporate. The remainder contains the Tontine hotel, which was enlarged by subscription upon lives. The coffee-room is, perhaps, the largest and finest in Europe. It is supported by annual subscription, the subscribers amounting to upwards of 1000, who pay one pound five shillings each.

Bridges.—Three of these are of stone, and a fourth was actually built in the year 1755, when the river rising rapidly, in consequence of excessive rains, it was swept away in one night when very nearly finished. The arches being very flat, and the extremities not sufficiently secured, the accident was attributed, by professional persons, to the lateral pressure. Its place has since been supplied by a very handsome wooden bridge for foot passengers. The two bridges highest upon the river are plain, but very well built and paved. The lowerr, or new bridge, is very finely executed, and is esteemed one of the most compleat specimens of this species of architecture in Britain.

Water-works.—The city of Glasgow, until lately, was supplied with water by pits-wells, and the water of these, although abundant in quantity, was of inferior quality both for washing and culinary purposes; as, besides other impurities, it holds in solution a considerable portion of marine acid, by which it is rendered hard and brackish. To remedy this inconvenience a public company was formed, who, at the expense of upwards of 60,000l., brought water filtered from the river into every part of the city and suburbs by cast iron pipes, and from these pipes into every house, upon receiving a moderate annual payment from the proprietor or lessee. The capital necessary was raised by transferable shares of 50l. each. The rapidity with which those shares were bought induced others to form a separate establishment, and to raise water also from the river for the supply of the city. The first supply is drawn from the Clyde by two large steam engines, into a reservoir about two miles to the eastward of the town. From this reservoir it is filtered into another, and from thence conveyed by the pipes to a third immediately contiguous to the town. The whole lower part may be supplied from this without further forcing, but to supply the higher parts, a portion is again forced by another smaller engine to a cistern on a higher elevation, which commands every part above the former level.

The western water-work company draw their supply from the river to cisterns situated on an eminence about one mile west of the town, where it is filtered, and conveyed by pipes, without requiring to be forced a second time. The inhabitants are left to their own free choice from which company to take their supply.

River Clyde.—The Clyde takes its rise about 60 miles to the south-east of Glasgow, in the same mountain which forms the sources of the Tweed and the Annan. Near the county town of Lanark, about 28 miles above Glasgow, it has three remarkable falls or cataracts, much visited by strangers. From Lanark to Glasgow it passes through a fine valley, richly wooded in many places, fertile and highly cultivated. From the new bridge of Glasgow, where it becomes navigable, until it terminates in St. George's, or the Irish channel, about 80 miles distant. About thirty years ago, Mr. Goldsmith, an eminent engineer, was employed by the city of Glasgow to deepen the river, from the Broomielaw or harbor, to the sea-port towns of Port Glasgow and Greenock, the former situated 21, and the latter 24 miles below the city. This he effected in a very judicious, although gradual and economical manner. The beneficial effects of his plan became soon apparent, having been, every successive year, improving, and must continue so for many years to come. He began by constructing, on either bank, projecting dykes, or jetties, into the river, at right angles, to the banks on either side, and placed at small distances from each other along the whole course of the navigation. These jetties intercept much of the earth and gravel washed down by successive floods, and thus supply the materials for ultimate construction without the expense of carriage. Besides this, a number of farmers are employed every summer season to drag the bottom of the river, and lodge the stuff which is withdrawn from the bottom between the projecting jetties. By the constant repetition of this simple process, a great part of the river is now contracted to less than half of its original breadth, and has gained above four feet of additional depth. As the tonnage dues, the greater part of which is appropriated for this purpose, now exceed 6000 per annum, these operations promise to be continued on a more extended scale than ever; and it is probable that in a few years vessels of large burthen may be brought up to the city. The largest hitherto brought up are about 130 tons, the depth of the channel being about nine feet at high water. The gentleman who now directs these improvements thinks, that in a few years this depth may be increased to 14 feet by the present plan.

It was lately proposed to improve the harbour by the construction of huge docks; but a difference of opinion having arisen respecting the cost, under which these improvements were to be placed, the scheme has been suspended, but it is hoped not finally relinquished. The tonnage dues are one shilling per ton on merchandise, eighteen pence on foreign produce, and four-pence on coals, brick, and other building materials. Manure, carried upon the river for the improvement of the adjacent country, is exempted from any tax.

The country stretching along the banks of the Clyde, for a number of miles, both above and below the city, is generally fertile, and, in most places, highly cultivated, and well enclosed. The parish of Govan, situated on the south bank of the river, is, perhaps, as highly improved as any district in Britain. Besides the natural fertility of the soil, this may be accounted for by the plentiful supply of coal, lime, and manure, which are supplied at cheap rates by water-carriage. It must also be greatly promoted by the circumstance of there being many landed proprietors, whose estates, although abundantly sufficient to maintain themselves and their families in comfort and affluence under their personal superintendence, are not so large as to induce them to relinquish the profits and emoluments of cultivating their own property, which, of course, derives the united benefit of their personal skill, industry, and capital, besides that emulation which a laudable spirit of rivalry excites among them to surpass each other. The higher lands, both to the north and south, are considerably inferior, both in soil and cultivation, to those in the valley. In every direction round Glasgow, coal, lime, and iron-stone are found in great plenty, and give great advantages to the agricultural and manufacturing classes of the community.

The suburbs of Glasgow, which form the chief residences of the operative tradesmen, are the following:

Cathcart—a very populous village, immediately adjoining to the city on the south-east, and bordered on the Green of Glasgow. This village contains upwards of 20,000 inhabitants, with many manufactories, distilleries, &c. The green serves both for pasture and for the purporses of washing and bleaching. There are a commodious washing-house, and fine walks for the recreation of the inhabitants. The dues of washing and pasture form part of the city revenue. The green contains upwards of 100 acres of ground.
G L A S G O W.

Bridgetown—another suburb adjoining to the former, and similar in every respect.

Greenock—a village on the opposite bank of the Clyde, governed by a chief magistrate, appointed by the council of Glasgow, and two resident bailies.

Jagelon, Bezwfield, Finnington, and Partick.—These four villages lie to the west of Glasgow, on the north bank of the Clyde; they also are residences for operative tradesmen, and contain several extensive manufactories, viz. three large cotton mills, an extensive printfield, and porter brewery, at Anderlon; a large and flourishing glass-work at Finnington, and the very large flour-mills belonging to the incorporation of bakers at Glasgow, at Partick, where are also the ruins of an ancient castle, formerly belonging to the archbishop.

Municipal Government of Glasgow.

This, as formerly remarked, in ancient times, was almost exclusively vested in the archbishop and chapter. Since the reformation, it underwent various changes during the successive alterations of government in Scotland at large. The last arrangement made by royal and parliamentary authority, was early in the 18th century, under William and Mary. It has since been modified by the authority of the Scottish convention of royal boroughs, who exercize this power without dispute. As at present constituted, the government of the city is vested in the lord provost, three merchants, and two trades bailies, the dean of guild, or president of the merchants, the convey, or president of the trades, the city treasurer, and master of the public works, twelve counsellors from the merchants, and eleven from the incorporated trades, in all 33 counsellors. To this body the regulation of all the public business belongs; the lord provost being president, with the casting or deciding vote in cases of parity. The courts of justice within the city are the following:

1. The circuit court of judicature, for the cognizance of criminal actions, which is held twice a year at Glasgow, for the counties of Lanark, Renfrew, and Dumbarton, generally before two of the lords commissioners, although any one of their number is competent. This court also decides appeals in civil causes from any of the inferior courts within the district.

2. The magistrates or town court. This court is held under the authority of the magistrates, assisted by the town clerks as legal afforers. The jurisdiction of this court extends to any amount subject to an appeal to the court of seisin.

3. The conscience court, for the decision of petty causes under twenty shillings, where the formality of an oath is dispensed with, or any written pleading.

4. The fitting magistrate also decides daily trifling claims under five shillings. The magistrates also exercize a criminal jurisdiction in petty crimes, and punish by imprisonment, pillory, and sometimes public whipping and banishment from the city.

5. The sheriff court, for the under-ward of Lanarkshire, is also held at Glasgow, before the sheriff substitute. His jurisdiction is equal to that of the magistrates, not only within the city, but the district. The decisions of this court are subject to appeal to the sheriff depute and to the court of seisin.

6. The justice of peace court also decides civil causes to a limited amount, and regulates disputes between masters and servants. The appeal from this court is to the quarter seisins, and finally to the court of seisin.

7. The small debt court is held by two or more justices, for the decision of causes under 10/.. No professional lawyer is heard here, and the pleadings are verbal. They review their own decisions upon appeal, provided the sum demanded for be lodged with the clerk of court.

8. The commissary court is the remotest of the bishop's courts. It decides for sums under 3/. 6s. 8d., and also in cases of defamation. Its jurisdiction extends over all the ancient bishopric.

Police Establishment.—This establishment was constituted a few years ago under the authority of a special act of parliament. The commissioners named in the act are, the lord provost and bailies, and twenty-four commissioners elected by twenty-four wards, into which number the city is divided. The qualification of a commissioner, is the occupation of a dwelling house valued at 15/. or upwards of yearly rent; and of a voter, that of any house at 10/. or upwards. The business of this establishment is the lighting, cleaning, and guarding of the streets, and suppression of quarrels, riots, and other breaches of the public peace. For this purpose a master, or intendt of police officers, and watchmen are employed. A magistrate sits every morning at the police office to decide upon those who have been apprehended during the night. Where the charge is serious, he generally remits the cognizance of it to the town court, and punishes petty delinquencies by a small fine. The expense is defrayed by a tax on the valued rents of shops, warehouses, and dwelling houses, by fines levied in the course of the year by the sale of manure, from cleaning the streets, &c. The maximum of the tax is from 6d. to 11d. per pound of valued rent, but much less has been generally found sufficient. This institution has been always hitherto conducted with the most vigilant attention to economy, and is very popular even among those of the citizens, who strenuously opposed its original adoption.

Commerce and Manufactures.—The commercial importance of Glasgow only began to rise subseqently to the Union, and had attained no very important extent until the colonization of North America opened a wide field for the exportation of British commodities, and the importation of American produce in return. Previous to the commencement of the American war in 1775, it had, however, engaged very extensively in the tobacco trade, for it appears that of 50,000 bales of tobacco imported into Britain in 1772, 49,600 bales were brought into the Clyde alone, and, in 1775, the importation was 57,113 bales.

The operations of the war necessarily put a stop to this intercourse, to the great loss of the merchants engaged in it; many of whom have never been able to recover their debts. Upon the restoration of peace in 1783, the trade with America revived, and continued again in a flourishing state, until again recently superseded by the American non-intercourse act. In 1783, the registered vessels of the Clyde, were 386, and their tonnage 22,896, and in 1803, the number cleared outwards and inwards was as follows:

Total 3095 238,799 17,077.
From this note some idea may be formed of the extent of the trade; but many of these vessels having probably made several voyages in the course of the year, it is not to be inferred that this number of vessels actually belongs to trades to the Clyde. The articles of exportation are chiefly British manufactured goods, coal, fife, &c., and the imports European, American, and colonial produce.

The city of Glasgow had also a very considerable commercial intercourse with the eastern parts of the island, and with the northern states of Europe, until this was suspended by the events of the war. This intercourse is carried on by means of the Forth and Clyde canal, which interfaces Scotland, and forms a junction between the eastern and western seas, some account of which has already been given under the article Canal.

The manufactures of Glasgow had obtained no very great extent previous to the commencement of the American war; although they had been progressively advancing during the whole course of the eighteenth century. So far back as the reign of Charles II. indeed, some attempts had been made to introduce the manufacture of soap, refining of sugar, and some other branches, all of which proved abortive, and were discontinued. The linen manufacture was the most extensive of the various attempts made, and the most successful during the time that it lasted. It commenced about the year 1725, and continued progressively advancing until it was almost entirely superseded by the cotton towards the close of the century. The cotton manufacture, which is now unquestionably the staple trade of Glasgow, was prosecuted to very small extent until after the year 1784, but when once introduced it advanced with unprecedented rapidity. It is impossible to ascertain with any precision its actual amount either in quantity or value at any given period for want of proper data. A computation in 1791 makes the number of looms employed 15,000, and the persons who earned their subsistence by various parts of the processes of spinning, weaving, bleaching, &c. 125,000. It also estimates the total value of the goods made yearly at 1,500,000/. The grounds of this calculation are not stated, and little reliance can be placed on it, for the value of cotton goods has fluctuated as remarkably as the quantity has extended.

Two manufactories of calico are carried on in Glasgow, but neither of them extensively. Indeed a much greater quantity of Staffordshire ware is used in the city itself than of the produce of either. Two or three rope works are also carried on, but to no great extent.

The printing of calicos and other goods is, however, a very extensive branch of the manufacture of Glasgow and its vicinity. The most extensive of these works, are those situated upon the water of Leven, in Dumbartonshire, about 18 miles distant. The extension of the cotton trade has also greatly improved and enlarged the number of dye-works, and the manufactures of chemical preparations for the various processes of bleaching, dyeing, and printing. These works are situated in the vicinity of the city, chiefly on the banks of the river Leven.

Of the chemical works carried on in Glasgow, some are peculiar to it.

The manufacture of the oxy-muriate of lime, in a dry form, for the purposes of bleaching, &c., is also almost peculiar to Glasgow. Its object is to decrease the expense of bleaching by the substitution of lime for potash. This article is made to great extent by Mr. Tennent the inventor.

Iron liquor, for the use of printers, is made here by various persons, and large alum works are established in the neighbourhood. Manufactures of red and white lead are also carried on.

Miscellaneous Remarks.

It will appear that the city of Glasgow has undergone three remarkable changes. Its first state was the residence of a great archiepiscopal see, and consequently it was for many ages entirely under clerical influence and control. Its first eminence as a commercial place arose from its favourable situation for commerce with the American and West Indian colonies, and through this traffic it made rapid advances in commercial importance during the whole course of the eighteenth century. One branch of this traffic being at least for the present suspended, it now depends chiefly on the other, and upon its manufactures for support. From the facilities of acquiring a good education, the inhabitants of Glasgow have generally added a considerable taste for literary attainment even to their commercial habits, and this style prevails, perhaps, in a degree superior to any other commercial place in Britain. The system of education is, however, rapidly adapting itself to the modern pursuits of the inhabitants, and more pains are now taken to qualify the rising generation for eminence in the counting-house than the cloister. However defirable a thorough knowledge of the principles of commercial economy, and the details of business may be in a commercial community, it is still to be hoped, that all the benefits arising from intellectual attainment will not be deemed altogether nugatory, and consequently neglected. In every situation of life, they are sources of rational and innocent amusement, and, in the wisdom by which commercial enterprise is peculiarly supported, may often prove of real benefit and utility to the possessor.

The city of Glasgow returns a member to the British parliament, conjunctly with the neighbouring burghs of Rutherglen, Ruthven, and Dumfartan.

Glasgow, Port, situated on the river Clyde, about 22 miles below the city, is a handsome small town, and was projected by the magistrates of Glasgow at the request of the merchants as a harbour for their ships and vessels. It is said that the first plan was to improve the harbour of Dumbarton for this purpose, but Dumbarton being a royal borough, the consent of its magistrates became necessary, and that when made, it was rejected by that body, who preferred the full enjoyment of their chartered privileges to the idea of falling into the mere fea-port of Glasgow, however much their wealth, revenue, population, and general prosperity might be benefited by such an union. If this were the case, it is one among the numberless instances where comfort and prosperity have been sacrificed to a mere empty title. The harbour of port Glasgow is good but shallow. The disadvantage of the bank, noticed in the article Greenock, is also much against it as a haven. At port Glasgow there is a custom-house, where the general customers of the Clyde are collected. There is here also a fine graving or dry dock, built by the merchants of Glasgow long before that of Greenock was executed, and this circumstance alone brought many ships up to this port which now come no further than Greenock. The situation of port Glasgow is more pleasant than that of Greenock, the country more level, and better adapted for cultivation. In other respects it is certainly less
Glasgow

of calculated for the general purposes of maritime traffic than its rival, and therefore there is little probability of its extension. Indeed the shipping belonging to Glasgow is certainly on the decrease, the foreign merchants finding it more for their advantage to freight or charter vessels for any purpose than to build or buy vessels of their own, which both confine and rob a considerable portion of their capital, and may, from the many casuals and fluctuations to which commerce in this eventful age is exposed, prove rather burdens to advantages, while the mere ship-owner, if deprived of a freight or charter-party at one port, may with greater facility seek it at another, than the perfon with whom freight is only a secondary and inferior consideration.

Port Glasgow is governed by magistrates, appointed by the council of Glasgow, and some resident magistrates. Its exports and imports have been already given and compared with those of Greenock under the article Glasgow, which indeed furnishes by far the greater part of the freight to and from both ports.

There are no manufactures here of any extent, excepting those which are to be found at almost all sea-port towns, viz. ship building and rope spining. Both of these are carried on to a very considerable extent. A work was erected some years ago for refining of sugar, and also a small cotton-mill, but neither have ever been prosecuted to any great extent.

A plan has been formed, and its execution is now begun, which in time may produce a great effect, both on this town and Greenock. This plan has for its object the formation of a more direct communication between Glasgow and the west sea, than the present circuitous navigation of the Clyde, by means of a navigable canal to be carried from Glasgow to Arrochar, near Irvine, which is about thirty miles farther down the river than the present seaports. This canal was projected under the sanction and patronage of the present Earl of Eglinton, (lord Ardrossan of Great Britain,) a part of whose estates lie in that neighbourhood. Its objects are two-fold. First, to facilitate the maritime intercourse of Glasgow and Paisley with the New World, by a more direct channel and better harbour. Second, to improve the agricultural and internal trade of Renfrewshire, as the northern district of Ayrshire, by forwarding means for the cheap conveyance of coal, lime, manure, and other heavy articles by means of the canal. Arrochar is situated not more than thirty miles from Glasgow, by the line of the projected canal, and therefore the carriage of goods will not be more expensive or tedious than by the Clyde, for the canal being free from the constant interruptions arising from the operation of wind and tide upon the river, the time of arrival and departure may be depended upon at all seasons and in all weathers. A considerable sum has already been sub-fired for the canal, and also, for the harbour, and from the well-known energy and activity of his lordship's general character, there is no reason to doubt that every exertion for its speedy completion will be used.

It is natural to expect that every opposition will be given by those whose local interests will suffer by the success of this undertaking, and who comprehend many wealthy and powerful classes; but whilst some oppose, others will find it their interest to promote it, and the competition must be ultimately advantageous to the general body, however it may terminate as to those more immediately interested.

The other part of the plan is the formation of an excellent and secure harbour at Arrochar, capable of receiving ships of large burthen, and this also is begun. The subsciptions for the two undertakings are conducted separately. The coast here is in some places reckoned dangerous during the prevalence of strong gales from the north-west, when vessels are making the land; but it is said that the bay of Lamlash, in Arran, will afford a safe and easy shelter within a few hours after, if this may prove to be the case. The survey, plans, and estimates for the canal and harbour of Arrochar were made under the superintendence of Mr. Telford. It must be perfectly evident that this canal will in all events produce much benefit as it passes through the most populous and flourishing manufacturing district in Renfrewshire.

Glasgow, a new county of America, in Newbern district, North Carolina, taken from Dobbs's county, bounded N. by Edgecomb, S. by Lenoir, E. by Pitt, and W. by Wayne.—Also, a town of New York, on the E. coast of lake Cayuga; eight miles S. of Cayuga.

GLASS, in the general acception of this term among Chemists, denotes any substance or mixture, earthly, faline, or metallic, which is reduced by igneous fusion to the shape of a hard, brittle, uniform mass, which breaks with a conchoidal fracture, passing into splintery, and with a high degree of luster. Most glasses of this kind are also transparent. See ViTRUvius, Vitrum, in a more restricted sense, and as the term is commonly used in the arts and manufactures, signifies that transparent, solid, brittle, facitious substance, produced by the vitrification of silicious earth with various salts and metallic oxides, which is applicable to innumerable purposes of ornament and comfort, as well as of scientific investigation and research.

As to the antiquity of the term glafs, Tarsus (Germ. c. 45.) and Pliny (l. xxxvii. c. 3.) inform us, that amber was called among the ancient Gauls or Germans by the name of glefum or gleffum; and from the similarity which glasses bore to amber with respect to transparency and brightnes, it acquired a name, which was, in all probability, originally the same. The word glefum denoted, without doubt, a shining; or transparent substance, as glefum expreses at present in the German language to shine; and our English word to glife is derived from it, and has nearly the same significance. Duncan says that some critics were of opinion, that the word glefum itself implied glafs rather than amber. The ancient Greeks, as it has been already observed, applied the same term (S. Vitrum) both to glafs and amber. The herb with which the Britons painted their bodies had also the name of glefum, perhaps from the shining appearance it might give to their limbs, or possibly because its ashes might be used in the making of glafs. The Latins called the same plant by the name of vitrum, the word they used to signify glafs. (Cesar, Bell. Gall. l. v.)

We find frequent mention of this plant in ancient writers, particularly Cesar, Vitruvius, Pliny, &c. who relate, that the ancient Britons painted or dyed their bodies with glefum, gradum, vitrum, &c. i.e. with the blue colour procured from this plant. And hence, as some have supposed, the facitious matter we are speaking of, came to be called glafs, as having always somewhat of this bluehupe in it.

Merret (Not. in Ant. Neri de Art. Vitrat,) gives us the following characters or properties of glafs, by which it is distinguished from all other bodies, viz. 1. That it is an artificial concrete of earth and sand, &c. 2. Produced by a strong fire. 3. When fused, tenacious and coherent. It does not break or confume in the fire. 5. When melted, it changes to iron. 6. Ductile, when red-hot, and fashionable into any form, but not malleable; and capable of being blown into a hollownes, which no mineral is. (See Ductility of Glafs.) 7. Frangible when thin, without annealing. 8. Friable when cold. 9. Always diaphanous, whether hot or cold. 10. Flexible and elastic. 11. Dissilable by cold and moisture. 12. Only capable of being graven, or cut with a diamond.
diamond or other hard stones, and emery. 13. Receives any colour or dye, both externally and internally. 14. Not discoloured by aquafortis, aqua-regia, or mercury. 15. Neither acid juices, nor any other matter, extract either colour, tare, or any other quality, from it. 16. It admits of polishing. 17. Neither loses of weight nor fulbance, by the longest and most frequent use. 18. Gives fusion to other metals, and softens them. 19. The most pliable thing in the world, and that which best retains the fashion given it. 20. Not capable of being calcined. 21. An open glass, filled with water in the summer-time, will gather drops of water on the outside; but so far as the water on the inside reaches; and a man's breath blown upon it will manifestly moisten it. 22. Little glasses balls, filled with water, mercury, and other liquor, and thrown into the fire, as also drops of green glafs broken, fly asunder, with a loud noise. 23. Neither wine, beer, nor any other liquor, will make it muddy, nor change its colour, nor ruffle it. 24. It may be cemented as stones and metals. 25. A drinking-glass, partly filled with water, and rubbed on the brim with a wet finger, yields musical notes, higher or lower, as the glass is more or less full; and this makes the liquor frisk and leap. See ARIONICA. For the electrical properties of glafs, see ELECTRO, &c.

GLASS, origin and history of. De Neri will have glafs as ancient as Job; for that writer, chap. xxxvii., ver. 17, speaking of wisdom, says, "gold and glafs cannot equal it."

Thus, we are to observe, is the reading of the Septuagint, Vulgate Latin, St. Jerom, Pindar, &c. for in the English version, instead of glafs, we read crysál; and the same word is done in the Chaldee, Arius Montanus, anid the king of Spain's edition. In other versions, &c. it is read flone; in others crysál: in the Italian, Spanish, French, High and Low Dutch, &c. diamond; in others, carbuncle; and in the Targum, looking-glass.

In effect, the original word is σκουλάθρον (σκουλαθρον), which is derived from the root zac, to purify, cleanse, stone, white, transparent; and the same word (Exod. xxv. 34.) is applied to frankincense; and rendered in the Septuagint peladion. Hence the reason of so many different renderings, for the word signifying beautiful and transparent, in the general, the translators were at liberty to apply it to whatever was valuable and transparent.

Herodotus (i. 3.) is, according to Dr. Falconer (Manchester Memoirs, vol. ii.), the most ancient writer (B.C. 440) who used the word σκουλάθρον, which is generally understood to signify glafs. But he evidently does not mean artificial glafs, nor crysál, but, most probably, somewhat of the tallow kind, or lapis specularis, which might readily be framed in such a manner, as to form a convenient transparent cask, such as the ancient historian has described. Arkophanes (B.C. 400) seems to be the next writer who mentions glafs: that poet, in his comedy called the Clouds, Scene i. act. 2, uses the word ὕππαλως, which is now ordinarily rendered glafs. He there introduces Strephias teaching Socrates a new way to pay old debts, σκουλάθρον, "by placing a fair transparent stone, fold by the druggists, from which the fire is struck, between the funny and the writing, and so melting away the letters thereof." This same Socrates calls χαλάθρον, which the Scholion on Arrostophanes derives from δραμαλον, from the likeness it bears to ice, which is rain, or water congealed; though, it must be owned, the word σκουλάθρον is ambiguous, and signifies ὑππαλώς as well as χαλάθρον; and Gorraus observes, that the ancients had a kind of yellow amber, transparent as glafs, called by some χαλάθρον.

Aristotle (B.C. 340) has two problems upon glafs: the first, Why we see through it? The second, Why it is not malleable? If these problems be Aristotle's, which the learned doubt very much, this would properly be the earliest testimony in favour of the antiquity of glafs. Theophrastus (B.C. 325) seems to have been well acquainted with glafs; for he describes it as having been made of the sand of the river Belus, which was called vater, to which he adds, that the common kinds are made with copper. The celebrated sphere of Archimedes (B.C. 250), if it be truly described, is a remarkable influence of the perfection to which the art of making glafs had been brought at that early period.

Lucian mentions large drinking-glasses; and Plutarch, in his Symposicon, says, that the fire of tannakim wood is the fittest for making of glafs.

Among the Latin writers, Lucretius is the first that takes notice of glafs: "Nil recta foraminis transt, quin fulcit vitri," lib. vi. v. 3. Dr. Merret, however, adds, that glafs could not be unknown to the ancients, but that it must needs be as ancient as pottery itself, or the art of making bricks; for scarcely can a kiln of bricks be burnt, or a batch of pottery-wares be made, but some of the bricks and ware will be at least superficially turned to glafs.

Hence, Ferrant. Imperialis, lib. xxv. cap. 7. "Glas, like the common kind, is found under ground, in places where great fires have been. Other glases are found in round clods, like fire-clods, some brittle, others firm, &c. This kind of glafs is wrought by the Americans, and used instead of iron. And no doubt but vivifications were more common in the ancient bricks than they are in ours; as they tempered their earth two years together, and burnt them better.

Virgil (B.C. 390) compares the clearness of the water of the Euxine lake to glafs. Horace (B.C. 36) is more express, and mentions glafs in terms that shew its clearness and brilliancy; and have been brought to great perfection. Carm. iii. Od. 2. Od. 13 In the time of Strabo, (A.D. 77) the manufacture of glafs was undoubtedly well understood, and had become a considerible article. Seneca (A.D. 65) was not only well acquainted with glafs as a substance, but also understood its magnifying powers when formed into a convex shape. Quesil. Natur. lib. iii. vi.

Pliny (A.D 77) relates the manner of the discovery of glafs: it was first made of sand, according to that author, (Nat. Hist. i. xxxvi. c. 66, &c.) found in the river Belus, a small river of Galilee, running from the foot of mount Carmel, out of the lake Cesarea. The part of the shore where the sand was dug did not exceed 500 paces in extent, and had been used many ages before by the same purpose. The report of its discovery was, that a merchant ship, laden with nitre, or fojil alkali, being driven upon the coast, and the crew going ashore for provisions, and dressing their victuals upon the shore, made use of some pieces of fojil alkali to support their kettles. By these means a vivification of the sand beneath the fire was produced, which afforded a hint for the manufacture. In proceeds of time the calx of iron, in form of the magnetic stone, came to be used along with the fojil alkali, from an idea of its not only containing iron, but glafs, in a liquid form. Clear pebbles, shells, and fojil sand, were also in many places employed for the same purpose. It is said, that in India pieces of native crysál were used for that purpose; and on that account the Indian glafs was preferred to any other. Pliny adds, that light and dray woods were used for the melting of glafs; to which they added copper from the island of Cyprus, and the fojil alkali, especially that which is brought from the East Indies. The furnaces are kept burning without intermission, that the copper may be melted with the glafs, and out of this compound are made mallees of a comne blackish colour. These lamps or mallees are
G L A S S.

again melted, and tinged of the colour required. Some of the idle pieces are brought to the flame required by blowing with the breath; some are ground on a lathe, and others are embossed in the same manner as silver. Sidon was formerly famous for these manufactures, as specula or looking-glasses were first invented there; "liquidum etiam specula excogitaverat." Such is the ancient method of making glafs, described by Pliny. In his time, it was made with sand found at the mouth of the river Vulturinus, upon the shore, for six miles between Cuma and the Lacinian bay. This sand was very fine, and was ground to powder with a ball or sphere and a mill. It was then mixed with three parts of the toffil alkali, either by weight or measure; and being fused, was conveyed in a liquid state into other furnaces, where it was formed into a mass, called "ammuniment," (or sand combined with the toffil alkali,) which mass was melted, and became then pure glafs, and a mass of white vitrified matter. The same method of making it prevailed in Spain and Gaul. Glafs was likewise made to imitate the lapis Obsidianus, a sub stance found by a person of the name of Obsidius, in Egypt and Ethiopia. This substance was of a very hard, yet obscure, transparent, and often placed among specula in the walls of rooms, to reflect the shadow of objects. It was also used for the same purpose as gems (probably for engraving upon) and even for statues. Pliny mentions, that he few flat specula of the emperor Augustus made of this material; and the same emperor dedicated four elephants made of the same substance in the temple of Concord. It seems to have been used from great antiquity; but in the time of Pliny the artificial imitation of it by glafs was used instead of the native material; and he intimates that the black colour was produced by some coloring ingredient. The Romans had likewise an opaque red kind of glafs, used for plates and dishes for the table, called "hematomin," one of various colors, called "myrrhinum," a white, a clear red, a blue, and indeed most other colours. Pliny observes, that no sub stance was more manageable in receiving colours, or being formed into shape, than glafs. The perfectly clear glafs, which bore the greatest resemblance to crystal, was, however, most valued. Nero gave for two cups, with two handles to each, and of no extraordinary size, "freeselvetis," or nearly 5000, almonds. The inferior kinds were not uncommon, as Pliny informs us, that the use of glafs cups had nearly superseded those of gold and silver. We shall here add, that Pliny knew the power of a hollow glafs globe, filled with water, in concentrating the rays of light, so as to produce flame in any combustible substance upon which the focus fell; and he also mentions, that some surgeons in his time made use of it as a cauticum for ulcers (I. xxxvii. c. 2.). He was likewise acquainted with the comparative hardness of gems and glafs. As he observes, that the lapis Obsidianus would not scratch the true gems; and he also mentions (I. xxxvii. c. 13.), the counterfeiting of the latter, in his time, as a very lucrative art, and brought to great perfection. He also says, that glafs might be cut or engraved upon by means of diamonds, which art is evidenced by the antique gems so frequently found (See Gæt.) Josephus, (Bii. c. 10.) mentions the sand of the river Delus, in Gaul, as fitting for making glafs.

The first time we hear of glafs made among the Romans was in the reign of Tiberius, when Pliny relates that an artist had his house demolished for making glafs malleable, or rather flexible; though Petronius Arbiter, and some others, assure us, that the emperor ordered the artist to be beheaded for his invention. In the time of Martial, (A.D. 81.) glafs was not only brought to great perfection, and in common use for drinking vessels, but was employed (as it seems) for bottles in which wine was kept, and likewise for pots to hold flowers. (Epig. I. lii. 22. 40. I. iv. 86.) Galen (A.D. 143) frequently mentions glafs in several parts of his works, and seems to have been well acquainted with the method of making it. Apuleius (A.D. 161) mentions the manufacture of glafs cups, in his time, as highly wrought and carved in various ways, and of great value. Alexander Aphrodisiensis (A.D. 214) a Greek writer, and a commentator on Aristotle, has several remarks on glafs respecting both its brittleness, especially on change of temperature, and its transparency.

The manufacturers of glafs formed a company at Rome, and had a direct affiliation to them, in the first region of the city, near the Porta Capena. A tax was laid upon them by Alexander Severus (A.D. 220) which subsisted in the time of Aurelian, and probably longer after.

Mr. Nixon, in his observations on a plate of glafs found at Herculaneum, which was destroyed A.D. 86, on which occasion Pliny lost his life, offers several probable conjectures as to the uses to which such plates might be applied. Such plates, he supposes, might be used for writing, or当作 looking-glasses; for Pliny, in speaking of Sidon, adds, "liquidum etiam specula excogitaverat," the reflection of images from these ancient specula being effected by beaming them behind, or tingling them through with some dark colour. (See Mirr.) Another use in which they might be employed, was for adorning the walls of their apartments by way of wainscot, to which Pliny is supposed to refer by his vitrea cannae (lib. xxxvii. cap. 25 § 64.). Mr. Nixon further conjectures, that these glafs plates might be used for windows, as well as the laminae of lapis specularis and phengites, which were improvements in luxury mentioned by Seneque, and introduced in his time, Ep. xc. However, there is no positive authority relating to the use of glafs windows earlier than the close of the third century: "Manifellus est," says Lactantius, "mentem eis, per oculos ea que sunt oppollia, tranfcript, quasi per fenaeiras in vaso ant speculairi lapide obtutxas." De Opticio D.4, cap. 5. See Phil. Trans. vol. i. art. 86. p. 601, vol. ii. art. 28. p. 125.

St. Jerome (Epig. A.D. 422) speaks of windows formed of glafs, melted and cast into thin plates, as being used in his time. Paulus Silentiarius, a poet and historian of the 6th century, mentions the custom of the window of the church of St. Sophia, at Constantinople, which windows were covered with glafs. Gregory of Tours (A.D. 571) laments the devastations frequently committed in the windows of the churches by the ravages of war. Johannes Philoponus, who lived about the year 650, or, as some say, a century earlier, not only speaks of glafs, but of the panes being fastened in with paffier, much in the same way as at present.

If the opinion of Pennant, suggested under the article Aquarium vivum, be well founded, we have reason to believe, that, long before the conquest of Britain by the Romans, the art of manufacturing glafs into such ornaments as beads and amulets was known among the Druids; and if the art was thus applied, it is not improbable to suppose, that it was employed for more important and useful purposes, as in the manufacture of glafs vessels. Nor is it likely that the Britons derived this art from the Romans, who preferred silver and gold to glafs for the composition of their drinking vessels. Besides, the glafs that was commonly used by the Romans was of an inferior quality, and appears from some remains of it discovered at their stations and
and houses to have confromd of a thick, sometimes white, but mostly blue-green, metal.

According to venerable Bede, artizans skilled in making glases were brought over into England, in the year 1674, by abbot Benedict, who were employed in glazing the church and monastery of Weremouche. According to others, they were first brought over by Wilfrid, or Wigfrid, bishop of Worcester, about the same time, or, as others think, at a later period, A.D. 726. Till this time, the art of making glases, or at least of applying it to this purpose, was unknown in Britain; though glase windows did not begin to be used before the year 1480: till this period they were very scarce in private houses, and considered as a kind of luxury, and as marks of great magnificence. Italy had them first, next France, from whence they came into England.

Leo Ollifens (A.D. 760) speaks of the windows in his time being made with glase-plates fixed in lead, and fastened together with iron. Ananias, an historian of Rome, who was librarian to the pope, mentions, that in the pontificate of Leo III. who came pope about the year 800, painted glases in windows was in use. The statutes of the church of Trujicier, in Lower Brittany, about the year 1156, speak of the windows of churches and chapels being ornamented with arms and military emblems, painted upon the glases in them. A charter of Richard II. of England, quoted by Rymer, (A.D. 1386), contains a paragraph in which is mentioned glases, together with the manufacture of it for windows.

Venice, for many years, excelled all Europe in the finenes of its glases; and in the thirteenth century, the Venetians were the only people who had the secret of making crystal-looking-glases, and which they performed by blowing, much in the fame manner as a considerabfe quantity of the common mirror-glases is now manufactured. The great glases-works were at Muran, or Murano, a village near the city, which furnished all Europe with the finest and largest glases.

The glas manufacture was first begun in England in 1557: the finer fort was made in the place called Crutchet Friars, in London; the fine flint glases, little inferior to that of Venice, was first made in the Savoy-house, in the Strand, London. This manufacture appears to have been much improved in 1635, when it was carried on with sea-coal or pit-coal, instead of wood, and a monopoly was granted to Sir Robert Manell, who was allowed to import the fine Venetian flint glases for drinking, the art of making which was not brought to perfection before the reign of William III. But the flint plates, for looking-glases and coach windows, were made in 1673, at Lambeth, by the encouragement of the duke of Buckingham; who, in 1670, introduced the manufacture of fine glases into England, by means of Venetian artizans, with amazing success. So that in the eighteenth century, the French and English have not only come up to, but even far surpassed, the Venetians, and we are now no longer supplied from abroad.

The French made a considerabfe improvement in the art of glases, by the invention of a method to cast very large plates, till then unknown, and scarce practised yet by any but themselves and the English. That court applied itself with a laudable induftry to cultivate and improve the glas manufacture. A company of glase-men was established by letters patent; and it was provided by an act, not only that the working in glases should not derogate any thing from nobility, but even that none but nobles should be allowed to work therein.

It was in the year 1665, under the ministry of the great Colbert, that a company for “blown-mirror-glasses” was first established near Cherbouy, in Normandy, on the plan of the Venetian manufacture; but the beautiful art of casting glases was invented in France about the year 1688, by a perfon of the name of Abraham Thivart; and a company was soon established for this branch of manufacture, which was first carried on at Paris, and soon after removed to St. Gobin, where it still exists in full activity, and unmindful of reputation. An extensive manufacture of this kind was first established among us near Prefet in Lambour, about the year 1775, by a respectable body of proprietors, who were incorporated by an act of parliament. They struggled for a considerable time with difficulties; but being nobly rehenced and encouraged by government, they have succeeded in producing plates, rivaling, if not surpassing in size, quality, or brilliancy, the most celebrated continental manufacturers. This company furnishes, at Albion Place, London, plates of various dimensions, from 12 to 144 inches in length, and from 10 to 72 inches in breadth; and also convex and concave mirrors, from 12 to 36 inches in diameter.

Glass, Ingredients of: The materials used in the composition are some saline substance and some sort of silicious earth.

1. The first ingredient we shall specify is flux or fluxes. The flux is that which will melt, and which is white and transparent. It is this that gives confidence and firmness to the glases. This is found principally in Italy, being a sort of stony substance called terrae; the next is pauca, or congola, a sort of pebbles found at the bottoms of rivers, and gathered for the Venetian manufacture out of the river Po, which are said not to be inferior in whiteness to abbeater.

Indeed, nothing makes finer and clearer glases than common flint, distinguished for this use by its clear transparency, black color; this, when first used, must be heated red-hot, and then immediately quenched in cold water. The heat whitens it, and the water cools it to split it in every direction, and facilitates the grinding of it. The charge of preparing this deters the glases-men from using it. The rounded fragments of quartz, found in the beds of rivers among mountains, are sometimes used in foreign countries, being first heated and ground to powder. Indeed, the preparation necessary for flour, in general, is to calcine, powder, and Pearce it.

Ant Neri observes, that all white transparent flones, which will not burn to lime, are fit to make glases; and that all flones which will strike fire with fuel, are capable of being employed in making of glases. But this latter rule, Dr. Meret observes, does not hold universally. Where proper flone cannot be had, find is used; and it is now almost the only kind of sublimation employed in the British manufactures of glases. The best for this purpose is that which is white, small, and thinning; examined by the microscope, it appears to be small fragments of rock crystal. For green glases, that which is of a soft texture, and more gritty it is to be well washed, which is all the preparation it needs. Our glases-houses are furnished with white sand for their crystal-glases from Lynn in Norfolk, and Maidstone in Kent, and from the western extremity of the Isle of Wight; and with the coarser, for green glases, from Woolwich.

2. The second ingredient in the manufacture of glases is an alkali, which is either soda, or pot-ash. It is always used at first in the state of carbonat, though the carbonic acid flies off in the process. For the method of preparing each, see Carbonat. These alkalis are used in different degrees of purity according to the required quality of the glases. The finest sort of glases requires the bell pearl-ashes, purified by solution and evaporation, to dry; but for inferior glases coarser alkalis, such as barids.
GLASS.

wood-ashes, and kelp, are employed. The ashes of fern will also yield a salt, which will make excellent glafs; and, moreover, the ashes of the cods and stalks of beans, as also those of coleworts, bramble buffalo, millet-rattles, rushes, cypresses, and many other plants, may be used for the like purpose, and after the same manner.

There are other fluxes used for different kinds of glafs, and for various purposes. Lime, in the form of chalk, is employed in the manufacture of glafs; but the mixture used only in small proportions; for an excess would act powerfully on the sides of the glass-pots, in consequence of the escape of the carbonic acid from the chalk during the fusion, and, besides, it would render the glafs opaque and milky in cooling, however clear it might be when hot. It is known by experience, that to 100 parts of flex and the requisite quantity of alkali, no more than about six or seven parts of quick-lime, or chalk, can be added, without affecting the clearness of the glafs. Borax is another very valuable flux; but its high price restricts the use of it to the finest kinds of glafs, and to those which are required to be free from specks and bubbles. A very small quantity of borax will correct any deficiency of strength in the alkali.

Of the oxys of lead, litharge and minium are found to be of singular use in the manufacture of glafs. Litharge is a powerful flux, and imports to glafs the valuable qualities of greater density and greater power of refracting the rays of light, and of bearing sudden changes from heat to cold, without being so liable to crack, and also greater tenacity when red-hot, so that it is more easily wrought. A considerable quantity of this oxys is contained in the finer glafs; such as the London flat glafs, and that which is used for the table, for lustres, for artificial gems, and for most optical purpofes. Glafs, however, that contains much lead, is extremely soft; and liable to be injured by hard bodies that come into contact with it; and it is also very fusible. It is also liable to be corroded by very acid liquors. Besides, the use of lead renders it difficult to unite the flex and alkali, that a piece of glafs shall be throughout of uniform densit. Another ingredient occasionally used in glafs is the black oxys of manganese, called "glafs-fop," from its use in clearing the glafs from any accidental fouls of colour, and more especially from the green tinge, owing to the presence of iron. Scheele and Bergman in their respective "Effays," have illustrated many curious circumstances that attend the use of manganese in glafs, which are particularly noted in Alkali's Dictionary. The manganese should be chosen of a deep colour, and free from specks, of a metallic appearance, or a lighter call; and it requires to be well calcined in a hot furnace, and then to undergo a thorough levigation. The effect of manganese in destroying the colours of glafs is accounted for by M. Montamy, in his "Traité des Couleurs par la Peinture en Email," in the following manner; the manganese destroys the green, olive, and blue colours of glafs, by adding to them a purple tinge, and by the mixture producing a blackish brown colour; and as blackness is caused merely by an aborption of the rays of light, the blackish tinge given to the glafs by the mixture of colours, prevents the re-diffuion of so many rays, and thus renders the glafs less coloured than before. But the black produced by this substance suggests an obvious reason for using it very sparingly in those compositions of glafs, which are required to be very transparent.

This purple colour may be corrected by charcoal, or in the glafs-house, by thrusting a billet of wood down into the melted glafs, which becomes charred by the intense heat, and causes the purple hue to vanish, with a slight effervescence of the glafs, and escape of numerous small air-bubbles. On the other hand, if a small quantity of nitre is added to glafs containing manganese, the purple colour is restored, or, if present, the discoloring effect of the charcoal is prevented, till the nitre becomes alkalized by the heat, and mixes with the other ingredients of the crucible. For the explanation of these phenomena, it is observed, that the oxyd of manganese gives the metal to such an extent as it remains in its higher state of oxygenation; but when in contact with charcoal, the latter partially deoxygenates it, carbonic acid gas is formed, the caufe of the bubbles observed on this occasion, and the colour is now lost. Nitre, on the other hand, is known to give out oxygen largely as soon as red-hot; and hence the manganese immediately retakes from this source the oxygen of which the charcoal had deprived it, and refumes its colouring power. The other substances which take away the colour from glafs, tinged red with manganese, are all the salts with the basis of sulphuric acid, such as gypsum, sulphate of soda, &c. and also sulphur itself; likewise the oxys of tin and iron, and of some other metals. Nevertheless these substances have this power only when in contact with charcoal. The tinging power of manganese is perfectly destroyed by the addition of arsenic in any form. Thus, a mixture of oxyd of cobal and oxyd of manganese, in the colouring state, is of a dark purple; but on the addition of any arsienit, or of white arsenic, the manganese is made inactive, and the proper cobalt-blue alone appears. Hence we perceive the necessity, when the red colour of manganese is wanted, to avoid any thing arsienical; and nitre is also generally added to keep the manganese always at the proper state for imparting its colour. The oxyd of manganese is a very powerful flux for all earthy matters; and this, as well as lead, gives a great density to glafs. The white oxyd of arsenic is another powerful and cheap flux in the making of glafs; but it should be very moderately used; for it takes a longer time to mix intimately with glafs, and to allow it to be perfectly clear, than any other of the additions commonly employed. For want of this the glafs has a milky hue, which increases with age; and when the arsienic is in excess, the glafs becomes gradually soft, and is decomposed. Besides, glafs of this kind is unsafe to be used in the form of drinking-vessels.

Nitre is also used, in small quantities, in the manufacture of glafs, and is designed to answer particular purpofes, some of which we have already specified. It not only serves to destroy the strong tinge of yellow which is found in glafs, prepared with lead as a flux; but in falcine glafs, it is requisite, in a smaller proportion, to render it sufficiently transparent, as in the case of looking-glasses, and other kinds of plates. For an account of Mr. Dollond's excellent contrivance for destroying the colours in the object-glasses of telescopes, &c. see Aberration.

With regard to the several fluxes above enumerated, we may observe, in general, that the more calx of lead, or other metallic earth, enters into the composition of any glafs, so much the more fusible, soft, coloured, and dense this glafs is; and reciprocally.

The colours given to glafs by calces of lead are shades of yellow; on the other hand, glafs that contain only falcine fluxes partake of the properties of falt-s; they are less heavy, less dense, harder, winter, more brilliant, and more brittle than the former; and glafs, containing both falcine and metallic fluxes, do also partake of the properties of both these subfubstances. Glafs too falcine are easily susceptible of alteration by the action of air and water; especially those in which alkalis prevail; and these are also liable to be injured by
GLASS.

by acids. Those that contain too much borax and arsenic, though at first they appear very beautiful, quickly tarnish, and become opaque when exposed to air. By attending to these properties of different fluxes, phosphoric or saline, the artizan may know how to adjust the proportions of these to fand, or powdered flints, for the various kinds of glafs.

Glass, proportion of ingredients in. Different kinds of glafs require different proportions; nor have these been precisely ascertained. We shall here give a table showing the average of several of the most usual and approved mixtures that have been proposed. When asphalt is melted with twice its weight, or more, of dry carbonated alkali, either potash or soda, the result is a very soft deliquecent vitreous mass, always more or less opaque, strongly alkaline to the taste, and which, on exposure to moist air, or more speedily in water, totally dissolves into a clear liquor, which is a solution of fexe in alkali. When the feme alkali is equal to the fexe in weight, or does not much exceed it, the glafs is now transparent, but it is still insoluble in water. It is not till the alkali is diminished to about one-half of the weight of the fexe, that the glafs becomes perfectly hard and insoluble in any corrosive liquor, (the fucic acid excepted,) and, in short, acquires the character of a perfect glafs. This proportion, therefore, of two parts of fand to one of alkali, is usually the datum on which the doses of glæs actually used are regulated. Thus, if common wood ashes (of which the alkali part is reckoned at no more than 10 per cent.) are employed, 10 lbs. of these would require no more than about 20 lbs. of fand. If the better Spanish slags, containing from 45 to 50 per cent. of carbonate of soda, be used, an equal weight of fand may be added; but if purified pearl-ash be taken, it will melt down perfectly twice its own weight of fand. But glæs composed merely of pure alkali and fand, require a very strong fire for their fusion, and are hard, harsh, and difficult to break: they are therefore never used alone. As one half the weight of the fand is reckoned an abundant allowance of alkali, it follows of course that when licharge, arsenic, borax, or any other fluxes are employed, the quantity of alkali will be proportionally diminished. The following proportions are extracted from Macquer's Chemical Dictionary.

If a glafs be required that is dense, fusible, and not faine, one part and a half of red lead or litharge may be mixed with one part of fand, and fued together: if equal parts of fand and of calc of lead be employed, a glafs somewhat less dense and harder will be produced: if a glafs be required of very little density, only faine fluxes must be employed. A glafs of this kind may be composed of fix parts of falt of tartar, or of potash, or of purified soda, mixed with eight parts of fand or of fllts; or of four parts of any of the above-mentioned alkali, mixed with two parts of nitre or of borax, and eight parts of vitrifiable earth. When a crysfal glafs is required, which shall be of an intermediate quality between the metallic and faine glæs, it may be made from a mixture of one part of the above-mentioned falt, one part of calc of lead, and two parts of fand or other vitrifiable earth. By varying the proportion of these ingredients, many different kinds of glæs may be produced, each of which may be good, if the quantity of each of the fluxes employed be proportionable to its vitrifying power.

Glass, instruments for manufacturing. These are fullest for two different purposes; viz., the levigation and mix-ture of the ingredients, and the fusion or vitrification of them. To the former class belong horfe or hard-mills, mortars and peffels, flat fones and mufflers, and fstores or fives. The other sort of utenfils are furnaces, with the proper iron work, pots for containing the composition when put into the fire, and iron instruments for shifting the matter out of one into the other, in case of accidents; and for taking out small portions, in order to judge of the progress of the vitrification, and the quality of the glæs, &c. See the following articles. See also GLASS-blowing, Furnace, and GLASS-pots.

Glass, fusion of. When the ingredients are selected and duly proportioned, they are first calcined for a longer or shorter time, before they are put into the glæs-pots. This operation is called "fritting," and is performed either in small furnaces adjoining to the proper glæs-furnace, and heated by the same fuel after its chief force has been spent upon the glæs-pots, or else in small furnaces or ovens constructed for this purpose. The uses of fritting are, to expel all moisture from the ingredients, by which the glæs-pots would be endangered; to discharge part of the carbonic acid from the alkali and chalk, and thus to moderate the dwellings in the glæs-pots, and especially to cause an adhe-sion, or commencement of chemical union, between the alkali and fexe, and metallic oxys. This operation should be performed gradually, and carried to the point of semi-vitrification, in which the materials strongly adhere, and begin to become pasty, but are still opaque and not homogeneous. This operation serves also to destroy any carbo-naceous matter. When the ingredients are sufficiently fritted, they are thrown with clean iron flouvs through the fide-opening of the furnaces into the glæs-pots, the fire having been previously raised to its greatest intensity, to prevent the furnace from being chilled and to save time. The pots are charged by two or three successive portions, the preceding one being thoroughly melted down before another portion is thrown in. When filled, the fide-opening is closed up with wet clay, excepting a small hole for ex-amining the work, which closet is pulled down when the glæs is well refined and about to be worked off. As soon as the frit begins to feel the action of the fire in the glæs-pots, which is immediately raised to its greatest pitch, it sinks down into a soft palty flate, increasing in ten-a-city till the fusion is complete. However, it is still opaque, from the rising of a white porous fæcum, known by the name of "fandiver," or "glæs-gall." This fub-fance appears to be a confudied mas, confiding of all those falt contained in common alkali, which readily melt at somewhat less than a glæs-melting heat, and are either naturally soluble in a considerable degree, or have little, if any, affinity for fexe, and not mixing with the composition of glæs, but being lighter, rise to the top. Another hetero-geneous fub-fance, called "fandiver," is sometimes found at the bottom of the pots. This is quite different from the other, and seems to confid of a vitrified mas of arsenic and other impurities. But the fæcum, or proper "glæs-gall," is almost entirely faine. When laded out and cooled, it forms a crumbly mas, sometimes white, at other times brown and foured, and strongly faine, but not uniform in its composition, being sometimes merely falt, often very but-ter, probably as common falt or sulphat of potash predominates. It is so volatile in a strong fire, that it is constantly difpersing from the surface of the glæs in a dense vapour, which is first thick and black, afterwards whiter, and which corrodes the top of the crucible in its passage. With long continued fusion it would entirely escape in this flate, if it were not fommed off with long kales, and fold to metal refiners as a powerful flux. Abundance of this glæs-gall is attended with one of the greatest inconveniences to the maker of glæs, as it requires a considerable conurnance of ftrong
from heat to dissipate the whole of it, or otherwise the glass would be full of bubbles, unformed, and having a cloudy gelatinous appearance. It is observed, that glass from potash is more likely to suffer from glass-gall than the soda-glass is, because the potash glasses are harder, and do not run so thin as the other, and the glass-gall from them does not so easily dissipate in the fire.

During this process samples for examination are drawn out of the pots with an iron rod; and the glass gradually becomes more and more flexible, dense, and hissitical, and at last the glass-gall is entirely dissipated. While cracks or bubbles are continued, the glass which was full of seeds and bubbles is refined, and becomes smooth, clear, transparent, and colourless; and this process, which goes on from the cessation of the vapour of the glass-gall and its entire removal to the time when the glass is altogether clear and free from bubbles, is called the "refining." After this the glass is quite complete; but being too thin for working, it is cooled, by flowing the draught of fire round the pot which contains it, and in cooling it thickens to a flat plate for being wrought.

For glasses that is cast into plates, this cooling is necessary, as it is required to flow very thin and hot. On an average it takes about 48 hours for the fine flint glasses, from the time when the pots are first filled till the glass is ready for working, in which state it is of a very full red colour, and possesses a sanguinary kind of confidence and tenacity. It is just foit enough to yield with ease to any external impulsion, even to the force of the breath urged pretty strongly in the centre of the glowing mafs, and may be bent and shaped in every possible way; and fuch is its tenacity, that it extends uniformly without any cracks or failures; but when stretched out to the utmost, it forms a solid string, the diameter of which is constantly decreasing till it separates from the mafs in a thin capillary thread. It flows as it cools, and becomes perfectly brittle and also transparent. As melted glass adheres very readily to polished metal, it is very easily wrought with bright iron tools.

Glass, working or blowing round.—Every kind of glasses, plate-glasses excepted, is formed from a hollow globe that has been produced by blowing. For this purpose the operator takes his blowing-iron, which is a hollow tube, about four or five feet long, and dipping it in the melting-pot, turns it about there till the metal adheres to the iron like some glutinous or clammy juice; he then holds it near the ground, so that the mafs is extended by its own weight, and blows strongly into the tube. With his breath thus penetrating into the centre of the red-hot mafs, he enlarges it into an uniform hollow globe of the requisite thickness and bulk, keeping the force of his breath upon it for a few seconds till it thins by cooling, and thus preventing its thickening by the compression of the denser external air. This globe, adhering by a neck to the iron rod, is formed by the dexterity of the workman, and by a variety of ingenious manoeuvres into all the common vessels. As a specimen of his art, we may mention a common tumbler. The hollow globe already mentioned is taken off the iron rod by the following simple process: An assistant dips the end of a short solid iron rod into the glasses-pot, and, bringing out at its extremity some of the melted glasses, thrusts it immediately against the hollow of the globe at the part directly opposite to the neck, to which it firmly unites, and thus the globe is cemented by the melted glasses to the second rod. The workman then wets a small piece of iron with his mouth, and lays it on the neck of the globe, which is extremely hot, and this, in a second or two, cracks it round; so that with a flint pull it comes off and detaches the hollow rod, leaving the globe open at the neck, and transferred to the second rod at the opposite side. The open globe is again softened by holding it a few seconds over the mouth of the glasses-pot, and is cut away from the open end to the form of a cup by iron shears. The operator, when employed in fashioning the globe, usually sits upon a kind of arm-chair, with its arms sloping forwards and covered with a flat smooth iron-plate; and by laying the iron rod straight before him, reaping from both his sleeves, and turning it backwards and forwards, the hot glasses at the cold end grade like clay, and the mafs is formed, and thus is opened, widened, or compressed at pleasure by any simple iron instrument that is pressed against it. The globular cup is thus extended easily into a cylinder, or made into the shape of a barrel, if this form be required, and is smoothed up at the edges. In order to separate it from the iron-rod, it is wetted as before at the point of attachment, and the tumbler drops off complete. This last operation leaves that burn or roughness, with sharp fragments, which is seen at the bottom of all glasses-tumblers, unless it be taken off by polishing. The next operation is that of cooling the vessel very gradually, called "annealing."

GLASS.

Glass, different kinds of. The manufactured glasses now in use may be divided into three general kinds; white transparent glasses, coloured glasses, and common green or bottle-glasses: Of the first kind, there is a great variety; as the flint glasses, as it is called with us, and the German crystal glasses, which are applied to the same uses; the glasses for plates for mirrors or looking-glasses; the glasses for windows and other high uses, and the glasses for phials and small vessels.

And these again differ in the substances employed as fluxes in forming them, as well as in the consistencies or finishes of such as are used for their body. The flint and crystal, mirror, and bell window glasses, not only require such purity in their fluxes, as may render it practicable to free the glasses perfectly from all colour: but for the same reason likewise, either the white iron sand, calcined flints, or white pebbles, should be used. The others do not demand the same nicety in the choice of the materials; though the second kind of window glasses, and the bell kind of phials, will not be so clear as they ought, if either too brown sand, or impure fluxes, be suffered to enter into their composition.

Of coloured glasses there is a great variety of sorts, differing in their colour, or other properties, according to the occasions for which they are wanted. The differences in the latter kind depend on the accidental preparation and management of the artificers by whom they are manufactured.

Glass, Crystal. Forgers use this term for our flint glasses, and for making them give the following directions: Take of the whitest tares, pound'd small, and heated as fine as flour, two hundred pounds; of the salt of polverine, a hundred and thirty pounds; mix them together, and put them into the furnace, called the calcar, firr heatting for it. For an hour keep a moderate fire, and keep stirring the materials with a proper rake, that they may incorporate and calcine together; then increase the fire for five hours; after which take out the matter; which, being now sufficiently calcined, is called frit. From the calcar put the frit in a dry place, and cover it up from the dust for three or four months.

Now, to make the glasses, or crystall: Take of this crystall frit, called also bellato; let it in pots in the furnace, adding to it a due quantity of manganese; when the two are fused, call the flour into fair water, to clear it of the salt, called funker; which would otherwise make the crystal obscurc and cloudy. This lottion must be repeated again and again, as often as needful, till the crystal be fully purged; or, this fume may be taken off by means of proper ladles. Then let
G L A S S.

It to boil four, five, or six days; which done, see whether it have manganese enough; and if it be yet greenish, add more manganese, at discretion, by little and little at a time; taking care not to overdo it, because the manganese mingles it to a blackish hue. Then let the metal clarify, till it becomes of a clear and shining colour; which done, it is fit to be blown, or formed into vials at pleasure.

Glass, Flint, as it is called in our country, is of the same general kind with that in other places is called crystal glass. It has this name from being originally made with calcined flints, before the use of the white wood was understood; and retains the name though no flints and now used in the composition of it. This flint glass differs from the other, in having lead for its flux, and white sand for its body; whereas the flints used for the crystal glass are fillets or arcines, and the body consists of calcined flints, or white river pebbles, taris, or such stones. This glass, on account of the quantity of liquor, which enters into its composition, is the heaviest, the most brilliant, the finest, and most easily to work, and also the most expensive. It is that fine glass of which the common and most valuable articles of white glass in domestic or ornamental use are manufactured; and besides, many optical instruments are made of this substance. To the white sand and lead a proper proportion of nitre is added, for the purposes specified in a former part of this general article, and also a small quantity of manganese, and in some works they use a proportionable quantity of arfentic acid to aid the fluxing ingredients. The most perfect kind of flint glass may be made by fusing with a very strong fire a hundred and twenty pounds of the white sand, fifty pounds of red lead, forty pounds of the bell pearl-ashes, twenty pounds of manganese, and five ounces of arfentic acid.

From others we have the following composition for glass of this kind, said to be of the best quality, viz. 120 parts of fine clear white sand, 40 of pearl-ashes well purified, 35 of litharge or minium, 13 of nitre, and a small quantity of black oxys of manganese.

The following composition for a fine crystal glass is given by Loyce: 100 pounds of white sand, 80 to 85 of red oxys of lead, 55 to 40 of pearl-ashes, 2 to 3 of nitre, and one ounce of manganese. The specific gravity of this glass, and of the common London flint-glass, is about 3.2.

Another composition of flint glass, which is said to come nearer to the kind now made, is the following: a hundred and twenty pounds of sand, fifty-four pounds of the bell pearl-ashes, thirty-six pounds of red lead, twelve pounds of nitre, and six ounces of manganese. To either of these a pound or two of arfentic may be added, to increase the flux of the composition. A cheaper composition of flint glass may be made with a hundred and twenty pounds of white sand, thirty-five pounds of the bell pearl-ashes, forty pounds of red lead, thirteen pounds of nitre, six pounds of arfentic, and four ounces of manganese; or, instead of the arfentic, may be substituted fifteen pounds of common salt; but this will be more brittle than the other. The cheapest composition for the worst kind of flint-glass, consists of a hundred and twenty pounds of white sand, thirty pounds of red lead, twenty pounds of the bell pearl-ashes, ten pounds of nitre, fifteen pounds of common salt, and six pounds of arfentic. The bell German crystal glass is made of a hundred and twenty pounds of calcined flints, or white sand, seventy pounds of the bell pearl-ashes, ten pounds of salt-pearl, half a pound of arfentic, and five ounces of manganese. And a cheaper composition is formed of a hundred and twenty pounds of calcined flints, or white sand, forty-five pounds of pearl-ashes, seven pounds of nitre, five pounds of arfentic, and five ounces of manganese.

A glass, much harder than any prepared in the common way, may be made by means of borax in the following method: take four ounces of borax, and an ounce of lime sand; reduce both to a subtile powder, and melt them together in a large close crucible set in a wind-furnace, keeping up a strong fire for half an hour; then take out the crucible, and when cold break it, and there will be found at the bottom a pure hard glass, capable of cutting common glass like a diamond. This experiment, duly varied, may lead to several useful improvements in the arts of glasses, chasms, and factories, and shews an expeditious method of making glass, without any fixed alkali, which has been generally thought an essential ingredient in glasses; and it is not known whether calcined crystal, or other substances, being added to this salt instead of sand, it might not make a glass approaching to the nature of a diamond. Shaw's Lectures, p. 426.

Glass, Crown, is the best sort of window-glasses, and differs from the flint-glass in containing no lead, nor any metallic oxys, except manganese, and sometimes oxys of cobalt, in minute doses, not as a flux, but for correcting the natural colour. This glass is much harder and tougher to the touch than the flint-glass; but when well made it is a very beautiful article. It is compounded of sand, alkali, either potash or soda, the vegetable ashes that contain the alkali, and generally a small portion of lime. A small dose of arfentic is often added to facilitate the fusion. Zaffre, or the oxys of cobalt, with ground flint, is often used to diffuse the dingy yellow of the inferior sort of crown-glass, and by placing the blue natural to glass coloured with this oxys, to convert the whole into a soft light green. One ounce of zaffre is sufficient for 1000 lbs. But when the sand, alkali, and lime are very fine, and no other ingredients are used, no zaffre nor correetive of bad colour is required. A very fine glass of this kind may be made by 200 parts of very good soda, 300 of fine sand, 33 of lime, and from 250 to 300 of the ground fragments of glass. We had formerly in London two kinds of crown glasses, distinguished by the places where they were wrought; viz. 1. Ratcliff crown glasses, which is the bell and cleanest, and was first made at the Bear-garden, on the Bank-side Southwark, but since at Ratcliff: of this there are twenty-four tables to the case, the tables being of a circular form, about three feet six inches in diameter.

2. Landell crown glasses, which is of a darker colour than the former, and more inclining to green. The following composition has been recommended for the bell window or crown glasses, viz. white sand, sixty pounds; of purified pear-ashes, thirty pounds; of salt-pearl, fifteen pounds; of hornes, one pound; and of arfentic, half a pound. If the glass would prove yellow, manganese must be added. A cheaper composition for window glasses consists of sixty pounds of white sand, twenty-five pounds of unpurified pearl-ashes, ten pounds of common salt, five pounds of nitre, two pounds of arfentic, and one ounce and a half of manganese. The common, or green window glasses, is composed of sixty pounds of white sand, thirty pounds of unpurified pearl-ashes, ten pounds of common salt, two pounds of arfentic, and two ounces of manganese. But a cheaper composition for this purpose, consists of a hundred and twenty pounds of the cheapest white sand, thirty pounds of unpurified pearl-ashes, sixty pounds of wood-ashes well burnt and sifted, twenty pounds of common salt, and five pounds of arfentic.

The manufacture of the common window glasses, though made by blowing, is conducted differently from that of the flint glasses articles; as it is the object to produce a large, flat, very thin plate of glass, which is afterwards cut by the glazier's
GLASS.

Glass, diamond into the requisite shape. Without minutely detailing the several gradations of the process, it may be here mentioned, that the workman takes a very large mass of melted glass on his hollow iron rod, and by rolling it on an iron plate and swinging it backwards and forwards, causes it to lengthen, by its own weight, into a cylinder, which is made hollow and brought to the required thimnes, by blowing with a fan of breath, which perfoins accustomed to the business know how to command. The hollow cylinder is then opened by holding it to the fire, which, by expanding the air confined within it, (the hole of the iron rod being flopped,) bursts it at the weakest part, and while still soft, it is rolled up through its whole length by iron lears, opened out into a flat plate, and finished by annealing as usual.

The large crown glass of Mifri. Hammond and Smith is superior in quality as well in use to that of any other manufacture. The natural diameter of the table in the other manufactures may be taken at 47 or 48 inches, with an occasional variation in a table of one or two inches; and the largest square which can be cut from these measure about 23 inches by 20, and in some circumstances one inch wider or longer. Whereas the glass of Mifri. Hammond and Smith is 63 inches in diameter, and will admit of being cut into squares of about 33 inches by 23 inches, and a little more or less. This glass is almost free from those specks, wreaths, &c. which disfigure other glasses, and disturb the objects seen through it. It now supplies the place of German sheet glass for prints, large fishes, and exportation to those foreign markets where that glass was formerly in use.

Glass, French, as also called Normandy glass, and formerly Lorraine glass, because it was made in those provinces, though it has since been made wholly in the Nine glasses works; five of which were in the forest of Lyons, four in the country of Eu; the last at Beaumont, near Rouen. It is of a thinner kind than our crown glass; and, when laid on a piece of white paper, appears of a dirty-green colour. There are but twenty-five tables of this at the cafe.

Glass, German, is of two kinds, the white and the green: the first is of a whitish colour, but is subject to those small curved streaks, observed in our Newcastle glasses, though free from the spots and blinmifies thereof. The green, besides its colour, is liable to the same streaks as the white; but both of them are straighter, and less warped, than our Newcastle glasses.

Glass, Dutch, is not much unlike our Newcastle glasses, either in colour or price. It is frequently much warped, like that, and the tables are but small.

Glass, Newcastle, is that most used in England. It is of an ash-colour, and much subject to specks, streaks, and other blemishes; and, besides, is frequently warped. Ley-bourn fays, there are forty-five tables to the cafe, each containing five vertical feet: some fay there are but thirty-five tables, and fix feet in each table.

Glass, Phil., is a kind of glasses between the flint glasses and the common bottle, or green glasses. The best kind may be prepared with a hundred and twenty pounds of white sand, fifty pounds of unpurified pearl-ashes, ten pounds of common salt, five pounds of arsenic, and five ounces of manganese. The composition for green or common phial glasses, contains of a hundred and twenty pounds of the cheapest white sand, twenty pounds of wood ashes, well burnt and fitted, twenty pounds of pearl-ashes, fifteen pounds of common salt, and one pound of arsenic.

Glass, common green bottle, is made almost entirely of sand, lime, and sometimes clay, alkaline ashes of any kind, as cheapness or convenience direct, and more especially of help in this country, of barilla, varee, and the other varieties of soda in France, and of wood ashes in many parts of Germany, and the like. To these ingredients is sometimes added the earth remaining from faifie ashes, after the alkali and falta have been extracted by lixiviation, and in England flags from the iron furnaces. Bottle-glasses is a very hard well-vitrified glasses, which resists the corrosive action of all liquids much better than flint glasses. It is used, not only for wine-bottles, but for very large retorts, subliming vellsels, and other articles of the chemical apparatus; and it has for this purpose the advantage of bearing as much as a pretty full red heat without melting or sinking down into a shapeless lump, as the lead-glass is wound do. The following composition is given by Leyfyl as a good and cheap material for bottle-glasses; viz., 100 parts of common sand; 32 of varee (a kind of coarse help made on the western coasts of France), 160 of the lixiviated earth of ashes, 30 of fresh wood-ash, or any other kind of ash, 80 of brick-clay, and any quantity, generally about 100, of broken glasses. This composition yields no glasses-glass. This kind of glasses is formed of sand of any kind, fluxed by the ashes of burnt wood, or of any parts of vegetables; to which may be added the fclirna or clinkers of forges. When the softest fand is used, two hundred pounds of wood-ashes will suffice for a hundred pounds of fand, which are to be ground and mixed together. The composition with the clinkers consists of a hundred and seventy pounds of wood-ashes, a hundred pounds of sand, and fifty pounds of clinkers, or fclirna, which are to be ground and mixed together. If the clinkers cannot be obtained, they must be broken into small pieces, and mixed with the other matter without any grinding.

A good bottle-glass, but nearly black and opaque, has been made in France, glassed over with a black earth found in the valleys of all basaltic countries. In France it abounds in the Vivara, in Languedoc, and Arvern. The first glasses of this kind appears to have been made in 1780 by a M. Duclos at the suggestion of Chaptal, who simply melted some of this basalt without addition in a glass-fruit, and formed of it two very light, black, or rather deep yellow, finishing, perfect bottles. In subsequent trials by another artist, a mixture of equal parts of basalt and sand was employed, as preferable to the basalt alone; but notwithstanding a considerable demand for bottles of this material, the manufacture was abandoned owing to want of uniformity in the ingredients, which made them often fail. The colour of this glass was of a green-olive.

The green colour, transmitted by bottle-glasses, when in its perfect state, is owing to the iron contained both in the vegetable ashes and in the sea-sand, which enter into its composition. This glass affords an influence of a semi-liquid substance, which exhibits a blue colour by incident light, and a yellow or orange colour by that which is transmitted. Soireau laid on the cause of the permanent colour of opaque bodies.

Glass, Plate, is the most perfect and beautiful glasses, of which all the kinds of mirrors and looking-glasses are composed. The materials of which this kind of glasses is made are much the same as those of other works of glasses, viz., an alkali salt, and sand.

To prepare the salt, they clean it well of all foreign matters; pound or grind it with a kind of mill, and finally sift it pretty fine.

Pearl-ashes, properly purified, will furnish the alkali salt requisite for this purpose; but it will be necessary to add borax, or common salt, in order to facilitate the fusion, and prevent the glasses from stiffening in that degree of heat, in which
which it is to be wrought into plates. For purifying the
pearl-sables, dissolve them in four times their weight of boil-
ing water, in a pot of cold iron, always kept clean from
rust. Let the solution be removed into a clean tub, and
remain there twenty-four hours, or longer. Having decanted
the clear part of the fluid from the dregs or sediment, put
it again in the iron pot, and evaporate the water till the fats
are left perfectly dry. Preserve them in stone jars, well fo-
cured from air and moisture.

Pearl-sables may also be purified in the highest degree, so
as to be proper for the manufacture of the most transpar-
ent glass, by pulverizing three pounds of the best pearl-
sables, with six ounces of salt-petre, in a glass or marble
mortar, till they are well mixed; and then putting part
of the mixture into a large crucible, and expelling it in a
furnace to a strong heat. When this is red-hot, throw in the
rest gradually, and when the whole is red-hot, pour
it out on a moistened stone or marble, and put it into an
earthen or clean iron pot, with ten pints of water; heat it
till over the fire till the fats be entirely melted; let it then
cool, and filter it through paper into a power vessel.
When it is filtered, put the fluid again into the pot,
and evaporate the salt to dryness, which will then be as
white as snow; the nitre having burnt all the phlogistic
matter that remained in the pearl-sables, after their former
calcination.

As to the sand, it is to be sifted and washed, till such
time as the water come off very clear; and when it is well
dried again, they mix it with the salt, passing the mixture
through another sieve. This done, they lay them in the
annealing furnace for about two hours; in which time the
matter becomes very light and white, in the ashes, which
are called frit, or fritsa; and are to be laid up in any clean
place, to give them time to incorporate. They lie here for
at least a year.

When they would employ this frit, they lay it for some
hours in the furnace, adding to form the fragments or
shards of old and ill-made glasses; taking care first to cal-
cine the shards by heating them red-hot in the furnace, and
then cooling them into cold water. To the mixture must
likewise be added manganese, to promote the fusion and
purification.

The best composition for looking-glass plates is said to
consist of sixty pounds of white sand cleansed, twenty-five
pounds of pure pearl-sables, fifteen pounds of salt-petre,
and seven pounds of borax. If a yellow tinge should affect
the glass, a small proportion of manganese, mixed with an
equal quantity of arsenic, should be added. An ounce of
the manganese may be first tried; and if this proves insuffi-
cient, the quantity should be increased.

A cheaper composition for looking-glass plates consists of
sixty pounds of the white sand, twenty pounds of pearl-sables,
ten pounds of common salt, seven pounds of nitre, two
pounds of arsenic, and one pound of borax.

The materials of the finest plate glass, such as that of
French manufacture, are white sand, soda, and lime, to
which are added manganese and zaffre, or any other oxide
of cobalt for particular colouring purposes. The sand is
of the finest and whitest kind, which should be previously
pulverized; the soda and lime, melted very hot, are put into water,
in which it should be well thinned and washed. The shrapt
grained sand is preferred, and it is found that grains of
moderate size melt with the alkali sooner, than the very
fine dust or the larger fragments. The alkali is always
fossa, which is preferable to potassa, as glasses made with
fossa are found to be softer and to flow thinner when hot,
and yet to be equally durable when cold. Besides, the
neutral fats with the base of soda which constitute the glass-
gall in this inclusion, such as the muriat and fulphat of
fossa, appear to be dissipated more readily by the fire than
the corresponding fats of potassa. The fossa that is used is
considerably pure, or such as is separated from the rough
ashes of bardilla, and other fossa plants by lixiviation. Lime
adds to the fusibility of the other materials, supplying
the use of litharge in the finest glasses; but excess of it would
impart the colour and solidity of the glass. About 1:15th of
the whole is so much as can properly be used; but some
reduce the quantity to 1:24th. The decolouring substances
are azure, or cobalt blue, and manganese. Besides these,
there is always a great quantity of the fragments of glass,
collected from the walls of the manufactories, which are
made fusible by quenching in water when hot, and used in
this plate together with the fresh materials. As to the quanti-
ties and proportions of the ingredients, much latitude
is allowed. The following are said to produce a very fine
glass: 30 lbs. of sand; 260 lbs. of soda; 56 lbs. of lime; 32 ounces of manganese, three times, and of azurite
and 34 lbs. of fragments of glass. In the manufacture of St.
Gobin's glass is observed with regard to the materials; but
it is affirmed, and with much probability, that borax is used
in small quantity.

Of the materials now enumerated the sand, soda, lime,
and manganese are first mixed together with more care than
for ordinary glasses, and they are fired in small furnaces built
for this purpose, the heat being gradually raised to a full red-
white, and then kept with frequent stirring till the materials
undergo no further change, nor yield any kind of vapour.
The azure and glass fragments being already in a state of
perfect vitrification are not added till just at the end of the
process, which lasts about six hours. When the materials
are thus prepared, they are fire for plate-glasses, to be formed
either by blowing or casting. The largest glasses at St.
Gobin are run; the middle-sized and small ones are blown.

Blowing looking-glase plates. The work-houses, furnaces,
&c., used in the making of this kind of plate-glasses, are
the same, except that there are flues, and that the car-
quaries are disposed in a large covered gallery, over which
the furnace, as those in the following article, to which the
reader is referred.

After the materials are vitrified by the heat of the fire,
and the glass is sufficiently refined, the workman dips in his
blowing iron, six feet long, and two inches in diameter,
sharpened at the end, which is put in the mouth, and widened
at the other, that the matter may adhere to it. By this
means he takes up a small ball of matter, which sticks to
the end of the tube by conflux turning it. He then
blews into the tube, that the air may swell the annexed
ball; and carrying it over a bucket of water, which is
placed on a support at the height of about four feet, he
sparks the end of the tube to which the matter adheres,
with water, still turning it, that by this cooling, the mat-
ter may cohere with the tube, and be fit for furnishing a
greater weight. He dips the tube again into the flame pot,
and proceeds as before; and, dipping it in the pot a third
time, he takes it out, loaded with matter, in the shape of a
pear, about ten inches in diameter, and about a foot long, and
cools it at the bucket; at the same time blowing into the
tube, and, with the assistance of a labourer, giving it a
balancing motion, he causes the matter to lengthen; which,
by repeating this operation several times, assumes the form
of a cylinder, terminating like a ball at the bottom, and in
a point at the top. The assistent is then placed on a stool
three feet and a half high; and on this stool there are two
Tu

upright
upright pieces of timber, with a crofs beam of the fame, for supporting the glafs and tube, which are kept in an oblique position by the affistant, that the matter workman may with a puncheon feet in a wooden handle, and with a ma
dlet make a hole in the mafs; this hole is drilled at the
centre of the ball that terminates the cylinfer, and is
about an inch in diameter. When the glafs is pierced,
the defects of it are perceived; if it is tolerably perfect,
the workman lays the tube horizontally on a little iron
trefTel, placed on the support of the aperture of the furnace.
Having exposed it to the heat for about half a quarter of an
hour, he takes it away, and with a pair of long and broad
fears, extremely sharp at the end, widens the glafs, by infi-
nuating the fears into the hole made with the puncheon,
whirl the affistant, mounted on the floor, turns it round, till,
at last, the opening is fo large as to make a perfect cylinder
at bottom. When this is done, the workman lays his glafs
upon the trefTel, at the mouth of the furnace, to heat it: he
then gives it to his affistant on the floor, and with large
fears, cuts the mafs of matter up to half its height. This
is at the mouth of the furnace an iron tool, called pontil,
which is now heating, that it may unite and coalesce with
the glafs just cut, and perform the office which the tube did
before it was separated from the glafs. This pontil is a piece
of iron, fix feet long, and in the form of a cane or tube,
having at the end of it a small iron bar, a foot long, laid
equally upon the long one, and making with it a T. This
little bar is full of the matter of the glafs, about four inches
thick. This red-hot pontil is prefented to the diameter of
the glafs, which coalesce immediately with the matter round
the pontil, fo as to support the glafs for the following ope-
ration. When this is done, they separate the tube from the
glafs, by striking a few blows with a chaffee upon the end
of the tube, which has been cooled; fo that the glafs breaks
directly, and makes this separation, the tube being discharged
of the glafs now adhering to the pontil. They next present
to the furnace the pontil of the glafs, laying it on the trefTel
to heat, and redden the end of that glafs, that the workman
may open it with his fears, as he has already opened one
end of it, to complete the cylinfer; the affistant holding it
over his head as before. For the half time they put the pontil
on the trefTel, that the glafs may become red-hot, and the
workman cuts it quite open with his fears, right over-
against the fore-mentioned cut: this he does as before,
taking care that both cuts are in the fame line. In the
mean time, the man who looks after the carquaisie, comes
to receive the glafs upon an iron shovel, two feet and a half
long without the handle, and two feet wide, with a small
border of an inch and a half to the right and left, and
wards the handle of the shovel. Upon this the glafs is
bad, flattening it a little with a small thick a foot and a half
long, fo that the cut of the glafs is turned upwards. They
separate the glafs from the pontil, by striking a few gentle
blows between the two with a chaffee. The glafs is then re-
moved to the mouth of the hot carquaisie, where it becomes
red-hot gradually; the workman, with an iron tool, fix feet
long, and widened: the end in form of a club at cards,
four inches long, and two inches wide on each side, very flat,
and not half an inch thick, gradually lifts up the cut part of
the glafs, to unfold it out of its form of a flattened cylin-
der, and render it smooth, by turning it down upon the
hearth of the carquaisie. The tool, already described, being
valuated within the cylinder, performs this operation, by
being pulled hard against all the parts of the glafs. When
the glafs is thus made quite smooth, it is pulled to the
bottom of the carquaisie, or annealing furnace, with a small
iron raker, and ranged there with a little iron hook. When
the carquaisie is full, it is flapped and cemented as in the
cafe of run glafs, and the glafs remains there for a fort-
night to be annealed; after which time, they are taken out
to be polished. A workman can make but one glafs in an
hour, and he works and rolls for fix hours alternately.

It may be observed, that looking-glafs, thus blown,
should never be above forty-five, or at most fifty inches long,
and of a breadth proportionable. Thofe exceeding these
dimensions, as we frequently find among the Venice glafs,
cannot have the thickness sufficient to bear the grinding;
and, besides, are subject to warp, which prevents them from
regularly reflecting objects. Whereas plates as large as
nine feet in length and proportionally wide, have been man-
ufactured by casting.

A casting in running large Looking-glafs plates. This art, as
we have obferved in the History of Glass, is of French
invention. It is owing to the Sieur Abraham Vlehart, who
first propofed it to the court of France, in 1688.

It is performed much like the casting of lead among
the plumbers; and by means hereof we are not only enabled
to make glafs of more than double the dimensions of any
made by the Venetian way of blowing; but also to cast all
kinds of borders, mouldings, &c.

The furnaces for melting the materials of this manufacture
are of large size, being about 18 feet long and 15 wide; and
thofe for annealing the glafs, when formed, are much more
fo. Round a melting-furnace, there are at least twenty-four
annealing furnaces or ovens; each from twenty to twenty-
five feet long; they are called carquaisies: each carquaisie
has two tiffarts, or apertures, to put in wood, and two
chimneys. Add, that beside the annealing furnaces, &c.,
there are others for making of frit, and calcining old pieces
of glafs.

All these furnaces are covered over with a large shed;
under which are like wife forges, and work-houfes for smiths,
carpenters, &c. continually employed in repairing and keep-
ing up the machines, furnaces, &c. as also lodges, and apart-
ments for thefe, and the other workmen, employed about
the glafs, and keeping up a perpetual fire in the great fur-
nace, fo that the glafs-house, as that in the calle of St.
Cebbin, in the foref of Fero, in the Scaffions, appears more
like a little city, than a manufactory.

The infide of furnaces is formed of a fort of baked earth,
or refractory clay, proper to fulfill the action of fire; and
the fame earth serves also for melting-pots, ciferns, &c.
The furnaces feldom laft above three years; after which
they are to be rebuilt, from bottom to top; and to keep
them good, even for that time, the infide muft be refeted
every fix months, at which time the fire is extinguifhed.
The melting-pots are as big as wine hogheads, about three
feet in height, and in diameter; and contain above two
thousand weight of metal. They are in the form of an in-
verted and truncated cone. The ciferns, or pans, called
"cuveters," are much smaller, being about thirty-six inches
long, eighteen inches wide, and as many deep; and serve
for the conveyance of liquid glafs, which is drawn out of
the pots to the casting tables. They do not contain much more
than a fifth, or when large plates are cast, a third of the
pots.

When the furnace is in condition to receive the pots and
ciferns, they heat it red-hot, which requires fifty cords, or
a hundred cart-loads of wood. That kind of wood which
emits the largest and brighteft flame, without much refinous
smoke, is preferred. This done, they fill the pots with the
materials, or soda and sand, which is done at several times,
to facilitate the fufion. When the matter is sufficiently
vitrified, refined, and settled, which ufually happens in thir-
G I A S S.

thirty-six hours, they fill the cisterns, which are in the same furnace, and which are left there about six hours longer, till such time as they appear all white through the excessive heat.

To get the cisterns with the metal out of the furnace, they make use of a large iron chain which opens and shuts with hooks and eyes. From the middle of this, on each side, arise two massive iron pins, by which, with the assistance of pulleys, the cisterns are raised upon a kind of carriage of proper height; and thus conducted to the table where the glass is to be run. The cistern is then raised above the tables with an engine, in form of a crane, by means of two iron bars, so contrived as to throw the cistern into an inclined position, which discharges a torrent of matter, all on fire, with which the table prepared for this purpose is presently covered.

The table on which the glass is to be run, is of smooth thick copper-plate, about ten feet long, and six feet broad. It is supported on a wooden frame, with truckles, for the convenience of removing from one cistern, or annealing furnace, to another; in proportion as they are filled.

Or, when each pot has a cistern table, it is strongly supported by masonry, and contiguous to each table on the same level are the annealing ovens, upon which, being flat, the glass, when cold and sufficiently cooled, may be filled from off the copper-table without much difficulty. The tops of the flat ovens and the tables are on a level with the corresponding opening of the furnace, whence the cisterns or cisterns are withdrawn. When the glass is melted and fined in the manner already stated under the article Flint Glass, the cistern or cistern, previously made hot in the furnace, is filled out of the pot with a copper ladle, about ten inches in diameter, fixed to an iron handle seven feet long, properly supported on an iron flay by two workmen; and after remaining in the furnace for some hours, till the samples taken out for trial appear to be quite clear and limpid, the door of the furnace is opened, and the cistern is pulled out and removed to the side of the copper table. It is then frozen with an instrumcnt consisting of a copper blade hot in iron, and hoisted for the discharge of its contents on the table, in the manner already mentioned.

To form the thickness of a glass, and to make the surface smooth and even, there are two iron rollers or rims, placed round the edge of the table; and on these rest the two extremes of a kind of roller, or hollow heavy cylinder of copper, turned after being call, and about 500 pounds in weight, which serves to drive the liquid matter before it to the end of the table, or mould. The iron rollers being moveable, and capable of being set closer, or farther apart, at pleasure, determine the width of the glases, and retain the matter, that it does not run off at the edges. The white glases, if any, falls into a vessel of water, and is reserved for the next melting.

As soon as the matter is arrived at the end of the table, and the glases is come to a confidence, examined by the directors of the manufacture, and approved, they move it off into the annealing furnace, with an iron raker, as wide as the table, that has a handle two fathoms long; being assisted by workmen on the other side of the carquais, who, with iron hooks, pull the glases to them, and range it in the carquais, which holds six large glases.

What is most surprising throughout the whole of this operation, is the quickness and address wherewith such sally cisterns, filled with a flaming matter, are taken out of the furnace, conveyed to the table, and poured on it, the glases spread, &c. The whole is inconceivable to such as have not been eye-witnesses of that surprising manufacture.

As fast as the cisterns are emptied, they carry them back to the furnace and take fresh ones, which they empty as before. This they continue to do, so long as there are any full cisterns; laying as many plates in each carquais as it will hold, and stopping them up with doors of baked earth, or clay, and every chink with cement, as soon as they are full, to let them anneal, and cool again, which requires about fourteen days.

The first running being dispatched, they prepare another, by filling the cisterns anew, from the matter in the pots; and after the second, a third, and even a fourth time, till the melting pots are quite empty.

The cisterns at each running should remain at least six hours in the furnace to whiten; and when the first annealing furnace is full, the casting table is to be carried to another. It need not here be observed, that the carquais, or annealing furnaces, must first be heated to the degree proper for them. It may be observed, that the oven full, or the quantity of matter commonly prepared, supplies the running of eighteen glases, which is performed in eighteen hours, being an hour for each glase. The workmen work six hours, and are then relieved by others.

When the pots are emptied, they take them out, as well as the cisterns, to scrape off what glases remain, which otherwise would grow green by continuance of fire, and spoil the glases. They are not filled again in less than thirty-six hours, so that they put the matter into the furnace, and begin to run it every fifty-four hours.

The manner of heating the large furnaces is singular enough; the two tifors, or persons employed for that purpose, in their shirts, run round the furnace without making the least stop, with a speed scarce inferior to that of the lighted courier: as they go along, they take two billets, or pieces of wood, which are cut for the purpose; these they throw into the first tiffair; and continuing their course do the fame for the second. This they hold without interruption for six hours successively; after which they are relieved by others, &c. It is surprising that two such small pieces of wood, and which are consumed in an instant, should keep the furnace to the proper degree of heat; which is such, that a large bar of iron, laid at one of the mouths of the furnace, becomes red-hot in less than half a minute.

It is computed, that a furnace, before it be fit to run glases, cools above three thousand five hundred pounds; that at least six months are required for the building it anew, and three months for the refitting it; and that when a pot of matter burris in the furnace, the loss of matter and time amounts to above two hundred and fifty pounds.

The glases, when taken out of the melting-furnace, needs nothing further but to be ground, polished, and foliated. But before these operations are performed, they cut and square the edges of the plates; which is performed with a rough diamond, passed along the surface of the glases, upon a square ruler, like that of the glaziers, and made to cut into the substance of the glases to a certain depth. This cut is then opened by gently knocking with a small hammer on the under side of the glases, just under it; by which means the piece comes off, and the roughness of the edges are removed by pincers. The plates are then laid by for grinding, polishing.
GLASS.

Glass. Annealing, or Heating of. The operation of annealing of glasses is performed in a peculiar furnace called the lehr, which consists of two parts, the tower and lehr. The vessels as soon as made, are placed by the workmen on the floor of the former to anneal; which done, they are drawn slowly in a sort of a pan, called fractures, by an operator called the farrel-man, all along the latter, the space of five or six yards, to give them time to cool gradually; so that when they reach the mouth of it, they are found quite cold. Merret, Not. to Nari, p. 243, fig.

This annealing is generally performed in a hot chamber, built for the purpose, at the top of the glasses-house, above the crucibles, and a little below the chimney. Without this precaution, the glasses would be liable to fly and break, by the heat change of heat and cold, by the smallest scratch, and sometimes without any apparent external cause. The hard glasses, and those especially that are made with alkali and earths, require much more annealing than the softer and more fusible glasses, containing in their composition much limestone.

The particles of glasses by annealing are supposed to lose part of their springiness, and their brittleness at the same time. A gradual heating or cooling of glasses, according to Dr. Hook, anneals or reduces its parts to a texture more loose, and easy to be broke; but virtual more flexible than before. And hence in some measure the phenomena of glasses-drops.

Some of the phenomena depending on the fragility of unannealed glasses deserve the attention of the curious. Those of the lacrymiae, or glasses-drops, were among the first taken notice of; and it has also been observed, that hollow bells made of unannealed glasses, with a small hole in them, will fly to pieces by the heat of the hand only, if the hole by which the internal air is expelled be closed.

One whole bottom is three fingers breadth in thickness, dies with as much ease as the thinest glasses. Some of these vessels have been used with strokes of a metal sufficient to drive a nail into wood tolerably hard, and have resisted fracture. They also refill the stock of several heavy bodies let fall into their cavities, from the height of two or three feet. For instance, mallet-balls, pieces of iron, or other metal; pyrites, Jasper, wood, bone, &c.; but this is not surprising, as other glasses of the same size do the same. But the wonder is, that taking a flint of the fire of a small pea, and letting it fall into the glasses only from the height of three inches, in about two seconds the glasses flies, and sometimes in the very moment of the stroke; nay a list of flint, no longer than a grain, dropped into several glasses successively, though it did not immediately break the m, yet they all flow, being set by, in less than three quarters of an hour. Phil. Trans. ibid. p. 529.

Some other bodies produce a like effect with flint; for instance, sapphire, porcelain, diamonds, hard tempered steel, as also marbles, such as boys play with; to which add pearls from the animal kingdom.

The experiment succeeded also when the glasses were held in the hand, reflected on a pillow, put in water, or filled with water. It is also remarkable, that the flints broke upon their bottoms being slightly rubbed with the finger, though some of them did not fly till half an hour after the rubbing.

If the glasses be every where extremely thin, they do not break in these circumstances.

Some have pretended to account for these phenomena, by saying, that the bodies dropped into these vessels cause a concussion, that is stronger than the cohesion of the parts of the glasses, and that consequently a rupture of the same must ensue. But why does not a ball of gold, silver, iron, copper, or several other bodies, even a thousand times heavier than a flinter of flint, equally cause this concussion, and break the glasses?

Mr. Euler has endeavoured to account for these appearances from his Principles of Perfection. He thinks this experiment entirely overthrows the opinion of those who measure the force of concussion by the weight; and he thinks the principles he has established give a clear solution of this phenomenon. According to these principles, the extreme hardness of the flint, and also its angular figure, which makes the space of contact with the glass vessel extremely small, ought to cause an impression on the glasses vastly greater than lead or any other metal; and this may account for the flints breaking the vessel, though the bullet, even falling from a considerable height, does no damage. Mem. Acad. Berlin, 1745, p. 47.

Hollow cups, made of the green bottle-glasses, some of them three inches thick at bottom, were instantly broken, by a flint of flint weighing about two grains, though they had refilled the shock of a market bulb from the height of three feet. Phil. Trans. ibid. p. 515.

"The precise mechanical cause of this disposition to crack in unannealed glasses, is very difficult to explain," says Aikin (Dict., "but generally speaking, it is supposed to be the forcible contraction of the outer part by sudden cooling, whilst the inner portion is still soft and half-fluid, so that the whole fixes with a permanent strain or inequality of pressure of one part upon the other; and as glasses is extremely elastic, though brittle, any force which tears a fragment, however small, of the tense part, communicates a strong and sudden impulse over the whole mass." "This most singular phenomenon," (of the Rupert's drop) says the same ingenious chemist, in confedence of his own experiments, "is obviously owing to some permanent and very strong inequality of pressure, for when they are heated to red, as to be soft and merely let to cool of themselves, this property of bursting is entirely lost, and, at the same time, the specific gravity of the drop is increased. The peculiar brittleness of the Bologna phial is also removed by again heating and cooling slowly." The common window-glasses, when badly annealed, is cut by the diamond with difficulty, and the cut often lies in a direction different from what is intended, or the glasses entirely breaks.

Among other more common defects of glasses, we may mention its liability to be acted upon by corrosive liquors, as is the caie when too much saline flux has been used. As impermeable as glasses is to the common menstruums, we find it eaten by the air in length of time, when exposed in old windows; but the effects of its being kept in a subterraneous place are much more strange. Berthollet tells us, that at the
the time when he was at Rome, there was dug up a whole house from under the kitchen garden of a citizen. The house had been buried there ten ages, and there were found in it several glass jars, or lacrymatories. The glass of these had no holes made in it, as our old glass in chamber-windows has, but still retained its smooth surface and transparence; but it was split into a vast number of thin laminae, which were as pellucid and fine as Mufcovy glads; and in some places were tinged with all the beautiful colours that art could have given. We are not acquainted perfectly with the ancient way of working their glads; but it is not probable there could be any thing particular in the formation of the vessel, to determine it to split thus into flakes; but that glads of the fame kind, in any form, would have done the fame. 

Borrich de Ortu Chemie.

There are other visible imperfections in glads, materially injuring its foundness and beauty, and enumerated by Aikin (Dict. art. Glass; under the denominations of frieves, threads, tears, and knots. The former are undulating waves in the glads, arising from the imperfect mixture of the materials, and their different specific gravities. Accordingly, we may observe, that the most transparent glads is subject to bubbles and veins, the methods of preventing which are yet little known; and this is an inconvenience by which Mr. Dollond's excellent discovery is affected; for the flint-glasses which he uses is peculiarly subject to small veins, that disturb the rays in their passage, and render the vision confused. This effect is owing to the density of these veins being greater than that of the rest of the glads, as appears from their image received on white paper, when the glads is held between the paper and a candle, or other luminous object: for this image of a vein, thus received, is a line brighter than the rest of the image of the glads, and this bright line is defined by a dark edge on each side. But the bright line evidently shows a convergence of rays, which can only be effected by the veins being denser than the medium in which they are placed. The reason why flint glads is more subject to veins than other glads is, says the translator of Macquer's Chemical Dictionary, because it is composed of materials of more different densities.

Mr. Macquer, with a view of improving the manufacture of this glads, proposes to facilitate the union of the ealx of lead and sand, of which it is composed, by depriving the ealx of lead, as much as possible, of its phlogiston, which may be done by combining the vitriolic acid with minium, or red-lead, and expounding this composition to the operation of fire, to difengage it from the acid; and also by giving these two sublimations the greatest possible degrees of fluidity and mobility, which may be done by mixing with the composition of them a considerable quantity of solvents. Hist. Acad. Science. for 1773.

Thread in glads, are those finey filaments which arise from the vitrification of the clay; being generally green, and rendering the glads more liable to crack at these parts. But one of the worst defects (says Aikin, ubi supra) is "tears, or drops of vitrified clay falling down from the furnace into the pots, and entangled with the glads. Articles made of glads with this defect, are always very brittle, and generally break themselves by slight changes of heat and cold." Small bubbles appear in glads not sufficiently refined by a continuance of the melting heat; and these may be owing to a deficiency of flux, so that the glads is less fusible, and the bubbles cannot easily be disengaged. "Hence," says the author now cited, "the soft fusible glads which are much lead are much less liable to this fault than the hard, green bottle-gads, which is made only of alkali and earth." The knots in glads arise either from a portion of sand that has escaped vitrification, and remains entangled in the glads, or from a remaining quantity of glads-gall; or from bits of the crucible which may be accidentally knocked off by the iron instruments used in the working.

Glass, Axungia of. See AXUNGIA, SANDIVER, and Glass, jasper.

Glass of Borax. See BORAX.

Glass, Colouring of; to imitate gems. See Gems.

Glass, Gold-coloured. This kind of glads may be made by taking ten pounds of either of the compositions for hard glads, omitting the salt-petre; and for every pound adding an ounce of calcined borax; or, if this quantity do not render the glads sufficiently fusible, two ounces; ten ounces of red tartar, of the deepest colour, two ounces of mangane, and two drums of charcoal of fallow, or any other soft kind. Precipitate of silver baked on glads will stain it yellow, and likewise give a yellow colour on being mixed with and melted with forty or fifty times their weight of vitreous compositions; the precipitate from aqua-fortis by fixed alkali leaves to answer well. Yellow glads may also be obtained with certain preparations of iron, particularly with Prussian blue. But Dr. Lewis observes, that the colour does not conftantly succeed, nor approach to the high yellow of gold, with silver or with iron. The nearest imitations of gold which he has been able to produce, have been effected with antimony and lead. Equal parts of the glads of antimony, of flint calcined and powdered, and of minium, formed a glads of a high yellow; and with two parts of glads of antimony, two of minium, and three of powdered flint, the colour approached still more to that of gold. The last composition exhibited a multitude of small sparkles interferred through its whole sublimation, which gave it a beautiful appearance in the mafs, but were really imperfections, owing to air-bubbles.

Neri chrcêts, for a gold-yellow colour, one part of red tartar, and the fame quantity of mangane, to be mixed with a hundred parts of flint. But Knuckel observes, that these portions are faulty; that one part, or one and a quarter of mangane, is sufficient for a hundred of flint; but that six parts of tartar are hardly enough, unless the tartar is of a dark red colour, almost blackish; and that he found it expedient to add to the tartar about a fourth of its weight of powdered charcoal. He adds, that the glads swells up very much in melting, and that it must be left unflirred and worked as it stands in fusion. Mr. Samuel More, in repeating and varying this process, in order to render the colour more perfect, found that the mangane is entirely essential to the gold colour, and that the tartar is no other wise of use, than in virtue of the cloudy matter, to which it is in part reduced by the fire; the phlogiston or inflammable part of the coal appearing in several experiments to be the direct tinging sublimation. Mr. Pott also, in his Nene Wichtige Physico-Chimische Materien, &c. printed in 1762, observes, that common coal gives a yellow colour to glads; that different coaly matters differ in their tinging power; that auyt mortum of foot and lump-black answers better than common charcoal; and that the sparkling coal which remains in the retort after the rectification of the thick empyreumatic animal oils, is one of the most active of these preparations. This preparation, he says, powdered, and then burnt again a little in a close vessel, is excellent for tinging glads, and gives yellow, brown, reddish, or blackish colour, according to its quantity; but the frit must not be very hard
hard of fusion; for, in this case, the strong fire will destroy the colouring substance before the glafs melts; and he has found the following compositions to be nearly the best; viz., four parts, alkali three parts; or four two, alkali three; calcined borax one; or four two, alkali two, calcined borax one; and though salt-petre is hardly used at all, or very sparingly, for yellow glases, as it too much volatilizes the colouring substance; yet here for the most part a certain proportion of it, easily determined by trial, is very necessary; for without it, the concentrated colouring matter is apt to make the glafs too dark, and even of an opaque pitchy blackness. It does not certainly appear that there is any material diversity in the effects of different coals; the difference being probably owing to the different quantities of the inflammable matter which they contain; so that a little more shall be required of one kind than of another, for producing the fame degree of colour in the glafs. Nor does the fineness or fulness of the frit appear to be in any respect necessary.

Gold-coloured ftrangles may be diffused through the substance of glafs, by mixing the yellow tals with powdered glafs, and bring them into fusion. See Lewis's Com. Phil. Techn. p. 252. 626, &c.

GLASS for counterfeiting lapis lazuli. See Lapis Lazuli.
GLASS refilling opal. See Opal and Gems.

GLASS. Ruby. The way to give the true fine red of the ruby, with a fair tranpareence, to glafs, is as follows. Calcine in earthen vessels gold diffolved in aqua regia, the mercury being evaporated by distillation, more aqua regia added, and the abfraction repeated five or six times, till it becomes a red powder. This operation will require many days in a hot furnace; when the powder is of a proper colour, take it out; and when it is to be used, melt the finest crystal glafs, and purify it, by often casting it into water; and then add, by small quantities, of enough of this red powder to give it the true colour of a ruby, with an elegant and perfect tranparence. Neri. See Gems.

The procfs of tinging glafs and enamels by preparations of gold, were first attempted about the beginning of the 17th century. Libavius, in one of his tracts, entitled Alchymia, printed in 1626, conjectures that the colour of the ruby proceeds from gold, and that gold diffolved, and brought to rednesses, might be made to counterfeit the colour of other gems and glafs. On this principal Neri, in his "Art of Glafs," dated 1611, gives the procefs above recited. Glauber, in 1648, published a method of producing a red colour by gold, in a matter which is of the vitreous kind, though not perfectly glafs. For this purpose he ground powdered frit or sand with four times its weight of fixed alkaline falt; this mixture melts in a moderately strong fire, and when cold looks like glafs, but exposed to the air runs into a liquid state. On adding this liquor to solution of gold in aqua regia, the gold and fmit precipitate together in form of a yellow powder, which by calcination becomes purple; by mixing this powder with three or four times its weight of the alkaline solution of fmit, drying the mixture, and melting it in a strong fire for an hour, a mass is obtained, of a transparent ruby colour, and of a vitreous appearance, which neverthelefs is soluble in water, or by the moisture of the air, on account of the redundance of the falt. The honourable Mr. Boyle, in a work published in 1685, mentions an experiment, in which a like colour was introduced into glafs without fusion; for, having kept a mixture of gold and mercury in digelation for some months, the fire was at last immediately mercufed, so that the glafs hurft with a violent expanfion; and the lower part of the glafs was found tinged throughout of a transparent red colour, hardly to be equalled by that of rubies. See Porphyry of Bodies, in Shaw's Abridgment of Boyle's Works, vol. i. p. 459; and Appendix to the Sceperical Chemif. About the same time Cassius is said to have discovered the precipitation of gold by tin, and that glafs might be tinged of a ruby colour by melting it with this precipitate: though he does not appear, says Dr. Lewis, from his trinit De Auro, to have been the discoverer of either. He describes the preparation of the precipitate and its use, but gives no account of the manner of employing it; only that he says, one dram of gold, duly prepared, will tinge ten pounds of glafs. See Gold precipitate with tin.

This procfs was soon after brought to perfection by Knuckel; who says, that one part of the precipitate is sufficient to give a ruby colour to 1280 parts of glafs, and a fnallfn redness to upwards of 1600 parts; but that the success is by no means confant. Knuckel also mentions a purple-gold powder, refembling that of Neri, which he obtained by infipitating solution of gold to drynefs, abstracting from it the aqua regia three or four times, till the matter appears like oil; then precipitating with strong alkaline ley, and wafting the precipitate with water. By diffusing this powder in spirit of falt, and precipitating it again, it becomes, he fays, extremely fair; and in this flate he directs it to be mixed with a due proportion of Venice glafs.

Ofrach in his treatife entitled 3ol nere Verde, gives the following procfs for producing a very fine ruby. He directs the purple precipitate, made by tin, to be ground-with six times its quantity of Venice glafs into a very fine powder, and this compound to be very carefully mingled with the frit or vitreous composition to be tinged. His frit consists of equal parts of boras, nitre, and fixed alkaline falt, and four times as much calcined flint as of each of the farts; but he gives no directions as to the proportion of the gold precipitate, or mode of folution. Hellot describes a preparation, which mixed with Venice glafs, was found to give a beaufiful purple enamel. This preparation consists of equal parts of folution of gold, and of folution of zinc in aqua regia, mixed together with the addition of a volatile falt prepared from falt ammoniac, in quicklime, in fufficient quantity to precipitate the two metals. The precipitate is then gradually heated, till it acquires a violet colour. However, though a purple or red colour, approaching to that of ruby, may, by the methods above recited, be baked on glafs or enamels, and introduced into the mafs by folution, the way of equally diffusing such a colour through a quantity of fluid glafs is fwall, fays Dr. Lewis, a fecret. The following procfs for making the ruby glafs was communique to Dr. Lewis by an artifit, who afcribed it to Knuckel. The gold is directed to be diffolved in a mixture of one part of spirit of falt, and three of aqua-fortis, and the tin in a mixture of one part of the former of these acids with two of the latter. The folution of gold being properly diluted with water (see Gold precipitate, &c.) the folution of tin is added, and the mixture left to fland till the purple matter has settled to the bottom. The colourles liquor is then poured off, and the purple sediment, while mofit and not very thick, is thoroughly mixed with powdered fmit or fand. This mixture is well ground with powdered nitre, tartar, boras, and arsenic, and the compound melted with a suitable fire. The proportions of the ingredients are 3560 parts of sand, 583 of nitre, 240 of tartar, 240 of boras, 28 of arsenic, 5 of tin, and 5 of gold. Lewis's Com. Phil. Techn. p. 171. 621, &c.

GLASS, suble-opaque, and semi-transparent, may be made of ten pounds of either of the compositions for hard glafs, and one
one pound of well calcined horn, iron, or bone; or an opaque whiteness may be given to glass, by adding one pound of very white alkane to ten pounds of flux glass. Let them be well powdered and mixed, by grinding them together; and then fused with a moderate heat, till they are thoroughly incorporated. A glass of this kind is made in large quantities at a manufacture near London, and used not only for different kinds of vessels, but as a white ground for enamelled in dial-plates and snuff-boxes, which do not require polishing with much fire, because it becomes very white and fusible with a moderate heat.

Glass, Yellow. See Golden-coloured Glass.

Glass-balls, which are circular or otherwise shaped hollow vessels of glass, may be coloured within, so as to imitate the semi-polluted gems. The method of doing it is this: make a strong solution of ichthyocolla, or finginglass, in common water, by boiling; pour a quantity of this while warm into the hollow of a white glass vessel; shake it thoroughly about, that all the sides may be wetted, and then pour off the rest of the moiilure. Immediately after this, throw in red lead, have it lie and turn it about, throw into many places with a tube, and the moilure will make it stick and run in waves and pretty figures. Then throw in some of the painter's blue smalt, and make it run in waves in the ball as the red-lead; then do the same with verdigris, next with opaliment, then with red lake, all well ground; always calling in the colours in different places, and turning the glasses, that the moilure within may run them into the waves. Then take fine paller of Paris, and put a quantity of it into the ball; shake it alto nimibly about; this will every where fickle firmly to the glasses, and give it a strong inner coat, keeping all the colours on very fairly and strongly.

These are set on frames of carved wood, and much esteemed as ornaments in many places. Neri.

Glass-drops. See Rupert's drops.

Glass, Frothing of. See Frothing and Looking-glass.

Glass-gall, or sandero, is the cemen of the glairs pots, which arises during the vitrification of the fire. See Glass, Figura.

Glass, Gilding of. See Gilding of enamel and glass.

Glass, Grinding of. See Grinding.

Glass-house Furnace, is the place in which the ingredients, or materials of glass are fused and vitrified. There are three kinds of furnaces used in the glass-works. The first, called the "calcine" furnaces, serve for preparing or calcining the fire. It is made like an oven, 10 feet long, 6 feet broad, and two deep. The fuel, which is sea-coal, is put in a trench, on one side of the furnace, and the flame reverberates from the roof back upon the frit. The coals burn in an iron grate, and the ashes fall thence into holes underneath.

The second is the "working furnace," in which the ingredients are melted, and the glass is made. Its figure is round, resembling a dome, three yards in diameter, and two high, supported on arches, beneath which is a large space for a brisk and copious draught of cold air from without; round the inside there are arranged eight or more pots, and these piling-pots, every where closed except at one face opening, which communicates with a small recess formed by the ultimate projections of the masonry and flues of the oven or kiln, in which recedes the workmen's fire. The furnace has two passages, the lower, separating the pots from the fire-place, has a circular hole in the centre covered with a grate, through which the flame pusses from the fire-place into the furnace, being afterwards reverberated from the arched sides and roof to the melting-pots, and passing out with the smoke through the top of the dome, which is strengthened into a chimney for the space of a few feet. The second partition divides this from the hear or annealing furnace, through the bocces, or working-holes, when there are more than one, the metal is taken out of the pots and the pots put into the furnace; the bocces are flapped with moveable covers, made of flue and brick to screen the eyes of the workmen from the fire; and sometimes on each side of the bocce is a beccacera, out of which coloured glass, or fine metal is taken from the piling-pot.

To the furnace likewise occasionally belong ovens, or holes near the hear, for the calcining of tarter, iron, &c.

The hear, which serves to anneal and cool the vessels, and which Agricola makes a particular furnace, consists of a tower, beside the hear; the tower has directly over the melting furnace, with a partition betwixt them about a foot thick, having an aperture called secino, or lanella, through which the flame or heat ascends out of the furnace into the tower; on the floor or bottom of this tower, the vessels, fashioned by the artificer, are set to be annealed; and as the flame has here a lot's degree of intensity than that which is fulfilled by the pots, the vessels, after they have been formed, are slowly and gradually, this being usually two or three months, by which the glasses are put in with a fork, and placed on the floor. The hear is an avenue, five or six yards long, continued to the tower; through this the glasses, when annealed, are drawn in iron pans, called frecker, by which they come to cool by degrees, being quite cold by the time they reach the mouth of the hear, which enters the "favole," or room where the glasses are to be fet.

The third is the "green-glass furnace," which is a kind of compound of all the former. It is made square, (the two former being circular,) having an arch at each angle for annealing and cooling the glasses. The metal is wrought on two opposite sides, and on the other two they have their calcaries, into which are made litre-holes for the fire to come from the furnace, to bake the frit, and also to discharge the smoke. Fires are made in the arches to anneal the vessels, so that the whole process is done in one furnace. The materials with which the inides of these furnaces are contracted are not ordinary brick (which would soon melt into glass, as would also all the latter stones,) but hard and prime kinds, called by Imperator "pyramachia." But when bricks are used, they should be formed of an earth which pollutes in the highest degree the qualities of density and infusibility, for refilling the fire, which continues to act upon them, without cessation for a long time; as the fires in a glais-house are seldom sufficed to go out, from the time when the furnace is first employed till it needs repair, and the interval may be two or three years; the walls of the furnace, for this reason, as well as the pots, are constructed chiefly of clay, mixed with sand, and other materials of a refractory kind, in due proportion. See Glass-pots.

Glass of lead, a glas made with the addition of a large quantity of lead, of great use in the art of making counterfeit gems. The method of making it is: put a large quantity of lead into a potter's kiln, and keep it in a state of fusion with a moderate fire, till it is calcined to a grey loofe powder; then spread it in the kiln, and give it a greater heat, continually stirring it to keep it from running into lumps; continue this several hours, till the powder becomes of a fair yellow; then take it out and sift it fine; this is called calcined lead.

Take of this calcined lead fifteen pounds, and crystalline, or other frit, twelve pounds; mix these as well as possible together; put them into a pot, and let them in the furnace for ten hours; then call the whole, which will be now perfectly melted, into water; separate the loofe lead from it, and return the metal into the pot; and after flanging in fusion
fusion twelve hours more, it will be fit to work. It is very tender and brittle, and must be worked with great care, taking it slowly out of the pot, and continually wetting the marble it is wrought upon. Neri.

It is well known, that cermis, or white lead, minium, litharge, and all the other preparations and calces of lead, are, at least, if not of a moderate fire, and baked into a transparent glass of a deep yellow colour. But this glass is so penetrating and powerful a flux, that it is necessary to give it a greater confidence, in order to render it fit for use. With this view, two parts of calc of lead, e.g. minium, and other parts of sand, or powdered flints, may be put into a crucible of refractory clay, and baked into a compact body. Let this crucible, well closed with a luted lid, be placed in a melting furnace, and gradually heated, for an hour, or an hour and a half; and afterwards let the heat be increased, so as to obtain a complete fusion, and continued in that state for the same time: let this crucible remain to cool in the furnace, and when it is broken, a very transparent yellow-coloured glass will be found in it. Some add nitre and common salt to the above mixture, because these salts promote the fusion and the more equal distribution of the sand. This glass of lead has a considerable specific gravity, and its lowest part is always the heaviest. It is an important flux in the affrays of one's to facilitate their fireifications.

Glasses of lead is capable of all the colours of the gems in very great perfection. The methods of giving them are these: for green, take polverine frit twenty pounds, lead calcined fourteen pounds; mix both in the pot upon the fire; then mix them into a glass, separating the unmixed lead, by planting the mass to water; after this return it into the pot, and add braze the calcined five ounces, and one pennyweight of crocus martis made with vinegar; put this in at six different times, always carefully mixing it together; let it finally sate an hour, then mix it together, and take a proof of it; when the colour is right, let it stand eight hours, and then work it. If instead of the calcined braze the same quantity of the calx mortum of the vitriolum venetis be used, the green is yet much finer.

For topaze-colour take crystal frit fifteen pounds, calcined lead twelve pounds; mix them well together, by letting the powders through a fine sieve; then let them into a glass, separating the unmixed lead, by planting the mass to water; after this return it into the pot, and add braze the calcined five ounces, and one pennyweight of crocus martis made with vinegar; put this in at six different times, always carefully mixing it together; let it finally sate an hour, then mix it together, and take a proof of it; when the colour is right, let it stand eight hours, and then work it. If instead of the calcined braze the same quantity of the calx mortum of the vitriolum venetis be used, the green is yet much finer.

For topaze-colour take crystal frit fifteen pounds, calcined lead twelve pounds; mix them well together, by letting the powders through a fine sieve; then let them into a glass, separating the unmixed lead, by planting the mass to water; after this return it into the pot, and add braze the calcined five ounces, and one pennyweight of crocus martis made with vinegar; put this in at six different times, always carefully mixing it together; let it finally sate an hour, then mix it together, and take a proof of it; when the colour is right, let it stand eight hours, and then work it. If instead of the calcined braze the same quantity of the calx mortum of the vitriolum venetis be used, the green is yet much finer.

Glasses, Painting in. The primitive manner of painting in glasses was very simple, and of consequence very rude: it consisted in the mere arrangement of pieces of glass of different colours, in some sort of symmetry; and constituted a kind of what we call Mosaic work.

 Afterwards, when they came to attempt more regular designs, and even to represent figures raved with all their finesses, their whole address went no farther than to the drawing the contours of the figures in black, with water colours, and hatching the dresses, after the same manner, on glases of the colours of the object intended to be painted. For the carnations, they chose glases of a bright red; upon which they designed the principal lines of the face, &c. with black.

At last the taste for this sort of painting being considerably improved, and the art being found applicable to the adornment of churches, baiiiacs, &c. they found means of incorporating the colours with the glasses itself, by exposing them to a proper degree of fire, after the colours had been laid on.

A French painter at Marfelles is said to have given the first notion hereof, upon going to Rome, under the pontificate of Julius II. But Albert Durer, and Lucas of Leyden, were the first that carried it to any height.

The colours used in painting on glases are very different from those used either in painting in oil, or water.

The black is made of two-thirds of flakers, or scales of iron, beaten up, and mixed with another third of rockeille, or little glass beads. White, with sand, or little white pebbles, calcined, pounded in a mortar, and afterwards ground on marble; with one fourth-part of salt-petre, added there-to, and the mixture calcined and pulverized over again: to which, when they are ready to use it, is added a little gypsum, or plaster of Paris well ground, &c. For yellow, they use leaf-silver ground, mixed up in a crucible, with sulphur or salt-petre; then well beaten and ground on a porphyry stone; and, at length, ground over again with nine times as much red ochre. Red is made of lathage of silver, and scales of iron, gum Arabic, ferretta, glasses, and blood-done, nearly in equal quantities. This is one of the most difficult colours, and the preparation only to be learned by experience. Green is made of as sulphuret, one ounce; as much black lead, and four ounces of white sand, incorporated by the fire. After calcination, they add a fourth part of salt-petre; after a second calcination, a fifth part more; after which they make a third cohesion before it is used. Azure, purple, and violet, are prepared like green, only leaving out the as sulphuret, and in the lieu thereof using sulphur for azure; periguese for purple; and both these drugs for violet. Carnations are made of ferretta and rockeille. And lastly, colours for the hair, trunks of trees, &c. are made of ferretta, rockeille, &c.

This account of colours we have from M. Felibien's excellent work Des Principes d'Architecture, &c. though it must be owned, that all the painters on glasses do not use them; there being few artists of that kind but have invented their own particular ones, whereof they usually make great secrets. But this is certain, that these above described are sufficient for the best paintings of all sorts; provided the person has but the skill to manage them.

In the windows of divers ancient churches, chapels, colleges, &c. we meet with the most beautiful and lively colours imaginable; such as far exceed any used among us; but it is not that the secret of making those colours is lost; but that the moderns would not go to the expense of them; nor take all the necessary pains; because this sort of painting is not now so much esteem'd as formerly.

Mr. Walpole, in his Anecdotes of painting in England, has traced the history of this art from the reformation, when misguided zeal destroyed most of the monuments of it in our churches, through a series of professors to the present time. Among the later proficients in this art were Isaac Oliver, who painted the windows at Chriftchurch, Oxford, in 1700; William Price, who in the same year painted the windows in Merton chapel; William Price, the son, to whose art we owe the windows at Queen's, New-college, and Madelin, of whom Mr. Walpole says, that his colours are fine, his drawing good,
G L A S S.

good, and his taste in ornaments and Mosaic far superior to any of his predecessors, and equal to the antique. In 1761, Mr. Powell, an auctioneer late of Elfen-house, in London, exhibited the two first auctions of painted glasses imported from Flanders; and undertook also to establish a manufacture of painted glasses: several of the pieces of this ingenious artist exhibited colours varying in perfection with the old paintings.

Those beautiful works, among the painters in glasses, which were made in the glasses-house, were of two kinds: in some, the colour was diffused through the whole body of glasses; in others, which were the more common, the colour was only on one side, scarce penetrating within the substance above one-third of a line; though this was, more or less, according to the nature of the colour; the yellow being always found to enter the deepest.

These glass, though not so strong and beautiful as the former, were of more advantage to the workmen; because, on the fame glasses, though already coloured, they could skew other kinds of colours, where there was occasion to embosser draperies, enrich them with foliages, or represent other ornaments of flowers, etc.

In order to this, they made use of emery, grinding, or wear ing down the surface of the glasses, till such time as they were got through the colour, to the clear glasses: this done, they applied the proper colours on the other side of the glasses. By this means the new colours were prevented from running and mixing among the former, when the glasses came to be exposed to the fire, as will hereafter be shewn.

When the intended ornaments were to appear white, or silvered, they contented themselves to bare the glasses of its colour with emery, without applying any new colour at all; and it was in this manner that they wrought the lights and heightenings on all kinds of colours.

The painting with vitreous colours on glasses depends entirely on the fame principles as painting in enamel; and the manner of executing it is likewise the same; except that in this the transparency of the colours being indispensably requisite, no substrances can be used to form them but such as vitrify perfectly: and, therefore, the great object is to find a set of colours, which are composed of such fusible matter, by the admixture of other bodies may promote their vitrification and fusion; are capable of being converted into glasses; and melting, in that state, with less heat than is sufficient to melt such other kinds of glasses as may be chosen for the ground or body to be painted; to temper these colours, so as to make them proper to be worked with a pencil; and to burn or reduce them by heat, to a due state of fusion, without injuring or melting the glasses which constitutes the body painted. The first thing to be done, in order to paint on glasses, in the modern way, is to design, and even colour, the whole subject on paper. Then they make choice of pieces of glasses proper to receive the several parts, and proceed to divide or distribute the design itself, or the paper it is drawn on, into pieces suitable to those of glasses; having always a view that the glasses may join in the contours of the figures, and the folds of the draperies; that the curvatures and other finer parts may not be damaged by the lead wherewith the pieces are to be joined together.

The distribution being made, they mark all the glasses, as well as papers, with letters, or numbers, that they may be known again; which done, applying each part of the design on the glass intended for it, they copy or transfer the design upon this glass, with the black colour, diluted in gum-water; by tracing and following all the lines and strokes, as they appear through the glasses, with this point of a pencil.

When the first strokes are well dried, which happens in about two days, the work being only in black and white, they give it a slight wash over, with urine, gum Arabic, and a little black; and this several times repeated, according as the shades are designed to be heightened; with this precaution, never to apply a new wash, till the former is sufficiently dried. This done, the lights and risings are given, by rubbing off the colour in the respective places, with a wooden point or the handle of the pencil.

As to the other colours above-mentioned, they are used with gum-water, such as in painting in miniature; taking care to apply them lightly, for fear of effacing the outlines of the design; or even, for the greater security, to apply them on the other side, especially yellow, which is very pernicious to other colours, by blending therewith.

And here too, as in pieces of black and white, particular care must be always had, not to lay colour on colour, or lay on a new layer, till the former is well dried. It may be added, that the yellow is the only colour that penetrates through the glasses, and incorporates therewith by the fire; the red, and particularly the blue, which is very difficult to use, remaining on the surface, or at least entering very little. When the painting of all the pieces is finished, they are carried to the furnace or oven, to anneal or bake the colours. The furnace here used is small, built of brick, from eighteen to thirty inches square: at six inches from the bottom is an aperture, to put in the fuel, and maintain the fire. Over this aperture is a grate, made of three square bars of iron, which traverse the furnace, and divide it into two parts. Two inches above this partition is another little aperture, through which they take out pieces, to examine how the coating goes forward.

On the grate is placed a square earthen pan, six or seven inches deep; and five or six inches less, every way, than the perimeter of the furnace. On one side hereof is a little aperture, through which to make the trials, placed directly opposite to that of the furnaces designed for the same end.

In this pan are the pieces of glasses to be placed in the following manner; first, the bottom of the pan is covered with three strata, or layers of quicklime, pulverized; those strata being separated by two others, of old broken glasses: the design whereof is to secure the painted glasses from the too intense heat of the fire. This done, the glasses are laid horizontally on the left, or uppermost, layer of lime.

The first row of glasses, they cover over with a layer of the fame powder an inch deep; and over this they lay another range of glasses; and thus alternately, till the pan is quite full; taking care that the whole heap always ends with a layer of the lime-powder.

The pan thus prepared, they cover up the furnace with tiles, on a square table of earthenware, closely luted all round; only having five little apertures, one at each corner, and another in the middle, to serve as chimney.

Things thus disposed, there remains nothing but to give the fire to the work. The fire for the two first hours must be very moderate; and must be increased in proportion as the coating advances, for the space of ten or twelve hours; in which time it is usually completed. At last, U
the fire, which at first was only of charcoal, is to be of dry wood: so that the flame covers the whole pan, and even lies out at the chimney.

During the 2d hours, they make assays from time to time, by taking out pieces laid for that purpose, through the little aperture of the furnace, and pane, to see whether the glass be perfect, and the other colours in good order. When the annealing is thought sufficient, they proceed with great haste to extinguish the fire, which otherwise would soon burn the colours, and break the glazes. See Painting.

GLASS, painting on, by means of stains. See Back-printing.

GLASS, polishing of. See Polishing and Grinding.

GLASS-porcelain, the name given by many to a modern invention of imitating the china-ware with glasfs. The method given by M. Reaumur, who was the first that carried the attempt to any degree of perfection, is delivered by that gentleman in the Memoirs of the Academy of Sciences of Paris, to this effect. This change of glasfs was first noticed of by Neumann, who, in distilling milk in a glafs retort, observed, that the bottom of the vessel acquired the appearance of porcelain, which he attributes to the fine white earthy matter of the milk forced into the glasfs by heat. Neum. Chem. Works 5th Dr. Lewis, \(5^{71}\). The means of reducing to powder, with other means vitrifiable substances for forming a paste, to be afterwards made into a sort of a porcelain, has been a contrivance long practised, but it is very troublesome, and the result subject to many faults; but this new ware is made of glasfs alone, and that with much less trouble, and without the reducing it to powder. By this art, vessels of glasfs are changed into vessels of a sort of porcelain, without altering their form, and the meanest glasfs made only of sand, lime, and stable ashes, forces as well as the bell for that purpose: our common coarse green quart-bottles, or the great bell glasfs with which gardeners cover their melons, &c. being by this means changeable into a beautiful white sort of porcelain ware; and this is to be done in so easy a manner, and with so small expense, that it requires no more trouble or charges, than that of baking a common vessel of our coarse earthen-ware; and for this reason the vessels of this sort of ware may be afforded extremely cheap.

It is very certain, that all porcelain ware is a sublimate in the state of semi-tranferable; and in order to bring glasfs, which is a wholly vitrifiable substance, into the condition of porcelain, there requires no more than to reduce it to a less perfectly vitrified state.

The question which would naturally start on this occasion, is, whether it be possible to reduce glasfs to a less vitrified state, it having already undergone what is called the last change by fire. But when we consider, that the mass of antimony, the vitrifications of many of the metals, as the glasfs of lead, and the counterfeit gems coloured by the metals, are more or less easily reduced again by chemistry to metals, &c. the reducing of sand, flints, &c. after they are vitrified, at least a little way back toward their native or primitive state, may appear not wholly impracticable, and the attempts which M. Reaumur made on this occasion; called from his name "Reaumur's porcelain." The method of making it is this. The glasfs vessels to be converted into porcelain, are to be put into a large earthen vessel, such as the common line earthen dials are baked in, or into sufficiently large crucibles; the vessels are to be filled with a mixture of fine white sand, and of fine gypsum or plaster alone burnt into what is called plaster of Paris, and all the interstices to be filled up with the same powder, so that the glasfs vessels may no where touch either one another, or the sides of the vessel they are baked in. The vessel is to be then covered down all round, and the fire continued at the head of the work; for this is only to be put into a common potter's furnace, and when it has stood there the usual time for the baking of the other vessels, it is to be taken out, and the whole contents will be found no longer glasfs, but converted into a white opaque sublimation, which is a very elegant porcelain, and has almost the properties of that of China. Memoirs Acad. Sciences Paris, \(17^{35}\).

The powders which has served once, will do again as well as fresh, and that for a great many times: nay, it seems, ever so often. The cause of this transformation, says Macquer, is probably that the vitrificatory action of the gypsum quits its basis of calcareous earth, and unites with the alkaline salt and saltness of the glasfs, with which it forms a kind of salt or felsenes, differing from the calcareous felsenes, by the interposition of which matter the glasfs acquires the qualities of porcelain. Dr. Lewis, from a variety of experiments on the nature and qualities, and method of producing this porcelain, has deduced the following conditions: 1. Green glasfs converted with white fire received to heat: in a bath: in a bell: or in a crucible: the change proceeded very slowly; but in a strong red heat, approaching to whitness, the thickest pieces of glasfs bottles were thoroughly changed in three hours. 2. The glasfs sustained the following progression of changes. Its surface first became blue: its transparency was diminished, and when held between the light and the eye, it appeared of a yellowish hue: afterwards it was changed a little way on both sides into a white sublimation, externally still blue: and as this change advanced still farther and farther within the glasfs, the colour of the vitreous part in the middle approached nearer to yellow: the white coat was of a fine fibrous texture, and the fibres were disposed nearly parallel to one another, and transverse to the thickens of the piece: by degrees the glasfs became throughout white and fibrous, the external blacknesses at the same time going off, and being succeeded by a dull whiteness or dun colour: by a still longer continuance in the fire, the fibres were changed gradually from the external to the internal part, and converted into glass; and the texture then, was not united, but merely composed. The first fibrous and somewhat glistening appeared afterwards larger and diller, and at length the sublimation of the glasfs became porous and frisible, like a mass of white sand thinly cohesion. 3. Concerning the qualities of the converted glasfs Dr. Lewis observes, that the whitenss of the internal part was not inferior to that of porcelain, but that the surface was the best beautiful; that the thick pieces were quite opaque, and that several thin pieces were semi-transparent; that while it remained in a fibrous state, its hardnes became greater than that of glasfs; or of the common kinds of porcelain; it was capable of subduing sudden changes of heat and cold better than any porcelain; and in a moderate white heat, it was flexible into a sublimation not fibrous, but vitrisc and smooth, like white enamel: that when it texture had been coarsely granulated, it was now much softer and unprofitable; and lastly, that when some coarsely granulated imperfect pieces which, with the continuance of a moderate heat, would have become porous and frisible, were suddenly exposed to an intense fire, they were rendered remarkably more compact than before; the solidity of some of them being superior to that of any other ware. 4. No differences appeared in the internal colour, hardnes, texture, or the regular succession of changes, from the use of different cementing substances; though
though in external appearances the differences were considerable. All the pieces which had been surrounded with charcoal or with foot were externally of a deep black colour, which did not disappear by exposure to a strong fire during an hour, with free access of air. Coloured clays and frits communicated different shades of a brown colour; and white clays gave whitish, greyish, or brownish tinges. White frit, calcined frits, and gypsum, gave in general the greatest whitenesses, and tobacco-pipe clay the greatest glossiness and brightness. Glazes composed of earths without alkaline falt, glazes of lead, fmit-glazes, crown-glaees, looking-glass plates, a glaze prepared with calcined frits and a fixed alkaline falt, and even green glazes which had been fused together with a ninth part of alkaline falt, suffered none of the above alterations by cementation. Green bottle-glazes and common window-glasjes were most susceptible of those alterations. 6. The changes produced by cementation could not proceed from any absorption of matter from the cementing fubstance; because no increase of weight was given, and because the same changes were produced upon a piece of glases merely by heat, without any cementing fubstance. See Com. Phil. Trans. p. 350—555.

Mr. Gregory Watt, in his valuable paper on bafalt (Phil. Trans. for 1834, cited by Aikin,) alleges this porcellaneous change of glases as an illustration of his important principle, viz. "that bodies whose fibres have a natural tendency to a crystalline arrangement, or a polarity, when vitrified by a sufficient heat and cooled hastily in the vitreous state, are able subsequently to return to their natural crystalline arrangement of fibres, when exposed to a heat merely sufficient to soften the texture, though not enough for fusion. This, in the instance of bafalt, he flew by the singular crystallizations formed in the cells of fused bafalt, long after it had lost the liquidity of fusion. The circumstance of no material change occurring in the weight of glases by this conversion into the fibrous state, flew incontestably that it cannot be owing either to any thing gained during the process, nor to any material loss of the alkali; and this is also rendered manifest by its return to the vitreous state and vitreous qualities when again melted. This too may again be porcelaneous in the same way, and again be melted into glases, and so on alternately." See Porcelain.

Glass-pots, the vessels in the glases manufacture used for melting the glases. Those for the white glases works are made of a tobacco-pipe clay, bought from the Ille of Wight, which is first well wallled, then calcined, and afterwards ground to a fine powder in a mill; which being mixt with water, is then trod with the bare feet till it is of a proper consistence, to mould with the hands into the proper shape of the vessels. When these are thus made, they are afterwards annealed over the furnace. Those for the green-glases work are made of the nonfuch, and another fort of clay from Staffordshire; they make those so large as to hold three or four hundred weight of metal. And besides thse, they have a small fort called piling pots, which they set upon the larger, and which contain a liuer and more nice metal for the nicest works. Nerig.

The clay that is used for this purpose should be of the purest and most refractory kind, and well c‘anoned from all sandy, ferruginous, and pyritic matters; and to this it will be proper to add ground crucibles, white fand, calcined frits duly levigated, or a certain proportion of the same clay buried, and pounded not very finely. The quantity of baked clay that ought to be mixed with the crude clay, to prevent the pots from cracking when dried, or exposed to a great heat, is not absolutely determined, but depends on the quality of the crude clay, which is more or less fat. M. D'Antic, in a memoir on this subject, proposes the following method of ascertaining it; the burnt and crude clay, being mixed in different proportions, should be formed into cakes, one inch thick, and four inches long and wide. Let these cakes be slowly dried, and exposed to a violent heat, till they become as hard and as much contracted as possible, and in this state be examined; and the cake, he says, which has suffered a diminution of its bulk equal only to an eighteenth part, is made of the best proportions. He observes, in general, that most clays require that the proportion of the burnt should be to the fresh as four to five.

It is of great importance that the material of which the pots are made should be carefully selected, as they are exposed to the action of a very fierce fire, and also to the fervent activity of the glases with its powerful fluxes. They should also be made very thick and strong, as they are intended to last for many months. When finished, they are placed in a warm room in order to discharge their moisture, and any small figures arising from the unequal shrinking of the clay are closed by gently beating with a mallet. They are afterwards gradually heated in a small oven, constructed for this purpose, and slowly brought to a red heat; and after remaining for some time in this state, they are removed to the furnace, and fixed down in their places by fire-clay. Here, on account of a further shrinking, they remain for a day or two before they are fit for receiving the glases materials. Pots of this kind are said to last, at an average, about a year.

Glass Tubes are of various lengths, diameters, and forms, according to the purposes to which they are applied. These are often formed with the lamp and blow-pipe, in the manner described under the article Lamp-Blowers. In this way tubes are sealed hermetically (see Hermetical Seal,) tubes are bent, others are joined, bulbs are annexed to tubes for thermometers, &c., and glases is drawn out into threads.

It has been observed, that glases tubes laid before the fire in a horizontal position, and with their extremities supported, have had a rotatory motion about their axes; and also a progressive motion towards the fire, even when their supports are inclined from the fire, so that the tubes will move a little upwards. See Phil. Trans. N° 476. § 1.

When the progressive motion of the tube is stopped by any obstacle, its motion about its axis will still continue. When the tubes are placed in a nearly upright posture leaning to the right hand, the motion will be from left to right; but if they lean to the left, the motion will be from right to left; when the nearer they are placed to the perfectly upright posture, the left the motion will be either way.

If the tube be placed horizontally on a glases plate, the fragment, for instance, of coach window-glasses, instead of moving towards the fire, will move from it, and about its axis, in a contrary direction to what it had done before. Nay, it will recede from the fire and move a little upwards, when the plane inclines towards the fire.

Neither the draught of air up the chimney, nor attraction or repulsion, are the cause of these phenomena. It seems rather owing to the feeding of the tube towards the fire; for allowing such swelling, gravity must pull the tube down, when supported near its extremities horizontally; and a fresh part being exposed to the fire and swelling out again, will fall down again, and so on successively; which will produce a rotatory motion towards the fire.

If the tube be supported by two other tubes, and these be brought near to each other, and to the centre of the supported tube, then its parts hanging over on each side, being larger than the part which lies between the supports, will,
by their weight, pull downwards, and consequently force the middle part, refting upon its two props, upwards; and being lefs advanced towards the fire, as being lefs heated, will, by their oblique situation, pull the middle part backwards also from the fire, which will caufe a rotary regenerative motion, quite contrary to what the tube had when supported near its extremities. And when a fingle tube lies inclining opposite to the fire, either to the right hand or to the left, out of a plane perpendicular to the surface of the fire, gravity will not permit the curved part to reft, but pull it down till it coincides with a plane perpendicular to the horizon; and consequently, as new curvcs are generated, new motions will be fo too; that is, the tube will be made to move about its axis, with this difference, when the tube inclines to the right hand, the motion will be from east to west; when to the left hand, from west to east. The juftnefs of this reafonmg is made manifefl, by bending a wire, and supporting it firft near its extremities, then near its centre on each fide, afterwards inclining it to the right and to the left; the bending in every cafe refpefting the curved part of the tube next the fire. This folution of the phenomena is rendered the more probable from hence, that if four supporters were made use of, one at each extremity, and two near the middle, there was no motion at all, either backward or forward. Nor does the increafe of contact hinder the motion, because the plate of glafs was fo broad as to have a much greater contact with the tube, and yet both the rotary and regenerative motions were manifefl.

These experiments succeeded with tubes about twenty or twenty-two inches long; the diameter about one-eighth of an inch; and they had in each a pretty strong pin hard in cork, for an axis to roll with on the supporting tubes.

Phil. Trans. N. S. 178.

GLASS, &c. how to cement the crofts of. See CEMENT and REPAIRER.

GLASS, how to take the impression of antique gems in. See GEM.

The property which glafs possesses in common with other substances of being expanded by heat, and contracted by cold, was long ago obferved and evinced by Mr. Hook. See Birch's Hift of the Royal Society, vol. i. p. 411. See THERMOMETER.

GLASS, Law relating to. No glafs shall be imported into Ireland, other than the manufacture of Great Britain, on pain of forfeiting the fame, and fhip, and 10s. a pound. 19 G. II. c. 12. If any foreign glafs shall be landed or unshipped before entry and payment of the duties, or without warrant from the proper officer, the fame shall be forfeited, or its value; and the master or other perfon having command of the veffel, and every other perfon concerned in such landing or unloading, shall forfeit 100l. 17 G. III. c. 39. And by 58 G. III. c. 33, for preventing the fraudulent importation of glafs, every package containing any plate or plates of glafs unframed, being plate, crown, or fleet glafs, which shall be imported, or brought into this kingdom for exportation, shall be marked on the outside in Roman letters four inches long at lead, with the word GLASS, on pain of forfeiture, together with the package, and all goods contained in it. The matter of the veffel importing fuch package, fhall, in reporting his cargo, express every fuch package of glafs, on pain of forfeiting the fame, and also 100l. Nor fhall any fuch package be imported, which fhall not contain 500 weight, on pain of forfeiture; but not extending to any part of glafs 60 inches in length or upwards, on account of the package not being marked. By 43 G. III. c. 69. For every 100 weight of materials, &c. that shall be made use of in Great Britain for the making of plate or fleet glafs,
Buildings of this kind may be constructed, occasionally, either against some ready-built south wall, which serves for the back, or against any other part of the building which will admit of being built up; or detached in a similar situation, so as to shew the whole wall may be fluted from the south; the back being framed of brickwork, &c. or of wood double planked; but the former is preferable; the whole being generally ranged lengthways, nearly in an east and west direction.

The dimensions may be from five to six, or eight to ten feet in width, by ten, fifteen, or twenty feet in length or more, as may be required; and from six or eight, to ten feet high behind, by five or six, or seven or eight, in the front. Both ends in proportion with the top, sloping gradually, as suit noticed, from the back, having an entrance, or door, in front, or at one end. The glass-work should be made to slide readily backwards and forwards.

Sometimes fire-places are carried along the back and front internally, proceeding from an external furnace, for occasional fire-heat in winter, which renders them more convenient and useful for various purposes.

These cafes, as mentioned above, are used as preparatory departments, in which to winter many sorts of curious exotics of the harder greenhouse kinds, which only want protection from severe cold, as well as many choice kinds of the open ground, which are rather tender than in their minor growth, or any other particular or curious hardy plants, whether flowers, shrubs, or young trees, especially the choice evergreen kinds, which require effectual protection from the ravages of rigorous frosts or cutting winds, in winter or early spring; and, at the same time, in mild open weather, to enjoy the full air by opening the glasswork; all which, being in pots, can be readily put out in the greenhouse, or may be kept in the coldframe, if the weather be severe, and be thus kept in good condition till settled weather in spring, &c.; then removed into the full air.

In summer and autumn, when unoccupied in this way, these cafes may be of some utility to place some curious kinds of tender plants in, when in flower for feeding, to guard them from heavy or incessant rain, or cold night dews in autumn, which, in many sorts of plants, retard, or sometimes wholly frustrate their production of good seed, in as many sorts of curious tender annuals; particularly the fine double balansaums, cock's-combs, tricolours, double iramouniums, diamond feodics, and various others.

They are also capable of being used in spring and the early part of summer, as in April, May, and June, as a kind of drawing-frames, for some particular sorts of curious annuals to bring them to a tall growth, such as the large or giant cock's-combs, tricolours, double iramouniums, double-striped balansaums, egg-plants, &c. the plants being first raised in hot-beds, under garden-frames, till of twelve or fifteen inches height, then a hot-bed made in the glass-cafe, carted at top, and the plants in pots, thinly planted into the earth of it; the glasswork, in these cafes, should be that close, only a necessary admission of fresh air being given every day, by which they run up to a tall stature in the best perfection of strength for flowering. See Annual Planets.

These sorts of glass-cafes are also sometimes made use of as a kind of appurtenances to hot-houses, or stoves, detached from them, having, as observed above, internal flues for fireheat, when necessary, serving as preparatories for many sorts of exotics, which are tenderer than common greenhouse plants, but do not require the constant full heat of the more tender hot-house kinds, but only the affinities of moderate fireheat in winter, in cold nights, or when very damp, cloudy, foggy-weather and severe frosts prevail. They are sometimes used in the business of forcing different kinds of flowering plants and esculent, either by means of an internal bark-bed, or flues for fireheat.

When intended for this purpose, it is convenient to have both an internal pit for a bark-bed, and flues for fireheat, in order to use either separately, or sometimes both, as may be found necessary. See Hot-House.

Glass Faces, in Mining, is a term for the polished surfaces, or flikened sides, which are found in some of the mineral veins in Derbyshire, something like the polishing which is seen on the sides of faults. See Slieken Side.

Glass fibre, called also Scalphy, in Geography, one of the Hebrides, near the N.E. extremity of Harris. It is a small, round island, covered with heath, and indented by the sea. Near its western extremity are two good natural harbours, and on its call point a light-house was erected A.D. 1788. It lies at the entrance of Eas Loch Tarbot. N. lat. 57° 50'. W. long. 6° 40'.

Glass Lead, in Mining, according to Mr. Mawe, "Mineralogy of Derbyshire," p. 105, is an opaque waxy lead-ore found in that county; sometimes also it is transparent and crystallized, appearing as though it had undergone the action of fire.

Glass, Leugh, in Geography, a lake of Ireland, in the county of Doneghoul, near which is a village of the same name, about five miles from the town of Doneghoul. The lake contains 120 acres; and a wood, spreading over a fine bold hill, hangs down to the water in one deep shade, the effect of which is remarkably beautiful. The county around is very fine. Young.

Glasses are distinguished, with regard to their form, use, &c. into various kinds, as drinking-glasses, optic-glasses, looking-glasses, burning-glasses, &c.

Glasses, Drinking, are simple vessels of common glass or crystal, usually made in form of an inverted cone.

Each glass consists of three parts, viz. the calyx or bowl; the bottom, and the foot; which are all wrought or blown separately.

Nothing can be more dexterous and expeditions than the manner wherein these parts are all blown: two of them opened, and all three joined together. An idea is only to be had thereof, by seeing them actually at work.

The glasses chiefly used in England are made of the ashes of horn; crystal glasses being less frequent in use. The exceeding brittleness of this commodity, notwithstanding the caly rate of each glass, renders the consumptio thereof very considerable. For the method of gliding the edges of drinking-glasses, see Gilding on Enamel and Glass.

Glasses, Metallic, in Chemistry, are the oxides, or sometimes the sulphuretted oxides of the different metals, vitrified by heat.

Glasses, Optic, are three made use of to strengthen, improve, or preserve the sight. See Optic Glasses.

Glasscones. See Convexity.

Glasscones, Concave. See Concave.

GLASSHATTEN, or GLASHITTEN, in Geography, a
town of Hungary, celebrated for its hot-baths, and having
near it some rich gold mines; 7 miles from Schenmitz.
GLASS-HOUSE, Bay, a bay on the E. coast of New
Holland, between cape Moreton, and the Ghafu-houses,
which are three hills, so called by captain Cook in 1779,
for 38° 8' 48" S.
GLASSHUTTEN, a town of Saxony, near which is a
silver mine; 8 miles S. of Dresden.
GLASSIUS, Solomon, in Biography, was born in the
year 1593, and it is supposed he was educated at Jena,
where he was admitted to the degree of doctor of divinity,
and for some time filled the theological chair with distinc-
tious reputation. He was appointed superintendent of
the churches and schools in the diocese of Sax-Gotha, and
exercised the duties of his function with prudence, equity,
and impartiality. He died at Gotha in 1596, and left be-
hind him, as a memorial of his fame and learning, a work
published in quarto in 1623, entitled "Philologia Sacra,"
which is pronounced by Molinus an ineflaimable and immor-
tal work, than which none can be more useful for the inter-
pretation of Scripture, as it throws much light upon the
language and phraseology of the inspired writers. He was
author, likewise, of "Chromologia Meiae Propheciae,"
"Chroinologia Mosae et Davidica," "Exegetis Evange-
!icrum et Pelagii," and four other pieces.
GLASSNEVIN, in Geography, a village near Dublin,
In Ireland, remarkable for the very extensive and valuable
botanical garden belonging to the Dublin society. See
DUBLIN SOCIETY.
GLASSY HUMOUR. See Eye and VITREOUS.
GLASTONBURY, in Geography, a market town in
the hundred of Glaston, and county of Somerset, England,
is situated on the great road from Wells to Exeter. The
feite occupied by it was originally called Yewitiwyn, or
the Ghaf Island, and in Latin Avalonia.
A town is said to have been built here; and largely en-
dowed by king Ina about the year 768; in the next cen-
tury it was laid waste by the Danes, and rebuilt by king
Edmund, who granted it many additional privileges. In
1184 it was destroyed by fire, and was again restored by
the munificence of Henry II. The chief celebrity attac-
ted to the town was derived from its abbey; which, during
five centuries, flourished in authority and renown every
other in England, excepting that of Westminster. The
abbots enjoyed a plate of regal fulness, with an income
of nearly 40,000l. per annum, had the title of lords, and
fat with the barons in parliament. The abbey and its
offices occupied an area of land of nearly sixty acres within
the walls.
The late abbot, Richard Whitting, who was the sixteenth
in succession, refusing to surrender his abbey to king Henry
VIII., was, with two of his monks, drawn on a hurdle to
the Torr, near the town, and there hanged; the abbot's
head was set on the gate of the abbey, and his quarters
were sent to Bath, Wells, Bridgewater, and Ichbeler.
It being traditionally recorded, that this was the burial
place of king Arthur, Henry II. ordered a search to be
made, when a leaden crosier was discovered with a Latin in-
scription in rude characters, thus translated: "Here lies
the famous king Arthur, buried in the isle of Avalon." Beneath was found a coffin hollowed out of the solid rock,
wherein were the bones of a human body, suppos'd to be
those of Arthur: which were then deposited in the church
under a monument. Scarcely any vestige remains of these
extensive buildings, except some ruins of the church, part
of a chapel dedicated to Joseph of Arimathea, and the
abbots' kitchen, which seems to be of a more recent struc-
ture than the other offices.
Among the religious relics with which the town and its
environs abound, the most conspicuous is the Torr, or
St. Michael's Tower (on which abbot Whitting was ex-
cuted,) standing on an eminence east of the town, where
was formerly a small oratory, dedicated to St. Michael the
archangel.
The town of Glastonbury consists of two principal streets,
and is divided into two parishes, St. John's and St. Bene-
dict's. It was formerly a parliamentary borough, but was
disfranchised on the confiscation of the abbey in 1539.
A charter of incorporation was granted by queen Anne,
by which the civil government was vested in a mayor, a jus-
tice, eight aldermen, and sixteen burgesses. The principal
buildings are the two parih churches, two meeting-houses,
two almshouses, and a free school. The George, a respectable
inns, was an hospital for the accommodation of pilgrims
returning to the shrine of St. Joseph. In the centre of
the town was formerly a large stone cros, originally appro-
piated to shelter persons who attended the market. It
was taken down about five years ago: but a plate and
description are preserved in the first volume of the Archi-
etical Antiquities of Great Britain. Glastonbury is 130
miles distant from London; has a market on Tuesdays, and
four annual fairs: the population, in 1821, was 410
houses, and 2255 inhabitants, of whom only 124 were
employed in trade, which is chiefly that of manufacturing
wrought lookings.
South-west of the town is Wearall hall, so called from a
tradition that St. Joseph and his companions, weary with
their journey, rolled here; and that St. Joseph flung his
hawthorn staff in the earth; it took root, and constantly
budded on Christmas day. This famous thorn had two
trunks, of which one was destroyed in queen Elizabeth's
reign; the other in the great rebellion; but there are trees,
originally from the old flock, still growing in the gardens
of Glastonbury, and in various other parts of the king-
dom. Collinson's Hill, Somersetshire, 3 vols. 4to. Maton's
Western Counties, 2 vols. 8vo.
GLASTONBURY, a township of America, in the county
of Hampden, and part of Vermont; having only 48 in-
habitants.—Also, a handsome little town in Hartford county,
Connecticut, situated on the E. side of Connecticut river,
opposite to Westerfield; containing 2718 inhabitants.
GLASTONBURY TOWN, in Botany. See VITREOUS.
GLASTUM, from the German word Glas, an old name
for Wood; (see ISATEN) Hence several plants have the
specific name of glasiafida, on account of the similarity of
their leaves to that herb.
GLA

GLATT, in Geography, a river of Germany, which runs into the Neckar, 2 miles N. from Sultz in Wurttemberg.

GLATZ, or Glatten, a town of Germany, in the county of Panser; 4 miles E. of Dornfetten.

GLAV, a river of Switzerland, which runs into the Rhone; 2 miles below Eglisau.

GLATITEN, a mountain of Switzerland; 10 miles S. S. W. of Glarus.

GLATZ, a principality of Silesia, bordering on Bohemia, and surrounded by mountains. The internal territory is mountainous, intersected with vallies, meadows, corn-fields, woodlands and small rivers. It produces wheat, generally sufficient for its inhabitants, and has pasture for a great number of cattle. It contains quarries of mill-stones, freestone, and marble; as well as a great variety of precious stones. It has also mines of coal, copper, and silver; with several mineral springs. From 1561 to 1742, Glatz was annexed to the crown of Bohemia; in 1742 it was ceded by the empires Maria Theresa to Frederick II. king of Prussia, and his heirs. It forms one circle, divided into six districts.

GLATZ, the capital of the principality above-mentioned, is situated on the Neisse, and built on the site of a mountain, having upon its summit a strong castle. The town contains about 400 houses within the walls, and as many in four suburbs. It is a place of considerable trade. It has been frequently pillaged and burnt; 54 miles E. of Breslau. N. lat. 50° 16'. E. long. 16° 26'.

GLATZ, a mountain of Austria; 12 miles S. of Steyr.

GLAVACIA, a town of Walachia; 35 miles W. of Bucharest.

GLAUBER, John Rudolph, in Biography, a celebrated chemist of Amsterdam, who was esteemed the Paracelsus of his age, was born in Germany in the beginning of the sixteenth century. He travelled much in the pursuit of chemical knowledge, and collected many secret processes; and his experiments contributed to throw much light on the composition and analysis of the metals, inflammable substances, and salts. In fact he paved the greater part of his life in the laboratory. He did not always see the proper application of his own experiments, and vainly fancied that he had discovered the panacea, and the philosopher's stone, which were at that time objects of pursuit; and the disappointment of many persons, who had been induced by his promises, contributed to bring the art of chemistry into contempt. His theory is full of obscurity; but his practice has perhaps been misrepresented by those who listened to his vain and pompous pretensions; and who accuse him of a dishonourable trafficking, in first selling his secrets to chemists at an enormous price, of again dispossessing them to other persons, and lastly, of making them public in order to extend his reputation. Glauber published about twenty treatises; in some of which he appears in the character of physician, in others in that of an adept or metallurgist; in the latter he most particularly excelled. However, it would be unjust not to give the praise of acuteness of mind, of facility and address in the prosecution of his experiments, and of extensive chemical knowledge. He was the inventor of a falt, which to this day retains his name in the shops of our apothecaries. The works of Glauber have appeared in different languages; the majority of editions are in German, some in Latin, and others in French. A collection of the whole in Latin was published at Frankfurt in 1658, in 8vo, and again 1659 in 4to. An English translation was published by Christopher Park, London, 1689, in folio. Eley. Dict. Hist.

GLAUBER SALT, native or natural, in Mineralogy, the sulphate of soda of chemists, was discovered by Baron Born in the salt mines of Upper Austria; after which Moenne, Volta, Suckow, Gruenberg, Breitkau, Pallas, and others have added to the list of the localities of this saline substance, which is more frequently found in a native state than has been supposed by some writers. It generally occurs as mealy efflorescence; sometimes massive, seldom tabular or crystallized; in which latter case the crystals are described as acicular and as fixed-framed prisms, more or less flatly acuminiated by three planes, set on the lateral edges, or sometimes on the lateral planes: they are shining: their internal lustre is vitreous. Fracture of the crystals small conchoidal. It varies from transparent to opaque according to its cleavage. It is brittle. Its taste is a mixture of salt and bitter. Besides in the above forms, it occurs also, and most frequently, diffused in certain mineral waters, in the neighbourhood of salt mines and salt lakes, where also the efflorescence is mostly found on morrhain ground, found stone, marble slate, and new walls. For the chemical character of this salt, see Soda, Sulphate of.

Glauber's Salt, in Chemistry and Materia Medica. See Sulphate of Soda.

Glauber's Spirit of Marine Salt. See Muratic Acid.

Glauber's Spirit of Nitre. See Nitre Acid.

Glauberite, a lately discovered mineral, belonging to the class of salts, and of which M. Bronniart has given the description and analysis. This substance (called glauberite by its discoverer, both in honour of the well-known Glauber, and on account of its containing a considerable quantity of the salt which bears the name of that alchimist) was found among pieces of rock-falt brought from Grecua in New Cadle, in crystals resembling those of thumelone, or astatite. They were (chiefly on account of their mode of occurring) mistaken in Spain for gypsums.

The form of these secondary crystals, is that of an oblique very
very short prism with rhomboidal base. The planes of the base are generally smooth and shining; the lateral planes flattened parallel to the edges of the base. Cleavage double, the one parallel to the bases, the other less distinct and parallel to the edges of the base; in all other directions the fracture is vitreous. Hence the primitive form is an oblique prism with rhombohedral base, the obtuse angles of which correspond with the obtuse angles of the secondary prism. The crys- tals are from topaz yellow to nearly colourless; they are transparent, and, provided they are kept dry, preserve their transparency and insolubility when exposed to the air. Their hardness surpasses that of sulphur, but is inferior to that of carbon of lime.

Exposed to an intense heat, the glauberite decrepitates and melts into a white enamel. Immerred in water, its surface is covered by a milk-white crust, which penetrates deeper and deeper, till the whole crystal is white and opaque throughout; taken out of the water and dried, the white crust crumbles into dust, leaving the nucleus, if there be any remaining, unaltered and perfectly transparent. Specific gravity about 2.73.

From M. Brongniart’s experiments it appears, that glauberite is essentially composed of anhydrous sulphate of lime and of sulphate of soda, equally anhydrous. That these two salts exist in this substance nearly in the following proportions:

<table>
<thead>
<tr>
<th>Substance</th>
<th>Proportion</th>
</tr>
</thead>
<tbody>
<tr>
<td>Anhydrous sulphate of lime</td>
<td>0.49</td>
</tr>
<tr>
<td>Anhydrous sulphate of soda</td>
<td>0.51</td>
</tr>
</tbody>
</table>

A trace of water, indicated by the calcination, is not brought into account, as little as the accidental admixture of a scarcely perceptible quantity of iron, to which the yellowish colour of this substance appears to be owing.

Mr. B. adds the following observations: the above-mentioned pieces of salt from Ocan, which contain this substance, have generally some clay adhering, which penetrates into the [frz] of the surfaces, but seldom into the substance of the glauberite.

The effervescence on glauberite, when moistened, and the property this salt possess of becoming opaque in water, proceed from this, that the water, by dissolving the sulphate of soda, transforms the sulphate of lime into a foppy sulphate, and thus produces a phenomenon which is the reverse of that exhibited by the hydrophane.

The existence of native sulphate of soda, or Glauber salt, is well known to mineralogists, and, indeed, it has been met with in the neighbourhoods of rock-salt; but this was only as solution in the water of salt-furrows, or as effervescence near salt-mines: in a solid and crystallized state, entirely destitute of water of crystallization, and intimately united with feldspar, it had never before been observed. Even the anhydrous sulphate of soda was almost entirely unknown, till Berthier proved that it constitutes nearly the fifth part of those hard scales found at the bottom of the pans in which the sea-salt is obtained by evaporation.

It remains to be ascertained, under which circumstances the rock-salt occurs which contains the glauberite, and particularly in what relation this latter flatters to it, and whether it occur in the rents or on the surface of the beds. See Journal des Mines for 1808.

Hairy places the glauberite separately at the end of the substances acidifires; and it appears to this mineralogist, that the integral molecules of the two salts of which it is composed exist together in the glauberite. He refers, for an analogous combination, to Leblanc’s experiments, according to which a solution of sulphate of copper and sulphate of iron mixed, yielded crystals composed of these two substances, while their primitive form proved to be that of the latter, which had impressed on this mixture the character of its particular crystallization. The question, therefore, is, whether the glauberite be in a similar case. Its form has, indeed, nothing in common with that of the anhydrous sulphate of lime; but we are totally unacquainted with the crystalline form of the anhydrous sulphate of soda. But even if it should be found that in this case the two molecules combine in such a manner as to produce a third of a different form from either, this circumstance could, according to Hairy’s opinion, not be adduced as an objection against the theory of crystallization, and must be considered as a problem, the solution of which is more interesting to the chemist than to the mineralogist.

GLAUBOTTE, in Geography, a town of Prussia, in Natangen; 14 miles S.E. of Bartenstein.

GLAUCEDO, in Surgery. See GLAYCOS.

GLAUCHA, in Geography, a town of Saxony, in the lordship of Schönburg, on the Mulda, containing about 600 houses; the inhabitants are employed in the manufacture of tuffs: 46 miles W. of Dresden. N. lat. 50° 45’. E. long. 12° 25’.

GLAUCHE, a town of Germany, in the duchy of Magdeburg, adjoining to the town of Hale, but governed by its own magistrates; in which are four feitories, where the languages, theology, mathematics, music, &c. are taught by 120 preceptors.

GLAUCION, in Ornithology, a species of Anis, the grey-headed duck. See DUCK.

GLAUCUS, in Botany, is so named from its glaucous, or sea-green, colour. Whether the plant intended by Pliny as the Yellow Horned Poppy, according to the opinion generally received, or by maritime species of Eselthria, seems a point not easily determined. Dioscorides indicates that the juice of the first-mentioned in its wild state, though he compares it to its gomix xiriom, (which is evidently the Yellow Horned Poppy itself,) saying the plant which yields the gomix, and grows at Jerusalem, has almost the leaves of the gomix xiriom, but thicker, and spread on the ground, strong smelling, and more bitter, yielding plenty of taffron-coloured juice. Possibly this may refer to one of our other species of Glaucom, if not to the common wild lettuce. Most commentators have taken Argemone mexicana for the plant of Dioscorides; but that is a tropical production, unknown in Europe, as we premise, previous to the discovery of America, though now naturalized in the East Indies; see ECHTRUS. Neither does the above description suit this plant, for its leaves are much thinner than those of the Horned Poppy, and their juice pale yellow; nor are they spread on the ground. Matthioli seems to take the drug Gambege for gomix, but this does not at all help us, as to the botanical question, nor has it any probability in its favour—Tourn. Inv. 254. t. 150. Pl. 252. Exs. Pl. 252. Prod. Fl. Græc. v. t. 557. Linn. ins. 26. Germ. t. 155. (Chelidonium; Linn. Gen. 262. Spr. 270. Willd. see, Linn. Gen. 262. Illust. t. 550. t. 2. Mart. Mill. Dict. v. 2.)—Clas and order, Polyander Mamugna. Nat. Ord. Rhusacea. Linn. Papaveracea. Jussif.

Gen. Ch. Cal. Perianth inferior, of two ovate, concave, bluntish, deciduous leaves, often tipped with a point near the summit. Cor. Petals four, large, roundish, slightly concave, nearly equal, with a shining spot near the base. Stam. Filaments numerous, shorter than the corolla, flat, incurved, rather dilated upwards; anthers erect, roundish, of two lobes. Pist. Germen nearly cylindrical, curved, longer than the
the flamine; style none; stigma with two or three lobes, downy. *Papaver.* Pod linear, curved, very long, of two or three cells, and as many contain valves. Seeds numerous, globular, dotted. *Coronaria.* Annual, parallel to the valves, its surface cellular to receive the seeds.

Eff. Ch. Calyx of two leaves. Petals four. Pod superior, long, or two or three cells and two or three valves. Seeds numerous, dotted.

Obst. This genus is very naturally distinguished from *Chelidonium* by its habit, and essentially characterized by having more than one cell in its pod, and no criss to its seeds.

1. *G. luteum.* Yellow Horned-Papery. Scop. Carn. v. 1. 369. Geertn. v. 2. 216. (G. flore luteo; Tourn. Infl. 254.) Chelidonium luteum; Linn. Sp. pl. 724. Engl. Bot. t. 8. Papaver cornutum, flore luteo; Ger. em. 367.)—Stem smooth. Stem-leaves rounded, waved. Pods roughs with minute tubercles. Flowers glabrous.—Native of sandy sea-shores throughout Europe, flowering in summer and autumn. Root perennial, tap-rooted. Whole herb roughs and very glabrous. Stem three to four feet high, spreading, branched, leafy, smooth. Radial leaves numerous, entire, silky in a linear form; the red rounded, wavy or fan-shaped, alternate, leafless, clasping the stem. Flowers solitary, on axillary or terminal flanks, two inches broad, of a full flaming yellow. Their calyx is lypid and deciduous, and the petals last but one day. The pods are often near a foot long, cylindrical, but compressed.

2. *G. fulvum.* Orange Horned-Papery. Sm. Exot. Bot. v. 1. 15. 7. (G. glabrum, flore phlomeo; Tourn. Infl. 254.) Chelidonium cornutum; Donn. Cant. ed. 5. 131.)—Stem smooth. Stem-leaves rounded, waved. Pods rough. Flowers nearly glabrous.—Supposed to be a native of the south of Europe, but we know it as a garden plant only. This differs from the former in the rather more blue cast of its herbage, nearly or quite glabrous flowers, and smaller petals of a rich tawny orange-colour. We have thought the root annual, but we find it will survive a mild winter, about as well as the form species, which indeed is often killed, and never lives many years, at least in a garden. The *G. fulvum,* whether a distinct species or only a permanent variety, propagated by seed and root, its flowers, petals, and leaves, have a singularly elegant effect. Their petals fall, in hot weather, before noon, but in the autumn will endure till the next morning, or longer, which is also the case when they are gathered and placed in a room.
—If our quotation of Tournefort be right, our plant is figured in Lobel's *Icones* 271, f. 2, but not happily.

3. *G. rubrum.* Red Horned-Papery. Sm. Prodr. Fl. Grce. v. 1. 427. (G. orientale, flore magno rubro; Tourn. Cor. 18.)—Stem hairy. Stem-leaves pinnatifid, cut. Pod slightly hairy.—Gathered by Dr. Sibbthorp by the way with Smyrna and Burfa, as well as in the island of Rhodes. The root seems to be annual. Stems spreading, or nearly prostrate, clothed with soft expanded hairs. Stem leaves elongated, and deeply pinnatifid, by which in effect it differs from the preceding, as it does from the following in the soft hairs, instead of rigid bristles, which clothe the pods and stem. The flowers are glabrous, with oblong petals, narrower and flatter than in either of the form species, of a tawny red, with a violet spot on the claw. Lobel's *Papaver cornutum* plancenum alatum, L. 271, f. 1, agrees with this rather than with the last in its petals, and somewhat in its leaves; but if Tournefort be correct, it cannot be designed for the present species, which he gives in his *Corollia* as different from all he had previously enumerated, including Lobel's plant.

Vol. XVI.
are pendent from the base of the lower mandible on each side, and in texture resemble the wattle of the common cock; the colour at first blue, and afterwards orange. The irides are blue. From the forehead to the eye the colour is deep black; the other parts of the plumage dark ash-colour. The tail long, wedge-shaped, and composed of twelve feathers. Legs long, and the hind claw much longer than the rest.

This bird inhabits New Zealand, where it subsists on berries and insects, and is sometimes seen perched on trees, though rarely, as it is usually seen walking on the ground. Its note is a kind of whistling or rather murmuring noise; and the flesh savoury and delicate.

Glaucum, in Ancient Geography, a promontory of the Libyan name, on the confines of Marmarica and Egypt, upon which was a town of the same name. Prolemny.

Glaucus, a river of the Peloponnesus, in Achaea, near Patras. Paulinus—Alfo, a river of Aia Minor, in Lycia, having its mouth N. E. of the town of Telmissus, in the gulf of Glaucus. Alfo, a river of Asia, in the territory of Colchis, where it discharges itself into the Phasis. Pliny. Alfo, a gulf of Aia Minor, in a direction from N. W. to S. W. More anciently this gulf was denominated the gulf of Telmissus, from the name of the town, situated near its termination in the eastern part of it.

Glaucus, in Ichthyology, a species of Chetodon; which see. Alfo, a species of Scabar. Also, a species of Fucus, which see respectively.

Gen. Ch. Coll. none: unless the corolla be considered as such. Cor. of one petal, five-keeled, bell-shaped, erect, permanent, with oblong rounded lobes. Stam. Filaments five, awl-shaped, erect, one of the corolla; anthers roundish, yellow, German ovate; style uniform, as long as the filaments; stigma capitata. Peric. Capsule globose, pointed, of one cell, with five valves. Seeds five, roundish; receptacle very large, globose, hollowed for the seeds. Effl. Ch. Calyx of one leaf. Corolla none. Capsule of one cell, with five valves and five seeds.

1. G. maritima. Black Saltwort. Limn. Sp. Pl. 301. Engl. Bot. t. 13. This is the only species known, being very frequent in salt-marshes throughout Europe, and flowering in summer. The root is perennial and creeping. Stem about four inches high, erect, somewhat branched, thickly covered with ovate, fiddle-shaped, and fleshy-coloured, purplish, or whitish flowers. Dr. Withering has remarked that cows eat this herb, and that it is used for a pickle, being found everywhere from Lapland to the Archipelago. The description in Dioscorides, book 4. chap. 141. is so exact that it is impossible to be mistaken; yet we do not find this plant in the Pharmacopoeia Florae Germanicae, because Dr. Sibthorp did himself observe it in his journey.

Glaucic, in Geography, a small island in the English Channel, near the coast of France. N. lat. 47 26. W. long 2 56.

Glauser, an artificer or dealer in glazes.

Glausing. The Roman method of glazing some of their urns might give our workmen a hint toward a method greatly superior to any thing now in practice for the glazing of earthen-ware. There is a sort of red urns found in Yorkshire, which are, instead of glazing, covered all over inside and out with a fine coral-coloured varnish, that gives them a beauty, which no earthen-ware of our times can attain; and is not only far more durable than our way of doing it with lead, which is apt to crack and fly, both with wet and with heat, but far more safe and wholesome; and being well known to be a vapourable metal, and its fumes very noxious, there is great reason to suspect that it must be unwholesome when brought to the fire. This ancient glazing feems to have been done either by the brush, or else by dipping, for both the inside and outside are varnished with equal regularity; and something may be grieved at as to the materials they used in it, from what Pliny has left us. This author occasionally observes, that such earthen-ware as was painted with bitumen never loft its beauty; and afterwards, that it was a custom to cover over whole flutes with this sort of glazing, which he observs did not only make a smooth coat, but sunk into the wood-ckese not be likely to crack and fly off like our lead-ccots on plates, &c. which is merely a curl laid over them. Hook's Philos. Collect. p. 89.

A common glazing for any kind of earthen-ware may be made of white sand forty pounds, of red-lead twenty pounds, of pearl-ashes twenty pounds, and of common salt twelve pounds. Powder the sand by grinding it, and then add it to the other ingredients and grind them together: after which calcine them for some time with a moderate heat, and when the mixture is cold, pound it to powder; and when wanted for use, temper it with water. The proportion of these ingredients may be occasionally varied. We may observe, in general, that lead ought to be excluded from the composition of glazings, and other fluxes substituted in its stead. See Colica Damaniorum.

A transparent glazing may be prepared, without lead, by calcing forty pounds of white sand, twenty-five pounds of pearl-ashes, and fifteen pounds of common salt; and proceeding as before: and a more perfect transparent glazing may be made of sand forty pounds, of red-lead, perfectly burnt, fifty pounds, of pearl-ashes ten pounds, and of common salt twelve pounds. The following recipes are taken, for the most part, from Kuckeln, who says that they are the true glazings used at Delft, and other Dutch manufacturies.

Glausing. Black, is made of eight parts of red-lead, iron filings three, copper-ashes three, and zaffer two meafures. This, when melted, will make a brown black; and if you want it blacker, add more zaffer to it.

Glausing. Blue, is thus prepared: take lead-ashes, or red-lead, one pound, clear sand, or powdered flints, two pounds, common salt two pounds, white calcined tartar one pound, Venice or other glais half a pound, zaffer half a pound: mix them well together, and melt them for several times, quenching them always in cold water. If you would have it fine and good, it will be proper to put the mixture into a glaes furnace for a day or two.

Another blue glazing may be formed of one pound of tartar, a quarter of a pound of red-lead, half an ounce of zaffer, and a quarter of a pound of powdered flints, which are to be fused and managed as in the last recipe. Or, take two pounds of calcined lead and tin, add five pounds of common salt, five pounds of powdered flints, and of zaffer, tartar, and Venetian glais, each one pound. Calcine and fuse the mixture as before.

Or, again, take of red-lead one part, of sand three parts, and of zaffer one part. For a violet blue glazing, take four
ounces of tartar, two ounces of red-lead, five ounces of powdered flints, and half a dram of manganese.

Glazing, Brown, is made of red-lead and flints, of each fourteen parts, and of manganese two parts, fused: or, of red-lead twelve parts, and manganese one part, fused. A brown glazing, to be laid on a white ground, may be made of manganese two parts, and of red-lead and white glafs, of each one part, twice fused.

Glazing, Flints-coloured, is made of twelve parts of lead-ashes, and one of white glafs.

Glazing, Gold-coloured. To make gold-coloured glazing, take of litcharge three parts; of sand, or calcined flint, one part: pound, and mix these very well together: then run them into a yellow glafs with a strong fire. Pound this glafs, and grind it into a subtile powder, which moisten with a well saturated solution of silver; make it into a paste, which put into a crucible, and cover it with a cover. Give at first a gentle degree of fire; then increase it, and continue it till you have a glafs, which will be green. Pound this glafs again, and grind it to a fine powder; moisten this powder with some beer, so that by means of a hair pencil you may apply it upon the vessels, or any piece of earthen ware. The vessels that are painted or covered over with this glazing, must be first well heated, then put under a muffle; and as soon as the glafs runs, you must moisten them, by holding them over burning vegetables, and take out the vessels. Mr. Heinicus of Peterborough, who sent this receipt to the Royal Society, uses the words afflare debeb famum, which is rendered finok tham, in the Transactions. Phil. Trans. N 465. 6.

Kuncel gives several preparations for a gold-coloured yellow glazing. This may be produced by fusing a mixture of three parts of red-lead, two parts of antimony, and one part of fahion of Mars; by again melting the powdered mafs, and repeating the operation four times; or, by fusing four or five times a composition of red-lead and antimony, of each an ounce, and of scales of iron half an ounce; or by calcining and fusing together eight parts of red-lead, six parts of flints, one part of yellow ochre, one part of antimony, and one part of white gläs. A transparent gold-coloured glazing may be obtained by twice fusing red-lead and white-flints, of each twelve parts, and of filings of iron one part.

Glazing, Green, may be prepared of eight parts of litcharge, or red-lead, eight parts of Venice glafs, four parts of brafl-dufl, or filings of copper; or, of ten parts of litcharge, twelve of flints or pebble, and one of red-lead, or copper-ades.

A fine green glazing may be produced by using one part of the Bohemian granate, one part of filings of copper, one part of red-lead, and one part of Venetian gläs; or by fusing one part of white gläs, of the same quantity of red-lead, and also of filings of copper; powdering the mafs, and adding one part of Bohemian granate to two parts of this powder. A fine green may be obtained by mixing and grinding together any of the yellow glazings with equal quantities of the blue glazings; and all the shades and tints of green will be had by varying the proportion of the one to the other, and by the choice of the kind of yellow and blue.

Glazing, Iron-coloured, is prepared of fifteen parts of lead-ashes, or red-lead, fourteen of white sand, or flints, and five of calcined copper. This mixture is to be calcined and fused.

Glazing, Liver-coloured, is prepared of twelve parts of litcharge, eight of salt, fift of pebble or flint, and one of manganese.

Glazing, Purple-brown, consists of lead-ashes fifteen parts, clear-sand, or powdered flint, eighteen parts, manganese one part, and white glass fifteen measures; to which four add one measure of zaffer.

Glazing, Red, is made of antimony three pounds, litcharge, or red-lead, three, and ruff of iron, one; grind them to a fine powder. Or take two parts of antimony, three of red-lead, and one of calcined fahion of Mars, and proceed as before.

Glazing, Sea green, is made of five pounds of lead-ashes, one pound of tin-ash, three pounds of flint, three quarters of a pound of salt, half a pound of tartar, and half a pound of copper dust.

Glazing, White. A fine white glazing for earthen-ware is thus prepared: Take two pounds of lead, and one of tin; calcine them to ashes: of this take two parts, calcined flint, white sand, or broken white gläs, one part, and the other part: mix them well together, and melt them into a cake for use. The trouble of calcining the tin and lead may be prevented, by procuring them in a proper flate.

The white glazing for common ware is made of forty pounds of clear sand, fifty-five pounds of litcharge, or lead-ashes, twenty-five of pot-ashes, and ten pounds of salt: these are three times melted into a cake, quenching it each time in clear cold water. Or, it may be made of fifty pounds of common sand, seventy-five of lead-ashes, thirty of wood-ashes, and twelve of salt.

A very fine white glazing may be obtained by calcining two parts of lead, and one part of tin; and taking one part of this mass, and of flints and common salt, of each one part, and fusing the mixture. See Delf-ware.

A white glazing may be prepared by mixing one hundred pounds of multicol, fifty-five pounds of red-lead, twenty pounds of calcined tin or putty, and ten pounds of common salt; and calcining and powdering the mixture several times.

Glazing, Yellow, is prepared of red-lead, three pounds; calcined antimony and tin, of each two pounds; or, according to some, of equal quantities of the three ingredients. These must be melted into a cake, then ground fine; and this operation repeated several times: or, it may be made of fifteen parts of lead-ore, three parts of litcharge of silver, and fifteen parts of sand.

A fine yellow glazing may be procured by mixing five parts of red-lead, two parts of powdered brick, one part of sand, one part of the white glazings, and two parts of antimony, calcining the mixture and then fusing it. Or, take four parts of white gläs, one part of antimony, three parts of red-lead and one part of iron scales, and fuse the mixture; or, fuse sixteen parts of flints, one part of iron-filings, and twenty-four parts of litcharge. A light yellow glazing may be produced with ten parts of red-lead, three parts of antimony, and three of glass, and two parts of calcined tin. See Gold-coloured Glazing.

Glazing, Ciron-yellow, is made of six parts of red-lead, seven parts of fine red brick-dust, and two parts of antimony. This mixture must be calcined day and night for the space of four days, in the ah-hole of a glafs-house furnace, and at last urged to fusion.

Glazing of Delf-ware. See Delf-ware.

Glazing of Porcelain. See Porcelain.

Glazing of Stone-ware, and Queen's ware. See Porcelain.

Glazing for Tobacco Pipes. See Tobacco-pipes.

Glazing, in Painting, a term of the art, expressive of a peculiar mode or variety in the practice of it. It consists in laying a transparent colour, made very thin by a great quantity of oil, or other vehicle, over a field body of opaque colour.
GLAZING.

colour: and its intent is, to give a greater degree of clearness and brilliancy to the colour produced by this process, than can be obtained by mixing together in imitation the two colours thus employed. In this mode their hues are blended, without disparagement of each other; whereas, in mixing them in the ordinary way, a certain diminution of their brilliancy takes place, produced by the different nature of their qualities.

Glazing appears to have been practised very early in oil-painting; and probably the use of varnishes over pictures painted with water-colours may have first shown its utility. Indeed it could not fail to be the case, if the varnish employed happened to be tinged with any colour; for the latter pictures acquired by that circumstance must be strikingly engaging: a harmony and sweetness are thereby gained, which all other means are vainly employed to obtain. It is therefore surprising that all those who practised the art of painting after the discovery of the use of oil, should not have given it to the application of it. Yet it is certain that the Roman school is remarkably deficient in the knowledge of the value of this practice, and most frequently neglected to use it; owing probably to the employment painting found in fresco. The Venetian and Dutch schools, on the other hand, employed it in perfection, and it is in their works that a knowledge of it may best be acquired.

The principal difficulty attending the use of glazing, is to avoid the too common application of it; as it does not suit the representations of all subjects, in its more immediate sense; though one general glaze over a picture, completed in its forms, will at all times benefit the work; if it happens not to be too low, or impudic, in its tones of colour.

All kinds of gems and polished substances, such as metals, filks, velvets, &c. are imperfectly wrought to effect, when it is not employed; and which, which is in nature compounded of a great variety of colours, is seldom quite perfect in its hue, when glazing is not employed to finish with. It is a species of it, produced by the yellow varnish being but partially removed from old pictures, which gives them their peculiar and brilliant luster. It is quite impossible to make any effect exactly like it with fresh colours, unless some artifice be used to furnish the effects of time; such as rubbing in dirt, and then partially removing it, &c. tricks which picture dealers are perfectly conversant with; and by which many an ingenious copy is passed off upon the unlearned amateur, to the enhchment of the dealer, and the future annoyance of the buyer, when time and improved information let him into the secret.

Glazing is the most valuable part of the practice of painting, when judiciously employed; as it produces clear broken tones of colour, which leave no reminiscence of the palette, but deceive the eye by the variety of hues, and dazzling effect of light, produced by one colour shining through another in different degrees of illumination; much more like the effects of natural objects, than the use of opaque colours can possibly produce. But then great dexterity and judgment are required to use it properly in so general a manner. A well-informed and scientific artist knows the tone which one colour glazed over another will produce; and without that knowledge, a dirty dulness may be the effect, instead of the cleaned required: and if not successul, it is always injurious; there is no medium in the application of it. If the under colour is not improved, it is soon to be wearied, and it will require repainting, to restore its original freshness. So that when a painter has prepared a work for glazing, which should always be done with great clearness and precision, the most extreme caution is requisite in adapting the tone of the glaze which he proposes to use to the general hue of the picture before he applies it. It is not possible to give rules more explicit on this matter; the indefinite subdivisions of hues which all colours are capable of, must for ever leave to the feeling and judgment of the artist their peculiar application. It is hardly necessary to trace that a glaze of red, over blue, will produce purple; of blue, over yellow, green; and of red, over yellow, orange; but it may aid the student in his practice, if he considers, that all the varieties of tone the original colours are capable of, will, when equally employed, produce a corresponding compound; and, of course, if his picture be of too red a hue, though of a light tone, a corresponding one of blue, or of yellow, will change it to the one he may require; and if he use the blue and yellow together as a green, it will produce a negative colour; totally destroying their red: but the varieties are too complicated and numerous to follow.

GLAZING of Glob. The process of glazing is used for all the flout fabrics of cotton goods, and sometimes for those of linen. It is a part of the general processes of finishing goods for the market, and which is carried on by those who are generally called cloth-hatters, or calender-men. The glazing is done by putting on the cloth a small quantity of white wax, such as that used in the manufacture of wax candles, and the glos is afterwards effected by the friction of any smooth body on the surface of the cloth. By the ordinary process the apparatus is very simple, consisting merely of a smooth table, a little inclined towards the operator, like a common writing desk, upon which the cloth to be glazed is spread smoothly, and drawn over, as occasion requires, from one end of the piece to the other. Above this is a lever, suspended from any convenient fixture to the roof, the lower end hanging in contact with the cloth, and by moving this backward and forward, the necessary friction is produced. The end of the lever next to, and in contact with the cloth, is faced with a smooth piece of flint or pebble, finely polished, and of a cylindrical form, the under surface of which is in contact with the cloth. This lever being drawn backward and forward by the operator's hands, the whole cloth is polished or glazed in succession, the joint at the top of the lever being fitted into a horizontal slider, which allows the polisher or flint to be moved from side to side of the cloth to the other. In this way of glazing, the whole is performed by the power of a man's arms and hands; and, from the position of his body being constantly inclined over the table, is found to be a very laborious and fatiguing operation. The great number of people necessarily employed by this operation, and the difficulty of getting large quantities of goods rapidly glazed to answer the demands of hurried shipments for exportation, suggested lately the idea of a more speedy and efficacious manner of performing the operation of glazing by an improvement and alteration in the construction of the common five-bowl calender. This improvement was planned and executed at the extensive works of the late Mr. John Miller of Glasgow, who furnished the inventor with the means of carrying his plan into effect, and upon a proof of its efficacy on trial, his majesty's royal letters patent for its exclusive use to the inventor or his assigns within Scotland were obtained in the usual form. Two or three machines were then constructed for his own works, to which, as far as we know, they are still confined; and these machines have given the most universal satisfaction to all who have had their goods glazed by them, while at the same time an immense reduction of labour has been effected by their use.

The patent glazing machine, like the common calender, consists of five bowls, or cylinders, four of which are of

wait
caft iron, smoothly turned, and finely polished on the surface, and the large or intermediate cylinder is generally of plateboard on an iron axis. In the common operation of smoothing by means of the calender, the velocity of the cylinders revolving upon their own axes, is in the ratio of their respective diameters, so that an equal quantity of superficies is constantly exposed of each. In the glazing-calender, or machine, it is only necessary that the motions of one of the cylinders should be so much accelerated as to produce the friction necessary to effect the glazing by rubbing against the other cylinders with which it is in contact, so as not to be liable to tear or otherwise injure the fabric. This motion is produced by means of wheels placed in the following manner: On the axis of the middle cylinder, A, a small hollow wheel of any convenient diameter and number of teeth. This wheel works into the fluid-wheel B, the number of whose teeth is not material to the speed, and whose diameter may be regulated so as to pitch well into the remaining wheels. The wheel is placed to revolve loosely on an iron flord, screwed into the framework of the machine. The fluid-wheel B gives motion to the second fluid-wheel C, and it continues the motion to the wheel D, which is fastened on the axis of the first iron cylinder. The upper cylinder works merely by friction, as in a common calender, and when the intermediate fluid-wheel B is removed by being taken off the fluid, the whole cylinders will revolve exactly as in the common machines, without producing any glazing effect. The simplicity of this machine, the regularity of the glofs which it gives, and the immense saving of labour, are powerful recommendations in its favour. The great quantity also which may be effectuated by it in a very limited time,renders it peculiarly adapted to meet the occasional exigencies of the exporter; and the additional advantage of its facility of adaptation to the purposes of the common calender, when glazing is not required, adds to its value and utility. Upon paying occasions, one of these engines, by being constantly employed night and day, will glaze from 600 to 800 pieces of cloth, of 28 yards each, weekly.

Those employed in the late Mr. Miller's works are driven by means of a steam engine, by which also various other kinds of machinery, adapted to the various operations of the business, are set in motion. Should any machinery of this description be constructed in works where there may be a general necessity of keeping them constantly employed for the purpose of glazing, it will be very necessary that care should be taken that the moving power, whether water, steam, or horsepower, should be ample; as it must be evident, even to those who are not practically conversant with the calculation of power and refititute, that this calender, when employed to glaze, must require considerably greater force to keep it in motion, than when the cylinders revolve in the ratios of their diameters, for the mere purpose of common calendering or smoothing.

We are not in possession of sufficient data to enable us to ascertain, with any tolerable precision, the quantum of reftitute made by the friction; nor are we aware that any accurate experiments have been made for that purpose: But it is evident that it must be very great in all cases. It is reasonable also to infer, that it may be considerably increased or diminished by the texture or fabric of the floff upon which the glazing operation is performed. Hence, if these machines be employed constantly in large works, and set in motion by the same power, which also drives machinery adapted to other purposes, care must be taken that the power be sufficient to effect all the various purposes to which it is applied. And should this be attempted, under the impression that the glazing might be performed by the same power as common calendering, a deficiency would be found, which must render it necessary to diaphragm part of the machinery, in order to give sufficient momentum to the rest. This is, perhaps, one of the most common, and at the same time, most ruinous errors into which the projectors of large works, who are not mechanics, are apt to fall. In the first instance, it is evident, that a large establishment should be set to work at the least possible expense, they too frequently calculate too hardly, and are then obliged either to abandon their whole scheme of a great lobs, to work it under serious and ruinous inconveniences, or to repair, at a triple expense, what they have left deficient at first.

GLAZOV, in Geography, a town of Russia, in the government of Viahs, on the Tchetcza; 95 miles S.E. of Viahs. N.lat. 58° 5'. E. long. 51°.

GLEAN, or GLADE, in Ornithology, a name used in the northern parts of the kingdom for the milvus, or kite. See FALCO MILVUS.

GLEAM is popularly used for a ray or beam of light. Among falcons, a hawk is said to glean when the calls or throws up flint from the goole.

GLEAN, in Geography, a river of England, which rises about four or five miles N. of Stamford in Lincolnshire, and runs into the estuary called the With, five miles N.E. of Spalding.

GLEANING, the act of gathering or picking up the ears of corn left behind, after the field has been reaped, and the crop carried home.

By the custom of some countries, particularly those of Meux and Ellamps, all farmers and others are forbidden, either by themselves or servants, to put any cattle into the fields, or prevent the gleaners in any manner whatever, for the space of twenty-four hours after the carrying off the corn; on penalty of confiscation, &c. It hath been said, that by the common law and custom of England the poor are allowed to cut and glean upon another's ground after the harvest, without being guilty of trespass. Gilb. Jo 253. Trials per pari, ch. 15. 538. This humane provision is to be borrowed from the Mosaic law. Levit. xix. 9, xxiii. 22. Deut. xxiv. 19, &c.

Gleaning is a practice that is little heard of in the more northern parts of the kingdom, but which prevails greatly in some of the southern districts. The custom is of great antiquity; and whether or not the poor have any legal right, in this country, to glean, except by the express permission of the farmer, it has however been so long functioned by its continuance, that it is but rarely interrupted or put a flop to by him.

In some places where it is carried on to excess, it would seem necessary for the farmers to make regulations in respect to it, that should not be broken through on any account whatever. If this be not the case, the abuse is frequently so great that they are much injured by it, "as the poor glean among the flaves, and too often from them," as is notorious to those who have attended to the practice. It has been thereforef suggested to make it a rule not to suffer a gleaner to enter a wheat field until it is wholly cleared of the crop, which would, in the end, prove a very beneficial regulation. It does not, however, upon the whole, appear that much benefit is derived to the poor from the custom, while it evidently leads to idleness, immorality, pilfering, and a host of other abuses.

GLEBA ALANA, a name by which some call the yellowish white tripod.

GLEBI, Additi. The rule of the patrimonage should be annexed to the glebe; i.e. they went with it, were sold with it, &c.

GLEBE,
GLEBE, Gleba, in Natural History, Chemistry, &c. a clod, or piece of stone or earth, frequently containing some metal or mineral.

The clods are carried to the forges to be washed, purified, and melted, &c.

Glebe, or Glebe-land, is properly used for church-land.

Glebe-land is most commonly used for land belonging to a parish-church, before the tithe.

Thus, Lindwood: "Glebe est terra in qua consinit dos ecclesea; generatit tamen furnitur pro foleo, vel pro terra culta." Though in the most general, and extensive use of the word, glebe is applicable to any land or ground belonging to any benefice, see, manor, inheritance, or the like.

If any parson, vicar, &c, hath caused any of his glebe lands to be manured and sowed at his own costs, with any corn or grain, the incumbents may devife all the profits and corn growing upon the said glebe by will. (Stat. 28 H. 8. cap. 11.) And if a parson fows his glebe and dies, the executors shall have the corn sowed by the tector. But if a glebe be in the hands of a tenant, and the parson dies after the levantee of the corn, and before the term is done; it is said, neither the parson's executors or his successor can claim the rent, but the tenant can retain it and allow the crop, unless there be a special covenant for the payment to the parson's executors proportionably, &c. Wood's Inl. 163.

GLEBEC, in Geography, a town of America, in the state of Virginia; 12 miles S.E. of Tappahannock.

GLEBOUS, in Rural Economy, a term sometimes provincially signifying the turf or grasy surface.

GLEBOW, in Geography, a town of the duchy of Courland; 18 miles S. of Wittau.

Gen. Ch. Cal. Perianth of one leaf, tubular, cylindrical, fringed, very small, permanent; its mouth having five sharp unequal teeth. Cor. of one petal, inserted in tube, solitary, compressed; upper lip erect, obtuse, lower lip spreading, larger than the upper one, oblong, three-cleft, its middle lobe larger, emarginate. Stam. Filaments four, under the upper lip, two of which are shorter; each pair of anthers forming themselves into a croos. Pfl. German four-cleft; style thread-shaped, bending under the upper lip; stigma cleft, acute. Peric. none; the calyx nourishing four, ovate feeds in its booms.

1. G. hederaea. Ground-ivy. Linn. Sp. Pl. 827. Engl. Bot. t. 853.—"Leaves kidney-shaped, crenate."—Found in woods and hedges, flowering in April and May. Root perennial, and creeping. Leaves on foot-flabs, dotted beneath with glandular points. Flowers axillary, about three to each leaf, pretty speckled with white and blue. Calyx dilated. Anthers white. Ground-ivy has been so long and so generally known, that it has obtained various apppellations, such as Al-hoo, Gill, Robin-wood-in-the-hedge, Cat's-foot, &c. Before the introduction of Hops its leaves seem to have been used for flavouring and clarifying ale. Gerard has enumerated a long train of "Vertues" supposed to be possessed by this plant; and when infused into tea or honey, it is still a favourite medicine with the common people for coughs. Many animals eat it, though it is said to injure

horses if taken too copiously. The specific character is now superseded, as two species enumerated in the first edition of the Species Plantarum are now referred to other genera.

GLECHOMA. Hederacea, growing wild, in the Materia Medica, is a well known plant, growing commonly under hedges and flowering in April. Ground-ivy has a peculiar strong smell; the leaves, according to Dr. Withering, boiling befet underneath with hollow dots, in which are glands secreting an essential oil, and above with little eminences, which do not secrete any odoriferous oil; for this surface, when rubbed, yields no peculiar scent, whereas the under surface affords a pleasant reviving scent. The taste is bitterish, and somewhat aromatic. This plant was formerly supposed to provide great medicinal powers, not discovered by later experience; accordingly it is omitted in the materia medica by the London college. Its qualities have been described by different authors, as pectoral, detergent, aperient, diuretic, tubercular, corrodorant, erithmic, &c. and it has been recommended for the cure of those diseases to which these powers seem to be most adapted, but chiefly in pulmonary and naphritic complaints. In obilinate coughs it is a favourite remedy with the patients, who, probably deriving benefit from it, pennit in its use. Ray, Mead, and some others, speak of its being usefully joined with fermenting ale; but Dr. Cullen observes, "it appears to me frivolous. In short, in many cases where I have seen it employed, I have had no evidence either of its diuretic or of its pectoral effects. In common with many others of the verticillate, it may be employed as an erithmic, and in that way cure a head-ache, but no otherways by any specific quality." It is usually taken in the way of infusion, or decoction, as tea. Woodville Med. Bot.

GLECHONITES, a name given by the ancient Physicists, to a sort of wine impregnated with penny-royal, much recommended in all obstructions. It takes its name from glebo a, the Greek name of penny-royal, or pulgum.

Female, on a separate plant, Cal. Perianth like the male, but of five leaves. Cor. Petals five, long, acute, rather spreading. Nectaries two, short, like abortive filaments. Pfl. German superior, broad, compressed, longer than the corolla; style short, reflexed; stigma thick, the length of the flky, to which it is longitudinally affixed, down the upper part. Peric. Legume very large, broad, compressed quite flat, divided by numerous transverse partitions, and filled with pulp. Seeds solitary, roundish, hard, and pollinised.

At the summit, generally, of the male spike is an unit flowers, with four calyx-leaves and as many petals, with a nectary and flaments like the male, but with a pistil, producing perfect fruit, as in the female. Hence Linnaeus referred this genus to his class Polygania, but if it remains there
there it must rather be on account of the difference of structure in its male and female flowers, than for their flight, sexual anomalies. Even for this difference of structure we should rather place it in Daciea. See Sm. Introd. to Botany, 479, 485.

Obs. This genus has considerable affinity with Ceratonia, especially in the fruit. We cannot apply the term amomcnum to its inflorescence, which is a spike.

Female, Calyx of five leaves. Petals five. Nectaries two. Pillar one. Legume.

Some flowers united, four-clad.

The species of Gladiolus are as yet a mafs of confusion. G. tricantbus, Linn. Sp. Pl. 1599, the original one, a native of North America, was cultivated by bishop Compton in 1709, and is a tall handsome tree, which bears our climate well, except being sometimes broken, like Roebus Pseudo-acaciis, by strong winds. It is remarkable for its large trilobed or compound spines, which grow on the trunk, to the length of six or eight inches, from a very tender half. The leaves are deciduous, bipinnate, large, confounding of innumerable elliptical, slightly toothed, nearly smooth leaflets, half an inch or near an inch long. Flowers greenish, in axillary spikes. Some leaves appear to be simply pinnate, but we know not whether this is a specific difference or not.

A very distinct species is cultivated with us by the name of G. ethamii, which Linnaeus also had at Upsal, but he does not seem to have described it. The spines are compound. Leaves simply and abruptly pinnate, of seven or eight pair of thin, squarish, unequal-sized, crenate leaflets, gradually larger upwards, the terminal pair being sometimes twice the dimensions of the next.

In Sloth gardens, belonging to the duke of Northumberland, is a tree of another species, of which we find no mention. Its leaves are simply pinnate like the lily, and the leaflets also gradually larger upwards, but they are crenate, elliptical, their sides very seldom unequal. The calyx leaves and petals are narrow, shorter, and blunter than in G. trianctbus. Of its spines we have no account, but the leaves and flowers were communicated to us by Mr. Hoy, in August 1796, as a Gladiolus not in the Hortus Kewensis, where, indeed, all that are known are made varieties of the trianctbus. From the new edition of this valuable work perhaps more information may be expected.

G. incarnata, first mentioned by Linnaeus in the second edition of Sp. Pl. 1599, seems to have been adopted without a specimen, from Plunket's t. 123. f. 3, to which is added Miller's t. 5, which latter represents a Mimosa, nor does any subsequent writer appear to know any thing of this species.

It would be a tedious and unprofitable task to attempt a determination of the synonyms of this genus, even if the species were defined. The latter is a desirable object, and worthy the attention of those who have perpetual access to the old botanic gardens about London, and can observe these trees at different periods of growth. It is necessary to determine whether the simply or doubly pinnated leaves mark a specific distinction; whether the spines vary according to the species of the tree; and whether the legume is, in any species, constantlyinglee-feedcd, or merely from accidented abortion. Travellers in America can scarcely be expected to throw any light on such botanical questions as these, though a careful observer, resident there, might render highly important services to botany, and to the most useful arts of life, by determining first the specific differences, and then the economical qualities, of all the American trees, among which the Gladiolus claim a distinguished place. The labours of a Lambam among the Pines, and a Michaux among the Oaks, are models for future enquirers.

Gleditsia, in Gardening, comprehends a plant of the deciduous tree or shrub kind; of which the species usually cultivated is the three-thorned acacia (G. trianctbus), which seldom rises higher than a shrub in this country.

There are several varieties with different numbers of spines, and with stronger and weaker spines.

Method of Culture—These trees are capable of being increased by sowing the seeds, which are obtained fresh from America, in a bed of light earth, in the early spring season, watering them occasionally when the scaven is dry. It is, however, a much more expeditious practice to few them in pots, and plunge them in a moderate hot-bed. The plants should be kept clean during the first summer after they appear, and in the succeeding winter be well protected from severe frosts, especially such as are in pots.

The young plants may, most of them, in the following spring, be removed and set out in nursery rows, at a foot or eighteen inches distant from each other, and eight or ten inches in the row. Such small plants as remain, may be put out in the same manner in the next autumn or springing.

The plants should continue in this situation till they have had two or three years growth, after which they may be transplanted into the situations in which they are to remain any time towards the latter part of the spring season.

These plants are found to succeed well in situations where the soils are of the more light deep kinds, and rather sheltered from the incommode of the atmosphere.

They are all very ornamental trees, and well adapted to large shrubberies, plantations, and pleasure grounds. When planted alone, on lawns, and large open spaces that are kept in short grass, they produce a fine appearance. They have, however, the disadvantage of putting forth their leaves at rather a late period.

Gleditsia, or the Sycamore, is a musical term derived by Skinner, Junius, Johnson, and all the etymologists, from Gledis, Saxon, glee, mirth, sport.

His merry men commanded he
To make him both game and glee.

Chaucer, Rim. S.* Ta'p. v. 126.

The term, we believe, is not to be found in music-books, or musical writers, before the middle of the 15th century. The first time it appears in the title of a collection of canons, rounds, and catches, is in a publication by John Playford, 1667, under the title of "Dialogues, Glesse, Ayres, and Ballades, of two, three, and four Voices." A glee in music implies nothing more in its original sense, in our printed music-books, than "a song of three or more parts, upon a gay or merry subject, in which all the voices begin and end together, singing the same words." When subjects of fugue or imitation occur, and the composition is more artificial than simple counterpoint, it is only a glee than a madrigal, which it might, with more propriety, be called, if the words are serious: for a serious glee feems aolecinium, and a direct contradiction in terms. The word glee, in Saxon, German, and English dictionaries, ancient and modern, implying mirth, merriment, and in Chaucer and other old authors, mafic itself.

Gleeb, in Surgery, commonly signifies the continuation of a thin discharge from the urethra, after the inflammatory symptoms of a clap have for some time ceased. However, the running which takes place from the urethra in cases of frictures, diseased prostate gland, &c. is also frequently called a gleeb. A mere glee, unattended with any other disease of the parts, is not accompanied with the remarkable pain.
GLEET.

pain and falling sensation in making water, which are produced by gonorrhrea. The latter affection may be considered as acute, while the gleet is quite of a chronic nature. It was one of the opinions of Mr. Hunter, that a gleet differed from a gonorrhrea, likewise, in not being infectious. It is well known that it was one of the doctrines of this eminent surgeon, that the poison of gonorrhrea, and that which is productive of lues venerea, are of the same quality, and that the different effects are owing to the different structure of the parts concerned in the two diseases. We need not here enter into an investigation of this part of the subject. All that we wish to observe is, that if Mr. Hunter means, when he states, that a gleet differs from a gonorrhrea in not being infectious, that a gleet is not capabie of communicating the general disease, no one can question the accuracy of the observation. But, on the contrary, if the assertion implies that the matter of a gleet, when applied to the pudenda: muliebris, will not bring on a pain in making water, a discharge, &c. then we differ from the opinion altogether. We have known a instance, in which a gentleman, who had had a gleet upon him for upwards of a year, and who, on one occasion, was not infectious, ventured to have connection with a young woman, of whole continency, with regard to other men, we ourselves entertain no doubt. However, there may be gleets of various kinds, and some of them may be infectious, and others not so. When, after a gonorrhrea, a thin discharge continues, for a long while, to take place from the urethra, the complaint may depend upon a weakness of the vessels, or, as Mr. Hunter expresses it, upon a habit of action, which the parts have contracted. When a gleet arises from a friability in the passage, or from a diseased of the prostate gland, the caufe must be referred to irritation, and the cure depends on the removal of the original complaint.

Gleets, which are the consequence of gonorrhrea, are often exceedingly difficult of cure, and what is very curious, it frequently happens, that, after they have relapsed every 3 or 4 of remedy, and after the patient has long given up the use of medicines and injections, a sudden cure spontaneously occurs. Many gleets undergo a temporary floppage under particular circumstances of treatment; and, instead of recurring, regularly return again. A vast number of gleets depend upon the presence of a friability in the urethra, and of course are not curable by injections. We have often thought that in all cafes of gleets, it should be the invariable custom of the surgeon to introduce a bougie, for the purpose of ascertaining whether there is any obtrusion in the passage; for, when the discharge depends upon a friability, the patient might make use of balsams, turpentine, and bougies, for years, and yet receive no benefit whatever. At all events, whenever a gleet relapses ordinary means, the state of the urethra and of the prostate gland ought to be examined.

See Prostate Gland, Diseafe of; and Stricture.

Mr. Hunter was of opinion, that the spontaneous appearance of a gleet, after a long relapse to every sort of medicine and application, very frequently depended upon accidental changes in the patient's constitution. It was another sentiment of this celebrated surgeon, that some gleets were connected with fevers. This idea is founded on the circumstance, that more gleets may be cured by febrifugous than any other kind of bathing. It is also supported by the fact, of sea water being sometimes an effectual means of cure, when employed as an injection.

We have always found fault with this plan of judging of the nature of diseases. If a disorder yields to mercury, practitioners are apt to decide immediately, that the complaint is venereal. If a malady, like a gleet, gives way to sea bathing, which benefits scrofulous complaints, such surgeons, as reason on Mr. Hunter's principles, will immediately lay down the cause as scrofulous. It is never remembered in this calculation, that mercury cures many diseases besides the venereal; and so does sea bathing many complaints besides those which are of a venereal nature.

Gleets have also been represented as always connected with a relaxed constitution, though we think we have seen the complaint in subjects, who were strong, robust, and young, with every appearance of general health, and whose state seemed to us a striking exception to the foregoing observation.

Gleets, as we have before stated, are often exceedingly difficult of removal. Sometimes, indeed, they may be got rid of with tolerable ease; but in other instances, they completely frustrate the art of surgery, and the patient, tired of the inefficacy of different remedies, relinquishes the trial of all. In light cafes, and occasionally in inveterate ones, a cure may be effected by exhibiting internally the balm of copina, the olyum terrichlorin, or the tincture of lettuce (see page 231). In other cases, the cure can be accomplished by these means, benefit is soon derived from their employment. For this reason, when they neither diminish, nor remove the gleet in the course of five or six days, Mr. Hunter made it a rule never to continue their use any longer, but have recourse at once to other methods. We have already remarked the great tendency of many gleets to return, after being for a time flopped by different modes of treatment. Hence practitioners should never discontinue the successful plan immediately the discharge ceases, but persist in its adoption for ten days or a fortnight, after all the symptoms have entirely gone off.

In relaxed habits, gleets are very likely to be cured by the cold bath, sea bathing, bark, and febifugous medicines. Cold bathing indeed often succeeds in every kind of constitution, when other methods are of no avail. We have known strong young men labouring under gleets, who could not get rid of them in any way in London; but who got well almost immediately on going to the sea side, and bathing there. There can be no doubt also, that some beneficial resolution in the fever arising from the change of air, might have a considerable share in the cure. We lately had under our care a gentleman with a gleet, which had lasted nine months, but disappeared all at once on the patient going for a short time to a part of the country which was not near the sea.

There are two principal kinds of injections in use for the cure of gleets, viz. allringent and irritating ones.

The allringent ones are, for the most part, such as the decoction of bark, and mixtures of zincum vitriolatum, alum, or acetate of lead. An injection of proper strength, containing cuprum vitriolatum, bals gallicus, and camphor, is also an exceedingly efficacious one.

The bell irritating injection which we know of, is that made by dissolving two grains of the hydrargyrum muriaticus in eight ounces of distilled water.

Bougies may also be considered as acting on the urethra as irritating applications, and hence they are occasionally recommended to be used for the cure of gleets. In general, common bougies are employed; but sometimes others, medicated with camphor or other volatile substances, are used.

In irritable constitutions, the latter kind of injection and the bougies may excite a good deal of irritation, pain, inflammation, &c. &c. so that some circumspection is necessary in the employment of such means. We may state, indeed, that no undertaking should ever be made to cure a gleet, by exciting irritation in the urethra with irritating injections, or bougies, before milder means have failed. We have found a weak
weak injection of the hydrargyrum muriatius more frequently successful than any other. One grain to six ounces of water is quite strong enough to begin with, and the strength may be gradually augmented, in proportion as the urethra appears capable of bearing it. The practitioner must not leave off the injection as soon as the discharge ceases; for if he does so, the gleet will generally recur. The plan should still be followed up for about a fortnight.

When gleet are to be cured by bougies, it is necessary to wear these instruments about a month or six weeks before any dependence can be put in the permanence of the cure.

Neither the surgeon nor the patient should be deterred from pursuing the trial of irritating injections or bougies, by the circumstance of their appearing to increase the discharge at first. This they always do.

Mr. Hunter thought that moderation and regularity in diet were conducive to the cure of gleet. So is a quiet kind of life in the generality of cases, but there are instances in which gleet seen to be benefited and cured by rough exercise on horseback.

A return or an increase of a gleet is very apt to be the consequence of intercourse with women, and the patient often thinks that he has received a fresh infection. Mr. Hunter thought that the case might be discriminated by the short time which intervenes between the connection and the reappearance of the discharge. Gleet are so often exceedingly obdurate, that the surgeon cannot be informed of too many modes and principles of cure. On this account we deem it right to mention that gleet seem to be curable on the principle of counter-irritation. Hunter has seen a gleet stop on the breaking out of two chances on the penis, and the discharge has been known to stop as soon as a blister was applied to the under part of the penis.

Gleets have likewise been cured by electricity.

Women are liable to gleet, and the disease being situated in less irritable parts, whatever injections are used, may be made stronger for male patients.

It is almost unnecessary to remark, that blains and turpentine, internally given, can have no specific effect on the parts affected in women, as they have on the urethra in men. Hence it would be absurd to prescribe such medicines for female patients.

GLEITZBERG, or Glitzberg, in Geography, a town of Germany, in the principality of Nauff Weilburg; eight miles N.E. of Wetzlar.

GLEICHAN, a county of Germany, in the principality of Gotha, divided between the princes of Gotha, Hohenlohe, Hatzfeld, and Schwartzburg, situated on the banks of the Ohr, between Erfurt and Gotha.

GLEICHEN, Frederic von, in Biography, was born in the year 1714. He was intended and educated for the profession of arms, and spent the early part of his life as an officer in the service of Bayreuth, and was distinguished by his attention to military discipline. He rose to the rank of lieutenant-colonel, and obtained the favour of the margrave. His honours did not fit easily upon him, hefigured for retirement, and in 1756 his wives were accomplished; he obtained a dismission from the service with a handsome pension, to which was afterwards added the rank of privy councillor. He now had leisure to distinguish himself as a philosopher, a naturalist, and a writer. His attention was accidentally excited to microscopic observations, and not satisfied with the instruments already in existence he constructed an universal microscope, with which he combined the solar microscope. His principal observations relate to seminal animalcula, and infusion animals: he would fit day after day at his glafs, and was always displeased if he experienced any interruption while engaged in his favourite pursuit. By daily practice he had acquired uncommon acuteness of sight, which was of the greatest advantage to him in his researches. Though he had an ardent attachment to science for the love of it, yet he deviated various economical plans, from which he expected to derive great emolument, but they were the schemes of a theorist, and did not prove of real advantage either to himself or the world. He died in June 1783, leaving behind him numerous works in natural history, as "Observations on the Parts of Fructification in Plants in Bloom, and on the Insects found in them?" "History of the Common House Fly." "Treatise on Fumal Animalcula and Infusion Animals." "Essay towards the History of the Trees of the Elm:" this insect, the aphid alni campeltrix, coit our author the labour of eight years; it is the cause of the bladders on the leaves of the elm-tree during the foring. Gen. Biog.

GLEICHENBERG, in Geography, a town of the duchy of Sireia; 10 miles N. of Racketburg.

GLEICHENBERGAN, or Gleich Berg, a town of Germany, in the county of Henneberg; four miles E. of Romhold.

GLEICHENIA, in Botany, named by the writer of this article in honour of Philip Frederick, Baron von Gleichan, author of a splendid microscopic work on the structure and physiology of the parts of fructification in several plants, published at Nuremberg, in folio, with coloured plates, in 1764. As the seeds of ferns were among the subjects to which Baron Gleichan paid great attention, a genus belonging to this curious tribe was judged peculiarly proper to commemorate him. Smith in Mem. de l'Acad. de Turin, 1785. 419. t. 9. f. 10. Tractis, 258. t. 1. f. 10. Swartz. Fil. 165. Brown. Prod. v. 1. 160. (Mertensia; Willden. in Act. Holm. ann. 1804. 165. t. 4. 5. Swartz. Fil. 163.)—Chas. and order, Cryptogamia Filices et. Annullae. Nat. Ord. Filices daffferae.

Eff. Ch. Capsules in a simple, concentric, orbicular feries; each feries constituting a round separate dot, on the back of the leaf. Cover none.

This genus was first founded on the Onoclea papyrioides of Linnaeus, an elegant and singular fern, native of the Cape of Good Hope. In this the capsules are usually three, rarely four together, half imbedded in the under side of the frond, and as each burr by a longitudinal fissure, they all together have exactly the appearance of a single capsule, of three cells, and three valves, the partitions seeming to originate from the centre of each valve. Traces of a joined ring appear on some of the valves only, and rather resemble the corrugations of those ferns termed "punctiforty annulated." Several other species, chiefly allied to the original one in habit and appearance, so as to be at first sight scarcely distinguishable from it, have been found in New Holland, and have been defined by Dr. Swartz and Mr. Brown. In these the capsules are not imbedded in the leaf, though each feries ends in a single depression. In G. dispersa of Brown there are only two together; in others three, four, or even five. These new discovered species evidence the propriety of Mr. Brown's measure, of reducing the Mertensia of Willdenow and Swartz to Gleichenia, as their fructifications exactly agree. Dicranopteris of Bernhardi does not in our opinion to well accord with them, having an irregular accumulation of stalked capsules in each dot, though its habit is precisely that of Mertensia. Mr. Brown, having examined these ferns alive, determines them to be furnished with a complete, flattened, transfervic, rarely oblique, ring.

This
The genus naturally divides itself into two sections. The original *Glechonum*, of which there are five species, have the ultimate branches of their repeatedly forked form pinnate, their leaflets or *pinnae* deeply pinnatifid, with short, triangular, or rounded segments, each segment bearing a single dot or series of capules. The *Menyanthes* have their ultimate branches deeply pinnatifid, the segments linear, with a row of numerous dots on each side of the midrib of each segment, especially at its lower half. Of these we are acquainted with five or six species, all natives of the East or West Indies, or of New Holland and its neighbourhood.

**Gleichenstein**, in Geography, a town and castle of Germany, in the territory of Eichsfeld; seven miles S.E. of Heiligenstadt.

**Gleinstollen**, a town of the duchy of Stiria; 14 miles S.E. of Voitsberg.

**Gleiss**, a town of Switzerland, in the Valais; 26 miles E. of Sion.

**Gleiwitz**, or **Gleiwitz**, a town of Silesia, in the principality of Oppeln; 20 miles N. E. of Ratibon. N. lat. 52° 17'. E. long. 18° 35'.

**Glen River**, is a river of Lincolnshire, which rises near Ropley, and pursues a course nearly S.S.E. to Braceborough, when, turning suddenly N. E., it passes to Kate's bridge and through the Fens, by Surfleet, to the sea at Fosdyke Wash; for the greater part of its course through the Fens this river is navigable for barges, a circumstance which was overlooked in compiling the alphabetical list of inland navigations in our article CANAL.

The small river or drain called the Bourne, which branches from the Glen and proceeds up to Bourne town, is also navigable for some distance upwards. The South Forty-foot navigable drain commences very near to this river, below the mouth of the Bourne, and proceeds by a circuitous route to Bolton. See South Forty-foot.

**Glenaa**, a mountain in the county of Kerry, Ireland.

**See Killarney**

**Glenan Islands**, a cluster of small islands in the Atlantic, near the coast of France. N. lat. 47° 43'. W. long. 3° 55'.

**Glenarm**, a poth town of the county of Antrim, Ireland, on the coast of it, adjoining which is Glenarm castle, the seat of the countes of Antrim. The town is pleasantly situated on the sea-shore, near the bay of the same name. It is 104 miles N. from Dublin, and 24 N. from Belfast.

**Glenavy**, a poth-town of the county of Antrim, Ireland, situated near the eastern border of Lough Neagh. It is 77 miles N. from Dublin on the road to Antrim.

**Glencoe**, a vale of Scotland, in the county of Argyyle, near Loch Leven, where, in the year 1691, the inhabitants were massacred contrary to the faith of a royal proclamation, 17 miles N. of Inveraray.

**Glenalough, Glennalought**, or **Glenaladach**, commonly called the Seven Churches, an interloping object to travellers in the county of Wicklow, Ireland, 22 miles S. from Dublin, and about seven or eight miles west from Rathdrum. Its name is derived, according to Mr. Ledwich, from its being situated in a valley with lakes, from *glen*, a valley, and *leab*, a lake. That this was the true origin of the name seems to be confirmed by Hoveden, who was chaplain to Henry II., and who calls it equivalently in Latin, *Episcopatus Birtagnensis*, the bishopric of the two lakes. Glenalough is surrounded on all sides, except to the east, by stupendous mountains, whose vall perpendicular height throws a gloom on the vale below, well suited to inspire religious dread. From these, many mountain-
other, confines the view up the river to the valley; at the end of which the great round tower, and the other ruins, appear to great advantage. As the new military road has made Glendalough easily accessible, it is frequently visited by travellers. Ledwich's Antiquities.

GLENE, 2, properly signifies the cavity or socket of the eye.

GLENE is more frequently used by anatomists for the shallow cavities of bones, into which some other bone is received and articulated.

By which it stands distinguished from 

GLENEGAD HEMP, in Geography, a cape of Ireland, in the peninsula of Inis Lwenum, county of Donegal. W. long. 7° 41' from Greenwich, N. lat. 55° 20'.

GLENGARRIFF, a harbour of Ireland, in the county of Cork, on the north-east part of Bantry-bay. The arbutus grows in this neighbourhood in great perfection.

GLENGARY, the name of a county in Upper Canada, bounded on the E. by the line which separates Upper from Lower Canada; on the S. by the river St. Lawrence; and on the W. by the township of Cornwall, running N. 42° W., until it intersects the Ottawa or Grand river, thence defending the said river till it meets the fore-mentioned separating line. Glengary county comprehends all the islands contiguous to it in the river St. Lawrence.

GLENCIZA, a river of the duchy of Warsaw, which runs into the Odra, near Koblen.

GLEKEN'S CANAL, the parliamentary name of an inland navigation, made since the year 1802, in Kirkcudbright county in Scotland. See CANAL.

GLENLUCE, a town of Scotland, in the county of Wigtown, which sprang from an abbey of Cistercians, founded in 1140, called "Vallis Lucis." It is situated at the northern extremity of a large bay to which it gives name; 18 miles W. of Wigtown. N. lat. 54° 58'. W. long. 4° 27'. The bay extends on the S. coast of Scotland from the Mull of Galloway to Burrowhead. N. lat. 54° 50'. W. long. 4° 50'.

GLENMORE, a small island on the W. coast of Scotland, at the mouth of Loch Snart. N. lat. 56° 38'.

GLENOID, in Anatomy, from γλωυς, the articular cavity of a bone, and όδος, form, a term applied to certain articular surfaces, particularly where the hollow is not deep.

GLERS, in Geography, a town of Germany, in the county of Tyrol; 21 miles W. of Bolzano.

GLESE, a river of Louisiana, which runs into the Mississippi, N. lat. 32° 15'. W. long. 90° 14'.

GLESUM, or GLESEM, in Natural History, a name given by many of the ancients to the common yellow amber or succinum. The word seems to have been originally German, and to have been adopted by the Romans in their conquests in that part of the world. They seem to have used the word in general for any transparent substance, and thence to have applied it to amber as a transparent stone. See GLASS.

GLETSCHERHORN, in Geography. See JUNGFRAU.

GLIANY, a town of Poland, in Galicia; 20 miles E. of Lemberg.

GLIANA, a town of Sweden, in Vell Bothnia; 25 miles W. N. W. of Tornoa.

GLIGVI, a town of Alia, in Dageltan; 90 miles N. of Trjeby.

GLIKEON, a town of European Turkey, in the province of Epyr; 26 miles W. of Artua.

GLIMES HOLT, one of the small Orkney islands, which affords pastures; 2 miles S. of Pomona, between that and Barry.

GLIMMER, or CAT-SILVER, in Mineralogy, according to Dr. Woodward, "Method of Fossils," p. 14, are names for Mica, which fce. Glith, splangles, daze, and silver, are other names by which the miners and quarrymen designate the flaking plates of this substance which they meet with dispersed in the earths and stones in their works. The late Mr. William Martin observes, "Outlines," p. 141, "Glimmer is frequently dispersed through the sand-stones and clay, forming vegetable petrifactions, but never constricts their whole flakiness." In Derbyshire, it is not uncommon to find nodules, or round mélts or mæiffs of mica, in thin and separate plates, in the firld, or millilomays grit, which fall out on exposure, and leave 'peric' holes, a circumstance which has, according to Mr. Farey, given rise to rock-basins or holes on the tops of large looke blocks of flake where the water flakes in many instances after rain, but not perpetually, as the vulgar opinion is. See ROCK-BASINS.

GLINA, in Geography, a river of Croatia, which runs into the Sava; 12 miles W. of Patrini.

GLINLOUGH, a lake of Ireland, in the northern part of the county of Leitrim, from which a small river flows to Sligo bay.

GLINNINO, a town of Ruflia, in the government of Novogorod, on the Mita; 12 miles S. E. of Borovitchi.

GLINSK, a town of Ruflia, in the government of Tchernigof, on the river Sula; 80 miles S. E. of Tchernigof.

GLINUS, in Botany, derives its name from γλυκός; or γλώγος, a word used by Theophrastus, and denoting a kind of maple, though we cannot trace any similitude between that tree and the little herbaceous plant, by which the name was applied by Loefling; but it was adopted by Linnaeus.

Gen. Ch. Cal. Periakus inferior, of five ovate, acute, concave leaves, coloured within, permanent, and downy. Cor. none; nectaries about five, resembling narrow petals, shorter than the calyx, and unequally two or three-cleft. Stam. Filaments about fifteen, awd-shaped, flat, as long as the calyx; anthers incumbent, oblong, comprefsed, two-lobed. Pyl. German of five fide; styles five, short; figmas simple. Peric. Capsule ovate, with five cells, five sides, and five valves. Seeds numerous, roundish, in a single row at the base of the valves, tubercled, each attached by a long thread-like flak.

1. G. lotoides. Linn. Sp. Pl. 663. Burm. Ind. 112. t. 36. f. 1. "Stem hairy. Leaves obovate." — Native of Spain, and found by Loweling in a gravelly soil near Talavera de Badajoz, also in a dried-up rivulet between Merida and Truxillo. Root annual. Stems procumbent, jointed, hairy. Leaves obovate, on foot-stalks. Flowers nearly in fide; crowded together, found virile on very short hairy flaks. A figure of this species is defined to appear in the Flora Grecia, t. 472, from a drawing made at Smyrna, and from which it appears that what Gartner considered as petals, are more probably nectaries, as not being external to the stamens; after all, they ought perhaps to be called

Y Y 2

barren
GLI

GLO

barren filaments. They seem, from the dried specimen, to be ranged alternately with the real lamins.

2. G. distichus, Willh. Sp. Pl. v. 2. 929. Pluk. Amal. 10. 1. 356. f. 6.—"Leaves round, hairy. Stem thrubby, proliferate. Leaflets of the calyx lanceolate."—Native of India. It feems dothful whether G. distichus be not merely a variety of lotsides; but as Willdenow fill keeps them separate, on the authority of a dried specimen, we have retained the species.

3. G. fitzefem. Willh. Sp. Pl. v. 2. 929. Vahl. Synb. 3. 64.—"Leaves obovate, plaited. Stem thrubby. Leaflets of the calyx ovate."—Native of inundated woods in Arabia Felix during the rainy season. The whole plant is hoary, from very thick hairs, which are longer than in G. lotsides. This species was first described by Vahl, from Forskål's specimen which we have examin'd. The puberulence is beautifully flabillated and very dense.

GLINUS, in Leechology, a name by which Bellomus and some other authors have call'd a small sea-fish, more commonly known by the name of the sacrumculus.

GLIS. In the common acception of the word, this only signifies the dormouse; but Linnaeus has used /gles in a larger sense: and, in the Systema Zoologiae, makes it the name of the fourth order of the mammallians, class of animals. The creatures of the class are, that they have only two fore-teeth in each jaw; they have no dentes canis, or dog-teeth, and the feet have toes, and are formed for leaping when they run. The animals of this class are the several species of the Hybri, Cavia, Cailor, Mus, Arctomys, Steuris, Myoxus, Dipus, Lepus, and Hyrax; which see respectively.

GLIS, a name given to several species of Myoxus; of Didelphis; of Mus; and of Arctomys; which see respectively.

GLIS Volum. See Vespertilo Spalma.

GLISCHROMICTHES, in Natural History, the name of a genus of compound earths. The word is derived from glis, touch, and -chromia, mixed. The bodies of this genus are loams composed of sand and a more vitrific clay, and are of a tough and firm texture.

The earths of this genus are used in making bricks, and on some other occasions; and are of several distinct species.

GLISSA, in Ophthalmology, the name of a sea-fish of the tunny kind, but of a perfectly smooth skin, and wholly free from scales. It usually grows to the length of two cubits, and the thickness of a man's body: it is of a very round body, and has very rough jaws, but no distinct teeth; its tail is forked, but not so arched or lunate as that of the tunny; it lives in deep water, and is a fish of very delicate taste. Gafner. De Pisc. p. 1158.

GLISSON, FRANCIS, in Biography, was born at Ramphall, in Dorsetshire, in the year 1591, and educated at Caen college, Cambridge, of which he became a fellow, and in 1627 was incorporated M.A. in Oxford. He then applied himself to the study of physic, in which faculty he took his degree of doctor at Cambridge, and in that university was made regius professor of physic, which office he held about 40 years. He settled in London for the practice of his profession, and was admitted a fellow of the College of Physicians in 1635. In 1639 he was chosen reader of anatomy in the college, and in that department acquired great reputation by his lectures "De Morbis Partium," which he was particularly requested by his colleagues to make public. During the civil wars he retired to Coleheffer, where he practised with great credit in those times of confusion, and was in the town at its memorable forge by the parliamentary forces in 1648. He was one of that small, but illustrious society, who instituted a weekly meeting in London about the year 1645, for the purpose of promoting inquiries into natural and experimental philosophy, which, after having removed to Oxford during the troubles, was augmented in London after the restoration, and became ultimately the Royal Society. He was afterwards several years president of the College of Physicians, and died in 1677, in the parish of St. Bride's, London, aged 80. Glisson left the following works: 1. "Tractatus de Rachitide, seu morbo puerili Rickets dicto," first published in 1650; it went through several editions abroad, and two translations into English the year after its publication, by Philip Armin, and Nicholas Culpepper. 2. "Anatomie Hepatis, &c." London, 1644; afterwards reprinted at Amsterdam and the Hague. This work contains a much more exact description of the liver than had before appeared. The capsule of the /vea portarum was supposed to be first discovered by him, and he has ever since borne his name; but Wallis and Pecquet had seen it a short time before, and he has only the merit of having first examined and described it with accuracy. Dr. Glisson's largest work is a metaphysical piece, viz. "Tractatus de Natura Substantia Energetica, feu de Vita Naturae, ejusque tribus primis Facultatibus," Lond. 1672, in 4to., a profound and laborious performance, in the very depth of the Aristotelian philosophy, with all its numerous divisions, and an extraordinary effort of the understanding in a man of an advanced age.—1. His last publication, "Tractatus de Ventriculo et Intellinii, cui praemittitur alius de partibus continentibus in genere, et in specie, de eius Abdominis," Lond. 1676, 4to., Amst. 1677, 12mo., contains every thing at that time known concerning the alimentary canal, arranged in a clear manner, with various new observations. In a word, Glisson was exceeded in judgment and accuracy by none of that group of English anatomists, who followed the steps of Harvey with great arbour and industry; infomuch that Boerhave terms him "omium anatomicorum excellissimum," and Haller speaks in prose of all his writings. Akin Bied. Mem. of Med. Ely. Diot. Hist.

GLISTER. See CLUSTER.

GLITNESS, in Geography, one of the smaller Shetland islands, on the E. coast of Shetland; 11 miles N. of Lerwick. N. lat. 62° 22'. W. long. 1° 16'.

GLIUBEN, a town of European Turkey, in Dalmatia; 18 miles S.E. of Mollax.

GLIZEADE, in Fencing, is an operation performed by dextrously making your blade slip along that of your adversary by a movement of the wrist, and a quick forward extension of the arm, without deviating from the line of direction. This is a simple, and at the same time a most easy movement in fencing.

GLIODE, in Botany, a Malay name adopted by Rumplins and Linnaeus, under which, however, they have included a very heterogeneous assemblage of species. We shall speak only of such as agree in generic character with the original one, seen and described by Linnaeus, and preferred in his herbarium. Linn. Nat. 2. 142. Schreb. 25. Willd. Sp. Pl. v. 1. 153. Mart. Mill. Dict. v. 2. Rolfe in Tr. of Linn. Soc. v. 8. 355. t. 1. 20. f. 1. 3. Hort. Kew. ed. 2. v. 1. 9. Jiff. 63. Lamarck Dict. v. 2. 729.—Cladis and order, Monandria Monogyyna. Nat. Ord. Schimae, Linn. Cana, Jiff.

Gen. Ch. Col. Perianth superior, of one leaf, tubular, permanent; its border three-lobed. Cor. of one petal; tube long, cylindrical, slender; outer limb in three, nearly equal, ovate, spreading lobes; inner of two similar lobes, and a central,
central, vertical, prominent lip, cloven at each extremity. Stam. Filament one, prominent, long, linear, channelled, dilated at its summit; anther oblong, of two distinct parallel lobes, attached by its back to the dilated part of the filament. Pist. Germen inferior, roundish; style thread-shaped, the length of the filament and embraced by it; stigma obtuse. Pet. Capsule roundish, of three cells and three valves. Seeds numerous.

Eff. Ch. Anther in two parts. Filament elongated, incurved, bearing a lobed appendage. Style thread-shaped, embraced by the anther. Corolla with three outer lobes and three inner, the middlemost vertical and cloven.

1. G. marantina. Linn. Mant. 2. 170. Sm. Exot. Bot. v. 2. 85, t. 103. (Colebrookia bulbifera; Donn Cant. 1.)—Appendage of the filament four-lobed, divaricated, terminal. Spike not taller than the leaves. Bracteas elliptical, broad, longer than the calyx.—Native of Bengal, from whence it was sent by Dr. Roxburgh to the late lady Amelia Hume in 1800. It flowers in the flave in July and August. Root perennial, tuberous. Stems several, herbaceous, about two feet high, simple, leafy. Leaves elliptical, acute, entire, with one rib and numerous parallel fimple veins; smooth above; soft and finely downy beneath; their footstalks long, sheathing, bearded at the top, which is extended upwards into a pair of rounded auricles. Spike terminal, solitary, fimple, erect, more or less lax, about as tall as the leaves, or rather under that height. Bracteas alternate, fesse, elliptical, broad, concave, many-ribbed, somewhat downy, minutely dotted; the lower ones each bearing one ovate bulb; the upper ones a cluster of several flowers, each of which is accompanied by its own smaller bractea. These flowers are very transient, fimbried, orange-coloured, with a deeper spot in the centre of the lip.

2. G. racemosa. Sm. Exot. Bot. v. 2. 115, t. 117. (Deodara; of the inhabitants of Nepal.)—Appendage of the filament arrow-shaped, narrower than the anther. Callus elongated, cylindrical. Bracteas shorter than the calyx, deciduous.—Gathered by Dr. F. Buchanan in the woods of Upper Nepal, flowering in June. Habit of the leaf, but taller, with larger more pointed leaves. The inflorescence is much more striking, and consists of a long terminal raceme of numerous orange-coloured flowers, which are twice the size of the former, and essentially distinguished from that by the arrow-shaped form of the appendage to their filament, which does not extend beyond the anther, except at its rounded termination.

3. G. vericolor. Sm. Exot. Bot. v. 2. 116, t. 117, a, b, c. (Hura Siamenium; Kenig in Retz. Obf. f. 3. 49.)—Appendage of the filament four-lobed, divaricated. Calyx somewhat corymbose. Bracteas shorter than the calyx. Lip towards the middle of the filament.—Found by Kenig plentifully in graily shady parts of the island called Young Ceylon, in the East Indies. The clughs of flowers is shorter and more corymbose than in G. racemosa, and the corolla is variegated with orange, white, and different shades of violet. The appendage of the filament nearly resembles that of G. marantina, but the situation of the lip, thurf, as it were, half way up the filament, above the other lobes of the corolla, is altogether peculiar. For this, however, we depend on a drawing made by Mr. Sidney Parkinson, and communicated by Sir Joseph Banks, of the accuracy of which we have no reason to doubt. Kenig mentions a more dwarf variety, found near the town of Malacca. Can this be what has lately been introduced into the flaves about London by Dr. Roxburgh, and which we have seen and examined at Sir Abraham Hume's, and at Meffra. Lee and Kennedy's, flowering in June 1810? It is figured in Curtis's Magazine, t. 1359, where Dr. Sims has, we think, justly made this pretty plant a new genus by the name of Manduca foliariia. It differs from Globia in having a radical, not terminal, inflorescence, which, as far as we know, is an infallible indication of a generic difference in this natural order, and therefore the flower affords, as was necessarily to be expected, clear essential characters of distinction, in the two long linear appendages to the lower part of the filamento, which supply the place of two of the inner segments of the corolla, while the lip, which makes the third, is not fimbri at its upper extremity. The large purple bracteas, and the branched flower-stalk, are also remarkable. S.

GLOBE, in Geometry, a round or spherical body, more usually called a sphere; which term.

The earth and water together are supposed to form a globe; hence called the terrestris globe.

The planets, both primary and secondary, are supposed, as well as our earth, to be solid globes.

The earth is, in a particular sense, called the globe, or globe of earth; though it is now well known that this is not its true figure. See Figure of the Earth.

GLOBE, Refllexion of a. See Resistance.

Globe is more particularly used for an artificial sphere of metal, platter, paper, or some other matter; on whose convex surface is drawn a map, or representation, either of the earth or heavens, with the several circles conceived thereon.

Gloves are of two kinds, terrestrial and celestial: each of very considerable use, the one in astronomy, and the other in geography, to perform many of the operations thereof in an easy, feasible manner, so as to be conceived without any knowledge of the mathematical grounds of those arts.

The fundamental parts, common to both globes, are an axis, representing that of the world, and a spherical shell or cover, which makes the body of the globe, on whose external surface the representation is drawn.

Gloves, we have observed, are made of divers materials, viz. silver, brass, paper, platter, &c. Those commonly used are of platter and paper; the construction whereof is as follows.

Globes, Construction of. A wooden axis is provided, somewhat less than the intended diameter of the globe; and into the extremes hereof two iron wires are driven for poles: this axis is to be the beam or baits of the whole structure.

On the axis are applied two spherical, or rather hemispherical caps, formed on a kind of wooden mould or block. These caps consist of pulpboard and paper, laid, one lay after another, on the mould, to the thickness of a crown piece; after which, having fixed to dry and embody, making an inclion along the middle, the two caps, thus parted, are flapped off the mould.

They remain now to be applied on the poles of the axis, as before they were on those of the mould; and to fix them in their new place, the two edges are fown together with packthread, &c.

The rudiments of the globe thus laid, they proceed to strengthen and make it smooth and regular. In order to this, the two poles are halped in a metaline semi-circle of the size intended: and a kind of platter, made of whiting, water, and glue, heated, melted, and incorporated together, is daubed all over the paper surface. In proportion as the platter is applied, the ball is turned round in the semicircle, the edge whereof pares off whatever is superfluous, and beyond the due dimension, leaving the rest adhering in places that are short of it.

After such application of platter, the ball stands to dry; which done, it is put again in the semi-circle, and fresh matter
GLOBE.

matter applied: thus they continue alternately to apply the composition, and dry it, till such time as the ball everywhere accurately touches the semi-circle; in which state it is perfectly smooth, regular, firm, &c.

The ball thus finished, it remains to paste the map or description thereon: in order to this, the map is projected in several gores or gulfs, all of which join accurately on the spherical surface, and together cover the whole ball. To direct the application of these gores, lines are drawn by a semi-circle on the surface of the ball, dividing it into a number of equal parts corresponding to those of the gores, and subdividing those again answerably to the lines and divisions of the gores.

The papers thus pasted on, there remains nothing but to colour and illuminate the globe, and to varnish it, the better to retain dull, moisture, &c.

The globe itself thus finished, they hang it in a brass meridian, with an hour circle and quadrant of altitude, and thus fit it into a wooden horizon.

Globes, Description of. The things common to both globes are either delineated on the surface, or added as appendages without it. Without the surface are, 1. The two poles whereon the globe is turned, representing those of the world. (See Pole.) 2. The brass meridian, which is divided into degrees, and parallels through the poles. 3. The wooden horizon, whose upper side represents the horizon, and is divided into several circles; the meridian whereof contains the twelve signs of the zodiac, subdivided into their degrees; the next the Julian; and the third the Gregorian calendar, without sides of all these, are drawn the points of the winds. 4. A brass quadrant of altitude, divided into 90 degrees, to be fastened on the meridian at the distance of 90 degrees from the horizon. 5. The hour-circles, divided into twelve hours, and fitted on the meridian, round the poles, which carry an index pointing to the hour. A mariner's compas is sometimes added on the bottom of the frame, and sometimes a semi-circle of position.

On the surface are delineated, 1. The equinoctial line, divided into 360 degrees, commencing from the vernal interfection. 2. The ecliptic, divided into twelve signs, and the zodiac subdivided into degrees. 3. The zodiac. 4. The two tropics. And, 5. The polar circles. All which fee under their proper articles.

What else belongs to globes, either as to construction or description, is different as the globe is either celestial or terrestrial.

Our common globes, though instructive instruments for explaining the first rudiments of geography and the spherical doctrine of astronomy, yet labour under several defects: as they do not shew how the phenomena, illustrated by them, arise from the motion of the earth, which is the principal thing beginners especially should have in view, and as they are only formed for the present age, and do not serve the purposes of chronology and history, which they might be made to do, if the poles, wherein they turn, were contrived to move in a circle round those of the ecliptic, according to its present obliquity.

Mr. John Senex, F. R. S., invented a contrivance for remedying these defects, by fixing the poles of the diurnal motion to two shoulders or arms of brass, at the distance of 23° 27' from the poles of the ecliptic. These shoulders are strongly fastened at the other end to an iron axis, which passes through the poles of the ecliptic, and is made to move round with a very slight motion; so that when it is adjusted to any point of the ecliptic, which the equator is made to intercept, the diurnal motion of the globe on its axis will not be able to disturb it. When it is to be adjusted for any time, past or future, one of the brass shoulders is brought under the meridian, and held fast to it with one hand, whilst the globe is turned about with the other, so that the point of the ecliptic, with which the equator is to intercept, may pass under 0 degree of the brass meridian: then holding a pencil to that point, and turning the globe about, it will describe the equator according to its position at the time required; and transferring the pencil to 23° 27', and 66° 33' on the brass meridian, the tropics and polar circles will be so described for the same time. By this contrivance, the celestial globe may be so adjusted, as to exhibit not only the rulings and settings of the stars, in all ages and in all latitudes, but likewise the other phenomena that depend upon the motion of the diurnal axis round the annual axis. Senex's celestial globes, especially the two greatest, of fourteen and twenty-eight inches in diameter, have been constructed on this principle: for that by means of a nut and screw, the pole of the equator is made to revolve about the pole of the ecliptic. Phil. Trans. N. S. 447. p. 201. 202. Or Martyn's Abr. vol. viii. p. 217, and N. 494. art. 18. in Phil. Trans. vol. lib. p. 396. Mr. Joseph Harris, late Surveyor of the mint, contrived to remedy the former of the defects above-mentioned, by placing two horary circles under the meridian, one at each pole; these circles are fixed tight between two brass collars placed about the axis, so that when the globe is turned, they are carried round with it, the meridian serving as an index to cut the horary divisions. The globe, in this state, serves readily for solving problems in north and south latitudes, and also in places near the equator; whereas, in the common construction, the axis and horary circle prevent the brass meridian from being moveable quite round in the horizon.

This globe is also adapted for shewing how the vicissitudes of day and night, and the alteration of their lengths, are really occasioned by the motion of the earth; for this purpose, he divides the brass meridian, at one of the poles, into months and days, according to the sun's declination, reckoning from the pole. Therefore, by bringing the day of the month to the horizon, and rectifying the globe according to the time of the day, the horizon will represent the circle separating light and darkness, and the upper half of the globe the illuminated hemisphere, the sun being in the zenith.

Mr. Harris also gives an account of a cheap machine for shewing how the annual motion of the earth in its orbit causes the change of the sun's declination, without the great expense of an orrery. Phil. Trans. N. S. 466. p. 321. &c. or Martyn's Abr. vol. viii. p. 352.

The late Mr. George Adams, mathematical instrument maker to his majesty, has made some useful improvements in the construction of the globes. His globes, like others, are suspended at their poles in a strong brass circle, and turn therein upon two iron pins, which are the axis. They have besides a thin brass semi-circle, moveable about the poles, with a small, thin, sliding circle upon it. On the terrestrial globe, the thin brass semi-circle is a moveable meridian, and its small sliding circle the visible horizon of any particular place to which it is set. On the celestial globe, the semi-circle is a moveable circle of declination, and its small annexed circle an artificial sun or planet. Each globe hath a brass wire circle, placed at the limits of the twilight, which, together with the globe, is set in a wooden frame, supported by a neat pillar and claw, with a magnetic needle at its base. On the terrestrial globe the division of the earth into land and water is laid down from the latest discoveries; there are also many additional circles, as well as the rhumbs-lines, for solving all the necessary geographical and nautical
nautical problems. On the celestial globe, all the southern constellations, lately observed at the Cape of Good Hope by M. de la Caille, and all the stars in Mr. Flamsteed's British Catalogue, are accurately laid down and marked with Greek and Roman letters of reference, in imitation of Bayer. Upon each side of the ecliptic are drawn eight parallel circles, at the distance of one degree from each other, including the zodiac; and these are crossed at right angles with segments of great circles at every fifth degree of the ecliptic, for the more readily noting the place of the moon, or of any planet upon the globe. The author has also inferred, from Ulugh Begh, printed at Oxford in 1665, the mansions of the Moon of the Arabian Astronomers, so called, because they observed the moon to be in or near one of these every night during her monthly course round the earth, to each of which the Arabian characters are fixed. On the strong brazen circle of the terrestrial globe, and about 23½ on each side of the north pole, the days of each month are laid down according to the sun's declination; and this brafs circle is so contrived, that the globe may be placed with the north and south poles in the plane of the horizon, and with the south pole elevated above it. The equator, on the surface of either globe, serves the purpose of the horary circle, by means of a semicircular wire placed in the plane of the equator, carrying two indices, one of which is occasionally to be used to point out the time. For a farther account of these globes, with the method of using them, the reader may consult Adams's Treatise on their Construction and Use, &c. 1769.

Globe, terrestrial, is a spherical figure, on whose convex surface the fixed stars are laid down, at proportionable distances, together with the principal circles of the sphere.

The surface of the celestial globe may be esteemed a just representation of the concave expanse of the heavens, notwithstanding its convexity; for if the eye were placed in the centre of it, and the globe made of glass, the stars that are drawn upon it would appear in a concave surface, exactly corresponding to those in the heavens. The use of these globes is to exhibit the phenomena of the motions of the sun and stars, in an easy and obvious manner; which, though somewhat inaccurate, is yet exact enough for the common uses of life, and may save the trouble of trigonometrical calculations.

To exhibit the stars, circles, &c., on the surface of a given sphere or ball, and fit for the use of astronomy—1. Assume any two points diametrically opposite to each other, as P and Q (Plate XIV. Astronomy, fig. 117.) and in these fix up axes, PA and QC, for the ball to turn round on. The points P and Q, or A and C, will exhibit the poles of the world.

2. Divide a brazen circle A B C D into four quadrants, A E, E C, C F, and F D; and subdivide each quadrant into 90 degrees, numbered from the points E and F, towards the poles A and C.

3. Inclose the globe in this circle, as in a meridian, at the points A and C, so as it may freely turn therein.

4. Apply a style or pin to the surface of the globe, in the first degree of the meridian, and turn the ball round; by this means will a circle be described on the surface, representing the equator to be divided into degrees.

5. From the pole of the world P towards M, and from the other pole C towards N, number 23½ degrees; the points M and N will be the poles of the ecliptic.

6. Apply a style to the meridian, in the point M, and turn the globe round; by this rotation will the arctic polar circle be described; and after the same manner is the antarctic polar to be described about the point N.

7. Number 23½ deg. from the equator towards the poles P and Q, and note the points H and I; then applying a style to the meridian, as before, two circles will be described parallel to the equator, whereof that drawn through H will be the tropic of Cancer, and the other through I the tropic of Capricorn.

8. Hang the globe within the meridian, in the poles of the ecliptic, as before in the poles of the world; and applying a style to E, turn it round: by this means will the ecliptic be delineated, which remains to be divided into twelve signs; and each of these, again, divided into thirty degrees.

9. While the globe remains thus suspended, bring the degree of longitude of any star under the meridian; and in the meridian, number as many degrees towards the pole as is the degree of latitude of the place; the point of intersecion is the place of that star on the surface of the globe. After the like manner may the place of the star be determined from the right ascension and declination given, the globe being supposed suspended from the poles of the world, or of the equator.

10. All the stars of a constellation thus laid down, the figure of the constellation is to be designed; after which it may either be coloured or engraven.

11. Place the globe with the meridian, in a wooden frame or horizon, D B L., supported on four feet, in such manner as to be divided thereby into two hemispheres, and that the pole A may be raised or depressed at pleasure.

12. On the limb or edge of the horizon describe a circle, which divide into 360 degrees, and infer the calendars and winds.

13. Lastly, To the pole A fit a brazen circle, divided into twenty-four horary parts, and numbered twelve, so that the line of division of XII. may be in the plane of the meridian, on either side the pole; and on the pole itself apply an index, to turn round with the globe. See Horary Circles. This is the globe complete.

It may be here observed, that as the longitude of the stars is continually increasing, a common globe does not remain of perpetual use; but the increase in seventy-two years only amounting to a degree, the globe will make no considerable error in a hundred years; the design of a globe being only to represent things something near the truth.

Globe, to make a celestial. This method is that most frequently used; and we only premised the former as being the most clearly conceived, and leading more naturally to this.

1. From the given diameter of the globe, find a right line A B, fig. 118, equal to the circumference of a great circle, and divide it into twelve equal parts.

2. Through the several points of division, 1, 2, 3, 4, &c., with the interval of ten of them, describe arches, mutually intersecting each other in D and E: these figures or planes, duly pained or joined together, will make the whole surface of the globe.

3. Divide each part of the right line A B into thirty equal parts, so that the whole line A B, representing the periphery of the equator, may be divided into 360 degrees.

4. From the poles D and E, fig. 119, with the interval of 23½ deg. describe arches a, b; there will be twelve parts of the polar circles.

5. After the like manner, from the same poles D and E, with the interval of 66¼ deg. reckoned from the equator, describe
describe arches $c, d$; there will be twelfth parts of the tropics.

6. Through the degree of the equator $r$, corresponding to the right ascension of any given star, and the poles $D$ and $E$, draw an arch of the circle, and taking in the complements of the declination from the pole $D$, describe an arch intersecting it in $i$; this point $i$ will be the place of that star.

7. All the stars of a constellation being thus laid down, the figure of the constellation is to be drawn according to Bayer, Hevelius, or Flamsteed.

8. Lastly, after the same manner are the declinations and right ascensions of each degree of the ecliptic $d g$ to be determined.

9. The surface of the globe thus projected on a plane is to be engraved on copper, to save the trouble of doing this over again for each globe.

10. A hall, in the mean time, is to be prepared of paper, platter, &c. after the manner above directed, and of the intended diameter of the globe: on this, by means of a semi-circle and style, is the equator to be drawn; and through every 30th degree a meridian. The ball thus divided into twelve parts, corresponding to the segments before projected, they are to be cut from the printed paper, and pasted on the ball.

11. Nothing more remains but to hang the globe, as before, in a brazen meridian and wooden horizon; to which may be added a quadrant of altitude $H I$, fig. 120, made of brass, and divided in the same manner as the ecliptic and equator.

If the declinations and right ascensions of the stars be not given, but their longitudes and latitudes in hemispheres, the surface of the globe is to be projected after the same manner as before: except that, in this case, $D$ and $E$, fig. 121, are the poles of the ecliptic, and $f b$ the ecliptic itself; and that the polar circles and tropics, with the equator $g d$, and the parallels thereof, are to be determined from their declinations.

One of the fullest catalogues of the stars is that of Mr. Flamsteed; wherein the right ascensions and declinations, as well as the longitudes, latitudes, &c. are everywhere expressed.

Globe, use of the celestial. The use of this instrument is very extensive; there being scarcely any thing in the spherical astronomy but may be exhibited thereby.

The principal points are contained in the following problems, with their solution; which will lead the reader enough into the nature and reason of this noble instrument, to apply it, of his own accord, in any other cases.

To find the right ascension and declination of a star, represented on the surface of the globe.—Bring the star to the graduated side of the brazen meridian; then the number of degrees intercepted between the equator, and the point on the meridian cut by the star, gives its declination; and the degree of the equator which comes under the meridian, together with the star, is its right ascension.

To find the longitude and latitude of a star.—Apply the centre of the quadrant of altitude over the pole of the ecliptic in the same hemisphere with the star, and bring its graduated edge to the star; the degree on the quadrant cut by the star is its latitude, reckoned from the ecliptic; and the degree of the ecliptic cut by the quadrant its longitude.

To find the sun's place in the ecliptic.—Seek the day of the month in the proper calendar on the horizon, and against the day in the circle of signs is the sign and degree the sun is in for that day; this done, find the same sign upon the ecliptic, on the surface of the globe; this is the sun's place for that day.

To find the declination of the sun.—The sun's place for the day given being brought to the meridian, the degrees of the meridian intercepted between the equinoctial and that place, are the sun's declination for that day at noon.

To find the place of a planet, with its right ascension and declination; its longitude and latitude for the time being given.—Apply the centre of the quadrant of altitude on the pole of the ecliptic (the pole, we mean, of the same denomination with the latitude), and bring it to the given longitude in the ecliptic: this point is the planet's place; and bringing it to the meridian, its right ascension and declination will be found, as already shewn of a star.

To rectify the globe, or adjust it to the place, &c. so as it may represent the present state or situation of the heavens.—1. If the place be in north latitude, raise the north pole above the horizon; if in south, raise the south pole; till the arch intercepted between the pole and horizon be equal to the given elevation of the pole. 2. Fix the quadrant of altitude on the zenith, $z$, on the latitude of the place. 3. By means of a compass or meridian line, place the globe in such a manner as that the brazen meridian may be in the plane of the terrestrial meridian. 4. Bring the degree of the ecliptic the sun is in to the meridian, and set the horary index to twelve; thus will the globe exhibit the face of the heavens for the noon of that day. 5. Turn the globe till the index come to any other given hour; thus will it shew the face of the heavens for that time.

To know all the stars and planets by means of the globe.—1. Adjust the globe to the place of the heavens for that time. 2. Look on the globe for some one star which you know, e. g. the middlemost star in the tail of the Great Bear. 3. Observe the positions of the other more conspicuous stars in the same constellation; and by transferring the eye from the globe to the heavens, you will easily note the star there. 4. After the same manner you may proceed from this to the neighbouring constellations, till you have learned them all.

If the planets be represented on the globe, after the manner above described, by comparing them with the neighbouring stars you will likewise know the planets.

To find the sun's oblique ascension, his eastern amplitude, and azimuth, with the time of rising.—1. Rectify the globe for the hour of twelve, and bring the sun's place to the eastern side of the horizon: then the number of degrees, intercepted between that degree of the equator now come to the horizon and the beginning of Aries, is the sun's oblique ascension. 2. The degrees on the horizon, intercepted between the east point thereof and the point wherein the sun is, is the ortive or rising amplitude. 3. The hour, pointed to by the index, is the time of the sun's rising. 4. Turning the globe till the index points to the present hour, lay the quadrant to the sun's place; the degree cut by the quadrant, in the horizon, is the sun's azimuth.

To find the sun's oblique ascension, western amplitude, and azimuth, with the time of setting.—The solution of this problem is the same as that of the former; excepting that the sun's place must be here brought to the western side of the horizon, as in the former it was to the eastern.

To find the length of day and night.—1. Find the time of the sun's rising, which being numbered from midnight, the double thereof gives the length of the night. 2. Subtract the length of the night from the whole day, or twenty
GLOBE.

To find the rising, setting and culminating of a star; its
continuance above the horizon for any place and day; to-
tgether with its oblique ascension and descension, and its easter
and western amplitude and azimuth.—1. Adjust the globe
to the state of the heavens at twelve o'clock that day.
2. Bring the star to the eastern side of the horizon; this
will give the western amplitude and azimuth, and time of
rising, be found, as already taught of the sun.
3. Bring the same star to the western side of the hori-
zon; thus will the western amplitude and azimuth, and the
time of setting, be found.
4. The time of rising, subtracted from that of setting, leaves the continuance
of the star above the horizon.
5. This continuance above the horizon, subtracted from twenty-four hours, leaves the time of its continuance below the horizon.
6. Lastly, the hour to which the index points, when the
star is brought to the meridian, gives the time of its cul-
imination.

To find the altitude of the sun, or star, for any given hour
of the day or night.—1. Adjust the globe to the position
of the heavens, and turn it till the index point at the
given hour. 2. Fix on the quadrant of altitude, at
90 degrees from the horizon, and bring it to the sun’s or
star’s place; the degrees of the quadrant, intercepted
between the horizon and the sun or star, is the altitude
required.

The altitude of the sun by day, or of a star by night, being
given, to find the time of that day or night.—1. Rectify the
globe as in the preceding problem. 2. Turn the globe
and quadrant, till such time as the star, or degree of the
ecliptic the sun is in, cut the quadrant in the given de-
gree of altitude; then does the index point at the hour
fought.

The azimuth of the sun or a star given, to find the time of
the day or night.—Rectify the globe, and bring the quad-
rant to the given azimuth in the horizon; then, turn the
globe, till the star come to the same; then will the index show
the time.

To find the interval of time between the risings of two stars,
or the culminations.—1. Raise the pole of the globe so
many degrees above the horizon, as is the elevation of
the pole of the place. 2. Bring the first star to the hori-
zon, and observe the time the index points to. 3. The
same do by the other star; then subtracting the former
time from the latter, the remainder is the interval between
the risings.

After the like manner is the interval between two cul-
iminations found, by bringing both stars to the meridian.

The day of the month being given, to find when any star will
come to the meridian.—Rectify for the sun’s place; turn the
globe till the given star comes to the meridian; then the
index will point to the time fought.

To find when any given star will come to the meridian, at
any given hour of the night.—Bring the given star to the meri-

dian; set the index to twelve above noon; then turn the
globe eastward, till the index points to an hour as far
distant in the forenoon from twelve as the given hour is
in the afternoon, observe the degree of the ecliptic then at the
meridian, over-against which degree, in the calendar, is the
day of the month, when the given star will be upon the
meridian at the given hour.

By observation of a star upon the meridian, to find the hour
of the night.—Rectify for the latitude and the sun’s place;
bring the given star to the meridian, and the index will
show the hour of the night.

Vol. XVI.

To find the beginning and ending of the twilight.—1. Rectify the globe, and set the index to the
thirteenth hour, the sun’s place being in the meridian.
2. Note the sun’s place, and turn the globe westward, as
also the quadrant of altitude, till the point opposite the
sun’s place cut the quadrant of altitude in the eighteenth
degree above the horizon; then will the index show the time
when the twilight commences in the morning.
3. Taking the point opposite to the sun, bring it to the eastern hemisphere, and turn it, till it meet with the quadrant of latitude in the eighteenth degree; then will the index show the time
when the twilight ends.

Given the sun’s longitude and the obliquity of the ecliptic, to
find the sun’s right ascension and declination.—Find the sun’s
longitude or place on the ecliptic, and bring it to the

meridian. Then the arc of the equator, between the
first point of Aries and the meridian, shows the sun’s
right ascension; and the arc of the meridian between the
equator and the ecliptic shows the declination.

Given the obliquity of the ecliptic and the sun’s declination, to
find the sun’s longitude and right ascension.—Mark the sun’s
declination on the meridian, and turn the globe till the
 ecliptic comes under the figure; then will the distance from
the meridian to the first point of Aries show the sun’s
longitude on the ecliptic, and its right ascension on the

equator.

Given the obliquity of the ecliptic and the sun’s right ascen-
sion, required the sun’s declination and longitude.—Bring the sun’s
right ascension in the equator to the
meridian, then
will the interpolated arc of the ecliptic to Aries show the sul’s
longitude; and the arc of the meridian, that is between the
sun’s right ascension and longitude, will show the declination.

To find on what day the sun begins to shine constantly at any
given place in either of the frigid zones, and how long he con-
tinue to shine without intermission at that place.—Subtract
the latitude of the given place from 90, and find in what
two days of the year the sun’s declination is exactly equal to
the remainder, and of the same kind as the latitude of the
place; then on the first of these days in the spring quarter,
the sun shines to set at the given place, and shines without
intermission there till he arrives at another point of the
ecliptic, as many degrees on the other side of the summer
solstice, when his declination is again equal to the comple-
ment of the latitude; the space of time between those two
days is the length or duration of the long day.

To find the latitude of those places in the north frigid zone,
where the sun begins to shine constantly on any day between the
vernal equinox and the summer solstice, or in the south frigid zone
on any day between the autumnal equinox and the winter solstice.

Find the sun’s declination for the given day; subtract it
from 90, and the remainder will be the latitude of those
places: where the sun begins to shine constantly the latitude
is of the same kind as the sun’s declination.

To determine under what latitude two given stars rise or set at
the same time.—Bring one of the stars to the horizon, and,
keeping it there, raise or depress the pole till the other is on
the horizon at the same time, observing whether this is
affected on the east or west position of the horizon; then
the degree of the meridian, intersected by the horizon, will
be the latitude of the place required.

To find at what place a given star is vertical at any given hour
at London; e.g. at what place will Capella be vertical the
24th of March at 10 o’clock afternoon, at London time.

N. B.—This problem requires the assistance of both the
terrestrial and celestial globes.

1. Find, as above, the time of the meridian passage of the
star;
GLOBE.

1. The given place being brought to the meridian, count as many degrees on the meridian from the equator towards the other pole; the point which is thus arrived at is the place of the anteci.

2. Note the degree of the meridian over the given place and its antecedent, and turn the globe till the opposite degree of the equator come under the meridian; or, which amounts to the same, till the index, which before stood at twelve, come to the other twelve: then will the place, corresponding to the former degree, be the periclin; and the latter, that of the antecides.

3. Find what place of the earth the sun is vertical at any time given. 1. Bring the sun's place found in the ecliptic to the meridian, and the index to the hour of twelve, noting what point of the meridian corresponds thereto. 2. If the given hour be before noon, subtract it from twelve hours, and turn the globe towards the west, till the index points at the hours remaining; thus will the place required be under the point of the meridian before noted. 3. If the hour be after noon, turn the globe in the same manner towards the east, till the index points at the given hour; thus, again, will the place required be found under the point of the meridian before noted.

If, at the same time, you note all the places which are under the same half of the meridian with the place found, you will have all the places to which the sun is then in the meridian; and the opposite half of the meridian will shew all the places in which it is then mid-night.

A place being given in the torrid zone, to find the two days in the year wherein the sun is vertical in the same. 1. Bring the given place to the meridian, and note the degree of the meridian corresponding thereto. 2. Turn the globe about, and note the two points of the ecliptic passing through that degree. 3. Find on what days the sun is in these points of the ecliptic: for on these days he is vertical to the given place.

To find those places in the torrid zone wherein the sun is vertical on a given day. Bring the sun's place in the ecliptic to the meridian; then turning the globe round, note all the places which pass through that point of the meridian; those are the places required.

After the same manner may be found what people are afflicted for any given day.

The day and hour at any place being given, to find where the sun is vertical at that hour. Bring the sun's place to the meridian, and the degree over it is the sun's declination at that time; then bring the given place to the meridian, and set the index to the given hour; turn the globe till the index points at twelve, and the place on the globe which is under the degree of the sun's declination has the sun then vertical.

A place being given in the frigid zone, to find the time when the sun begins to appear above the horizon, and when it begins to disappear; and also the length of the longest day or night in that place. Rectify for the latitude; bring the ascending part of the ecliptic, i. e. for latitudes north of the tropic of Cancer the semicircle intercepted between Capricorn and Cancer, to the fourth point of the horizon; observe the degree of the ecliptic which cuts that point; and find when the sun enters that degree, and this will give the time when the sun begins to appear in that latitude. Bring the descending part of the ecliptic to the same point of the horizon, and the calendar will shew when the sun leaves that latitude and disappears. Again, bring the ascending part of the ecliptic to the north point of the horizon, and the degree, as before, will shew, in the calendar when the longest day begins; and by bringing the descending part of the ecliptic to the same north point, we shall find, in the same manner, when the longest day ends.

To find the latitude of the places wherein any given day is of any given length. 1. Bring the sun's place for the given day to the ecliptic, and set the index to the hour of twelve. 2. Turn the globe, till the index points at the hour of rising or setting. 3. Raise and depress the pole till the sun's place appear in the eastern and western side of the horizon; then will the pole be duly elevated, and, consequently, the latitude given.

To find the latitude of those places in the frigid zone wherein the sun does not set for a given number of days. 1. Count so many degrees from the next tropic, towards the equinoctial point, as there are units in half the number of the given days; because the sun, in its proper motion, goes nearly a degree every day. 2. Bring the point of the ecliptic, thus found, to the meridian; and its distance from the pole will
GLOBE.

will be equal to the elevation of the pole, or latitude of the places required.

Any hour of the day or night being given, to show all those places to which the sun rises and sets; where it is noon or midnight; and where day or night.—1. Find what place the sun is at that time vertical to, as already taught. 2. Let this place be brought to the zenith of the wooden horizon, i.e. elevate the pole as the latitude of that place requires and then will the places on the eastern side of the horizon be those the sun is setting to; and on the western side, those he rises to; those under the upper semi-circle of the meridian have it noon; and those under the lower, midnight. Lastly, to those of the upper hemisphere it is day; and to those in the lower, night.

Hence, as in the middle of an eclipse, the moon is in that degree of the ecliptic opposite to the sun's place; by the present problem it may be shown what places of the earth then see the middle of the eclipse, and what the beginning or ending.

To find what places of the earth a planet, e.g. the moon, is vertical to any day of the year.—1. Mark the planet's place on the globe, as above taught. 2. Bring this place to the meridian, and note the degree over it. 3. Turn the globe round, and the places which pass under the point are those required.

The declination of a star, or any other phenomenon, given, to find the place of the earth the star is vertical to.—Count as many degrees in the meridian, from the equator towards one pole, as are equal to the given declination; viz. towards the north, if the declination be to the northward; and towards the south, if the declination be south. Then turning it round, the places that pass through the extremity of this arch in the meridian are the places required.

To determine the place of the earth where any star, or other celestial phenomenon, will be vertical at a given hour.—1. Elevate the pole according to the latitude of the place, from whole noon or midnight the hours are numbered. 2. Bring the sun's place for that day to the meridian, and set the index at twelve o'clock. 3. Determine the place of the star on the surface of the globe, and bring it to the meridian; the index will show the difference of time between the impulse of the sun and star to the meridian of the place: note the point of the meridian over the place of the star. 4. Find in what places of the earth it is then noon, and set the index to twelve o'clock. 5. Turn the globe towards the well, till the index has passed over the interval of time between the culmination of the sun and star. Then, under the point of the meridian, before observed, will the place required be found. And hence may always be found what place a star, or other phenomenon, rises or sets at any given time.

To place the globe in such manner, under any given latitude, as that the sun shall illuminate all those regions which be actually illuminated on earth.—1. Rectify the globe, i.e. elevate the pole according to the latitude of the place; bring the place to the meridian, and set the globe north and south by the compasses; thus, the globe having the same situation with regard to the sun as the earth has, that part thereof will be illuminated which is illuminated on earth. Hence also the globe being set in the same manner, when the moon shines, it will show what parts are then illuminated by the moon.

And in the like manner, we may find when the sun and moon rise and set at any given time.

To find the distance of two places on the globe.—Take the given places in the compasses, and apply them to the equator: the degrees which there subtend being reduced into miles, leagues, or the like, give the distances required.

The same may be done, and that more commodiously, by laying the graduated edge of the quadrant of altitude over the two places, and noting the degree intercepted.

To find how any one place bears from another.—Bring one place to the meridian, and lay the quadrant of altitude over the other, and it will show on the horizon the point of the compass on which the latter bears from the former.

Problems on the terrestrial globe may sometimes be advantageously solved, by considering the horizon as the circle of illumination, and bringing the sun's place to the zenith.

To find for any given day and hour those places where the sun is then rising or setting: these places are, where it is noon, and in particular that place where the sun is vertical: these places have morning or evening twilight; and those places where it was midnight.—Find the sun's place in the ecliptic for the given day, bring it to the brazen meridian, and mark its declination.

Elevate the (north or south) pole as many degrees above the horizon as are equal to the sun's declination (north or south). Bring the given place to the meridian, and set the index to the given hour, then turn the globe on its axis, till the index comes to the upper twelve, and fix the globe in that position. All these places along the western edge of the horizon have the sun rising; those along the eastern edge have the sun setting; it is noon to the places under the brazen meridian, and amongst them the sun is vertical to that place, which stands under the degree of the sun's declination.

Those places that are within 18° of the western semi-circle of the horizon have morning twilight, and those within 18° of the eastern semi-circle have evening twilight: and it is midnight at all those places under that part of the brazen meridian which is below the horizon. In short, it is day to all places above the horizon, and either twilight or dark night to all those which are below it.

The day and hour of a lunar eclipse being given, to find those places where it will be visible.—Find the place where the sun will be vertical when the eclipse begins, and rectify the globe, in respect to latitude, for the antipodes of that place. Then bring the antipodes to the upper part of the brazen meridian, and fix the globe in that position, and the beginning of the eclipse will be visible to all places which are then above the horizon.

To find the proportion which the land bears to the sea.—For this purpose Dr. Long proposes to take the papers of a large terrestrial globe, and after separating the land from the sea with a pair of scissors, to weigh them carefully in scales. This method supposes the globe to be exactly delineated, and all the papers of equal thickness. By an experiment on the papers of Mr. Senex's eighteen inch globe, he found that those comprehending the sea weighed 245 grains, and the others only 124; whence he infers, that almost three-fourths of the surface of our earth between the polar circles are covered with water, and that little more than one-fourth is dry land. Dr. Long omitted weighing the papers within the polar circles, because the proportion which the land bears to the sea within them is not ascertained. Long's Astron. vol. i. p. 163. See Magnitude of the Earth.

GLOBE. To confirm a dial by the. See Dial.
GLOBE.

Standing directly over the north pole of the ecliptic, and perpendicular to that part of the surface of the globe. On this pin are two moveable collets at D and H, to which are annexed the quadrantal wires N and O, carrying two little balls representing the fun and moon. The collet D is fixed to the circular plate F, on which are engraved the 293 days of the moon's age, beginning under the wire N, which, as it turns round, carries with it the plate B. The wires are fixed or slackened by the screw G, and the two little balls are made to rise and set at the same time and on the point of the horizon, for the day to which they are rectified, as the fun and moon do in the heavens. The ball representing the moon may be screwed as many degrees to either side of the ecliptic, as her latitude amounts to at any given time; and for this purpose, S is a small piece of paleteboard, the curved edge of which at S is to be set upon the globe at right angles to the ecliptic, and the dark line over S to stand upright upon it: from this line, on the convex edge, are drawn the 51 degrees of the moon's latitude on both sides of the ecliptic; and when this piece is set upright on the globe, its graduated edge reaches to the moon on the wire O, by which means she is easily adjusted to her latitude found by an ephemeris. The horizon of this globe is supported by two semi-circular arches, because pillars would stop the progress of the balls, when they go below the horizon in an oblique sphere. This globe is rectified by elevating the pole to the latitude of the place, bringing the sun's place in the ecliptic for the given day to the brazen meridian, and setting the hour-index to twelve at noon; then, setting the fun directly over his place in the meridian, and the moon over her place in the ecliptic, by fixing her wire under the number that expresses her age for that day on the place of F; and, lastly, having the curved edge of the palette-board S over the ecliptic below the moon, and adjusting the moon to her latitude over the graduated edge of the palette-board. Having thus rectified the globe, turn it round, and observe on what point of the horizon the sun and moon balls rise and set; for these agree with the points of the compass on which the sun and moon rise and set in the heavens on the given day: and the hour-index shows the times of their rising and setting, and also the time of the moon's setting over the meridian. This globe is also contrived for exhibiting the phenomena of the harwest-moon, &c. Phil. Trans. No. 483. art. 21. in vol. xiv. p. 535; or Ferguson's Atron. p. 291.

Globe, Distilling. See Dialling.

Gloves, Patent, are those with the improvements of Mr. Neale, for which he obtained his majesty's letters patent; by means of which he solves several astronomical problems, which do not admit of solution by the common globes.

Globe, Planetary, is a machine contrived and described by Mr. Ferguson; in which T (Plate XV. Afternoon, fig. 135.) is a terrestrial globe fixed on its axis standing upright on the pedestal C D E, on which is an hour circle, having its index fixed on the axis, which turns somewhat suddenly in the pedestal, so that the globe may not be liable to shake: to prevent which, the pedestal is about two inches thick and the axis goes quite through it, bearing on a shoulder. The globe is hung in a graduated brazen meridian, much in the usual way; and the thin plate N, N E, E, is a moveable horizon graduated round the outer edge, for shewing the bearings and amplitudes of the fun, moon, and planets. The brazen meridian is grooved round the outer edge; and in this groove is a slender semi-circle of braza, the ends of which are fixed to the horizon in its north and south points: this semi-circle slides in the groove as the horizon is moved in rectifying it for different latitudes. To the middle of the semi-circle is fixed a pin, which always keeps in the zenith of the horizon, and on this pin the quadrant of altitude q turns; the lower end of which, in all positions, touches the horizon as it is moved round the same. This quadrant is divided into 90 degrees from the horizon to the zenithal pin on which it is turned, at 90. The great flat circle of plate A B is the ecliptic, on the outer edge of which the signs and degrees are laid down; and every fifth degree is drawn through the rest of the surface of this plate towards its centre. On this plate are seven grooves, to which seven little balls are adjusted by fixing wires, so that they are easily moved in the grooves, without danger of starting out of them. The ball next the terrestrial globe is the Moon, the next without it is Mercury, the next Venus, the next the Sun, then Mars, then Jupiter, and lastly Saturn; and in order to know them, they are separately stampt with the following characters: G, S, G, 0, G, S, 2, b. This plate or ecliptic is supported by four strong wires, having the lower ends fixed into the pedestal at C, D, and E, the fourth being hid by the globe. The ecliptic is inclined 23 1/2 degrees to the pedestal, and is therefore properly inclined to the axis of the globe which stands upright on the pedestal.

To rectify this machine.—Set the Sun, and all the planetary balls, to their geocentric places in the ecliptic for any given time, by an ephemeris; then set the north point of the hor-
the time of the day, and the quadrant will cut the true azimuth, or bearing of the sun for that time: the difference between which, and the bearing shown by the azimuth compass, is the variation of the compass in that place of the earth. Ferguson's Alphon. p. 292, &c.

Globe Amaranth. See Gomphrena.

Globe Amaranth, in *Natural History*, is a singular, minute, aquatic animal, whose form seems exactly globular, without either heads, tails, or limbs. Leaves in all directions, either rolling like a bowl, or gliding along smoothly without turning itself at all. Its whole body is transparent, except where it is covered with circular black spots; some of which have fix or feven, some one, two, three, four or five, and others none at all. These spots are probably the eggs or young ones of the animal. The general appearance of the body exhibits a kind of soft moveable hairs or bristles, by means of which it is conjectured the motions of the animal may be performed. Baker's Microf. 1753, p. 322, &c.

Globe Daisy. See Globularia.

Globe Fjó, in *Ichthyology*, a name by which some species of the obstruction are called. See Ostracion.

Globe Flower, in Botany. See Schizanthus.

Globe Ranunculus. See Thollouis.

Globe Thistle. See Echinops.

GLOBULAR CHART, a representation of the surface, or some part of the surface, of the terraqueous globe upon a plane; wherein the parallels of latitude are circles nearly concentric, the meridians, curves, bending towards the poles; and the rhumb-lines also curves. The merits of this chart consist in this, that the distances between places on the same rhumb are all measured by the same scale of equal parts; and the distance of any two places in the arch of a great circle, is nearly represented in this chart by a straight line. Hence land-maps, made according to this projection, would indisputably have great advantages above those made any other way. See Map.

But for sea charts, and the use of navigation, it is yet controverted, whether the globular chart be preferable to Mercator's, where the meridians, parallels, and particularly the rhumb-lines, are all straight lines; inasmuch as straight lines are found more easy to draw and manage than curves, especially such as rhumb-lines on the globular chart are. This projection is not new, though not much taken notice of till of late. It is mentioned by Thoemsy in his Geography; as also by Blondeau, in his Exercitix. See Chart.

Globular Projection. See Projection.

GLOBULAR Sailing. See Great-circle Sailing.

Gen. Ch. Cal. Common perianth imbricated, with equal scales, the length of the disc; proper perianth of one leaf, tubular, five-leaf, acute, permanent. Cor. General one nearly equal; proper one of a single petal, tubular at the base: limb in five segments; the upper lip very narrow, the lower rounded; the lower consisting of three larger, equal segments. Stam. Filaments four, simple, as long as the proper corolla; authors distinct, incumbent. Fil. Germ. superior, ovary, style simple, the length of the filaments. Stamina obtuse. Fertil. none; proper calyx flattening up and enclosing the solitary, ovate fruits. Common receptacle oblong, divided by scales.

Eff. Ch. Common calyx imbricated; proper one tubular, inferior. Partial corolla with the upper lip cloven; under one three-leaf, Receptacle chaffy.

1. G. longifolia. Long-leaved Globularia. Willd. Sp. Pl. v. 1. 539. (Alpum live Herba terriblis; Sloan, Jun. v. 19. t. 5. f. 5.) — Stem furzy. Leaves linear—linear, entire. Heads of flowers axillary. —This green-house shrub is a native of Madeira, flowering in July and August. The wood of this plant is hard and white, with a very large pith, and an unequal light brown or grey bark. Leaves growing very thick towards the ends of the branches. Flowers consisting of several spherical heads, of a blueish colour. Seed pappus, all over downy.

2. G. Alysum. Herb Terrible. Linna. Sp. Pl. 139. (Alpum montis Ceti; Ger. em. 506.) — Stem furzy. Leaves obvato-lanceolate, three-toothed or undivided. Heads of flowers terminal. —This green-house shrub, found in various parts of the south of Europe, flowering from August to November. Root woody. Leaves alternate, falcated in the lower acida, near an inch long, glaucous, some are undivided, others three-toothed. Flowers blue or purple. The whole plant is bitter, and purgative in a violent degree.

3. G. bifragaria. Linna. Sp. Pl. 139. (Scabiosa bifragaria five G. frutecens; Plini. Amath. t. 52. f. 5.) — Stem furzy. Radial-leaves wedge-shaped, abrupt; stem-leaves lanceolate. — Native of the woods of India. Stem of many straight, hard, leafy branches, each about five or six inches high. Flowers in a blue terminal head.

4. G. vulgaris. Blue Daisy. Linna. Sp. Pl. 139. (Aphyllanthus anguillarum; Camer. Hort. t. 7.) — Stem herbaceous. Radial-leaves three-toothed. Stem-leaves lanceolate. — A hardy perennial, common in some parts of Europe, and flowering in May and June. Root woody. Stem a pan high, terminated by a head of deep blue flowers. Willdenow mentions two varieties of this species, one with a cHaffy stem, the other with ribbed flowers.

5. G. spinosa. Linna. Sp. Pl. 139. — Radial-leaves crenate-prickly; stem-leaves entire, pointed. — Native of Spain, Alhdbus having gathered it in Granada. It flowers in May. —Radial-leaves numerous, small, stiff and notched, each notch ending in a prick. Flowers composing an oblong sphere, hairy. — We are not acquainted with any figure of this species.

6. G. cordifolia. Linna. Sp. Pl. 139. Jacq. Autr. t. 245. — Stem nearly naked. Leaves wedge-shaped, with three points; the middle one very small. — Native both of hills and vales in Hungary, Austria, and Switzerland, flowering from April to July. Root creeping, each joint throwing out a cluster of leaves, from the centre of which springs a smooth purplish stem about four inches long, terminated by a head of blue flowers.

7. G. hena. Willd. Sp. Pl. v. 1. 532.— Flower-flasks naked, very short, leaves spatulate, somewhat ovate, entire. — Found in the south of France, and on the Pyrenees, where our dried specimen was gathered by Dr. Noeiden. Root woolly and very thick, bearing numerous tufts of little leaves, among which arise the short, solitary flower-flasks. Flowers forming a terminal head. — It has never been figured.

per side. *Flower-flax* about six inches long, smooth, fili-ated, purplish towards the top, bearing a roundish head of blue flowers.

G. *orientalis*. Linn. Sp. Pl. 140. — "Stem nearly naked. Hands of flowers alternate, siliques, leaves ovate, somewhat lanceolate, entire."—This species is a native of Natalia.

—Root perennial. Leaves numerous, obovate, running down into the foot-falks, acute, undivided, naked. Stem a foot high, herbaceous, perfectly simple. Leaves alternate, small, lanceolate, remote. Heads of flowers alternate, siliques, from seven to ten, at the summit of the stem.—Linnaeus described *G. orientalis*, having received it from M. Biorling, but it is nowhere figured.

*Globularia*, in Gardening, contains plants of the herba-
ceous, flowery, perennial kind; of which the species chiefly cultivated are the three-toothed globularia (*G.* alc-
pum); and the common globularia or blue daisy (*G.* vulgaris); but others may be easily raised.

There are two varieties of the half-fast, one with a white flower, and another that has a leafy stem.

Method of Culture.—In the first it may be effected by plant-
ing cuttings of the young branches in April, just before they begin to shoot, in pots of light fresh mould, plunging them in a very moderate hot-bed, and giving them due water and shade, till they have stricken root. After this they should be removed from the bed, and be gradually hardened to the open air, being protected during the winter months.

The second may be readily increased by parting the roots, as in the common daisy, planting them out in the early part of the autumn, in moist shady situations. They succeed best in such loamy soils as are rather moist in their quality.

The first affords variety among potted plants, and the latter in the fronts of the more moist and shady borders and clumps of pleasure-grounds.

*Globule, Globulus*; a little globe; otherwise called a *sphærule*.

Thus the red particles of the blood are called globules of the blood, on account of their redness and smallness. (See Blood.) The Cartesians call the particles broken off the matter of the first element, globules of the second element. See *Cartesian, &c.*

*Globulus Nast* is used for the lower, flexible, cartilaginous part of the nose.

*Glochidion*, in Botany. See *Bradlea*.

*Gloesztli*, in Geography, a town of Walachia; 50 miles N. of Bucharest. N. lat. 49° 13'. E. long. 26° 16'.

*Gloau*, a principality of Silefia, on the E. side of the Oder, bordering on Poland; producing corn and wine in abundance, in some parts affording mines of iron. The salt mines feed many theep, and the wool is wrought into different manufactures. It is divided into six circles. In the year 1241, it was governed by its own princes; but afterwards it belonged to the king of Poland, to the king of Bohemia, to the emperor, and half of all to the king of Prussia.

*Gloau*, Gros or Great, the capital of the principality of the same name, built in 1110 on the S. side of the Oder, taken by the Prussians in 1741, and strengthened by new fortifications. It is the seat of a governor, a command-
ant, divers tribunals, and a bishop's court, &c. It contains two Catholic churches, of which one is collegiate, three convents, a Lutheran church and school, and a chapel for Calvinists; 62 miles N.W. of Breslau. N. lat. 51° 39'. E. long. 16° 5'.

*Gloav*, Ober, or Little, a town of Silefia, in the prin-
cipality of Oppeln; 19 miles S. of Oppeln. N. lat. 50° 16'. E. long. 15° 48'.

*Glochmis*, a town of Austria; 28 miles S. of Vienna.

Gloken-Spessse, in Mineralogy, a term used by the Germans to express a sort of impure regular of bismuth, obtained by accident, sometimes in the making of smalt. The bismuth ores are often so intimately mixed with the cobalt, that they cannot be separated from them. In this case, the arsenic being raised in the flowers, there remains at the bottom, instead of the fixed vitrifiable earth of the cobalt, a sort of impure regular of a reddish col-
our. This is bismuth, with admixture of the earth of cobalt, and other extraneous matter. They sometimes call this whole matter by the common name of specifie; but more usually they separate it into two parts, and call the under part, which is most solid, gloken-specifie, and the upper part they distinguish by the name of zs calda-
rum.

Gloomerellis, in our Old Writers, commissaries ap-
pointed to determine differences between scholars of a school or university, and the townsmen of a place. In the edict of the bishop of Ely, anno 1276, there is mention of the master of the gloomerells.

Gloomme, or Glomen, in Geography, called also the Star Ely, or great river, the chief river of Norway, springs from the lake of Orfunden on the north of the Farnund, and after running a course nearly south about 300 British miles, discharges itself into the Northern Ocean near Fredriclkabt, to which town about 50,000 trees are annually floated upon it. This river, being full of cataracts and shoals, is not navigable. Before it receives the Worme, which flows from the lake Mofs, it is about as broad as the Thames at Henley. In its course it presents a broad surface, some-
times watering pleasant valleys, sometimes intercepted by sand-banks, over which it frequently shifts its course, some-
times winding between rocky cliffs, and precipitating itself in frequent cataracts. Near Kongsvinger it is as broad as the Thames at Putney. Its rugged course, however, must render it a tremendous torrent.

Glôni, a river of Bavaria, which runs into the Ammer, near Crantzberg.

Glôns, a town of France, in the department of the Ourte, and chief place of a canton, in the district of Liege. The place contains 1,500, and the canton 8,850, in-
habitants, on a territory of 127½ kilometres, in 23 com-
mmunes.

Glor-Fat, in Rural Economy, a term applied to ani-
imals that are extremely fat.

Gloria Patri, in the Liturgy, a formula of words repe-
et at the end of each Psalm, and on other occasions, to give glory to the Trinity; called also the *Doxology*. It is thus denominated, because it begins in the Latin office with these words; Gloria Patri, q. d. Glory be to the Father, &c.

Pope Damascus is commonly said to have first ordered the rehearsed, or rather, fingling the Gloria Patri at the end of Psalms. Baronius, indeed, will have it to have been used in the times of the apostles; but its use, then, he al-
 lows to have been more obscure, and that it did not become popu-
lar till after the rise of Arianism, when it was made a kind of symbol of orthodoxy.

The fifth canon of the council of Vaison, held in 529, decrees, "that the name of the pope shall always be re-
hearsed in the churches of France, and after the Gloria Patri shall be added *fict erat in principio*, as is done at Rome, in Africa, &c. on account of the heretics, who say,
**GLO**

Globrig, that the "Soa of God had his beginning in time." Fleury.

Gloria in excelsis is also a kind of hymn rehearsed in divine service, beginning with the words Gloria in excelsis Deo, & in terra pax hominibus, &c. Glory be to God on high, on earth peace, &c.

Gloriosa, in Botany, so named on account of the splendour and magnificence of its flowers. Tournefort, objecting to the name given by Linnaeus because it is an adjective, called this genus Metelonica, in which he has been followed by Jussieu, and indeed by all French botanists, though the Linnaean school have refused to adopt this barbarous name.—Linn. Gen. 164. Schreb. 220. Willd. Sp. Pl. v. 2. 95. Ait. Hort. Kew v. 1. 434. Mart. MILL. Dict. v. 2. Gerin. t. 18. Juff. 48. Clats and order, Hexandria Monogynia. Nat. Ord. Sarmentaeceae, Linn. Lilia, Juff.

1. G. Superba. Superb Lily. Linn. Sp. Pl. 437. Rodout. Liliae t. 26. — "Leaves furnished with tendrils." — Native of Malabar and Guiana. It was introduced into Kew Garden in 1600 by the first earl of Portland. A tender flow plant, flowering in July and August. The stem is herbaceous, about a fathom high, round, having two opposite lateral branches, and putting forth a flower-flask from the bosom of each leaf. Leaves alternate, smooth, each ending in a tendril. Flowers pendant, of a most beautiful red and yellow colour. Petals lanceolate, long, waved at the edge, reflexed near the base. This remarkably handsome plant requires an excessive heat to make it flower.

2. G. simplex. Linn. Mant. 62. Willd. Sp. Pl. v. 2. 96. — "Leaves pointed." — Native of Senegal. The leaves are not furnished with tendrils. Flowers blue.—There is no figure of this species known. It was merely taken up from Miller, nor has any thing been found which answers to the description.

Obs. This very beautiful genus is nearly allied to Erythronium.

Gloriosa, in Gardening, comprises a plant of the herbaceous, flowering perennial kind; of which the species cultivated is the superba (G. superba.)

Method of Culture.—It is capable of being increased by planting the offsets from the old roots, either in the autumn after the leaves decay, or in the early spring before they shoot, in pots filled with light earth, plunging them in the barkbed of the flow. The old roots, when taken out of the ground, should be preferred in dry sand during the winter in the flow, or in a dry warm room. It is the practice of some to let the roots remain during the winter in the mould, keeping the pots in the tan-bed; planting out the offsets early in the spring. In either way they should have very little water given them.

When the offsets appear they should be supported by sticks, and in hot dry weather a little water should be sparingly given, as there may be occasion. And the pots in which they are planted should be small, that they may be confined, and put forth stronger pets. Two-penny pots will be large enough for the roots of the greatest sized plants of this nature.

The plants afford much effect by their beautiful flowers among those of the fove kind, when properly intermixed with them.

Glorious Islands, in Geography, two small islands in the Indian sea. S. lat. 11° 32'. E. long. 47° 15'.

Glosskar, a small island in the Baltic, E. of Aland. N. lat. 60° 20'. E. long. 20° 15'.

Gloss, Glossa, a comment on the text of any author, to explain his sense more fully and at large, whether in the same language, or in any other. See Commentary.

The word, according to some, comes from γλόγος, tongue; the office of a gloss being to explain the text, as that of the tongue is to discover the mind. Others derive it from the Latin glos, a filter-in-box, which among lawyers sometimes floats for filter; the glos being, as it were, filter to the text.

Nic. de Lyra composed a gloss or gloss in the Bible, in five volumesfolio. The French say, proverbially of an ill comment, that it is glos d'Orland, plus obscure que le texte.

Gloss is also used for a literal translation, or an interpretation of an author in another language, word for word. Young scholars need an interlineral gloss for the understanding of Juvenal, Horace, Sallust, Periplus, &c.

Gloss is also used in matters of Commerce, &c. for the fibre of silk, fluff, or the like.

Glossary, Glossarium, a kind of dictionary for explaining the obscure, ancient, and barbarous words and phrases of an altered, corrupted, or refined language.

Spelman's glossary, entitled Archaiologicum, is an excellent work; though that author did not begin to study in this way till fifty years of age. M. Du Cange's Latin Glossary in five volumes, Paris, fol. 1733, Balfil, fol. 1762, is a work in high estimation, and containing a fund of the most curious and amusing intelligence. Charpentier's supplement to this work, in 4 volumes, fol. Paris, 1766, is necessary to render this fet of books complete. Du Cange's Greek Glossary in two volumes, fol. Lugd. 1688, is an excellent performance, full of uncommon erudition.

The Greek, Latin, and French glossaries of Du Cange form a series of the most instructive articles in the study of jurisprudence and belles lettres. There is an abridgment of this work in 6 vols. 8vo.; which, however, contains some matter not common to either of the preceding. This abridgment is exceedingly rare. As a caution to the purchasers of the Greek Glossary, we inform them that in the article "Moneta" (Coins, vol. iv. p. 592) there should be 10 plates of engravings of coins, and monograms of various princes and sovereigns of Europe, which are sometimes wanting, and thus the value of the edition is materially depreciated.

Lindenbrook has a Glossary on the laws of Charlemagne, &c.

Glossocatochos, in Surgery, an instrument for depressing the tongue. It is described by Paulus Aegineta, and the term is derived from γλώσσα, the tongue, and κατά, to r p ref in.

Glossocellae, denoting a swelling and protrusion of the tongue. The word comes from γλώσσα, the tongue, and κελαί, a tumour.

Glossocoma, a retraction of the tongue.

Glossocomia, in the Instrumental Music of the Greeks, a name given by the ancients to a kind of cale for the glottis, or tongues of their flutes, which probably were hautboys, and, consequently, that glottis was a reed. See Glottis.

Glossocomon, in Mechanics, is a name given by Hip-
eru, to a machine composed of divers dented wheels, with pincions serving to raise huge burdens.

GLOSSOCOMON, a term in Surgery, derived from γλωσσα, the tongue, and νυχης, to guard; originally a cafe for the read of a hauboy, but used metaphorically to signify a cafe for a fractured limb.

GLOSSODIA, in Botany, γλωσσα, having the form or appearance of a tongue; in allusion to the peculiar appendage to the internal part of the flower, which resembles the tongue of a serpent, and affords the essential character. Brown Prod. Nov. Holl. v. 1 325—Clafs and order, Gymandra Monogynia. Nat. Ord. Orchidace.

1. G. major. Brown 326.—Appendage cloven half way down; its lobes spreading, acute.

2. G. minor. Ibid.—Appendage to the base; its lobes parallel, obtuse.

Both species are natives of the country near Port Jackson, New South Wales. Their bulbs are undivided, with a laminated coat, and grow in the earth, not parasitickly. Herb hairy. Leaf solitary, radical, its base enclosed in a membranous sheath. Stalk radical, bearing generally one blue flower, rarely two, and furnished with one træctæ besides what accompanies each flower. Brown.

GLOSSOIDES, in Natural History, a name given by some authors to a species of flone, resembling the figure of the human tongue. This is a mere accidental configuration of a common flint or pebble, perfectly indeterminate in size and colour, and owing its form to no animal mould, as the flones found in shells usually do, but is a mere lufus naturæ in the concretion of the flone.

Gen. Ch. Cal. Perianth superior, of one leaf, turbinate, four-toothed, permanent. Cor. Petals four, equal, lanceolate, and suddenly shorter than the calyx, recurved. Nectary a ring round the base of the flyle. Stam. Filaments four, very short; anthers oblong, nearly united into a cylinder, elongated at the top into a membranous lanceolate expansion of two cells, opening inwardly. Flgfl. German inferior, obvolute; flyle thread-shaped, as tall as the flaments; fligmas four, acute. Peric. Drupa pear-shaped, of one cell, crowned by the calyx. Seed solitary, ovate, fricated.

Obf. The above characters appear to be taken by Schreber from Aublet, nor have we any better materials. The only species known is,

1 G. arborensis; Willd. nov. (Votomita guianensis; Aubl. v. 1. 91. t. 35.)—A shrub of a middling size, whose trunk is five or six feet high, and five or six inches thick; the wood yellow, hard and compact. Branches knotty, spreading gradually, leafy. Leaves opposite, elliptical, pointed, entire, six inches long, thick and firm, of a shining green, placed on short stalks, with a deciduous stipula at each side of their base. Flowers white, on short, umbellate, axillary flasks, their petals about half an inch long. This plant is found in the extensive forests of Guiana, about the habitations of the natives. Nothing is recorded respecting its qualities or uses.

Gen. Ch. Cal. Perianth half inferior, of one leaf, minute, five-toothed, permanent. Cor. Petals five, lanceolate, spreading, acute, much longer than the calyx, each bearing at its point a linear-lanceolate, abrupt appendage, almost of the length of the petal, bent back and lying upon it. Stam. Filaments five, very short; anthers roundish. Flgfl. German roundish, encred by a glandular ring, which bears the petals and stamens; flyle none; fligmas five, acute. Peric. Berry roundish, with five furrows, of one cell. Seeds five, angular.

Eff. Ch. Calyx half inferior, with five teeth. Petals five, each bearing an indexed longitudinal appendage. Berry with five seeds.

Obf. Schreber, p. 826, suspècts this genus not to be distinct from Aralia, but the habit confirms Jufliciu's opinion, who separates them widely. Two species are described by Aublet.

1. G. glabræm. (Goupia glabra; Aubl. v. 1. 296. t. 116.)—Leaves smooth.—Native of the forests of Guiana, 30 leagues from the sea, bearing flowers and fruit in November. The trunk is 60 feet or more in height, and two or three feet in diameter, serving to make canoes; the bark smooth and grey; the wood white and light. Branches drooping, furnished with alternate leaves of an ovate, pointed, somewhat unequal figure, entire, rigid, thinning, and smooth, with a branching rib, and fine transverse veins at the back. Flowers yellow, small, many together in foliar axillary umbels. Berry black, globular.

2. G. tamentofsum. Willd. Sp. Pl. v. 1. 1522.—Leaves downy.—Native of the forests of Cayenne and Guiana. Not half so lofty as the former. The bark is wrinkled and dark-coloured. Leaves clothed on both sides with some short hairs. Their juice, which, as well as the bark, is bitter, is used to cure inflammations of the eyes.

GLOSSOPETRA, or GLOTTOPETRA, in Natural History, called also ichthyodontes, steak's teeth, dej-fob's teeth, &c. a kind of extraneous follic, somewhat in form of a serpent's tongue; frequently found in the island of Malta and divers other parts. Some of them are in a high state of preservation, having their enamel and points perfect, and their sharp edges finely ferrated as in the recent teeth.

Naturalists have been much divided as to the nature and origin of these bodies. Steno, De Corpore solido intra folium contento; Ol. Wormius, Differt. de Gloppetra; and Reynchius, De Gloppetris Lunebergiæ, treat of them at large.

The vulgar notion is, that they are the tognes of serpents petrified; and hence their name, which is a compound of γλωσσα, tongue, and νυκης, floure. Hence, also, their traditionary virtue in curing the bites of serpents.

The general opinion of naturalists is, that they are the teeth
teeth of fishes, left on land by the waters of the deluge, and since petrified.

They even specify the very kind of fish, and take it to be that which Theophrastus and the Greek writers call ἀργυρόκτης, and the moderns the flæsk or feadog.

Camerarius cannot persuade himself that the glossopetrae found in England, Malta, and round Montpelier, were ever the teeth of a sea-dog, or any other fish. The chief difficulty, he suggerles, is the small quantity of volatile salt and oil which they afford by distillation. To which Dr. Woodward answers, in defence of the common system, that having lain so long buried underground, it is no wonder they should have lost the best part of their volatile principles. It is certain, that human bones and skulls, long interred, do not afford nearly the quantity of those principles that they would have done immediately after the person's death.

Another example, proposed by Camerarius is, that the glossopetrae, when exposed to the naked fire, turn to a coal; and not to a calx; contrary to what is asserted by Fabius Columba. Dr. Woodward answers, that it is likely enough the glossopetrae, in burning, may assume the form of a coal, before it arrive to that of a calx.

The several sizes of the teeth of the same species, and those of the several species of sharks, afford a vast variety of these foliaceous substances. Their usual colours are black, blue, whitish, yellowish, or brown; and in shape they usually approach to a triangular figure. Some of them are simple; others are trichupidate, having a small point on each side of the large one; many of them are quite straight, but they are frequently found crooked, and bent in all directions; many of them are serrated on their edges, and others have them plain: some are undulated on their edges, and slightly serrated on these undulations. They differ also in size as much as in figure; the larger being four or five inches long, and the smaller of less than a quarter of an inch.

They are most usually found with us in the Irata of blue clay, though sometimes also in other subfusates, and are frequent in the clay-pits of Richmond and of Shelly island, and in other places. They are very frequent also in Germany, but nowhere so plentiful as in the island of Malta.

In the British Irata they rarely occur. Mr. Farey has found them in these Irata only in five places, viz.: in the London clay, probably obtained from the clay-pits above-mentioned; in a bed of the soft or upper chalk in Kent, at Haresfield, near New Malton, &c.; in a green flinty Irata below the chalk, N. of Dunstable, &c.; in the Stonesfield and Collywaxon slate fences, above the Bath free-lime rocks, at Enstone in Oxfordshire, where Woodward procured specimens of these teeth in the jaw, &c.; and in the thick grey lime-rock which lies under and surrounds the South-Wales coal basins (Phil. Trans. N. 334.) Glossopetrae are sometimes found in gravel-pits and other collections of alluvial matters. It is seldom possible to determine to what place in the series of Irata these belong, and they should therefore be carefully distinguished from such as are actually found in the Irata.

The Germans attribute many virtues to these foliaceous teeth; they call them cordials, tubercules, and alexipharmics; and the people of Malta, where they are extremely plentiful, hang them about their children's necks to promote dentition. They may possibly be of as much service this way as an anodyne necklace; and if suspended in such a manner that the child can get them to its mouth, may, by its hardness and smoothness, be of the same use as a piece of coral. See SERPENT'S TONGUE.

GROSSO-PHARYNGEUS, in Anatomy, from γλωσσα, the tongue, and ψαθαι, the words, another name for the constrictor pharyngis superior, which arise from the side of the tongue.

GROSSO-SPATHA, in Surgery, an instrument, called by some the speculum lingue, and used to depress the tongue, in order to look into the fauces.

There are many inflammatory disorders of the mouth, fauces, and palate, which require a depression of the tongue, while they are inspected and treated with proper remedies. The handle of a fiber spoon is made to supply the place of this instrument in soft cases, and answers the purpose very well. Whenever is used, care should be taken to depress gently, in order to avoid the patient pain, as also to avoid irritating the mouth and inflamed parts.

When injections are to be made into the mouth, this instrument or the spoon should also be applied, and the syringe should be conveyed into the mouth over it.

GROSSO-STAPHYLINUS, in Anatomy, from γλωσσα, the tongue, and σταφύλι, the words, another name for the constrictor pharyngis superior. See DEGLUTITION.

GLOTTIDIS RIMA, the fame opening as the glottis. The term rima particularly denotes its slit-like form.

GLOTTIS, from γλωσσα, the tongue, is the opening through which the air passes to and from the lungs in respiration. In this passage the voice is formed. See DEGLUTITION AND LABYRINTH.

Julius Pollux makes the glottis a joint or part of a flute, and Hefychius says that the glottis were little tongues, acted upon by the breath of the player. This description of Hefychius seems to confirm the idea of the ancient nomad flutes being a kind of hautboys.

GLOTTIS, in Ornithology, a name given by many authors to a bird of the long-legged kind, approaching to the nature of our red-hank, but larger and longer legged, and generally known by the name limpha. See SCOLOPAX GLOTTIS.

GLOUCESTER, in Geography, a city in Gloucester-shire, England, is situated in a vale, on a gentle eminence, rising, on the call side, from the river Severn. This opulent city appears to have originated in a Roman station which was situated at King's Holm, near the north-eastern extremity of the present city. The Romans continued to occupy this spot till the disbanding of their own empire occasioned them to quit the island. Its government then reverted to the British princes, under whole domination it continued till about the year 577, when, according to the Saxon Chronicle, it was subjected to the West Saxons, and was reputed one of their principal cities: it was afterwards subjugated by the Mercians, who also obtained possession of the other parts of the county. Under the Saxons it acquired the appellation of Gleau-cellere. The strength and consequence of the city rendering it an object of frequent enterprise, its vicinity was several times the scene of action between the Britons and Saxons. By these conflicts, its buildings were nearly ruined; and the whole place might have sunk into complete decay, if Wolphere, son of king Penda, had not enlarged and adorned it, about the year 679.

This restoration was so perfect, that Bede informs us, it was effaced, about the commencement of the 8th century, as one of the noblet cities in the kingdom. Its early importance is evinced by its having been the residence of various Saxon monarchs; and hence it was denominated a royal city, as it is expressly termed in a grant made by king Edgar to the monks of Worcester, dated at Gloucester in the year 964. By this monarch a battle was fought here with the Danes, who had twice plundered the city in the preceding reigns, and who again ravaged, and partly consumed it by fire, in that of his son Ethelred. Several of the
the Norman and English kings also occasionally resided and transacted public business in this city. A memorable era in the eventful history of Gloucester originated in a contest between Henry III and the barons. "That monarch, in 1253, appointed Sir Maci de Beville, a French knight, sheriff of the county, and constable of the castle within the city. The preference thus given to a foreigner was violently resented by the indignant nobles, who immediately made choice of Sir William Tracy, a native of the shire. He accordingly proceeded to execute the duties of his office in holding a county court, but was suddenly interrupted by De Beville, who, entering with a party of the king's troops, seized the knight, and, with circumstances of peculiar cruelty, hurried him to the castle, where he was committed to close confinement. After this outrage, the barons deputed Sir Roger de Clifford, and Sir John Giffard, with their dependants, to besiege the castle, for the double purposes of rescue and revenge; in a few days they obtained an entrance, and compelled De Beville to retire to the keep; he afterwards surrendered, and was sent as a prisoner to Evesley castle, in the marches of Wales. In the year 1258 Edward I assembled a parliament here, and several laws, connected with the statute of Quo Warranto, were enacted, and have, from that period, been known under the general appellation of the Statutes of Gloucester. In the course of the two next centuries, four parliaments were held here.

The opposition of the Gloucesters to the royal cause, during the reign of Charles I, is generally supposed to have operated fatally against his interest throughout the kingdom: so early as the year 1641, they declared for the parliament; raised a company of volunteers, which they added to their trained bands; procured cannon from London and Bristol, and repaired and strengthened the fortifications; though frequently besieged by the royalists, they successfully re- fused every attack. The ecclesiastical state of Gloucester, during the Roman and former part of the Saxon period of its history, is involved in much obscurity; but in the year 657, Edwy, king of Northumberland, having subdued Mercia, erected Lichfield into a bishop's see, and included Glouceshire within its diocese. This bishopric was soon afterwards divided into the five smaller of Lichfield, Dorchester, Leicester, Hereford, and Worcester; to the last of which this district was annexed, and continued subject, till the reign of Henry VIII., who, by letters patent, dated September 3d, 1541, and afterwards confirmed by act of parliament, erected "the city of Gloucester, the county of that city, and all the county of Gloucester, into a bishopric, with a dean and chapter, by the name of the diocese of Gloucester; and ordained that such part of the then vill and county of Bristol, as formerly was in the diocese of Worcester, should be from henceforward in the diocese of Gloucester for ever."

The church appointed for the cathedral of the new see, was that belonging to the abbey, founded by Wolphere, first Churlian king of Mercia, and Ethelred, his brother and suffecessor, in the year 681. The New Minster, as it is termed in the records, was burnt, with the monastery, in 1087 or 1088; probably at the same time that the city was partly destroyed by the adherents of Robert, brother to William Rufus. Scirlo, then abbot, began a new church in June, 1089; the first stone was laid by Robert, bishop of Hereford; and on the completion of the edifice, in the following year, it was dedicated to St. Peter, by the bishops of Worcester, Rochester, and Bangor. The abbey was again destroyed by fire in 1101 or 1102, but the church was saved. The present magnificent and interesting edifice has been erected at different periods, and consequently displays various specimens of ancient ecclesiastical architecture, in the Saxon, Norman, and English styles. The conversion of the abbey church into a cathedral was the chief cause of its preservation at the reformation; and, to the honour of the inhabitants of Gloucester, it became the object of their peculiar care during the civil wars, after which they obtained a grant of it from Oliver Cromwell. Hence the cathedral has been transferred to the present age, as nearly perfect in all its parts, with regard to its general construction, as it was left by the most favoured of its architects. The eras of erection of the principal parts are known; and hence the characteristic styles of each can be satisfactorily ascertained. The lower part of the nave, the chapels that surround the choir, and the crypt, are presumed to have belonged to the building erected by bishop Aldred, before 1089; the roof of the nave obtained its finishing and form in 1248. In 1310 the south aisle was begun; and part of the south transept was added in 1350. The building of the north transept and choir commenced about the same year; the latter was completed in 1457. Between the years 1301 and 1306, the chanciate cloisters were finished. The chapel of our Lady was built between the years 1457 and 1498; and the centre tower between 1457 and 1518. The interior of this splendid fabric consists of a nave, choir, side aisles, and transepts, with a chapel of our Lady, and several smaller chapels or oratories. From the intersection of the nave and transepts rises a high tower, and on the south side a handsome projecting porch. The roof is sustained on twenty-eight columns, which extend in two rows from the west end to the high altar, where the presbytery forms nearly a semi-circular sweep: the transepts have no isolated pillars. The chapel of our Lady is, as usual, attached to the presbytery; and there are chapels in the north-east and south-east angles of the transepts and choir, with two others projecting in the sweep between those and the chapel of our Lady. The outline, or ground plan of the cathedral, is probably the same at present as designed by bishop Aldred previous to the year 1089; and the crypt remains almost as perfect as the masons left it. The architecture of this subterraneous and gloomy place is massy, and suited to the immense weight resting on the arches, which are turned upon huge short pillars, and strengthened by groins of proportionate solidity. The nave is an interesting specimen of the style which continued to prevail for nearly two centuries after the Norman conquest. The arcade of pendentive round columns, and the rows of semi-circular arches above, impress the mind with ideas of the strength, solidity, and profound solemnity which must have accompanied its original state. The architecture of the well-end is very different from the other parts of the nave; and the vault is covered by intersecting ribs, and ornamented key-ropes; but the remainder is of the plainest description, with three ribs only to each pillar; yet the key-ropes are carved. On each side are eight massive columns; the arches between them are bounded by large mouldings, carved into zig-zags, and other ornaments. Directly over each column, and at some distance, is a range of heads of various characters; some ferone, and others terrac. These serve as brackets to clusters of short pillars, whose capitals display the most beautiful variety of foliage, on which zig-zag wrings extend, serving as a base to other clustered pillars with equally elegant capitals: from these the ribs of the vault commence. The gallery windows, pierced through the wall above the arches, are divided by short thick pillars, and bounded by others, with zig-zag arches: a twisted string separates them from the clerestory windows. The north and south aisles of the nave are nearly in the style of the well-end, with pointed windows, rich ramifications in the arches from the mullions, and fillet-
ed vaults. The arch of entrance to the cloisters from the north aisle is mort elaborately and exquisitely adorned by pil- 1ars, buttresses, niches, pinnacles, foliage, and pendants, and the ingular ornament of twisted pinnacles under the arch. In the south aisle, nail-headed mouldings are introduced as embellishments on each side of the windows. An advanced graduation of style is exhibited in the interior of the south transept; but the most perfect and ornamental degree is diplayed in the chapel of our Lady. The choir is divided from the nave by a screen, designed by Kent.

The dimensions of the cathedral and its several parts are as follow: entir length, indefinite, four hundred and twenty-three feet; length of the nave, one hundred and seventy-five feet; breadth, forty-one feet one inch; height, sixty-four feet six inches; breadth of the north aisle, twenty feet ten inches; height, forty feet six inches; breadth of the south aisle, twenty-two feet; height, forty feet; length of the south transept, fifty-six feet; breadth, forty-three feet six inches; height, eighty-six feet; length of the choir, one hundred and forty feet; breadth, thirty-four feet six inches; height, eighty-six feet; length of our Lady's chapel, ninety-two feet; breadth, twenty-four feet four inches; height, forty-six feet six inches; height of the tower, including the pinnacles, two hundred and twenty-five feet. The great chandeliers, which were completed by abbot Franecester, are the most elegant and perfect of the kind: the sides and roof are profusely embellished, and the windows are filled with multitudes and tracery.

This cathedral contains several curious specimens of monumental sculpture. On the tomb of Edward II., which was erected by his son and successor, and exhibits great perfection of art, is a recumbent figure, in alabaster, of the deceased monarch, regally robed and crowned. Another monument, worthy of notice, is that to the memory of alderman Black- leach, and his wife, whose figures, in white marble, lie on a table tomb, dated 1659, and from accurate copies of the portraits by Vandeyck; they are evidently the work of a skilful artist. A third, deserving observation for its design and chalice style, displays a group by Flaxman, erected to commemorate Mrs. Morley, who died at sea, in childbed; she is represented as rising from the waves with her infant in her arms, and conducted by two angels. Between the north aisle and the choir is a monument, erected by abbott Parker to perpetuate the memory of king Offie: and in a chapel nearly opposite, is a figure, supposed to represent the unfortunate Robert Curtois, duke of Normandy, and elder son of William the Conqueror.

The walls that surrounded Gloucester are mentioned in an ancient prophecy, attributed to Merlin; and tradition ascribes them to Cifta, the second king of the south Saxons. The Norman conqueror caused them to be strengthened and embattled; and they were again repaired in the nineteenth of Edward III. Leland describes Gloucester as "well-built of tymbre, and strongly defended with walls, where it is not fortified with the deepe streame of Sewen water." The walls were completely demolished under the Reformation; and the only memorial of their former strength now remaining is the Wilit Gate; this is embattled; and was erected in the time of Henry VIII. The castle, was probably built about the period of the Norman invasion; the remains were lately destroyed; and on its site was built the county gaol, which was completed in 1795; it consists of three divisions, respectively named the Penitentiary House, the Bridewell, and the Sheriff's Prison; these all have their distinct and appropriate regulations. The gaol contains 203 separate cells; 164 for seep, and 39 for employment.

In this city and its suburbs were formerly eleven parochial churches; but only six are now standing: those of St. Michael, St. Mary de Crypt, St. Nicholas, St. Mary de Lode, St. John, and St. Aldate; the others having been either destroyed at the siege in 1643, or since taken down. In St. Michael's church is a Blue Coat hospital, so called from the similarity of its regulations to those of Chrift Church, Lon- don, founded and endowed in 1666 by Sir Thomas Rich, bart. Among other benevolent establishments that confer honour on the inhabitants of Gloucester, may be mentioned the county infirmary, erected by voluntary contributions, and opened in the year 1775. Its annual receipts, arising from donations and the interest of funded property, amount to between two and three thousand pounds.

The principal trade of Gloucester results from the navigation of the Severn, from the hemp and flax-drefling busi- nesses, and from the pin manufacture. The latter, which is the principal source of labour to the inhabitants, appears to have been introduced into this city by John Tilley, in the year 1626, and is now carried on to a far greater extent than at any other place in England; there being nine manufactory, which furnish employment to about 1500 persons. The pins conveyed annually to the metropolis, are said to amount to the value of 42,000l; but the principal demand is from Spain and America. A bell-founding has been esta- blished here above three hundred years. The clothing trade, formerly the chief support of the inhabitants, is now nearly lost; one falling mill only remains.

Various and important privileges have been granted to Gloucester by several monarchs: it was erected into a borough by charter from king John; Henry II. granted the burgesses the fame liberties and customs as had been enjoyed by the citizens of London; by the act 33 Hen. VIII., which established the bishopric of Gloucester, it is ordered that the town should thenceforth be termed a city. It is also privileged as a county within itself. The corporation, acting under a charter of Charles II., consists of a mayor, twelve aldermen, a high sheriff, recorder, town clerk, two sheriffs, common-council, &c. The title of mayor first oc- curred in the year 1453. The high sheriffs have generally been persons of great eminence. Two representatives to parliament are elected by the inhabitants and freemen; the number of voters is about 3,000; the earliest return was made in the twenty-third year of Edward I. The elections are carried on in an ancient structure, called the Boff Hall, which is also appropriated to the alizes and other county busineses. The public affairs of the city are transacted at the Tholdey, a building supposed to have derived its name from the toll formerly received in it by the lords of the manor. Very considerable improvements have been made, within the last seventy years, in the appearance and buildings of this city. It consists, principally, of four spacious streets, meeting each other at right angles, and taking their names from the situation of the gate which originally stood at the bottom of each, as East Gate street, West Gate street, North Gate street, and South Gate street. At the inter- section of the streets, formerly stood a large and beautiful crofs; but falling to decay, and impeding the passage of carriages, it was removed in 1750; its site still retains the name. The city is well paved and lighted; and its elevated situation, with a gradual descent on every side, greatly contributes to health and cleanliness. The markets had long been established by preceptive right; but those now held, on Wednesdays and Saturdays, were chartered by Henry III. Three fairs are held annually and much frequented. The...
house and population have varied considerably in different ages, according to the degree of security or danger which the inhabitants experienced: the progress has been several times interrupted by fires and civil commotions. Since the siege in 1643, the increase has been regular. On the last enumeration, under the act of 1801, the houses, in the city alone, amounted to 1568, the population to 7255; the inhabitants of the suburbs being 1500 more. Gloucester is situated 106 miles W. from London.

Among the more eminent natives of this city is Robert of Gloucester, who wrote a chronicle of Britain in verse, from the age of Brutus to his own time, the reign of Henry III.

On the north-west side of Gloucester is the celebrated Site of Abbey, a small tract, formed by the separation of the stream of the Severn into two channels. This was the scene of a combat between Edmund Ironside and Canute the Dane, in the year 1016.

In the southern suburbs of Gloucester are the remains of St. John's priory, founded in 1187. After the dissolution, the monastic buildings were converted into the offices of a farm. The only parts now left are a large barn, and the principal entrance, or gateway; on which are the arms, among others, of the Bishops. earls of Hereford, who were great benefactors to the priory. Rudders History, &c. of Gloucester. Beauties of England and Wales, vol. v.

Gloucester and Berkeley, in the parliamentary county of Gloucester, are the names of several places in the county.

Gloucester, or Cape Ann, a township of America, in Essex county, Massachusetts, whose east coast forms the N. side of the bay of Massachusetts. It contains 3513 inhabitants, and is divided into five parishes, besides a society of Universalists. It is a post-town and a town of entry. The harbour is open and accessible to large ships, and is one of the most considerable fishing towns in the commonwealth. At the harbour, properly so called, are fitted out annually from 50 to 70 vessels, and from Squam and Sandy bay, two small harbours, the fishery is carried on with great facility, and to a large amount. Thatcher's island, on which are two lights, lies close to the S. E. side of the township, which is itself joined to the continent by a bank of sand, that is rarely overflowed with the water. Here is a fine white sand, fit for the manufacture of glues. The harbour is defended by a battery and citadel erected in 1795—16 miles N.E. by E. of Salem, and 34 N.E. of Boston.

Gloucester, the N. watermost township, and the largest, in Providence county, Rhode Island, being 111 miles square, containing 4359 inhabitants.

Gloucester, the name of a county in New Jersey, bounded N. by Burlington county, S. by Salem, Cumberland, and Cape May counties, E. by the Atlantic ocean, and W. by Delaware river. Its length on the Delaware is about thirty miles, and on the sea it is about 22 miles. Great and Little Egg Harbour rivers are both navigable for vessels of about 200 tons about 20 miles from their mouths. The streams which fall into Delaware river are navigable for small vessels, a few miles up from their mouths, and afford some fuel, roach, herrings, and perch. Its adjacent islands are Red Bank, Pett, and Old Man's creek. Two of the county is a mixture of sand and loam, and the tract bordering on the Delaware is in a high state of cultivation. The chief productions are beef, pork, fish, hay, corn, lumber, butter, cheese, &c. It is divided into ten townships, viz. Woodbury, Waterford, Newtown, Gloucester township, Gloucester town, Deptford, Greenwich, Woolwich, Egg harbour, and Galloway. Musicus river divides the county from Burlington, and is navigable 10 miles for vessels of 60 tons. Maurice river runs southerly about 40 miles through Cumberland county into Delaware bay, and is navigable for vessels of 100 tons 15 miles, and for halfhops 10 miles further. It contains 27,365 inhabitants, of whom 61 are slaves. In this county are found quantities of bog-iron ore, which is manufactured into pig, and bar iron, and hollow ware. Here is also a glass-house. The chief town is Woodbury, nine miles S. of Philadelphia.

Gloucester, a small town in the above-mentioned county, on the E. side of Delaware river, three miles below Philadelphia. Also, a poll-town in Virginia, in the county of its own name, on a point of land on the N. side of York river, 17 miles distant from York town.

Gloucester, a county in Virginia, fertile and well cultivated, bounded N. by Piankisunk river, which separates it from Middlesex, E. by Matthews county and Chesterfield bay, N.W. by King and Queen, S. and S.W. by York river, which divides it from York county. It is about 55 miles long and 30 broad, and contains 3727 free inhabitants, and 4999 slaves. The low lands produce excellent barley, and Indian corn, the staple produce of the county.

Gloucester Haff, a flatness belonging to the Hudson bay company, situated in New South Wales, on the N. side of the waters which form a communication through a chain of small lakes, between Winnipig lake and Albany river. Henley haff lies N.E. of this, nearer the mouth of Albany river in James's bay. N. lat. 54°. W. long 87° 30'.

Gloucester, a township in the county of Dundas in Upper Canada, which is the seventh in ascending the Ottawa river; E. of, and contiguous to, the river Rideau.

Gloucester, Cape, a cape on the S. coast of Terra del Fuego—also, a high promontory on the S. coast of New Holland. S. lat. 59°. E. long. 148° 11'. Also, a cape on the coast of New Britain. S. lat 5°. E. long. 148° 15'.'

Gloucester Island, an island in the S. Pacific ocean, about six miles long, and from one to a quarter of a mile broad, discovered and so called by captain Wallis in 1767. It is surrounded by rocks, full of trees, and inhabited by persons who appeared armed with long pikes or poles, but deftate of canoes. S. lat 10°. W. long 140° 3'.'

Gloucester, Duke of, Island, two islands in the S. Pacific ocean, discovered and so called by captain Carteret in 1767, which were covered with trees, but appeared to be uninhabited. The southermost of them was a slip of land in the form of a half-moon, low, flat, and sandy; the appearance of it was pleasant, but it had neither vegetables nor water; but it abounded with birds, so tame that they might be taken by the hand. The other island very much resembled this, and is distant from it about five or six leagues; they lie W.N.W. and S.E. of each other. One of them is in S. lat. 20° 38'. W. long. 146°; the other in S. lat. 20° 34'. W. long. 146° 13'; the variation 5° E. These islands are probably the land seen by Quiros, as the situation is nearly the same.

GLOUCESTERSHIRE, one of the western counties of England, is surrounded by Herefordshire, Oxfordshire, Berkshire, Wilts, Somersetshire, and Monmouthshire. It comprehends an area of nearly seventy miles in one direction, by forty in a transverse line. This district, during the Roman domination in Britain, was much occupied.
plied by the Romans. Mr. Folbrooke (one of the historians of the county) observes, "from the ruins which have at various times been excavated, it is evident that this county, from Cirencester to Painwick, Bifkey, Sapperton, Woodchester, Uley, Kingscote, and other adjoining places, was much peopled by Romans, or Romanized Britons; that Cirencester was the great metropolis, or resort of pleasure and amusement; while Gloucester, and the hills about the Severn, were the great military postures; the city, on account of the river, having peculiar advantages with respect to commerce." The principal Roman roads which passed through this county, were the Icenhill street, the Iving or Erming street, the Fosse-way, and the Vin John. Under the dominion of the Saxons, Gloucestershire formed part of the Mercian kingdom, and Winchcombe and Kingstanley are mentioned as refuges of the Anglo-Saxon monarchs. On the division of Mercia into five bishoprics, after the conversion of the Saxons, the greatest part of this country was included under that named Wiccia, and from this appellation the Dobuni, the early inhabitants of this part of Britain, were afterwards termed Wiccis. Gloucestershire is separated into four divisions; these are subdivided into twenty-eight hundreds, containing 320 parishes, one city, and twenty-eight market towns. The number of houses, as returned under the population act, amount to 37,176; of inhabitants, 187,164; of which 96,027 were males, and 90,997 females. The whole county, with the exception of the chapelry of Ichorn, and Cowhowby, is included within the diocese of Gloucester, which comprehends one arch-deaconry, and ten deaneries. The number of representatives returned to parliament are eight; two for the city, two for the county, and two for Cirencester. The general aspect of Gloucestershire is greatly diversified; nature having divided it into three districts of very different character, respectively named the Hill, the Vale, and the Forest. The Hill district, including the Cotswolds, and the Stroudwater hills, may be regarded as a continuation of the central chain proceeding south from Pembroke, and passing through this county with a smaller elevation into Wilts; there swelling into the Salisbury Downs, and afterwards running west towards the Land's End in Cornwall. The extent of the Cotswold hills, from Broadway hill to near Tetbury, is thirty miles; and from Birdlip hill to Burford, about twenty miles: the area they include is estimated, by Mr. Marshall, to contain nearly 200,000 acres. The surface is hilly; and the climate, confidering the natural elevation of the land, unusually mild. The sides of the hills abound with springs; and almost every dip has its well, and every valley its brook. The primary object of the Cotswold habitants is sheep; these have been long famous; and it is a prevailing tradition, that the Spaniards originally procured their breed of fine woollen sheep from these hills, though this asserion is contradicted by several modern writers. The inclosures are chiefly stone walls, about four feet and a half high, exclusive of a coping of flat stones. The Vale district includes the entire tract bounded on the east by the Cotswold hills, and by the river Severn on the west; and is, in a large part, divided into the Vales of Exwell and Gloucester, and the Vale of Berkeley; the latter of which is separated from the former by a natural interjection, and is very different in produce and rural management. The Forest district is separated from the rest of the county by the river Severn, and is principally comprehended by the Forest of Dean, which was formerly of particular value for the goodness and strength of its timber. Its oaks were so greatly renowned that Evelyn observes, that in Elizabeth's reign, an ambaflador was purposely sent from Spain to procure its destruction, either by negotiation or treachery. It also abounds in beech; and the soil is considered as peculiarly favourable for the growth of the Stile apple. Its principal minerals are iron, ore, and coal: iron appears to have been wrought here even in the time of the Romans; and so early as the reign of Edward I., seventy-two furnaces, for melting iron, are recorded to have been built here. In a survey made in the seventeenth year of Charles I., the forest is estimated as originally containing upwards of 43,000 acres, of which above 14,000 were woodland. Several thousand acres have, however, been granted away, by different sovereigns, and disafforested. The miners have different courts, and, like those of Derbyshire and Devonshire, are governed by their own customs.

The principal rivers connected with Gloucestershire, are the Severn, the Frome, the Wye, and the Isis or Thames. The canals that intersect the county are distinguished by the names of the Thames and Severn, the Stroudwater, the Berkeley, and the Hereford and Gloucester. The Severn, the second commercial river in England, renders essential service to a large portion of this county. It enters Gloucestershire near the ancient town of Tewkesbury, where, uniting its waters with the Upper Avon, and pursu-ing a south-westerly course, it traverses a wide vale, which is rich in palmage, and in some places abundantly wooded. About one mile above Gloucester, 10 divides into two streams: these again unite a little below the city, forming the tract of land called Abbey island. In the course of its passage through the county, it receives the streams of the Upper Avon, the Chelt near Wainслоe, the Leden near Over'sbridge, the Frome at Framilode, the Avon at Berkeley, and the Lower Avon below Bristol. The Wye separates part of this county from Monmouthshire and Herefordshire, and forms the grand natural western boundary to the forest of Dean, whose noble wooded eminences constitute many fine features on its meandering banks. The Thames, the most important of the British rivers, has its source in this county, at a place called the Thames-head, near the village of Cotes, about two miles south-west of Cirencester. Near this place the Thames and Severn canal emerges from under ground, and receives a considerable quantity of water, occasionally from this spring. The junction of the Thames and Severn was an object of favourite speculation with the London and Bristol merchants for many generations; but not completely formed till the close of the sixteenth century, after that project was obtained in 1735, and the design was brought to perfection in 1792, when the first vessel passed from the Severn into the Thames. This canal begins at Wallbridge, near Stroud, (at the place where the Stroud navigation ends,) and proceeds in a deviuous course through the county to Lechlade, where it joins the Thames. This course includes a distance of thirty miles, seven chains and a half. The water, in its progress from Stroud to Sapperton, (seven miles three furlongs,) is raised by means of locks 241 feet 3 inches; between Sapperton and Lechlade it falls 135 feet 6 inches. The Stroudwater canal encounters many obstructions; yet in defiance of all opposition, an act was obtained in 1773, under the operation of which it was finished.

The manufactures of Gloucestershire are numerous: clothing fluffs, blankets, rugs, rugs, carpets, stockings, &c. are made in different parts of the county. Bat, iron, edge tools, herring, and many other articles, are also manufactured in large quantities. Near Bristol are some extensive foundries; as well as different works for making brass and wire, vitrili, red-lead, sal-ammoniac, &c. At Gloucester, vast quantities of pins are made; and at Frampton-Cotterell is a considerable

GLOVE, CHLOTHICA, a habit or covering for the hand and wrist, used both for warmth, decency, and as a shelter from the weather.

Gloves are distinguished, with respect to commerce, into leather gloves, silk gloves, thread gloves, cotton gloves, worsted gloves, &c.

There are also gloves of velvet, satin, taffety, &c. Leather gloves are made of shawm, kid, lamb, doe, elk, buff, &c. There are also perfumed gloves; washed, glazed, waxed gloves; and white, black, saff'nt-colour, &c. gloves; single, lined, topped, laced, fringed with gold, silver, silk, fur, &c.

It is a proverb for a glove to be good and well made, three kingdoms must contribute to it; Spain to drefs the leather, France to cut it, and England to sew it. But, of late, the French seem to have appropriated the functions of the other two; the gloves of the French manufacture being now said to have the advantage, in point of dressing and sewing, as much as of cutting.

By 34 Geo. III. c. 19. the British duty on gloves and mittens imposed by 25 Geo. III. c. 55. is repealed, except the duty on laces; and by 36 Geo. III. c. 80. the said duty on licences is also repealed. By 6 Geo. III. c. 19. and 25 Geo. III. c. 55. foreign manufactory leather gloves or mitts shall not be imported, under the penalty of forfeiture; and the importer or seller incur, besides forfeiture, a penalty of 200l. with double costs.

GLOVE, to throw the, was a practice or ceremony very usual among our forefathers, being the challenge whereby another was defied to single combat. It is still retained at the coronation of our kings, when the king's champion calls his glove in Westminster-hall.

Fawyn supposes the custom to have arisen from the eastern nations, who, in all their fables and deliveries of lands, goods, &c. used to give the purchaser their glove by way of livery or investiture. To this effect he quotes Ruth iv. 7 where the Chaldean paraphrase calls glove what the common version renders by thole. He adds, that the rabbins interpret by glove, that passage in the 34th Psalm, "In Thine abundant calmecatum nunc, over Edem will I call out my thole." Accordingly, among us, he who took up the glove, declared thereby his acceptance of the challenge; and as part of the ceremony, continues Fawyn, took the glove off his own right hand, and call it upon the ground, to be taken up by the challenger. This has the force of a mutual engagement on each side to meet at the time and place which should be appointed by the king, parliament, or judges.

The same author affirms, that the custom which obtained of blessing gloves, in the coronation of the kings of France, is a remain of the eastern practice of giving investiture with the glove, Lib. vi. p. 1817, &c.

The delivery of a glove was in frequent use formerly, as a symbol of investiture. See Du Cange, Gloss. Lat.

Gloves were also used to signify the reward or halfpenny, or part of the price of the investiture or purchase-money of the land. "Si aliquam territortiam partem venundarii contigerit, domini venditiones habebant; sefticis, tot denarios quot venditor inde habuerit folidos. Major vero terra illius pro quius occuparent duos donarios." Where quidem significant gloves, or, in French, gants.

Hence the common custom, in many bargains, of givingervants money for a pair of gloves.

Anciently it was prohibited the judges to wear gloves on the bench; and at present, in the tables of most princes, it is not safe going in without pulling off the gloves.

GLOVER, Richard, in Biography, was born at London in 1712. He received the elementary instructions in classical learning at Cheam, and exhibited a considerable taste for the classics, and an attachment to science. When he was only 16 years old, he wrote a copy of verses "To the memory of Sir Isaac Newton," which is prefixed to Dr. Pemberton's view of the Newtonian philosophy. He engaged in commercial pursuits, and became eminent in the mercantile world, to which he was introduced by his father. In 1737, he married a lady with a handsome fortune; and in the same year he published his epic poem of Leonidas. Glover had joined the opposition of the day, at the head of which was Frederic prince of Wales, and his poem, founded on the struggles of free Greece against Asiatic despotism, was calculated in a high degree to serve a generous cause. It abounds in noble sentiments, and is considerably varied by incident and description. Its plan is admirably adapted for poetical effect: it was received by Lyttleton and others with high applause, and very soon passed through three editions. "But it labours," says the critic, "under that want of interest which attends all modern epics, especially such as are built upon some of the sublimer events of ancient history; and its poetry is not of a character sufficiently elevated to engage the reader by the beauty of detached passages." The reputation which it first acquired soon subsided, and it now lives rather in memory than in the actual acquaintance of readers. He published in 1739, his poem, entitled "London, or the Progress of Commerce;" and the ballad of "Fofier's Ghost." Mr. Glover was not only a poet but an ardent politician, and was distinguished in various infinities for his eloquence in the caufe of freedom.

His talents gained him great credit, and he was appointed by the merchants of London to conduct an application to parliament, complaining of the neglect with which their trade had been treated. The speech which he pronounced at the bar of the house of commons on this subject, in January 1742, was greatly admired, and was published. His celebrity as a public character, did not favour his progress in commerce; his affairs became embarrassed; he was, to use a modern fashionable phrase, obliged to suspend his payments, and at length retreated from active life, to practice economy in an obscure situation. The duchess of Marlborough bequathed him, and Mallet, five hundred pounds each on condition of their joining to write the history of the great duke. Glover renounced the task, and Mallet never executed it. He now wrote several pieces for the stage, which being successful to a considerable degree his circumstances became so much improved, that he ventured to return to public life, and fat as member for Weymouth, in the parliament of 1761. His commercial knowledge made him extremely useful on several important occasions. In the year 1775, he took an active part in an application to parliament on behalf of the West India merchants, and for his zeal and fidelity he was complimented with a valuable present of plate. He died in November
November 1785, and left behind him another poem, entitled
the "Athenaids," relating, in thirty books, the wars between
the Greeks and Persians. This was published in 1788, in
three volumes 12mo., but it failed completely in attracting
public attention.

GLOVER, in Geography, a township of America, in the
state of Vermont and county of Orleans, N. E. of Crafts-
borough, adjoining. It has 36 inhabitants.

GLOVER'S Reef, rocks on the bay of Honduras. N. lat.
16° W. long. 88° 26'.

GLOW-worm, in Entomology. See Cicindela. Can-
tharis and Cicindela have been often used, indiscriminately,
for the glow-worm; but they form two distinct genera of
the same order in the Linnaean system. See Cantharis.
The glow-worm is often seen in the day time.
The male and female differ greatly in this species of insect.
The male has wings, and is a small fly; the female has no
wings, but is a large crawling worm.
The body of the male is oblong, and somewhat flattened;
the wings are shorter than the body; the head is broad, dun,
and flat; the eyes are large and black. This has no light
sufficing from it, and is not commonly appooped to be at all
of kin to the glow-worm.
The female is what we expressly call by this name; this
is a very flow-paced animal, without wings, and somewhat
resembling a caterpillar; the head is small, flat, hard, and
black, and sharp towards the mouth; it has short antenna;
and fix moderately long legs; the body is flat, and is com-
posed of twelve rings, whereas the body of the male consists
only of five; it is of a dusky colour, with a streak of white
down the back. It is often seen in the day-time, but it is
not known except in the dark; at which time it is easily
distinguished by the glowing light, or lommert flame, that is
seen near the tail, sufficing from the under part of the
body.
The common glow-worm is frequently met with under
our hedges, and, if carefully taken up, may be kept alive
many days on fresh tufts of grass; all which time it will
continue to shine in the dark.
The light of this little insect is so strong, that it will inflow
itself through several sublimates, in which the creature may
be put up; a thin pellio coarsely shews it through, and even
when lined with paper, the light is not impeded in its
passage by both. The creature is sluggish, and appears
dead in the day-time, and its light is not distinguishable;
even if carried into a darkened room, unless the creature be
turned upon its back, and disturbed, so as to be put in
motion, and then it is but faint; after fun the light
begins to return, and with it the light and motion of the
animal. The motion and light of this creature sjeem, in
some measure, to depend upon one another: it never shews
but when the body is in some sort of motion; and when it
shines most, the body is extended to one-third more than its
length in the day-time. In the time of brightest shining,
it will sometimes on a sudden turn its body about, and the
light will not be larger than the head of a pin; and, on
being touched, it will then immediately extend itself, and
the light will become as large and bright as ever. Phil.
Trans. N. 71.

Two points seem to be agreed upon by naturalists, with
regard to the light sufficing from the tail of a glow-worm;
that it is phosphoric, and secondly, that its use is to
to attract the male insect. Should the singularity, if any
such there be, in the natural history of this animal, which
should render a provision of this kind more necessary for the
glow-worm, than for other insects, be a subject of inquiry;
it may be observed that this singularity seems to be the
difference, which subflects between the male and the female,
which difference is greater than what is found in any other
species of animal whatever. The glow-worm, as we have
observed, is a female caterpillar, the male of which is a fly;
likely, comparatively small, dissimilar to the female in ap-
pearance, probably also as differing from her in habits,
purposes, and manners, as he is unlike in form and external
constitution. Hence it appears, that the caterpillar cannot
meet her companion in the air. The winged rover disdains
the ground. They might never therefore be brought to-
tgether, did not this radiant torch direct the volatile mate to
his sedentary female.

"In this example," says the ingenious author now cited,
"we see the resources of art anticipated. One grand opera-
tion of chemistry is the making of phosphorous; and it was
thought an ingenious device, to make phosphoric matches
supply the place of lighted tapers. Now this very thing is
done in the body of the glow-worm. The phosphoric is not
only made, but kindled; and caused to emit a steady and
powerful beam, for the purpose which is here stated, and which
I believe to be the true one." Paley's Natural Theology,
p. 353.

Glow-worm, Flying, cicindela volans. In the warmer
months of the year, this creature is sometimes caught in our
housetops flying to the flame of a candle, and when examined
in the dark, it is found luminous at these times, though
perhaps less, or not at all so, at others; which may be a
reason of its not being known, though caught in the fields;
and to this it may be owing, that many who have described
it have thought it not a native of England. Without wings
it is frequently enough found in form of the common glow-
worm, and then always flies. Aldrovand has very well
described the cicindela volans, and says, that it lays eggs,
which hatch into small worms, and that these after a time
become flies, by the same fort of change which happens to
caterpillars and other reptiles which become butterflies,
and other species of winged insects. Monfett, and Thomas
Bartholomew, both describe the animal much as Aldrovand
has done, but they allow the male only to have wings; but
Julius Scaliger contradicts this, and says, that he has caught
them both winged in the act of generation: this is a plain
proof that both sexes are winged; yet it has not happened
that both sexes have been acknowledged to be so, even by
those who have quoted this passage. And Mr. Walker,
who gives an account of them in the Philosophical Trans-
actions, offered them in the same manner in the act of
copulation both winged, and with no other difference be-
tween them but that the female was the larger of the two,
which is the case in regard to many insects. Julius Scalig.

The male and female in this winged forme both shine in
hot weather, and their light is so vivid as to be easily seen
while there is a candle in the room; the vibrations of it are
irregular and its colour greenish. The luminous parts are
two small specks under the tail at the end, and the light continues
in these same time after the tail is cut off, but then gradually
goes out.
The parts of insects continue alive in some degree for a
considerable time after they are cut off, and probably the light
in the tail of this animal continues just as long as that fort
of life remains in it. Monfett. Cap. 15.
The use of this light seems to be to direct the animal in its
course, and in the taking of its prey, and to this purpose it
is admirably placed. The tail is easily bent under the belly;
then throws the light full upon any object about or under
the head of the animal, and the eyes are placed not on the upper
part but on the under side of the head; so that they have
all
all the advantages of it, while the light in this part is not offensive to the eyes, as it naturally would have been if carried before the head. The creature can, upon occasion, cover this light, so as not to be known, or purposed by it, by its enemies. Thomas Barthol. de Luce Anim. lib. ii. cap. 12.

This insect is of the beetle kind, of a brown and dusky colour. It has hard case or shell wings, as the other beetles have, and when these are expanded, there appear a pair of very large membranous ones; its head is covered with a sort of shield or broad-brimmed hat: under this hat are placed the eyes, which are black and large, and are movable, so that the creature can, upon occasion, thrust them forward: it has two hairy antennae, and its legs are like those of the common fly, hard, fuzzy, and hairy. Its eyes afford an elegant object for the microscope, being composed of an infinite number of lenses, as those of the lichelle and other insects. Aldrovand. de Insect. lib. i. cap. 8.

Gen. Ch. Cal. Perianth superior, of five oblong, spreading, nearly equal leaves. Cor. of one petal, obliquely bell-shaped; gibbous at the base; its border in five round-obtuse lobes, the four uppermost recurved, the lower one prominent, concave and inflexed. Stam. Filaments four, much shorter than the corolla, with the rudiment of a fifth; inserted into the receptacle, connected with the base of the corolla, incurved, downy, converging laterally in the upper part, two of them rather the short; anthers ovate, peltate, two-celled, cohering together, their lobes diverging. Pyl. Germen inferior, turbinate, furrowed; style cylindrical, as long as the fructification, stigma capitate. Peric. Capsule imperfectly, two-celled, with two valves, and two lateral divided receptacles. Seeds numerous. Juff.

Ef. Ch. Calyx superior, of five leaves. Corolla bell-shaped, with an oblique irregular border. Filaments, with the rudiment of a fifth, inserted into the receptacle. Capsule bell-shaped, with many seeds, inserted into lateral receptacles.

1 G. maculata. Curt. Mag. t. 1191. (Martynia perennis; Linn. Sp. Pl. 862. Hort. Chiff. t. 18. Ehret. Dict. t. 9. f. 2. Mart. Mill. Dict. v. 3.—Native of South America; the seeds having been sent from Carthage by Mr. Robert Millar, before 1739. It requires with us the cool heat of a hard flow, by means of which it flowers late in autumn. It is propagated abundantly by the little tuberous roots, which are perennial. The stem is herbaceous, simple, leafy, round, very smooth, spotted with purple. Leaves large, ovate, recurved, flaked, broad-ovate, acute, serrated, smooth and shining, pale at the back, with prominent veins. Flowers axillary from the diminished leaves, or bractes, at the upper part of the stem, solitary, flaked, large, drooping, of a fine blue with a dark spot at the bottom within. Their scent is very peculiar, resembling mint, which no writer seems to have noticed.
GLUCK.

The music of France had reached a high point when Gluck arrived. His friends feared its fierce onslaught, but there was much melody and always movement, in the music, though it was full of new and ingenious passages and effects; he would like much to hear this air well performed at the opera; it is kept alive from beginning to end. Something might be expected from a young man able to produce this opera, imperfect as it was. It had, however, but five representations.

From London he returned to Italy, and composed several operas in the style of the times, such as that of Terradellas, Galuppi, and Jomelli; and he heard little of him till he embarked with the Italian poet Calzabigi, with whom he joined in a conspiracy against the poetry and music of the melodrama then in vogue in Italy and all over Europe.

It is extraordiary that Calzabigi, editor of the beautiful Paris edition of the works of Metastasio in 1755, in the preface to which there is the highest and seemingly mild cordial praise of the works of the imperial laureate, should be the first, ten years after, to find them so defective; writing his "Orfeo" in a different style, and joining with Gluck in decriing the lyrical style both of the music and poetry of the Italian opera.

In 1764, the year in which the late emperor Joseph was crowned king of the Romans, Gluck was the composer, and Guadagni the principal singer. It was in this year that a species of dramatic music, different from that which then reigned in Italy, was attempted by Gluck in his famous opera of "Orfeo," which, with Guadagni's admirable action, succeeded so well, that it was soon after attempted in other parts of Europe, particularly at Paris and Berlin. This is not the place to discuss its merit; we shall here only observe, that the simplifying dramatic music in Gluck's manner, in favour of the poet, at the expense of the composer and singer, is certainly very rational, where an opera is performed in the language of the country, and the singers have no great abilities to display, as in France; but in England, where we have frequently fingers of uncommon talents, and where so small a part of an opera audience understands Italian, by abbreviating the symphonies, and prohibiting divisions and final cadences, in favour of an unintelligible drama, we should lose more than we should gain.

After its successes at Parma and Paris, "Orfeo" was exhibited at Bologna, Naples, and in 1770 in London; where the principal parts were filled by Guadagni and Grafix, after-warly very popular.

The unity, simplicity, and new dramatic excellence, which at Vienna, and afterwards at Paris, rendered this drama so interesting as to make the audience think more of the poet than the composer, were greatly diminished here, by the heterogeneous mixture of music of other composers in a totally different style.

In 1769, Calzabigi and Gluck, encouraged by the successes of "Orfeo," produced "Alcaide," a second opera, on the reforming plan, at Vienna, which received even more applause than the first. In 1771, the same poet and musician brought a third opera, "Paride ed Elena," on the stage at Vienna, written and composed in the same new, or rather old, French style, with better music, in which Mellico was the principal singer, and which afforded the audience such pleasure as seemed to have impressed the lovers of music in the imperial capital with a partiality for that species of dramatic music, which was not likely to be soon obliterated.

In 1772, Gluck let to music an opera taken from Racine's "Iphigenia," in which he so far accommodated himself to the national taste and style of France, as frequently to imitate and adopt them. And as this opera was intended for Paris, his friends feared for its success, as there was frequently melody, and always movement, in his music, though set to French words, and for a serious French opera.

But the year 1774 was rendered remarkable in the annals of French music, by the arrival of the chevalier Gluck at Paris, whose operas, by his conforming to the genius of the French language, and flattering the ancient national feeling, were received with acclamation. He began his career in this capital by his celebrated opera of "Orphée," of which the reputation was already established; and this was followed by "Iphigenia," taken from one of Racine's best tragedies, which had all the success that may be imagined from the force of his genius applied to a favourite drama, set in the style of their favourite composers, Lulli and Rameau.

In his opera of "Cycthe Asphodes," 1775, where more delicacy and tenderness, than force, were required in the composition, he was not so successful. Nor was his "Alembe," the year following, received with the same rapture as at Vienna. Indeed his "Armide," in 1775, did not quite fulfil the ideas of grace, tenderness, and pathos, which some of the scenes required, and auditors accustomed to Italian music expected; however, his operas were excellent preparations for a better style of composition than the French had been used to; as the recitatives were more rapid and the airs more marked, than in Lulli and Rameau; the airs were likewise more voluntary in their beginning, and infinitely more force and effect in his expression of grief, remorse, vengeance, and all the violent passions.

Gluck's music is so truly dramatic, that the airs and scenes, which have the greatest effect on the stage, are cold, or rude, in a concert. The situation, context, and interest, gradually existing in the audience, give them their force and energy.

Indeed, he seems so much the national musician of France, that since the best days of Rameau, no dramatic composer has excited to such enthusiasm, or had his pieces so frequently performed. It has been said in the "Journal de Paris," that each of his pieces had supported two or three hundred representations. The French, who feel very enthusiastically whatever music they like, heard with great rapture the operas of Gluck, which even the enemies of his genre allowed to have great merit of a certain kind; but though there is much real genius and intrinsic worth in the dramatic compositions of this master, the congeniality of his style with that of their old national favourite and Rameau was not unmixed with the friends of that music. The almost universal cry at Paris was now, that he had recovered the dramatic music of the ancient Greeks; that there was no other worth hearing; that he was the only musician in Europe who knew how to express the passions; those and other encomiums preparatory to his apotheosis, were uttered and published in the journals and newspapers of Paris, accompanied with conflabulations and contemplative cenuses of Italian music, when Piccini arrived. This admirable composer, the delight and pride of Naples, as Gluck of Vienna, had no sooner erected his standard in France, than all the friends of Italian music, of Rondeau's doctrines, and the plan, if not the language, of Metastasio's dramas, enlivened in his service. A furious war broke out; all Paris was on the qui vive; no door was opened to a visitor, without this question being asked previous to his admission: "Monseigneur, cherchez-vous Piccini ou Gluckart?" These disputes, and those of musical critics, and rival artists throughout the kingdom, seem to us to have fumed and diminished the pleasure arising from music in proportion as the art has advanced to perfection. When every phrase or passage in a musical composition is to be analyzed and dissected during performance, all delight and enthusiasm are extinguished.
enthusiasm vanish, and the whole becomes a piece of cold mechanism. It is certainly necessary for professors to study care and effect, and to make themselves well acquainted with the fundamental rules of their art; but we would advise true lovers of music to listen more than talk, and give way to their feelings, nor lose the pleasure which melody, harmony, and expression ought to give, in idle enquiries into the nature and accuracy of their auricular sensation.

The cavalier Gluck, after returning to Vienna from Paris, and being rendered incapable of writing by a paralytic stroke in 1784, only lingered in a debilitated state till the autumn of 1787, when he died at the age of seventy-three.

Gluck had great merit as a bold, daring, nervous composer; and as such, in his French operas, he was unrivalled. But he was not so universal as to be exclusively admired and praised at the expense of all other composers ancient and modern. His style was peculiarly convenient to France, where there were no good singers, and where no good singing was expected or understood by the public in general; and where the poetry was set up against music, without allowing equality, or even an opportunity of manifesting her most captivating vocal powers.

It is, however, allowed by an exclusive admirer of Gluck, in the Encyc. Meth., that "the Italians have the glory of having furnished examples of almost every kind of beauty of which music is susceptible, and of having disseminated their taste in every part of Europe;" but adds, that "France will owe to the celebrated Gluck the having first conceived the system of a music truly dramatic, and our theatre will furnish true models of it to other nations, and to posterity. Let us be content to dwell from the Italians and the Germans the glory of laying the true foundation of a musical system and of transforming the most amiable and touching of arts, into a science as intertesting as it is fertile."

Gluck, in a moment of "frantage," over a bottle, said: "The French are a very good sort of people, who love music, and what songs in their operas; but they have no fingers." And Scribe, being asked how his operas were executed at Paris, said, "God forbid I should ever go to hear them performed!" And there are the people who are to furnish models of dramatic music to Italy, and to all the rest of Europe!

GLUCKSBURG, in Geography, a town of Denmark, with a fortress, in the district of Skelwick; nine miles E. of Flensburg.

GLUCKSTADT, a sea-port town of Germany, in the kingdom of Holstein, belonging to Denmark, situated on the Elbe. This town is regular and well-built, and its market place commands the chief streets. Several canals run through it, and the principal one crosses near the market place, and is here connected with another, which divides the town into two nearly equal parts. On the land side it may be laid under water. Gluckstadt is the feast of the king's regency, and of the offices and courts connected with it. Here is also a grammar-school. The Calvinists are permitted to have a church, the Roman Catholics a chapel, and the Jews a synagogue. In 1738 a commercial college was instituted here by king Christian VI., as it was a place of some trade; and in 1750, king Frederic V. established an office for keeping the harbour, adjoining to which is a basin for the reception of vessels, in good condition. Gluckstadt was built in 1620 by permission of Christian IV. in a walled town called the Wildenreis, and in the patent granted to it, he ordered that it should be called Gluckstadt, or the Fortunate Town; he also conferred upon it many customs, rights, and privileges, such as were enjoyed by the town of Wilt: and it was soon after invested with the Lubeck and Hamburg rights. It is distant 28 miles N.W. from Hamburgh. N.lat. 53° 51'. E. long. 9° 20'.

GLUE, Glue has a number of uses, tenacious matter, serving as a cement to bind or connect divers things together.

There are divers kinds of glues made use of in the divers arts; as the common glue, glue glue, parchment glue; but the two last are more properly called fes.

The common or strong glue is a commodity used by numerous kinds of artificers; as joiners, cabinet-makers, cafe-makers, hatters, book-binders, &c. and the consumption thereof is very considerable. The bill is made in England, in square pieces of a ruddy brown colour: Flanders glue, which is whiter and transparent, is held the next after the English. The most ordinary glue of France is black and opaque.

Glue is made of the skins of all kinds of beasts; as oxen, cows, calves, sheep, &c. The older the beast is, the better is the glue that is made of its hide. Indeed, it is rare they use whole skins for this purpose; those being capable of being applied to better purpose; but they make use of the shavings, parings, or scraps of the hides, and also horns; and sometimes they make it of the feet, haws, nerves, &c. of birds; and also of the pelts obtained from furriers.

That made of whole skins is the best, and that of fowees, &c. the worst; and hence, chiefly, arises the difference of glues, and the advantage of English and Flemish glues.

GLUE, method of making.—Mr. Clesnel, in the Monthly Magazine for 1802, gives the following statement of the general mode of its manufacture. The materials above enumerated are "first digested in lime-water, to cleanse them from grease or dirt; they are then steeped in clean water with frequent stiring, and afterwards laid in a heap and the water pressed out. They are then boiled in a large brass cauldron with clean water, scumming off the dirt as it rises, and it is further cleansed by putting in, after the whole is dissolved, a little melted alum or lime finely powdered. The scumming is continued for some time, after which the mass is strained through baskets, and suffered to settle, that the remaining impurities may subside. It is then poured gradually into the kettle again, and further evaporated by boiling and scumming, till it becomes of a clear dark brownish colour. When it is thought to be flxing enough, it is poured into frames or moulds about six feet long, one broad, and two deep, where it gradually hardens as it cools, and is cut out when cold by a spade into square cakes. Each of these is placed in a fort of wooden box open in three divisions to the back; in this glue, while yet foid, is cut into three slices, by an instrument like a bow, with a brafs wire for its string. These slices are then taken out into the open air, and dried on a kind of coarse net-work, fastened in movable heds four feet square, which are placed in rows in the glue maker's field. When perfectly dry and hard it is fit for sale. That is thought to be the best glue which swells considerably without melting by three or four days' immersion in cold water, and recovers its former dimensions and properties by drying. Glue that has got froth, or that looks thick and black, should be melted over again. To know good from bad glue, the purchaser should hold it between his eye and the light, and if it appears of a strong dark colour, and free from cloudy and black spots, the article is good. When glue is used by the carpenters, they break it and soak it for about 24 hours in cold water; and then melt the leaked pieces, causing it to simmer for a quarter of an hour over a slow fire and frequently stiring it. When cooled it becomes a firm jelly, which may be cut by any instrument. It is merely warmed for use, and in this state spread over the surface of the wood with a flat brush. In an interval from one
one to three days the pieces of wood will be so perfectly coagulated, that boards, thus coagulated, will as readily break in any part as separate at the juncture. Glued boards will not set in a freezing temperature; the stiffening being occasioned by the evaporation of the superfluous matter of the glue, which is prevented by a considerable degree of cold.

GLUE, Bee. See WAX.

GLUE, Fjib, is a sort of glue made of the nervous and mucilaginous parts of a large fish, found chiefly in the Russian seas. These parts, being boiled, bear a near resemblance to that viscid matter found on the skins of cod-fish. When boiled to the consistency of a jelly, they spread it on a leaf of paper, and form it into cakes; in which state it is sent to us.

Fish-glue is of considerable use in medicine, and divers others arts; where it is better known under the name of flinglafs and ichthyocolla. See IINGLASS.

A strong and fine glue may be prepared with flinglafs and spirit of wine thus: Keep the flinglafs for twenty-four hours in spirit of wine or common brandy. When the mezelrum has evaporated and clarified the flinglafs, they must be gently boiled together, and kept simmering till they appear well mixed, and till a drop thereof, suffered to cool, presently turns to a strong jelly. Then strain it, while hot, through a clean linen cloth, into a vessel to be kept close stoped. A gentle heat suffices to dissolve this glue into a transparent and almost colourless fluid, but very strong; so that pieces of wood, glued together with it, will separate elsewhere than in the parts joined. Boyle’s Works abridg. vol i. p. 150.

A strong compound glue may be made by infusing a mixture of common glue, in small pieces, with flinglafs glue, in as much spirit of wine as will cover them, for about twenty-four hours; then melt the whole together, and add as much powdered chalk as will make it an opaque white.

A strong glue, that will retain moisture, may be obtained by dissolving gum sandarac and mastic, of each two ounces, in a pint of spirit of wine, and adding about an ounce of clear turpentine; then take equal parts of flinglafs and parchement glue, and having pounded them into small pieces, pour the solution of the gums upon them, and mix the entire mixture in a covered vessel, with a heat less than that of boiling water: then strain the glue through a coarse linen cloth, and putting it again over the fire, add about an ounce of powdered glafs.

Or, a strong glue, that will retain water, may be made by adding half a pound of common flinglafs glue to two quarts of skimmed milk, and evaporating the mixture to a due consistence.

A glue, that will hold against fire and water, may be made by mixing a handful of quicklime with four ounces of limed oil, boiling them to a good thicknes, and spreading the mixture on tin plates in the shade; it will thus become exceeding hard, but will easily be dissolved over a fire, and be fit for use. See CEMENT.

GLUMA, a Hugh, in Botany, is the peculiar calyx of grasses and grass-like plants, and indeed their corolla, at least what is so termed by Linnaeus, is of the same chaffy nature. Huks or Glumae are usually comprized, embracing each other at the base; more rarely they are deprefsed, flattened vertically, as i Quaking-gras or Briza. To the hulk belongs the arill or arm, (see ARIST) which is a brittle-shaped appendix, usually spiral, and possessing the properties of an hygrometer. It originates from the midrib or keel of the hulk, and is either terminal or doralf, being in the latter case placed sometimes very far down the back of the hulk, as in many species of Avena, and in these instances it belongs to the glumes that constitute the corolla, not the calyx. The arillæ, though so remarkable, is by no means always constant in the same species, though nearly invariably so in the flowers of the same individual plant.

Huks are mostly furnished with one central longitudinal rib, though the inner glume of the corolla in grasses have two nearly marginal ones. They have in most instances, besides the central rib, a greater or less number of lateral ones, all likewise longitudinal, of great use in distinguishing species of Poa and other difficult genera. Their margin is commonly thin and more or less membranous or fesride. Some glume always remain separate and distinct from the seed which they commonly unfold; others are closely incorporated with that part as it ripens, of which a curious example may be seen in Briza.

Some sorts of viviparous grasses exemplify the transformation of glumes into leaves in a remarkable manner, the awn remaining at the summit being perhaps the only indication of their original nature. See Airo Lirigata, Engl. Dict. 2132. The same metamorphosis of a petal into a leaf is indeed not rarely seen in a Tulip and other cultivated flowers. We have a wild species of a similar change in Arranum alpina, part of whole leafy involucrum is become a perfect petal.

Glumes are, we believe, invariably permanent, never deciduous, till the seed ripens, when those of the corolla fall off along with the seed, serving the purpose of a pericarpium.

GLUMACEOUS FLOWERS, a term applied by some botanists to the flowers of the natural order of grasses, expressive of their chaffy nature.

GLUMMEN, in Geography, a town of Prussia, in the province of Natangien; 24 miles S. of Königsberg.

GLURANTZ, or GLUES, a town of the county of Tyrol, situated on the river Adige, built in 1562, and surrounded with walls in 1530. It was taken by the French in 1799: 36 miles W. of Brixen. N. lat. 45° 38'. E. long. 10° 26'.

GLUS, in Surgery, a species of dysuria, attended with a copious quantity of mucus in the bladder. Hence, the malady has been named dysuria mucosa.

GLUT, among Fowlers, the fliny substance that lies in a hawk’s pouch.

GLUE, in Rural Economy, a term sometimes provincially applied to a large wooden wedge.

GLUTA, in Botany, so called by Linnaeus, from the Latin word glutus, thrust close together, in allusion to the close application of the claws of the petals to the stalk which elevates the organs of fructification. Professor Martyn seems not to have been aware of this derivation. We are led to it by the repeated indication of the circumstance in Linnaeus, and his use of the word adglutinata, even in the generic character, as well as in his subsequent observations. Linna. Mant. t. 2. 160. Syll. Veg. Ed. 14. 821. Schreb. 1:25. Willd. Sp. Pl. v. 1. 1120. Mart. Mill. Dict. v. 2. Jull. 427. Clas and order, Pentandria Monogynae. (Linnaus refers it to Gynandra Pentandria.) Nat. Ord. Capparidae, Jull.

Gen. Ch. Cal. Perianth inferior, of one leaf, membranous, bell-shaped, obtuse at the base, cloven half way down into two lobes, deciduous. Cor. Petals five, equal, lanceolate, bluish, somewhat oblique, four times the length of the calyx; their upper part spreading horizontally; their claws cohering round the stalk of the germen, and attached to it. Stam. Filaments five, bristle-shaped, rather shorter than the petals, inserted into the summit of the stalk of the germen; authors various, rather oblong. Pfiff. Germen 3 B 2 obovate,
GLO

above), standing on a cylindrical stalk, which is rather longer than the calyx; style thread-shaped, equal to the filaments; stigma simple, obtuse. Peric. and Stells unknown.

Of Ch. Calyx bell-shaped, cloven, deciduous. Petals five; their claws coiling round the stalk of the germin. Stamens inserted into the top of that stalk, of the germin.

1. G. Benghaii. Linn. Mant. 2. 292. Native of Java, where it is called Bengha, and if we mistake not, in the Malay language Dodee. This plant is unknown to all botanists except Linnaeus, by whose herbarium alone it can be determined. His remarks have led the fludants of natural orders wide of the truth concerning it, for nothing can be more like the solla. To Sterculia it has some resemblance, and we have been much inclined to refer it to Judieen's Malvaceae, especially from its likeness in some respects to the Affania of that author and of Cavanilles; but on examination this likeness proves fallacious. The most probable place for it is among or near the Capparidaceae, but the fruit being unknown, leaves this matter in great doubt. After all, it may be thought to belong to some near order, which the fludants of natural arrangement are but too prone to make on every emergency, and the French in particular seem to think they drew their skill by their reminiscences on this head, whereas it is but an easier fault, though a more fatal one, than that of making too many genera, and ought to be watched with tenfold care.

The Glaea Benghai appears to be a frond or tree, with slightly pubescent branches and buds. Leaves scattered, most numerous about the ends of the branches, from three to ten inches long, elliptic-lanceolate, bluntish, entire, tapering down at the base into a short footstalk; they are smooth on both sides, furnished with one rib and many transverse veins connected by innumerable reticulations. Sipulata none. Flowers nearly the size of Glaea Flammula, or, as Linnaeus says, of a cabbage blossom, in a coriaceous pance; whether terminal or axillary cannot be determined from the specimen, though he affirms the former. There is some appearance of a glandular depression at the back of the footstalk where it joins the leaf.

S.

GLUTEA, ARTERIA, in Anatomy, a large artery distributed chiefly among the gluteal muscles. See Artery.

GLUTENS, ANIMAL, in Chemistry. See Animal Fibre and Glue.

GLUTENS, VEGETABLE, a substance resembling the former, and found in several vegetables. (See Vegetable Fibre.) Bozachi first found that wheat-flour contained glutens in considerable quantity, and from this it is obtained by the following process. (Aikin's Dict.) Mix 16 great quantity of wheat-flour with a little water, and knead it with the hand into a tough ductile paste, then let a very slender stream of water keep dropping on the paste, while it is incessantly worked about with the hands, and the water will run off white and turbid, owing to the fecula or flarch which it carries off. The paste in the mean time gradually becomes more of a grey and almost semi-transparent appearance; and when the water runs off quite clear, nothing is left in the hands but pure gluten. No other precaution is required in this preparation but that of not dressing the flour at first with water, but only using a very small quantity with much kneading, that the gluten may not be carried off along with the flarch. Good wheat-flour will yield in this way about a fourth of its weight of gluten, and no other flour but that of wheat will yield it, except in a very small proportion, and hence probably the peculiar property of wheat-flour to make bread without any other addition than a ferment." See Bread.

Gluten is contained in small quantity in several vegetable juices and other parts, and may be separated from them. Bird-lime is supposed to be chiefly gluten, and the green fecula of plants abounds with it. See Bird-lime and Fecula.

GLUTEUS, in Anatomy, a name given to three large muscles, concerned in the motions of the pelvis and thigh, and distinguished from each other by the epithets magnus, medius, and minor. They occupy the outer and posterior part of the pelvis, from which they arise, and form the large flaky prominences named the buttocks.

The gluteus magnus, or maximus, is a very broad, thick, and bulky muscle, composed of large fasciculi loosely connected together, and separated to a considerable depth by adipose and cellular substanse, of an irregularly quadrilateral figure, and situated obliquely at the outer and back part of the hip. The round ed swelling, which forms the outline of the buttock at its back part, and the projection of which hides the termination of the large intestine, is formed entirely by this muscle. Its external surface has the same degree of convexity as that of the buttocks; the internal, which covers the tenderness of the ischium, and the great trochanter, is proportionally concave. It arises, on. By short aponeurotic fibres, from about one inch of the posterior extremity of the crista ili, where the bone extends beyond the facia, and from the neighboring part of the immediately subjacent nates. At this origin an aponeurosis may be observed, continuous with that of the thigh, and of the vertebral muscles. 2ndly. From the ligament connecting the posterior end of the iliac crista, to the back of the facia; and here it is continuous with the tendinous origin of the latissimus dorsi, longissimus dorsi, and semitendinosus. 3rdly. From the external margin of the facia, near its left foramen, from the tubercle at the side of the termination of the canal containing the medulla spinalis, and from the articulation between the facia and coccyx. 4thly. From the posterior surface of the coccyx. 5thly. From the surface of the great sphenoid ligament. From these points the fibres all proceed obliquely downwards and outwards, nearly parallel to each other; the muscle is at first rather thinner and narrower, and grows broader and thicker as it proceeds. Its upper margin is closely attached to that part of the femoral facia, which covers the glutaeus medius. The superior fibres, having turned over the great trochanter, join the upper part of the common tendon. The latter is most intimately connected to the facia lata; so that, on the first inspection, the glutaeus magnus appears to be inserted into this facia, throughout the whole line of its front edge; we cannot, however, easily distinguish these parts by cutting through the muscle, and turning it aside. The common tendon receives the muscular fibres from above the trochanter, to below the quadratus femoris, where it begins to be attached to the bone. It is very firmly attached to the rough line, which commences at the root of the trochanter, and joins the linea aspera, occupying by its insertion a space of about three inches; it is situated here between the vastus externus and adductor magnus, to the former of which it is connected by tendinous and muscular fibres.

The exterior convex surface of this muscle is covered for a small space towards its upper part by a thin plate of the facia lata, and is everywhere immediately subjacent to the integuments. The inner surface covers the os ischiium, the facia and coccyx, the origin of the vertebral muscles, the glutaeus medius, the pyramidalis, the gemelli, the obturator internus, the quadratus femoris, the tenderness of 6
the ilium, the origins of the femintendinosus and biceps, the adductor magnus, the sciatic nerve, and the great trochanter. A large synovial membrane, placed between this muscle and the ilium, arises from the surface of the former and is considered to afford a clear proof that man was designed for the attitude on two feet. This gives to the human frame the beauty and symmetry which we see in the mammals. The pelvis has been turned forwards, and the gluteus magnus will restore it; and if the circumstances admitted of this part being carried backwards, the same muscle would produce that motion. The other two glutei are not efficiently concerned in the attitude of standing on both feet; but they are the principal agents in supporting and balancing the trunk on one foot, and inclining the pelvis over the head of that thigh bone on which the body rests, so that the centre of gravity of the trunk may be in a line drawn through that lower extremity. In this case their exertion counteracts the tendency of the trunk to fall on that side which is not supported. These muscles are further employed in the same kind of way in progress: the gluteus magnus balances the pelvis which one leg is carrying before the other, and brought to the ground; and the two others support the trunk laterally, while the limb of the opposite side is in the air. In the attitude on one leg, the gluteus magnus can rotate the pelvis on the thigh-bone of its own side, so as to turn the symphysia pubis towards the opposite side. When the glutei move the thigh on the pelvis, the magnus reduces the bone to its former position, where it had been previously bent; and, if the pelvis be carried forwards, it may move the former still farther in the direction of extension; the medius and femi-medius move the thigh away from the opposite limb. The gluteus magnus has the effect also of rotating the thigh outwards; while the anterior fibres of the two smaller muscles will rotate it inwards. The former is a tenor of the facia lata.

GLUTTON, in Zoology. See Vursus Gula.

GLYCAS, Michael, in Biography, a Greek historian, who is supposed to have flourished in the 12th or 13th century, though by some others he is referred to the 15th. He was a native of Byzantium, but spent a great part of his life in the island of Sicily. He published, in four parts, containing the history of the world, from the creation to the birth of Christ, and that of the Byzantine emperors down to the death of Alexius Comnenus in 1188, interpolated with a number of theological, philosophical, and physical discussions. An edition of the "Annales" in Greek and Latin was given to the public by father Lübke, in 1668. The third part has been published separately by Meurinus, with a version and scholia. Several letters of Gleys have been published in different collections. He was undoubtedly a very learned man, and the correspondence which he maintained with the literati of his age shew that he lived in very high reputations. Moreci.

GLYCERIA, in Botany, from ψίρες, sweet, the seeds being eaten in Germany, and called Mamma-seeds, on account of their sweet taste. Brown Prod. Nov. Holl. v. 1. 179—Class and order, Triandria Digynia. Nat. Ord. Gramma. This new genus of grasses is founded by Mr. Brown on the "Pennis fluitans" of Linnéus, Penna fluitans, Sm. Fl. Brit. 95, with the following characters.

"Glycera" (Calyx) of two valves, containing many flowers. "Spicis" cylindrical, awnless. "Perianth" (Corolla) bearded, its valves of equal length. "Scale under the greenen foliary, sickly, like a half shield. Stigmae doubly compound. Seed
GLYCINE.

unconnected, oblong, with a furrow at one side. Flowers somewhat panicled."

We cannot but advert to the propriety of separating the genus in question from Pass and Pfefferia, as far as habit is concerned, but we are very certain that Pass diffusa, marrineri, precumbers, and rigid of Fl. Brit. and Cynanchus durus of Linnæus cannot fail to go along with it, though we fear the characters given by the gigantic writer above quoted will not be found to hold good in all, if in any, of these. Perhaps the following definition of Glycine, formed on simple and obvious Linnæan principles, may be unexceptionable, as embracing them all, and preferring an analogy with genera already established.

Calyx of two valves, containing many florets. Spikelet linear. Corolla of two oblong, obtuse, bearded valves. S.

GLYCINE, from glycos, sweet, the particular application of which is not very obvious, having originated merely from the sweet taste noticed by Cornuti in the leaves and tuberous roots of G. Apis. This indeed is the original, and perhaps the only true Glycine, the numerous assemblage of species ranged under this genus, by recent writers, being very various and in fruitification, especially those of New Holland, as will appear by Mr. Bucquoi's definition of the second part of his valuable work.——Linn. Gyn. 373. Schreb. 495. Willd. Sp. Pl. v. 3. 1053. Mart. Mill. Dict. v. 2. Ait. Hort. Kew. v. 3. 73. Juss. 357. Lamarck Illustr. t. 1. 529. DC. t. 154. Clasf and order, Diadelphus Decandria. Nat. Ord. Papilionaceæ. Linn. Leguminosæ. Juss.

Gen. Ch. Cal. Perianth inferior, of one leaf, compressed, two-lobed; upper lip notchèd, obtuse; lower longer, three-lobed, acute, its middle tooth longest. Cor. papilionaceous. Standard inerely heart-shaped, deflexed at the fides, gibbose at the back, the extremity at the top, and straight, till driven back by the keel. Wings small, oblong, ovate towards the extremity, bent downwards. Keel linear, falcate, curved upwards, prelving the standard upward by its obtuse and dilated extremity. Stam. Filaments in two sets, (one simple, the other in nine divisions,) gradually separated at the top, revolute; anthers simple. Pet. German oblong; style cylindrical, rolled spiral; stigma obtuse. Peric. Legume oblong. Sedi kidney-shaped. Eff. Calyx two-lobed. Stamens in distinct sets. Keel of the corolla forcing back the standard with its point.

Obf. Glycine Apis and frutescens have a two-celled legume. G. moschata is a singular instance of a separation of sexes in flowers of this tribe.

This genus has accumulated from two species (G. Apis and frutescens) in the Hortus Cliffortianus, to eight in the firft edition of Species Plantarum, nine in the second, fifteen in the fourteenth and last edition of Syst. Vegetabilium, and finally to forty-four in Willdenow. These now form a very heterogeneous assemblage, and the New Holland ones constitute a distinct genus, the Kennedean of Ventenat, distinguished by its spontaneously reflexed standard, and legume of many cells. The whole requires a thorough revision. Some are of opinion that G. Apis is generically distinct from all the others, and if so it would be more convenient, though this is one of the original species, to give it the generic name of Apis, retaining Glycine for such more common and more numerous ones as may answer to the usual idea of the genus, an essential character being selected to combine them together.

Glycine, in Gardening, contains plants of the shrubby climbing kind; of which the species cultivated are the shruoby glycine, or Carolina kidney-bean tree (G. frutectens); the two-spotted glycine (G. bimaculata); the reddish-flowered glycine (G. rubicunda); and the fawyer glycine (G. coccinea).

Method of Culture.—In the first it may be effected by laying down the young branches in the early autumn. When well-rooted in the following autumn, they may be taken off and planted where they are to remain, or in nurseries-rows, being watered when the weather is hot, and the roots protected in the winter by some fort of hawny material. They are found to succeed best in dry, warm, light soils of ground.

And the other kinds may be raised by sowing the seeds when they can be obtained from abroad, or produced here in pots of light earth, in the early spring, being afterwards removed into other pots, and placed in the green-house, or Cape flow. It has been surpassed by Mr. Curtis, that the two last may succeed in the open air, when planted out in warm sheltered situations, and protected during the winter season by some convenient matting or other means.

All the sorts are ornamental in their flowery climbing growth; the first in the open ground, and the latter in the green-house and flower collections.

Glycine, Glycine, Fr. in Chemistry. This earth was first discovered by M. Vaquelin in 1798. He detected it in the analysis of the beryl, undertaken at the desire of Hali, who wished to have it ascertained by a strict chemical inquiry, whether the beryl and emerald were as similar in their composition as in the form of their crystallizations. The results of this inquiry were conformable to the expectations which gave rise to it, and the existence of a new earth in the beryl and emerald was confirmed by the experiments of Klapproth. Vaquelin, in the memoir in which he announced his discovery, called the new substance merely the earth of the beryl: afterwards, with his associates, Guyton, Fourcroy, and Chaptal, he determined on the name glycine, derived from the Greek glykos, sweet, because all the soluble salts of this earth have the property of producing a certain sweet astringent tincture. When the name was selected, the character on which it was founded was peculiar; but though it ceased to be fo on the discovery of vitriol, yet as the name conveys no erroneous ideas of the body, to which it is applied, there is no impropriety in adhering to it: besides, the table full forms as a physical characteristic for, according to Vaquelin, the sweetness of the salts of glycine has a sensible difference from that of the salts of vitriol, particularly of the sulphate.

Glycine, in its pure state, has not yet been discovered in nature; indeed, its occurrence in compound minerals is exceedingly rare, for it has only been found in the beryl, or ultramarine, and the emerald and the gadolinite; and it enters but sparingly into the composition of these bodies; the beryl, in which it is most abundant, containing, according to the analysis of Vaquelin and Rabe, no more than 17 per cent. From the analogy which exists between glycine and alumine, the former is very liable to be taken for the latter by chemists who do not pay particular attention to accuracy in their analytical inquiries. The first analyses of the emerald made by Klapproth and Vaquelin afford an infall of this kind; and M. Bindeheim committed a similar error in his analysis of the beryl.

To obtain glycine in a state of chemical purity, finely powdered beryl is to be effused with three times its weight of caustic potash in a silver or platinum crucible: the crucible is to be exposed for two hours to a strong red heat, and the mixture in fusion is to be frequently stirred with an iron rod, in order to keep the earth as much as possible suspended.
The description of the document content is as follows:

**GLYCINE.**

Glycine is a white, translucent glass, which does not become opaque on cooling. It refines on mixing with sulphur or phosphorus, but it appears from Fourcroy that a sulphur may be formed by decomposing the sulphate of glycine by charcoal. Glycine is soluble in a saturated solution of sulphuric acid. A hydro-sulphate of this earth, it is likewise said, may be obtained by dissolving the sulphate in water. In these properties it approaches the alkaline earths, and constitutes apparently the link of union between them and the clays to which it belongs. It is dissolved by both the fixed alkalies in their liquid state, but in a less degree than alum, and, like alumine, is not taken up by amonia. It is dissolved in a solution of carbont of amonia, as has already been mentioned. It very readily unites with acids. All its soluble salts produce, when first tainted, the formation of sweetnefs, which gradually becomes alriagent.

In relation to its affinity for acids, glycine appears to be intermediate between alumine and magnesium, for it decomposes only the salts of alumine, yttria, and zircon. And the order of its affinities is much the same, according to Fourcroy, as that of the other earths, sulphuric acid holding the first place, and nitric, muriatic, phosphoric, fluoric, boracic, and carbonic following. No experiments have been undertaken yet, to ascertain what combinations of glycine is capable of forming with the earths and metallic oxides.

Yttrium and alumine are the only earths for which glycine is liable to be mistaken: the properties in which it resembles them are, rather unfortunately, of a most striking kind, but it has a number of other characters which are very distinctive, and fully demonstrative of its peculiar nature. Glycine is similar to alumine, in being soluble in certain solutions of the fixed alkalies, and in some of its physical qualities; but it differs from alumine in affording with acids sweet alrimental salts, in not yielding alum with sulphuric acid and potash; in posilising a greater affinity for acids; in being entirely soluble in carbont of amonia; and lastly, in not being precipitated from its solutions by oxalat, tartrat, or prussiat of potash. It is to be distinguished from yttrium, by its greater solubility in carbont of amonia, the latter requiring for its solution five times as much carbonted alum as glycine, by its fall of solubility in carbont of amonia, the latter requiring for its solution five times as much carbonted alum as glycine, by its fall of solubility in carbont of amonia, the latter requiring for its solution five times as much carbonted alum as glycine, by its fall of solubility in carbont of amonia, the latter requiring for its solution five times as much carbonted alum as glycine.

Glycine was considered as a simple body, till the important discoveries of Mr. Davy gave it new analogies; and though the compound nature of this earth is not yet fully demonstrated, yet there is every reason to believe that glycine, like the alkalies and alkaline earths, is a metallic oxide; and the results of the experiments which Mr. Davy made on this body are explained by such a supposition. This gentleman negatively electrified glycine, slightly moistened in contact with an amalgam of potassium, under naptha, by a battery of 200 plates. After an hour the amalgam was thrown into water, and an alkaline solution was produced, which became cloudy when neutralized by acid, thus indicating the presence of the earth. Mr. Davy, following the nomenclature which he has adopted in respect to the new metals, has proposed glucium for the name of the metal of glycine, when its existence is no longer doubtful.

Carbonate of glycine, as well as all the other metals of this earth, has not yet been discovered ready formed in nature. It is procured by precipitating the sulphate, nitrat, or muriat of glycine, by either of the carbonate fixed alkalies. The precipitate, which is the salt sought after, being well washed and dried, appears in the form of soft white powder, having a greasy feel and great lightness. Carbonate of glycine is insoluble in water, and it is unaltered by exposure to the air. It is decomposed by all the acids, and by the action of a red heat; most probably all the alkaline earths deprive it of carbonate acid in the moist way. According to Klaproth it is composed of

**Phosphat of Glycine.**—Phosphat of soda, added to a neutral solution of nitrat of glycine, throws down this salt either in a white plumbous form, or in a mucilaginous state. It is insoluble in water, impid and uncremallizable. It is not decomposed by a violent heat, but it fuses into a white transparent glass, that does not become opaque on cooling. Phosphat of glycine is soluble in phosphoric acid. The sulphuric and nitric acids first diffuse this salt, and
and afterwards decompose it. Muratic acid produces a
fumarolic effect, but in a less degree. It is likewise readily
decomposed by the carbonated alkalis and by all the car-
bonated earths, except carbonat of magnesia. With the ful-
phat, nitrat, and muriat of alumine, it suffers decomposi-
tion, a mutual exchange of acids taking place between the
two earths.

**Sulphat of Glycine.**—Glycine, both in its pure and car-
bonated state, diffuses very readily in dilute sulphuric acid.
The solution by spontaneous evaporation affords octahedral
crystals, composed of two oblique four-sided pyramids
joined base to base, with their edges and solid angles trun-
cated. It also, but with difficulty, yields when evaporated
on a sand bath small needle-form crystals. The solution,
when evaporated nearly to dryness, assumes a fumarous con-
finement. Sulphat of glycine, has a remarkable sweet
and alluring taste. It is very soluble in water. Heated,
it intumescence, suffers the watery fusion, and becomes pul-
verulent from the distillation of its water. It is completely
decomposed by a strong red heat, the acid being expelled
and the earth left in its pure state. It has been already ob-
erved that fulphat of glycine is converted, when heated
with charcoal, into a fulphurat, but this fulphurat, according to
Fourcroy, does not become a pyrophorus, like alum
thus treated, though fulphat of potash be present. A sotu-
ion of nut-galls, added to this salt dissolved in water,
produces immediately a white precipitate. Previous to the
knowledge of this fact, such a property was conceived to
be peculiar to metallic salts.

Sulphat of glycine, slowly evaporated with a small
quantity of fulphat of potash, forms minute crystalline
grains, which dissolve with ease in seven or eight times
their weight of cold water. Glycine, added to a solution
of alum, precipitates the alumine, and most probably pro-
duces a compound, similar to the preceding one. Sulphat
of glycine is decomposed by all the alkalis and earths,
except alumine, yttria, zircon, and flix.

**Nitrat of glycine** is procured by saturating nitrif acid
with glycine. The solution of this salt does not afford
crystals by evaporation, but produces a ductile and adhesive
mass, which, when further dried, falls into powder. It is
very soluble in water and insensitive in the air. It attracts
moisture so strongly, that it might, if strongly pressed, be ad-
vantageously employed for absorbing the hygrometrical
water of gases. Its taste is suffocating and balsamic.
Thickening of galls dropped into a solution of this salt pro-
duces a yellowish brown precipitate. Nitrat of glycine
fuses at a low heat, but if the heat is increased, the acid is
expelled. It is decomposed in the moist way by fulphuric
acid, and by the same alkalis and earths as the sulphat.
The proportions of its component parts are not known; but
Vauquelin has observed that a given quantity of nitrif acid
requires rather more glycine than alumine for its complete
saturation; yet the former earth, though in combination with
nitrif acid more soluble than the latter, decomposes, with
the assistance of heat, nitrat of alumine, precipitating the
alumine, and forming nitrat of glycine.

**Muriat of glycine** is procured by dissolving glycine in
muratic acid. It is in some respects similar to the nitrat,
but differs in its solution, affording by careful management
small crystals, the form of which, on account of their size,
have not yet been determined; and in not being subjected to
deliquescence on exposure to the atmosphere. Its taste is
similar. A solution of this salt in dilute alcohol is said to
be an agreeable sweet liquid. When distilled per fes, the
acid distills off, and leaves the earths in a state of purity. It
is also decomposed when heated with phosphoric acid. The
fume effect is produced by sulphuric and nitrif acids, and
by the alkalies, and all the earths that decompose the nitrif.

**Actat of glycine.** which is prepared by dissolving
the earth in acetic acid, has not yet been procured in a crys-
talline form. Its solution, when evaporated, acquires a gluttonous
confinement, and the salt becomes brittle as it slowly

**Succinat of Glycine.**—Any of the succinates added to
the nitrat, muriat, or sulphat of glycine, precipitate the
salt in question. Its properties have not yet been enquired
into.

We are indebted for the imperfect knowledge we have of
the combinations of glycine, with the several acids above-men-
tioned, principally to the celebrated discoverer of this earth.
Glycine, in no form as yet, has been usefully employed; yet
Vauquelin conceives that the earth itself and some of its
fats, when they can be procured with facility, may admit
of such an application in chemistry, in medicine, and the
arts. Its marked attraction for animal and vegetable col-
ouring substances induced him to think that there was
a probability of its being serviceable as a mordant; and
the peculiar taste of some of its fats gave rise to the hope
that these combinations might produce salutary effects on
the animal system. If his expectations should be realized, we
must agree with Vauquelin, that these fats will be some of
the most agreeable medicines that exist. Ann. de Chem.
part. ii. 1808. p. 352.

**GLYCONIAN, GLYCICON.** in the Greek and Latin
poetry.

A Glyconian verfe is that consisting of two feet and a
yllable; at least this is Scaliger's opinion; who adds, that
the Glyconian verfe was also called the Europician verfe.
See Verses.

Others hold, that the Glyconian verfe consisted of three
feet, a pondece and two dactyls; or rather a pondece, chlo-
riambus, and an iambus or a pyrrhic; which opinion is
the most followed.

"Si te diva potens Cypris," is a Glyconian verfe.

**GLYCYRRHIZA, in Botany.** Liquorice. Glycyrrhiza
is of Dioscorides, who describes the plant very faithfully and
accurately; but it is remarkable that he says the flower
is like a hyacinth, which can allude to the colour only, whether
his name be the Delphic hypsithros of modern botani-
tains. The word is composed of γύκος, sweet, and ρηζις, a
root; and the name in apothecaries' Latin, liquiritia,
as well as the English one, liquorice, the French reglifre,
the Italian regalzina, &c. with all their corruptions, originate
t. 625. Ger. t. 148. Clairv. and order, Diadepia Decan-
Gen. Ch. Gen. Pieranth inferior, of one leaf, tubular,
two-dipped, permanent; upper lip in three deep segments,
of which the lateral ones are linear, the central broadened
and cloven; lower perfectly simple, linear. Cor. papilion-
aceous. Standard ovato-lanceolate, fragrant, longell. Wings
oblong, very like the keel, but rather larger. Keel of two
petals, acute, its claw the length of the calyx. Stam.
Filaments in two fes, one much, the other in nine divisions,
fragrant; anthers simple, roundish. Fil. German shorter
than the calyx; styleawl-shaped, as long as the flumes;
 stigma obtuse, ascending. Petio Lappate ovate or oblong,
compressed, acute, of one cell. Seeds very few, kidney-
shaped.
GLYCYRRHIZA.

Eff. Ck. Calyx with two lips; the upper three-leaflet; lower simple. Stamens in distinct sets. Legume ovate, compressed, of one cell. Seeds one or two.

2. G. fetida. Desfont. Atlant. v. 2. 1709. t. 159.—Legumes prickly. Flowers spicked. Stipulas lanceolate. Leaflets feally beneath; the terminal one nearly sessile.

5. G. aesculina. Linn. Suppl. 330. Pallas. Reis. v. 3. t. G. 1. 1. 2. (G. hispida; ibid. 754.)—Legumes smooth, beaded. Flowers spicked. Stipulas lanceolate. Leaflets roundish, prickly beneath. Stem and footstalks prickly. Found by professor Pallas in sandy ground between the river Wolga and the Tanais. Pallas MSS. The root is extremely sweet, especially in the spring. Stems usually two, rarely three, aching, a span high, nearly simple, leafy, rough with numerous little rigid prominent prickles, as are the footstalks, and backs of the leaflets. The latter are roundish or obovate, obtuse with a little point, smooth and velvety above. Flowers longish, pale violet, with white wings and keel, in one or two thick spikes at the top of each stem. The legumes are drawn by Pallas above an inch long, recurved, of a necklace-like form, and smooth, containing many seeds. The calyx is oblong, purplish, rather hairy. It has the habit of a Glycyrrhiza, flowers of an AfroGalana, and fruit apparently of a Coronilla; nor does the calyx answer to the generic character, being five-leaflet.

6. G. hirsuta. Linn. Sp. Pl. 1046. (G. orientalis, filicaulis hirsutiflora; Tourne. Cor. 26.)—Legumes hairy. Leaflets oblong-lanceolate, the terminal one on a long stalk. Flowers spicked. Found by Tournefort in the Levant. Root perennial. Of this we have seen neither a specimen, figure, nor any further description.

GLYCYRRHIZA., in Gardening, furnished a plant of the herbaceous perennial kind, the common liquorice (G. glabra). It is a plant which has the roots running very deep into the ground, and creeping to a considerable distance, especially where they stand long uninjured.

Method of Culture.—A light sandy soil is the most adapted to the growth of this sort of crop, as its good effects consists in the length of the roots. The ground in which it is intended to be planted should be well dug and dunged the year before planting, that it may have become perfectly mellow, and the dung well rotted and mixed with the earth, otherwise it will be apt to flow the roots from running down and being properly supported; and immediately before planting it should be well dug again to the depth of three spades, and be laid very light and open.

When the land is thus prepared, fresh plants taken from the sides or heads of the old roots should be provided, care being taken that they have each a good bud or eye, being about ten inches long and perfectly found.

The operation of planting them should be performed about the middle of March, which is done in this manner: a line is first set across the ground, then, with a long dibble made on purpose, the flowers or cuttings are put in, so that the whole plants may be set into the ground, with the heads about an inch under the surface, in a straight line about a foot asunder in the rows, and a foot and a half or two feet row from row.

When the whole spot of ground has been thus planted, a thin crop of cowans may be sown over the land. These must be kept perfectly clean by the hoe, care being taken not to cut off the tops of the liquorice plants, as it would greatly injure them. All the onions which grow near the heads of the liquorice should also be removed. In October, the flowers of the liquorice should be removed, and a little very rotten dung spread upon the surface.

In the following spring, about March, the ground should be slightly dug between the rows of liquorice, burying the remaining part of the dung, being very careful not to cut the roots.

During the summer they must be kept quite clean by occasional hoeing. The same operations must be annually performed, so as to keep the ground and plants in perfect order.

These plants must remain three years from the time of planting, when they will be fit to take up for use, which should be done when the flags are perfectly decayed; as when taken up too soon, the roots shrink greatly, and lose in weight.

In taking up the roots the ground is trenched over, row after row, to the full depth, and the young roots taken from the old roots cut into lots for new plantations; which should be made annually, in order to keep a constant succession of roots fit for being taken up.

The great art in this culture is to have the earth well trenched to a proper depth, to have good sets, and to keep the
GLYSTER. See CLESTER.

GMELIN, John George, in Biographia, a physician and eminent botanist, was born at Tubingen on the 12th of August, 1709. He was distinguished by his diligence and early attainments at school, and at the age of fourteen was deemed ready for entrance upon the academical studies of his native place. In 1727, he took the degree of doctor of physic, and went to Peterburgh, whither some of his teachers had been invited. Here he gained many favours from Blumentooff, the director of the academy, and was so highly esteemed, that, in 1729, he was elected one of the members of the academy, and in 1731 was appointed professor of chemistry and natural history. In 1733, he was selected for the department of natural history, in a commission formed by the Russian government, for the purpose of exploring the boundaries of Siberia; and set out on the 19th of August, with G. F. Muller, and Louis de l'Isle de la Croeyer, and a party of twenty-eight persons, consisting of draughtsmen, miners, hunters, land surveyors, and twelve soldiers, with a sergeant and drummer. In the month of February, 1743, Gmelin returned safe to Peterburgh, after having employed nine years and a half in this long and dangerous journey, which proved highly interesting to the sciences, and he returned the offices which he had before filled. In the year 1749, he entered upon a new professorship, to which he had been appointed, on the death of his predecessor, and on his return to Tubingen. He died of a fever in May, 1755, in the forty-fifth year of his age. The works, which were the result of his travels through Siberia, obtained for him a considerable celebrity, especially his "Flora Siberica, seu Historia Plantarum Siberiae," Peterburgh, 1747, 1749, in two parts, large 4to, with one hundred plates: the third and fourth parts were published by S. G. Gmelin. He also published his "Reise durch Sibirien," &c.; or Travels through Siberia between the Years 1733 and 1743, Gottingen, 1751, 1752, in four parts, 8vo, with plates. Gen. Biog.

GMELIN, Samuel Gottlieb, son of Philip Frederick Gmelin, was born at Tubingen in 1743; where he obtained both his philosophical and academical education, and graduated M. D. in 1763. He gave early proofs of genius, and during his travels in France and Holland distinguished himself so much by his knowledge of natural history, that he was appointed professor in the Academy of Sciences at Peterburgh. Like the subject of the preceding article, he spent several years in travelling through the distant provinces of the Russian empire, for the purposes of scientific investigation; but ultimately with a less fortunate result. He was appointed, together with professor Goldschnitt, to explore the province of Astraran, at the time that the transit of Venus over the sun's disc was expected, and set out in June, 1768. Having examined the countries on the western side of the Don, the Peridan provinces on the south and south-west side of the Caspian sea, the banks of the Wolga, and, lastly, the eastern side of the Caspian, so dangerous to travellers, he was recalled to Peterburgh. But when he had arrived within three days journey of Killar, a fortress on the Russian borders, he was seized by the chieftain of Chitakes, who plundered him of all his property, treated him with great barbarity, and imprisoned him. The health of Gmelin suffered considerably at this time, and he laboured under a flux, brought on by improper food and the effects of climate; yet the barbarian chief intercepted the provisions sent to him from Killar. The emperor gave orders that he should be released by force; but this was rendered impossible at that time by the rebellion of Paganief, and Gmelin died in confinement, on the 27th of July,
July, 1774. His death was much regretted by Catherine II., who made a liberal provision for his widow.

His works are: "Historia Fucorum," printed at Petersburg in 1768, 4to.; a subject to which botanists had paid little attention before him. "Reisen durch Russland, &c.:" or, Travels through Russia, for the purpose of exploring the three kingdoms of nature. This work was published in separate parts, as follows:—Part I. Journey from St. Petersburg to Tcherkaf, in the years 1768 and 1769. Petersburg 1771 with thirty-two plates. Part II. Journey from Tcherkaf to Astrakan, from April 1769 to June 1770; ibid. 1774, with forty plates. Part III. Journey through the northern districts of Persia, from that period to April 1772; ibid. 1774, with fifty-one plates.—Part IV. ed. after the author’s death, by professor Pallis, Journey from Astrakan to Cazirizyn; and also a second Persian Journey, 1772–74; ibid. 1786, with eighteen plates. The various and important information, contained in these publications, renders the imperfections of the style of this author of little moment. Gen. Biog.

GME, in Botany, received its name from Linnaus, in honour of John George Gmelin, a native of Tübingen, professor of chemistry and natural history at Petersburg, who spent ten years in travelling through Siberia, at the expense of the Russian government, and whose Flora Siberica, in four vols. quarto, with plates, is a book of great reputation and merit. The first and second volumes were published in his lifetime; the third and fourth long after his death, which happened in 1755, at the age of 46. He took his arrangement from Van Royen. Haller says the plates are unworthy of the beautiful drawings, which he himself had seen. This genus also serves to commemorate four or five more botanists of the family, especially Samuel Theophilus Gmelin, nephew of the former, and his successor in the professorship, who published a Historia Fucorum, with plates, in 1768, one of the most popular books on submarine botany, and who died in 1774, aged 31. Linnaeus 315. Schreb. 412. Willk. Sp. Pl. v. 3. 513. Mart. Mill. Dict. v. 2. Jaff. 108. Lamarck. Illust. t. 542. Caussin. t. 56. (Michelia; Amman in Ait. Petr. v. 8. 218. t. 18.)—Clafs and order. Didynamia Angiospermae. Nat. Ord. Peronoeae, Linna. Pictas, Jaff. Gen. Ch. Cal. Perlantia very small, inferior, of one leaf, nearly globular, with four small unequal teeth, permanent. Cor. of one petal, ringed, inflated; its limb four-cleft; the upper segment large and vaulted; lower, and lateral ones, smaller, obtuse, rounded, spreading. Stam. Filaments four; the two uppermost shorter and thicker; two lowermost curved upwards; anthers two-lobe; two of them sometimes smaller and simple. Pyl. German superior, roundish or obovate; style as long as the longer filaments, ascending; stigma acute. Peric. Drupa ovate, of one cell. Nutri. Obovate, smooth, of three cells, the lowermost abortive. St. de foliis. Eff. Ch. Calyx with four flat teeth. Corolla four-cleft, ringed, bell-shaped. Anthers cloven. Drupa superior. Nut of two fertile cells.

1. G. afsetosa. Linnaeus, Sp. Pl. 873. Burman. Ind. 132. (Jambula sylvatica parvifolia; Rumph. Amb. v. 1. 129. t. 40.)—Leaves roundish, somewhat three-lobe, acute, downy beneath. Native of Java, Amboina, and other parts of the East Indies. A tree, with straight, roundish, thinly downy branches. Leaves opposite, scarcely two inches long, of a roundish or elliptical form, acute, most generally furnished with a short broad lobe at each side, entire; smooth above; pale and downy beneath; the midrib fending off two principal lateral ones, a little above its base, and several smaller ones higher up, all which are branched. Foot- leafs downy, various in length, often nearly equal to the leaf, each with a small hairy bud above its insertion, and above that usually a straight, downy, horizontal spine. Flowers in a short, simple, downy, terminal raceme. Calyx downy, bespangled with several large, shield-like, smooth glands. Corolla large, yellow.

Rumphius's figure unquestionably belongs to this plant, but his description terms that of an Eugenia. Plukent's t. 305, f. 3. is certainly Eugenia dumetorum, and resembles our Gmelina only in being thorny; his t. 97, f. 2, may possibly be intended for Gmelina parvifolia, but is of no use as determining it.

2. G. elliptica.—Leaves elliptical, undivided, obtuse, downy beneath. Thorns none. Native, we presume, of the East Indies, confounded in the Linnucean herbarium with the foregoing, from which it differs in having rather larger leaves, which are exactly elliptical and blunt, more densely downy beneath, and not lobed. There are no traces of thorns. The inflorescence is rather more compound, but the remarkable glabrous calyx is the same. If a variety it is a very extraordinary one.

3. G. parvifolia. Roxb. Corom. v. 2. 31. t. 162. (G. coromandelica; Burman. Ind. 152.)—Leaves obviate, undivided or three-lobe, smooth on both sides. Common in evergreen and uncultivated places on the coaft of Coromandel, flowering in October and November. Roxburgh. It is often intermixed with G. affedosa, from which it differs in its more humble size, larger and conical thorns, and especially in its smaller leaves, which are smooth on both sides. Their flowers and fruits are alike, the latter being yellow, obovate, the size of a small cherry. We perceive on one calyx in our specimen a solitary gland, like those described in the two former.—Dr. Roxburgh mentions that cold water, stirred with a leafy branch of this shrub, becomes thick, from the abundant mucilage of the leaves, and is used in that state as a remedy for the heat of urine which accompanies gonorriphra. Water stirred with branches and leaves of Pediluminus Murex becomes in like manner mucilaginous, and is used for the same purpose, but soon loses its consistency, which is not the case with such as is prepared with this Gmelina. The Telingas call the plant Sibiri goosmadoo. It may possibly be Plukent's Lyricum Maderaspatumum, t. 97. f. 2, as Burman takes it to be, but Skoane's Rhamnus, Hilt. of Jamaica, v. 2. t. 207. f. 1, cannot be the same, though his figure affords no distinct indication of what he means.

4. G. arbores. Roxb. MSS. (Cumbulu; Rheed Hort. Mal. v. 1. 75. t. 41.)—Leaves heart-shaped, undivided, pointed, downy beneath; their lateral ribs cloven. Thorns none.—Sent from the coast of Coromandel by the Rev. Dr. Rottler, with the above name of Dr. Roxburgh. Gærtner has most justly pointed out the Cumbulu of Rheed as a Gmelina, though quoted by Linnaeus, doubtfully indeed, for his Bignonia Catalpa. This is a tall and upright tree, growing in sandy ground, with downy branches, and large, opposite, dalkeo, heart-shaped, entire leaves, downy and veiny beneath. Thorns none, as far as we can learn. The flowers are numerous and handsome, yellow, growing in compound, hairy, terminal clusters. Fruit yellow, obovate, rather small.

5. G. indica. Burman. Ind. 132. t. 59. f. 5. (Dorye Zock-kan of the Malay.) Leaves alternate, heart-shaped, crenate, smooth on both sides. Native of Java. Herb. Linna. A shrub or tree, with round, somewhat zig-zag, slightly downy branches. Leaves from half an inch to an inch long, alternate, or short hairy stipules. Vom, bluntly crenate. Thorns
straight, slender, acute, mostly longer than the leaves. The flowers and fruit seem to be unknown. We have only Bartram's very feeble authority for making this a Genista, which its alternate crenate leaves strongly disconcert, nor did Linnaeus ever venture to adopt it. S.

G. MONI, in Geography. See GESUNDEN.

G. NAA, a town of the district of Sturlia; 24 miles S.E. of Graz.

G. NADENJUETTEN, a settlement of the Moravians in America, situated on Muhkingum river, opposite to Salem, in the lands which belonged to the Mahican Indians.

Alfo, the name of a Moravian settlement, on the S.W. bank of Lehigh river, in Pennsylvania, about 20 miles N.W. of Bethlehem.—Alfo, a Moravian settlement, called New Nadianuetten, on Harlem river, about 24 miles from lake St. Clair, in the county of Wayne, and 28 N.W. of Detroit.

G. Napeezie, a town of Birma, on the Irrawaddy; so called from Napier, or Naples, a fort of sprat, half pickled and half putrid, used as a sauce by the Birmanis, and forming an extensive branch of trade: 116 miles N.N.W. of Rangoon.

G. Naphalium, in Botany, a plant, an ancient Greek name, from παφαλιον, fast down or weed, such as is plucked in cloth in dressing it, alluding to the woolliness of the herbaceus. Many writers have contended that Sambula marina of Linnaeus, and Sam. Fl. Brit. 867, is the true παφαλιον, an opinion extremely difficult to establish or to contradict, as all he says of it, that "its leaves are white and soft, useful for stuffing." However this may be, Tournefort, and lately Gaertner, have retained that plant, as the true and only species of Gnaphalium. The Gnaphalium of Linnaeus however is a very extensive and comprehensive genus, from which all species have of late been separated. See EVENKVEST—Cud-wool.—Linn. Gen. 419. Schreb. 550. Willd. Sp. Pl. v. 3. 1849. Mart. Mill. Dict. v. 2. Ant. Hort. Rar. v. 3. 173. Sm. Fl. Brit. 867. Jul. 179. (Elenchum; Gartn. t. 166. Antennaria; Gartn. t. 167. Anaisen; Gartn. t. 168. Filago; Gartn. t. 166. See Filago.) Chaff and order, Spongiastrum Polygamy-sperma. Nat. Ord. Composita Nutricula. Linn. Cylindracea, Jul. 179. Ch. Gaertn. 1829. Pit. matted, rounded; scales numerous, the marginal ones rounded, scarce, coloured. Car. compound, florets of the disk perfect, tubular, funnel-shaped, in five equal reflexed marginal segments; some female ones, without a corolla, are often intermixed towards the margin. Sain (in the perfect florets) Filaments five, very short, capillary; anthers forming a cylinder. Pfli!. (in the same floret.) German ovate; style thread-shaped, the length of the filaments; stigma cloven. In the female ones the same. Peri. none, except the permanent thinning calyx. Seeds in both kinds of florets alike, solitary, oblong, small, crowned with capillary or feathery down. Recipt naked. Edi. Ch. Receptacle naked. Down capillary or feathery. Calyx incised, its inner scales rounded, scarce, coloured. Willdenow reckons 145 species of Gnaphalium, of which 32 are shrubby, with allwo, white or crimson flowers, or rather without any golden ting; 12 are of a yellow or golden colour, likewise shrubby; 19 are herbaceous, with yellow, white or crimson flowers; 28 herbaceous, with white or reddish ones; and 20 have the inconspicuous whitish blossoms of the Filago family. The remaining 26 are species defined by Thunberg, without any attention to these leading features of the genus, so that it is impossible to lay to which they belong. Ten species, all herbaceous, are described as natives of Britain.

In this large genus it is by no means certain that all the species correctly answer to the generic character, particularly in the receptacle, which is not always flirrely naked, but bears a few bristles towards the margin, thus becoming an Ananthus of Gaertn. The marginal scales also, being sometimes a little pointed and reflexed, intertuch upon the proper character of Elchbrum: see for that article. In fact these genera are naturally one and the same, but, on account of their great extent, are conveniently separated by the character, though an imperfect one, of the more radiating calyx of Elchbrum. Linnaeus's error consisted in referring the latter to Xyranthum, which has a different habit and a chalky receptacle.

The first species in Wildenow, G. erosum, Linnaeus. 573. Curt. Mag. t. 360, is one of the most splendid. The leaves are clothed with very thick white wool, and the shrubby stem is terminated by a large corymbus of flowers, whose calyx is the size and shape of a rasperry-fruit, of a rich thinning crimson. The florets are orange-brown. It grows about 500 miles by the country above the Cape of Good Hope, and was for a long time known to European botanists merely by dried specimens, (one of which is figured by Edwards in his History of Birds, t. 183), brought occasionally to the Cape by the distant settlers.

Several others of the shrubby kinds are very ornamental to our green-houses.

Of the herbaceous sorts G. fistulm, whole flowers, usually yellow, are occasionally white or flirrey, always very splendid, is one of the most remarkable, but the strong scent of its vivid herbage when touched is offensive to most people. G. orientale is somewhat shrubby, though ranged with the herbaceous ones. Its thinning lemon-coloured flowers frequently serve for ornamental purposes, and are known by the name of Everlasting, a name appropriate to the whole genus.

G. margaritaceum, Engl. Bot. t. 2918, feres in Wales, where it grows wild, to adorn the Graves of the departed, elegantly alluding to immortality by the unfading nature of its flowers, and to spotless purity by the country where it grows. This plant is oft cultivated in cottage gardens.

G. deivum, Engl. Bot. t. 267, the Antennaria of Gaertn., so called from its plumy crown to the seed, is one of our most elegant species, found on dry rather mountainous heaths. The flowers are of a beautiful rose-colour.

The Cape of Good Hope is most fertile in this genus, but several fine species grow in South America, and there are some from New Holland to be added to what are enumerated in Wildenow. The mountains and fields of different parts of Europe produce various species, but few of the more handsome, except G. aranum, Fl. Dan. t. 641, and its near relation G. olympos in our gardens, gathered about the Bithynian Olympus by Dr. Sibthorp; both which vie with G. oriente in their thinning golden or lemon colour, and the olympos at least is a hardy perennial, of easy culture.

G. Naphalium, in Gardening, affords plants of the herbaceous and under shrubby kinds; of which the species mostly cultivated are, the tree everlasting (G. artemisia); the red-flowered everlasting (G. igneum); the eam ever- lasting, or immortal flower (G. oriente); the sweet-scented everlasting, or eternal flower (G. odoratissimum); the American everlasting, or eternal flower (G. marginalis).
the plantain-leaved everlasting (G. plantagineum); the common farinby everlasting, or rachas (G. rachas). Many of these are curious plants.

**Method of Culture.** — The first four sorts may be increased by slips from the heads or cuttings; by planting them in pots of light earth in the spring or summer months, and plunging them in a moderate hot bed, refreshing them often with water. When they have taken full root, they may be removed into separate pots, and be placed among other plants of the hardy exotic fort. They require the protection of a frame in the winter season.

The seventh species may be increased in the same manner, being placed at once where it is to remain, in a stilly sheltered borders, or other place that is proper.

The fifth and sixth sorts may be early raised by dividing and planting their creeping roots where they are to grow, either in the autumn or spring months.

These last are sufficiently hardy to stand the open air in warm situations.

They are all ornamental plants, the former in the greenhouse, the latter in the open ground.

**G. napheus.** — A plant given by Atthis and other of the Greek writers to the touch.

**G. narus.** In **G. graphes.** a town of Sweden, in the province of Helingland; 26 miles N. of Hudwickfaw.

**G. n. in **Antsology.** See Culex.

There is no species of insect that we have so much reason to dislike in regard to the injury it does us as the gnats. Others indeed give us more pain with their wings, but it is but by accident that we are struck by them; the gnats thirst for our blood, and follow us about in whole companies for it. There are many marshy places where the legs and arms are all the summer swelled to an enormous size by the repeated bitings of these insects, and in many other countries they are much more troublesome than with us.

But as troublesome enemies as these little creatures are to us, there is that about them which is extremely worthy our admiration; nor can we indeed fail greatly to admire even the very instrument of the mischief they do. They have beside this many very observable particulars in the construction of the creature.

All the naturalists of late years have applied the microscope to the examination of the parts of this little animal, and Swammerdams, Hook, Bonnuit, Leeuwenhoek, &c., have given very good accounts, and very valuable drawings of the creature.

There is a great number of very small species of gnats, and though none are considerably large, yet none of these approaches to the size of the tipula, or father long-legs, as commonly called. The larger tipules are therefore easily distinguished from the gnats; but Swammerdams, Goedart, Liefer, and others, have very often given us the smaller tipule among the species of gnats. Both have long slender bodies, and both prominent corselets, which make them look hump-backed; but when either of their insects is taken into the hand it is very easily known, the gnat having a very long trunk, and the tipula no trunk at all.

There is a prodigious number of species of the gnat kind, comprehending the smaller ones; Dr. Derham observed near forty different species about Upminster in Essex; but of those of a size to be remarked with care, and without the help of glasses, there are three principal kinds; the one has its body variegated with white and black; this is the larger kind, and its corselet is flecked with black or deep brown, and white lines or greyish ones; these have brown eyes; another is smaller than this species, and has a plain brown body, the colour of the corselet, and that of the eyes is the same as in the larger or frill species; the third kind is the smallest of the three and the most common, has its corselet reddish, or a faded reddish yellow, and the body whitish, and on the under part of the belly every ring has one single brown spot; the ring is grey: the eyes of this species are of a very pleasant green.

All the gnats have a long cylindric body composed of eight rings; their corselet is short but large, in proportion to the size of the fly, and to the are fixed the feelers, which are hairy, with six joints to each, and at the end two little claws, the wings, and the balancers: four frills are also found here, as is the case in other flies: the two feelers of these are placed near the head, and have been mistaken for ears.

The antennae of gnats are extremely worth observation, and differ much from one another. Some of them are elegantly feathered; these belong to the males of certain species, for the antennae of the females are not so beautiful. The brachi-horned or male gnat has two pairs, one of which is surmounted, at small distances, with long hair, forming out circularly, each circle Asiating as it approaches the extremity of the antenna; the other pair are longer and much thicker, and hairy from end to end. In the great bellied or female gnat, the first pair of antenna, though of the same figure as the male's, has hairs not near so long, and the second pair is shorter than the first by at least three parts in four.

**G. nat. Egg of.** See Eggs.

For the Eyes of Gnats, see Eyes of Flies.

**Gnat-worm, in Natural History, a small water insect, produced of a gnat, and which is, after its several changes, transformed into a gnat again.

From the eggs, deposited by the gnat on the surface of the water, proceed a number of minute worms, which sinking to the bottom of the water, form for themselves coverings of fine sand or earth, cemented together with a sort of glue, but open at both ends, that they may come out and enter as occasion requires.

These worms do not live in stagnant waters; but ditches, ponds, and other standing waters, afford them in vast abundance, from the middle of May till toward the beginning of winter. This is the reason why water and marshy places are found most to abound with gnats, and why the water fumers are found to produce the greatest numbers of them; because in dry seasons, the ponds and ditches, where they are to pass their worm-state, are dried up, and the worms killed. These are creatures, however, that one need not go far to seek, since a vessel of water, exposed in any open place in the summer months, will not fail to afford plenty of these worms in a little time.

Before these worms are arrived at their full growth, though they are then but small, they are easily found, because they are under a necessity of coming frequently to the top of the water, by having occasion for frequent respiration; and to do this, they are obliged to keep the end of a small pipe they are furnished with, from the fall ring of their body, above water. The end of this pipe is hollow and indented, and forms a sort of funnel on the surface of the water, it is of the length of about three rings of the body, and is somewhat thicker at its insertion than at its extremity.

As there is a vast number of species of gnats, there is no loss of the worms from whence they are produced: and to this is in a great measure owing the variety in the figures given of.
of the worms by the authors who have treated of them; which may also be not a little added to by the particular view in which those draughts have been taken. Notwithstanding all the variations of these figures, the general form of the animal is however the same in all, and the species cannot but be known from any of them. While the worm is young, the body is whitish or greenish; but when it is at its full growth, and draws near the time of its changes, it becomes greyish. The great transparency of the body of this worm gives a fine view of what paffes within it; it is at any time easily to see into the motion of the intestines, by which the food is pushed on towards the anus. The two principal trachæ are also seen very distinctly in this creature; they are two white tubes placed in a parallel direction one to another, and run from the first ring to the tube of respiration.

The great worm several times changes its skin in the course of its life. After three changes of this kind, which usually happen in the space of three weeks, or thereabout, it undergoes a fourth, where the old skin as if easily thrown off in the skin, but the animal now appears in a new form, that of a nymph; it is now shorter and rounder than before, and the body is so bent that the tail is tucked and placed in the head of the head; this, however, is only its form in a voluntary state of rest, for it can yet move, and when it pleases extends its tail, and seems about as fixed as when in its other state.

When the creatures have quitied their first habitations and the figure of worms, they re-ascent to the top of the water, inclosed in a kind of shell, with a large head and mouth, two black eyes, two horns, several tufts of hairs on different parts of the body, and a tail with a brush of hair at the end of it, which, being maceared over with an oily fluid, serves to keep them above water; their heads being sometimes lifted in the air, and sometimes plunged into the water, while the tail slides along the surface: and when the oil on the tail begins to dry, they shed from their mouth a fresh supply, which renders it capable of steering where they please, without being wetted and damaged by the water.

All the parts of the future great may be seen in this nymph; the skin of it is extremely thin and transparent, yet sufficiently tough and firm for the use it is intended for. It is uncertain how long exactly the animal lives in this state, for after it is turned and has been a nymph, its change into a great is very quick, and is attended with great danger to the animal, since multitudes are drowned in the act of getting out and springing into the air. Rambur, Hist. Inf. vol. iv. Baker's Microf. 1743. p. 88.

Gnat, in Rural Economy, a small well-known insect, which is said to destroy the leaves of some tender vegetables as soon as they appear, such as the turnip, &c.

GNEISS, in Min.alogy, a primitive rock, composed of feldspar, quartz, and mica; ingredients which are likewise those of granite, from which it differs in the arrangement of those parts; for while in the latter rock they usually appear as granular aggregations, those of gneifs are dispersed in such a manner as to exhibit a more or less flatly structure. This structure pafles through various degrees of dilatements; on one hand it approaches so near to the granular texture, that the dilatation between gneisfs and granite ceases to exist, while, on the other hand, when its peculiar texture is very obvious, and becomes what is termed this flatly, a paflage is formed into the primitive rock, next to it in antiquity, called micro-flate.

It is observable that as the stage of nature or granite, the feldspar is generally predominant with regard to the mica; while those varieties approaching mica-flate gradually exhibit a smaller proportion of feldspar and much mica. Sometimes, however, the mica is only apparently predominating, and from the circumstance, that on breaking a mass of gneisfs, the line of separation will more frequently pass through the mica than through the other layers, and display a whole surface of that substance; but another fracture, perpendicular to this, will, in this case, soon undeceive the observer. Though feldspar is, generally speaking, the predominant ingredient of gneisfs, yet the proportion of mica in this rock is, upon the whole, greater than what we see in granite; and the first this is the case, the more the mass appears granular, and the more it approaches to granite. It is often a matter of difficulty, in viewing small specimens only, to discern some kinds of gneisfs from the last-mentioned primitive rock; when the inspection of the former in their natural situation, and on a large scale, would have left but little doubt in the mind of the examiner.

Gneisfs, viewed in the large, as a mountain mass, always exhibits thick and distinct strata, whose outgoings, or upper terminations, are generally lower than the subjacent granite, and higher than those of the superincumbent mica-flate.

Werner (to whom we owe more correct ideas respecting this rock,) distinguishes four kinds of gneisfs, viz. that approaching the granular structure, the waved or undulated, the common, and the thin flatly gneisfs. As particular varieties of this, we have 1. The striped gneifs, in which the quartz is disposed in narrow bars, surrounded by feldspar, producing, on its longitudinal fracture, a striped appearance, not unlike that of some kinds of petrified wood; while its transversal fracture exhibits a granular disposition of the parts. This striped variety generally occurs together with the waved: such as at Ober-Newihofen, Reithand and Hartmannsdorf, near the Bohemian frontiers. 2. The sprinkled, or that kind of gneisfs in which the feldspar and mica exhibit themselves in the form of small neifs, such as at Hartmannsdorf and Bobitzer, near Freberg, and at Kuffenberg in Bohemia. 3. The short lamellar or flaky variety, such as it is found at Marienberg. The colour of the ingredients of gneisfs is not subject to great variation. The feldspar is generally of a greyish, yellowish, and reddish-white colour, feldorn yellowish-grey, or deep flesh-red, as it appears in many varieties of granite; upon the whole, its tint resembles that of the quartz with which it is accompanied, and which feldorn appears smoke-grey or brown. The colour of the mica is generally black or brownish-black, sometimes brownish, yellowish, and at, grey, and rarely silver-white or of a golden hue.

The component parts are found to vary also in regard to their fleisch; i.e. in general the feldspar is perfectly folted and shining; but sometimes it appears in incipient decomposition, or even converted into petrume; in the same manner as the mica is now and then seen falling into a greenish substance resembling felspar. Dr. Retsf. found that the porcelain earth dug at the Galgenberg, near Puchwitz, in the Sattz district of Bohemia, where it is used for whitewashing walls, is the result of the highest stage of decomposition of gneisfs; it forms thick strata, and contains a great quantity of small yellowish white, light grey, and pale clove-brown grains of quartz. In the same manner this mineralogist observed in that country frequent proofs of the conversion of the feldspar of gneisfs into a ferruginous clayey mafs. Near Kloeterly it is seen converted into bunt-stone or variegated clay.

Besides the more effential feldspar, quartz, and mica, the following accidental ingredients are now and then met with in gneisfs. 1. Hornblende: both the common and black tourmaline short, sometimes occur in the gneisfs of Freberg, and particularly of Spain. 2. Garnet: rare, but much more frequently than in granite; it occurs at Wiefenhal in Saxony, in Norway, in the island of Zealand, in Moravia, &c. 3. Hornblende...
blende: is but seldom found, and only in the thin flaty variety of gneifs, which passes into mica and hornblende slate.

4. Biotite: occurs principally in the gneifs forming the walls of the metallic veins in the Freiberg district; it is considered by some as mica thus transformed by sulphuric acid.

5. Actinote: is said sometimes to constitute an ingredient of gneifs in Switzerland and Hungary. Metallic substances that are sometimes found disseminated in gneifs, in the vicinity of veins, cannot properly be enumerated even as accidental component parts of this rock.

Gneifs abound in metals more than any other rock, as may be seen from the richness of the Saxou and Bohemian mines, those of Salzburg, &c. There are but few among the known metals that are not found in it, either in veins or beds.

"The oldest gneifs in the Saxou Erzgebirge," says Mr. Jamefon, "that with reddish-coloured feldspar, is the best productive in ores; but the newer, with white coloured feldspar, is the most productive; and the veins, though small, are numerous.

The oldest venigous formation appears to be that which contains tin-flone. The tin-ore is accompanied with wolfram, molybdenum, arsenic-pyrites, fluors-par, chlorite, topaze, and opal. The second venigious formation appears to be a lead-glance formation. The third formation contains principally of copper, and the ores are grey copper-ore, copper-glance, copper-pyrites, and variegated copper-ore.

The fourth formation, which is very extensive, contains ores of coal. The newest formation is that which contains ores of silver. Veins containing antimony, and red iron-flone occur in gneifs, and there are supposed to be newer than any of the preceding. The metallic beds that occur in this rock contain argentiferous lead-glance, blende, copper and iron-pyrites. It sometimes also contains formations of gold.

There are three considerable beds of rocks superincumbent to, and synchronous with, gneifs, and which are therefore not seen in granite, viz. granular linealstone, as it is observed, for instance, near Freiberg; primitive trap, such as hornblende-flate, at Kuttenberg in Bohemia, at Kongberg in Norway, &c.; and the older porphyry. (See LIMESTONE, TRAP, AND PORPHYRY.) Also small beds of common garnets, actinote, with magnetic iron-flone, iron-pyrites, galena, &c. now and then occur in gneifs.

Gneifs being generally superincumbent on granite, is hence considered as next to this primitive rock in point of age; there is, however, also a difference in the relative antiquity of the different kinds of gneifs, and on the whole it may be said that the nearer it approaches in its texture to Mica-flate, (see that article,) the more recent is its origin. From this it does not, however, follow that there should not be found kinds of gneifs which surpass in antiquity even some kinds of real granite. (See GRANITE.) The very thick flaky varieties of gneifs, with black mica and a small proportion of mica, may, in general, be said to be of more ancient formation.

Gneifs, though far less widely distributed than granite, has still a considerable range; it extends over the greater part of the Saxon Erzgebirge; the country about Freiberg, Glaubütte, Marienberg, Ehrenfriedersdorf, consisting almost entirely of it. In the same manner it is the characterizing rock of the Bohemian mountainous mining district. It is also found in Sicilia, Carinthia, in some parts of the Black Forest in Swabia; nor is it wanting in the Taurilikan mountains, in Salzburg, in the Swiss Alps, the Pyrenees and Vogdes, in Scandinavia, Greece, &c. In Great Britain it has been observed particularly in Scotland, in the islands of Coll, Tiree, Islay, and in the Shetland islands. It should however be observed, that frequently other rocks have been described as gneifs by topographical writers.

The economic use made of gneifs is that for paviug, and for the construction of walls; for both which purposes it is extremely well calculated, by reason of the facility with which it is wrought by the mason. Hence in the Saxon mining district not only all buildings are constructed of gneifs, but also the wailing of the thaths and levels is most advantageously executed in this useful rock.

GNÉMON, in Botany, a tree so called in the island of Ternate and others of the Moluccas, which is named in the Malay language Meninge, or Meninga, a word apparently of the same derivation, whatever that may be. See GÉNÉSCULES.

GNÉRGEN, in Geography, a town of Peria, in the province of Irak; 150 miles E. of Halyan. N. lat. 32° 26'. E. long. 55'.

GNÉRROTOOH, a town of Birnur, on the Irak, 150 miles N. E. of Paghman.

GNÉSEN, or GNÉSA, a city of Poland, in the duchy of Warsaw, built, as it is said, by king Lechus I., founder of the monarchy, and called Gnesia, from an eagle's nest found there, denominated in the Polish language Gnosia. The kings of Poland were crowned in this city, and the regalia were kept here till, in the year 1295, they were removed to Cracow. During the independent existence of Poland, it was famous as the site of an archbishop, who was primate of Poland, and who acted as interrex or regent upon the king's absence; and who also announced the event, convoked the diets and dictates of convocation, and performed the functions of royalty. Gnesia is 100 miles, N. E. from Bredow, and 150 W. from Warsaw. N. lat. 52° 26'. E. long. 17° 42'.

Genus Ch. Catkin composed of several remote, calous, thickened stools, each inhabited by a small partial colpus, which is entire, orbicular, but, entire, containing several fertile stools, the male ones inferior, the females superior, in the same whorl. Perianth of the male a minute ovate, covered scale. Cor. none. Stam. Filament one, thread-like, longer than the scale; anthers in pairs, connated.

Perianth of the female a rude, lacertate scale. Cor. none. Pijl. Genus ovate, superior, imbricated in the receptacle of its own whorl, the length of the flowers; style conical, short; stigma three-cleft, acute. Periz. Drupa ovate, of one cell. Sccd. Nut solitary, oblong, flattened, of one cell.

Opp. Linneus observes that Rumphius makes his plant dioecious, but he found it monocious, and even now one catkin entirely male, standing on its own stalk, near a female florae. The Vicia of Aubl., though somewhat differently described, is undoubtedly the same genus, and indeed is like the original Gynna in foliage, that it is not very easy to distinguish them.

J. G. Gneisenau.
1. G. Gnomon. Linn. Mant. 125. (Gnomon domeica; Rumph. Amb. v. 71. t. 71. 72. Beretinus fruticif; Chl. Exot. 55.)—Lateral veins of the leaves prominent, inter-branching archwise half way towards the margin. Catkins opposite, axillary, on simple stalks.—Native of the Molucca islands, and other places in the East Indies. We have it from Java. A tree, with slant, round, slender, smooth branches, swelling at each joint, under the inflorescence of the leaves, and somewhat forked at the ends. Leaves opposite, stalked, ovate, inclining to lanceolate, pointed, entire, smooth and shining, three or four inches long, furnished with a midrib, channelled above, prominent beneath, fending off several alternate, spreading, prominent though slender veins, which meet rather more than half way towards the margin in one common arching vein, whence numerous reticulations originate. Sisylus sum. Fpoitsalks half an inch long, channelled and keeled Catkins axillary, shorter than the leaves, two together from each opposite leaf, on simple stalks, their whors when young, crowded, but soon becoming dilate and broad-like, every sport bearing males or females. Linnaeus describes as a torn scale in the former, seems rather a very dense ensiform of short tufted fibres. Fruit the size of an ordinary acorn or bilber, its coat thin, sweetish according to Rumphius, but with too much acrimony to be eaten raw; as it is also the case with the leaves, which, when dried, are in almost daily use among the natives of Ambonya, though thought mawkish and unifid by Europeans.

2. G. Tba. (Thoa ureus; Aubl. Guian. v. 2. 387. t. 336.)—Lateral veins of the leaves oblique, inter-branching archwise. Catkins on simple stalks, from the repeated forks of the branches.—Gathered by Aublet in the woods of Guiana, where the natives call it Tba. His own speciemen in our polieeion has no fructification nor inflorance, so that we have been obliged to take part of our character from his figure. The leaves seem in general to be rather shorter and broader than in the former, but the chief distinction is observable in their lateral veins, which though they do in a similar manner run into one common arching vein, above half way towards the margin, are all together far more flint-like and prominent than in the first species. The fruit is like the former, reddish, and elliptical. Aublet says that when its outer skin is taken off, a dry substance is found underneath, composed of stiff depressed hairs, which easily separate from each other, and if any of them fall upon the human skin, they cause a great itching. The kernel of the nut, boiled or toasted, is good to eat. Birds of the owl or pheasant tribe feed in the woods upon this fruit, which they swallow whole. The same author affirms us that a clear gum issues from the bark and branches, but that when the main trunk or great branches are cut, a clear taflecks water liquor runs out, which may be drank by those who are distirred for water. This tree is almost always in flower and fruit. Aublet describes the catkins as male, with two female flowers at their base. This is so different from our specimens of G. Gnomon, that it might almost afford a specific character, but Rumphius describes the same circumstance in what he terms his male Gnomon, and Linnaeus advert to something like it. It should seem, however, that at the first, from the number of spicules, the genus is imperfectly dicotyled, one tree bearing catkins with female flowers, with perhaps left perfect males, in every whorl, while on another are found more efficient males in every whorl, with females at the base only, as in Aublet’s Tba. Such examples throw great light on the phytology of vegetable generation, and confirm the Linnaean theory.

3. G. funiculare. Buchanan MSS. (Gnomon funiculare; Rumph. Amb. v. 5. 12. t. 8. Ula; Rhed. Hort. Mal. v. 7. t. 12.)—Lateral veins of the leaves separate to the margin. Catkins opposite, axillary, on branched stalks.—Native of Ambonya and other places in the East Indies. This is a long trailing branched smooth frutic, turning black in drying, which the two former do not. The leaves are four or five inches long, various in breadth, pointed, firm, shining, distinguishe by their veins continuing distinct to the edge of the leaf. The flower-stalks are axillary, in pairs, more or less branched and forked; each catkin being about an inch long, composed of numerous orbicular imbricated scales concealing the flowers, and not unaptly compared in the Hortus Malabaricus to Long Pepper. Each stands on a partial stalk, of about its own length. The fruit resembles that of the foregoing, and is rounded over the fire, which renders the kernel edible. The tender leaves serve for a pot-herb, like those of G. Gnomon. The bark of the young twigs, split into thread, serves to make nets.

Rumphius’s vol. 5. t. 75, which he calls Ficus Gnomonformingis, but of which he seems not to have known the flowers, may possibly be the male plant of our last-described species, bearing only one or two female flowers at the bottom of the stalks of the male catkins, according to the analogy observed in the foregoing ones.

GNIAPDA, in Geography, a town of Hungary; 7 miles W.S.W. of Balatza.

GNIDIA, in Botany, from Guidius, where Venus had her temple. A feed, reported to be brought from thence, had been called Cucuradium; and there is a guidus, or Guides, supposed to be a kind of Orache; but Linnaeus probably had not these so much in view as the affinity of this genus to Paffiera, named after a favourite bird of the goddeis, in allusion to which it was first named Strutus by Van Royen. It is moreover akin to Daphne, one species of which, Daphne Guidus, has been taken for the ancient yadox.

Gen. Ch. Cal. Perianth inferior, of one leaf, funnel-shaped, coloured; its tube thread-shaped, very long; limb flat, in four deep segments. Cor. Petals four, fife, flat, inserted into the edge of the tube of the calyx, and shorter than its limb. Stan. Filaments eight, bristle-shaped, erect, inserted into the tube in two rows, the uppermost reaching nearly to the top; anthers roundish, erect, simple, of two cells. Pflt. German ovate, superior; style thread-shaped, as long as the tube, inserted laterally into the gynæum; stigma capitate, hispid. Peric. a dry berry, with a thin coat. Seed faltary, ovate, obliquely pointed.

Eff. Ch. Calyx funnel-shaped, four-clft, withering, including the stamens. Petals four, inserted into the calyx. Style lateral. Seed coated.

Obf. It differs from Paffiera only in having petals; which are often rather of a glandular appearance. The habit is altogether that of Daphne and Paffiera. Wildenow enumerates sixteen species, but of these G. pinifolia and radiata are one and the same, and G. daphnolc, Linn. Suppl. 225, seems rather to belong to Dais.

All the genuine species are natives of the Cape of Good Hope, of a humble shrubby growth, with white or yellowish sweet-scented flowers.

GNIEWE, or Mine, in Geography, a town of Prussia, in the province of Pomélie, on the Villula; 30 miles S.S.E. of Danzick.

GNOIEN,
GNOMON, a town of the duchy of Mecklenburg; 11 miles E.S.E. of Rottlock. N. lat. 53° 59'; E. long. 12° 53'.

GNOLL RAIL-WAY. This is an establishment in Glamorganshire, in South Wales, which we had not heard of at the time of compiling our article Canal; it is called an iron waggon-way, the flanch being on the wheels of the waggon, instead of being on the tram-plates, as is more common in that district. It commences at the flipping-place 200 yards below Neath bridge, on the Neath river; crosses the Neath canal on a wooden bridge, and proceeds about E. half a mile to the late Sir Herbert Mackworth's Gnoll collieries, of run coals, which are drawn up forty fathom, to be loaded into the wagons on this waggon-way, which has so regular a descent, as to require no inclined planes, or other considerable works.

GNOMES, Gnomi, a name which the Cabbalists give to certain invisible people, whom they suppose to inhabit the inner parts of the earth, and to fill it to the centre.

They are represented as very small of stature, tractable, and friendly to men; and are made the guardians of mines, quarries, hidden treasures, &c. Vigenure calls them Gnomons; the females of this species are called Gnomades.

Vigenure de Marville, in his Melange de Histoire et de Literature, tome i. p. 100, gives a relation of a conference with a philosopher of this class, who held, that an infinity of spirits inhabited each of the four elements, fire, air, water, and earth, under the denomination of Salamanders, Sylphs, Oudins, and Gnomes; that the Gnomes are employed in working or actuating the machines ofbrutes upon earth.

He added, that some philosophers of that sect held that these spirits were of two sexes, for the two sexes of brutes or moving machines; that they were more or less perfect as the brutes were; and that there was an infinite number of exceedingly small ones, to actuate the infinite number of insects and animals, both those that are visible, and those which are too small to come under our senses; that all these spirits, in general, govern their respective machines according to the disposition of the parts or organs, the humours, temperaments, &c. that they do not hay hold of all machines indiscriminately, but of those suited to their own character, element, &c. that a hungry one, for instance, feeds a Sylph or gnomon; a cruel one a tyrant, &c.

Gnomon, or Chria, is also used for a short, pithy, and sententious observation, reflection, or the like, which is worthy to be treasured up and remembered.

Such is that of Juvenal, "Orandum est ut fit mens fanam in corpore fane." The writers of rhetoric distinguish several kinds of gnomons, according as they turn on words, on actions, or both; denominating them verbal, active, and mixed gnomes or chrias. See APOPHTHEGM.

GNOMON, in Dialling, is the yule, pin, or cock of a dial, the shadow whereof pointeth out the hours.

The word is Greek, gnōmon, which literally imports some-what that makes a thing known; because the yule or pin indicates or makes the hour, &c. known.

The gnomon of every dial is supposed to represent the axis of the world; and therefore the two ends or extremities thereof must directly answer to the north and south poles.

See Dial and Dialling.

GNOMON, in Geometry. If a parallelogram be divided into four lesser ones, by two lines intersecting each other, and one of these parallelograms be retracted or taken away, the other three will make a gnomon, ordinarily called a figure.

Vol. XVI.

Or, a gnomon, in a parallelogram, may be said to be a figure formed of the two complements, together with either of the parallelograms about the diameter. Thus, in the parallelogram A C, Plate VIII. Geometry, fig. 96, the gnomon is M + x + z + N; or M + N + X + Z.

GNOMON, in Astronomy, the name given to any upright pillar, when used for the purpose of determining the altitude of a celestial object, but particularly the sun.

The extreme simplicity of this instrument renders it very probable, that it was the first ever used for astronomical purposes. It fortunately happened for the science, that it was capable likewise of being a very exact one; and all the knowledge the ancients had of the solar theory seems to have been derived from this instrument. The principle of it is so simple, as hardly to require explanation. If the height of a vertical pillar be compared with its shadow on a horizontal plane, the altitude of the sun may be deduced by trigonometrical calculation, since these two quantities are to each other, as the tangent to the radius, or as the sine to the cofine of the altitude required. The ancient obelisks found in Egypt and the East were probably instruments of this kind: it would be too much to conclude that every one was erected for astronomical purposes, but this was probably their original destination; and the figure of an obelisk being rather pleasing to the imagination, it was adopted as an ornament to public squares and buildings. As practical astronomy advanced to accuracy and perfection, however, the gnomon appeared to be subject to considerable defects. The shadow is found to be generally ill defined, so that its length cannot be very accurately measured; and to obviate this, the gnomon must be of greater height than is easily practicable. In modern Europe, therefore, the original gnomon has been entirely abandoned, and a new one substituted upon principles nearly similar, but of a somewhat different construction.

The gnomons of modern Italy are usually constructed in very large edifices; a small aperture is made in the upper part of the building, which permits a luminous circular image of the sun to be formed on the pavement, on which a meridian line is accurately traced; a plumb line is suspended from the aperture to the floor, and thus both the height of the aperture, and the distance of the solar image from the point immediately beneath it, is very accurately ascertained.

There are upon record some very ancient observations made with instruments of this kind, particularly of Pythias, who observed the solstices at Marseille about three centuries before the Christian era. Pliny mentions an obelisk erected by Augustus; this obelisk was brought from Egypt, and was said to have been made by Scopas, near a thousand years before Christ. It was used by Manlius for the same purpose for which it was originally defined, namely, to measure the height of the sun.

The Chinese have from the earliest time been in the constant practice of making use of a gnomon.

In the year 1278, a gnomon 40 feet high was erected at Pekin, by the Chinese emperor Co-cheou King.

Ulah Beigh, in the year 1357, observed the solstices at Samarcand by the shadow of a gnomon 165 feet high: and similar instruments are even said to have been used by the ancient inhabitants of Peru.

The gnomons to which modern astronomy is the most indebted, are chiefly those of France and Italy.

Paul Tofanelli constructed a gnomon in the cathedral of Florence, whose height was 280 feet. Xenenes repaired this, and published an account of it in 1757.
Gnomic projection is also called the "horologigraphic projection," because it is the foundation of dialling. In other respects it is not much used, because the circles of the sphere are projected into conic sections, which are difficult to be described. However, this projection has its conveniences in the solution of some problems of the sphere, on account of the great circles being all projected into right lines.

Mr. Emerson, known by an ingenious Treatise upon Fluxions, and a variety of other publications, has given the theory and practice of the gnomonic projection, in his Treatise on the Projection of the Sphere, Lond. 1749, 8vo. See Projection.

Gnomonica, "Groenouw, or Gnomonics, the art of dialling, or of drawing sun and moon-dials, &c. on any given plane.

It is thus called, as it shews how to find the hour of the day, &c. by the shadow of a gnomon or styke.

Gnomon, or Gnomonical projection, that which represents the circles of a hemisphere, upon a plain touching it in the vertex, by lines or rays from the centre of the hemisphere to all the points of the circles to be projected.

In this projection, all the great circles of the sphere are projected into right lines. Any lesser circle parallel to the plane of projection is projected into a circle. And any lesser circle not parallel to the plane of projection, is projected into a conic section.

The first and last of these gnomons are accompanied by a meridian line, often highly ornamented with the names of the months and signs of the zodiac, so as to serve the purpose of a calendar. One of the finest in Italy is in the Carthusian convent at Rome; built on the ancient Therme of Diocletian. There are two, one to the north 62 feet, another on the south 55 feet high: they were constructed by Bianchini in 1721.

Picard erected a gnomon in the royal observatory at Paris, which still exists.

The meridian line in St. Sulpice, at Paris, was begun in 1727 by Sully, a watchmaker, and has since been much improved and highly ornamented; its height is 80 French feet.

M. de Cerasis and Reggio in 1786, constructed a gnomon and meridian line in the cathedral at Milan: its height is 73 feet.

The reason why none of these gnomons are to be found in England, is that we do not regulate our clocks by solar, but by mean time: to this may be added our unfavourable climate, which would very much diminish the interest which they obtain in other countries, where they are made to serve the useful purposes of civil life.

Notwithstanding the great attention that has been paid to the construction of these gnomons, their use has been entirely superseded by modern instruments of small dimensions, so that to the astronomer they are now become merely objects of curiosity; yet to no instrument has astronomy greater obligation. The solar theory was first brought to a very improved state by the use of this simple instrument alone. The length of the year, and the obliquity of the ecliptic, were determined by it with very great exactness. The ancient method of deducing the solar theory was nearly as follows.

To determine the obliquity of the ecliptic, the length of the shadows were observed at the period of the solstices, and the extreme points to which the longest and shortest shadows extended at the moment of noon were carefully observed, and the altitudes of the sun deduced at each of these periods: half the difference of the greatest and least altitudes would be the obliquity of the ecliptic, subject to a small error arising from refraction, the effects of which were not known at that early period, nor were they very considerable in those southern portions of the globe in which astronomy had its origin. But though it was not difficult to deduce the length of the solstitial shadows, it was by no means easy to determine the day on which either of the solstices actually happened, because the length of the shadow would appear to be the same at those feasons for several successive days. It appears, by some very ancient Chinese observations still on record, that this inconvenience was remedied by observing the length of the shadow, ten or twenty days before the solstice; then waiting till they found the meridian shadow again of the same length, they concluded that the moment of the solstice happened on the intermediate day between these corresponding observations.

The length of the year was determined from observations of the equinoxes, which could be much more exactly observed; for the obliquity of the ecliptic being determined by the method above described, the length of the equinocial was known, and the day on which the shadow corresponded to the computed shadow was evidently the day of the equinox.

It was by examining a succession of these simple observations, that Hipparchus first discovered the great inequality in the length of the four seasons, arising from what is now called the equation of the orbit: and from the discovery of this important fact, we may date the origin of physical astronomy.

Gnomonica, Polyhedron. See Polyhedron.

Gnomonic. See Polyhedron.
The peculiar circumstance, and, indeed, the fome circumstances, and, but large, and, a peculiar kind of divine proceedings or emanations, which had no other foundation but in their own wild imagination.

In effect, the Gnostics confided, that these seons or emanations were no where expressly delivered in the sacred writings; but inferred, at the same time, that Jesus Christ had intimated them in parables to such as could understand him. They built their theology not only on the gospels and the epistles of St. Paul, but also on the law of Moses and the prophets.

These left laws were peculiarly serviceable to them, on account of the allegories and allusions with which they abound; which are capable of different interpretations.

However, their doctrine, concerning the creation of the world by one or more inferior beings of an evil or imperfect nature, led them to deny the divine authority of the books of the Old Testament, which contradicted this idle fiction, and filled them with an abhorrence of Moses and the religion he professed; alleging, that he was seduced by the malignant author of this world, who confuted his own glory and authority, and not the real advantage of men. Their persuasion that evil refered to matter, as its centre and source, made them treat the body with contempt, discourage marriage, and reject the doctrine of the resurrection of the body, and its reunion with the immortal spirit. Their notion, that malicious geniit professed in nature, and occasioned diseases and calamities, wars and defections, induced them to apply themselves to the study of magic, in order to weaken the powers or suspend the influence of these malignant agents.

The Gnostics considered Jesus Christ as the Son of God, and, consequently, inferior to the Father, who came into the world for the rescue and happiness of miserable mortals, oppressed by matter and evil beings; but they rejected our Lord's humanity, on the principle that every thing corporeal is essentially and intrinsically evil; and, therefore, the greatest part of them denied the reality of his sufferings. They set a great value on the beginning of the gospel of St. John, where they fancied they saw a great deal of their own or emanations under the Word, the Life, the Light, &c. They divided all nature into two kinds of beings, viz. hylic, or material; psyllic, or animal; and pneumatic, or spiritual.

On the like principle they also distinguished three sorts of men; material, animal, and spiritual. The first, who were material, and incapable of knowledge, inevitably perished, both soul and body; the third, such as the Gnostics themselves pretended to be, were all certainly saved; the psyllic, or animal, who were the middle between the other two, were capable either of being saved or damned, according to their good or evil actions.

With regard to their moral doctrines and conduct, they were much divided. The greatest part of this sect adopted very auline rules of life; recommended rigorous abstinence, and prescribed severe bodily mortifications, with a view of purifying and exalting the mind. However, some maintained, that there was no moral difference in human actions; and thus, confounding right with wrong, they gave a loose rein to all the passions, and affected the innocence of following blindly all their sensations, and of living by their tumultuous dictates. They supported their opinions and practice by various authorities; some referred to fictitious and apocryphal writings of Adam, Abraham, Zoroaster, Christ,
and his apostles; others boasted that they had deduced their sentiments from secret doctrines of Chrift, concealed from the vulgar; others affirmed, that they arrived at superior degrees of wisdom by an innate vigour of mind; and others affirmed, that they were instructed in those mysterious parts of theological science by Theudas, a disciple of St. Paul, and by Matthias, one of the friends of our Lord. The tenets of the ancient Gnostics were revived in Spain, in the fourth century, by a sect called the PræsHellens. (See Meheim's Eccl. Hist. vol. I.)

The appellation Gnostic sometimes also occurs in a good sense, in the ancient ecclesiastical writers, and particularly in Clemens Alexandrinus, who, in the person of his Gnostic, describes the characters and qualities of a perfect Christian. This he laboures in the seventh book of his Stromata, where he shews, that more the Gnostic, or learned person, has any true religion. He affirms, that were it possible for a knowledge of God to be seperated from eternal salvation, the Gnostic would make no scruple to choose the knowledge; and that if God would promise him impurity in doing of anything he has once spoken against, or offer him heaven on these terms, he would never alter a whtt of his measures.

In this sense the father uses Gnostics, in opposition to the heretics of the same name; affirming, that the true Gnostic is grown old in the study of the holy scripture; and that he prefers the orthodox doctrine of the apostles, and of the church; whereas the false Gnostic abandons all the apostolical traditions, as imagining himself wiser than the apostles.

At length the name Gnostic, which originally was the most glorious, became infamous, by the idle opinions and drollary lives of the persons who bore it; much as, in the present age, it has fared with the name quidst, aper, &c.

GNU, in Zoology, a species of Antelope, having horns thick, rough, and bent much forwards at the base, then suddenly turned backwards, a ferruginous body, a neck with a mane, and a tail whitish. This animal inhabits the country of the great Namaques, to the north of the Cape of Good Hope. It feeds in large flocks in the plains; is exceedingly fierce, very swift, and fights with its horns; it frequently drops on its knees, runs quickly in that posture, pursuing the ground with its horns and legs. It is a singular animal, having the body like a horfe, with a thick buffalo-like head, elegant taper legs like a deer, and the lachrymal furrows of the Antelope tribe. It is about 6 feet long, and 3/4 high at the shoulders; of a rufby brown colour, having its hair tippd with white, but on the breast and forelegs long and black; the head is large and clumsy, with a square mouth and broad flaps over its nostrils; on the chin and gullet is a long hanging beard, or bunch of white hairs; the neck is short, thick, and somewhat arched, with an erect ash-coloured mane; the tail is long, white, and flowing like that of a horfe; the feet have only one spurous hoof on each. The fleece is reckoned very good.

GO sometimes used in Laws, in a special signification. Thus, to go without day, and to go to God, denote as much as to be dissolved the court, and to be acquitted.

GOA, in Geography, an island in the East Indian sea, near the west coast of Hindostan, seperated from the continent by a river called "Mandora;" about eight leagues in circumference. The soil, especially in the valleys, is fertile; the trees are always covered with leaves, flowers, and fruit; and springs in abundance issue from the mountains. The rainy season continues here from June till September or October; and the land-floods bring down such quantities of mud and sand as stop up the haven and impede the navigation. In the months of April and May the weather is sultry, but from October to March it is very moderate.

GOA, a city and capital of the Portuguese settlements in India, the seat of a vicerey, and see of an archbishop, taken by the Portuguese general Alberquerque in 1516, from a prince of Saracen extraction. The port of Goa is naturally, and still more by the improvements of the Portuguese, one of the best in India; it is fortified with many armed towers, and adorned with abundance of good cannon. Beyond these walls the channel becomes narrow, frightening sometimes to one, sometimes to two miles, and its banks are planted with the beetle fruits and fine trees which India affords. Eight miles up the channel is the town of Goa. About the middle of this distance is a palace, now serving as a barrack for the garrison; and here begins a strong broad wall, two miles in length, which is a footwall when the country is overflowed, and in the vicinity of it a great quantity of salt is collected. This channel, which forms so excellent a port, runs many miles into the country, dividing it into several fruitful islands and peninsulas, which plentifully furnish the city with necessaries. Adjoining to this port is the haven of Mormugao, formed by the other channel, that runs between the island of Goa and peninsula of Salsete, and affords a safe retreat to the Portuguese and other ships, when they are shut out of the port by the floods which are brought down by the river Mandora, in consequence of the heavy rains of June, and till the passage is opened in October. The port of Mormugao is defended by a castle and island on the island of Salsete, and a good garrison.

At the south entrance into the channel are the ruins of Old Goa; and from thence to the new city is a commodious road, elegantly adorned with trees for fruit and shade. The walls of the new city, which is decaying, include a space of 12 miles in circuit; and the public structures that remain sufficiently evince its former grandeur as well as extent. The number of inhabitants is said to be about 20,000; they consist of native Portuguese, Melikos, and Canarines, or natives, who are black as jet, with long black hair, and fine features; here are also many negro slaves, and Pagans of different nations. As to the character of the inhabitants, the men are faith to be, for the most part, proud, indolent, jealous, revengeful, and indigent; the women lazy, lascivious, and as well skilled in poisoning as any in the world:—215 miles S.S.E. from Bombay. The inquisition, formerly existing in this place, is now abolished. N. lat. 15° 28' 20".

E. long. 73° 45' 47''.

GOA, or GOA, a kingdom on the west and south-west coast of the island of Celebes, which after many conquests and revolutions, is now dependent on the kingdom of Boni. The capital of the same name stands on a little island, on the banks of a river, whence the kingdom derives its denomination. It was built about the same period as Samboupo and Tello; and was taken by the Dutch in 1778. S. lat. 5° 12'. E. long. 119° 51'.

GOACHIO, a town of Peru, in the diocese of Lima, near the Pacific ocean; 65 miles N.N.W. of Lima. S. lat. 11°.

GOAD, in Rural Economy, a term applied to a pointed instrument, by which oxen are driven when employed in team-labour. It has frequently, likewise, a leather thong attached to the contrary end of it, so as to form a form of whip.

GOAFFI, in Geography, a town of Africa, in the kingdom of Mandingo, on the Senegal.

GOAHIROS, a nation of South America, situated between the jurisdiction of Maracaibo and the Rio de river
de la Hache: they occupy the coast for more than 30 leagues, and extend equally far into the interior part of the country. They have at all times been considered as the most ferocious of the maritime Indians. The Spaniards never even attempted to conquer them. Some missionaries have made efforts for instructing and proselytizing them to the Christian faith, but without any permanent effect. Their number amounts to 30,000. They are governed by a cacique, for whom they have erected a citadel upon a small eminence, called "La Teta," the Pop; at the distance of some leagues from the sea. They breed horses upon which they ride with incredible rapidity. Their troops are all mounted, each soldier carrying a carbine, cartridge-box, bow and quiver. They experience much friendship from the English of Jamaica. They affil them with advice, and supply them with arms. Their marauders have rarely any communication with Maracaibo, because, as its jurisdiction is the principal scene of their robberies and atrocities, the inhabitants are obliged to be continually on their guard, so as to be always ready to repel the aggressions of such troublesome neighbours. The Spanish city to which they chiefly resort is Rio-de-la-Hache, depending upon the viceregalty of Santa Fé, where they barter their commodities. They set out in bands, most commonly preceded by their wives, who carry their children upon their backs, besides other loads, too heavy even for beasts of burden. Dreading impostion, they have never adopted the use of specie, but barter their horses and oxen chiefly for spirituous liquors, to the use of which they are much addicted. Urged by their necessities they recur to arms, and threaten the nearest city or village. After some harrassments, the Spaniards sue for peace, and obtain it in consideration of some pipes of brandy and other smaller articles. Although these Indians are well received in the Spanish cities, they will not admit any Spaniard into their country; and yet some Spanish smugglers contrive, for pecuniary considerations, to obtain a passport and escort for travelling the country of the Goashiros, and they have thus acquired many partizans among the Spaniards themselves; but their principal and most useful connection is formed with the English of Jamaica. By them they are supplied, not only with arms and ammunition, but with the fluffs that clothe them. Their dress is ornamented by a great variety of feathers, fragments of shining metals, and gold ridiculously fixed to their ears, nose, and arms. The articles with which they furnish the English in exchange for the merchandise they receive are pearls, which they sell in their own ports, and horses, males, and oxen. Their ferocity is such, that even the English will seldom go far confide in them as to venture on shore, but the buccaneers of bartering is transacted on board, and the ships hasten to depart. The ships that are accidentally call upon the coast, immediately become the prey of these cannibals, who massacre the crew and devour their flesh; dividing the cargo among those whom they are present on the occasion. The Goashiros are said to be a formidable nation, well mounted, armed, and disciplined and able to bring into the field 40,000 effective men.

The eastern part of the island of the Goashiros are the "Canaan" Indians, who live like savages, but are so cowardly and pusillanimous as to allow the Goashiros to exercise an authority, which the bold always acquire over the timid. These savages are, in fact, merely the slaves of other savages. Depoer's travels, vol. i.

GOAL. See GAO.

GOAL-FETCH, a name sometimes applied to the summer wheat. See FARE and WITCH.

GOARING, or Ship-board. The farmers lay a fail is cut earliest, when it is cut Hoping for degrees, and is broader at the elve than at the ear-ring, as all top-fails and top-gallant-fails are.

GOAS, in Geography, a town of Bengal; 11 miles E. of Moorshedabad.

GOAT, in Zoology. See CAPRA.

GOAT, in Rural Economy, is an animal, that in particular situations may be kept with advantage by the farmer, as where the country is rocky and barren, and there is little keep for any other sort of animal. The goat is capable of climbing the steepest rocks, and of browsing upon the briars, heath, and shrubs of several different kinds, which are rejected by other sorts of animals. When turned into pasture grounds they shoult confequently be prevented from nipping the young shoots of trees and other woods, as they prefer them to the graps.

They are beneficial in several different points of view, as in their milk, which they afford plentifully, and which is of a very excellent quality. In some cases, this and cow's milk are mixed together, and a highly valuable cheese prepared from them.

The young kids are likewise very excellent food, and two or three are frequently brought forth at a time, often twice in the course of the year.

The hair of the goat is also very valuable for different purposes, as the making of ropes to be used in the water, which are extremely durable. A fort of fluff is also formed from it in some places. It may be sheared in the same manner as wool from the sheep.

The fleece of the goat is excellent, the animals being in some places, as in Cumbrovantho, killed merely for the object of their skin, which is capable of being made into candles of a superior quality to those of the common kind.

Their horn constitute valuable handles for rakes and pen-knives. The skin of the young kid is well suited to the glove manufacturer, from its taking on a dye better than any other sort of skin. The old skin is highly useful also, being in many cases preferred to that of the sheep; besides, the fluff affords a cheap and abundant food for the winter months, especially when the kids have been fed early to market. The bitches of the goat are often salted and dried, and supplied all the uses of bacon; and are known by the Welch under the name each yr eden, or hagg venison.

In cleaning goats for keeping, the following directions should
should be attended to. The male should have a large body, with long hair, and straight stiff legs; the neck should be plain and short, the head small and slender, the horns large, the eyes prominent, and the beard long.

The female ought to have a large udder with well fixed teats, and with none or very small horns.

Goats are bell kept in flocks, in order that they may have the use of a sash to scrape and rub; and they should have good fodder both for summer and winter, great heat and cold being equally injurious to them.

The period of coupling is about December. They are mated and kept without litter in the winter season, in clean paved places or other places.

The kids may be prepared for the table in a manner similar in some degree to that of the lamb.

They have been vulgarly supposed useful in stables from the disagreeable odor that issues from the males at particular seasons, but there are probably no real grounds for such a conclusion.

Goatfish, Capereusus, in Ichthyology, the name of a fish, called also by some Caper. It is a species of Ballistes.

In the middle of its back it has three very strong and large prickles, the first of which is three times as large as any of the others, and all are connected by a membrane.

The whole fish is covered with a scaly skin, but the fishes have the appearance of those of a great and small of the fish; for they are placed in cannulated lines intermixing one another, and are so well fixed, that they with difficulty come off; and wood or ivory may be polished with the skin, as with the common fish-kin and by the turners, &c. It is of a blue-green colour, spotted with a fine blue, and the back and belly fins are black, with some blue and red spots. Its whole figure is very broad and flat, as well as short, so that it approaches to a round form. It seldom exceeds two pounds in weight. It is caught in the Mediterranean, but not commonly. The skin of it is frequently found in the cabinets of the curious.

Goat Island, in Geography, two small islands near the S. coast of Jamaica, they are denominated Great and Little; the former is situated in N. lat. 17° 33'; E. long. 76° 51'; and the latter about a mile N. W. from it.

Goat Island, the southernmost of the Bathie islands, in the East Indian sea. N. lat. 25° 0'; E. long. 121° 26'. Also, a small island among the Philipines, near the S. W. coast of Luzon. N. lat. 13° 52'; E. long. 120° 13'. Also, a small plot of America, in the West Indies, called the island of the Fort of Rhode island, opposite to the town of Newport, and which is Fort Washington.

Goat's Beards, in Botany. See Tragopogon.

Goat's Eye, in Surgery. See Eye.

Goat's Horns, petech'd. In Dr. Grew's "Rarities of the English Colleague," p. 255, a Tephritus besti, or goat's horn, in that collection, is described as broken at both ends, about six inches long, and 2½ inches across at the broadest part, the belly an inch over and furrowed, the back somewhat edged, of an athen colour, inwardly blueish grey, outwardly mixed with oblique and white streaks, banded, one end thicker than the other: it is added, that such are found in Germany, Moravia, Siberia and other parts, and efervescence with nitric acid.

In the Analysis of the Labours of the French national Institute for 1809, it is mentioned that M. Cuvier in the affinial fields near Etampes had discovered horns, some of which do not seem to differ essentially from the horns of the existing species of goats. The evidence in neither of the above cases, or any other which we have seen, is sufficiently strong to prove the fowl horns of this class to have really belonged to goats; and analogy would justify us rather, in referring them to the extinct race of animals, the only, and vegetables with which the plants are so abundantly found, in some parts of the series.

Goat's Rue. See GALEGA.

Goat's Ticks. See SCALE-GOAT.

Goat's Strokes. See CAPPULARIS.

Goat's Stones, greater. See SATYRUM.

Goat's Stones, lesser. See Orchis.

Goat's Thorn. See ASTRAGALUS.

Gosfield, in Geography, a mountain of Scotland, in the island of Arran; the summit of which is 2840 feet above the level of the sea.

Gosford, Grand, a town of the island of Kipsinola: 10 miles S.W. of Leogane.

Gosford, Petit, a sea-port town of the island of Kipsinola, with a harbour capable of receiving vessels of the largest size safe from winds; in its environs are plantations of sugar, coffee, indigo, and cotton. The town is the emporium to which the inhabitants of Grand Gosford, and other places, lend their commodities; 20 miles W.B.W. of Leogane. N. lat. 18° 26'. W. long. 73° 37'.

Gobi, a town of Persia, in the province of Chaffitan; 75 miles S. of Sufur.

Gobbin, or Goblie, a small island in the mouth of the Euphrates, or Shat el Arab, at the entrance into the gulf of Persia, with a town upon it; 50 miles E.S.E. of Babara. N. lat. 30° 10'. E. long. 48° 25'.

Gobranium, in Ancient Geography, a town of Bithia, placed in Antiochus's Itinerary between Barrium or Ull, and Magnis or Kechelber, 12 miles from the former and 22 from the latter, and supposed to be Abercagnyn, which fea.

Gobbi, in Geography, a country of Africa, between that of Commara, and Cape Lopez Goufello; the chief trade of which consists in elephants and ivory. The chief town is about a day's journey distant from the Atlantic. N. lat. 1° 30'. See Camma.

Gobbins, in Mining, is a name with the colliers of several districts for the bulking stuff and other refuse of their works; as also for the hollows or spaces behind them, into which they throw the refuse coal, earth, and stones; which last are also called walls and old-hollows. In the coal-pits about Weddavby in Staffordshire, and at Donithorpe, Donby-Hall, &c. in Derbyshire, the gobbi take fire spontaneously after some time, unless the air is excluded from them, owing to dams, tow, taw, or earth, a thin stratum found near the coal, which heats, fumes, and spontaneously inflames, by the contact of air and moisture. At Donithorpe they encase their gobbbins in walls of tempered clay at certain distances, for excluding the air.

Gobbs, otherwise Cobbles, are pieces of coal from the size of walnuts to that of a man's fist or larger, which are occasionally picked up in the hill or refuse small coals at the colliers, either by poor perfons, who are allowed to do so, or for sale. These are what in London, and many places in the east and south of England, would be called round-coals and highly valued, on account of the absence of very small or dust coals among them. Where the rage among the buyers and dealers is for large coals, as about Weddavby in Staffordshire, and the Erewhon vale in Derbyshire and Nottinghamshire, an inconsiderable wall is made of cobbles and fluy; in working the thick coal about Weddavby, a heap of such, fix or seven yards thick, is laid to be left and walled on the floor of their works; and
and to occasion a further wake of a rib or wall of cold coal, round each hall or chamber, for excluding the air, which would otherwise fire these wake heaps. See Gobins.

GOBELINS, a celebrated manufactory, established at Paris, in the Faubourg St. Marcel, for the making of tapestry, and other furniture for the use of the crown. The house where this manufactory is carried on was built by two brothers, Giles and John Gobelin, both excellent dyers; and the first that brought to Paris, in the reign of Francis I., the secret of dyeing that beautiful scarlet colour still known by their name; as well as the little river Bièvre, on whose banks they fixed their dye-house; and which is now known by no other name than that of the river of the Gobelins.

It was in the year 1667 that this place, till then called "Gobelin's Folly," changed its name into that of "Hotel Royal des Gobelins," in consequence of an edict of Louis XIV. Mons. Colbert having re-established, and with new magnificence enriched and completed the king's palaces, particularly the Louvre and Thilleries, began to think of making furniture suitable to the grandeur of those buildings; with this view he called together all the ablest workmen in the divers arts and manufactures throughout the kingdom; particularly painters, tapestry-makers, sculptors, goldsmiths, chisellers, &c. and by splendid offers, pensions, privileges, &c. called others from foreign nations.

And to render the intended establishment firm and lasting, he brought the king to purchase the Gobelins, for them to work in, and draw up a system of laws, or policy, in seventeen articles.

By these it is provided, that the new manufactory shall be under the administration of the superintendent of the king's buildings, arts, &c. that the ordinary masters thereof shall take cognizance of all actions and proceeedings brought against any of the persons in the said manufactory, their servants and dependants; that no other tapestry work shall be imported from any other country, &c.

The Gobelins has ever since remained the first manufactory of this kind in the world. The quarter of the finest and noblest works that have been produced by it, and the number of the best workmen bred up therein, is incredible; and the present flourishing condition of the arts and manufactures of France is, in a great measure, owing thereto.

Tapestry work, in particular, is their glory. During the superintendence of M. Colbert, and his successor M. de Loustois, the making of tapestry is said to have been practiced to a degree of perfection, scarce inferior to what was before done by the English and French.

The battles of Alexander, the four seasons, four elements, the king's palaces, and a series of the principal actions of the life of Louis XIV. from the time of his marriage to the first consort of France, Comte, done by the designs of M. Le Brun, director of the manufactory of the Gobelins, are master-pieces in their kind.

GOBEMOUCH, the fly-catcher lizard, a species of American lizard that is always employed in catching of flies. It is the smallest of all the lizard kind, and is very beautiful, its skin often appearing as if covered with leaves-gold, or leaf-silver, and in some others of a green, or red and gold, wonderfully bright and beautiful. They are not at all shy or fearful of men, but as they do not hurt, if they feel to dread none; they enter chambers and closets, and do no sort of damage, but destroy the flies and other troublesome vermin they find there. Their whole lives seem spent in the chase of these insects, and it is a very pleasing thing to observe the various ways they have of catching them. They are very cleanly creatures, and may be suffered to run over the table at meal times; and, if they see a fly, they will pursue it over the very hands or cloaths of people, or over the dishes, without doing the least hurt.

Notwithstanding their great beauty while alive, they are only a dudley grey when dead, all their other colours immediately vanishing.

GOBEMOUQUE, in Ornithology, a name given by Buffon to several species of Linnæus, Todius, Turdus, Melitophus, and Melascula, which fee respectively.

GOBIN, Sr., in Geography, a town of France, in the department of the Aine; celebrated for its manufacture of plate-glass; 4 miles S. of la Ferre. See Glass.

GOBIO, in Ichthyology, a species of Cotton; and also of Cyprinid, which see respectively.

GOBIUS, a genus of the thoracic order, possessing, according to Linneus, the following essential character. Head small, eyes approximately with two pedicles between; gill-membrane four-rayed; body small, compressed on each side, covered with small scales; and furnished with a small tubercle behind the vent; the central fins united into an oval or funnel shape; and the dorsal fins two in number.

At the time Linneus wrote his Systema Naturae, the above character was probably found sufficiently explicit to embrace, in a correct and lucid order, all the species of this natural tribe of fishs at that period known. This, however, it must be confessed, is not precisely the case at present. The number of species has been materially augmented by the recent discoveries of naturalists; and among these are certain kinds which exhibit differences essentially dissimilar from each other; but still, in the idea of the Linnean student, they can be only referable to the genus Gobius; while others, no less intimately allied, cannot, without a palpable innovation on the order of nature, be consigned to that genus. The later French writers, as Latreille, Bore and others, after the example of Lacépedé, divide the Linnean Gobius, and their natural affinities, into four distinct genera, namely, Gobius, Gobioidea, Gobiosoma, and Gobionotus, an extension perhaps requisite, or at least admissible. This extension is, indeed, in our own opinion, render desirable, and we refrain from adopting it only to avoid that degree of perplexity which might probably result from the dispersion of the species into the several distinct articles, which would then become necessary. For this reason, we propose to concentrate the whole in one point of view, observing only to refer the species respectively to their different genera as we proceed, and by this means leave it to the judgment of the reader, whether those recently established genera ought to be in reality considered essentially distinct, or as only constituting the natural subdivisions of the Linnean genus Gobius.

The habits of these fishes in general appear to correspond, they are chiefly inhabitants of waters contiguous to the shores, and lie concealed among the rocks, under stones, or in the sand and mud of lakes and rivers: they feed on worms, insects, and the spawn and fry of fishes; and adhere firmly to the rocks or other hard substances, by means of their ventral fins.

Species.

Gobius Gobius.—Central fins united; dorsal fins two.
† Section. Pectoral fins attached close to the body.

Boddaerti. Rays of the anterior dorsal fin cirrhi, the third very long. Pullus.
GOBIIUS.

A native of the Indian seas, in common about six inches in length, and never exceeding eleven or twelve inches. The head thick, blunt, and somewhat convex, with spots of brown and white; crown convex, and gradually sloping down; jaws of nearly equal length; lips thick and flethy; eyes vertical and oblong; gill-membrane lined. The body is rather convex, tapering slightly towards the tail, and covered with small and soft scales; the colour bluish brown above, beneath pale yellow, inclining to white; the back marked with a longitudinal series of seven brown spots, beneath which, on the sides, are four other spots of the same colour, but these latter are speckled with white; the vent, which is situated rather nearer the head, is surrounded by a black circle, behind which is a conic peduncle. The dorsal fins are bluish black, the first including five rays, has the membrane spotted with white; the membrane of the second is remarkable in having fixed white lines between each ray, these rays are feta-

ceous, and amount to twenty-five in number; the pectoral fin is roundish, and includes twenty-one rays; ventral, thirty-
four; anal, twenty-five; and the tail, which is bluish white, slighted rays.

LAGOCOEPHALUS. Upper jaw hemispherical; no tongue and lateral line. Pallas.

The native place of this species is uncertain; it was first described by Kolreuter, in the Transact. of the Royal Academy of Peterburgh, and afterwards by Pallas in his "Spezies von Skandinavien." The head is short, thick, and delituate of scales, the mouth transversel; eyes dilute, small, and covered witha common skin; upper jaw very thick, the lower with a few larger teeth, which are a little hooked; the lips cleft in the middle, doubled, the upper flethy and very thick, and also reaching much beyond the jaw; palate with numerous crowded teeth of small size on the margin. The body round, compressed towards the tail, of a grey or brown colour, and covered with minute scales; vent in the middle of the body. The first dorsal fin contains five rays of a simple form, the rays in the second fin, like those of the tail, are branched, and amount in number to eleven; the pectoral fin lanceolate oval, with fifteen rays; ventral, with eight short crowded rays; anal, ten rays; and caudal, twelve. The total length of this fish about three or four inches.

CYPRINODUS. Body covered with large sub-ciliated scales; tail rounded; the membrane connecting the rays tej-

celled with brown. Pallas.

About the size of a finger, the body of a compressed form, thickish, convex, grey brown above, beneath whitish; skin folt and ciliated with fine lines; teeth minute and nearly equal; tongue flat, soft, and obtuse; eyes lateral and between them a blackish semi-lanceolate eel; rays of the fins mostly branched; lateral line obsolete. The species inhabits Amboulo.

Inhabits the brooks and rivers of Martinicne, where Plu-

mer saw it in great abundance. The body is oblong, and covered with round, lubricated scales, which are longer on the posterior part. The head is long and truncated; the eyes vertical with black pupil, and golden iris; jaws equal; tongue flat and acute; cheeks bluish edged with red; lateral line in the middle of the body, and the vent nearer the head; dorsal and anal fins with simple, soft, distant rays, connected by a thin membrane; rays of the first dorsal membrane extended far beyond the membrane; between the dorsal fins on each side a brown spot; pectoral fin yellow edged with blue; tail at the base greenish yellow, the edge violet. The flesh excellent.

MINUTUS. Whitish, spotted with ferrugineous; rays of the dorsal and caudal fins obfuscely streaked with the latter. Donov. Gobius minutus; albicans ferrugineo-unicalciatus, radiis dorso dissectis, et caudalis ferrugineo obsolto fimbriatus. Pallas. Mi-

nute or spotted goby. Pennant.

"The minute or spotted goby is a pretty, delicate, little creature, whose usual length very rarely exceeds two inches and a half, or at the utmost three inches. Pallas, who describes this species, defines its character with much precision; he speaks especially of the obfuscely streaks across the rays of the two dorsal fins and tail, which are sufficiently distinct, except when the fins happen to be considerably expanded, at which time they indeed appear as to many series of unconnected dots. These streaks or dots are uniformly confluent in all the specimens of the fish that have fallen under our observation, varying a trifle only in the tint or density of colour.

"Block does not include this species in either of his works on fishes. Pennant considers it as the Gobius aspila of Linnaeus, in which particular later writers are unhappy; it must however be confessed, that there still remains some little doubt as to the precise difference between the aspila and minutus; Linnaeus tells us the former has the body and fins barred with brown, and this will, in a certain degree, apply to the characters of minutus. That the spotted goby is the minutus of Pallas cannot admit of doubt.

"It has been imagined, on the authority of Mr. Pennant, that the spotted goby appeared on our coasts only during the summer months, and was besides extremely local. This idea is certainly unfounded, for we have received them from various parts of the sea-coast in all seasons of the year. In the wide sweep of lands, called 'Traeth Lleven,' which extends along the south side of Beaumaris bay; upon the shores of the Severn; and also many other of our sandy coasts, this diminutive fish has attracted our remark swimming or lurking among the shrimps in the shallow pools left by the sea at ebb-tide. The same species is likewise not unfrequently captured with the sprats, at a short distance from the shore.

"In the first dorsal fin are five rays, in the second eleven; the pectoral fin contains twenty rays; the ventral, nineteen; anal, eleven; and tail sixteen."

We have been the more explicit in detailing the character and history of the spotted goby, in order to enable the reader to comprehend the precise difference between this and the following species.

Described as a very small species found in the Nile and some parts of the Mediterranean; the length about an inch. The first dorsal fin, as in minutus, contains six rays, the second sixteen or seventeen; pectoral, according to Linnaeus, eighteen, or one less, as Artedi mentions. Linnaeus fixes the number of rays in the ventral fin at twelve, Artedi at six only, and in describing those of the anal fin they differ again, these being, as Artedi informs us, no more than eleven, though Linnaeus says they amount in number to ten less than four and twenty-five in number. Linneus.

JOSA Rays of the dorsal fin fetaeous, and extending above the membrane. Linnaeus. Josa, Salv. Gobius altius, Ren-

del. Gobius turrbus, Wits.

This is an inhabitant of the European and Mediterranean seas; its length is from four to six inches; the body above brown, beneath whitish, and the whole covered with scales. The head is compressed; pupil of the eye black with the iris white; the back slightly arched; jaws of equal length, and armed with numerous small teeth; the lateral line.

straight,
straight, blackish, and placed in the middle of the body. The colour of the fins, which is blue, confluates, according to Bloch, the characteristic distinction of this particular species. Its haunts are the sandy shores of the sea, and its food teleftaceous animals, crabs, and other marine creatures. Though highly prolific, it is observed not to multiply very fast, its eggs being eagerly sought after by the larger kinds of fishes. The flesh is indifferent, being hard and meagre.

**Eleotris.** Anal fin with nine rays; tail roundish. *Lageriroluem.* *Gobius Chinenis.* Olebeck.

Whitish, covered with large, round, and smooth scales, and marked on the back near the Gill-covers with an ample violet spot; both the dorsal fins of equal height, the first containing six rays, the second eleven; pectoral fin twenty; ventral, ten; anal, nine; and tail ten. The species inhabits China.

**Pectinrostris.** Teeth in the lower jaw horizontal. *Gmel.—Lageri. Apocryptes Chinenis.* Olebeck. A fish of small size found in China; the first dorsal fin contains five rays, the second twenty-five; pectoral, nineteen; ventral, twelve; anal, twenty-five; and caudal, fifteen.

**Bicolor.** Fuscous; all the fins black. *Linn.—Brünn pifs.* Length from three to four, or rarely exceeding six inches, and inhabits the Mediterranean sea. The rays of the fins project very incomparably above the connecting membrane.

**Centarius.** Mouth putulata with red; rays of the dorsal fins reaching above the membrane. *Brünn.*

About a span in length, the mouth, Gill-covers, chin, and fins putulata with fanguienne red spots; behind the eyes a tranverse membraneaceous line, and two others placed longitudinally before the dorsal fin; fins generally brownish, with facetaceous rays; pectoral rounded; ventral, bluish, with the rays split at the end; tail pointed and lightly banded with black. *Gmelia* is inclined to think this may be only a variety of the species *Zojo.*

**Pagonellus.** Tail and second dorsal fin purplish at the base; the first dorsal fin edged with a yellowish line. *Linn.* *Gobius pagonellus.* Hauffelqufl.

Length three, four, or six inches; the body slightly compressed and whitish, with a green tinge, and marked with blackish dots or small spots. Native of the Mediterranean.

**Arabius.** Five posterior rays of the first dorsal fin terminating in a red filament twice the length of the membrane. *Fork.*

Native of Djidda in Arabia. The body is about the size of the little finger, and of a greenish-brown colour, with numerous confluent violet spots and specks of blue; fin soft and covered with minute firm scales; fins spotted; tail cuneated.

**Nerolus.** Second ray of the first dorsal fin ending in a black filament twice as long as the body. *Fork.*

Inhabits the same sea as the former, and nearly the same size; body whitish, with brown confluent spots, beneath white without spots; scales rhombic and rigid; pectoral fins glaucous, with obsolete brown spots at the base; ventral brownish; dorsal fin and tail transparent, dotted with brown; anal fin hyaline, with the outer edge black.

**Plumieri.** Upper jaw prominent. *Blüch.*

This, according to Plumier, inhabits the rivers of the Antilles in great numbers, and is in much esteem for the table, its flesh being of good flavour, and very wholesome. The body is round, fleshy, above tawny, yellow on the sides and white beneath; the whole covered with small scales; head large; vent in the middle of the body; lateral line straight; fins yellow; pectoral and caudal yellow at the edge, with branched rays; dorsal and anal with ample rays.

**Celtaris.** Upper jaw longer; first dorsal fin fixed, with a black ocellated spot near the base on the posterior part. *Broussonet.*

Found in the fresh waters of Otaheite. The head is rather compressed, sub-conic, blackish, above slightly curved, obtusely carinated in the middle; teeth unequal, and minute, those of the lower jaw smaller; body compressed, lanceolate, covered on the posterior part with imbricated, ciliated scales, and obscurely clouded with olive and black; beneath glaucous.

Native of the European and Asiatic seas. Length six to nine inches; colour blueish black, varied.

**Boscii.** Body and tail grey, speckled with brown; the former marked with seven transverse whitish bands. *Lacépède.* Described and figured in the work of Lacépède, on the authority of Bosc, who observed it on the coasts of North America; it grows to the length of four inches; the head is broader than the body; the first four rays of the anterior dorsal fin terminate in a filament; and the body, which is smooth, is apparently without scales. The flesh is never eaten.

**Carulus.** Body blue; caudal fin red, with black border. *Lacépède.*

Inhabits the seas on the eastern coasts of Africa, where it was observed by Commeron, who describes its appearance in the water; when the sun shines, as splendid in the highest degree, though its size is small, the total length not exceeding three inches. The first dorsal is somewhat triangular, with the rays terminating in the fins, the second contains fourteen rays, the filamentous appendice of the tail ray in which is thrice the length of the rest. The flesh is not eaten by the natives, but is used as bait in fishing.

**Sect. Pectoral fins attached or placed on a fleshy process or elongation.**

**Schlosseri.** Blackish-brown, beneath whitish; rays of the first dorsal fin spinous. *Pallas.* *Schlosseri goby.*

This is about a span in length, the body, rather compressed, decreasing in an inconconsiderable degree towards the tail, and covered with large round corious scales; the head long, much thicker than the body, and sloping in front; the mouth transverse; lips thick, fleshy, granulous within, and the upper one folded; teeth large, unequal, dilated, and irregularly alternate; palate fleshy; tongue thick, soft, and fleshy; the eyes vertical and placed forward, protuberant, the pupils turned to the sides with a large lunar cavity beneath each; Gill-covers oblong and fleshy; tail ovate-acute; and the vent in the middle of the body. In the first dorsal fin are eight rays, in the second thirteen; pectoral, sixteen; ventral, twelve; anal, twelve; and tail nineteen. The species inhabits the fresh waters in the island of Ambaima, generally retiring in the soft mud at the bottom, and subsisting on worms; the flesh is excellent. The same fish occurs also in many parts of China. In the Gymnolius Syn. Nat. The species is described under two dillicent names, Ichtholiferi and barbatus, the latter of which Linnaeus defines as having the pectoral fins fan-shaped, and the first dorsal fin with twelve rays, the second thirteen. *Lacépède,* Bosc, and other late writers agree in considering them the same.

**Genus Gobius.**

Ventral fins united; dorsal fin one; head small; Gill-covers closed nearly throughout their contour.

*Vol. XVI.*

Described by Gmelin on the authority of Broussonet's Ichth. dec. 1.; it is mentioned as a small species, the habitat of which is unknown. Bosc believes it was brought from the South sea.

AMGUILLARI. Dorval fin single; tail red. Gmel.

The general figure of this species is somewhat anguilliform, or shaped like an eel, and like that: first the body is fat and slippery; the teeth are small, and project out of the mouth; the dorval and anal fins are large, and extend to the tail, with the fin of which they are united; the colour of the body is pale brown, of the fins red; the first dorval fin includes fifty-two rays; the pectoral, twelve; ventral, ten; anal, forty-three; and tail twelve. The fish is a native of the coast of China and other parts of India.

Smyrnesius. Edge of the jaws formed of a bony plate, and delicately of teeth. Lacépede.

Described on the authority of the new memoirs of the Transactions of the Academy of Petersburg. It is a native of the Mediterranean; the skin very vivious, and the dorval fin furnished with forty-three rays.

Broussonetii. Body very long and compressed; tail elongated. Lacèpede.

Supposed to be a native of the Indian seas. The example described by Lacèpede appertained to the fladhooler's museum. The dorval fin contains thirty-three rays, and extends nearly to the tail, as does likewise the anal fin; the body nearly transparent, and the jaws furnished with small teeth.

Genus Gobiomorphae.

Head small; eyes approximated; gill-covers closed nearly throughout their contour; dorval fins two.

* Section. Pectoral fins connected close to the body.

STRIGATUS. Ventral fin divided; first caudal fin six-rayed. Broussonet.

Native of the Pacific ocean, near Otaheite. The head is composed, yellow, streaked and spotted, and greenish yellow above; body composed, lanceolate and covered with imbricated, subquadrated, and slightly crenated scales; colour pale blueish-green; beneath whitish, with brownish streaks behind the pectoral fins; beneath the lateral, on the hind part, varied with oblique reddish spots; first dorval fin green, with red rays and four fillets of the latter colour; the second dorval fin with nine red fillets; pectoral fin pale green, the marginal rays shorter and bimple; ventral whitish; anal long, greenish-red; tail round-oval, yellowish-green, the rays red and bimple, with a broad oblique, slightly curving reddish fillet each side.

DORMITOR. Upper jaw longest; tail rounded. Lacée pede.

Described from the drawing of Plunier, who saw it in the fresh waters and rivers in the marishes of South America. The second dorval fin contains eleven rays, and each of the pectoral fins eight.

Inhabits the seas of South America. The body is silvery above, black, and spotted on the sides with black; feathers small and imbricated. The head of this species is naked; eyes large and lateral; mouth narrow; teeth equal, in the jaws and palate; tongue rounded, thin, smooth; gill-covers smooth and roundish; back a little convex; lateral line curved and parallel to the back; vent in the middle of the body.

** Section. Pectoral fins attached or placed on a flesh process or elongation.

KOELREUTHERI. Ventral fins divided; first dorval fin with eleven rays. Pallas.

Length about nine inches, the body soft, fat, and whitish-grey; head long, thick, and convex in front; eyes on the top of the head; lips doubled and fishy; teeth unequal, conic, the anterior ones larger, and one larger on each side of above the aperture of the gills nutated; lateral line impressed; vent about the middle of the body with a peduncle behind; fins soft; the first on the back large and brown, with a black terminal band, the rays from the second narrower, yellowish, with a longitudinal deep brown band, and branched rays; pectoral fan-shaped or oval, and placed on a broad pedicle; tail oval and lanceolate, with naked rays.

Genus Gobiomorphae.

Head small, with the eyes approximated; gill-covers closed nearly throughout their contour; dorval fin one.

PROBUS. Ventral fins divided; lower jaw longer. Gmel. Asper fusca, Pflü.

A small species found in South America. The head is depressed and covered with scales in size equal to that on the back; the mouth furnished with several rows of teeth; and the tail rounded.

Gobius After, a name given by Geyer and others to a species of perch called by many after pöciculus, a name confounding it with many other similar fishes, and by Linnaeus pera after. It is distinguished among the perch tribe by Arteri under the name of the perch with eight or nine black lines on each side. See Perca.

Gobius Ehrensi, or Gudjon. See Cyprinus Gobius.

Gobius Mariae, or Goger. See Gobius Niger.

GOBLET, or Goblet, a kind of drinking cup, or bowl; ordinarily of a round figure, and without either foot or handle.

The word is French, goblet; which Salmasius, and others, derive from the barbarous Latin cupa. Budæus deduces it from the Greek κυριά. a cup.

Gobletts, made of the wood tamarisk, are ranked among medicinal drugs; because the liquors infused a while therein, are supposed to acquire a quality which renders them good in diseases of the spleen.

GOBONE', or Gobony, in Heraldy, the name as companion.

Gobyganoe, in Geography, a town of Bengal; eight miles S. E. of Goragot.

GOCEY, a town of Hindoothan, in Allahabad; 30 miles N. of Gazypour.

GOCH, a town of France, in the department of the River, and chief place of a canton, in the district of Cleves, situated on the Niers, surrounded with walls in 1291, and containing three churches; six miles S. of Cleves. The place contains 2412, and the canton 12,728 inhabitants, in 19 communes.

Gochlenius, Rodolphus, in Biography, a physician, was born at Wittenberg in 1525. His father was professor of logic at Marburg, where the subject of this article: studied medicine, and obtained the degree of doctor in May, 1601; and was himself elected professor of philosophy in 1603, and also professor of mathematics in 1612. He died on the 2d of March 1621, at the age of 49. Although his life was not long, by extreme industry he had written a considerable number of treatises, in which he evinced much of that erudition and sagacity, of which he was a zealous follower. It is unnecessary to enumerate the long list of titles to his works, which relate to philosophy, mag-
M. Hallenberg, a Swedish writer, in a work published at Stockholm in 1796, and entitled "Difertatio historiae et philologicae de origine nominis Dei God," &c. suggests that the names given by different nations to the deity might denote unity; as the word God itself, by which in all the Tetragrammaton dialects the Supreme Being is denominated.

Philologists have hitherto considered the word God as being of the same signification with God; and this is not denied by M. Hallenberg. But he thinks, that both words originally denoted unity; and that the root is נֵּגֶד אֱלֹהִים, whence the Syr. Ohad and Gada; the Arab. Abd and God; the Peric. edhus and enumas; the Greek αὐθαίρητος; and so the 'Tetragrammaton' the German Gott; and our Saxon God. The other names of God, this author thinks, are referable to a similar origin.

By his immateriality, intelligence, and freedom, God is distinguished from fate, nature, destiny, chance, anima mundi, and from all the other fictitious beings, acknowledged by the Stoics, Pantheists, Spinoists, and other forts of atheists.

The knowledge of God, his nature, attributes, word and works, with the relations between him and his creatures, makes the subject of the extensive science called theology. In scripture God is defined by, "I am that I am; Alpha and Omega; the Beginning and End of all things."

Among philosophers, he is defined being of infinite perfection; or in whom there is no defect of any thing which we conceive may raise, improve, or exalt his nature.

Among men, he is chiefly considered as the first cause, the first being, who has existed from the beginning, has created the world, or who subsists necessarily, or of himself.

Sir IAMB. Newton chooses to confider and define God, not as is usually done, from his perfections, his nature, existence, or the like; but from his dominion. "The word God, according to him, is a relative term, and has a regard to servants; it is true, it denotes a being eternal, infinite, and absolutely perfect; but a being however eternal, infinite, and absolutely perfect, without dominion, would not be God.

"The word God," the same author observes, "frequently signifies Lord; but every lord is not God; it is the dominion of a spiritual being or lord, that constitutes God; true dominion, true God; supreme, the supreme, feigned, the false God.

"From such true dominion it follows, that the true God is living, intelligent, and powerful; and from his other perfections, that he is supreme, or supremely perfect; is eternal, and infinite; omnipotent, omniexistent; that is, he endures from eternity to eternity, and is present from eternity to eternity.

"He governs all things that exist, and knows all things that are to be known: he is not eternity, or infinity, but eternal and infinite: he is not duration or space, but he endures, and is present: he endures always, and is present every where; and by existing always, and every where, he constitutes the very things, duration and space, eternity and infinity.

"Since every particle of space is always, and every indivisible moment of duration every where, the Creator and Lord of all things can never be unanimous, or unguam.

"He is omnipresent, not only virtually, but also substantially: for power without subsistence cannot subsist. All things are contained, and move, in him; but without any mutual passion: he suffers nothing from the motions of bodies.
G O D.

dies; nor do they undergo any resistance from his omnipre-
ence.

"It is confessed, that God exists necessarily; and by the
same necessity he exists always, and everywhere. Hence,
also, he must be perfectly similar; all eye, all car, all brain,
all arm, all the power of perceiving, understanding, and
acting; but after a manner not at all corporeal, after a man-
ner not like that of men, after a manner wholly to us un-
known.

"He is delirious of all body, and all bodily shape; and
therefore cannot be seen, heard, or touched; nor ought to
be worshipped under the representation of any thing corpo-
real.

"We have ideas of the attributes of God, but do not
know the substance even of any thing: we see only the
figures and colours of bodies, in a manner founds, touch only
the outward surfaces, smell only odours, and taste tastes; and
do not, cannot, by any sense, or any reflex act, know their
inward substances; and much less can we have any notion of
the substance of God.

"We know him by his properties and attributes; by
the most wise and excellent structure of things, and by final
causes; but we adore and worship him only on account of
his dominion: for God, setting aside dominion, providence,
and final causes, is nothing else but fate and nature."-Newt.

An ingenious divinity has wrought these thoughts of that
admirable philosopher into form, and ripened them into a
more expres system, in a discourse on this subject. Max-
well's Dis. concerning God.

We shall here subjoin a compendious abstract of the prin-
cipal arguments that have been alleged in proof of the ex-
istence of God. The admirable metaphysician and divine,
Dr. Clarke, has demonstrated this truth, with that clearness
and force of reasoning, for which he is so eminently dif-
tinguished, by a series of propositions, mutually connected
and dependent, and forming a complete and unanswerable
argument in proof both of the being and attributes of the
Deity.

1. Something has existed from all eternity; for,
there being nothing now is, something always was; otherwise
the things that now are must have been produced out of nothing,
and absolutely without cause, which is plain contradiction
in terms.

2. There has existed from eternity some one un-
changeable and independent being; or else, there has been an
infinite succession of changeable and dependent beings pro-
duced one from another in an endless progression, without any
original cause at all. From without, this series of beings
can have no cause of its existence, because it includes all
things that are or ever were in the universe; nor is any one
being in this infinite succession self-existent or necessary, and
therefore it can have no reason of its existence within itself;
and it was equally possible, that from eternity, there should
never have existed any thing at all, as that a succession of
such beings should have existed from eternity. Consequent-
ly, their existence is determined by nothing; neither by any
necessity of their own nature, because none of them are self-
existent; nor by any other being, because no other is sup-
posed to exist.

3. That unchangeable and independent be-
ing, which has existed from eternity, without any external
cause of its existence must be self-existent, i. e. it must exist
by an absolute necessity originally in the nature of the thing
itself, and antecedent in the natural order of our ideas to our
fupposition of its being. For whatever exists must either
have come into being out of nothing without cause; or it
must have been produced by some external cause; or it must
be self-existent: but the two former suppositions are contrary
to the two first propositions. From this last proposition it
follows, that the only true idea of a self-existent, or neces-
arily existing being, is the idea of a being, the supposition of
whole non-existence is an express contradiction; and this
idea is that of a most simple being, absolutely eternal and in-
finite, original and independent. It follows also, that noth-
ing is so certain as the existence of a supreme independent
cause; and likewise that the material world cannot possibly
be the first and original being, uncreated, independent, and of
itself eternal; because it does not exist by an absolute ne-
cessity in its own nature, so as that it must be an express con-
tradiction to suppose it not to exist. With respect both to
its form and matter, the material world may be conceived
not to be, or to be in any respect different from what it is,
without a contradiction. 4 and 5. The substance or essence
of the self-existent being is absolutely incomprehensible by
us; nevertheless, many of the essential attributes of his na-
ture are strictly demonstrable, as well as his existence. The
self-existent being, having no cause of its existence but the
absolute necessity of its own nature, must of necessity have
existed from everlastings, without beginning; and must of
necesary exit to everlastings, without end. 6. The self-
existent being must of necessity be infinite and omnipre-
ent.

Such a being must be everywhere, as well as always, un-
terably the same. It follows from hence, that the self-ex-
istent being must be a most simple, unchangeable, incorrup-
tible being; without parts, figure, motion, divinity, and
other properties of matter, which are utterly inconsistent
with complete infinity. 7. The self-existent being, must of
necesary be but one; because in absolute necessity there can
be no difference or diversity of existence; and, therefore, it
is absolutely impossible, that there should be two indepen-
dent self-existent principles, such e. g. as God and matter.
8. The self-existent and original cause of all things must be
an intellectual being. This proposition cannot be demon-
strated strictly and properly a priori; but a posteriori, the
world affords undeniable arguments to prove that all things
are the effects of an intelligent and knowing cause.
The cause must be always more excellent than the effect; and,
therefore, from the various kinds of powers and degrees of
excellence and perfection, which visible objects possess, from
the intelligence of created beings, which is a real distinct qual-
ity or perfection, and not a mere effect or composition of uni-
teilent figure and motion; from the variety, order, beauty,
and principality, and fitness of all things to their proper and
respective ends; and from the original of motion, the self-
existent creating being is demonstrated to be intelli-
gent. 9. The self-existent and original cause of all things
is not a necessary agent, but a being endowed with liberty
and choice. Liberty is a necessary concomitant of intelligence;
without liberty, no being can be said to be an agent, or
cause of any thing; since to act necessarily is really and pro-
perly not to act at all, but to be acted upon. Besides, if the
supreme cause be not endowed with liberty, it will follow,
that nothing which is not could possibly have been; that
nothing which is could possibly not have been; and that
no mode or circumstance of the existence of any thing could
possibly have been in any respect otherwise than it now actu-
ally is. Further, if there be any final cause in the universe,
the supreme cause is a free agent; and on the contrary sup-
position, it is impossible that any effect should be finite;
and in every effect, there must have been a progression of
causes in infinitum, without any original cause at all. 10. The
self-existent being, the supreme cause of all things, must of
necesary have infinite power; since all things were made
by him, and are entirely dependent upon him; and all the
powers of all things are derived from him, and perfectly sub-
ject
ject to him; nothing can reft the execution of his will. 11. The supreme cause and author of all things must of necessity be infinitely wise. This follows from the propositions already established; and the proof a priori, of the infinite wisdom of God, from the consideration of the exquisite perfection and concomitant excellence of his works, is no less strong and undeniable. 12. The supreme cause and author of all things must of necessity be a being of infinite goodness, justice, and truth, and all other moral perfections; such as become the supreme governor and judge of the world. The will of a being, infinitely knowing and wise, independent and all-powerful, can never be influenced by any wrong affection, and can never be misled or opposed from without; and, therefore, he must do always what he knows fittest to be done; that is, he must act always according to the strictest rules of infinite goodness, justice, and truth, and all other moral perfections, and more particularly, being infinitely and necessarily happy and all-sufficient, he must be unalterably disposed to do and to communicate good or happiness. See Clarke's Demonstration of the Being and Attributes of God.

To this more abstruse argument a priori, for the existence of God, we may add another, more generally obvious, and carrying irresistible conviction, which is deduced from the frame of the universe, and from the traces of evident contrivance and fitness of things for one another that occur through all the parts of it. These confpire to prove, that the material world, which in its nature is originated and dependent, could not have been the effect of chance or necessity, but of intelligence and design. The beautiful, harmonious, and beneficial arrangement of the various bodies that compose the material system; their mutual dependence and subordination; the regularity of their motions, and the aptitude of these motions for producing the most beneficial effects; and many other phenomena resulting from their relation, magnitude, situation, and use, afford unquestionable evidences of the creating power and wise disposal of an intelligent and almighty agent. The power of gravity, by which the celestial bodies preserve in their revolutions, deserves our particular consideration. This power penetrates to the centres of the sun and planets, without any diminution of its virtue, and is extended to immense distances, regularly decreasing, and producing the most sensible and important effects. Its action is proportional to the quantity of solid matter in bodies, and not to their surfaces, as is usual in mechanical causes; and, therefore, seems to surpass mere mechanism. But however various the phenomena that depend on this power, and may be explained by it, no mechanical principles can account for its effects; much less could it have produced, at the beginning, the regular situation of the orbs, and the present disposition of things. Gravity could not have determined the planets to move from well to call in orbits nearly circular, almost in the same plane; nor could this power have projected the comets with all the variety of their directions. If we suppose the matter of the system to be accumulated in the centre by its gravity, no mechanical principles, with the assistance of this power, could separate the huge and unwieldy masses into such parts as the sun and planets; and, after carrying them to their different distances, project them in their several directions, preserving still the equality of action and reaction, or the state of the centre of gravity of the system. Such an exquisite structure of things could only arise from the contrivance and powerful influences of an intelligent, free, and most potent agent. The same powers, therefore, which at present govern the material universe and conduct its various motions, are very different from those which were necessary to have produced it from nothing, or to have disposed it in the admirable form in which it now proceeds.

But we should far exceed the proper limits of this article, if, confining our observation to the earth, our own habitation was void of the principal traces of design and wisdom, as well as goodness, which are discernible in its figure and composition parts, in its annual and daily motion, in the position of its axis with regard to its orbit, in the benefit which it derives from the light and heat of the sun, and the alternate temperature of the seasons; in the atmosphere which surrounds it, and in the different species and varieties of vegetables and animals with which it is replenished. No one can survey the vegetable productions of the earth, so various, beautiful, and useful, nor the various gradations of animal life, in such a variety of species, all preferred distinct, and propagated by a settled law, each fitted to its own element, provided with proper food, and with instincts and organs suited to its rank and situation, and especially with the powers of sensation and self-motion, and all more immediately or remotely subservient to the government and use of man, without admiring the skill and wisdom of the original Creator. But these are more strikingly manifested in the structure of the human frame, and in the noble powers and capacities of the human mind; more especially in the moral principles and faculties, which are a distinguishing part of our constitution, and lead to the perception and acknowledgment of the existence and government of God. In those instances that have now been recited, and a variety of similar instances suggested by them, or naturally occurring to the notice of the curious and reflecting mind, contrivance is manifest, and immediately, without any nice or subtle reasonings, suggests a contriver. It strikes us like a sensation; and artful reasonings against it may puzzle us, without shaking our belief. No paragon, for example, that knows the principles of optics, and the structure of the eye, can believe that it was formed without skill in that science, and therefore, Sturmus held that the examination of the eye was a cure for atheism; and another excellent writer, cited below, observes, that if there were no example in the world of contrivance, except that of the eye, it would be alone sufficient to support the conclusion which we draw from it, as to the necessity of an intelligent creator; nor can it be supposed that the ear was formed without the knowledge of sounds; or that the male and female, created and preferred in due proportion, were not formed for each other, and for continuing the species. All our accounts of nature are full of instances of this kind. The admirable and beautiful structure of things for final causes excite our idea of the contriver; and the unity of design shews him to be one. The great motions in the system, performed with the same facility as the leaf, suggest his almighty power, which gave motion to the earth and the celestial bodies, with equal ease as to the minutest particles; the subtility of the motions and actions in the internal parts of bodies, shews that his influence penetrates the inmost recesses of things, and that he is equally active and present everywhere. The simplicity of the laws that prevail in the world, the excellent disposition of things, in order to obtain the best ends, and the beauty which adorns the works of nature, far superior to any thing in art, suggest his concomitant wisdom. The usefulness of the whole scheme, so well contrived for the intelligent beings who enjoy it, with the internal disposition and moral structure of those beings, shews his unbounded goodness. These are arguments which are sufficiently open to the views and capacities of the unlearned, while at the same
fame time they acquire new strength and lustre from the discoveries of the learned. The Deity's acting and interposing in the various ways in which he governs it as well as formed it; and the depth of his counsels, even in conducting the material universe, of which a great part furnishes our knowledge, tends to preserve an inward variegation and awe of this great being, and disposes us to receive what may be otherwise revealed to us concerning him. His essence, as well as that of all other substances, is beyond the reach of all our discoveries; but his attributes clearly appear in his admirable works. We know that the highest conceptions we are able to form of them are still beneath his real perfections; but his dominion over us, and our duty towards him, are manifest. See Mac Laurin's Account of Sir I. Newton's Phil. Difc. book iv. chap. q.

Those who wish to see the argument, which has been now stretched out in fome of its leading outlines, more fully illustrated and urged, may consult the works of Ray, Nieuwentyt, Baxter in his Matho, Derham, De la Planche in his Nature displayed, &c.; and more especially archdeacon Paley in his "Natural Theology, or Evidences of the Existence and attributes of the Deity, collected from the appearances of Nature." This admirable work, if our limits would allow it, would enable us very much to enrich this article.

One atheistic way, says this much approved and popular writer, of replying to our observations upon the works of Nature, and to the proofs of a Deity which we think that we perceive in them, is to tell us, that all which we see must necessarily have had some form, and that it might as well be in its present form as any. Let us now apply this answer to the eye.—"Something or other must have occupied that place in the animal's head; must have filled up, we will say, that focket; we will say also, that it must have been of that fort of fubstance, which we call animal fubfance, as flesh, bone, membrane, cartilage, &c.; but that it should have been an eye, knowing as we do what an eye comprehends, viz. that it should have confined, first, of a series of transparent leaves, (very different, by the bye, even in their fubstances from the opaque materials of which the rest of the body is, in general at least, composed; and with which the whole of its surface, this fingle portion of it excepted, is covered) secondly, of a black cloth or canvas (the only membrane of the body which is black) spread out behind these leaves, so as to receive the image formed by pencils of light transmitted through them; and placed at the precise geometrical distance at which, and at which alone, a distinct image could be formed, namely, at the concourse of the refracted rays; thirdly, of a large nerve communicating between this membrane and the brain; without which the action of light upon the membrane, however modified by the organ, would be loll to the purposes of fubfation. That this fortunate conformation of the parts first have been the hit, not of one individual out of many thousand individuals, like the great prize in a lottery, or like fome fanguity in nature, but the happy chance of a whole species; nor of one species out of many thousand species, with which we are acquainted; but of by far the greatest number of all that exift, and that under varieties, not cafual or capricious, but bearing marks of being fitted to their respective exigencies; that all this should have taken place, merely because fomething must have occupied these points in every animal's forehead; or that all this should be thought to be accounted for by the short answer, "that whatever was there must have had some form or other," is too absurd to be made more fo by any argumentation."—"Nor does it mend the answer to add, with respect to the fignality of the conformation, that, after the event, it is no longer to be computed what the chances were against it. This is always to be computed, when the question is, whether an useful or imitative conformation be the produce of chance or not. I defire no greater certainty in reafoning than that by which chance is excluded from the preient disposition of the natural world. Universal experience is against it. What does chance ever do for us? In the human body, for instance, chance, i.e., the operation of causes without design, may produce a wen, a wart, a mole, a pimple, but never an eye. Among inanimate fubstances, a clod, a pebble, a liquid drop, might be; but never was a watch, a telescope, or organized body of any kind, answering a valuable purpofe by a complicated mechanism, the effect of chance. In no affignable instance hath fuch a thing existed, without intention, somewhere. Some have faid "that the eye, the animal to which it belongs, every other animal, every plant, and every organized body which we fee, are only fo many out of the poible varieties and combinations of being, which the lapse of infinite ages has brought into exiftence; and that the preient world is the relic of that variety."—But "there is no foundation whatever for this conj-cture in any thing which we obferve in the works of nature: no fuch experiments are going on at prezent! No fuch energy operates as that which is here fup-posed, and which should be confidently putting into exiftence new varieties of beings; nor are there any appearances to support an opinion that every poible combination of vege-table or animal structure has formerly been tried." Should it be faid that the parts of animal bodies "were not intended for theufe, but that the ufe arose out of the parts; this difinition is intelligible."—But "there is little place for it in the works of nature. When roundly and generally affirm- ed of them, as it has fometimes been, it amounts to fuch an other fretch of affertion, as it would be to fay, that all the implements of the cabinet-maker's workshop, as well as his fhit-kin, were fubstances accidentally configured, which he had picked up and converted to his ufe; that his adzes, faws, planes, and gimlets, were not made, as we fuppofe, to new, cut, smooth, flape-out, or bore wood with; but, that thefe things being made, no matter with what defign, or whether with any, the cabinet-maker perceived that they were applicable to his purpofe, and turned them to account." If this kind of solution be applied to those parts of ani-mals, the action of which does not depend upon the will of the animal, it is fraught with still more evident absurdity. Is it poible to believe that the eye was formed without any regard to fivion, that it was the animal itself which found out, that though formed with no fuch intention, it would ferve to fee with; and that the ufe of the eye, as an organ of fight, refulted from this discovery, and the animal's application of it? The fame question may be asked of the ear: the fame of all the fenes, none of which depend upon the election of the animal; nor confequently upon his fagacity or experience. Others have choen to refer every thing to a principle of order in nature. A principle of order is the word; but what is meant by a principle of order, as different from an intelligent creator, has not been explained either by definition or example; and without fuch explanation, it should feem to be a mere fublimation of words for reasons, names for causes."—"Was a watch ever produced by a principle of order; and why might not a watch be fo produced as well as an eye?"—"The confidence," continues the author now cited, "which we place in our obseruations upon the works of nature, in the marks which we discover of contrivance, choice, and design, and in our reasoning upon the proofs afforded us, ought not to be shaken, as it is sometimes attempred to be done, by bringing forward to our view our own ignorance, or rather the general imperfection of
our knowledge of nature."—"True fortitude of understanding confides in not suffering what we know to be disturbed by what we do not know. If we perceive an useful end, and means adapted to that end, we perceive enough for our conclusion. If these things be clear, no matter what is obscure. The argument is finished."—"Our ignorance of many points need not suspend our assurance of a few."—"Contrivance," says our author, "if established, appears to me to prove every thing which we wish to prove. Amongst other things, it proves the personality of the Deity, as distinguished from what is sometimes called nature, sometimes called a principle: which terms in the mouths of those who use them philosophically, seem to be intended, to admit and express an efficacy, but to exclude and deny a personal agent. Now that which can contrive, which can design, must be a person. These capabilities constitute personality, for they imply conscious and thought. They require that which can perceive an end or purpose; as well as the power of providing means, and of directing them to their end. They require a centre, in which perfections unite, and from which volitions flow; which is mind. The acts of a mind prove the existence of a mind; and that, whatever it be, in which a mind resides, is a person.—"After all the struggles of a reluctant philosophy, the necessary refit is a deity. The marks of design are too strong to be got over. Design must have had a designer. The designer must have been a person. That person is God."—"But we must content ourselves with carnally recommending the works from which these detached extracts are made, to the perusal of our readers; for we cannot do justice to the author's admirable reasoning.

Another argument to prove the existence of God, as the creator and governor of the universe, may be deduced from the universal consent of mankind, and the uniform tradition of this belief through every nation and every age; it is impossible to conceive, that a fallacy so perpetual and universal, should be impaled on the united reason of mankind. No credible and satisfactory account can be given of this universal consent, without ascribing it to the original constitution of the human mind, in consequence of which it cannot fail to discern the existence of a deity, and to the undeniable traces of his being, which his works afford. Fear, flate-policy, and the prejudices of education, to which the concurrence of mankind in this principle has been sometimes resolved, are founded on this universal principle, suppose its being and influence, and are actuated by it. It is much more reasonable to imagine, that the belief of a God was antecedent to their operation, than that it should have been produced by them; and that it was dictated by reason and conscience, independent of the passions and policy of men. The uniform and universal tradition of this belief, and of the creation of the world by the divine power, affords concurrence evidence both of the principle and of the fact.

The existence of God is also farther evinced by those arguments which have been usually alleged to prove, that the world had a beginning, and therefore, that it must have been created by the energy of divine power. In proof of this, the history of Mole, considered merely as the most ancient historian, deserves particular regard. His testimony is confirmed by the most ancient writers among the heathens, both poets and historians. It may be also fairly alleged, that we have no history or tradition more ancient than that which agrees with the received opinion of the world's beginning, and of the manner in which it was produced; and that the most ancient histories were written long after that time.

And this consideration is urged by Lucretius, the famous Epicurean, as a strong presumption that the world had a beginning.

"... Si nulla fuit genitalis origo. Terra rum et caeli, temporaque interna fuere: Cur supra bellum Thba num, et funera Troje, Non alas ad quoque res exscrece poetae?"

Besides, the origina and progress of learning, and the most useful arts, confirm the notion of the world's beginning, and of the common era of its creation; to which also may be added, that the world itself, being material and corruptible, must have had a beginning; and many phenomena occur to the observation of the astronomer and natural historian, which furnish a strong presumption that it could have had no long duration, and that it gradually tends to dissolution. From all these considerations we may infer the existence, attributes, and providence of God. If we admit miracles, as facts authenticated by credible history, those, considered as deviations from the established course of nature, afford independent evidence of the being of God. See MIRACLE.

God is also used in speaking of the false deities of the heathens, many of which were only creatures to which divine honours and worship were superstitiously paid.

The Greeks and Latins, it is observable, did not mean, by the name God, an all-perfect being, whereof eternity, infinity, omnipotence, &c. were essential attributes; with them, the word only implied an excellent and superior nature; and, accordingly, they give the appellation gods to all beings of a rank, or class, higher and more perfect than that of men; and especially to those who were inferior agents in the divine administration, all subject to the one supreme.

Thus men themselves, according to their fysm, might become gods, after death; insomuch as their souls might attain to a degree of excellency superior to what they were capable of in life.

The first divines, father Boffin obsevrs, were the poets: the two functions, though now separated, were originally combined; or, rather, were one and the same thing. Now the great variety of attributes in God, that is, the number of relations, capacities, and circumstances, wherein they had occasion to consider him, put the% poets, &c. under a necessity of making a partition, and of separating the divine attributes into several persons: because the weaknesses of the human mind could not conceive too much power and action in the simplicity of one single divine nature. Thus the omnipotence of God came to be represented under the person and appellation of Jupiter; the wisdom of God under that of Minerva; the justice of God under that of Jutnos. The first idols, or false gods, that are said to have been adored, were the stars, sun, moon, &c. on account of the light, heat, and other benefits which we derive from them. (See Idolatry.) Afterwards the earth came to be deified, for furnishing fruits necessary for the subsistence of men and animals; then fire and water became objects of divine worship, for their usefulness to human life. In process of time, and by degrees, gods became multiplied to infinity; and there was scarce any thing but the weaknesses, or caprice of
fome devotee or other, elevated into the rank of deity; things
usefes, or even destrucfive not excepted.
The principal of the ancient gods, whom the Romans
called divi majorum genifum, and which Cicero calls celefial
gods, Varro felix deos, Ovid nobles deos, others confentcs deos,
were Jupiter, Juno, Vefla, Minerva, Ceres, Diana, Venus,
Mars, Mercury, Neptune, Vulcan, and Apollo. Jupiter
is confidered as the god of heaven; Neptune as god of the
sea; Mars as the god of war; Apollo of eloquence, poe-
dery, and phyfic; Mercury of thieves, Bacchus of wine, Cupid
of love, &c.
A fecond fort of gods, called demi-gods, demi-divi, divi
minorum genifum, indiigeis, that gods adopted, were men cano-
nized and deified. As the greater gods had possession of heaven
by their own right; these fecondary deities had it by right
and donation; being translated into heaven because they
had lived as gods upon earth.
The heathen gods may all be reduced to the following
classes:
1. Created spirits, angels, or daemons: whence good and
evil gods; Genii, Larces, Lemures, Typhones, guardian
gods, infernal gods, &c.
2. Heavenly bodies: as the sun, moon, and other planets:
alfo the fixed fars, confullations, &c.
3. Elements; as air, earth, ocean, Opis, Vefla; the ri-
vers, fountains, &c.
4. Meteors. Thus the Perifians adored the wind: thun-
der and lightning were honoured under the name of Gery-
on; and feveral nations of India and America have made
themselves gods of the fame. Cadhor, Polux, Helena, and
Iris, have alfo been preferred from meteors to be gods; and
the like has been praculfed in regard to comets: witnefs that
which appeared at the murder of Cefar. Socrates defied
the clouds, if we may give credit to Ariophanes; and the pri-
mitive Chriflians, Tertullian affures us, were reproached
with the fame thing.
5. They erected minerals, or foifs, into deities. Such was
the Batxylus; the Finlanders adored fonnes; the Scythians
iron; and many nations fiver and gold.
6. Plants have been made gods. Thus leeks and onions
were deities in Egypt; the Scavi, Lithuanians, Celts,
Vandals, and Peruvians, adored trees and forests; the ancient
Gauls, Britons, and Druids, paid a particular devotion to the
oak; and it was no other than wheat, corn, feed, &c.
that the ancients adored under the names of Ceres and Pro-
ferpine.
8. They took themselves gods from among the waters.
The Syrians and Egyptians adored fihes; and the Tri-
tons, Nereids, Syrens, &c. what were they but fihes? Se-
veral nations have adored ferpents; particularly the Egyp-
tians, Poffrians, Lithuanians, Samogitiens, &c.
8. Infedes, as flies and ants, had their priafe and votaries;
these among the Theliffians, and thofe in Acrania, where
bullocks were ofered to them.
9. Among birds, the flork, raven, the sparrowhawk, ibis,
eagle, giffon, and lapwing, have had divine honors; the laf
in Mexico, the reil in Egypt, and at Thibes.
10. Four-footed beafts have had their altars; as the bull,
dog, cat, wolf, baboon, lion, and crocodile, in Egypt, and
eelfewhere; the hog in the ifland of Crete; rats and mice in the
Troas, and at Tenedos; weafels at Thibes, and the
porcupine throughout all Zororaller's fchool.
11. Nothing was more common than to place men among
the number of deities; and from Belus or Baal, to the Roman
emperors before Constantine, the infinaces of this kind are
univerfable: frequently they did not wait fo long as their
death for the apothefis. Nebuchadnezzar procured his flature
to be worfhipped while living; and Virgil faws that Augus-
tus had altars and sacrifices offered to him, Eclog. i. 6, 7
As we learn, from other hands, that he had priafes called
Augufidae; and temples at Lyons, Narbona, and feveral
other places; and he muft be allowed the firit of the Romans,
in whole behalf idolatry was carried to fhuch a pitch. The
Ethiopians deemed all their kings gods: the Velleda of the
Germans; the Janus of the Hungarians; and the Thaut,
Woden, and Afta, of the northern nations, were, indifpu-
tably, men.
5. Not men only, but every thing that relates to man,
has alfo been defieued: as labour, ref, sleep, youth, age, death,
virtues, vives, occafion, time, place, numbers, among the
Pythagoreans; the generative power, under the name of
Pranpas. Infancy, alone, had a cloud of deities; as Vage-
tanus, Levana, Rumina, Edusa, Potina, Cuba, Cuminia,
Carna, Offiago, Statuhius, Fabulifus, &c.
They alfo adored the gods health, fever, fear, love, pain,
indignation, fame, impudence, opinion, renown, prudence,
ience, art, fidelity, felicity, calumni, liberty, money, war,
peace, victory, triumph, &c.
Lastly, nature, the universe, or re, was reputed
a great god.
Hevob has a poem under the title of Deprons, i.e. the ge-
neration of the gods; wherein he explains their genealogy and
defecf; fets forth who was the firft, and principal; who
next defcended from him, and what ifue each had; the whole
making a fort of fyllem of heathen theology.
Beside this popular theology, each philofophcr had his
fsylum: as may be feen from the Timax of Plato, and Cic-
ere De Natura Deorum.
A6us Martyr, Tertullian in his Apologetics, and in his
book Contra Genes; Arnobius, Miniatius Felix, La<ntius,
Eufebius, Prepar & Demonfl. Evangel. St. Augustine De
Civit. Dei, and Theodoret Adverf. Gentes, show the vanity
of the heathen gods.
It is very difficult to difcover the real sentiments of the
heathen with refpect to their gods: they are exceedingly
itriate and confused, and even frequently contradictory.
They admitted fo many superior and inferior gods, who shared
the empire, that all was full of gods. Varro reckons up no lefs
than 30,000 adored within a small extent of ground, and yet
their number was every day growing. The way to hea-
ten was fo easy for the great men of those days, that Ju-
enum in his Bifem explaining he was ready to fink under the
load of fuch a number of new gods as were daily placed in
the heavens; yet father Murgeres feems to have proved that
all the philofophers of antiquity have acknowledged that
there was but one God. Plan. Theol. de Sect. Scavans de

GODAGARY, in Geography, a town of Bengal; 18
miles N. of Moorheadabad.
GODALMING, a market town and parish in the
county of Surry, England, contains 474 houses and 3405
inhabitants. The town is built in a valley, on the banks of the
river Wey, which is divided into feveral small freams
here. The chief of this is navigable to Weybridge, where
it unites its waters with the Thames. In the vicinity of the
town are fome corn-mills, and paper-mills. Here are feveral
fab mechanies for weaving flockings, patent feecy fofetry,
and coarse woollen cloths; woof-combing and fpinning of
worfled alfo contribute part of the trade of the place. The
parish
Godama, Godama, Godama, Gotama, or Gautom, in Indian Mythology, different names applied in various parts of India, and particularly in the Burman empire, to their deity Buddha, or Booudh. (See Booodh.) Godama or Godama is the most common appellation among his worshippers in India beyond the Ganges; it seems also to be common among the Hindoos, who, according to the idiom of the Sanscrit, write it Gotamas. This name, as some say, literally signifies cow-herd, but metaphorically king; and, according to others, the meaning of Godama is eminently wise, or a sage. Many other appellations are given to this deity derived from the poisons in which his various images represent him. Godama was probably an Indian prince, deified by superstitiion; and in an ancient treatise, giving an account of the religion of Godama, entitled "Zaradu," Godama is said to have attained divinity at the age of 35 years, to have preached his law for 45 years, and to have brought salvation to all living beings. Dr. Buchanam, who cites this treatise (Af. Ref. vol. vi.) places the death of Godama 546 years B. C. The doctrine and laws, said in this treatise to be delivered by Godama, confid chiefly in observing the five commandments, and in abstaining from the ten sins. The five commandments are as follow: 1. From the meanest infect up to man, thou shalt kill no animal whatever. 2. Thou shalt not steal. 3. Thou shalt not violate the wife or concubine of another. 4. Thou shalt tell nothing false. 5. Thou shalt drink neither wine, nor any thing that will intoxicate; thou shalt not eat opium, or any other intoxicating drug. The person who keeps these five commandments shall attain high rank, and shall not be liable to poverty, nor to other misfortunes and calamities. The ten sins are the killing of animals—thief—adultery—falsehood—discontent—harsh and indignant language—idle and superfluous talk—the coveting of your neighbour's goods—envy, and the desire of your neighbour's death, or misfortune—and the following of the doctrine of false gods. Every one who abstains from these sins, will successively increase in virtue through all his successive transmigrations, till at length he will become worthy of beholding a God, and of hearing his great voice; and he will be exempted from the four human miseries, viz. weight, old age, disease, and death. The good works required are giving alms, and thoughtfully pronouncing three words. Whoever dies without the abstinence and good works here prescribed, will certainly pass into one of the infernal states, and be doomed to certain transmigrations. The precepts of Godama are called Rahans in the Burman language, and they have also bestowed upon them the title of Somoua or Samana, which is likewise applied to the images of the divinity when he is represented, as he commonly is, in the priestly habit. (See Rahans.) Godama commanded his images and relics to be worshipped. The largel and most celebrated temples in generally in the form of a pyramid; and contain some of these relics, such as a tooth, a bone, a hair, or a garment. To these temples the prayers of the devout are addressed, and their offerings presented. The images of the god are of various materials—clay, copper, silver, and alabaster. Many of them are richly gilt, and adorned with paintings of flowers; they are of different sizes, some being not above six inches high, and others of a colossal stature. Other objects of great veneration among the worshippers of Godama are stones of large dimensions, carved with various hieroglyphics, and said to represent, or to be the impressions of his feet. The principal disciples of Godama are by his followers considered as sages; and many images of these, in a priestly habit, accompany that of their master. Every true worshipper of Godama prays before he goes to sleep, and before he rises in the morning, which is generally at the dawn of day.

Besides their private devotions, which are numerous and regularly performed, it is customary to make offerings at the temple; the sacrifices for which are those of the four phases of the moon, especially the full and change, which may be considered as the Burana fables. Friday is with them reckoned an unfortunate day, and therefore on this day they undertake no business; but they keep holy no particular day of the week. The fact of Godama declare the opinion of a divine being, who created the universe, to be highly impious; and accordingly the followers of Godama are, fiercely speaking, atheists, as they suppose every thing to arise from fate; and their gods are merely men, who by their virtue acquire supreme happiness, and by their wisdom become entitled to impose a law on all living beings. See Burman Empire, and Booodh.

Godana, in Geography, a town of Persia, in the province of Trak; 105 miles E. of Ipahan.

Goadery, or Gonga Gondwy, a river of Hindostan, sometimes called the Gang in Ferihil's History, was, till very lately, considered as the same with the Cattack river, or Mahanuddy; but it is now ascertained to be a different river, which has its source about 70 miles N.E. of Bombay; and the western Gouts, more properly called the Sukhin mountains; and, in the upper part of its course, at least, is effemed a sacred river by the Hindoos; that is, ablutions performed in its stream have a religious efficacy superior to those performed in ordinary streams. The Godavery, after traversing the Dowatabad lounah, and the country of Tellagama, from west to east, turns to the south-east; and receiving the Bain Gunga, about 90 miles above the sea, besides many smaller rivers, separates into two principal channels at Rajamundry; and thence subdividing again, they form altogether several tide harbours, for vessels of moderate burden. Ingrum, Coringa, Yaram, Bandarma-lanka, and Narsapour, are among the places situated at the mouth of this river; which appears to be the most considerable one between the Ganges and Cape Comorin. Extensive forests of teak-trees border on its banks, within the mountains, and supply flint-timber for the use of the ports above-mentioned. The Killnala and Godavery rivers, however remote at their fountains, approach within 80 miles of each other in the lower parts of their course; and form an extensive tracts of country, composed of rich vegetable mould, such as is usually found at the mouths of large rivers. Renell. See Delta.

God, in our Ancient Saxon Cofram, an ecclesiastical or church fire, for crimes and offences committed against
against God. These, according to Blacklone, are opulency and liberty, which see.

GODDARD, Jonathan, in Biography, an eminent physician and chemist, was born at Greenwich in the year 1617. After studying for four years at Oxford, he set out on his travels, and on his return he settled in practice in London, having taken his degree at Cambridge. He was elected a fellow of the College of Physicians in 1645, and in 1647 was appointed lecturer on anatomy. In conjunction with some friends, he formed a society for experimental inquiry, which met at his lodgings in Wood-street, and in promoting the objects of which he was extremely assiduous. Having gained considerable reputation, and having, with the rest of his party, sided with parliament, he was appointed by Cromwell chief physician to the army, and in this capacity accompanied the usurper to Ireland in 1649, to Scotland in the following year, and thence returned with his master, who, after the battle of Worcester, rode into London in triumph, September 12th, 1651. He obtained many favours from Cromwell, who first made him warden of Merton college, Oxford, afterwards feke representative of that university in the Short Parliament in 1653; and in the same year one of the council of flate. These favours were sufficient to procure for him the displeasure of Charles II.; and, being driven from Oxford, he removed to Gresham college, where he had been chosen professor of physic in November 1655. Here he continued to frequent those meetings, which gave birth to the Royal Society, and was nominated one of the first council of that institution in the charter. Dr. Goddard was a conscientious and able practitioner. Partly from the love of experimental chemistry, principally from a distrust in the knowledge of apothecaries, he prepared his own medicines, and recommended the practice to be adopted by physicians in general. Finding numerous obstacles, however, in his way, he published "A Difcourse, letting forth the unhappy condition of the practice of physic in London," 1669. But this was of no avail. He died on the 24th of March, 1674, being seized with an apoplectic fit in Cheap-side, when returning from one of the philosophic meetings. Two papers of his was published in the Philosophical Transactions, No. 137, 159; and many others in Birch's History of the Royal Society.

GODDESS, Dea, Diva, a heathen deity, to whom they attributed the female sex.

The ancients had almost as many goddesses as gods. Such were Juno, the goddess of air; Diana, the goddess of woods and chastity; Proserpina, the goddess of hell; Venus, of beauty; Thetis, of the sea; such also were Victory, Fortune, &c.

Nay they were not contented to make women gods, and admit both sexes into the roll; but they had also hermaphrodite gods Thus Minerva, according to several of the learned, was both man and woman, and worshipped both under the appellation of Lunus and Luna. Mithras, the Persian deity, was both god and goddess, and the fexes of Venus and Vulcan are very dubious: whence, in the invocations of those deities, they used this formula; "Be thou god or goddess," as we learn from A. Gallus. It was a privilege peculiar to goddesses, that they might be represented on medals, naked. The imagination, it was supposed, must be axed, and kept from taking liberties, by the consideration of the divine character.

GODEAU, Anthony, in Biography, was born at the city of Druye in the year 1615. He was educated for civil and active life, but having met with a disappointment in the object of his affections, he repaired to Paris, where he cultivated the society of men of letters, and was one of the first of those who established the French academy of belles lettres. This society suggested to the cardinal Richelieu the foundation of the French academy, of which M. Godeau was an original member. He took orders in the year 1735, and having enriched his own mind with the most perfect maxims of Christian morality, he taught them from the pulpit with much eloquence, and he is said to have practised them in all his actions. In the year 1636 he was, by the influence of cardinal Richelieu, nominated to the bishopric of Grafe, and from this time he divided his time between his studies, and the diligent discharge of his episcopal functions. He found the state of ecclesiatical discipline exceedingly relaxed, and set about its reformation; he personally examined the qualifications of the clergy, and enquired in what manner they discharged the important duties of their office; he frequently preached in different parts of his diocese, and exhibited in his own life an admirable model of those virtues which he was anxious to recommend to the attention of his flock. He was in high favour with pope Innocent X. who granted him bulls of union of the bishopric of Venice with that of Grafe, but when he found that the people and clergy opposed the measure, he chose rather to give up his pretensions, than break in upon the peace of the church. He died in 1672, at the age of sixty-seven years. He was a considerate writer, chiefly on subjects connected with his profession, but his most important work was "The History of the Church from the commencement of the World to the end of the Ninth Century," in three volumes, folio. This is the first ecclesiastical history written in the French language; and though composed with less precision than that of the abbé Fleury, it possesses considerable merit. It is characterized by Dupin as "exact, faithful, and agreeable;" he farther adds, that it always will have a merit, which neither time, nor any other history will be able to efface. Besides the history, we may notice M. Godeau's "Paraphrases on the Epistles of St. Paul;" "The New Testament translated and explained;" "The Lives of St. Paul, St. Augustine, and St. Charles Borromeo, &c." Moreni.

GODEFROI, Denis, a very learned jurist, was born at Paris in 1549. He studied at Louvain, Cologne, and Heidelberg, and upon his return to France acquired a high reputation in the parliament, in which he was nominated to a councillor's place. In 1580 his religious principles obliged him to seek a refuge at Geneva, where he was admitted a burgker, and a professor of the law. In 1585 Henry IV. created him bailiff of some villages at the foot of mount Jura, and a supernumerary counsellor in the parliament of Paris. After this he was deprived of his employment and his valuable library by the invasion of the duke of Savoy, and in 1594 he accepted the professorship of the law in the university of Stralburg. In 1603, at the invitation of Frederick, elector-palatine, he went to settle at Heidelberg, and in 1618 that prince sent him on an embassy to Lewis XIII., who received him with marks of high esteem. He died at Stralburg in 1622, leaving behind him many works that testify to his great learning. The titles of these are enumerated by Moreni and others, and a few of the principal may be mentioned here: "Corpus Juris civilis cum notis;" this treatise has been frequently reprinted; the second edition is said to be that from the Elzevir press in two volumes folio. "Note in IV. Libros Institutionum;" "Praxis Civilis ex antiquis et recentioribus Scripturis;" "GODEFROI, Theodore, the eldest son of the preceding, was born at Geneva in 1580. He pursued his studies first
in that city, then at Strasbourg, and afterwards at Paris, where he embraced the Catholic religion. In 1643 he obtained the office of counsellor of state, and acted during the six last years of his life as counsellor and secretary to the French embassy for the general peace at Munster. Here he died in 1649. He was particularly vered in the genealogical and ceremonial history of France, and published several learned works for its illustration; such are "Le Ceremonial de France," 10, "Memoirs concerning the Prefidence des Rois de France sur les Rois d'Espagne;" "De la veritable Origine de la Maifon d'Autriche;" "Traité touchant les Droits du Roi Tres-chrétien sur plusieurs États vofînes," &c. Moreri.

GODEFROY, James, brother to Theodore, was born at Geneva in 1587. He followed the steps of his father by a strict adherence to the reformed religion, and by pursuing the studies of law, history, and philosophy. In 1619 he was created professor of the law at Geneva, and was called to a seat in the council in 1629. He filled with the greatest zeal and ability every public office with which he was entrusted. He was five times elected syndic of the republic, and was made secretary of state. He was chosen as a fit person to conduct various negotiations in France, Piedmont, Switzerland, and Germany; and, at the same period, he devoted all his leisure to public lectures in jurisprudence, and composed a variety of learned works. He maintained a correspondence with the most learned men of the age, by whom he was greatly respected. He died in 1652, and his works bear testimony to his profound erudition, and to his great and unwearied industry; among them may be mentioned "Fragmenta Duodecim Tabularum;" "Anamivalvations Juris Civilis;" "De Jure Præcedentibus;" "Codex Theodisciussianus," a pothumous work, regarded as a most valuable monument of ancient jurisprudence. He edited the works of Cicero, "cum notis Lambini et Gothofredi." He had likewise made large collections for the history of Geneva, which were afterwards used by Spon. Moreri.

GODEFROY, Denis, son of Theodore, born at Paris in 1615, was an able French historian. He was author of "Memoires et Instructions pour servir dans les Negotiations et les Affaires concernant les Droits du Roi," a work, which has sometimes been attributed to the chancellor Seguier, by whose order it was compiled. He re-edited the works of his father's works, adding to them new illustrations with learned notes. He continued to his own time Feron's "Hill. des Officiers de la Couronne." As a public man he was appointed in 1668 the director and keeper of the chamber of accounts at Lille in Flanders, where he died in 1681. Moreri.

GODEFROY, John, son of the preceding, succeeded his father in the direction of the chamber of accounts at Lille, where he died, much advanced in years, in 1732. He published an edition of the "Memoirs of Philip de Comines," in five volumes 8vo. "The Journal of Henry III." "The Memoirs of Queen Margaret." He is said to have contributed more than any other writer to the elucidation of the affairs of the League. Moreri.

GODERVILLE, in Geography, a town of France, in the department of the Lower Seine, and chief place of a canton, in the district of La Havre; 9 miles N.E. of Montville. The place contains 650, and the canton 15,339 inhabitants, on a territory of 150 kilometres, in 31 communes.

GODESCHALC, in Biography, a Benedictine monk, who flourished in the ninth century, was born in Saxony, and was brought up, contrary to his own inclination, to the profession, in the convent of Fulda. He was ordained priest when he was about forty years of age, and in 846 we find him at Rome visiting the holy places there; thence he proceeded to Pannonia and Dalmatia, where he commenced preaching the doctrine of predestination with much fervour, which it is supposed he imbided from the works of St. Augustine. Upon his return to his own country he had a conference with Nottingus, bishop of Verona, before whom he maintained that God, from all eternity, had pre-ordained some to everlasting life, others to everlasting punishment and misery. Nothingus, astonished and terrified at so daring a doctrine, as, he thought, impious a position, complained of it to Rabanus, archbishop of Mentz, who undertook to confute his error, in writing. Displeased, perhaps, with his own arguments, Rabanus summoned a council to meet at Mentz, in the year 848, to which, however, Godeschalc preferred a justification of his opinions, and resolutely perfilled in maintaining them to be consistent with the scriptures and the fentence of the orthodox fathers. The council passed sentence of condemnation upon him, and sent him prisoner to Hincmar, archbishop of Rheims, within whose jurisdiction he had received the priesthood. Hincmar, who was devoted to the interest of Rabanus, assembled a council in 849, in which he was a second time condemned, and rendered liable to a punishment repugnant to all the principles of religion and humanity. Godeschalc, however erroneous his sentiments might be, was not to be intimidated; he believed what he asserted, and he firmly adhered to the doctrine in spite of the higher powers. Hincmar accordingly proceeded to put the sentence into execution, degraded the monk from the priesthood, and ordered him to be scourged with the utmost severity. It appears that he was not prepared for so grievous a trial of his fortitude; the force of the pains inflicted on him obliged him, in compliance with the dictates of his persecutors, to throw into the fire the justification of his opinions which he had delivered into the council. The infamous persecutors were not contented with this triumph; they committed him close prisoner to the monastery of Hautvilliers, in the diocese of Rheims. In this, as in every other case of a similar kind, the sufferings of Godeschalc gained him followers and adherents, and many became advocates for his cause. A considerable schism was produced in the Latin church. Some confined themselves to the defence of his person and conduct, while others employed all their zeal and talents in the vindication of his doctrine. The spirit of the controversy ran so high between the contending parties, that Charles the Bald, in 853, summoned the council to meet at Quercy. Here the suffering monk was again condemned, but the decrees of this council were declared null and void, and Godeschalc and his doctrine vindicated and defended, in a council at Valence, in Dauphiny, in 855, the decrees of which were confirmed in the council of Langres, and in that of Touff. Such was the origin of the disputes concerning the doctrines of predestination and grace, which, from time to time, have divided the Catholic world into two parties, and which have fubscribed in full force among the Protestants. The unfortunate Godeschalc died in prison about the year 856, maintaining with his last breath the doctrine for which he had suffered. The only writings of this monk that have come down to the present times are, two "Confessions of Faith," inserted in archbishop Uther's "Historia Godeschalcii," printed at Dublin in 1641; an epitite to Ratramus, published in Cellot's "Historia Godeschalcii," at Paris, in 1635, and some fragments of other pieces, noticed by Cave. Godeschalc has immortalized his name by setting on foot the controversy
controversy to which we have referred, and by his sufferings in vindication of his favourite doctrine. In the year 1650, the celebrated Maguin published at Paris, in two volumes 4to, a collection of the early treatises produced on both sides of this controversy, entitled "Veterum Auctorum qui sive seculari de Praeludiationibus et Gratia scripturum, &c." "GOD-FA'ATHERS, and GOD-MOTHERS, persons who direct and attend at the baptism of infants, or other persons; who give the name, and who become sureties for the faith and good conduct of the infant baptized. Hence they are called confessors, or more commonly sponsors. To this purpose Dr. Nichols, (Def. part ii. p. 273.) says, that "the sureties in baptism religiously engage for the faith of the baptized; that they shall sincerely believe all that is revealed in the gospel, and shall direct the subsequent actions of their lives by the laws of Christ." Against this practice Protestant dissenters have alleged, that the parents, to whom both God and nature have committed the education of their child, are the proper persons to stand forth at its baptism, and take upon them this great and important trust; and to bind themselves by a solemn vow faithfully to discharge it. They object to the order and practice of the established church, that without sufficient authority from reason, or scripture, or the ancient practice of the Christian church, parents are set aside in this solemnity, and forbidden to stand forth, and take upon them this great charge to which God hath called them. For the 29th canon expressly commands, "that no parent shall be urged to be present at his child's baptism, nor be admitted to answer as god-father for his own child." They also object, that the forms of the church should require other persons to appear instead of the parents, and to take upon them this important trust, and most solemnly to promise before God and the church the performance of that, which few of them ever do, or perhaps ever intended to perform, or are capable of performing. It has been pleaded, and even generally allowed, that sponsors in baptism were not known or thought of in the primitive apostolic church. Tertullian, who lived about A.D. 200, seems to have been the first of all Christian writers who mentions persons of this description: "What necessity is there," says he, (De Baptism.) "that sponsors should expose themselves to danger, who, through death, may fail of the performance of their promises, or may be deceived by the wicked dispositions of those for whom they promise." "Whether the use of sponsors was from the apostles' days," (says lord King, in his Enquiry into the Constitution, &c. of the Primitive Church,) "I cannot determine, unless the negative may be conjectured from Justin Martyr, Tertullian's successor by 50 years, who, when he enumerates the method and form of baptism, says not one word of sponsors or god-fathers, as may be seen in his second apologue, p. 93, 94.) St. Austin, one of the earliest of Christian writers who mention sponsors, who lived about A.D. 350, informs us when, and upon what occasion, these sponsors were admitted: "A great many," says he, "are offered to baptism, not by their parents, but by others, as infant-slayers are sometimes offered by their masters; and sometimes when the parents are dead, the infants are baptized, being offered by any who can afford to shew this compassion to them. And sometimes infants, whom their parents have cruelly exposed, to be brought up by those who light on them, are now and then taken up by the holy church, and offered to baptism by them who have no children of their own, nor design to have any." Upon these words of Austin, Dr. Wall ingeniously confecs, (Hist. Inf. Bapt. vol. i.) "Here we see the ordinary use there was for parents to answer for the children; but yet that this was not counted so necessary, as that a child could not be baptized without it." Hence it has been inferred, that parents were never set aside, when they were capable and willing to offer their children; and that only in cases of the incapacity of parents, were sponsors admitted; and in all such cases, provided the practice be not enforced as a Christian institution, and as absolutely indispenfable, the dissenters, we conceive, could not reasonably object to it. Mr. W. S. a well-known writer on the Common Prayer, observes, that the god-fathers and god-mothers of persons baptized at riper years "are only appointed as assistants of the engagement, and undertake no more than to remind them hereafter of the vow and profession, which they made in their presence." And yet our church estátedin expressly affirms, and repeats the attention, that the sponsors, engaging for infants, engage that they shall believe and repent; for the infants are said to promise both these things by their sureties. Free and Candid Disquisitions, p. 131.

The number of god-fathers and god-mothers is now reduced to three in the church of England, and two in that of Rome: anciently, they had as many as they pleased.

The Romanists have also god-fathers and god-mothers at their confirmation. They even give god-fathers, &c. to children, at their baptism.

Among the ancients it was the custom for persons of quality to have others of like quality cut their children's hair the first time; by which they became reputed a sort of god-fathers; and the like was practiced with regard to the hair of the beard.

God-Father was also a name anciently given to a kind of feods, who attended and assisted the knights in tournaments, or single combats.

The god-fathers of deeds were a kind of advocates, who were chosen by the two parties to represent the reasons of their combat to the judges.

Something of this kind was long retained at solemn carousals. There were two or more in each quadrill. See Quadrill.

The institution of god-fathers and god-mothers, patrini and matrim, is originally Roman. They are said to have been people who, in the games of the Circus, attended the chariots, shows, and images, of the gods. Cicero makes mention of them, in his oration De Haruspicis Reponis. Their office was much like that of the children in some Romish ceremonies, who are drest in the habit of angels, to throw flowers, bear incense-pots, lights, &c. and accompany the relics and images of saints.

Godfrey of Bouillon, in Biography, celebrated for the part which he took in the first crusade, and king of Jerusalem, was the son of Eulace II., count of Boulogne. The appellation of Bouillon was derived from his lordship of that name in the Ardennes. In his youth he served in the armies of Henry IV., who, as a reward of his valor and fidelity, conferred upon him the title of duke of Lorrain. When the religious enthusiasm of the times set on foot an expedition for the recovery of the Holy Land from the possession of the Saracens, Godfrey was one of the earliest and most illustrious of the princes who took the cross. The command of the principal army was entrusted to his care, and it is agreed that none among the leaders were actuated by purer motives than Godfrey. He gave a distinguishing proof of the diklalere of conduct, by sacrficing almost all his property to defray the necessary expenses of the expedition. Godfrey set out in the autumn of 1096, and proceeded with his host through Germany and
and Bulgaria, taking care to abstain from those acts of hostility and rapine which characterized, and had caused the destruction of the fanatics of Peter the Hermit. It was not till June 1559, that Godfrey was able to lay siege to the renowned city, and though his army was greatly diminished in point of numbers, he was able to succeed, and on July 15th Jerusalem was taken by storm. The fanaticism and madness of the victors indulged themselves in a horrible massacre of the vanquished, which, it is believed, their general and leader was unable to prevent. Godfrey was almost immediately proclaimed sovereign of the new acquisition, but he refused to assume the title and emblems of royalty in the place where Christ, in whose cause he was acting, had been crowned with thorns, and he governed under the modest appellation of "Defender and Baron of the Holy Sepulchre." He was soon after attacked by the sultan of Egypt, but the Christians soon put him and his numerous forces to flight, and the whole of Palestine was reduced under the power of Godfrey. He established the feudal institution in his kingdom, and a code of jurisprudence, under the title of "The Adaiz of Jerusalem," gave a model of the purest form of European liberty in the midst of Asiatic despotism. He died, after he had sat on the throne about a year, and was succeeded by his brother Baldwin. The celebrity of Godfrey is immortalized as the hero of Tasso's "Jerusalem Delivered," one of the noblest of epic poems; nor has the bard found it necessary to borrow the colours of fiction, in order to throw splendour round a character so truly estimable: "Godfrey," says the historian in describing his character, "was the first who ascended the walls of Rome, and his flicks, his vow, perhaps his remorse for bearing arms against the pope, confirmed an early resolution of visiting the holy sepulchre, not as a pilgrim, but as a deliverer. His valor was matured by prudence and moderation; his piety, though blind, was sincere, and in the tumult of a camp he practiced the real and fictitious virtues of a convent. Superior to the private factions of the chiefs, he referred his enmity for the enemies of Christ; and when he gained a kingdom by the attempt, his pure and disinterested zeal was acknowledged by his rivals." Gibbon Univer. Hill. See also the article CROSAD.

GODFREY of Viterbo, an Italian historian of the 12th century, was chaplain and secretary to the emperors Conrad III., Frederick I., and Henry IV. According to his own account he was a great traveller for knowledge; and was conversant in several languages. His principal work was a "Chronicle," entitled the "Pantheon," as treating on the "Gods of Earth," is dedicated to pope Urban III., and is a general historical record from the creation of the world to the year 1186. It is written in the Latin language, and is deemed very worthy of credit for the events of its own time. It was first printed at Basil in 1559; then at Frankfort in 1584, and afterwards at Hanover in 1613, in the collection of German historians, edited by Pilgrim. Godfrey was author of a work intitled "Speculum Regum, sive de Genealogia omnium Regum;" the MS. is preserved in the Imperial library of Vienna.

GOD-GILD, in our Ancient Cof lanes, that which is offered to God, or for his service.

GODHEAH, or Good Hope, in Geography, a settlement in West Greenland. N. lat. 64° 35'. W. long. 58° 13'.

GODIN, Louis, in Biography, was born at Paris in 1704. He studied astronomy under de Piles, and in 1725 was made adjunct of the Academy of Sciences. To him was entrusted the care of editing its memoirs, and under his direction the first eleven volumes were published. In 1735 he was sent, with other members of the academy, to measure a degree of the meridian at Peru. He was some time professor of mathematics at Lima, and on his return in 1751, he was appointed a colonel in the Spanish service, and director of the naval academy at Cadiz, where he died in the year 1760. He was author of several astronomical papers in the memoirs of the academy from 1725 to 1739; and he published "Machines et Inventions approvées par l'Académie des Sciences," in 6 vols. 4to. "Connaissance des Temps," which he conducted five years. "Cours des Mathematiques," 1756. Gen. Biog.

GODING, or Hopöning, in Geography, a town of Moravia, in the circle of Brunn; 16 miles E.S.E. of Aufpesz.

GODO, a town of Arabia, on the coast of the Persian gulf; 140 miles W. of Julfar.

GODOUA, a small town of Fezzan; 50 miles N. of Mourzouk, and about the same distance from Sebba, which see.

GODRA, a town of Hindoooolam, and capital of a circar of the same name in Guzerat; 55 miles E. of Amedabad. N. lat. 22° 50'. E. long. 73° 40'.

GOD'S HOUSE, League of, a territory of Switzerland, formerly under the dominion of the bishop of Coire, until the people, oppressed by their rulers, threw off the yoke, and, forming a general league, compelled the bishop to ratify their independence. The revolution, which finally exalted this league into its present state of freedom, probably took place between 1424, the era of the formation of the Grey league, and 1436, the year in which the ten jurisdictions rose into independence. This league is denominated in Romanc, "La Légia de la Chiada," in German "Gottshaußbach," whence is derived the appellation of the "League of the house of God," which it takes from the cathedral situated in its capital, as well as because it was once under the jurisdiction of the bishop of Coire. This league is divided into eleven districts, each of which (Coire excepted) is subdivided into two little republics, or communities, and sends 22 deputies to the general diet. Formerly the burgomaster of Coire was perpetual chief of the league without election; but in the latter end of the 17th century the other communities claimed a power of nominating to this office in their turn. At length, by the arbitration of Zurich, it was decided, that the 22 deputies should choose two candidates from the members of the senate of Coire, who should draw lots for the charge. The chief thus appointed is called "Bundes-prefident," has several privileges which distinguish him from the chiefs of the two other leagues; he receives all the letters addressed to the republic of the Grisons from foreign powers, and is perpetual president of the congress, because that assembly is always held at Coire. See COIRE.
The league of God's house is divided into 11 high jurisdictions, and comprehends 21 communes.

God's Mercy. Islands of three or four small islands at the N.W. extremity of Hudson's Itrats. N. lat. 63 45. W. long. 75.

Godwin, Earl, in Biography, a powerful Saxon baron, was the son of Wolfnoth, governor ofSussex, and he himself, at the ascension of Canute, was earl of Kent, and lord of very great possessions. When the Danish possessions of Canute were attacked by the king of Sweden, Canute took over as auxiliaries a body of English commanded by the earl of Godwin, who obtained a complete victory, which so delighted the king, that he bestowed his daughter in marriage upon him, made him large grants of land, and admitted him to the closest confidence. After the death of Canute, the succession being disputed between Harold Harefoot and Hardicanute, Godwin espoused the part of the latter, and was instrumental in preventing a civil war. It is reported that he afterwards concurred with Harold in a plan for destroying the two English princes, sons of Ethelred II. and Emma, and the murder of one of them, viz. Alfred, is imputed to the vaillads of Godwin. In the reign of Hardicanute the surviving prince Edward preferred an accenuation against the earl for the murder of his brother, and loudly demanded justice for the crime; Godwin, to appease the king, made him a present of a galleon finely gilt and decorated, rowed by four coremen, each of whom wore on his arm a gold bracelet, weighing fifteen ounces, and they were all armed and clothed in the most sumptuous manner. Hardicanute, delighted with the spectacle, forgot his brother's murder, and on Godwin's own testimony he was allowed to be acquitted. In 1041, he was so completely reconciled to Edward, that on the death of Hardicanute he was the chief instrument of promoting him to the succession of the crown: he now acquired much influence in the state, and was created duke ofWessex, and the counties of Kent and Sussex were annexed to his government. The friendship between Godwin and the king was not of long continuance. Upon his refusal to act against the inhabitants of Dover, who had incurred Edward's displeasure, he was threatened with the royal vengeance. The earl, feeling his own power, actually excited a rebellion against his sovereign. Edward now summoned to his aid the dukes of Northum-
which was in the gift of the college, to resign his fellowship. He retired to this situation in 1549, and having married, continued there peaceable and happy during the reign of King Edward, devoting what time he could spare from the duties of his office to the study of theology and physic, and on the accession of Mary, he became an object of Bonner's fury, and was obliged to resign his school, and turn his attention to physic. By the practice of this, he maintained his family till Elizabeth ascended the throne. He now resolved to follow the bent of his inclination, devoted his whole time to theological studies, was admitted to holy orders, and appointed chaplain to the bishop of Lincoln. He was shortly after introduced to the queen, who made him one of the Lent preachers. This poll, which was probably attended with little emolument, he filled eighteen years, with great high reputation, during which he received no preferment in the church; but, in 1567, he was promoted to the deanship of Christ-church, Oxford, and in the same year a prebend was conferred on him. In 1566, he was advanced to the deanship of Canterbury, and attended the queen in her visit to the university of Oxford, on which occasion he took his degree of D.D. with great applause. In 1584, after eighteen years residence at Canterbury, he was nominated by the queen to the vacant see of Bath and Wells. This honour did not augment the happiness of Dr. Godwin: in refiling the unjust claims of one of Elizabeth's favourites, he lost the favour of the queen herself, which so affected his mind, as to render him incapable of performing his episcopal functions. The affairs of his diocese, being left to the management of others, fell into such disorder, that his metropolitan, archbishop Whitgift, thought proper to visit it in the year 1587. At this time Dr. Godwin's health was in a very bad state, and he gradually became worse till he funk under the effects of disease, in his forty-third year. He is highly spoken of for learning and unaffected piety, and was beloved and respected for his cheerful hospitality, benevolence, and charity. Biog. Brit.

Godwin, Francis, the son of the preceding, was born at Hasting, in Northamptonshire, in the year 1561, and having been carefully educated in grammar learning, he was sent to Christ-church college, Oxford, where he was in his sixteenth year, and in 1578 he was elected a scholar of that institution. In 1583, he took his degree of B.A., and three years after he proceeded to his degree of M.A. About this time he wrote an entertaining philosophical fiction, which he did not at that period publish, because it contained ideas at variance with the fystems then prevalent in the schools. It was given to the world five years after his death, under the title of "The Man in the Moon, or a Discourse of a Voyage thither by Domingo Gonzalez." The hints, conjectures, &c. contained in this piece, prove that the author was not ignorant of the writings of Copernicus, and was probably a convert to his doctrines. In 1587, he was a canon in the cathedral church of Wells, and promoted to the subdeanery of Exeter. The history and antiquities of his country became favourite subjects of his enquiries, and in the year 1590 he accompanied the celebrated Camden into Wales, in search of objects to illustrate them. In 1595, he took the degree of doctor in divinity, being in opinion of very considerable and lucrative preferment in the church. He published, in 1601, "A Catalogue of the Bishops of England, since the first Planting of the Christian Religion in this Island, together with a brief History of their Lives and memorable Actions, so near as can be gathered out of Antiquity." As a reward for the great diligence used in the composition of this catalogue, the queen promoted him, the same year, to the vacant see of Landaff; being allowed to retain, in connection with the bishopric, the subdeanery of Exeter, and a good rectory in the diocese of Bath and Wells. He now employed himself in improving his "Catalogue," and in making collections relative to civil and ecclesiastical history. In 1615 he published a new edition of his "Catalogue," to which he prefixed a discourse "Concerning the first Conversion of our Britain unto the Christian Religion." It was afterwards republished in Latin, under the title of "De Pre-fulbus Anglica Commentarium." In the same year he published "Rerum Anglicarum Henrico VIII., Edwardo VI., et Maria, regnantibus, Annalæ," which was highly admired for the elegance of the style. By King James he was translated from Landaff to the bishopric of Hereford in the year 1617, and from this period, he devoted such time as the discharge of his episcopal functions would permit, chiefly to the improvement of his former works; but in 1629 he published a discourse on the fentral methods of conveying secret and speedy intelligence, with the title of "Nuncius Inamnatus, Utopia." It has been suggested that this was written in obsolete and enigmatical language, with a design of concealing the author's secret; but from certain expressions, it should seem, that the hints contained in it might have led to an earlier establishment of public telegraphs. Besides several editions of the Annalæ, and a translation into English of the same work, we have a learned dissertation by the bishop, on the value of the Roman fefcience and attive talent, which was printed at the end of Hakewell's "Apology of Divine Providence." This was his last labour in the field of literature. He died in 1633 in his seventy-second year. Of his learning and classical taste, his works bear most decisive evidence, and they exhibit him as a zealous friend to the establishment, of which he was a member. According to Anthony Wood, "he was a good man, a grave divine, a skilful mathematician, an excellent philosopher, a good preacher, and a strict liver; but so much employed in his studies and matters of religion, that he was a stranger to the world and the things thereof." Biog. Brit.

Godwin, Thomas, a learned English divine and writer on Jewish antiquities, was born in Somertfethire in the year 1587. In his fiftenth year, he was sent from the grammar-school to Magdalen-hall, in the university of Oxford, where he was entered a scholar. Here, in due course, he took his degrees, and soon after was chosen master of the free-school at Abingdon, in Berkshire. In this situation he distinguished himself by his diligence and affinuity in teaching good scholars, who afterwards became eminent in various departments of literature, and in polls of honour and emolument in the church and state. In 1614 he published "Romane Historia Anthologia," an English exposition of the Roman antiquities, which went through several editions. Shortly after this, he entered into orders, and was appointed chaplain to Dr. James Montague, bishop of Bath and Wells, and in 1616 he was admitted to the degree of bachelor of divinity, and published a work, entitled "Synopsis Antiquitatum Hebraica rum ad Explanicionem utriusque Telfameli vanitatae necessaria, &c." lb 3. 410. About this period he resigned his school, upon obtaining a presentation to the rectory of Brightwell, near Wallingford, in Berkshire. In the year 1625, he published the work by which he is chiefly known, viz. "Moises and .aron; civil and eccleiafical Rites, used by the ancient Hebrews, observed, and at large opened, for the clearing of many obscure Texts, throughout the whole Scripture." This work was immediately regarded as a standard book in our places of academical education, and has been repeatedly printed. In 1636, Mr. Godwin was admitted to the degree of doctor of divinity. He died in
in 1642. Besides the works already noticed, Dr. Godwin was the author of "Florilegium Piraeanum,"—or A Survey of the Latin Tongue. And Three Arguments to prove election upon firft principles. Gen. Bibl.

Godwin, or Godwin Sams, in Geography, a bank in the sea, about five miles from Deal, near the coast of Kent, England, formerly formed part of the estate of the celebrated Earl Godwin, but were parceled and overwhelmed by a sudden inundation of the sea, about the end of the eleventh century. These sands are frequently fatal to mariners, but, notwithstanding, are of considerable use, as it is by them alone that the Downs are constituted a road or harbour for shipping. In all calmer winds they serve as a pier, or breakwater, and greatly mitigate the force and immensity of the waves, which, in stormy weather, would otherwise roll upon this shore with unabated fury. The sands extend in length about ten miles; the north sand-head being nearly opposite to Ramsgate, and the south sand-head to Kingsdown. The danger of striking upon them arises from their nature, which Mr. Smason describes as that of a quick-fand, clean and unconnected, yet lying so close, as to render it difficult to work a pointed bar to the depth of more than fix or seven feet. Their ingurgitating property is so powerful, that even the largest vessel driven upon them would, in a few days, be swallowed up, and seen no more. At low-water they are in many parts dry, and parties frequently land upon them; but when the tide begins to flow, the sand becomes soft, and is moved to and fro by the waves. The largest portion of this bank which becomes dry, is known to be near by the name of the Jamaican sand. Some years ago, in order to prevent the many accidents which occur to shipping on these sands, the Corporation of the Trinity-house formed the design of erecting a light-house on them; but after the sand had been penetrated by boring augers to a great depth, the scheme was given up as impracticable, as no solid foundation could be obtained. Floating lights have, however, been placed off these sands, consisting of three distinct lights in the form of a triangle, of which the middle one is considerably the highest; when they are obscured in hazy weather, a bell is kept constantly ringing.

Godwit, in Ornithology. See Sculopax Egorolartha.

Godwit, Great, or American. See Sculopax Fadoa.

Godwit, Lesser. See Sculopax Lumnus.

Godwit, Red. See Sculopax Lapponica.

Godwit, White. See Recurvirostra Alba.

Goelans, Point au, in Geography, a promontory on the N. side of Lake Ontario; about 33 miles S. W. of Fort Frontenac.

Goelheim, a town of France, in the department of Monté-Comines, and chief place of a canton, in the district of Keiferlautern. The place contains 865, and the canton 4999 inhabitants, in 16 communes.

Goeliske, Andrew Otton, in Biography, a German physician, who acquired considerable reputation at the beginning of the eighteenth century, and taught the science of medicine at Halls, in Saxony, and at Frankfort on the Oder, with distinction. His writings were in high estimation among the followers of the doctrines of Stahl, of whom he was one of the ablest defenders. Nothing more is known respecting his life. He left several works, which relate principally to the history of anatomy, of ancient and modern surgery, and of medicine. His "Hiloria Medicina Universalis, quæ celebratissimorum quorumque Medicorum, qui a prima Artis natalibus ad nostra usque temporae inculcarunt, vitæ, nomina, dogmata singularia, rationes insignias, hypotheces, &c., accuratissimae, quæ praecipue in varis discentibus, nōnnullis eae temporibus, picturae, specimina, &c., accuratissimae," was printed in six different portions or epochs, between the years 1717 and 1720. The first four brought down the history to Hippocrates; the fifth treated of the Hippocratic medicine alone; and the last part included a sketch of the descendants of the father of medicine, until the time when the art was divided into three professions. Elsen, Dls. Hill.

Goelius, in Geography, an island of Denmark, in Lym- ford, about 10 miles in circumference; on which are a town and a village or two; 6 miles W. of Aalborg. N. lat. 57°. E. long. 9° 49'.

Goelmé, a port of Egypt, in the Red sea, capable of accommodating only small vessels.

Goelwara, a city of Hindostan, in Guzerat, on the W. coast of the gulf of Cambaye.

Goere, William, in Biography, who flourished in the 17th century, was born at Middleburg, in Zealand, in the year 1635. He had a decided turn for literature, but by the death of his father while very young, he was confined to the care of an illiterate stepfather, who would not permit him to pursue the bent of his mind. Being obliged to fix upon a trade, instead of studying for one of the learned professions, he fixed on that of a bookseller, as that which he imagined best adapted for the improvement of his leisure hours in the acquisition of knowledge. His various works shall show how well he filled his time, and to what advantage he turned those intervals from occupation, which are too frequently spent in little trifles or devoted to pleasure. He died at Amsterdam in 1711, leaving his "Jewish Antiquities," in two volumes, folio. "The History of the Jewish Church," in four volumes folio. "History Sacred and Profane," "An Introduction to Painting" "A Treatise on Architecture;" and other useful works. Morei.

Goerzeod Ghezer, in Geography, a town of Alk- cterrain Turkey, in Natolia: 25 miles S. of Sinod.

Goet, a town of Portugal, in the province of Beira; 9 miles E. of Oeimbra.—Alto, a town of Holland, in Zealand, called "Ter-Goet," situated on the N. coast of the island of South Bevelands, on an arm of the Scheldt, with which it is connected by means of a canal. The great church is a handsome structure; and though the town is not large, it carries on a considerable trade, particularly in salt and grain; to miles E. of Flushing. N. lat. 51° 33'. E. long. 3° 49'.

Goetia, Færides, a species of magic, opposed to Theurgy, the object of which was mischief; and accordingly it invoked only the malevolent genii.

Goetz, Damiana, in Biography, a learned Portuguese, of the 16th century, was born at Alenquer, and educated in the court of the king Emanuel, to whom his brother was gentleman of the chamber. He was, as he advanced in life, employed in various negotiations from his court to the court of France, Germany, Poland, and the Low Countries. In 1534, we find him at the university of Padua, in which he studied four years under Buonomico, and contracted a friendship in Italy with Bembo, Sadolet, and other great men. He carried forward his studies at Louvain, where he fixed his residence after his marriage, and was the principal means of defending the city against the attack of Martin van Rossem. He was, however, feized by the enemy, under the pretence of a violation of the truce, and obliged to ransom himself. He was after this recalled by the king of Portugal, who wished to employ him to write the history of that country. The materials put into his hands were so confounded a file, and so fanciful in regard to quantity, that he was able to perform but a small part of the task. He was maliciously accused, arrested, and thrown into prison. At length, as there was nothing found against him, he was liberated, and return-
ed to his own dwelling, where he was shortly after found burnt to death; but the works of this enthusiastic, probably, of an apoplectic fit. His works are, "Legatio magni Iudorum Imperatoris ad Emanualem Lutitanac Regem," "Fides, Religion, Moræque Ethipion." "Hilpinaci Laudatio," "Urbis Laurinianus Obidido," "Comment Rerum Gotharum in India à Lutitanis. " "Urbis Ulybipponensis Descriptio. " "Historia del rey Dom. Manuel." "Chronica de Principe D. Juao II." Moret.

GOEZE, John Augustus Ethn, was born at Aachon in the year 1734, where he received the elements of a learned education. He was afterwards sent to Halle to pursue his studies preparatory to the exercise of the profession of preacher. In 1751 he settled in that capacity at Quedlingburg, which he retained till the period of his death. It was not till he was about forty years of age that he turned his attention to the microscope and natural history, for his skill in which he afterwards became so famous. At first he made use of his microscope only for amusement, but in a short time he found himself so instructed in the use of the instruments that he performed the most minute and highly complicated operations on the subject. He translated Bonnet's treatise on entomology, which met with a very favourable reception from naturalists. He set out without regard to money or order, but soon found that systematic knowledge was necessary in his pursuits; and completely acquainted himself with the Linnean arrangement; and his "Entomological Collections" were intended as a supplement to the works of the Swedish naturalists. The next considerable work of Goze was on the natural history of intestinal worms, which he published in quarto in 1782. This work contributed greatly to encrease his reputation as a naturalist, and entitles him to an honourable place among the discoverers of modern times. The interest which he took in the education and improvement of his own children led him to publish some works on natural history, intended particularly for young persons in general, and being a very agreeable as well as learned writer, his productions were well received, and to his honour it must be spoken that he never forgot to cultivate the duties of religion and morality while he was devoting the wonders of the natural world. After he had communicated to the public the result of his observations on intestinal worms, he sent his collections to Pavia, where it was sold for a thousand dollars. His fame, however, had extended much beyond his own country, and within a few weeks after he had parted or at least agreed to part with his curious collection for the above named price, he received a letter from Dr. Hunter, offering him nearly double the sum for it. He died in June 1786.

GOFABAD, in Geography, a town of Persia, in the province of Iran: 55 miles E. of Isphahan.

GOFFE. See GOFF.

GOFFSTOWN, a town of America, in Hillsborough county, New Hampshire, situated on the western bank of Merrimac river, 35 miles from Amhurst falls, or 62 miles W. of Portsmouth. It was incorporated in 1761, and contains 1612 inhabitants.

GOG and MAGOG, in Scripture History, are names generally connected in the sacred writings. (See Ezek. xxxviii., 2, 3, 4cow. xxix. 1, 2, Rev. xx. 8.) Moses (Gen. x. 2) speaks of Magog, the son of Japheth, but says nothing of Gog. According to Ezekiel, (vjd supra,) Gog was prince of Magog; the latter signifying the country or people, and the former, the king of it. The ancients generally represent Magog as the father of the Scythians or Tartars; and traces have been found of the name in the provinces of Great Tartary. Others say that the Persians are descendants of Magog; and to this purpose people have been found there called Magogians, and philosophers called Magoloi or Magi.

Some have imagined that the Goths were descended from Gog and Magog: and that the wars described by Ezekiel, and undertaken by Gog against the saints, are that one which the Goths carried on, in the 5th century, against the Roman empire. Bochart has placed Gog in the vicinity of Caucasus; and he derives the name of this celebrated mountain from the Hebrew גוג גוג-כסאן, the fortress of Gog. He also says, that Prometheus, said to be chained to Caucasus, is Gog; and it may be observed, that there is a province in Iberia S. of Caucasus, called the Gogarene. Most persons are of opinion, that Gog and Magog, in Ezekiel and the Revelations, are taken, allegorically, for such princes as were enemies to the church. Accordingly many, by Gog in Ezekiel, understand Antiochus Epiphanes, the persecutor of the Jews; and Gog in Revelations, they suppose to represent Antichrist. Calmet apprehends that the Gog of Ezekiel and Cambyses, king of Persia, were the same persons. The Armenians are of opinion that the descendents of Gog and Magog inhabit the northern parts of Asia, beyond the Tartars and Scythians: and hence it is probable that Gog and Magog, according to the notions of the Armenians, formerly inhabited the mountains of the Hyperboreans, and that they were known to the ancients by this name. This nation is unquestionably famous in antiquity, and there is reason for imagining, that they were some of the Scythians, and confounded among the Great and Little Tartars, and perhaps among the Muscovites, and other northern people. Calmet.

GOG-MAGOG HILLS, in Geography, hills so called, about three miles from Cambridge, remarkable for the intrenchments and other works found there, and supposed by some to be a Roman camp, and by others, a work of the Danes. GOG, a town of Abysinian; 30 miles S. of Gondar. Alto, a small town of India; on the western side of the gulf of Cambaya, about 28 or 30 leagues from Cambaya, abounding with banyans and fen-men.

GOGARD, a town of Sweden, in East Gothland, 23 miles N.N.W. of Linkoping.

GOGARENA, in Ancient Geography, a country of Asia, in Armenia. Strabo.

GOGARY, in Geography, a town of Bengal; 24 miles N.W. of Boglapur. N. lat. 25° 26′. E. long. 86° 36′.— Alto, a town of Hindooftan, in Bahar; 10 miles N.E. of Monghir.

GOGAVINUS, Antonius Graianiensis, or Anthony Gogavine de Grave, in Biography, a laborious writer, who, according to the indications of the famous Zarlimo, published in corso all the ancient authors on music, at Venice, 1562, 4to.

His compilation contains the books of Aristoxenus and Ptolemy, and the fragment of Ariotile, with the Commentary of Porphyry, the whole enriched with notes by Bottirgi. See MEHRISMUS, and BOTRIGARI.

GOGET, in Ichthyology. See GEBUS NGER.

GOGGLES, in Rural Economy, a morbid affection in 3 G

hep.
sheep, which is sometimes extremely destructive to them. It is suggested in the Bath papers as first playing itself, by a dropping of the ears, and frequent rubbing of the tail; but not to have any relation or affinity to giddiness, as the sheep do not run round as in that disease. It appears to have the greatest resemblance to the disorder called the flagggers in the lungs; but differs in no small degree, as the flaggery lungs display weaknefs before, and of course fall in that direction, while the goggly sheep shew weaknefs behind, and when forced to run fall backwards. Sheep under this disorder constantly get poorer and poorer, and become more weak, until they are not able to drag their lungs after them, and consequently die. Some have contended that it is a disease of the paralytic kind, and that the feat of the complaint is in the spinal marrow. It was formerly either wholly unknown, or unattended to by sheep-farmers, as it is now mentioned.

Hitherto no satisfactory method of cure has been pointed out for the disease, but warmth and frequent change of posture have been found beneficial in it.

Goggles, or glasses, are instruments used for curing eye-sinati, or that disfigurement of the eyes which occasions this disorder. They are thin conical tubes, composed of ivory flamed black, with a thin plate of the same ivory fixed in the tubes near their anterior extremities. Through the centre of each of these plates is a small circular hole, about the size of the pupil of the eye, for the transmission of the rays of light. These goggles must be continually worn in the day-time, till the muscles of the eye are brought to act regularly and uniformly, so as to direct the pupil straight forwards; and by these means the cure will be sooner or later effected. Warner on the Eye, p. 52.

GOGMOW, in Geography, a town of Hindoostan, in Ouade; 35 miles N. of Manjakpour.

GOO. See GOGA.

GOGODUNGA, a town of Bengal, on a small island formed by a branch of the Hoogly; 45 miles S. of Calcutta.

GOGOROMOW, a town of Guzerat, on the coast; 50 miles W. S. W. of Noonagur.

GOGRA, also called Deusah and Soorge, a river of Hindoostan, which proceeds from a lake named Lanke-Dhe, having to the E. of it another larger lake, named Manfaraw, both situated on the western side of Thibet, and forces its way through the vast ridge called Himmalack, and afterwards joins the Ganges. See DEWAL.

GOGUET, ANTONY-VEIS, in Biography, was born at Paris in 1716, where his father was an advocate. He himself became a counsellor to the parliament. By close study and by great industry in his pursuits, he produced in the year 1758, a work that has obtained a high reputation, and which has been translated into the English and other languages. It is entitled "L'Origine des Lois, des Arts, des Sciences, et de leur Progress depuis les anciens Peuples," in three volumes 4to. It was printed in 1778, in six volumes 8vo. This work treats of the origin and progress of human knowledge, from the creation to the age of Cyrus, and displays much erudition in historical discussions, though much of science and philosophy than might have been expected. He died of the small-pox almost immediately after the publication of this valuable work. He was a man of much private worth, modest and unassuming. He had begun another work on the Origin and Progress of the Laws, Arts, Sciences, &c. in France, from the commencement of the monarchy.

GOHANA, in Geography, a town of Hindoostan, in Ballooban; 54 miles W. S. W. of Delhi.

GOH, a town of Hindoostan, in Ballooban; 35 miles W. N. W. of Safarum.

GOHUD, a circar of Hindoostan, in the southe of Agra, lying on the right side of the river Jumna. It is bounded on the N. by the Chumbal, on the E. by Doob and Ouade, on the S. by Buckul, and on the W. by Rantampour and Cottah.—Alfo, a town of this circar, the revenues of which are estimated at 20 or 30 lacks of rupees per annum; 55 miles S. E. of Agra. N. lat. 26° 24'. E. long. 78° 43'.

GOI, a town of Croatia, on the river Mreznitas; 18 miles S. of Carlistadt.

GOJAM, a province of Abyssinia, about 80 miles in length, and 40 in breadth. It is a very flat country, altogether appropriated to pasture; it has few mountains, but there are very high, and are chiefly on the banks of the Nile, to the south, which river surrounds the province. Gojam is full of great herds of cattle, which are the largest in the high parts of Abyssinia. The country is populous, but the men are in the lowest estimation as soldiers. The Jefuits were settled in many convents throughout the province, and are held in the utmost detestation. The monks are theos of St. Euliatius, which may be called the Low Church of Abyssinia; they are said to be much inclined to turbulence in religious matters, and are, therefore, always made tools by discontented people who have no religion at all. On the S. E. of Gojam is Damot; which see. Bruce.

GOJAS. See GOYAS.

GOJAY, a town of Africa, on the Grain coast; 25 miles S. E. of Grand Sotto.

GOJEIDA, or GOUIA, a town of Algiers; 50 miles S. E. of Oran.

GOING, in the Mouse, called in French allcure, is the place or seat of a horse.

GOI, GURT, Gar, Locat, &c. are names for a ditch or trench for conveying water, used by engineers and miners of different districts.

GOITO, in Geography, a town of Italy, in the department of the Mincio, situated on the river Mincio, between the lake of Mantua and that of Garda; 9 miles N. N. W. of Mantua.

GOITRE, or GOUTIER, in Surgery, names sometimes applied to a morbid enlargement of the thyroid gland. See BRONCHOCELE.

Perfons labouring under this complaint are found in various mountainous districts of Europe, in China, in Bootan, and many other regions of the East, in Ceylon, &c. (See CRETINS.) Turner, in his "Account of an Embalmy to Tibet," says, that in Bengal this unhallowed tumour is known by the name of "Cheig," and "Aulx;" and in Bootan is called "Ba Ba," or "Ke Bé," the neck-swelling, and that it forms itself immediately below the chin, extending from ear to ear, and sometimes growing to such an enormous size, as to hang from the throat down upon the breast. It is particularly observable, he says, among the inhabitants of the hills of Bootan, immediately bordering upon Bengal, and in the tract of low country watered by the rivers that flow from them to the south, beyond the space of a degree of latitude. The same malady prevails among the people inhabiting the Moring, Nipal, and Almora hills, which, joined to those of Bootan, in continuation, and bound, to the northward, that extensive tract of low land embraced by the Ganges and the Berhampooter. The same disease is also more particularly met with in the low lands adjoining to these hills. From the frontier of Affan, N. lat. 27°. E. long. 91°, it is to be traced through Dimchar, Gouch Bahar, Rungøre, Dimapore, Pacha, Turcoo, and Behagh.
G O L

along the northern boundary of Oude, in Goorapore, Baratich, Pilibhit, and on the confines of Rohilkund, to Hur- dewar, situated in N. lat. 30° E. long. 78° 15'. It has the effect, he adds, or rather is accompanied with the effect, arising from the same cause, of debilitating both the bodies and the minds of those who are affected with it. Marsten, in his "History of Sumatra," observes, that it has been usual to

attribute this affection to the badlands, thawed flat, mineral quality, or other peculiarity of the waters: "My experience," he adds. "enables me to pronounce without hesita-

tion, that the disorder, for such it is, though it appears here to mark a distinct race of people, (orang geanang,) is immediately connected with the hilliness of the country, and, of course, if the circumstances of the water they use contribute thereto, it must be only so far as the nature of the water is affected by the inequality or height of the land. But in Sumatra neither snow nor other congelation is ever produced, which militates against the most plausible conjecture that has been adopted concerning the alpine goitres. From every research that I have been enabled to make, I think I have reason to conclude, that the complaint is owing, among the Sumatrans, to the fogginess of the air in the valleys, between the high mountains, where, and not on the fumits, the natives of these parts reside. I before remarked, that between the ranges of the hills, the "ca-

boot," or dense mist, was visible for several hours every morning; lining in a thick, opaque, and well-defined body, with the sun, and seldom quite dispersed till afternoon. This phenomenon, as well as that of the wens, being peculiar to the regions of the hills, affords a premonition that they may be connected; exclusive of the natural probability that a cold vapour, groats to an uncommon degree, and continually enveloping the habitations, should affect with tumours the throats of the inhabitants. I cannot pretend to say how far this dissolution may apply to the cafe of the goitres, but I recollect it to have been mentioned, that the only method of curing these people is by removing them from the valleys to the clear and pure air on the tops of the hills; which seems to indicate a similar source of the dis-
temper with what I have pointed out. The Sumatrans do not appear to attempt any remedy for it, the wens being confident with the highest health in other respects."  

GOKAUP, in Geography, a town of Hindooollan, in Vifapour; 16 miles S.S.E. of Raiboug. 

GOKLA, a town of Turkish Arabia; 30 miles E.S.E. of Akhaldz. 

GOLABAD, a town of Persia, in the province of Irak; 45 miles E. of Ipahan. 

GOLAH, a town of Hindooollan, in Bahar; 10 miles E. of Rangpur. 

GOLAN, a town of the duchy of Warfaw; 10 miles N.E. of Pofen. 

GOLAPILLY, a town of Hindooollan, in the circuit of Guntoor; 10 miles W. of Innacolsa. 

GOLAWARRY, a town of Bengal; 48 miles N.W. of Midnapour. 

GOLCONDA, a province of Hindooollan, part of the possessions of the Nizam, or Soubah of the Deccan, our firm ally, corresponds to the ancient province of Tellingang, or Tellung, situated between the lower parts of the confines of the Kñath and Godavary rivers; and is bounded on the N. by Berar, on the E. by the Circars, on the S. by the Muffree country and the Carnatic, and on the W. by Dow-

largei, and Vifapour. It takes its name from a famous fortres. The kings of this country were, at a former time, immensely rich and powerful; as they maintained in their pay 500,000 soldiers, and derived very large revenues from

their lands, customs of merchandizes and provision; but chiefly from the diamond mines, for which this country has been singularly famous. The winter in Golconda begins in June with rain and thunder; the rain pouring down, accompanied by violent storms of wind, till the middle of July, with occasional intervals of fine weather. In August, September, and October, the rains again fall, and very much swell the rivers. These rains render the land exceedingly fertile, particularly in fruits. Vines are plentiful, and of the grapes, which ripen in January, they make white wine. Two crops of rice are produced annually, and the country affords other kinds of grain. The capital of Golconda is Hyderabad. 

GOLCONDA is also the name of a fortres, surrounded by stone walls and deep ditches, which was formerly the residence of the kings of the country. This fortres, on account of its extent, might be denominated a city; a hill rose in the middle of it like a sugar-loaf, and the sides of it were encompassed by the king's palace, which was very large and well situated for air, and which had a good view of Hyderabad. When Aurungzebe conquered the kingdom of Golconda in 1687, this fortres was taken by treachery; the king offered to pay a tribute of 3,750,000 rupees, and become the servile of the conqueror; but he refused, and entered the palace in triumph. 

Mineralogical Description.—This metal never having been found in a mineralized state, we are acquainted with one species only, namely, 

Native gold, which is subdivided by Werner into three sub-

species, viz. gold-yellow, brazi-yellow, and greyish-yellow gold. Though this subdivision may appear arbitrary, and not found-
ed on constant characters exclusively belonging to each of the above varieties or sub-species, it is nevertheless entitled to attention, since colour, however unimportant it may be in the classification of earthy fossils, constitutes a character of considerable value in native metallic subfossils, the range of whose colours is confined to a narrow compass. But also their geognostic relation appears to constitute a dif-
tinction, at least between the two first of the Wernerian sub-species; for as to the third, or the greyish-yellow gold, its claims to be kept separate from the two others appear doubtful; all we know of it is its being found in small flat particles, along with that mixture of different metals called plati-
tina in grains, of whose colour it partakes in general, and with which it is suppos'd to have occurred also originally under the same geognostic relations. 

1. Light or Brazi-coloured native Gold. Melting-gold, gedigen gold of Werner. Its colour is pretty well indicated by its name; but it varies in intensity from what may be called pale-gold yellow to yellowish-filvery white. It is also sometimes found with deep-yellow, and with pavonine tarnish. 

It occurs massive, disseminated in angular and amorphous particles, but more frequently in films, membranes, and plates even and curled or twisted, and with smooth or drusy sur-
fase; also capillary, tooth and wire-shaped, shrub and fern-
like, and as mouldiform flings; often imitating reticulated and filigree work; all which forms are generally produced by the aggregation of minute imperfect crystals. Among these, perfect crystals are not unfrequently seen, sometimes single, often in groups, on the margin of the plates, &c. The growing secondary forms have been observed: the cube; the octahedron; the eubri-cheladon; the hexocto-

dodecaedron with trigeminal plates. Also modifications intermediate between the cube and the octahedron occur, but they

3 G 2
are scarce. The minute three-sided pyramids, which are often seen to druse the membrane, and the simple triangular marks on the plates of the Transylvanian native gold, are the results of hurried and disturbed crystallization; the former of them being the solid angles of the cubical, and the latter the rudiments of the octahedral variety.

The crystals are minute (those described by Mr. Esmer as octahedra and cubes of two lines in diameter, have never before been heard of; their surface is always smooth.

Lustrous metallic: externally splendent; while that of the grains is sometimes glittering, sometimes approaching to dull; internally it is glittering and glittering.

The fracture of gold is fine hackly. Its fragments are indeterminately angular.

It is soft, highly flexible, malleable, and ductile.

The specific gravity of pure gold is from 19.253 to 19.645; but that of the brassy-yellow variety, owing to a greater proportion of silver with which it is alloyed, is generally considerably less, though always above twelve.

The light, or brassy-yellow gold, occurs almost always in veins in greywacke, greywacke slate, and newer porphyry; seldom, as the following sub-species, in primitive rocks, or under other circumstances that bespeak a similar remote antiquity.

It occurs chiefly with quartz and iron pyrites, and not unfrequently with grey antimony. Other concomitant substances are, among the earthy fossils, calcareous spar, iron pyrites, barites, felenite, and feldspar; of metallic substances, red and vitreous silver ores, (feldspar native silver,) copper pyrites, grey copper ore, copper green, brown iron flume, galena, green lead ore, blende, with occasional traces of white cobalt, copper nickel, red orpiment, native arsenic, and arsenical pyrites.

2. Deep or Gold-yellow Native Gold.—Gold-calcos gediegen-gold of Werner.

Its colour is the highest gold-colour, seldom verging on brassy yellow.

It occurs massive and in small roundish and flattened pieces, as also in grains of various dimensions, detached or disseminated; seldom in particular external forms, such as in leaves and laminar, fibrous and mottled; scarcely ever crystallized: almost all the crystalline forms described by authors belonging to the light-coloured sub-species.

External lustre: glittering, sometimes (as in the variety called Spanish mufli) disseminated of all lustre. Its specific gravity is rather greater than that of the light or brass-coloured gold, with which it agrees in the remaining characters.

It occurs mostly loose, in alluvial situations, and in the sand of rivers, and, as such, appears to have been originally disseminated in rocks of ancient formation: it is, however, also found in veins in Norway, Siberia, Bohemia, Hungary, in the East Indies, &c. almost always disseminated in quartz, accompanied by iron-pyrites; but nothing is as yet known respecting the age of these veins. At Fattsebay it is found in minutely mottled external form, often of a dull powdery appearance, on common quartz sometimes mixed with iron pyrites; in this state it is by the miner called Spanish mufli.

Cry stalline substitution.—The following localities comprehend both the sub-species into which native gold is divided by Werner. By far the greater part of that found in Europe belongs to the brassy-yellow sub-species, except the gold of rivers and alluvial foil, which is principally deep yellow, and to which the immense quantities of this precious metal, furnished by the other parts of the world, appear likewise to belong.

Europe.—Hungary, the Banat, and principally Transylvania. In Upper Hungary it occurs in greifs; at Schamitz, in Lower Hungary, it is found accompanied with several silver ores, and with galena; at Kremsitz, in and on cellular and flattered quartz, lamellar barytes, with vitreous silver and grey copper ore, copper pyrites, brown spar, &c.; at Orava in the Banat, it occurs siliforn and disseminated in pale flesh-red and greenish-white limestone, with white cobalt ore and copper nickel. In Transylvania, the richest country of Europe in this metal, it principally occurs in a kind of clay-porphyr of different degrees of hardness, which is the Saxum metaliferum of Born, in greywacke and granite slate; at Kapnik it is sometimes found with red orpiment; at Staniš in calcareous spar, mixed with arseneous pyrites, &c.: other places of Transylvania abound in gold (which is for the greater part brassy-yellow), are Verebipatsz, Abruclany, Boiza, Offenbanya, Fatzebay, Toplitz, Traibhyan, &c. Also the rivers, both of Hungary and Transylvania, are richly auriferous; gold sand is found in the Nera, and underneath a dratum of chalk on the plain traversed by this river. The richest river of Transylvania is the Araníoth, and the plain bordering on the river Moróth, contains likewise gold in grains, between a dratum of mould, and another of schistus, either of which flata is in the leaf auriferous. Also at Olápin, gold is obtained by washing; it is there mixed with magnetic ironstone, titanium, garnet, and cyanite. The gold of the great rivers of Transylvania is generally of 21 carats, that of Olápin and Rothinar is even of 23 carats, six grains.

In Germany it is found in several places, at Johangeorgenbadt in Saxony, in Carinthia, where it accompanies copper ores, in Tyrol and Salzburg; but it is only in the lat of these districts, or rather in the chain of mountains, separating Tyrol from Carinthia, that gold-mines are worked: in the Zillerthal it is found in various external forms, and accompanied with iron-pyrites, &c. in mica flume. In Bohemia gold occurs in quartz.

Spain is probably very rich in gold; certain it is that considerable gold mines were worked there in former times, and, according to Diodorus Siculus, as far back as the time of the Phoenicians, after whom the Romans undertook to work them; and Pliny informs us, that those nations derived great profit from them. Altdorf was the province which furnished most of this metal. After the discovery of America these mines were entirely given up and lost. The Tagus and some other rivers of Spain are likewise auriferous.

France has no gold mine that is worthy to be worked; the first discovery of gold in that country was made in 1781, at la Gardette, in the valley of Oyons, in the present department of the Ifere; the mine was worked for six years, but the produce in gold and accompanying minerals was too small to compensate for the expense of obtaining them, and, indeed, the lobs amounted to upwards of 21,000 livres. It occurs there, with rock cryllals and iron pyrites, in greifs. The sand of several rivers of France is auriferous, such as that of the Arrive near Mirpoix, the Gardon and Ceze in the Cévennes, the Rhone in the Pays de Gex, the Rhine between Straiburg and Philippburg, the Salz in the neighbourhood of St Giron, in the Pyrenees, the Baronne near Toulouse, and the Hérsalt at Montpellier. Also most of the black sand and of the bog-iron found in the neighbourhood of Paris is laid to contain a small quantity of gold.

In Piedmont veins of auriferous pyrites and quartz are found near Macugnaga, at the foot of Monte Rosa; which mountain consists of veined granite in horizontal beds. The veins of pyrites and quartz have upon the whole a perpendicular direction, but in some parts they cross each other, and
GOLD.

and where this takes place, groups, or nests, are found which contain the greatest proportion of gold. The proprietor of these mines extracted out of such nests, in no more than twenty-two days, 189 mares of pure gold, although a hundred weight of the ore yields no more than from 10 to 12 grains of that metal. Formerly upwards of a thousand workmen were employed in these gold-mines, and the present priors still procure 80 mills, by which from 16 to 12 pounds (of 12 ounces) of mercury impregnated with gold are produced per day. Twelve pounds of mercury contain two mares of gold. There are likewise several auriferous rivers on the S. side of the Alpenine Alps, between Mount Rofa and the valley of Aola, such as the Avonfan, which runs from the valley of Chaltant into the Doire, and where some gold-mines were also worked by the Romans; the Oreo, &c.

Sweden has a gold mine at Edelfors in Smoland: the gangue, a brownish quartz, is laid to be in a kind of hornblende slate, which also contains the metal disseminated.

Gold has also been found in Great Britain: in Cornwall; at Leadhills, in Scotland, disseminated in quartz; at Wicklow, in Ireland, under the soil, and in a stream which runs over rocks of clay-slate with veins of quartz. It belongs to the deep yellow variety.

Africa.—The gold-ores of Siberia are partly of the light coloured, but principally of the deep coloured variety; that of Bearcots, which occurs in pyrites, or rather brown iron stone, and iron quartz; and in the rock which serves as gangue to the red lead ore, belongs to the latter. Patrin mentions a specimen of gold in fragments on hornblender, found in one of the silver mines of Schlangenberg.

The geographical relation of the gold found in several parts of India, in Japan, the Philippine and Malay islands, Sumatra, Borneo, &c. is not known; all the specimens from India, that have come under our inspection, were in the form of small rounded and amorphous particles in quartz, and belonged to the deep yellow variety.

Africa.—Of the occurrence of gold in this part of the world we know so much, that the greatest part, at least of that which comes to Europe, is deep yellow and in grains. African travellers have made us acquainted with a few of its localities, but not with any particulars relating to its geographical habitats. Though the commerce of gold-powder extends almost over the whole of Africa, yet, according to Herenn, there is none to be found in its northern parts. Among the principal African gold mines are those of Kordofan, between Darfur and Abyssinia, mentioned by Browne. The ancients, says Bronniart, appear to have been acquainted with these mines; they considered Ethiopia as a country rich in gold; and we find in Herodotus, that the king of that country exhibited to the ambassadors of Cambyses all the prisoners of war fettered with chains of gold.

A second most considerable district for gathering gold-powder appears to be southward of the great defart of Zahara, in the west of Africa, at the foot of those lofty ridges of mountains on which originate, among many smaller rivers, the Senegal, the Gambia, and Niger. The country of Bomahou, at the N.E. of those mountains, is, according to Golberry, which furnishes the greatest quantity of gold which is found on the west coast of Africa, from the mouth of the Senegal to the Cape Palmas. This gold is found in fragments and small lumps, principally near the surface of the earth, in the beds of rivulets, and always in a ferruginous soil. In some parts of the country the negroes sink something like shafts, but without giving any support to the sides of the pit; nor are they wont to follow up the vein, if any should appear, or to make galleries. The metal is obtained by repeated washing of the earth that includes it. The same country furnishes likewise the greatest part of the gold carried to Morocco, Fez, and Algiers, by the caravans which, from Tombuctoo, travel through the great defart of Zahara. The gold which is brought to Cairo and Alexandria from Sennaar comes likewife from thence. See Parke's travels, where also an interesting account is given of the gold in Manding, and of the procures by which the negroes obtain it.

The third principal district of Africa, for collecting gold, is on the S.W. coast, between 15° and 23° S. lat. opposite Madagascar. This gold comes principally from the country of Solaha. According to the relation of some travellers in this part of the world, the gold is found there not only in powder, but likewife in veins. Some are of opinion that the country of Ophir, from whence Solomon obtained gold, was situate on this coast.

America.—The gold of this part of the world, as far as we are acquainted with it, is so equal to the production of the sand of rivers and of alluvial land; but it is also, though rarely, found in veins. South America, particularly Brazil, Choco, and Chili, are the countries that yield most; but some is also found in North America, particularly in Mexico, where it occurs along with silver-ores. The annual produce of these Mexican mines is valued at from 12 to 1500 kilograms. All the rivers of the Caraccas, 10 north lat, are auriferous.

The gold of Chili, according to Frezier, is lodged in the alluvial formation.

The Peruvian gold occurs in ferruginous quartz; that of Choco, the richest province in gold in South America, is found as grains in alluvial country, and in rocks belonging to the new detz-trap formation. Almost all we know respecting the geographical situation of the gold of Spanish America, we owe to M. de Humboldt.

Brazil furnishes gold in abundance, and it is from thence that the greatest part actually seen in commerce is brought to Europe. There are, however, properly speaking, no gold-mines in that country; the gold is not found there in veins, but disseminated in sand and other alluvial deposits, out of which it is obtained in the usual manner.

The gold that has been furnished by Brazil within 120 years, may be valued (according to Correa) at 2,400,000,000 of French livres; and, according to other authors, the amount is calculated to be 24,000,000 per annum. Bronniart. See Ores.

Observations.—1. It would appear that most writers who adopt Werner's distinction between gold-yellow and brass-yellow gold, have mistakenly described the one sub-species for the other, and some even speak of "grey-yellow gold from Transylvania." The sub-division alluded to may be deemed inadmissible; but if it be at all adopted, by far the greater part of the native gold of Transylvania and Hungary, and consequently almost all crystallized gold, must necessarily be referred to the light-coloured, and that found in the sand of rivers to the deep-coloured sub-species; and this not on account of their colour only, but also indicative of differences in the chemical composition of metals, but principally on account of the geographical relations under which they respectively occur, and on which great stress appears to be laid by Werner.

2. Iron pyrites, containing not unfrequently a considerable portion of gold, in most cases invisibly diffused, and diffused, has been been considered as a species of gold ores; a distinction to which (though such auriferous pyrites are often subjected to metalurgical treatment for extracting that metal, as will be seen hereafter) it cannot be considered as entitled. See Pyrites, Auriferus.
GOLD.

The brown cubic crystals from Beref, in Siberia, which contain grains of gold, are considered by some as decomposed, by others as hepatic pyrites, and by some as brown iron stone in fupposititious crystals. Whatever they may be, they are certainly not what Werner means by hepatic pyrites.

3. The native gold of Transylvania is often accompanied, and sometimes inculted, by particles of a pale yellow curdulent substance, which was considered by Hacquet as an oxide of gold. Muller and others have described it as iron-ochre, from which, however, it appears to differ both in colour and consistence. It is almost always to be met with in the specimen of native gold from Verehpahtak, but sometimes in fine, fine particles as to appear merely as a tarnish on the metal. It is to this dust probably that the gold ore, called Spanish fluff, owes its name, yellow-brown colour. It deserves further examination.

4. The grey metallic substance occurring as accicular indeterminat crystals, along with the gold of Siberia, in quartz, and which has been described as tellurium, as grey copper ore, &c. appears to be native bismuth.

For the chemical characters of gold, and the use to which it is applied, see the sequel of this article.

Extraction of Gold.—This metal is obtained separate from foreign substances, with which it is mixed by amalgamation with quicksilver. After it has been freed, by pounding and washing from the muller matter, it is triturated with about ten times its weight of mercury. The more fluid part of the amalgam is forced through leather, while that which is more consistent, and which contains the chief part of the gold, remains. This subjected to distillation, the quicksilver is separated and evaporated, and the gold remains in a state of fusion. When this metal is found in other ores, they are first roasted, to difperse the volatile principles, and to oxidize the other metals. The gold, which is but little subject to oxidation, is extracted by amalgamation, by cupellation, or other methods adapted to each ore, according to its properties or constituent parts. The metal obtained in these ways is always more or less alloyed, particularly with silver and copper. The first step in its purification is the process of Cupellation, to which article in our Cyclopaedia the reader is referred for accurate information on this part of the subject.

The gold, after it has been submitted to this process, is often alloyed with silver, which, being nearly as difficult of oxidation, is not removed by the action of lead, and hence the necessity of the operations denominated Parting and Quatification, which may be explained in a few words.

In Parting, the metal is rolled out very thin, and cut into small pieces, which are digested in diluted nitric acid moderately hot. The acid has an action upon, and dissolves the silver, leaving the gold undissolved in a porous mass. When, however, the proportion of silver is very small in comparison of the gold, the latter sometimes protects the former from the action of the acid; in such cases the previous step of Quatification is employed, which is so named on account of the proportion of material employed. viz. three parts of silver, with one of gold, and then subjecting the alloy, rolled out, to the operation of the acid. Sometimes they are melted together, and sulphur thrown in, the sulphur combines with the silver, and the gold falls to the bottom. It is observed by Lagrange, that rolling and annealing are operations very necessary to the success of the parting process, and which require some precautions. If the plate must not be too thin, lest it should break in consequence of the motion communicated to it by the action of the acid; if it is too thick the acid could not penetrate to its centre.

The annealing of the plate, at the same time that it gives pliability, facilitates its being rolled without cracking; it also opens the pores of the metal, which the rolling may have closed together, and by these means favours the action of the acid.

The process recommended by Bergman is this: first to dissolve it in nitro-muriatic acid; the silver is deposited spontaneously in the form of muriate of silver, which is insoluble; the gold is precipitated in fine powder by the sulphate of iron. Each of the above-mentioned processes is performed in such a manner as to lead to an estimate of the quantity of gold, and also of the different metals with which it is alloyed.

Gold, it is said, by some able French chemists, as Le Sage and Ronelle, exists in the vegetable kingdom, having, in experiments instituted for the purpose, been extracted from the nches of certain plants; the quantity, however, being, of course, too trifling to be sought after for practical purposes, it is sufficient merely to mention the fact in passing.

GOLD. Chemical Properties of.—Gold melts at the temperature of 12 of the scale of Wedgewood; and what is very remarkable is, that it is more difficult of fusion in the state of filings and grains, than in larger masses; and that the small fragments, even after they are fused, remain in separate globules; and in order to make them run into one mass, a little nitre or borax is thrown into the crucible. Gold, which has only been subjected to a degree of heat barely necessary for its fusion, is brittle after cooling. To preserve its ductility, which, as will be seen farther on, is one of the more important mechanical properties of gold, the temperature must be raised much higher. It is brittle also when it is too suddenly cooled after fusion. By an increase of temperature while the gold is in fusion, it becomes convex on the surface, and when it cools, it sinks, circumstances which are ascribed to the expansion and contraction of the metal. When it is gradually and slowly cooled, it crystallizes in the form of quadrangular pyramids, or regular octahedrons. If the heat be continued while it is in perfect fusion, it seems to be thrown into a kind of ebullition. This circumstance was noticed by Homberg and Macquer, as well in the application of the burning-glasses, as when a small globule of the metal was acted on by the blow-pipe. Macquer affords that it rote in vapour to the height of five or six inches, and attached itself to the surface of a silver plate, which it completely gilded.

The strongest heat of a furnace, which has been applied to gold in fusion, has been found incapable of producing the smallest change or the least tendency to oxidation; but, by the action of a very powerful burning-glasses invented by Tichirnhausen, and which has been described under the article Burning-glasses, Homberg found that gold, placed in its focus, not only rote in vapour, but that it was covered with a violet-coloured vitreous oxyd. The experiment was frequently repeated, so as to ascertain the fact fully completely. The same thing has been done by means of the electric discharge, by which gold-leaf, placed between two cards, has been converted into a violet-coloured powder. These influences of real oxidation were, at first, regarded, by some who witnessed the experiments, as merely minute mechanical divisions of the metal, but this apparent objection has been removed by the experiments of Van Marum on the combustibility of gold by means of the large electrical machine at Haerlem. A strong electrical shock was passed through a golden wire suspended in the air. It kindled, burned with a perceptible green flame, and was reduced to fine powder, which was dissipated in the air. A similar oxidation has been observed to take place on the gilding in the inside of houses,
house; or on the furniture which has been exposed to lightning. The purple oxyd of gold, thus obtained, contains five or six per cent. of oxygen. By precipitation from some of its saline combinations, a yellow oxyd has been obtained, in which the proportion of oxygen amounts to ten per cent. The oxyd in both instances may be decomposed, and the oxygen completely expelled, by an elevation of temperature not much superior to that of ignition.

The attraction of gold to oxygen is so weak, that it is scarcely affected by the greater number of acids. It was formerly supposed to be perfectly insoluble in the nitrous and nitro-muriatic acids, which in general part with oxygen with so much facility, and when gold leaf is put into the acid gold, it seems after no change, but when nitric or nitrous acid is boiled on gold, it is capable of dissolving a small portion of it. The quantity dissolved is, however, so inconsiderable, and depends on so many conditions, which it is needless to enumerate, that the accuracy of the processes of assaying can scarcely be affected by it.

When gold is dissolved in the nitro-muriatic acid, or in a mixture of equal parts of nitric and muriatic acids, an effervescence takes place, and the solution becomes a yellow colour. In this process the nitric acid is decomposed, its oxygen combines with the gold, and the oxyd, as it is formed, is dissolved in the muriatic acid. By adding lime-water a precipitate is formed, which is the yellow oxyd of gold, confluent of from eight to ten parts of oxygen in the hundred. There is no action between gold and azote, hydrogen, carbon, or sulphur: but the oxyds of gold are readily decomposed by hydrogen, as will be soon seen.

Phosphorus combines with gold by heating together in a crucible a mixture of one part of gold in filings, with two parts of phosphoric glafs, and an eighth part of charcoal. Great part of the phosphorus is separated from the acid, and driven off, but there remains a small quantity united with the gold, forming a phosphuret of gold. It may be done also by adding phosphorus to gold in a red heat in a crucible. It is, in this state, pale coloured, granulated, brittle, and a little more fusible. The proportion of phosphorus is not more than one part in twenty-four; and the fusiblity may be decomposed by being kept in fusion; the phosphorus is driven off in the state of vapour, and inflamed. Bergman has arranged the affinities of gold and its oxyd in the following order:

| Iron | Salts of Gold.—These are the nitrate and muriate.

1. Nitrate of Gold. When concentrated nitric acid is several times successively poured upon gold, boiled and distilled to dryness, the gold is dissolved, and the solution assumes a yellowish colour. This solution is more readily effected in proportion to the quantity of gas or nitrous gas which the acid contains. Gold leaf, according to Fourcroy, is dissolved in nitric acid, impregnated with nitrous oxyd, and he supposes that it is owing to the nitrous oxyd that the gold is oxidized, this oxyd being so much more easily decomposed than the nitric acid. The acid which, at first, is deprived of its colour by the oxidation of the gold, as this oxyd is dissolved, assumes an orange-yellow colour, holding in solution the nitrate of gold with an excess of acid. The nitrate cannot be obtained in crystals, and it is decomposed by heat or by being exposed to the light of the sun; it is also decomposed by the alkalies, or by introducing a plate of tin or silver into the solution, and the purple oxyd is precipitated in the form of powder; and likewise by muriatic acid, which at the instant of combination converts the orange-colour to a pale yellow.

2. Muriate of Gold—Muriatic acid of itself has no action on gold, or on its purple oxyd, but gold is immediately oxidized and then dissolved in oxymuriatic acid; or if nitric acid be added to the muriate in certain proportions, the solution of gold in the mixture is readily effected; hence the oxymuriatic acid was distinguished by the name of "aqua regia," because it dissolved gold, which was regarded by the alchemists as the king of metals. The nature of the chemical action is thus explained. Gold is oxidized with great difficulty, but it is effected by oxymuriatic acid, which readily parts with its oxygen, or by the addition of the nitrous to the muriatic, the former of which is decomposed, giving out its oxygen to the gold, which being now oxidized is dissolved in the muriatic acid, forming with it a muriate of gold.

This solution of the muriate of gold is of a deep yellow colour, extremely acid and caustic; has an alranging metallic taint, and stains the skin of a deep purple colour, which becomes darker by exposure to the air and light. It produces a similar effect on all vegetable and animal matters, and on marble and siliceous stones. By evaporating the solution to one half, nitric acid is diffused, and crystals are obtained. These assume a red colour by the action of strong light. They attract moisture from the air, and spontaneously become liquid. When oxymuriatic acid is used, the oxygen of this acid being retained even by a weaker affinity than the nitric acid, the gold attracts it, and combines with the muriatic acid. In this case the solution is slow, and but a very small quantity of gold can be dissolved, partly from the oxymuriatic acid not being in a very concentrated state, and partly, it is supposed, from the quantity of oxygen present not being such as to form a sufficient quantity of oxyd to saturate the acid. It ought, however, to be observed, that if the late discoveries of professor Davy be established, which make the oxymuriatic acid a simple substance, and even possessing no oxygen whatever, then a new theory must be introduced to account for the facts above stated. In oxymuriatic gas, gold-leaf is instantly fused with inflammation, and diffused.

Gold cannot be dissolved by the other acids when in its metallic state, but its oxyd may be combined with them, and a number of the salts of gold be formed. The sulphate and nitrate also, as we have seen, do not crystallize; the phosphate of gold may be fused, and in this state it forms a fine red glafs. We shall now briefly notice some of the properties of the muriate of gold. In connection with this subjedt, we must not omit the experiments of Mrs. Fullam, which she announced in an "Essai on Combustion," with a view to a new art of dyeing and painting, &c. in the year 1794, and which were, at that period, expected to lead to some important practical results.

The muriate of gold is very soluble in water, and is decomposed in hydrogen gas. If a piece of silk be moistened
GOLD.

with a solution of muriate of gold, the salt is decomposed, and the gold, reduced to the metallic state, attaches itself to the film. It is decomposed also by phosphorus. If a fiek of phosphorus be introduced into a saturated solution of muriate of gold, the salt is decomposed, and the gold, being reduced to the metallic state, forms a cylindrical covering to the phosphorus, which may be separated by diluting the latter in hot water. A similar effect is produced by burning sulphur, by sulphurated and phosphorated hydrogen gases, and by sulphuric acid. If a solution of muriate of gold be cautiously added to sulphurous acid, a fine pellicle of gold appears on the surface, which is instantly precipitated in the form of small grains. These, and many other experiments equally curious and interesting, were first described by the lady above-mentioned, and the rationale of the subject is thus explained. All the substances which have been enumerated have a stronger affinity for oxygen than gold, so that the oxyd of gold, in combination with the acid, is decomposed; the oxygen combining with the hydrogen, and forming water, or with the phosphorus or sulphur, and forming sulphuric or phosphoric acid.

"The muriate of gold is soluble in ether, and forms with it a solution of a golden yellow colour, which floats on the top of the fluid. By the addition of ether to a solution of gold, and agitating the mixture, as soon as it is left at rest, the two liquids separate, the ether rises to the top, and assumes a yellow colour, while the nitro-muriatic acid remains below and becomes white. By a process of this kind a tincture of gold was prepared, called "potable gold." The solution of gold in ether is not permanent: it is quickly reduced to the metallic state, and is sometimes found crystallized on the surface. The etherial solution is used by Mr. Stodart for defending lances, and other surgical instruments, from injury by a moist atmosphere.

The muriate of gold is decomposed by all the alkalis and earths, and is reduced to the state of yellow oxyd. Most of the metals decompose the muriate of gold: copper, iron, zinc throw down the gold in its metallic state: other metals, as silver or lead, in the state of purple oxyd.

The precipitate obtained by means of tin is valued for the beauty of the colour which it gives to glafs and enamels. This preparation is known to artists by the name of the "Purple powder of Casius," and it may be obtained by various processes. That which is commonly referred to, is to diffuse pure gold in a nitro-muriatic acid, which is composed of three parts of nitric and one of muriatic acid. A solution of tin is to be prepared by diffusing the metal in small portions at a time, in an acid containing two parts of nitric and one of muriatic acid, previously diluted with an equal weight of water. This solution, after it is saturated, is largely diluted, perhaps with a hundred parts of distilled water: to this the solution of gold equal in quantity to half the quantity of solution of tin, is added, and the precipitate is obtained after it is allowed to infuse, which is to be washed and dried. This is the only known preparation capable of giving a red colour to glafs: and if the experiment be performed with accuracy and judgment, the glafs so treated serve as a capital imitation of the ruby. The process is, however, attended with considerable difficulty, owing to the colour of the precipitate being various, from circumstances not easily discovered. According to Pelletier, it is a compound of oxyds of tin and gold; and its formation is owing to the strong attraction of the tin for the oxygen, with which it is diffused to combine in large quantities. When the solutions, above described, are mixed, the oxyd of tin, which is nearly at the minimum of oxydizement, at-tracts part of the oxygen of the oxyd of gold; the two oxyds thus brought to states of oxydizement, different from those in which they existed in the separate solutions, and probably likewise exerting mutual affinities, are no longer soluble, and are precipitated in combination. Muriate of gold is decomposed by some other metal salts, in consequence of similar actions; the oxygen of the oxyd of gold being attracted by the oxyd of the other metal, which hence passes to a higher state of oxydizement. Those which have a strong tendency to exist in such a state, are capable even of completely de-oxydizing the oxyd of gold. Example.—If a solution of the green sulphate of iron be added to the solution of muriate of gold, the gold is precipitated in very minute particles in the metallic state, while the iron passes to the state of a red sulphate. A solution of muriate of gold, when concentrated by evaporation, yields beautiful yellow crystals, not unlike topazes.

Gold, as we have seen, does not combine with sulphur by fusion, and on this is founded a method of freeing it from silver or other metals, the alloy being fused with sulphur, the silver, &c., unite with the sulphur, leaving the gold separate. But gold and sulphur may be united by the medium of an alkali. Example.—Let a sulphuret of potash be fused with one-eighth of its weight of gold-leaf, and the combination is even soluble in water, the solution being of a green colour.

Alloys of Gold.—Gold forms alloys with the greater number of the metals, which produce on the metal to be alloyed a very particular change in its properties. An extensive and accurate series of experiments on these alloys was made by Mr. Hatchet, with the view of determining some important and interesting facts relating to the use of gold as a coin. Of these we shall give a brief abstract, referring our readers for a more particular account to the Transactions of the Royal Society for the year 1803.

The chief enquiry of Mr. Hatchet, as connected with the alloys of gold, was, whether soft and ductile gold, or gold made as hard as is compatible with the process of coining, fuses more by wear. His experiments were intended to examine the effects which various metals produce upon gold, when combined with it in given proportions, beginning with 1/6th, which is the standard proportion of alloy, and gradually decreasing to 1/35th part of metals. The results drawn from the trials were, that fine gold, alloyed with silver, with copper, and with tin, did not suffer any loss during the experiment. The gold alloyed with lead only lost three grains, chiefly by vitrification; with iron it lost 12 grains, which formed socian; with bismuth it lost 12 grains, chiefly by vitrification; with zinc it lost a pennyweight by volatilization; and with arsenic, it not only lost the whole quantity of alloy, but also two grains of the gold which were carried off in consequence of the rapid volatilization of the arsenic. Hence it was inferred that only two metals are proper for the alloy of gold coin, namely, silver and copper; as all the others either considerably alter the colour, or diminish the ductility of gold. In respect to the latter quality, the different alloys employed in this series of experiments appear to affect gold nearly in the following decreasing order:—1. Bismuth. 2. Lead. 3. Antimony. 4. Arsenic. 5. Zinc. 6. Copper. 7. Marganese. 8. Nickel. 9. Tin. 10. Iron. 11. Platinum. 12. Copper, and 13. Silver. The three first have nearly the same effect on gold, and bismuth is found to render gold brittle when the proportion of that metal is to gold only as 1 to 1520; even the vapour arising from bismuth, lead, and antimony in fusion, produces these changes.

2
GOLD.

The alloy with platina is of a yellowish white colour, very ductile, and of a considerable specific gravity. The alloy with silver in the standard proportion, or 1 to 12, approaches, as we have seen above, the nearest to the ductility of fine gold of any alloy, and its specific gravity differs but little from the mean specific gravity of the two metals. When the silver amounts to 1/12, the colour of the alloy approaches to green, and forms the green gold of the goldsmiths. In combination with copper, gold has its colour rather heightened than impaired; its hardness is increased and its ductility very little lessened, when the standard proportion of 1 part in 12 is not exceeded. This alloy of 22 carats fine is generally used, when gold is fabricated into plate or ornaments, and likewise forms the gold coin of the country.

With quicksilver, gold unites with great facility, making with it an amalgam which will be described hereafter. The alloy with iron is much harder than gold, very ductile and malleable; but the colour is debased to a dullish grey, inclining to white. Tin was formerly regarded as the metal which rendered the alloy with gold the most brittle of all the alloys, but the experiments of Mr. Bingley and Mr. Hatchet have shown that this notion is to a certain extent erroneous, and that the effects produced by the mixture of tin with gold, ought probably to be ascribed to other metals, with which the tin was contaminated, such as bismuth, antimony, lead, and zinc. The alloy, consisting of equal parts of zinc and gold, is very hard and infusible to a fine polish, and not being subject to much alteration from the air, it is recommended for the fabrication of the mirrors of telescopes. The alloy of gold with silver, in which there is only 1/5th part of silver, changes the colour of the gold very sensibly; and the alloy is employed for folding gold, being more fusible than this metal.

Physiological properties of Gold. aurum, a yellow metal, heavy, pure, ductile, malleable, and thinning; and on those accounts, the most valuable of all metals. In fusibility it ranks between silver and copper; it is not oxydizable by fusion in atmospheric air; nor is it acted upon by any of the acids, except the oxymuriatic and nitro-muriatic.

The yellow colour of gold is rendered paler by fusion with borax; but this may be prevented or corrected by fusion with nitre, or sal ammoniac. The colour of gold is heightened by an alloy of copper, and this property of copper has given rise to fundry processes for exalting the colour of this noble metal. Other metals render it paler. The alchemists call gold, fol, the sun; to denote its pre-eminence over the other metals, which are called by the names of the planets. Its symbol, or character, is O; which, in their hieroglyphical way of writing, denotes perfection, simplicity, solidity, &c.

The weight of gold is that of water, according to some statements, as 19,637 to 1000. Fine gold, impered in water, weighs nearly one nineteenth part less than in air, and consequently it is used in nineteen times heavier than its own volume of water. However, the specific gravity of gold, or its comparative weight with an equal volume of water, has been variously aligned: some have made it 19,637, others 19,642, and in the Swedish Trans actions it is made no less than 20,000; that of water being 1000. Others again have made it as low as 18.75. But from the experiments of Mr. Ellicot, it does not appear to have exceeded 19,207; and from those of Dr. Lewis, on the purest gold, well hammerd, its gravity is flatted between 19,300 and 19,400. In all experiments of this kind, the result should be specified with an account of the sensibility of the balance, and the quality and warmth of the water. An increase of heat rarefying water more than it does gold, the gold must turn out proportionally heavier than an equal volume of the expanded fluid; and this difference is more considerable than it has generally been supposed. From freezing to boiling water, or by an augmentation of heat equivalent to 180° of Fahrenheit's thermometer, Dr. Lewis found that a rod of gold was lengthened about one part in 700, and confequently its volume increased about one part in 233, while the volume of water is increased one twenty-sixth or more; hence it appears, that by an augmentation of 40° of the thermometer, or from a little above freezing to the summer heat, the volume of gold, if its expansion be uniform, is increased one part in 1048, and that of water one in 117; and the gravity of gold, weighed in the water so warmed and expanded, would be greater than when the gold and water are 40° colder, in the proportion of about 19,325 to 19,400: and this calculation gives a difference, in the gravity, of 0.034 for every 10° of the thermometer; but some trials seemed to make it greater. It has been imagined, that the comparative gravity of gold to brass's weights, which are more than double in volume to an equal weight of gold, must be so far influence by the variable gravity of the atmosphere, that there must be an advantage in buying gold by weight when the air is lightest. But Dr. Lewis observes, that this difference appears too inconsiderable to be regarded in a commercial view. For the loss of weight of the two metals in the air being as much kfs than their lots in water, as air is lighter than water; and air, if we admit the accuracy of the conclusion deduced from an experiment of Mr. Hawkchi, being in its lightest state about 1,048, and in its heaviest state about 1,000, the gravity of gold will be about 40°, or one grain in about 302 ounces; which is a difference too minute to be sensible in the nicest balance. If the mean gravity of gold be reckoned 19,320, as a cubic inch of water weighs about 254 grains, a cubic inch of gold will confequently weigh about 4,902, or 10 ounces, 102 grains. The pound weight, or twelve ounces Troy, of gold, is divided into twenty-four carats. Dr. Lewis states the specific gravity of fine gold at 53° Fahrenheit, to be 19,376. According to Brillon the specific gravity of fine gold in ingot is 19,358, and when hammered 19,361. The specific gravity of gold made standard by British copper, was found by Mr. Hatchet (see Phil. Trans. for 1823) to be 17,281, when cast in an iron mould; but when the same mould was cast in sand, it was only 16,904. (See Specific Gravity.) The softness of gold, for it is nearly as soft as tin, and its toughness, adapt it for receiving the impressions of dies, and of course to be reduced to the state of coin, and for various other purposes in the arts. It is but lightly elastic and fronsorous. With regard to tenacity, it is inferior to iron, copper, platina, and silver; and therefore the assertions of former chemists and philosophers have been contradicted by later experiments, for gold has been usually represented as the most tenacious as well as the most ductile of all metals. Its malleability and ductility are sufficiently evinced by the Gold-lea and Gold-wire, which see. See also Ductility.

The value of gold to that of silver, was anciently only as twelve to one. Indeed, this proportion varies as gold is more or less plentiful: for Suetonius relates, that Cesar brought from a quantity of gold from Italy, that the pound of gold was only worth seven pounds and a half of silver. In our coinage, the value of fine gold to fine silver is nearly as 15:1. (See Coin and Standard.) Sir Isaac Newton observes, in a representation to the lords of the treasury.
GOLD.

Gold may be recovered from wood, gilt on a water size, by steeping it for a quarter of an hour in a quantity of very hot water, sufficient to cover it; then scrub the wood in a little warm water, with short flint bristle brushes of different sizes; boil the whole mixture of water, size, gold, &c. to dryness; make the dry matter red-hot in a crucible to burn off the size, and grind the remainder with mercury. The gold will be more easily laid hold of by the mercury, by the addition of some clean sand.

GOLD. Alchemical History of. See Philosopher's Stone, and Transmutation.

GOLD. Amalgam of; is a preparation of gold much used by the gilders (see Gilding); and it is made by heating some pure quicksilver in a clean crucible, and adding to it, when it is nearly boiling, about a sixtieth of its weight of fine gold in thin plates that are hot; after this mixture has been kept hot for a few minutes, it becomes an homogeneous substance, and when cold, it is put into a piece of soft leather, and which is graduated to the fluid part of the amalgam, confining almost wholly of mercury, is forced through the pores of the leather; while the gold, combined with about twice its weight of mercury, will remain in the state of a yellow silvery mass, of the confecion of soft butter; when this mass has been bruised in a mortar, or shaken in a phial, with repeated portions of salt and water, till the water receives no founts from it, it is fit for use, and may be preferred for any time in a corked phial. For the purposes of gilding it is of great importance, that this amalgam should be formed of pure materials, as any portion of lead or bismuth would deteriorate the colour of the gold, and tarnish it with black specks. The mercury should therefore be previously distilled from the red precipitate (nitrus red oxide of mercury), either alone or mixed with a little charcoal powder. See Amalgam and Mercury.

GOLD-leafing, and GOLD-leather's skin. See Gold-leaf.

GOLD. Burnished, is that which is polished with afiled instrument, called a burnisher, if it be wrought gold, or gilding on metal; or with a wolf's tooth, if it be gilding in water. See Gilding.

GOLD-coloured Glazing. See Glazing.

GOLD-coloured Metal is produced by melting zinc with copper. According to the purity of the zinc and copper, the proportions in which they are mixed, and the intimacy of their union, the compound metal proves more or less malleable, and approaches more or less to the colour of gold. Some direct the zinc to be taken only in a fifth or sixth part of the weight of the copper, and others in an equal weight or more. Dr. Lewis observes, from the result of many experiments, that both with the smallest and largest of these quantities of zinc, the metal proves more like gold than with the intermediate proportions.

The colour of these compounds is improved by a small mixture of some other metallic bodies. Crider recommends the addition of a small quantity of pure tin to copper, melted with a fourth or sixth part of zinc, which forms a compound metal, that acquires, on being well cleansed, and laid in the air for some days, a superficial colour of fine gold. Geoffroy says that iron has the like effect: with the proportions of ten parts of zinc, eight of copper, and one of iron-fillings, he produced a metal of a fine smooth grain, compact, hard, and bright, and of a beautiful gold colour. By making the copper first into braids, and then melting it with a suitable quantity of zinc, a metal may be obtained of a

There are various methods of separating gold from gilt works: it may be separated from the surface of silver, either by spreading over the gilt silver a pail made of powdered kil ammoniac moistened with aquafortis, and heating it till the matter fumes, and is nearly dry; throw it into water, and the gold will easily come off by rubbing it with a soft brush; or, by putting the gilt silver into common aqua regia, nearly boiling, and turning the metal frequently, till it becomes all over black; then wash it with water, and rub it with the soft brush, which will disengage the gold left by the aqua regia. See Gilding.

Gold may be separated from gilt copper, by applying a solution of borax to the gilt parts with a pencil, and sprinkling over the place thus moistened a little powdered sulphur; when the piece is made red-hot and quenched in water, the gold may be wiped off with a brush.
GOLD.

perior quality to that produced either by melting the copper and zinc, or by impregnating the copper with zinc, by cementation and fusion with calamine; which is a method sometimes practiced. A very ingenious artifl, says Dr. Lewis, who now prepares a gold-coloured metal in great perfection, has a fine kind of brass made on purpose for this use. The union of the copper and zinc in fusion, succeeds best and with least loss of the zinc, according to Dr. Lewis, by using a mixture of black flux and borax, or a composition of twelve parts of green glass powdered, six parts of potash, two of borax, and one of powdered charcoal; when this flux is fused in the crucible, the copper and zinc are dropped into it; and when they appear perfectly melted, they are to be well stirred together with an iron rod, and expeditiously poured out. The same flux will serve for melting several fresh quantities of the metal. Dr. Hooke gives the following receipt for making a gold-coloured metal: eight parts of distilled verdigris, i.e. of verdigris purified by solution in distilled vinegar and crystallization, and four parts of Alexandrian tutton, with two of nitre, and one of borax, are directed to be mixed with oil to the confidence of pap; then melted in a crucible, and poured into a flat mould first well warmed. A composition of this kind is called aurum jophillicum.

The following method is recommended by Homberg for giving a gold colour to copper, without the addition of zinc; make an amalgam of one part pure copper, and three parts quicksilver; boil this in water for two hours, then distil off the quicksilver in a retort, and colohate it once; take out the copper and fuse it, and it will be found of a beautiful gold colour, more ductile than common copper, and extremely well fitted for watch-work, gilding, and the finer machines and utensils. The celebrated Mr. Pott affirms that a gold-coloured metal may be made from a mixture of copper and tin, and directs it to be compounded in the following manner: Take one half ounce of tin, and four half ounces of copper; melt them well together in a clofe luted crucible, with a strong fire; or take one half ounce of the pure tin cut in pieces, and sixteen half ounces of pure copper beaten into thin plates; lay the tin between the copper-plates, lute the crucible close, and melt with a strong fire. See Prince's Metal and Tombac.

Silver is tarnished superficially, by certain vapours, as that of putrefied urine, to a colour so like that of gold, that several edicts have been issued in France to prevent frauds of this kind with regard to wire and laces.

Gold-coloured Pigments. See Pigments.

Gold-coloured Varnish. See Lacquer.

Gold, Dutch, is a kind of leaf used in gilding, &c. which is copper gilt, or brass beaten into leaves like the genuine gold-leaf. It is said to be made from copperplates, by cementation with calamine, without subsequent fusion. The thickness, compared with that of leaf-gold, is as nineteen to four, and under equal surfaces it is considerably more than twice as heavy as the gold.

Gold, Fencing of. See Farting.

Gold, Fine or Pure, is that purged by the fire of all its impurities, and all alloy. The Latins call it aurum purum, aurum primum, aurum obvixum, aurum clemum.

The moderns frequently call it gold of twenty-four carats; but, in reality, there is no such thing as gold so very pure; and there is always wanting at least a quarter of a carat. Gold of twenty-two carats has one part of silver, and another of copper: that of twenty-three carats has half a part, i.e. half a twenty-fourth of each.

Boutier gives that the electrum of the ancients was gold of nineteen carats; or four parts gold, and a fifth silver.

From an ordinance of king John ofrance, it appears that the gold then struck at Paris was of nineteen carats one-fifth; and yet it is added that it was the bolt and finest gold then known on earth. See STANDARD.

Gold, Fulminating, aurum fulminans, a precipitate of gold from its nitro-murate solution by ammonia, which possesses a remarkable explosive property. See Aurum.

It is prepared by diluting a solution of muriated gold with six or eight times its bulk of distilled water, adding drop by drop liquid ammonia, till the precipitation ceases; then let the yellow powder thus obtained be separated by a filter, well washed in hot water, and afterwards dried. The fulminating gold, thus procured, will exceed the weight of the original gold by about 33 parts in 100. If a small quantity, e.g. half a grain, of this powder be held over a candle, in a spoon or on the blade of a knife, it preferably explodes with a very loud report. This powder should be very cautiously used; the temperature requisite for its explosion is flated at above 250 of Fahrenheit. Before it explodes, its yellow colour changes to black, and at the moment of its decomposition an instantaneous flash is observed. The principal energy in explosion is directed downwards, insomuch that two or three grains of it exploded on a moderately thick florin of copper will burk a hole in it. This falt is decomposed by an electrical shock, but it cannot be ignited by a spark from electricity or from flint and steel. It will vehemently explode by sudden friction, and therefore, in order to avoid dangerous accidents of this kind, it should never be kept in a ground-stoppered bottle. The facility of its explosion is very much increased by drying; so that if it be heated till it becomes black, and is immediately removed from the fire, it will frequently go off by a mere touch. If the fulminating gold be mixed with four or five times its weight of chalk, or pulpitate of potash, or with any pulverised sulphur, it becomes decomposable at a moderate temperature, and exploded gradually to a low heat, it will be quickly decomposed, leaving merely the purple oxyd of gold. The same effect may be produced by very cautiously heating the fulminating gold without any addition, removing it from the fire when it has changed its colour, and when cold heating it again, and proceeding in this way till the powder becomes purple, in which state it will have entirely lost its explosive faculty. A similar change occurs by melting sulphur at the lowest possible heat, and dropping in the fulminating gold by half a grain at a time, well mixing it; the sulphur may then be burnt off without danger, and minute grains of metallic gold will be left behind. "The true theory of the decomposition of fulminating gold was partially discovered by Bergman, and has since been fully illustrated by Berthollet. The former of these able chemists showed that this falt when decomposed in clofe vessels was reduced to gold, partly in the metallic state, partly in that of purple oxyd, and at the same time a gas was extricated in bulk, about a thousand times as great as that of the original fulminating falt, and which extinguished flame and animal life, was not absorbed by water, and gave no precipitate with lime-water. Berthollet, by decomposing the same substance in a copper tube, connected with a jar inverted in mercury, obtained azotic gas and a few drops of water, and the gold was reduced to the metallic appearance. Now as ammonia is composed of hydrogen and azot, and as the affinity of gold for oxygen is very slight, it is manifest that the decomposition and explosion, under the circumstances already mentioned, are occasioned by the oxygen of the 3H2 gold.
GOLD.

gold and the hydrogen of the ammonia combining to form water, and to the liberation of the azot and its sudden af-
sumption of the gaseous state.” Akin’s Dict.

Gold, Leaf, or beaten gold, is gold beaten with a hammer
into exceedingly thin leaves. It is astonishing to con-
sider the fragments to which a body of gold is thus reduced. In
an experiment of Reaumur’s, forty-two square inches and
three tenths of gold-leaf weighed one grain Troy; and Mr. Boyle found that fifty and seven tenths weighed but a
grain. As a cubic inch of gold weighs 1442 grains, the
thickness of the gold-leaf examined by the one was the
277355th, and of that by the other only the 248532nd
part of an inch. See Ductility of Gold.

This gold is beat on a smooth block of black marble,
from two hundred to six hundred pounds in weight, and
about nine inches square on the upper surface, fitted into
the middle of a wooden frame, about two feet square, so
as that the surface of the marble and frame form one even
plane. Three of the dies are furnished with a high ledge,
and the front, which is open, has a leather flap fastened to
it, which the gold beaters use as an apron, for preferring
the fragments of gold that fall off. Three hammers are
employed in this business, having two round and some-
what convex faces: the first, called the cutch hammer, is
about four inches in diameter, and weighs fifteen or sixteen
pounds: the second, called the shoading hammer, weighs
about twelve, pounds, and is of the same diameter: the
third, called the gold or finishing hammer, weighs ten
or eleven pounds, and is nearly of the same width. The
French use four hammers, differing both in size and shape
from those of our workmen.

The gold beaters also use three kinds of animal mem-
branes, some of which are laid between the leaves to pre-
vent their uniting together, and others over them to defend
them from injury by the action of the hammer. For
the outside cover, they use common parchment made of sheep
skin; for interlaying with the gold, first, the smoothest and
closest vellum made of calves skin; and afterwards, the
much finer skins of ox-gut, stripped off from the large straight
gut first open, prepared on purpose for this use, and hence
called gold-beater’s skin. The general process of their pre-
paration, is laid to consist in applying one upon another, by
the smooth sides, in a moist state, in which they readily
cohere and unite inseparably, stretching them on a frame,
and carefully ferappling off the flat and rough matter, so as
to leave only the fine exterior membrane of the gut; beat-
ing them between double leaves of paper, to force out the
remaining uneftuivity; moistening them once or twice with
an infusion of warm spices, and bailing, drying and prefling
them. It is laid, that some calcined gypsum, or platter
of Paris, is rubbed with a hare’s foot, both on the vellum,
and ox-gut skins, which fill up their pores, and prevent
the gold leaf from flicking. These skins, after twenty or
eighty repetitions, become unfit for use; but their virtue
may be restored by interlaying them with leaves of paper
moistened with vinegar or white wine, beating them for a
whole day, and afterwards rubbing them over with plater
of Paris; and even holes in them may be repaired by the
dextrous application of fresh skins.

Gold, the manner of preparing and beating. They first
make a quantity of the purest gold in a black-lead crucible,
with some borax, in a wind furnace, and pour it into an
iron ingot mould, six or eight inches long, and 4 of an inch
wide, previously prepared and heated; the bar of gold is
made red-hot and forged on an anvil into a long plate,
which is further extended, by being passed repeatedly be-
tween polished steel rollers, till it becomes a ribband, as
thin as paper. This ribband is divided by compasses, and
cut with thins into equal pieces, which are forged on an
anvil till they are an inch square, and afterwards well an-
nealed. Two ounces of gold, which is the quantity melt-
at a time, make one hundred and fifty of these squares,
so that each of them weighs six grains and two fifths;
and as 4902 grains of gold make a cubic inch, the thick-
ness of the square pieces is about the 766th part of an
inch. All these squares are interlaid with leaves or vel-
lum, three or four inches square; one leaf being laid be-
tween every two of them, and about twenty more of the
leaves are laid on the outsides; over these is drawn a
parchment caine open at both ends, and over this another,
in a contrary direction, so that the vellum and gold leaves
are kept tight and close. The whole is then beaten with
the heaviest hammer, till the gold is stretched to the ex-
tent of the vellum; the pieces taken out of this caine or
mould, are cut in four with a flex knife; and the six
hundred pieces thus produced are interlaid, is the fame
manner, with pieces of the ox-gut skins, five inches square.
The beating is repeated with a lighter hammer, till the
golden plates have acquired the extent of the skin;
when they are divided into four, by a piece of cane cut
to an edge. The whole number of leaves is then divided
into four parcels, which are interlaid, as before, and
beaten separately, till they are stretched for the third
time to the size of the skins. The French repeat the divi-
sion and beating once more. After the last beating, the leaves
are taken up by the end of a cane instrument, and being
thrown flat on a leathern cushion, are cut to a size, one
by one, with a square frame of cane made of a proper
harpanet, or with a frame of wood edged with cane. They
are then fitted into books of twenty-five leaves each, the
paper which is well smoothed, and rubbed with red bole
to prevent their flicking to it. The size of the French gold
leaves is from somewhat less than three inches to 3 2
square; that of ours from three inches to 3. We shall here obser
that the gold used for the above purpose is never pure,
because pure gold is too ductile to be worked between the
gold-beater’s skins. The newel skins will work the finest gold,
and make the thinnest leaf, because they are the smoothest. Old
skins, being rough or foul, require coarser gold. The
finest gold for this purpose has three grains of alloy in
the ounce, and the coarsest 12 grains. In general the alloy is
six grains, or one eighth part. The alloy of leaf-gold
is silver, or copper, or both, and the colour is produced of
various tints accordingly. Two ounces and two penny-
weights of gold are delivered by the maker to the work-
man, who, if very skilful, returns 2200 leaves, or 80 books,
of gold, together with one ounce and six pennyweights of
waite cuttings. Hence one book weighs 4.8 grains; and
as the leaves measure 3.3 inches in the side, the thick-
ness of the leaf is one two hundred and eighty-two thou-
sandth part of an inch.

The French prepare what is called green gold-leave, from
a composition of one part of copper and two of silver,
with eighty of gold; but Dr. Lewis observes, that such
an admixture gives no greenesse to gold, and that this kind
of leaf is made from the same fine gold as the highest
gold-coloured fort, the greenish hue being a superficial tinct
given to the gold in some part of the procces; this leaf
is chiefly used for the gilding of books. A kind of leaf,
called party-gold, is formed by laying a thick leaf of silver,
and a thinner one of gold, flat on another; they are
then heated and preflled together, so as to unite and cohere:

procces, the gold, though only in quantity a fourth of
GOLD.

of that of the silver, extends over it and every where covers it.

GOLD. Million of, a phrase often used to signify a million of crowns.

GOLD Money. See Money and Coin.

GOLD, Malleable, is gold applied in pannels on proper ground, distributed into squares, lozenges, and other compartments: part of which is shadowed to raise or heighten the ref. See MOSAIC.

GOLD Plates for Enamelling are generally made of ducat gold, whose fineness is from 232 to 234 carats: and the finest gold is the best for this purpose, unless where some parts of the gold are left bare and unpolished, as in watch-cases, snuff-boxes, &c. for which purpose a mixture of alloy is necessary, and silver is preferred to copper, because the latter dispoyses the plates to tarnish, and turn green. See ENAMELLING.

GOLD Pottage, aurum pottage. See AURUM Pottage, and GOLD.

GOLD Powder, for the purposes of gilding, may be made by grinding gold leaf with honey, or thick gum-water, (see Shell-gold): by diffusing to drawers a solution of gold in aqua regia: by evaporating the mercury from an amalgam of gold, taking care well to stir the mass near the end of the process with a glass rod or tobacco pipe; or by precipitating gold from its solution in aqua regia by applying to it a solution of common green vitriol in water, or some copper, &c.

GOLD Precipitate with Tin, called also, from its supposed discoverer, caele Caffis, is prepared with great care both in dissolving the tin, and diluting the solution. For this purpose, a mixture of two parts of aquafortis, and one of spirit of salt, is supposed to be the best menstruam for the tin. Into this mixture some fine black tin, granulated, is to be set full, grain by grain, waiting till one grain is dissolved before another is dropped in, that the dissolution may go on slowly, without any heat or discharge of fumes. The gold is dissolved in common aqua regia; and a few drops of this solution being mixed with some ounces of pure water, as many drops of the solution of tin are added. If the mixture changes immediately to a clear bright purplish red colour, the due degree of dilution has been determined; if the colour appears dull, a greater quantity of water must be added for the rest of the solutions. After the mixture has deposited its red matter, and become clear, a little more of the tin solution is to be dropped in, for dissolving and precipitating any gold that may still remain in it: the liquor being then poured off, the precipitate is washed and dried. Lewis's Corn. Phil. Techn. p. 176. See Ruby.

GLASS.

GOLD, Queen. See Queen gold.

GOLD, Shell, is that used by the gilders and illuminers, and with which gold letters are written. It is made by grinding gold leaves, or gold beaten's fragments, with a little honey, and afterwards separating the honey from the powdered gold by means of water. When the honey is washed away, the gold may be put on paper, or kept in flasks; whence its name. When it is used, it is diluted with gum-water, or soap-fats. The German gold-powder, prepared from the Dutch gold leaf in the same manner, is generally used, and when it is well mixed with varnish, answers the end in Japanese' gilding, as well as the genuine. See GILDING.

GOLD-see for burnished gilding, is prepared of one pound and a half of tobacco-pipe clay, half an ounce of red chalk, a quarter of an ounce of black lead, forty drops of sweet oil, and three drams of pure tallow; grind the clay, chalk, and black-lead separately, very fine in water; then mix them together; add the oil and tallow, and grind the mixture to a fine consistence; or it may be more simply prepared by grinding together some strongly calcined red ochre with the thickest and oldest drying oil that can be procured; and, previously to use, mixing it with a little oil of turpentine for giving it a proper consistence. See Oil Gilding.

GOLD-see of Japanese may be made by pulverizing gum anis and aphanturum, of each one ounce; red-lead, litharge of gold, and umbre, of each one ounce and a half, mixing them with a pound of linseed oil, and boiling them, observing to stir them till the whole be incorporated, and appears, on growing cold, of the consistence of tar; strain the mixture through a flannel, and keep it stopped up in a bottle, for use. When it is used, it must be ground with as much vermilion as will give it an opaque body, and diluted with oil of turpentine, so that it may be worked freely with the pencil. A simple preparation consists of one pound of linseed oil, and four ounces of gum anis; powder the gum, and mix it gradually with the boiling oil; let it continue to boil, till it becomes of the consistence of tar; strain it through a coarse cloth, keep it and use it as the other.

GOLDsmith, or as some choose to express it, silver-smith, the artist who makes vessels, utensils, and ornaments in gold or silver. The goldsmiths' work is either performed in the mould, or beat out with the hammer or other engine. All works that have raised figures are cast in moulds, and afterwards polished and finished; plates or dishes of silver or gold are beat out from thin flat plates, and tankards and other vessels of that kind are formed of plates folded together, and their mouldings are beat, not cast. The bains of the goldsmith formerly required much more labour than it does at present, for they were obliged to hammer the metal from the ingot to the thinnest that it was to be, and are now invented flattening-mills, which reduce metal to the thinnest that is required, at a very small expense. The goldsmith is to make his own moulds, and for that reason ought to be a good designer, and have a taste in sculpture: he also ought to know enough of metallurgy to be able to assay mixed metals, and to mix the alloy.

The goldsmith in London employs several hands under him for the various articles of his trade. In this great city there are always hands that excel in every particular branch of the trade, and there is commonly employment enough for every one in his particular branch. The jeweller, the snuff-box and toy-maker, the silver turner, the gilder, the burnisher, the chaser, the refiner, and the gold-beater, are all employed by and under the goldsmith.

GOLD-Thread, or spun gold, is a flattened wire, wrapped or laid over a thread of yellow silk, by twisting it with a wheel and iron bobbins. By means of a curious but complex machinery, a number of threads is thus twisted at once by the turning of one wheel. The principal art consists in so regulating the motion, that the several circumvolutions of the flattened wire, on each thread, may just touch one another, and form, as it were, one continued covering. At Milan, it is said, they make a fort of flattened wire, gilt only on one side, which is wound upon the thread, so that only the gilt side appears. There is also a gilt copper wire, made in the same manner as the gilt silver, chiefly at Nuremberg: and the ordinances of France
France require it to be spun on flaxen or hempen threads. The Chinee, instead of flatted gilt wire, use strips of gilt paper, which they interweave in their fluffs, and twist upon silk threads.

**Gold, Tun of.** is a kind of money of account, formerly used by the Dutch, and in some countries, containing a hundred thousand florins. A hundred pounds of, or in, gold, is found to weigh two pounds ten ounces; the sum in silver weighs twenty-six pounds four ounces. Twenty-two pence in copper farthings and half-pence, weigh one pound avoidujs. A tun of gold, at 4l. the ounce, amounts to 96,000/. A tun of silver, at 5/. 2d. the ounce, to 6200/. A pound flering of gold to 48l. An ounce is worth 4l. The penny-weight 4s. One grain, 2d. A pound of flering silver amounts to 5l. 2d. An ounce is worth 5l. 2d. The penny-weight, 3d. and something more; one grain a half-penny. A pound of silver avoidujs comes to 3l. 5l. 3d. half-penny.

**Gold, Virgin.** is pure gold, just as it is taken out of the mines, before it has undergone any action or preparation of fire; whence the Greeks call it *ortygios.*

Such is the *expurgatus,* or gold-dust, and that got by boiling down in water; or by a mixture of niter and water in Chilli; it is added, that there are maufes or lumps of pure gold found in the mines, particularly those of Hungary. Accordingly, in the emperor's collection, are still preferred several plates of gold, said to have been thus found.

Virgin gold is sometimes very pale, and so soft, that it may be moulded into any figure with the hand; it even takes an impression from a seal, like the softest wax. To harden it, as also to heighten its colour, they mix emery with it.

**Gold, White.** See Platina.

**Gold Wire.** is a cylindrical ingot of silver, above an inch thick, two feet in length, and weighing about twenty pounds, superficially gilt, or covered with gold at the fire, and afterwards drawn successively through a great number of little round holes of a wire-drawing iron, each less than the other, till it be sometimes no bigger than a hair of the head. There is very little wire made entirely of gold, and this chiefly for one particular purpose, that of filigree work.

It is amazing to what degree of fineness the gold is here drawn; and yet it still keeps firm together, and never flew the least sign of the silver underneath it. The reader may see a computation hereof, as also a more particular account of the manner of proceeding, under the article Ductility of gold.

**Gold Wire flattened,** is the former wire flattened between two rollers of polished steel, to fit it to be spun in silk, or to be used flat as it is without spinning, in certain fluffs, laces, embroideries, &c.

**Manner of forming Gold Wire and Gold thread, both round and flat.** — The fist object, which is of the utmost consequence, is the choice of the purest gold; for on this chiefly depends the beauty and durability of the colour of the laces, broacades, and other commodities prepared from it. To a difference in this respect, the boasted superiority of the French lace to the generality of those made in England, till of late, has been wholly owing. With regard to the silver that forms the body of the wire, it is said that there is an advantage in its being alloyed. The French silver for gilding is said to be alloyed with five or six penny-weight, and ours with twelve penny-weight of copper, in the pound Troy. The gold is employed in thick leaves, which are applied all over the silver rod, and pressed down smooth with a feel burner. Several of these leaves are laid one another, as the gilding is required to be more or less thick. The smallest proportion allowed by act of parliament, is 100 grains of gold to a pound, or 5750 grains of silver. The largest proportion for the best double-gilt wire was formerly 120 grains to a pound; but the proportion of gold has been of late increased to about 120 grains. The first part of the drawing processes, as well as the preparation and gilding of the silver rod, is performed by the refiner, who uses plates of hardened steel, with a piece of tough iron welded on the back, to prevent the feel from breaking. The holes in these plates are conical, being larger in the back part than in the feel, that the rod may not be lacerated against the outer edge, and that they may contain bees-wax, which makes the rod pass more freely, and preserves the gold from being rubbed off. One end of the rod, made smaller than the feel, is pulled through a hole that will admit it, where the plate has been properly secured, and laid held by long pincers, called clamps, adapted to the purpose; to these pincers, which are so contrived, that the force which pulls them horizontally, serves at the same time to press them together, a rope is fastened by one end, and the other end goes round a capstan with crofs bars, which requires the strength of several men to turn it. The rod, thus drawn through, is well annealed; it is then passed through the next hole; and the annealing and drawing are repeated, till, being reduced to about the size of a large quill, it is delivered in coils to the wire-drawers. The remainder of the processes requires plates of a different quality, which are brought from Lyons in France, and are formed of a metallic mass, whose prevailing ingredient is iron: the holes are drilled in them here. These plates are of two forts; some of considerable thickness, for the wire in its larger state, and others about half as thick, for the finer wire. In the use of these plates, furnished with a variety of holes, the dexterity of the workman principally consists in adapting the hole to the wire; for this purpose he uses a brafs plate, called a fuse, on which is measured, by means of notches, like lips cut at one end, the increase which a certain length of wire should gain in passing through a fresh hole; and if the wire is found to stretch too much or too little, the hole is widened or contracted. Slits of different widths, in thick polished iron rings, serve also as gages for measuring the degree of fineness of the wire.

The wire-drawer's processes begin with annealing the large wire received from the refiner, which he does, by placing it, coiled up, on some lighted charcoal, in a cylindrical cavity, called the pit, under a chimney, and throwing more burning charcoal over it. When it is cooled by being quenched in water, one end is passed through the first hole in the thick plate, and fastened to an upright wooden cylinder fixed or eight inches in diameter; in the top of which are two staples, and through these is passed the long arm of a handle, by which the cylinder is turned on its axis by several men. By this process, called destaffing, the wire is frequently annealed and quenched, after passing through every hole, or every other hole, till it is brought to about the size of the small end of a tobacco pipe, and then cut into portions for the fine wire-drawer. In this last part of the wire-drawing processes, annealing is not necessary, but the wire is waxed at every hole. The contrivance for drawing the wire through the plate in this case, when left force is needful, is a kind of a wooden wheel placed horizontally, having in its upper surface small holes at different distances from the axis, into one or other of which, according to the force required,
GOLD.

Gold of Pleionura, in Botany. See Myagrum.

Gold Coasts, or, as it is sometimes called, Guinea proper, a country of Guinea, on the S.W. coast of Africa, bordering on that part of the Atlantic which is called the gulf of Guinea, and extending between three and four degrees from the river Ankobar, or, as others say, from the Colta, or the Almaso, to the Volta, and deriving its name from the quantity of gold which it produces. It is bounded on the north by Congo or Conga, on the east by the Slave coast, on the west by the Ivory coast, and on the south by the gulf of Guinea. It comprehends a number of petty states or kingdoms, viz. Adomin, called likewise Sukru and Avena, Adam, Ankobar, Adom, likewise called Litttle Lakellan, or Wather, Jabi or Jabo, Commendo or Gussafo, Fetu, Sabo, Fantin, Acron, Agonna or Anguina, Amra or Aquambar, Lablede, and Ningo or Lambi. Each of these provinces or kingdoms contains one, two, or more towns or villages on the sea-coast, between, or under the European forts and settlements. Eight of these are real monarchies, having their own proper kings; the rest are republics, governed by magistrates, who are subject to the laws and periodical changes. Upon the river Ankobar, or Cobre, which some reckon the first proper county of the Gold Coast, there is a number of towns, which compose three different provinces of Ankobar or Ancober, Aborr or Aboero, and Eguira, at which latter place the Dutch had formerly a fort, and carried on a considerable trade in gold. Eight leages E. of cape Apollonius stands the town of Axim, called by some Acheniun. (See Achembome and Axim.) See Acrons, Adom, Adomin, Anta, Commando, etc. &c. The country throughout the Gold Coast abounds in hills, adorned with high and beautiful trees, among which are the palm, the cocoa-nut, the papaw, and the banana. The valleys between the hills are wide and extensive, and fit for the plantation of all sorts of fruit; and if they were as well cultivated as watered, they would supply half the coast with provisions. The soil produces in great abundance very good rice, the richest fort of millet with red grain, yams, potatoes, and other roots, all good in their kind. The sugar-cane grows here plentifully, and larger than any where else on the Coast of Guinea. Palm-wine and oil are very good, and very abundant; the country also has plenty of tame cattle and wild bristles. The domestic animals are bulls, cows, sheep, and goats, the last of which are numerous and their fleece is excellent; neither the mutton nor beef is good, but of all animal food dog's flesh is most preferred by the negroes. The wild animals are elephants, tygers, jackulls, boars, deer of various kinds, cats, porcupines, monkeys, rats, mice, &c. &c. Among the birds are pheasants, parrots, macaws, turtledoves, and several others. The reptiles are numerous; such as snakes, serpents, vipers, lizards, scorpions, spiders, &c. The coasts, lakes, and rivers abound with fish, and likewise with alligators and gannets, an amphibious animal, resembling the crocodile, and four feet in length. The climate is very hot from October to March, but during the other months tolerable. The natives are generally healthy; but to Europeans the climate is insalubrious, and often fatal, especially in the months of July and August.

It is observed that of all the countries on the coast of Western Africa, the Gold Coast experiences the most intense heat. Here, a modern traveller, near Rio Volta, has seen Fahrenheit's thermometer as high as 95° in his chamber, and 135° in the open air; compassing by 26° the greatest heat observed by Adamou on all the banks of the Senegal. Although this traveller advanced only 10 miles from Charlottenburg on this coast, his journey is curious. The...
GOLD.

The countries he visited during his short excursion in the interior, are represented as very beautiful, fertile, and populous; they are, in general, woody, but, nevertheless, more healthy than the shores; they are agreeably intermingled with mountains, vallies, and hills. Fresh water, which is scarce and bad on the coast, is here abundant. About five miles from Chritiansburg I first observed a chain of mountains covered with tall trees, and composed of large-grained granite, of gneiss, and of quartz.

The native negroes of the Gold Coast are in general tall, straight, and well-proportioned, with oval faces, sparkling eyes, regular, white teeth, mouths of a moderate size, and lips tinged with a better colour and thinner than those of the negroes of Angola. As to the qualities of the mind, they have a quick apprehension and ready memory, accompanied with an astonishing prescience of mind, and equanimity; but they are generally so indolent that mere necessity puts them upon exerting the faculties they possess. In general, they are crafty, fraudulent, and treacherous; thieves, gluttons, and drunkards, and equally inept and coveous. When they obtain a victory over their enemies, they return home dancing and finging, and when defeated do the same round the graves of their friends and fellow-soldiers. Alkike infensible of grief or joy, they fing till they die, and dance into the grave. The women are proportionably handier than the men, straight, slender, and well-limbed; their chels high, their mouths small, and their eyes indicating vivacity and spirit. They are quick, cheerful, and loquacious; gay in their disposition, and boole in their principles as to gallantry, but temperate in their diet. When the men and women overcome their natural indolence, they are laborious, industrious, and ingenious; and apply with activity and diligence to agriculture or fishing; so far as they are excited by poverty or avarice. Their drefs is various according to their rank and circumstances; but the rage of dres is chiefly prevalent among the women, who are fond of adorning all parts of their bodies with gold, coral, and ivory trinkets; and this rage they derived from the Portuguese and Dutch; as before their arrival men and women went naked to the age of maturity. They are fond of frequent ablutions, and being accustomed to the use of water, they are excellent swimmers and divers from their youth. Besides the natural inhabitants of the Gold Coast, there is a great number of Mulattoes, a mixed progeny, arising from the commerce of Europeans with the black women. This puruous race forms gangs of thieves and plunderers, void of decency, honour, honesty, or principle in their dealings with each other, with the Negroes, or the Europeans. These call themselves Christians, although they are the grosslest of all idolaters, and most of their women prostitute their bodies publicly to Europeans, and privately to the Negroes. The towns and villages of this coast consist of a multitude of little huts or cabins, dispersed in groups, without order or design, and communicating with each other by narrow crooked roads, which terminate in the centre of the town or market place.

It is observably that the further you remove from the coast, the more civilized do the natives appear, at least so far as relates to their mode of building and of living. The common food of the Negroes, in this part of Africa, is a pot of millet boiled to the confidence of bread, yams, and potatoes, over which they pour some palm-oil, and garnish the dish with herbs and putrid fish. This is their meal on common days; and on holidays they feast upon beef, mutton, and fowls. They begin the day with drinking brandy, and conclude the evening with palm-wine, mirth, riot, and tobacco, of which they are extravagantly fond. In eating they are temperate, but very profuse in drinking. Their marriages are encumbered with few ceremonies, and without any previous courtship; and they are as easily dissolved as contracted. Polygamy is allowed among them; and the women are generally doomed to the most laborious offices; they are obliged to cultivate the ground, grow millet, plant yams, and provide subsistence for the husband, who is still spending his time in golfitting, drinking, and smoking. The rich, however, have two wives, who are exempted from labour and all servile employment; and to them the management of the house is intrusted, and a sort of authority over all the other women is committed. It is said to be no uncommon expedient among Negroes to marry, in order to obtain a livelihood by the prostitution of their wives. As the wealth of the Negroes consists chiefly in the number of their family, they are anxious for multiplying their children; and a pregnant woman is treated with great tenderness and respect. A child, as soon as it sees the light, is consecrated by the priest, and has three names given to it. Circumcision is, it is said, though practised in other parts of Africa, is hardly known on the Gold Coast, except at Acra, where it is performed at the time of baptism or consecration. Besides their lawful wives, the Negroes often keep concubines, who are preferred to their wives, and more tenderly treated; nevertheless their children are reckoned illegitimate. But legitimate children never inherit any paternal fortune, in any kingdom on the Gold Coast, except at Acra. In the countries of Egùira, Aćim, Ancobar, Anta, and Adom, there are certain women who never marry, but are dedicated by profession to the public use, and initiated in their vocation in a formal manner. Among the Negroes there is a variety of mechanical arts, in which they are expert; such as the making of wooden and earthen vessels and plates, chair-matings, copper ointment boxes, braclets, necklaces, rings, and ear-rings of gold, fingers, or ivory; and also all sorts of weapons and instruments of war. Their tools, which are rude and simple, consist only of a flone for an anvil, a pair of tongs, a pair of bellows, a file, a saw, and a hammer. They can smith with extraordinary exactness flue-wire, and materials of gold, bracts, and copper. In building canoes, which are of various sizes, from 30 to 14 feet in length, and three or four feet in breadth, the Negroes are very ingenious, and they are no less dex- trooms in the use of them. With regard to the husbandry of the Negroes, they sow in the rainy season, the soil at other times being unmanageably hard; and they adapt their ground to the nature of the grain; owing maize in elevated and dry situations, and rice or millet in low marshy lands, subject to inundations. The natives of the coast, finding it easy to dispose of all their grain, have established corn markets in every village, and the price of grain, in gold-duft, cowries, &c. is rated by certain officers of police, appointed by the king. Hither the men and women meet from considerable distances, bearing heavy burden; and the women especially submit to great labour and fatigue in this way, that they may exchange their heavy loads for European commodities, such as looking-glades, bracelets, ear-rings, glass-beads, and other female trinkets, suited to their taste for dres and finery. The markets are exempted from all duties and imposts. Besides these frequent markets, they have also fairs twice a year for European wares. All the diversions among the Negroes consist of dances, to which they are excessively addicted, music, and mock combats, which often terminate tragically. The principal musical instruments among the Negroes are horns, made of ivory, trumpets, drums of different sizes, and a kind of harp, with five or eight strings.
The honour of the first discovery of the Gold Coast is contested between the French and Portuguese; the French pretend that they were acquainted with Ngritia and Guinea above 100 years before the Portuguese began their discoveries, or about the year 1546 or 1544, but little credit is attached to their accounts of French writers. The Portuguese, it is said, fitted out a ship at Lisbon, under the protection of Don Henry, for the sole purpose of making discoveries along the coast of Africa. At this time Alphonso I. reigned in Portugal. The navigators, it is further said, were driven on an island in the gulf of Guinea, which they called St. Thomas, and where they made a long stay, laying the first foundation of a colony in this island. Having repaired their vessel, they returned to Lisbon, and arrived there in 1544. The Portuguese soon equipped a fleet, and pushed their discoveries as far as Bein, and in process of time arrived in the road of Acre, on the Gold Coast, where they procured a quantity of gold. A number of adventurers from the island of St. Thomas arrived at Elmina four years after the departure of the French. Purchas relates, that Alphonso, having little leisure for pursuing discoveries towards the latter end of his reign, gave an exclusive privilege for five years to Ferdinand Guinea, a citizen of Lisbon, to sail to the coast of Africa: and a person, reputed by him, says Purchas, discovered Elmina; and during this period, were also discovered the islands of St. Thomas, St. Matthew, Annobon, and del Principe. In 1561, John II. encouraged the commercial spirit of his subjects, and projected further discoveries; and it was probably upon this occasion, notwithstanding the assertions of French writers, that the king of England sent a ship and a number of adventurers from the island of St. Thomas, to explore the coast of Guinea, with exclusive privileges. In the reign of Henry III. of France, the French began to renew their voyages to the Grain and Gold Coast. From this period the credit of the Portuguese began to decline, and other Europeans began to open a commerce with the Coast of Guinea. Among others the Dutch engaged in the warfare, which had been prosecuted between the Portuguese and other Europeans; and by perseverance they made themselves masters of the forts of Elmina and Axim; obtaining, by their courage, that security, which the Portuguese had lost by their infidelity and cruelty. The first Dutchman who led the way to Guinea, was one Bernard Erck, in 1597. Running along the Gold Coast, he established a correspondence with the natives, treated them with civility, and alienated their affections from the Portuguese. At length, by their intrigues with the king of Saba, the Dutch obtained permission to build a fort, three leagues E. of Cabo Corfo, or Cape Coast. This fort was finished in 1624, and the Dutch power founded in Guinea, at the time when the States were engaged in a war with Philip IV. of Spain. In the year 1637 they succeeded, after much resistance, in taking the fort of St. George d'Elmina, and in the year 1642 the fort of Axim also fell into their hands. The Dutch, having thus far been successful, proceeded to attack the English settlements. In tracing the first British establishments on the Coast of Guinea, we may begin with observing, that a trade here had been carried on by some private adventurers, without the aid or protection of the government. In 1575 and 1588, Queen Elizabeth granted two patents to certain rich merchants of England, for an exclusive trade to the coast of Barbary, and another for that of Guinea. In 1592 a third patent was obtained by the same body of merchants. In 1651 the republic of England encouraged the African trade; and in 1662 Charles II. granted a charter to a body of merchants, under the name of the Royal Company of England trading to Africa, excluding their limits from the mouth of the Straits to the Cape of Good Hope. This affair of this company falling into disorder, the king created another corporation, called the "Royal African Company," which was founded to this day. This charter bears date, Sept. 27, 1662. This company, with a small capital, was diligent and successful; Cape Coast was enlarged and beautified; the forts of Accra, Dixcove, Winneba, Sakkonda, Commando, and Ananw, were built or repaired, all of them on the Gold Coast, and several within musket-shot of the Dutch settlements. They bought Frederickburg of the Danes, and built a new fort in Winchard. See African Company.

GOLD CROMACH, a town of Germany, in the principality of Bayreuth, which had formerly a gold mine; 5 miles N. of Bayreuth.

GOLDAPP, a town of Prussian Lithuania; 68 miles E. S. E. of Königsberg; Allo, a river of Prussia, which runs into the Romshe; 6 miles N. of Goldapp.

GOLDAST, MELCHIOR HEIMENSVELD, in Biography, a learned writer of the 16th century, was a native of Switzerland. He studied the civil law at Altdorf, but he is better known as a man of letters. His works, though not marked for originality, were highly esteemed by the learned of the period in which he flourished: the principal of these are, 1. "Monarchia Sancti Imperii Romanii," in three volumes folio, published in 1611-14. These volumes consist of a collection of treaties on the civil and ecclesiastical jurisdiction of the empire. 2. "Alemanie Scriptores," in three volumes folio, 1730. "Commentarius de Bohemien Regno," 40. "Informatio de flatu Bohemise quod Jus," 40. "Sylvia Fracnica," being a quarto collection of pieces relative to the maid of Orleans: "Scriptores Rerum Sacram," "Collectio Consuetudinum et Legum Imperialis," "Politica Imperialis," and a collection of letters, written to him by several men of learning. This last work was printed at Frankfort in 1688. Mr. Goldast was of a capricious temper and of changeable habits, which prevented him from rising in the world. He died in 1655, having long struggled with poverty. Moreri, Bayle.

GOLDBERG, in Geography, a town of Silesia, in the principality of Lignitz, deriving its name from a gold mine in its vicinity, which was formerly very rich. The earth, called giglata terra, is dug near it; and the inhabitants are employed in the woollen and linen manufactures; 12 miles S.W. of Lignitz. N. lat 51° 4'. E. long. 15° 53'.—Also, a town of the duchy of Mecklenburg; 15 miles E. of Wilmar.

GOLDECK, a town of the archbishopric of Salzburg; 28 miles S. of Salzburg.

GOLDEN, something that has a relation to gold, or consists of gold, is valuable like gold, or the like.

GOLDEN BELL, Bolla Aurea. See BELL.

GOLDEN CALF was a figure of a calf, which the Israelites cast in that metal, and set up in the wilderness to worship, during Moses's absence in the mount, and which that legislator, at his return, burnt, ground to powder, and mixed with the water the people were to drink of, as related Exod. xxxii.

The commentators have been greatly divided on this article: the pulverizing of gold, and rendering it potable, is an operation in chemisty of the hait difficulty; and it is hard to conceive how it should be done at that time, before chemistry was ever heard of, and in a wilderness too! Many, therefore, suppose it done by a miracle; and the ref, who
allow of nothing supernatural in it, advance nothing but con-
jectures as to the manner of the procets.
Mofes could not have done it by a simple calcination, nor
amalgamation, nor anthony, nor calcination: nor is there
one of those operations that quadrates with the text.
Mr. Stahl has endeavoured to remove this difficulty. The
method Mofes made use of, in making his aurum potabile,
according to this author, was the fame with that which now
obtains; only, instead of tartar, he made ufe of the
Egyptian satron, which is common enough throughout
the East.
Golden Caps, in Geography, a cape of England, on the
W. coat of Dorseth. N. lat. 50° 43'. W. long. 2° 50'.
Golden Caps, a name by which fame call the ranunculus,
or cow-foot.
Golden Eyes, in Ornithology, the Anas Clangula. See
Duck.
Golden Eye, a species of fly. See Chrysopis.
Golden Fleece, in the Ancient Mythology. See Argo-
autic.
Golden Fleece, Order of the, is a military order, instituted
by Philip the Good, duke of Burgundy, in 1429.
It took its denomination from a representation of the
golden fleece, borne by the knights on their collars, which
confided of flints and fleeds. The king of Spain is now
gand master of the order, in quality of duke of Burgundy:
the number of knights is fixed to thirty-one.
It is usually said to have been instituted on occasion of an
immense profit which that prince made by fow; though
others will have a chemical mystery couched under it, as under
that famous one of the ancients, which the adept contem-
porary no other than the secret of the elixir, written on the
fleece of a sheep.
Golden Flower, in Botany. See Chrysanthemum.
Golden Flower-gentle, a name sometimes given to several
species of the amaranth.
Golden Head, in Ornithology, a water-fowl, otherwise
called anna artiea. See Duck.
Golden Island, in Geography, a small island at the entrance
of the gulf of Darien, in Terra Firma, S. America. N.
lat. 8° 20'. W. long. 72° 32'.
Golden Lake, a lake of the island of Borneo. N. lat. 3°
55'. E. long. 115° 45'.
Golden Lang-eart, in Botany. See Hierachum.
Golden Maiden-hair, See Adiantum aureum, and Pol-
ytrichum.
Golden Mouse-eart. See Hierachum.
Golden Number, in Chronology. See Cycle of the Moon,
and Number.
Golden Prelendary, of Hereford. See Prebendary.
Golden Rivers, in Geography, a river of America, which
runs into the Mississippi, N. lat. 43° 20'. W. long. 92° 2'.
Golden River, or Rio del Oro, a river of America, which
runs into the Spanish Main, N. lat. 14° 44'. W. long. 82°
55'.
Golden Red, or Sarracen's Wound-eart, v Regina aurea, in
Botany. See Soldago.
Golden Red Tree. See Boscia.
Golden Rule, in Arithmetic, a rule or praxis of great ufe
and extent in the art of numbers, whereby we find a fourth
proportional to three quantities given. The Golden Rule
is also called the Rule of Three and Rule of Proportion.
See its nature and ufe under the article Rule of Three.
Golden Sapphire is a species of the inda or eclecampane.
(See Ixila.) It grows naturally on the sea-coasts in many
parts of England, and is sometimes sold in the London mar-
ket for the true sapphire, though entirely deftitute of its
warm aromatic tale. See Sapphire.
Golden Saviffre. See Chrysopelum.
Golden Stede, order of the. See Stole.
Golden Sunflower of Antimony. See Antimony.
Golden Thistle, in Botany. See Scotoles.
Goldenstein, in Geography, a town of Moravia, in
the circle of Olmutz; 32 miles from Olmutz.
Goldentritt, a town of Germany, in the county of
Diepholz; 14 miles N. of Diepholz.
Goldentraun, a town of Upper Laffatia; 16
miles S.E. of Gorlitz. N. lat. 50° 27'. E. long. 15° 26'.
Goldingen, a town of the duchy of Courland, erected
near the river Weta, defended by an old castle, and con-
taining two churches; 48 miles W.N.W. of Mitoaw. N. lat.
56° 51'. E. long. 21° 44'.
Goldehlaute, a town of Germany, in the county of
Henneberg, 12 miles N.E. of Meiningen.
Goldman, Nicholas, in Biography, a mathematician,
was born at Bredaf, in Silefia, in the year 1625, and died at
Leyden in 1665. The works by which he is generally known
are "Elementa Architecrie Militaris," 1643, "De
Ufe Proportionum Circuli," "De Stylometria," 1662,
and another treatife on Architecture," published in 1696,
with numerous engravings, and the life of the author. Mo-
rer.
Goldoni, Charles, was born at Venice in the year
1707. Almoff from his infancy he gave indication of a hu-
morous charafter, and a propensity to dramatic performances.
Before he could well read he became an author, and wrote the
plan of a comedy by the time he was eight years old. This
piece presided so much merit, that it required the testimony
of respectable witneses to verify its being the production of a
child. He received the elements of education at Venice,
from this city he went to the Jesuits' college at Perugia to
study rhetoric, and afterwards he studied philosophy at Ri-
mont. His mind was, however, too deeply engaged in thea-
trical exhibitions to make the fylum of Aristotle a predo-
ninant purfit. Every leisure moment he spent at the thea-
tre, till at length he passed from the pit to the flage, and
joined a company of players. This, by his own account, was
an error, which drew after it many feros confequences. He
had been intended by his father for the profession of phyfic,
which he was unable to study: he was then solicited to prepare
himself for the bar, and was engaged, after many changes, in
practice at the courts of Venice. After this he was appointed
secretary to the Venetian refident at Milan, where he became
acquainted with the manager of the theatre, and wrote a
fare for him, entitled "The Venetian Gonderer," which
was performed and printed: by degrees he became united to
the company, and compos'd many pieces for them. He now
turned his thoughts towards reforming the Italian stage, and
so earnest was he in his projects, that it is laid in a single year
he wrote sixteen new comedies, besides forty-two other
pieces for the theatre, and among these are reckoned some of
his best productions. The first edition of his works was pub-
lished in 1753 in 10 vols. 8vo. After this he published many
additional pieces under the title of the "New Comic Theatre."
He had compos'd 59 other pieces so late as the year 1761,
and here closes the literary life of Goldoni in Italy. He
now repaired to Paris, and was as zealous in his endeavours to
reform the Italian theatre there as he had been in his own
country. His firft attempt was in a piece called the "Fa-
ther of Loves," but the bad fucceds of this comedy was a
fufficient warning to him to defist from his undertaking. He
continued, during the remainder of his engagement, to pro-
duce pieces agreeable to the general taste, and published twenty-
GOLDI is, perhaps, the only author of comic operas in Italy, who has given them a little common sense, by a natural plot, and natural characters; and his celebrated comic opera of the "Buona Figliuola," set by Piccini, and first performed in London Dec. 9th, 1766, rendered both the poet and composer, whose names had scarcely penetrated into this country before, dear to every lover of the Italian language and music, in the nation. This admirable production, before it was brought hither, had favored the imprezzario of the opera at Rome from ruin, and been performed in the principal cities of Italy. In the year 1760, Piccini, passing through Rome, in his way to Milan, was entreated to compose a comic opera for the Teatro delle Dame in that city, which had lately been very unfortunate. No libretto was ready, and application having been made to the poet Goldoni, at this time in Rome, he furnished the musical drama of "La Buona Figliuola," from his comedy of "Pamela," in a few days. Several of the original performers were now in London, particularly the first buffo, Lovatini, and the famous man Savoi, with the buffo carico Morigli. And though females are not allowed to appear on the stage at Rome, yet Signora Guadagni had previously performed the part of Cecchina in several cities of Italy, with great and well-deserved applause before his arrival here.

After the great success of the "Buona Figliuola," the public was disposed to hear with partiality any productions by the same authors; and when the "Buona Figliuola Mattita," (or Pamela in high life,) was brought out, the crowd at the opera-house was prodigious; but expectation, as usual, was so unreasonable as to spoil the feast; to gratify it was impossible. Some ascribed their disappointment to the composer, force to the performers, but none to themselves. The music was excellent, full of invention, fire, and new effects; but so difficult, particularly for the orchestra, that the performers forgot it was winter. The principal part of the Marchesa was given to Zamparini, a very pretty woman, but an affected singer. Multi fo difficult to perform was not easy to hear; and this drama was never sufficiently repeated for the public to be familiarly acquainted with it. They were glad, as well as the performers, to return to the "Buona Figliuola" for their own cause and relief from a too serious attention.

In France, Goldoni wrote several very successful comedies for declamation in the French language, but we are not acquainted with any dramas which he produced for music in that country. Poor Goldoni was in such favour with the royal family of France before the revolution, that he was never allowed to return to his own country; but died at Paris in the year of terror, 1793, at the age of 83.

GOLDSBOROUGH, in Geography, a small town of America, in Hancock county and state of Maine, incorporated in 1789, and containing 379 inhabitants; 47 miles E. of Penobscot. N. lat. 44° 19'.

GOLDSINNY, in Ichthyology, a fish discovered on the coast of Cornwall, in the whole form of the body, lips, teeth, and fins, resembling the wrasse, which is said never to exceed a palm in length; near the tail is a remarkable black spot; the first rays of the dorsal fin are tinged with black. See Labrus Cornubius.

GOLDSMITH, Oliver, in Biography, was born in the county of Longford, Ireland, in 1731, though, according to other accounts, this event took place at Elphin, in 1739. He was the son of a clergyman, who gave him a literary education, and sent him early to Dublin college. Being designed for the profession of medicine, he was removed to Edinburgh in 1751, where he continued till 1754, when he left that place to avoid a process against him for
for debts incurred, probably to administer to his dissolution. He was interdicted at Sunderland, and thrown into confinement, from which he was released by the kindness of two fellow-collegians. After this, he determined to visit the continent, embarked for Holland, and travelled through Flanders and part of Germany, paused some time at the universities of Strafburg and Louvain; at the latter place he took his degree of bachelor of physic, and thence accompanied an English gentleman to Geneva. Here he engaged himself as travelling tutor to a young man who had become possessed of a large fortune, but whose mind was ill-adapted to do credit to the gifts of Providence. They disagreed in the south of France, and Goldsmith was left to contend with the hardships of indigence in a foreign country. He returned in 1754, and had in most of his peregrinations trial for his support to his own exalted efforts. His learning enabled him a favourable reception at the monastery, and his German flute fiddle failed to procure him a maid and a night's lodging from the penury, who were delighted with strains which a poetical audience would have treated with disdain. His arrival at London with a few pence in his pocket, was not likely to be the termination of his precarious difficulties. He attempted to get into the employ of an apothecary, but his appearance being against him, his application was treated with disdain. He at length was admitted as usher to Dr. Miller, who kept an academy at Pockham. Here he remained but a short time, and then resolved to follow the profession of an author in London. He obtained some employment in the Monthly Review, and furnished papers for the public Ledger. He published a weekly pamphlet, entitled "The Bee," and "An Enquiry into the State of Polite Learning in Europe." After he had been some time exerting his pen in obscurity, he became a member of a club, and as poet, by the publication of his "Traveller," or a Prospect of Society. This work had him by him in MS. some years, and it was at the instigation of Dr. Johnson that he prepared it for the press. That great critic declared it as his opinion, that there had not been so fine a poem since the days of Pope. In this decision the public concurred, and the author was, almost immediately, introduced to the most eminent literary characters of the age. In the following year was published his novel of the "Vicar of Wakefield," which had been sold to a bookseller some years before, but had been kept back as the work of an unknown writer, and exciting no expectations of success. It was, however, received with unbounded applause, and has ever since borne a distinguished rank among similar compositions. His next work was a "History of England," in a series of letters from a nobleman to his son, in two volumes 12mo., a work that still continues to be read with great delight. His poetical fame reached its summit in 1756, by the publication of his "Deserted Village," which was universally admired. For this he obtained of his bookseller 100l. a sum which appeared to the author so exorbitantly great, that he refused to take it; but the sale of the work convinced him that he might fairly appropriate the sum out of the profits. As an author of comedy, he produced in 1768 "The Good-natured Man," which was not very successful; and in 1772 another play, entitled "She Stoops to Conquer," or "The Mill-dakes of a Night." From this Goldsmith cleared a large sum, and it is still occasionally reprinted to applauding audiences. Notwithstanding the successes of his pieces, by some of which he is alleged to have cleared 120,000l. in a single year, his circumstances were never very prosperous, which was partly owing to the liberality of his disposition, and partly to an unfortunate habit which he had contracted of gaming; the arts of which he knew very little of, and consequently became the prey of those who were base enough to take advantage of his simplicity. Besides the works already treated of, Dr. Goldsmith, as he was called, though he had only taken a bachelor's degree, compiled an English history in four volumes, and a Roman and Grecian history in two volumes each; and "A History of the Earth and Animated Nature," in eight volumes 8vo. Such was the confidence which he acquired in his skill at composition, that he formed a plan for a much greater work, viz. "A Dictionary of Arts and Sciences," but this and other schemes which he had planned were cut off by his untimely death. A dependence of mind, probably occasioned by the consciousness of the bad state of his affairs, had been secretly weighing upon him, when in March 1774 he was attacked with the symptoms of a low fever, under which he died on the 4th of April. He was buried in the Temple churchyard without much attendance, but a monument has since been erected to his memory in Westminster Abbey, with a Latin inscription by Dr. Johnson.

Goldsmith, as a man, was rather admired for his genius, and beloved for his benevolence, than solely esteemed. The bent part of his moral character was a warmth of sensibility, which made him in all fortunes ready to share his purse with the indigent, and rendered him in his writings the constant advocate of the poor and oppressed. The world feature was a malignant envy and jealousy of successful rivals, which he sometimes displayed in a manner not less ridiculous than offensive.

As a writer, no one of his time was possessed of more true humour, or was capable of more poignancy in marking the follies of individuals. This talent he displayed in a very amusing manner in his poem entitled "Retaliation," written as a retort to the jocular attacks made upon him in a club of which he was a member. His literary fame stands highest as a poet, in which character a place may be given him perhaps at the head of the minor class, the term minor being applied with relation to the quantity, rather than the excellence of composition. It would not be easy," says his biographer, "to point out in the whole compass of English poetry, pieces that are read with more delight than "The Traveller," or "The Deserted Village." The elegance of the versification, the force and splendour yet simplicity of the diction; the happy mixture of animation with glowing description, are calculated to please equally the refined and the uncultivated taste. The moral and philosophical views of society they exhibit are, indeed, objectionable; yet upon the whole they exert a favourable influence over the heart. In addition to these capital works, the "Homer," and some short humorous and miscellaneous pieces, complete the catalogue of his performances in verse. As a profe writer he deserves high praise for style, which he adapts with great felicity to his subject, and which, whether elevated or plain, is always clear, pure, and unaffected. Life prefixed to his poems. Europ. Mag. A. A. Regis.

GOLDWIN, John, an ecclesiastical composer, was brought up under Dr. William Child, and, in 1667, succeeded him as organist at the free chapel of St. George at WindSOR. In 1703 he was appointed master of the choirs there, in both which stations he continued to the time of his death in 1719. Dr. Boyce, out of a great number of anthems by this composer, selected one for four voices, "I have set God always before me," which he has inserted in the second volume of his "Collection of Cathedral Music," and well characterized it with respect to the modulation, by saying that "it is singular and agreeable."
GOLDYLOCKS, in Botany. See CHYSOCOMA and CYPRIDIFLORUM.

GOLDAH, in Geography, a town of Bengal; 18 miles E. of Ramgun. N. lat. 22° 28'. E. long. 85° 51'.

GOLDET in Geography, a Portuguese, in the kingdom of Tunis; 25 miles N. of Tunis. Ala, a narrow channel between the lake of Tunis and the sea, defended on each side by a castle.

GOLF, or GOFT, the name of a diversion or exercise, much used in Scotland, and played upon the lawns or links, as they are there called.

It consists of driving a ball with clubs, between two goals or holes, half a mile or a mile asunder. He who can do this with the fewest strokes of his club is the conqueror.

GOLFO Trinidi, in Geography, a bay on the coast of South America, in the government of Caracas. N. lat. 10° 30'. W. long. 68° 20'.

GOLGAM, a town of Hindoustan, in Dowlatabad; 15 miles N. of Beder.

GOLGOM, a town of the island of Ceylon; 48 miles N.W. of Candy.

GOLGONTHA. See CALVARY.

GOLIATH, in Scripture History, a famous giant of Gath, who defied the armies of Israel, and was slain by David. 1 Sam. vii. 4, &c.

GOLICH, in Geography, a town of Ruffia, in the government of Irkottich, on the Lena; two miles S. of Orenburg.

GOLINDA, a small island near the N. coast of Cuba. N. lat. 23° 20'. W. long. 80° 4'.

GOLISANO, a town of Sicily, in the valley of Demara; 9 miles S. of Catania.

GOLTZ, a town of Nubia, on the left side of the Nile; 34 miles W.N.W. of Dongola.

GOLLIUS, James, in Biography, was born at the Hague in 1596; but he pursued his studies at Leyden with the most unremitting diligence and ardour, and became distinguished for his deep knowledge of the learned languages, antiquities, philosophy, and mathematics. In 1622 he accompanied an embassador of the United Provinces to Morocco, where he excelled the admiration of the emperor Muley Zedan, with whom he had frequent interviews. After his return to his native country he succeeded to the Arabic professorship on the death of Erpenius, under whom he had formerly studied. In 1625 he obtained permission to travel in the Levant, and sailed more than a year at Aleppo, whence he made various excursions into Arabia and Melopotamia. On his return he visited Constantinople, where he obtained very distinguished notice from the learned in that capital, by whose means he had access to the best libraries. During his absence he was appointed professor of mathematics, and returned to Leyden in 1629, and applied himself to the duties of his office. He died in 1667, having occupied with much credit the arduous situation of professor for more than forty years, and passed through all the academical honours. As an author he published the "Saracen History of Elmacins," which had been begun by Erpenius: also a life of the great Tamerlane, written by an eminent Arabian author: "The astronomic Elements of Alrigan," with a new version and learned commentaries: "An Arabic Lexicon," a "Persian Dictionary," which was printed in London. Bayle. Moret. Moret.

GOLIUS, Peter, brother of the preceding, entered when very young among the Carmelites; like his brother he excelled in the knowledge of the Arabic language, and taught it in the seminary belonging to his order at Rome, where those monks were educated who were intended to be sent on missions into the East. Golius was destined for this service, and having visited every part of Syria and Palestine, founded a monastery of his order on mount Libanus, over which he presided till he was recalled to Rome. Here he was employed as one of the principal scribes of Sergius Riusus, archbishop of Damascus, in preparing his edition of the Arabic bible, which was published in 1671 by the direction of the college "De Propaganda." After it was completed, Golius was appointed visitor of the missions of the East Indies. He died in this employment at Surat about the year 1673. He was an author of translations into Arabic of Thomas a Kempis' imitation of Jesus Christ: of sermons on the Evangelists: an "Historic distinctif of St. Gregory of Decapolis," several small devotional pieces, and a translation from Arabic into Latin of a "Collection of Parables and Proverbs," Moret.

GOLIUS, or GOLUS, in Geography, a town of Africa, near the river Grande, the inhabitants of which trade in flax, ivory, and cotton.

GOLLING, a town of the archbishopric of Salzburg, on the Sulza; 14 miles S.S.E. of Salzburg.

GOLLOSING, a town of Bengal; 70 miles W. of Midnapour.

GOLNITZ, a town of Hungary, on a river of the same name; 14 miles S.E. of Kapidoff.

GOLNOW, a town of Anterior Pomerania, formerly Hanizzac, situated on the Ihna; 12 miles N. of Stargard. N. lat. 53° 37'. E. long. 24° 57'.

GOL, a river of Corinca, which rises nearly in the centre of the island, and pouring a N.E. course, runs into the sea; 12 miles S.E. of Baia. It gives name to one of the two departments into which the island is divided; the other being Liame. Gol comprehends the northern division of Corinca, in N. lat. 42° 30'; and containing 165 square leagues, and 124,466 inhabitants, is subdivided into three circles, viz. Baia, whose inhabitants are 47,832; Calvi, having 26,282 inhabitants; and Corte containing 35,542 inhabitants. There are several lofty mountains near the centre of a chain that traverses the island longitudinally. The most considerable lakes are Ino and Cremo, the former of which is of unknown depth. The soil is tolerably fertile, yielding barley, millet, olives, cherries, wine, fruits, &c. On the hills are woods and excellent pastures. See CORINCA.

GOLDBUNGE, a town of Bengal; 10 miles E. of Silhet.

GOLPHINGTON, the chief town of Washington county and state of Georgia, in America, situated near the head of Ogeechee river, about 20 miles E.S.E. of Savannah town.

GOLPS, in Hertford, are roundels, or torteaux, of a purple colour.

GOLTBERGENSIS TERRA, in the Materia Medica, a whittish earth, used in the shops of Germany and Italy as an astringent, a cordial, and a sudorific, but little known among the English apothecaries. It is dug in many parts of Germany, as Goldberg and Strigaw, and Ligugut in Silesia; but particularly at this time in the neighbourhood of Halte, in the bishopric of Lige, in the circle of Wellphalia. It is taken up there in considerable quantities, and usually is mixed with the impression of an egg, and with its old name Golbergensit terra under it. It was imagined to contain some particles of silver, and thence to derive some of its virtues; on this account Montanus called it aequa bund; but experience shows that it doth contain a particle of that metal. It is a delectable compact
compact earth of a dull greyish white, soft and friable, and adheres firmly to the tongue, and makes no effervescence with acids.

GOLTZEN, in Geography, a town of Lusatia; 10 miles W. of Lubben. N. lat. 51° 58'. E. long. 13° 30'.

GOLTSZENUS, HUBERT, in Biography, a painter, who was born at Venlo in 1520, and studied under Lambert Lombard. Becoming enamoured of the antique by having copied several works of that class, he resolved to cultivate his taste by visiting the most important Greek works preserved at Rome; and therefore travelled to that city, where he resided some time, and thence drew an ample stock of materials for his future progress in the art he professed.

He lived principally at Antwerp, where he painted the history of Japhet; but as he was engaged in a variety of studies, his pictures are rare. Among other things he investigated coins and medals, and published a collection of them with critical annotations. He died at the age of 63.

GOLTSZENUS, HENRY, an artist of considerable talent, who practised both painting and engraving. As a painter, he drew his resources from the study of the antique, of Raphael, Phidias, and Michael Angelo; the last of whom appears to have been his favourite Apollo in the art, but while whole structures he exaggerated in an outrageous manner, seldom attaining any of his beauties. Hence his style of design is inharmonious and caricature; and his expressions partake of the same taste; but his sense of hue in colour is rich, vigorous, and transparent. He died in 1617, aged 59.

GOLUBERIK, in Geography, a town of Prussia, in the territory of Culin; 24 miles S.E. of Culin.

GOLUBENSIA, a town of Ruffia, in the country of the Coiffacks, on the Don; 200 miles E.N.E. of Azoph.

GOMAHNY, a town of Hindostan, in the circuit of Murghange; 45 miles N.W. of Harriopour.—Also, a town of Bengal; 8 miles S.S.E. of Goragot.

GOMAR, FRANCIS, in Biography, celebrated as the great opponent of Arminius, and from whom the Calvinistic party in Holland received the name of "Gomarists," was born about the year 1563 at Bruges. His parents had been brought up in the Roman Catholic religion, but having embraced the Protestant doctrines, they retired into the province of Limburg in 1578, for the sake of professing their principles in peace and security. Their son Francis was sent to Straf惊喜 for his education, and pursued his studies there under the celebrated John Secundus, after which he went to New-Radt, where the professors of Heidelberg had been obliged to retire by the elector Lewis, because they were the opponents of the Lutheran faith. In 1582 he took a journey to England, and attended the divinity lectures at the universities of Oxford and Cambridge. He was admitted to the degree of B.D. in the year 1584. By great affluence he became very deeply learned in the Greek and Hebrew languages, and in 1587 he settled with a Dutch congregation at Frankfurt, and continued to discharge his ministerial functions, in that connection, until the year 1591, when his flock was entirely dispersed by persecution. In the following year he was invited to accept the theological professorship at Leyden, and having taken his degree of D.D. he entered upon the duties of his new station. In 1603 Arminius was appointed his colleague, and openly and zealously opposed the gloomy doctrines maintained by John Calvin, and made many converts in the university. This roused the attention of Gomar, who declared himself his opponent, disputed with him in the schools of Leyden, and published treatises to excite the orthodox to make a firm stand against his doctrines, which he represented to be profane and impious; he went much farther, and endeavoured to provoke against him the indignation of the States of Holland, before whom the two combatants disputed twice in the year 1608. On one occasion, when Barneveldt exclaimed that he was grateful to God that their controversies did not affect the fundamental articles of the Christian religion, Gomar protested "that he could not appear before the throne of God with Arminius's errors," thus vainly setting limits to the mercy of the most high and most merciful God. In 1611, seeing that his opponents increased in numbers and in strength, Gomar resigned his office, and retired to Middleburg. After this, he accepted the professorship of divinity, first at the academy of Saumur, and then at the university of Groningen, and at the latter place he was employed as the Hebrew professor, in addition to that of theology. He was present at the synod of Dort, and took an active part in procuring the infamous decrees by which the Arminians were condemned and proscribed as corrupters of the true faith, and enemies to their country. He died at Groningen in 1641, leaving a distinguished character for sound learning, particularly in the Oriental languages, but it cannot, and it ought not to be concealed, that he disgraced the character of a Christian minister by his bigotry and intolerance. As an author, he published many treatises, but chiefly on controversial subjects, which were collected and printed at Amsterdam, in the year 1645. He was also concerned in revising the translation of the Old Testament, printed at Leyden, with notes in the year 1637. Moreri. Bayle.

GOMASTAHPOUR, in Geography, a town of Bengal, 42 miles N.W. of Nattore.

GOMAUN, or KEMISOON, the name of mountains of Afa, called also thosc of Sewalics; an extensive ridge, which seems to form the exterior barrier of the Thibetan Alps in Sirinagur, &c.

GOMBAULID, JOHN OGER DE, in Biography, a French poet of the seventeenth century, was the younger son of a gentleman of the Protestant religion, to which he adhered. He was educated at Bourdeaux, and came to Paris about the time of the death of Henry IV., and frequented the court of Mary de Medicis. Of her he obtained a pension of 1200 crowns, which was but ill-paid, and which was soon reduced nominally to one-third of that sum; so that, notwithstanding his high patrons, he passed much of his life in a state little above indigence. He was elected one of the first members of the French Academy, and was so extremely zealous for its great object, the purity of the language, that he once proposed to the academicians that they should bind themselves by oath to use no words but such as were approved by the majority of the society. He lived to a good old age, and died in 1666. He was author of many tragedies, tragi-comedies, pastoral and romances, sonnets, epigrams, &c. He also engaged in theological controversy, and wrote "Treatises and Letters concerning Religion," in favour of the Protestants. Gombauld was very ready at repartee, and his wit did not leave him even in old age, for his latest publication was a collection of epigrams. Moreri. Bayle.

GOMBERT, NICOLAS, a disciple of Jufquin, who published two books of motets for many voices in 1552. He set to music a Latin epitaph on his master Juf-quin;
and at this time composers being scarce, he gained some reputation among those of Flanders, with very little genius. For after performing the tedious task of scoring the music of the Anna at Julquin, we found its chief merit to consist in imitations of its admirable master. This composition was in the third ecclesiastical mode of E, with a minor second, as well as third; which M. Blainville some years afterwards paid to the public for a third or new key, different from the major and minor, which comprise all secular music at present. And it is extraordinary, that this pretension should have had any abettors in a Roman Catholic country, where old compositions in this mode are daily performed in cathedrals and collegiate churches. However, it was a matter of wonder and debate, during some time, in France. See Mercure de France, 1751, and Dict. de Mus, par Rouillé, art. Mode.

GOMBERVILLE, MARIN LE ROI, SIEUR DE, a man of letters, was born at Cherveure, in the diocese of Paris. He became distinguished at the age of fourteen by a collection of quatrains in honour of old age. In 1635 he was so much distinguished for a literary reputation, that he was of the number enrolled by cardinal Richelieu for the purpose of founding the French Academy, He had published romances and works of a light nature, of which he afterwards seemed to be ashamed, for at the age of forty-five he formed the resolution of confecrating his pen to religion. He even adopted a penitentary course of life, and is mentioned by some of his contemporaries as having joined the Christian virtues to those of morality. He died in 1674, leaving behind him many works, of which perhaps the best is a "Discours sur les Vertus et les Vices de l'Histoire et de la Maniere de bien écrire." This is deemed a fallen and very judicious performance. Moreiri.

GOMBESY, in Geography, a town of Africa, in Botonga, on the Zaanbeze S. lat. 13°. E. long. 36°.

GOMBESZALE, a town of Peria, in the province of Fariñata; 100 miles N.N.W. of Schiras.

GOMBIN, GABIN, or GABIS, a town of Poland, in the duchy of Warfaw, situated on the river Buira; 34 miles N.E. of Rawas.

GOMBRON. See GAMBRON.

GOMER, in Scripture History, the son of Japheth (Gen. x. 2.), and, according to Josephus, father to the people of Galatia. The ancient inhabitants of that country were called Gomares before the Galatians fixed possession of it. The Chaldees place Gomer in Africa; Bocchart in Phrygia, but the Phrygians, in Greece, have the same figuration (a coal) as Gomer, in Hebrew and Syrian. Others are of opinion that the ancient Chimri, or Cummerians, sprung from Gomer, and probably from them the Welsh, called Cymri. It is not improbable, that Gomer, or the Gomerites, his descendants, peopled likewise Germany and Gaul; the name German not differing much from Gomeron. Chavier (Germ. Antig. i. c. 6.) conjecturing that the ancient Celta comprehended Illyria, Germany, Gaul, Spain, and the British isles, as all these people successively spoke the same language; further supposes, that Gomer, or his family, peopled the countries in Asia, between the Parainius and Mount Imaus, and between the confines of the Oxus and Oby; whence these people are called Gomares by Poleni (l. vi. c. 17.) and Mela (l. i. c. 2.).

GOMER, or GOMER, an Hebrew measur. See CORUS.

GOMERA, or VELES DE PEISON, in Geography, a caille of Africa, in the country of Fez, built on a rock near the coast of the Mediterranean. Before this fortress there was an ancient city, called "Belis," supposéd to have been founded by the Cartagilians. The Arabs called it Bris and Velis, whence Veles. These two places, surrounded by mountains and forests, were supported by the building of ships for fishing and piracy, before they were taken by the Spaniards.

ALTO, a river of Fez, which runs into the straits of Gibraltar, near the above-mentioned fortresses.

GOMERA, or GOMERA, one of the Canary islands, about 20 miles long and 10 broad, having a capital of the same name, situated on the coast, with a good harbour. The island is fertile and well cultivated, and produces sugar-canes and vines in abundance, as well as silk, together with sufficient corn for the supply of the inhabitants, who amount to about 7000; 18 miles S.W. of Teneriffe. N. lat. 28° 6'. W. long. 17° 37'.

GOMETRA, one of the western islands of Scotland. This is a small island at the west end of Ulva, tolerably fertile, but without wood.

GOMEZ DE CIUDAD REAL, ALVAREZ, in Biography, a modern Latin poet, was born in 1858 at Guadalupe in Spain. He was page of honour to archduke Charles, afterwards emperor. As an author, who entitles him to a place in this work, he possessed a great facility in writing Latin verse, which is seen by his "Thalia Christiana," or the triumph of Jesus Christ, in twenty-five books: "Muta Paulina," or the epitaphs of St. Paul, in elegiac verse: the Proverbs of Solomon, and other works of a similar kind. His work on the order of the Golden Fleece, entitled "De Principis Burgundi Militia quan Vellera aurei vocant," is reckoned his master-piece. The subject which he chose in this instance was more favourable to poetry than the others.

GOMEZ DE CASTRO, ALVAREZ, a native of St. Enalha, near Toledo, was educated at Alcala, where he obtained a high character for diligence and zeal in learning. He was patronized by Philip III., who engaged him to prepare an edition of the works of Idorie, which death prevented him from completing. He was author of many works; but the chief, and that which is most esteemed, is a "Life of Cardinal Ximenes," infcrcted in a collection of the writers on Spanish history. Gomez died in 1580, at the age of 65. Moreri.

GOMEZ, SEBASTIANO, a Malatla slave of the Spanish painter Murillo, who employed his leisure hours in painting, and obtained considerable success. The city of Seville is, or was, adorned with many of his works; the most conspicuous among them were a "Madonna with the Infant," in the portico of Leof. Mercenarios Defchalos, and the "Flagellation of Christ," at the Capuchins. It is not known at what period he died; but he is said to have survived his master, whose decease happened in the year 1685.

GOMGAIHI, in Geography, a town of Hindoostan, in the circuit of Surgoga; 22 miles S.W. of Surgoga.

GOMI, a town of the province of Gueric, on the Black sea.

GOMMERN, a town of Saxony, on the Elbe; 8 miles E. of Magdeburg.

GOMNALPAR, a town of Hindoostan, in the circuit of Guntur; 8 miles E. of Innacanca.
GOMORA, a small island in the East Indian sea, near the west coast of Oby. S. lat. 1° 52'. E. long. 128°.

GOMORRAH, in Ancient Geography, a town of Palestine, and one of the principal cities of the Pentapolis, confused by fire from heaven. It was probably the most northern of the five cities. Gen. xix. 24.

GOMOZIA, or GOMEZIA, in Botany. See NERTERIA.

Gen. Ch. Cal. Perianth inferior, of five lanceolate, sharpish, ribbed, coloured, deciduous leaves, two of which have a membranous margin at each side, one on one side only, and two are defective of any. Cor. Petals five, spreading, longer than the calyx, rather unequal; the claws are shorter than the calyx, each gradually widening into a roundish, flat, entire border. Stam. Filaments ten, very short, thick and angular; anthers erect, shorter than the calyx, square, tapering upwards, bearded at the top, on the outside, by two pores. Pei. Germin placed on a short flabby angular receptacle, with five angles and five divisions; style longer than the flabbes, marked with five furrows; stigma acute. Peric. Drupes from one to five, most generally two, ovate, obliquely attenuated at the base, somewhat compressed, obtuse, erect, flabbling on a very large globular receptacle, which is undivided, if the berry be solitary, lobed if there be more, one lobe being appropriated to each berry. Seeds solitary, ovate.

Vahl and Swartz describe five species, all trees, natives of tropical climates. The chief and original one is G. Jabotopita, (Ochsa: Jabotopita. Linn. Sp. Pl. 732. Jabotopita pyramido foetra luteo, fructu rubro; Plum. t. 147. t. 153.) This is a native of South America, flowering in December and January. The wood is soft and tough. Leaves simple, as in the whole genus, alternate, thick, ovate, acute, ferrated. Flowers in terminal clusters, yellow, fragrant, compared by Markgrace to those of a Wall-flower in figure, or rather colour, but he says their scent is sweeter. The fruit and its receptacle are black, juicy, aromatic.

This genus is certainly very nearly related to Ochsa, both in habit and character.

GOMPHELIS, from γομπήλα, a nail, a disorder of the teeth, in which they become loose and painful. The connection of the derivative with the Greek is imputable to the circumference of the teeth being fixed in their sockets, like nails in a piece of wood.

Gen. Ch. Cal. Perianth inferior, small, in five acute, permanent segments. Cor. of one petal, regular, in five deep, reflexed segments, deciduous. Nectary of five hooded leaves, simple within, confined with a tooth at each side, placed on the top of the united filaments. Stam. Filaments five, coherent; anthers of two cells, terminated by a membrane, and producing two compressed masses of pollen, which attach themselves by a taper point to the stigma, and remain pendulous there. Pei. Germin two, superior, ovate, fleshy two, very short, standing close together; stigma common to the two, dilated, horizontal, flat, with five angles to receive the masses of pollen. Peric. Follicles two, inflated, ovate, pointed, clothed with soft spines. Receptacles membranous, longitudinal, linear, at length separate. Seeds numerous, imbricated, prismatic, crowned with silky down.

This genus is separated from Aplepis by Mr. Brown, (whole effay on the whole order, and whose discovery of the node in which the pollen is projected by the anthers upon the stigma, do him the highest honours,) on account of the inflated prickly fruit, and the angular horns which in Aplepis grow out from the bottom of the nectaries. It consists of Aplepis arborea, Linn. Mant. 215; suhrotis, Linn. Sp. Pl. 315; and setif, Vald. Synb. v. 1. t. 82; and, as Mr. Brown infers, of cripia, Linn. Mant. 215. Suppl. 170. A. pufite, Linn. Mant. 215; is, as he judiciously observes, on the authority of the late excellent Mr. Dryander, borrowed from the Linnaean herbarium, the same plant as arborea, with a synonym from Phikeot (t. 139. t. 11.) and Morison, which is presumed to be cripta.

GOMPHELLOLISM, so named by the writer of the present article, from γομπήλα, a nail, club, or anything swelling upwards from a narrow base, and γομπήλα, a pod, or legume, expressive of its tumid fruit. Sm. Tr. of Linn. Soc. v. 4. 220. Ann. of Bot. v. i. 505.—Clas. and order, Dendrosia Moneypug. Nat. Ord. Papilionaces. Linn. Leguminosae, Jaff.

Gen. Ch. Cal. Perianth inferior, of one leaf, coriaceous, short, bell-shaped, in five deep, oblong, pointed, unequal segments. Cor. papilionaceous. Standard very large, inferrly heart-shaped, carinated at the back, recurved, with a short claw. Wings shorter than the standard, parallel, horizontal, with a prominent lobe on one side near the base. Keel the length of the wings, of two half-ovate, tumid, clawed petals, with a revolved tooth at the upper edge of each. Stam. Filaments ten, concaved in the keel, and turned inwards, united, unequal in length; anthers vertical, roundish, two-lobed. Pei. Germin filiform, oblong, somewhat cylindrical; style awl-shaped, ascendent, as long as the flabbes; stigma simple, acute. Peric. Legume on a stalk, nearly globular, inflated, of one cell, crowned with the style. Seeds several, roundish, ranged along the upper future on short stalks.

Five species of this genus are defined in the Transactions of the Linnean Society, v. 9. 249. G. grandiflorus, Exot. Bot. t. 5. = J. tubuliflorum, (Jumbretiu; Exot. Bot. t. 58.) J. tubuliflorum, a species communicated by Mr. Menzies: minus, very near the last, except in the acute recurved points of the leaves: and pinatum, a small species from Port Jackson, remarkable for its pinnate leaves, and zigzag herbaceous form. Probably the subliterate volume of Mr. Brown's Prodromum will add more to this number.

The habit of Gomphelellis is marked by the compound (terinate or pinnate) leaves, and a certain aspect of rigidity and smoothness. The stipules are not intralocular as in Potter.
GOMPHOSIS, in Anatomy, from γομμα, a nail, denotes the manner in which the fangs of the teeth are fixed in their sockets.

Gen. Ch. reformed. Cal. Perianth inferior, coloured, membranous, permanent, double; the outer two large, compressed, keeled leaves, cohering by their inner margins, and one smaller; inner in five deep, awl-shaped, upright, downy segments. Cor. of one petal, tubular, cilindric, the length of the inner calyx; its margin equally five-cleft, spreading. Stam. Filaments five, very short, inserted into the orifice of the corolla, betwixt its segments; anthers erect, roundish, closing the mouth of the corolla. Pilt. Gernate ovate, pointed, superior; Hyles short, cohering at their bottom part; stipules simple, obtuse, scarcely reaching to the flaments. Peric. Capsule roundish, membranous, of one cell, bursting all round. Seed solitary, large, roundish, with an oblique point.

Eff. Ch. Calyx coloured, the outer of three unequal bands, inner in five deep segments. Corolla cylindrical, five-toothed, bearing the flaments at its orifice. Capsule bursting all round. Seed solitary.

The species of Gomphrena come under the denomination of Everlillas, or Amaranths, on account of the permanent nature of their calyx when dried, which retains its original colour and splendour.

G. globosa, Globe Amaranth, a native of India, is commonly raised on a hot-bed, and planted out in our borders, like other tropical annuals. It is also frequently kept in pots to decorate the flower or greenhouse. The original crimson form is much more handsome than the paler variegated variety.

G. prenus, figured in Dill. Hort. Elth. t. 20, a native of Buenos Ayres, is scarcely cultivated but in curious gardens, having small heads of yellowish flowers of no remarkable beauty.

There are eight species besides in Willdenow, of which the arborensis, Linn. Suppl. 173, is by far the most remarkable. This was not sent to Linnaeus by Mutis from New Granada, as erroneously affiated by the younger Linnaeus in the Supplementum, but by Vandelli, who received it from Brazil, and who has described it under the name of Dracaena, in his Fita. Plant p. 6. The stem is woody, round, leafy, clothed with rigid, prominent, brown hairs, as are also the leaves, which are opposite, ovate, ovate-oblong, entire, about three inches long, and half as broad. Heads terminal, solitary, the size of an African Carigold or Tagetes, pale red or whitish, composed of innumerable flowers, the segments of whose calyces are above an inch long, linear, acute and cataphyll, clothed in their lower part with long dense silky hairs. We know of no figure of this fine plant.

Mr. Brown, Prodr. Fl. Nov. Holl. v. 1. 416, adds four new species to Gomphrena, while he removes from it the begonias and veronicatc, which, with two new ones from the tropical part of New Holland, he forms into a new genus, Phlox. He considers what we term corolla in Gomphrena, as the tube of the united filaments.

Gomphrena, in Gardening, contains a plant of the flowery annual kind, of which the species cultivated is, the annual globe amaranth (G. globosa.)

It is a fine flowering plant, the heads of which at their first appearance are globular, but as they increase in size become oval, and, according to Martyn, the flowering heads are extremely beautiful, and, if gathered before they are too far advanced, retain their beauty several years.

There are varieties with fine bright purple heads, with white or silvery heads, which never alter from seeds, with mixed colours, with purple and with white head, which last are much smaller and rounder than the others; the plants also grow much larger and spread more into branches, and are later before they flower; these are called batclor's buttons in America.

Method of Culture.—It may be increased by sowing the seeds annually, in pots of light fresh mould, in the early spring months, and plunging them in the bark hot-bed. When the plants are up, they should be watered often with care; and, after they have attained some growth, be removed with balls about their roots into other pots, and replunged in the hot-bed. When they have had some growth in this situation, they should be removed into a deep frame, being placed in a fresh hot-bed, to bring them up tall and handsome. Afterwards they should often be refreshed with water, and have air admitted freely as the summer advances, till they are capable of bearing it without injury; when about Angust they may be set out during the day-time, being protected in the night, and from wet weather. At this period they should be watered three or four times a week at least, in a rather sparing manner.

They afford a good effect when set out in the principal situations about the house, in assemblage with other plants of the potted kinds.

GOMRAPENDY, in Geography, a town of Hindoostan, in the Carnatic; 25 miles N. of Madras.

GOMS, one of the seven independent dixains or commonwealths of the Upper Vallaus, in Switzerland, called dixain, because the Upper and Lower Vallaus comprehend 10 districts, each being a dixain or tenth of the whole. Goms is situated at the foot of mount Grison, and extends along the bank of the Rhone; and is from called from a town, 33 miles E. of Sion. See Vallaus.

GOMUT, a river of Bengal, which runs into the Magna, near Chandipour.

GOMUT PEPERS, a town of Hindoostan, in Doowatobad; six miles N. of Amedanagar.

GOMUTTRA SPALGITA, in Natural History, the name given by the Indians to a kind of foulfl, found in great plenty on the mount Vindy in the East Indies, in places, as they observe, where the cows frequently urinate. It is a bituminous substance, and after calcination the residuum is given in cases of internal ulcers and in gonorrhæas. The Indians suppos'd it formed by the drying up of the cow's urine.

GONAGRA, composed of γονας, knee, and γάρ, i.e., capturis, sitting in Medicine, the gout in the knee. See Gout.

GONAM.
GONAMBOUCH, in Ornithology. See Emberiza Gêrtha.

GONANPILLY, in Geography, a town of Hindoostan, in the coser of Ellore; 18 miles N. E. of Ellore.

GONAP, one of the smaller Banda islands, in the centre of which is a volcano. The only inhabitants are wild hogs, cows and serpents. S. lat. 4° 10'. E. long. 130° 34'.

GONARCHA, a term in the ancient dialling. Mr. Perrault, in his notes on Vitruvius, lib. ix. cap. 9, takes the gomarcha to have been a dial drawn on divers surfaces or planes; some of which being horizontal, others vertical, oblique, &c. formed divers angles.

Whence the appellation, from γον, knee, or γονα, angle.

GONARY, in Geography, a town of Hindoostan, in the Pylus; 12 miles S. of Rydroog.

GONAVE, LA, an island situated on the west side of St. Domingo, about 14° leagues in length, and about three in breadth. This is called Grand Gonave by way of distinction from Petit Gonave, another small island about two miles in each direction, separated from the S.E. corner of the former, by a channel three miles wide. Gonave is 13° 3 leagues W. by N. W. from Port au Prince. N. lat. 18° 51'. W. long. 73° 40'. See St. Domingo.

GONAVES, a sea-port in the above-mentioned island, at the head of a bay of its own name, on the S. side of a bay of Leogane. The harbour is excellent; the town has a medicinal spring, and in 1772 both were erected with lodging-houses for the accommodation of those who return to it, and an hospital for soldiers and sailors. It lies on the great road from Port de Paix to St. Mark, 16 leagues S.E. of the former. N. lat. 19° 22'. W. long. 73° 20'.

GONCANAAMA, a town of S. America, in the diocese of Quito 80 miles S. W. of Loxa.

GONCELIN, a town of France, in the department of the Loire, and chief place of a canton, in the district of Grenoble; 13 miles N. N.W. of Grenoble. The place contains 1558, and the canton 10,259 inhabitants, on a territory of 1074 kilometres, in 14 communes.

GONDAR, the metropolis of Abyssinia, is situated upon a hill, elevated 840 feet above the ocean, and consists of about 10,000 families in times of peace. The houses are chiefly constructed with clay, and the roofs are thatched in a conical form, which is the mode of building within the tropical rains. On the west end of the town is the king's houle, formerly a structure of considerable importance; it was a square edifice, flanked with square towers; formerly four stories high, and the top of it afforded a magnificent view of the whole country S. of the lake Tzama. Although the greatest part has been burnt at different times, there is ample lodging in the two lowest floors of it; the audience chambers being above 120 feet long. Annexed to this ruined palace are apartments, constructed by succeeding kings, also of clay, according to the fashion of their own country; for the palace itself, says Bruce (Travels, vol. iii.) was built by masons from India in the time of Facidias, and by such Abyssinians as had been instructed in architecture by the Jesuits, without embracing their religion, and afterwards remained in the country, unconnected with the expedition of the Portuguese, during this prince's reign. The palace and its contiguous buildings are surrounded by a stone wall, 30 feet high, with battlements upon the outer wall, and a parapet roof between the outer and inner, by which you may pass along the whole and have a view of the street. There never appear to have been any embrasures for cannon; the four sides of this wall are above 13 English mile in length. The mountain, on which the town is situated, is encircled on every side by a deep valley, which has three outlets; the one to the south, to Dembëa, Mainfâw, and the Agows, the second to the N.W., towards Sennar over the high mountain Debra Tzai, or the mountain of the Sun, at the foot of which Kofame, the palace of the Iteghé, is situated, as are also the low countries of Walkayt and Walduba; the third is to the N. to Woggora, over the high mountain Lamalmon, and on through Tigré to the Red sea. The river Kaha, coming from the mountain of the Sun, runs through the valley, and covers all the foot of the town; the Angrah, flowing from Woggora, surrounds it on the N.N.E.; these rivers join at the bottom of the hill, about a quarter of a mile S. of the town. On an eminence opposite to Gondar, on the other side of the river, is a large town of Mahometans, consisting of about 1000 houses. They are all active and laborious, and are employed in taking care of the baggage, and field-equipment of the king and nobility, when they take the field and return from it; but they never fight on either side. N. lat. 12° 34'. E. long. 37° 33'.

GONDEBAUD, in Biography, third king of the Burgundians, celebrated as a legislator among the barbarians over whom he reigned as sovereign. He obtained the crown in 491, and almost immediately, under pretence of afflicting Odoacer against Theudoric, entered Italy, carrying fire and sword through Æmilia and Liguria, and made a great number of captives, many of whom he liberated without ransom, at the request of Epiphanius bishop of Pavia. He assembled, in 499, a council at Lyons, in order to effect a reconciliation between the Catholics and Arians. He was himself an Arian, from habit and education; but he was unable to effect so laudable a purpose. About this time he was attacked and defeated by Clovis king of the Franks; who made the Burgundian monarch his tributary. Clovis returned to his own country, and Gondebaud revenge himself upon his brother Godegelf, who had joined Clovis, surpried him, and put him to death. From this period he reigned in peace over his people, whom he rendered flourishing by the arts of civilization, and by a regular system of laws. Thence, says the historian, were in general founded on equity, and display much sagacity in preventing all causes of dispute; nevertheless, they enjoin the barbarism of judicial combats, which the legislator justified as an inference from the admitted doctrine of the interference of a particular providence in human affairs. The Burgundian code, called "La loi Gombertette," has been published in several collections of ancient laws. This prince died in 516, leaving behind him, as memorials, letters upon theological subjects to Avitus, bishop of Vienne. Univer. Hist.

GONDICOTTA, or Gondlaomma, in Geography, a river of Hindoostan, which forms the nominal boundary of the Carnatic, and discharges itself into the sea at Medipelly, Combam, or Commun, is near its source. It is sometimes called Gillaugama, and Gunta-camma.

GONICOTTA, a town of Hindoostan, in Marawar, 33 miles N. of Trumian.

GONDOLA, a little flat boat, very long and narrow, chiefly used at Venice to row on the canals.

The word is Italian, gondola. Du Cange derives it from the vulgar Greek γόνδολη, a bark, or little flòs; Lancelot deduces it from γόνη, a term in Athenaeus for a sort of vase. The middle-sized gondolas are upwards of thirty feet long, and four broad, they always terminate at each end in a very sharp point, which is raised perpendicularly to the full height of a man.
The address of the Venetian gondoliers, in paffing along their narrow canals, is very remarkable: there are usually two to each gondola, and they row by pulling before them. The fore-man holds his oar on the left side of the gondola: the hind-man is placed on the stem, that he may fix the head over the till or covering of the gondola, and holds his oar, which is very long, on the right side of the gondola.

GONDOLA is also the name of a passage-boat of six or eight oars, used in other parts of the coast of Italy.

GONDOLIÆ, in Natural History, a name given by authors to a peculiar kind of **concha ____** (supposed, in some degree, to represent the shape of a Venetian boat. It is of the genus of the **dolium**, and there are seven species of it. See DOLIUM and CONCHOLEY.

GONDOMAR, in Geography, a town of Spain, in Galicia; 6 miles E. of Bayona.

GONDRECOURT, a town of France, in the department of the Meuse, and chief place of a canton, in the district of Commercy. The place contains 1113, and the canton 8773 inhabitants, on a territory of 340° kilometres, in 24 communes.

GONDUFEE, a town of Africa, in the kingdom of Kongo; 150 miles S.E. of Kongo.

GONDWARAH, a town of Bengal; 15 miles S.S.W. of Purnea.

GONESE, a town of France, in the department of the Seine and Oise, and chief place of a canton, in the district of Pontoise, nine miles N. of Paris. The place contains 2400, and the canton 14,811 inhabitants, on a territory of 1821 square kilometres, in 22 communes.

GONET, John Baptist, in Biography, was born at Bziers in the year 1616. He embraced the ecclesiastical life when he was young, and was admitted to the degree of doctor of divinity by the university of Bourdeaux in the year 1642. He was at the same time elected to the professorship of theology in that university, an office which he held with great dignity till the year 1671, when he was appointed provincial among the Dominican friars. In 1675 he refuted his labours as professor, which he continued about two years, and then retired to his native place, where he died in 1681. He was author of a voluminous work, entitled **"Clyperna Theologia Thomistica, contra novos ejus impugnatores"**, first published at Bourdeaux in 1666, in eighteen volumes 12mo., but it was afterwards enlarged, and printed in five volumes folio. He was likewise author of a **"Manuale Thomilariun, seu brevis Theologiae Cursius,"** which has passed through different editions, of which the best was published at Lyons in 1681: and **"Difficiliora Theologiae de Probabilitate."** Moreci.

GONFALON, or GONFAXON, a kind of round taut, borne as a canopy, at the head of the proceffions of the principal churches at Rome, in cafe of rain; its verge or banner serving for a shelter, where there is not a great deal of attendance.

GONG, a Chinese metallic musical instrument of percussion, in the form of a flat basoon, with a ridge round it, and beaten by a mallet covered with several folds of woollen cloth. It is carried on a pole by two men, and beaten by the hindmost. In the march of an army, it is used as a military instrument to regulate the steps of the soldiers; when struck with great force, it is sufficiently loud to be heard at a mile’s distance; but so confused is the sound, that no distinct tone can be ascertained. Yet by reiterated gentle strokes on the same part of the bottom of the basoon a musical tone may be produced; but different parts of the circle produce tones of different gravity and accent.
lyrical, in which style he so much excelled, as to be termed by his countrymen "the prince of lyric poets." Gon
gora poësties, in the elimination of his countrymen, a very high rank among the Spanish poets for an artificial elevation of language, and uncommon turn of thought, which were formerly the characteristics of the poetry of that nation. So much, indeed, did he surpass in these qualities, that he had many cenfurers in his own country, though he also met with as many warm defenders. He is said to have enriched his native language by the introduction of many Latin words happily employed. Morei.

GONGRONA, in Surgery, a hard tumour; but especially a bronchocele, or swelling of the thyroid gland. The tree is said to be derived from γυνώς, a round tubercle on the trunk of a tree.

GONHARY, in Geography, a town of Hindooftan, in Ouade; 40 miles W. of Lucknow.

GONIA, a town of Asitie Turkey, in Natahia; 16 miles W. of Aphiom-Karnian.

GONIAH, or Konig, supposed to be the Conche of D'Anville, and the Gong or Delibe, a kingdom of Africa, situated to the N. of Guinea, between the meridian of Greenwich, and 5 W. long, and between the 19th and 20th degrees of N. lat. It is about 870 miles westward from Cadha or Kaffina, and between 530 and 620 miles from the Gold Coast. Some say, there is no communication between this coast and the country of Gonjah; the king of Af
tonio, who poësties the intervening space, prohibiting his inland neighbours from passing through his country. Others report, that other races (e. g. the Fonctes, and their confedera
tes) lie between Affentio and the sea; and that the Affen
tois have often unsuccessfully attempted to open a communi
cation with the coast.—Alfo, the name of a town, which is the capital of the kingdom of Gonjah or Kong. N. lat. 11° 30'. W. long. 30'.—Alfo, the name of part of a chain of mountains, extending from almost the mouth of the river Gambia, in the Atlantic, to Nigritia, towards Aby
finia.

GONIAH, a decayed town and large castle of Asitie Turkey, belonging to the province of Guriel, at the mouth of a river which runs into the Black Sea. It is garrisoned by a few Janifaries, and inhabited chiefly by Kamen; 80 miles E.N.E. of Treibfond. N. lat. 41° 25'. E. long. 41° 10'.

GONJENPILLY, a town of Hindooftan, in the Car
tatie; 18 miles N.E. of Nellore.

GONIACARPUS, in Botany, so called from γωνία, an angle, and καρπός, fruit, expressive of one of its essential characters. The name, originally contrived by Thunberg, was Goniacarpus, which being incorrectly con
tstructed, and too near Coniacarpus, was judiciously changed by Mr. Konig. Schreber, Wildenow, and others, have made it Gonocarpus, for want of attending to its meaning and application, which has no reference to γωνία, γωνίς, a knee, but to the very pe

Gen. Ch. Calyx Perianth superior, in four deep, acute, equal, upright segments. Cor. Petals four, equal, oblong, concave, inserted into the rim of the calyx, and twice as long as its teeth. Stam. Filaments four or eight, very short, inserted into the calyx, opposite to the petals if four, to the petals and calyx-teeth if eight; anthers oblong, large, shorter than the corolla. Pfl. Germin inferior, turbinate, with eight furrows and as many angles, crowned with the permanent calyx; style extremely short; stigma four, ob
tu, downy.

Three species of this inconspicuous though curious genus are at present known.

1. G. mieranthus. Thumb. Jap. 69. t. 15.—Leaves ovate, obtusely crenate, smooth, as well as the stem.—Gathered by Thunberg in Japan. Root fibrous, annual. Stems three or four inches high, ascending, quadrangular, smooth, leafy, simple below, panicled above. Leaves opposite, on short flanks, ovate, rather acute, half an inch long, bluntly crenate and cartilaginous in the margin, smooth on both sides, minute
ly dotted, furnished with a rib, but no veins; the upper ones gradually smaller and more entire. Stipulas none. Flowers very small, purplish, drooping, in several broader, lax, upright, spikes, forming a sort of panicle. The petals as well as calís
are sufficiently evident in Thunberg's own specimens before us. The fruit is no bigger than the smallest pin's head, and the portion scarcely larger than the tube. In consequence of these
peculiarities, it is not much esteemed by the Indians.

2. G. rotundifolius. —Leaves rounded, somewhat heart-shaped, obtusely crenate, smooth. Angles of the stem rough. Spikes in a compound panicle.—Gathered near Port Jackson, New South Wales, by John White, M.D.—We are by no means certain that this is more than a variety of the former, but its different country, much more rounded leaves, heart-shaped at the base, and the brilly angles of the stem, induce us to propice it as a species. Possibly the panic
ded spikes may be owing to the greater luxuriance of the fse
cimens. The fruitification appears precisely like that of the frill species.

3. G. feaber. Konig Ann. of Bot. v. 1. 547. t. 12. f. 6.—Leaves elliptic-lanceolate, sharply ferrated, briskly as well as the stem.—Gathered by Mr. David Nelson, in cultivated ground in the island of China, near Macao. This appears to differ from the two former very materially, being all over rough, with defrizzled bristles, and having longer and nar
rower sharply ferrated leaves. The flowers, moreover, have eight filaments, and the angles of the fruit are wavy or crifi
ced, not smooth and even.

We have a plant gathered by Dr. White, near Port Jack
fon, which seems to answer in every point to Mr. Konig's description and figure of the bulb, except that its petals have a brilly keel, and the figmas are singularly branched and plumose, making a large tuft in the centre of each flower after the petals are fallen. Perhaps Mr. Konig's fpecimens had lost all their figmas. We remark, however, a further difference in the fruit, whose alternate angles are left distinct, or rather more cresped and interrupted than the rest. Not having examined authentic fpecimens of G. feaber, we must leave this matter in doubt.—Possibly this may be G. tetrag

GONIOMETER, an instrument used for the purpose of measuring fold angles (particularly of crystals), or the inflexion which one plane surface makes with another. The small goniometers, as usually found at the shops, are of a con
struction to simple, as to require but little description. They generally consist of a small pair of compasses orippers, de
tined to receive the angle of the crystal; and the legs of these being continued in the opposite direction, beyond the angular point or joint, the angle is measured by applying them to a protractor or semicircular scale of degrees.

But notwithstanding much ingenuity has been bestowed on instruments constructed on this principle, none of them have
GONIOMETER.

Goniometer.

have been found nearly accurate enough for the purposes for which they are required, many interesting questions in the modern science of crystallography requiring a much more exact determination of the angle than can possibly be obtained by instruments of this construction.

We are indebted to Dr. Wollaston for having removed all these difficulties, by the invention of an instrument which accomplishes all that the most scrupulous naturalist can possibly desire. The principle of this invention is entirely optical, and (Plate XIX. Mijoflans, fig. 2.) represents the instrument as made and held by Mr. Carty, in the Strand; but the reader, when acquainted with the nature of it, will readily see that any person possessed of a graduated instrument, such as a theodolite, transit, &c. may, without great difficulty, apply it to the measurement of angles, though in a much less commodious manner than on an instrument made expressly for the purpose.

Dr. Wollaston’s method consists in employing a ray of light reflected from the surface, instead of the surface itself; and thus, for a radius of 15-inch, we may substitute either the distance of the eye from the crystal, which would naturally be twelve or fifteen inches, or for greater accuracy we may, by a second mode, substitute the distance of objects seen at a hundred yards or more from us. The instrument described by Dr. Wollaston, in the Transactions for 1829, consists of a circle, fig. 3, graduated on its edge, and mounted on an horizontal axle supported by an upright pillar. This axle, being perforated, admits the passage of a smaller axle through it, to which any crystal of moderate size may be attached by a piece of wax, with its edge, or intersection of the surfaces, horizontal and parallel to the axis of motion. This position of the crystal is first adjusted, so that by turning the smaller axle, each of the two surfaces, whose inclination is to be measured, will reflect the same light to the eye. The circle is then set to zero, or 180°, by an index attached to the pillar that supports it.

The small axle is then turned till the further surface reflects the light of the candle, or other definite object, to the eye; and lastly, (the eye being kept steadily in the same place,) the circle is turned by its larger axle, till the second surface reflects the same light. This second surface is thus ascertained to be in the same position as the former surface had been; the angle through which the circle has moved, is, in fact, the supplement to the inclination of the surfaces; but as the graduations on its margin are numbered accordingly in the inverted order, the angle is correctly shown by the index, without requiring any computation.

It may be here observed, that it is by no means necessary to have a clean uniform fracture for this application of the instrument to the cructure of laminated substances; for even all those small portions of a flattered surface that are parallel to one another, (though not in the same plane,) glinten at once with the same light, the angle of an irregular surface may be determined nearly as well as when the reflecting surfaces are actually in the same plane. In this method of taking the measure of an angle, when the eye and candle are only ten or twelve inches distant, a small error may arise from parallax, if the intersection of the planes or edge of the crystal be not accurately in a line with the axis of motion. But such an error may be rendered insensible, even in that mode of using the instrument, by due care in placing the crystal; and when the surfaces are sufficiently smooth to reflect a distinct image of objects, all errors from the same source may be entirely obviated by another mode of using it.

For this purpose, if the eye be brought within an inch of the reflecting surface, the reflected image of some distant chimney may be seen inverted beneath its true place, and, by turning the small axis, may be brought to correspond apparently with the bottom of the house, or some other distant horizontal line. In this position the surface consequently bicsets the angle which the height of that house subtends at the eye, or rather at the reflecting surface: then, by turning the whole circle and crystal together, the other surface, however small, may be brought exactly into the same position; and the angle of the surfaces may thus be measured, with a degree of precision that has not hitherto been expected in goniometry.

The accuracy, indeed, of this instrument is such, that a circle of moderate dimensions, with a vernier adapted to it, will probably afford corrections to many former observations. Dr. Wollaston has remarked one influence of a mistake that prevails, reflecting the common carbonate of lime, which he mentions, because this substance is very likely to be employed as a test of the correctness of such a goniometer, by any one who is not convinced of its accuracy, from a distinct conception of the principles of its construction.

The inclination of the surfaces of a primitive crystal of carbonate of lime, is stated with great appearance of precision to be 104. 28° 30′: a result deduced from the supposed position of its axis, at an angle of 45°, with each of the surfaces, and from other deducing circumstances of apparent harmony by simple ratios.

But however strong the presumption might be, that this angle, which by measurement approached to 45°, is actually so, it must nevertheless be, in fact, about 45° 20′; for the inclination of the surfaces to each other is found to be very nearly, if not accurately, 105°, as it was formerly determined to be by Huygens; and since the measure of the supficial angle, given by Sir Isaac Newton, corresponds with this determination of Huygens, his evidence may be considered as a further confirmation of the same result; for it may be presumed, that he would not adopt the measures of others without a careful examination.

Explanation of the Figure.

a b, Is the principal circle of the goniometer, graduated on its edge.

c c, The axe of the circle.

d, A milled head, by which the circle is turned.

e e, The small axe for turning the crystal, without moving the circle.

f, A milled head on the small axe.

g, A brass plate supported by the pillar, and graduated as a vernier to every five minutes.

h, The extremity of a small spring, by which the circle is turned at 180°, without the trouble of reading off.

i i and k k, Are two centres of motion, the one horizontal, the other vertical, for adjusting the position of a crystal, one turned by the handle l, the other by the milled head m.

The crystal being attached to a worm head at the point n, in the centre of all the motions, with one of its surfaces as nearly parallel as may be to the milled head m, is next rendered truly parallel to the axis, by turning the handle l till the reflected image of a horizontal line is seen to be truly horizontal. By means of the milled head f, the second surface is then brought into the position of the first, and if the reflected image from this surface is found not to be horizontal, it is rendered so by turning the milled head m, and since this motion is parallel to the first surface, it does not derange the preceding adjustment.
GONIMETRICAL LINES, derived from lines, angles, and angles, in Geometry, used for measuring or determining the quantity of angles. Such are lines, tangents, secants, versed lines, &c.

We have a paper by Mr. Jones, in the Philosophical Transactions, containing a commodious disposition of equations for exhibiting the relations of goniometric lines, from whence a multitude of curious theorems may be derived. See Phil. Trans. N. 483. sect. 26.

GONIUM, in Zoology, a genus of Vermes, characterized only by their very simple, flat, and angular form, and being invisible to the naked eye. The species at present known are few, amounting to no more than five in number; and for the existence of these we rely chiefly on the microscopical researches of Muller and Schrank, the former of whom describes four of these minute creatures with great accuracy in his "Zoologia Danica." They are mostly inhabitants of fresh or pure water, though some of them occur in flagrant water or in dung-hills.

Species.

POLYSPIERIUM. Orbicular, pellucid, with immemorable spherical molecules. Schrank.

Found in flagrant water; the colour greenish-yellow, and general appearance that of a thin membrane filled with immemorable lucid globules. Very common in the month of July.

PECTORALE. Quadrangular, pellucid, with sixteen spherical molecules. Müll. Goere, &c.

The molecules are oval and nearly of an equal size, their colour greenish, pellucid, and diffused in a quadrangular manner within the membrane, like diamonds in a ring; or rather, as Müllé compares them, to the jewels in the breast-plate of the high priest among the Jews, and reflecting light on both sides. Its progress is by an advancement alternately towards the right and left, at which time all the molecules are in motion, and assume their oval form, these molecules being round when the animal is in a quiescent state.

TRUNCATUM. Angles obtuse; posterior part arched. Müll.

This occurs in fresh or pure water, and is rarely met with; its size is rather considerable; the fore-part is a straight line, the sides forming therewith obtuse angles, the extremity of the sides being united by a curved line; the internal organs, perceptible to the eye by the assistance of the microscope, consist of a number of molecules of a dark green colour, and two vesicles of peculiar brightnes in the middle. Its motion is languid.

The projection of the body of the body in this species is placed in a right angle; the intestines green, with the larger vessels transparent.

PLANATUM. Quadrangular, opaque, with four cylindrical protruberances. Müll.

This species, according to Müller, appears under a light magnifier like a quadrangular membrane, plain on both sides, but, when a deeper lens is applied, resembles the figure of a botter, formed of three or four cylindrical pillows, flattened or fink in various places; this was the appearance it assumed when first examined; some days after all the sides were plain without convexity and decoluted, or divided into little squares by the interjunction of straight lines. It is found in puddles under dung-hills.

GONKEER, in Geography, a town of Chinefe Tartary. N. lat. 44° 50'. E. long. 117° 51'.

GONKOFEN, or Gankofen, a town of Bavaria; 14 miles E. of Landshut.

GONNA, a town of Hindooftan, in Lahore; 12 miles W. of Nungorete.

GONNI, or Gono, in Ancient Geography, a town of Greece, in the Peraeis; situated near Panonis, towards the strait where the Olympus and Offa approached each other.

GONOCONDLUM, a town of Greece, in Macedon, in the Peraeis.

GONOESSA, a town of Greece, in the Peloeponnesus.

In the time of Pausanias it belonged to the Sicyoniens.

Gen. Ch. Cal. Perianth inferior, of one leaf, in five deep, acute, spreading segments, permanent. Cor. of one petal, wheel-shaped, in five deep spreading segments. Nectary like a shield, crowning the stamens, lobed. Stam. Filaments five, thickish, united into a short tube; anthers burring transversely, terminated by a membrane, their malleus of pollen attached to the outer extremity, with respect to the cell, and covered by the stigma. P. Germanus two, ovate-oblong; filies two, very short, close together; stigma common to both, flatish and depressed, with five angles. Peric. Pouches inflated, or less angular or ribbed. Seeds numerous, imbricated, oblong, crowned with down.

This appears to be a numerous genus, properly separated from Cymosia, and consisting of climbing shrubs, with opposite broadish leaves, and flowers growing in umbels between the infection of the foot-stalks. They are natives of America, chiefly within the tropics. Examples of it are Cymosia matthewi, Linn. Nat. 54. Jacq. Amer. 87. t. 56, a hairy plant, with dark-purple blossoms; falsa, Linn. Sp. Pl. 316, figured in Dilh. Hort. Eth. 239. f. 256, likewise a downy species, with purplish-green flowers; and crispiflorum, Ait. Hort. Kew. v. 1. 302. Plum. 1c. t. 216. f. 1; as well as many others presumed to have the same generic characters, but which, according to Mr. Brown, require to be thoroughly examined, as does the whole genus. Michaux enumerates three species, natives of the warmer parts of North America, and which he calls G. macrophyllus, bifurtes, and levis.

GONON DESAIR, in Geography, a mountain on the E. side of the island of Java, famous for the quantity of pepper which its trees produce.

GONG, or GANAPHE, one of the group of Asiatic flies, called Banda, in which there is a remarkable volcano.

GONOR, a town of Hindooftan, in the circuit of Go-

GONORHYNCHUS, in Ichthyology, a species of Gyrinus, which feed.

GONORRHCEA, in Surgery, a disease in which a kind of matter, which is either actually put, or a fluid of very similar qualities, is discharged from the urethra of the male subject, and from the surfaces of the labia, nymphi, clitoris, and vagina of the female, attended with more or less heat, pain, and difficulty in making water. The discharge is infectious, and capable of communicating the complaint from one person to another, whenever it comes into
into contact with any of those surfaces, which are susceptible of contamination by it, and which, we believe, must be such as are naturally defined to secrete mucus. On the foregoing account, the disorder is almost always caught, or communicated, in the venereal connection, when one of the discharge of the diseased person is applied to the parts, which are liable to be infected in the healthy one. However, a gonorrhoea may be produced in any manner, which brings the infectious discharge into contact with the mouth of the urethra, the surfaces of the labia, &c. In the article Ophthalmry, we shall have occasion to notice a particular inflammation of the eyes, attended with a copious discharge of matter from beneath the eye-lids, which is represented, by surgical writers, as originating from the inadvertent application of gonorrhoeal matter to the eye-lids, the inner surfaces of which are well known to be mucous ones.

The Hunterian doctrines go so far as to assert, on the authority of experiments, that the poison of the lues venerea, and that of gonorrhoea, are in fact the same, though usually productive of opposite effects, by reason of the parts affected in a change, and those concerned in gonorrhoea having quite different structures. These things, if true, tend to prove, that the matter of a clap may under certain circumstances, impart the venereal discharge to the constitution. However, it should be understood, that the statement just now made can only refer to the gonorrhoea virulenta; for it is certain, that a simple discharge from the urethra, and a scalding sensation in making water, which would constitute a gonorrhoea, may be the consequence of any thing which produces mere irritation in the passage without the possibility of the venereal or common gonorrhoeal virus being at all concerned. Thus, a man may have a irritation, and begin the employment of bougies for its cure; their irritation may bring on a forens on the urethra, and excite a discharge. Here we have an instance of the complaint arising from the operation of no virus whatever; but altogether from the unequino, mechanical, irritation of the bougies. Doubtless, also, there are sometimes discharges both from the male and female parts of generation, which, when applied to other persons, are capable of bringing on certain kinds of gonorrhoea by the entire effect of their irritation. So were a man, with a gonorrhoea, excited by the irritation of bougies to have connection with a woman, there is no doubt that the latter would be very likely to become troubled with a discharge and scalding in making water, merely in consequence of the application of some of the matter from the male urethra to the surfaces of the labie, nymphae, &c.

The arguments which have been adduced to shew that the poison of one form of gonorrhoea, and that of the venereal disease are the same, will more properly come under consideration hereafter. In the meanwhile, it is our part to enter a little more particularly into the history of gonorrhoea.

The etymological meaning of gonorrhoea is a running of the semen, the term being derived from γόνον, signifying the seminal fluid, and γένεσις, to flow. The ancients are said to have entertained the very erroneous notion that the discharge consisted of an oozing of the semen in a morbid and altered state. As it is long since no absurd supposition has had any partisans, a refutation becomes superfluous, and every one now knows, that in the preface, as in many other examples, truth and etymology are not coupled together. Dr. Svedenius, who has found fault with the term gonorrhoea, as conveying an untrue idea, has not been happy in a substitute.

He remarks, that if a Greek name is to be retained, he would call the complaint blenorragia, from βλένω, mucus, and μετέχειν, to flow. Now this epithet is objectionable, on the identical principle which makes Dr. Svedenius wish for the relinquishment of gonorrhoea; for it is generally thought by all the most eminent modern surgeons, that the discharge is pus, and not mucus. Besides, we do not see much utility in abandoning the ancient appellation. The knowledge of surgery is now so highly cultivated, that there is not the least danger of any man imbuing an absurd opinion respecting this common complaint, from the etymological import of its name. Every juvenile apprentice knows that a clap is a running of matter from the urethra. Few common practitioners trouble themselves about Greek derivations; and where is the object of changing the name of one disease, while many hundred other surgical terms flound in equal, and often greater, need of alteration?

The first perceptible symptom of a gonorrhoea is generally a kind of itching about the orifice of the urethra, attended with a slight swelling of its edges, and sometimes extending over the whole of the glans penis. Very shortly afterwards the running commenceth, and the itching sensation changes into pain, which is severely felt at the time of making water. In some few instances, no considerable pain is experienced, till a long while after the access of the discharge and other symptoms. It is said that there are certain cases which are attended with no pain whatsoever, while other instances occur, in which patients suffer severely, even before the discharge makes its appearance.

When the inflammatory symptoms have come on, the penis seems swollen, and as if it were in a state of half-elevation. The glans appears red, smooth, and enlarged, with a kind of transparency about it. Sometimes it is affected with a slight excoriating, which makes it exceedingly tender, and is the source of some trivial quantity of matter. The canal of the urethra becomes narrower than natural, if we may form a judgment from the diminution which takes place in the diameter of urine. Indeed, very frequently, this fluid can only be discharged in a broken scattered current, or by drops. We have often seen severe retentions of urine attendant on the inflammatory stage of a gonorrhoea.

Small tumours may frequently be noticed along the inferior surface of the penis, in the course of the urethra. These swellings have been considered as the mucous gland of that canal in a swelled state. Sometimes they acquire a very large size, and ultimately suppurate and form abscesses, which, in some instances, burst externally, while, in others, they break into the urethra itself. In the latter event, the swelling all on a sudden subsides, as soon as the contained matter has escaped. Sometimes, after a certain interval, the tumour is seen to re-appear, which circumstance is said to be owing to a premature cloiture of the opening. Abscesses of the preceding kind are often met with in the situation of Cowper's glands. Here they also sometimes burst outwardly, sometimes inwardly, sometimes in both ways, in the same patient. In this last case a new passage is made for the urine, termed a fistula in perineum. See Fistula.

A painful sensation is frequently felt by the patient along the lower surface of the penis, extending as far as the anus, and depending on the inflamed state of the urethra. In most cases the erections are frequent, and generally productive of infinite pain, particularly when a forensis exilis along the track of the urethra towards the anus, or when the complaint is complicated with chordee. See Chordee.

The viscid transparent fluid which is naturally secreted by the glands of the urethra changes into a whitish aqueous liquor,
GONORRHEA.

Liquor, and the secretion which takes place from the lining of this canal, and is intended for its lubrication, also becomes less transparent. At length both these fluids, becoming thicker and thicker, gradually assume more and more the qualities of pus. The discharge often undergoes an alteration in its colour and consistence, a circumstance which Mr. Hunter imputed to the disposition of the parts by which the matter is formed. Sometimes it is white, sometimes yellow, sometimes of a greenish colour. Various species depend upon the diminution, or increase, of the inflammation, and not upon the poisonous quality of the matter; for the same appearances happen whenever the parts are irritated in a certain degree by any cause whatsoever, as several facts confirm. Dr. Swedaur injected into his urethra some caustic volatile alkali mixed with water, by way of experiment. The usual symptoms of a gonorrhœa ensued, together with a discharge which had the same appearances and alterations of colour, as the matter of the gonorrhœa virulentia. We have already stated that the same circumstances most frequently attend the employment of bougies.

In the generality of instances, the discharge does not proceed from any great extent of the urethra, not from more than an inch, or an inch and a half of that part of the passage, which is nearest the orifice in the glans penis. This distance was what Mr. Hunter used to name the specific extent of the inflammation. Before this celebrated surgeon flourished, it was commonly supposed, that the matter came from the whole of the urethra, and even from Cowper's glands, the prostatic, and the vesiculae seminales. Due attention to the symptoms, however, makes this idea seem quite improbable. If, for example, every part of the urethra, beyond the bulb, or if the bulb itself contributed to the discharge, the matter would be propelled out of the passage in the same manner as the semen, that is to say, by a sudden convulsive kind of action. It is well known that nothing can lodge in the bulb of the urethra, without immediately putting that part of the canal into action, particularly when in a state of irritation and inflammation. A drop of urine is not allowed to remain there, and if simple warm water be injected thus far, it is instantly forced out by the action of the acceleratores urinaris muscles. Therefore it seems rational to conclude, that if the membranous and bulbous parts of the urethra, Cowper's glands, the prostatic, and the vesiculae seminales, all had a share in forming the matter, no sooner would a certain quantity have collected in the bulb, than an immediate expulsion would be occasioned by the muscles of the part. No symptom of this kind, however, is usually observed, although it occasionally happens, that the acceleratores urinaris are affected with spasmatic contractions, which are particularly disposed to occur just after the patient has been making water, and do not seem to have any dependence on the discharge.

Mr. Hunter has taken notice that when the inflammation is violent, some of the vessels of the urethra often give way. Hence a hemorrhage arises, which is most profuse, just after the patient makes water, though it also continues at other times. Sometimes the blood is inconceivable in quantity, and only just sufficient to give a red colour to the matter. The emotions, which are so frequent in this complaint, are apt to occasion an extravasation of blood, a symptom which is always attended with an increase of the pain felt at the time of making water, but the bleeding always in the end lessens the inflammation, and tends to the relief of the part.

The inflammation, accompanying a gonorrhœa, is attended with several of the characters of common inflammation; but yet it differs also from the latter affection in many respects. It does not excite any pulvatory sensation; it causes little pain, except what arises from the irritation of the urine and the tension of the parts; and the inflammatory irritation seldom extends beyond the affected surfaces. The reason of so large a quantity of pus being secreted, in consequence of so moderate an inflammation, has been attributed to the parts being such as naturally secrete, so that they readily alter the natural into a morbid secretion.

Although the inflammation of a gonorrhœa is commonly moderate, there are instances in which it is exceedingly severe, and extends into the reticular texture of the surrounding corpus spongiosum urethra, particularly of that which is near the glans penis. Sometimes the inflammation advances further along the corpus spongiosum, and occasions a swelling, or extravasation of coagulating lymph, which is the cause of choree. We have already stated that the inflammation occasionally gives rise to abscesses of the glands of the urethra, particularly of those in the perineum.

It is not decidedly known in what manner the disease communicates itself to the urethra. Some suppose that the inflammation creeps from the glans penis to the edges of the orifice of the urethra, and thence further into the passage. These reasoners will not allow the probability of a common opinion, that some of the infectious matter gets into the urethra at the time of coition. At all events it seems clear, that none of the contaminating fluid can get as far as the diseaee extends in ordinary instances, much less in others, where the affection reaches a great way towards the bladder. There are some facts which tend to prove that the simple application of the infectious matter to the end of the penis may give rise to a gonorrhœa. A case related by Mr. Hunter in his treatise on the venereal disease, seems to confirm the truth of what we have mentioned.

As we have already observed, the complaint seldom extends further along the urethra, than about an inch and a half, or two inches. Mr. Hunter thought, that this part of the canal appeared to be most susceptible of the particular kind of inflammation brought on by the infection, and it constituted, what he used to term, the specific distance of the disorder. However, neither the fatigues of which the patient complains, nor the irritation of the parts, are confined to the real seat of the disease. The neighbouring parts are often affected with a variety of symptoms, of a nature more or less severe, such as uneasiness, and even pains every where about the pubes, scrotum, perineum, anus, and lips. It is often necessary to subdue the teaticles, which become so irritable, that the least accident, or exertion, which, in other circumstances, would have no effect, makes them swell. It frequently happens that the glands in the groin are sympathetically affected; they swell and inflame, though they do not commonly suppurate. Cysts also occur in which the irritation extends to the buttocks, thighs, and abdominal muscles, occasioning acute pain, swelling, and extreme forenoon of the parts, and putting the patient under the necessity of always continuing in an horizontal posture. These symptoms, however, are not strictly inflammatory; if the patient be bled, his blood does not exhibit the inflammatory crust, and the constitution is little or not at all affected.

When the case, independently of the affections arising from sympathy, is not more violent than what has been described, it is called a common gonorrhœa; but the violence of the effential symptoms of the disease will be more or less considerable, according as the patient is more or less susceptible of such complaints as depend upon irritation. Thus, in particular habits, the inflammation does not con-
GONORRHEA.

fine itself to the specific distance, but reaches all along the urethra. Severe pain is also frequently experienced in the perineum. Sometimes the accelerators urinæ muscles are affected with the spasm-like contractions, of which some mention has already been made. Such spasm is particularly apt to come on when the patient has just finished making water; it flows itself by the manner in which the last drops of urine are expelled; and it is generally attended with contractions of the erectile muscles. Sometimes the inflammation is so great as to occasion a swelling, and even an abscess in the cellular membrane. It has already been observed, that the most common situation of such suppuration is in Cowper’s glands; but the small glands of the bulb may also be affected in a similar manner, and the irritation, in certain instances, is found to extend even to the bladder itself.

When the latter organ is once affected, it becomes more susceptible of every kind of irritation, so that very distasteful complaints are apt to be produced. It is no longer capable of bearing the degree of dilatation of which it is capable in the healthy state. Hence the patient cannot hold his water in the usual way; but no sooner does the inclination to discharge it arise, than he is immediately compelled to make the evacuation, notwithstanding the severe pain, which, while the urine is escaping, is felt in the bladder, and especially about the glans penis. This pain has been compared with what is experienced in a fit of the stone, and it lasts for some time after the evacuation is completed.

The ureters, and even the kidneys, are sometimes sympathetically affected, when the bladder is considerably inflamed or irritated. Such an occurrence, however, is exceedingly uncommon. Mr. Hunter mentions his having seen an inflammation of the peritoneum brought on by a severe affection of the bladder in gonorrhoea; and others have observed a violent inflammation of the kidneys from the same cause. (See Encyclopædia Méthodique partie Chirurgicale, tom. 1. p. 584.) It has already been mentioned that a chordee is one of the occasional effects of a gonorrhœa. It arises in general from inflammation; but in some cases it appears to be entirely of a spasm-like nature.

When the inflammation is not confined to the urethra and its glands, but spreads further, it attacks the substance of the corpus spongiosum, where it occasions an extravasation of coagulating lymph, which, uniting the cells together, makes the urethra incapable of yielding and being filled with the same degree as the corpus cavernosum. Hence, during an erection, the penis becomes bent forward. The adhesion of the cells of the corpus spongiosum urethra together, which is the cause of chordee, in general, comes on in consequence of mere inflammation of the canal; but occasionally it is the effect of a species of inflammation, which is seen accompanying certain ill-conditioned chancres. A chordee often continues after all the other symptoms of a gonorrhœa have quite ceased.

A chordee is sometimes altogether spasmic, in which case it is seen to disappear and re-appear alternately, at indeterminate intervals. At one time the erections, which are so common in cases of gonorrhœa, happen without being attended with any curvature of the part; while at other periods the chordee takes place in a great degree; the intervals of time between these changes being sometimes remarkably short.

A swelling of the testicles is a frequent consequence of a gonorrhœa. It may happen in any stage of the disease; but, perhaps, it takes place most frequently when the complaint is on the decline. It was considered by Mr. Hunter as an affection arising from sympathy. It is seen attending any kind of irritation in the urethra, whether occasioned by injections, bougies, or any other circumstance. In many cases, the swelling comes on and disappears very suddenly, or seems to leave one testicle to attack the other.

The swelling of the testicle generally begins with a soft, pulpy tumefaction of its glandular part, which becomes rather painful when handled. The tumour afterwards increases in size and firmness, and produces considerable pain. The inflammation seldom ends in suppuration, though some instances of this kind are met with. The epididymis (especially its lower end) is usually the hardest part; but, frequently, the induration and swelling attack the whole of the epididymis, and form a sort of knot at its upper part. The spermatic chord also is often affected, especially the vas deferens, which is thickened, and exceedingly tender. Sometimes the veins of the testicles are varicose.

The inflammation of the testicle, as well as that of the urethra, is frequently attended with sympathetic symptoms of irritation in other parts; for instance, pain at the lower end of the spine, a sense of weakness in the loins, colic pains, nausæa, flatulence, disorder of the digestive organs, &c.

The swelling of the testicle is noticed to take place remarkably often just when the pain in the urethra has subsided, and the discharge has flopped; or else the truth is, that on the testicle becoming affected, the symptoms of irritation in the urethra immediately cease. Here it is somewhat difficult to determine which is the cause, and which the effect. However, it is worthy of remark, that it is not uncommon for the testicle to begin to swell at the very moment when the inflammation of the urethra, and the discharge, are becoming worse. Sometimes the epididymis alone is affected; sometimes only the vas deferens; and, on other occasions, only the spermatic chord. No reason can be assigned, why one of these parts should be affected rather than the rest. The inflammation of these organs is frequently attended with a strangury, especially when the discharge is suppured; and, indeed, it is remarked, that the flopping of the running generally brings on a tendency of that distressing complaint.

Another occasional effect of a gonorrhœa is a swelling of the lymphatic glands in the groin, a symptom, which is of the same nature as the inflammation of the testicle, but much more common. It has been supposed that the tumefaction of the glands depends on the absorption of some of the matter from the urethra; but Mr. Hunter contended against this opinion. He thought that, in gonorrhœa, the matter was seldom absorbed, and he derived this sentiment partly from seeing that a hue venerea was seldom the consequence of this disease. However, this argument will have no weight with those practitioners, who disbelieve in the doctrine that the poisons of gonorrhœa and the venerial disease are of the same nature. Another consideration, which influenced Mr. Hunter, will meet with more general approbation. It was the fact, that any simple mechanical irritation of irritable organs is capable of exciting an inflammation in theirabsorptions, and of the glands to which such excites run. Now, since the lymphatic and their glands usually inflame before suppuration has taken place in the part originally affected, and their inflammation often subsides as soon as this last occurrence begins, we must conclude, that the swelling of the inguinal glands, in gonorrhœa, arises altogether from the irritation in the urethra. It is observed also, that such swellings almost always admit of resolution, while those which originate from the absorption of venereal matter from chancres very frequently suppurate, burst, and turn into suppurative ulcers. It is true, however, that swellings of the inguinal glands, induced by the irritation of gonorrhœa,
do sometimes end in abscesses and fowes; but no lues venerea follows, nor is mercury requisite for the cure.

Another sympathetic affection, sometimes attendant on a clap, is a swelling of the absorbent vessels themselves. In some instances, this symptom accompanies the swelling of the glands. It makes its appearance in the form of a hard, painless cord, which, proceeding from the prepuce, extends along the dorsum of the penis, sometimes as far as the groins. This effect is not the consequence of the absorption of matter; for it is seen attending other irritations in the urethra, where no supposition of any irritating or poisonous matter being taken up by the lymphatics can be entertained by any kind of reasoning whatsoever. The symptom is sometimes brought on by the employment of bougies, in the treatment of strictures. It was for a long while suppos'd, that the matter which is discharged from the urethra, in cases of gonorrhea, was furnished from ulcers in this canal; but observation at length detected, that the opinion was delusive of all foundation. Dr. William Hunter is reputed to have been the first who ascertained, that in gonorrhca no ulcers existed in the urethra, and he is said to have begun to inculcate the fact in his lectures about the year 1750. This celebrated physician had derived his sentiment from some particular cases which he had seen, where a large quantity of pus had been formed upon the surface of the ulcer, without any ulceration of the parts whatsoever. In 1761, his brother, Mr. John Hunter, had an opportunity of dissecting the bodies of two mulattoes, who were executed, it is said, that they were affected with a severe gonorrhca. After a most careful examination, no ulceration could be discovered: the urethra of each was merely found to be rather redder than natural, particularly near the glans penis. Mr. Hunter afterwards opened the urethra of many patients who had died with gonorrhca upon them, and he never could find any vestiges of ulceration. It constantly appeared, that the membranous lining of the canal, near the glans penis, was redder than usual, and that the lacune were frequently filled with pus. Morgagni is said to have remarked the same fact. (De Sedibus et Caussis Morborum. Epit. 44, § 7.)

As an attempt has been made by a late writer, Dr. Swedman, to transfer the honour of the discovery from the Hunter to Morgagni, we deem it our duty to observe, that we cannot discover any accuracy, or justice, in the doctor's statement, since Morgagni's work was not published till 1761.

Although there can now remain no doubt, that in gonorrhca there are no ulcers essentially, or commonly present in the urethra, to furnish the matter which is discharged, yet Mr. Hunter himself has explained, that a very occasional by the cutting of an abscess in one of the glands of this package, is sometimes produced. This kind of ulceration, however, never takes place till long after the commencement of the running, and it is quite of a different nature from such cases as were fancied to be the cause of gonorrhca.

We shall now consider the identity of the gonorrhca and venereal poisons. It has been represented by some surgical authors, that the essential difference between gonorrhca and the venereal disease depends upon the circumstance of the first complaint being an affection of a secreting surface. Many other writers, and we may add, the generality of enlightened practitioners in this country, contend, that the two diseases originate from different poisons, a sentiment which is supported by the striking dissimilarity of the two affections, and the wide difference of the modes of cure.

Such authors, as maintain the doctrine of the two complaints being the consequence of different distinct poisons, found their arguments upon various circumstances. First, the history of these diseases, and of their progress in different countries. Secondly, the phenomena peculiar to each disorder. Thirdly, the remedies necessary for the cure.

It is ascertained, that the venereal disease and gonorrhca did not make their appearance in Europe at the same period; but that the former was many years antecedent to the latter. The same thing is stated to have happened in other parts of the world,whether Europeans have conveyed the venereal virus. For instance, the venereal disease was known in China almost immediately after it had made its appearance in Europe; yet it is remarked by Alfreu, that at the time when he wrote, gonorrhca was a malady which had only been very recently observed among the Chinese. Also, in the South-sea islands, discovered in modern times, where both the venereal disease and gonorrhca were unknown before the landing of European navigators, but where these maladies were afterwards diffused, gonorrhca was not noticed till several years after syphilitic disorders had begun to shew themselves. Claps are said to have been yet unknown to the natives of the South-sea islands, at the period when Captain Cook was performing his second voyage. (Duncan's Medical Cases and Observations.) All these circumstances have been adduced to prove the difference between that virus which gives rise to the venereal disease, and that from which gonorrhca has its origin.

On the circumstances attending the commencement of the venereal disease, in these remote countries, led Mr. Hunter to draw a conclusion diametrically opposite to the one deduced by the foregoing chefs de raison; for, he observes, that it is almost impossible for a man to have a chancre during a voyage of several months, without the whole of the penis being destroyed, while it is well known, that a gonorrhca may last an immense time, without losing the character of being virulent. It is related in the account of captain Cook's voyage, that the inhabitants of Otaheite, who were infected with the gonorrhca, went up the country and got well; but that when the consequence of the malady was the venereal disease, the latter was incurable. Hence it is inferred, that the complaint which the Otaheites contracted was the gonorrhca, since chancres and venereal affections would never have yielded to the simple means which were adopted. Besides, if the disorder had consisted of chancres, and the natives of Otaheite had been acquainted with the mode of curing such fowes, it is contended, that they could likewise have understood and been cured of the venereal symptoms. We find, also, from the perusal of captain Cook's third voyage, that the venereal diseases afterwards raged in all its forms in the island of Otaheite. Now, since there is no document to shew, that the gonorrhca was again introduced into that country, subsequently to Cook's second visit, it is concluded, that every form of the venereal disease which has been observed there has been derived from one source, which, in all probability, was a gonorrhca.

Mr. Hunter mentions a gentleman who had a gonorrhca threc, of which he was cured without mercury. About two months after each infection, he had symptoms of lues venerea. The first were ulcers in the throat; the second were blisters on the skin; both which forms of the disease yielded to mercury. Thirlby, two punctures were made on the penis, with a lancet dipped in the matter of a gonorrhca. One of these produced, on the part of the prepuce where it was made, a red, thickened speck, which increased and discharged some matter. This suppo'd chancre healed on having its surface repeatedly destroyed by cautery. The other puncture was made on the glans, where it was followed by
by a pimple, full of yellowish matter. This pimple was
touched with caustic, and healed in the same way as the fore
on the prepuce. Four months afterwards the chancre on
the prepuce broke out again; then it healed, and returned.
This it did several times; but always healed without any
application to it. While the fores remained on the prepuce
and glans, a bubo formed in the groin. A sufficient quan-
tity of mercury was given to cure the gland locally, but not
to prevent the affection from spreading. Two months
after the cure of the bubo, a venereal ulcer, according to
Mr. Hunter, formed on one of the tonsils. This was cured
by mercury; but the medicine was purposely left off as soon
as the fores was trimmed over, in order to see what parts
would next be affected.

About three months afterwards, copper-coloured blots
made their appearance in the skin, and the ulcer on the
tonsil recurred. This disease was again only palliated by
mercury; but the complaints returned in the same situation
as before; and were ultimately cured by a proper quantity
of mercury.

On the other hand, doubts must exist, concerning this ac-
count of the matter of gonorrhoea, when the following cir-
cumstances are taken into consideration:

16. It is impossible to say what time may elapse between
the application of venereal poison to the penis, and the com-
 mencement of ulceration. Therefore, Bongainville’s failurs,
alluded to by Mr. Hunter, might have contracted the infec-
tion at Rio de la Plata; but actual ulcers on the penis
might not have formed till about five months afterwards,
when the ship arrived at Otaheite. 2dly. The second ar-
gument added by Mr. Hunter is certainly inconclusive.
Every ulcer in the throat is not regularly venereal. A
common ulcer may heal while the patient is using mercury.
Hence the cure, apparently accomplished by this medicine,
is no proof that the complaint was syphilitic. 3dly. The
last fact of inoculation is undoubtedly very strong. But,
though the infection of gonorrhoeal matter, or any other
morbid matter, beneath the cuticle, will undoubtedly pro-
duce troublesome local complaints, may we not doubt that
the fores, in the above case, were actually venereal ones?
Can we implicitly depend on the continuance of the subject
of the above remarkable experiments, during the long space
of four months, between the healing of the sore on the prepuce,
and its recurrence? If we cannot, the inference, in regard to
the power of gonorrhoeal matter to communicate the venereal
disease remains unsubstantiated. How much more conclusive
in this respect, the experiments would have been, had the
inoculation been practiced on any other part but the penis.
If the matter of gonorrhoea be capable of communicating
the venereal disease, why does not the discharge commonly
produce chancres on the glans and prepuce, with which parts
it must lie in contact a very considerable time in every
case? Why also does not the presence of a chancre fre-
cquently cause a gonorrhoea? If the infection of gonorrhoeas,
and the venereal disease, be really of the same identical
nature, certainly, it seems very extraordinary, that the
former complaint should receive no benefit from mercury,
and the latter disease invariably require this specific re-
medy.

With respect to the venereal disease and gonorrhoea having
arisen in Europe and elsewhere at different periods, it has
been observed by such writers, as incline to the belief in
the identity of the virus of the two affections, that every kind
of contagious disease appears with greater violence in new-
infect ed countries, than in other situations where it has been
a considerable time endemic. In this manner, an endeavour,
which, in our opinion, is quite unsuccessful, is made to ex-
plain the cause why the gonorrhoea generally did not make
its appearance till a long while after the venereal disease had
swen itself in much worse shapes. The fame class of
reasoners also assert, that, notwithstanding the diligent en-
quiries of many able men, there is still a degree of doubt
concerning the exact time when these diseases originated,
and, of course, concerning the point, whether one of them
actually existed a long while before the other. As we shall
have occasion to allude to the origin of the venereal disease
hereafter (see Laca Venerea), we shall not enter into this
dilution in the present article. We may be per-
mitted, however, to express our suspicions, that discharges
from the urethra must have been occasional discharges from
time immemorial. Whether there be a species of gonorrhoea
truly venereal, that is to say, one which depends upon the
same virus, as syphilis, there may for ever remain doubts;
but, that there are laps or discharges which arise from
no poiso nous or infectious matter whatsoever, but altogether
from mere irritation in the urethra, as, in certain cases of
strictures, is certain and undisputed. These gonorrhoeas
must have prevailed as long as that canal has been liable to
various kinds of irritation.

One argument advanced against the identity of the virus,
and the striking difference observable in the progress and symp-
toms of the two diseases, is, that thevenereal disease is
deficient, it always grows worse and worse, and sooner or later brings on the patient’s dissolu-
tion. On the contrary, a gonorrhoea tends to a natural cure, and,
though left to itself, commonly ends in a favourable way.

The advocates for the identity of the poisons, however,
contend, that, in order to account for this full last (which
they state is not without exceptions), it is by no means
necessary to suppose a different virus. They bring into
consideration the circumstance of gonorrhoea depending upon
an inflammation of the surface of the urethra, and not ulcer-
ation; and they maintain, that the absorption of the
venereal poison generally happens much more easily from
ulcerated surfaces, than from such as are simply inflamed.
This mode of reasoning is brought forward as explanatory of
the cause why, in the majority of cases, a gonorrhoea re-
 mains entirely a local complaint, and admits of a spontaneous
cure, while the venereal disease is always prone to extend
itself, and spread from one part of the body to another.

An argument against the identity of the virus is also
 founded on the reflection, that the venereal disease is only
capable of communicating the venereal disease, and gonor-
rhoea of imparting gonorrhoea. The partisans of the de-
cline which imputes this latter affection to the venereal
disease, acknowledge, that things do usually correspond with
the statement just now given; but they assert, that the
contrary case is also frequently observed. They remark,
that we may easily convince ourselves of this circumstance,
by a fact which is well known to practitioners, namely,
that when persons, who have a gonorrhoea, are not parti-
cularly careful to keep the glans and prepuce clean, chan-
cres are very apt to form upon these parts, and by one such
factor the whole system may become infected. It is also
asserted, that, independently of the formation of any chan-
cre, there are cases proving, that the venereal disease may be the
consequence of a gonorrhoea, and that every surgeron of ex-
tensive practice must meet with instances of this kind.
One of the most remarkable on record, is that related by Mr.
Hunter; and it has been already noticed by us in this
present article, we need not dwell upon it again.

With respect to chancre arising from the matter of
gonorrhoea being in contact with the glans and prepuce,
we do, undoubtedly, see both men and women who have

3 L 2
(CO)
GONORRHEA.

claps and chances together; but, in our opinion, it is most
rational to impute the fores to the application of venereal
pox from chances, together with the gonorrhoeal matter,
at the time of coition. We have no doubt that this act is
often performed, when, between the two parties, both kinds
of infection are present.

Certainly it seems extraordinary, that if the virus be of
the same nature in both cases, the two effects should not always
appear in the same patient. We ought naturally to expect,
that when a gonorrhoea makes its appearance first, it would
always be the causie of a chancre; and that when a chancre
is the first symptom, it would invariably be the occasion of
gonorrhoea. We diffnus from prior consideration the
infection of such writers as defended the identity of the virus,
that in some few instances, one malady does become the
cause of the other. Mr. Hunter suspected, that the irratio-
ation of one of the parts, forming the face of the two dif-
cases, became the preparative of the other. He thought,
that when the urethra inflames and discharges matter, the
adjacent external parts might, on that very account, be
exempt from a disease which they otherwise inevitably
contract, by reason of the effect of the very virus which
gave rise to the gonorrhoea. The fame celebrated writer
also entertained a suspicion, that when a chancre attacks
the glass, or prepuce, the urethra might become ineffec-
tible of the irritation, which, without the external disease,
would certainly lead to a discharge from that canal.

This mode of explanation appears to us somewhat theo-
retical. We are of opinion, also, that in arguing in this way,
the advocates for the identity of the virus only bring for-
ward the shadow, instead of the substance of reason. In fact,
they say nothing more than that supposed venereal matter
cannot make the external parts of the penis ulcerate, because
there is an irritation in the urethra; and that the urethra
cannot be affected with gonorrhoea, because a chancre already
occupies the external parts. If this reasoning be not hypo-
thetical and fanciful, we cannot conceive what arguments
can ever be considered for. They who talk in this manner,
inaudently fall into difficulties, and make one opinion
inconsistent with another. Thus, they have already told us,
that, occasionally, a chancre is apt to occur, when patients
with gonorrhoea neglect to keep the glass and prepuce
clean; yet, according to their principles, a chancre renders
the external parts incapacitated of infection, and, of course,
there would be no need of cleanliness as a preparative. We
think that the weakness of the argument must be obvious to
the young student, who, on his entrance into any venereal
ward of an hospital, is almost Sure of immediately finding a
patient who has at the same time both chances and go-
orrhoea.

The different treatment required by gonorrhoea and the
venereal disease, is another argument against the identity of the
virus, mercury being unnecessary in claps, and the same
applicable in the other complaint. The partisans of the oppo-
site opinion endeavour to diminish the force of this fact, by
adverting to the different ways in which the two diseases
affect the parts which are attacked, and by manifesting that:
no just inference can be drawn from the difference of treat-
ment, while the particular action of mercury, on various
parts affected with the venereal poison, is not understood.
They also contend that, though mercury may have no effect
in gonorrhoea, when used in the same way as for other ven-
eral affection, yet, when applied to the urethra itself, it
leaves to moderate the symptoms, and accelerate the cure.

Having seen the colored injection employed in so many
hundreds of cases, with less benefit than the common vitriolic
one, we cannot ascribe to the last obsevation. The other
remarks, being bare opinions, may be received or not, as
the judgment of the reader may incline him; but, for our
own part, we have no hesitation in refusing them a place
among such information as is founded on rational evidence.

We shall now say a few words, respecting the time, be-
tween the application of the infection and the beginning of its
effects.

In the greater number of diseases, a certain space of time
always elapses between the application of the causie and the
first appearance of the effect. The time when a gonorrhoea
begins, after contamination, varies considerably in different
cases. In some examples, the poison takes effect in a few
hours, as Mr. Hunter has seen two or three times; while,
in other instances, the complaint does not show itself till the
end of five or six weeks. There are also cases to be met
with, in which the disorder begins at all the intermediate
periods. It is calculated, that the most common time of
its origin is in the space between the sixth and twelfth day.
In one instance, in which the malady did not commence till
the end of six weeks, it was noticed by Mr. Hunter, that
the affection was preceded by various symptoms of irrita-
tion, and uncommon sensation, in the parts. Hence, this
celebrated author concluded, that the virus seldom, or never,
remains so long inactive; but that the inflammatory state
cannot exist a good while before suppuration takes place.
The delay in the commencement of the discharge, however,
may be owing to causes which are not understood, and this
is very likely to be true, if we consider that some cases of
gonorrhoea do not begin for five or six weeks after infection,
and yet are not preceded by any remarkable symptom what-
ever.

The observations already made in a preceding part of this
article, must have apprized the reader, that discharges from
the urethra may originate from more causes than one, and
from more irritations than that which is produced by one
particular kind of virus. There are sometimes spontaneous
discharges from this passage, while no immediate cause what-
ever is assignable. Such discharges as occur independently
of a specific gonorrhoeal, or, according to the Hunterian
doctrine, the venereal virus, have been termed factor or be-
ign. Some affeet, that these cases may be known by their
coming on immediately after coition, and it is violent from the
very beginning: while the virulent gonorrhoea does not
commence till after some days, and grows gradually worse.
However, this criterion is insufficient: simple gonorrhoeas
are not always owing to coition, nor are they alwayssudden
in their appearance.

Mr. Hunter has seen the urethra sympathize with the
gums in dentition, and all the symptoms of gonorrhoea affect
the same infant several times. The author of the article
Gonorhœa, in the Encyclopaedia Méthodique, also mentions
his having seen two female children, who were affected
during dentition with a discharge from the pudenda, attend-
ed by a certain degree of inflammation, and pain in making
water.

We shall next introduce a few remarks on the effect of the
discharge on the parts producing it.

It was formerly not an uncommon opinion, that the dis-
charge was a means employed by nature for carrying off the
virus occasioning the complaint, and thus bringing about a
cure. However, it is impossible for this to be true, with
respect to inflammations, which arise from a specific virus;
for, supposing the suppuration could wash away all the
poison, causing the original irritation, yet, as all the mat-
ter afterwards secreted is equally virulent, no good would
be done: the irritation, according to the preceding idea,
would be perpetuated, and, of course, the discharge. This

Lift
eral occurrence, however, we need hardly remark, is not the case. The affection of the urethra in gonorrhoea is not kept up by the matter, but by the specific quality of the inflammation itself, which, in all probability, can never continue beyond a limited time, since the symptoms at length spontaneously subside. Had the infectious matter, which is formed in the course of the disease, the power of protracting the original irritation, the disorder would have no termination.

In gonorrhoea, as in many other diseases, the morbid action of the parts affected cannot go on for a long while in the same way. After having increased in violence to a certain degree, it naturally tends to become weaker; and the symptoms of the disorder which depend upon such action, at length, entirely subside. The time of this ceffation will vary according to circumstances; for if the irritated parts be very susceptible of the specific irritation, the diseased action must be more violent and lasting; but, in all cases, this difference is always owing to some particularity of constitution and not to any peculiarity of the virus.

The reader is aware that Mr. John Hunter regarded the gonorrhoea as one form of the venereal disease. It was the opinion of this distinguished man, that the venereal disease was only capable of a natural cessation, when it occupied a secreting surface, from which it produced pus. He believed that when the part attacked was not a secreting one, and an ulcer was formed, the disease would of itself go on for ever. He referred this difference between gonorrhoea and a chancre, however, more to the difference in the mode of action, than to that of the affected surfaces; for when the venereal virus produces an ulcer upon a secreting surface, as it sometimes does upon the tonsils, and even the urethra itself, such forces are not more disposed to heal, than if they were situated any where else in the body.

It is sometimes observed, in cases of gonorrhoea, that the parts which were irritated irritated well, while the irritation is communicated to another part of the same surface, as happens, when it leaves the urethra near the glans, and affects that part of the canal which is further on towards the bladder.

Admitting that every gonorrhoea is capable of getting well, without surgical assistance, it may be doubted whether a person, who already has a gonorrhoea, is susceptible of the irritation of fresh gonorrhoeal matter, or that the clap which exists could be augmented by its application. Mr. Hunter extended the same observation to every form of the venereal disease; and he states, that the matter of gonorrhoea, or of a chancre, put on an ulcerated bubo, does not in the least retard the cure, although, if venereal matter be applied to a common fore, the venereal irritation will frequently be excited. Such facts are strongly in favour of the opinion, that the matter of gonorrhoea has no effect in keeping up the complaint. The urethra is neither irritated by the infectious matter which it secretes, nor can the irritation already existing last beyond a certain period. Even were fresh matter applied to the urethra, the complaint would probably get well with equal quickness.

Mr. Hunter extended the idea farther, and even conceived that a fresh gonorrhoea could not be contracted, were fresh virus applied to the parts affected, at the period when the cure was just on the point of being completed. He thought that, in time, the parts might be so habituated to the impression of the virus, as to become insensible of it, and they must have regained their natural and original state, ere the infection can again have such effect upon them as to reproduce the complaint.

The foregoing opinions do not rest altogether upon theory; they are also founded upon experience and observation. Men, who have just had a gonorrhoea, have frequently been known to expose themselves to be infected again without any recurrence of the complaint taking place, while other healthy persons, who had connection with the same woman, have immediately caught the malady. Perhaps, it is on the same principle, that the first gonorrhoea is generally the most violent, and that such persons as are often affected with claps have them more and more mildly, particularly when the intervals are short.

In corroboration of these sentiments, Mr. Hunter relates several cases, among which is the following: a married man, who, for several years, had had no connection with any woman except his own wife, happened to meet with an old acquaintance, who gave him a severe gonorrhoea, though he declared her belief that she was quite well. Both adopted some means of cure; but continued to cohabit together during the treatment. The man got well, and it was presumed that the woman was also cured. They continued to live together several months; without the former experiencing any inconvenience, or having any reason to suppose that there was still any thing the matter with the latter. At length they parted, and the woman formed a new attachment. She had no sooner made this last connection, than she gave the new lover a gonorrhoea. She again consulted Mr. Hunter, whom she assured, that she had never cohabited with any others, except the preceding two; and consequently, if this be true, the infection of her first lover must have arisen from the very same gonorrhoea, of which she supposed that she had been formerly cured. However, she now used no remedies, and the man, after he was well, continued to cohabit with her for several months without receiving any new infection. But her old lover now returning, after a year's absence, and thinking that, as she was living regularly with the second, there could be no danger, ventured to have connection with her; the consequence was, that he caught another gonorrhoea.

Before describing the treatment, it is proper to lay a few words of the disease in women.

The gonorrhoea in females is not so complicated as in men, the parts affected being more simple and fewer in number. In women the disease is not so easy to be arrested, because they are also liable to a complaint, called the florid album, which has some resemblance. A mere running from the parts is not to much a proof of the existence of an infectious gonorrhoea in a woman, as a discharge without pain in a man; and in the former the discharge will often exit, while there is no increase whatever in the natural secretion from the parts. Nor can any criterion be deduced from the kind of matter, since the discharge of the florid album does not always cause the appearance of the discharge and the complaint in women. Mr. Hunter also remarks, that the appearance of the parts often gives us but little information, for he frequently examined them in patients, who complained of all the usual symptoms, from an increased discharge, pain in making water, a tendency to evil-smelling discharge, and yet he could find no difference in the look of the parts and of such as are quite healthy. When the patient was not conscious of any particular symptoms, or was disposed to conceal her knowledge of them, Mr. Hunter thought that some judgment might be formed from her having had connection with men supposed to be infected, and from her power of communicating the disease to others. However, it is acknowledged,
acknowledged, that as this last circumstance is derived from the testimony of another person, there are obvious reasons why it should not always be trusted.

When a woman contracts a gonorrhœa, the vagina must be first attacked. a part which is not ended with considerable facility. Frequently, however, the complaint extends much further, producing disagreeable fevers and forebodings of the inside of the labia, hymenæus, clitoris, carunculae myrtiformes, and means urinaris. The parts are sometimes so sore that the patient cannot bear them to be touched; she can hardly walk; and a great deal of pain is experienced when the urine comes into contact with the sore surfaces, as it must unavoidably do as often as the bladder is emptied.

When the disease extends to parts which are more sensible than the vagina, and more susceptible of inflammation, women have nearly the same symptoms as men; a fullness about the parts, a discharge from the urethra, violent pain in making water, and great uneasiness from the pressure on the parts in sitting. Sometimes the bladder is also affected.

The inflammation frequently extends to some depth, running along the ducts of the glands, and affecting the glands themselves, so as to occasion hard swellings under the surface of the inside of the labia. These tumours often spontaneus, and burst near the orifice of the vagina. They resemble the abscesses in the glands of the urethra in men.

The time in which a gonorrhœa may be cured is exceedingly variable, some cases terminating in a week, while others continue for months under the same treatment. According to Mr. Hunter, the object in the cure is to destroy the disposition and specific mode of action in the solids of the parts, and, as soon as that change is accomplished, the poisonous quality of the matter produced will also be destroyed. Thus the disease may be cured though not always its consequences.

A gonorrhœa is not capable of being continued beyond a certain time in any constitution, and when the complaint is violent and lasts a long while, it is owing to the parts being very susceptible of such irritation, and readily retaining it.

Since there is no specific medicine for the gonorrhœa, it is very fortunate, as Mr. Hunter observes, that time alone will effect a cure. This celebrated surgeoine was inclined to think, that, in cases of gonorrhœa, medicines were seldom of service, perhaps not more frequently than once in ten instances. With the idea, that every gonorrhœa cures itself, he gave certain, patients pills of bread, which were taken with great regularity. These pills all got well; but Mr. Hunter thought that some of them were not cured quite so fast as they would have been, had artificial means been employed.

The surgical methods of cure consist of internal remedies and local applications; but in putting any plan of treatment in execution, more attention should always be paid to the nature of the constitution, or to any attending disease in the parts themselves, or parts connected with them, than to the running itself.

The nature of the constitution is principally to be judged of from the local effects of the disease. These are so different in different people as to require a great variety of treatment, a circumstance, says Mr. Hunter, which has been too little attended to, every one endeavouring to attack the immediate symptoms, as if he had a specific for a gonorrhœa.

We are to consider, whether the inflammation is violent or mild, common or irritable. When the symptoms are violent, but of the common inflammatory kind, which is to be judged of from the attending circumstances, and particularly from the extent of the inflammation not exceeding the specific disease, the local applications may be either of the irritating or soothing kind. In this example, irritating applications may be left dangerous, than when the inflammation is of the irritable sort, and may have the effect of altering the specific action, the parts afterwards recovering of themselves, as from any other common inflammation. Mr. Hunter, however, expresses his belief, that the soothing plan is the best at the beginning.

When the inflammation is great, and of the irritable kind, no violence is to be used in the treatment, as the symptoms would thus only be increased. Mr. Hunter thought, indeed, that there were some cases, which are exceptions to the latter remark, the great degree of inflammation arising entirely from a susceptibility of this irritation, and not from any general irritability in the constitution. He confesses, however, that such examples can seldom be discriminated.

When the symptoms run very high, nothing should be done to stop the discharge, as, were it to be checked, the inflammation would still continue, and no good be effected.

Mr. Hunter recommends us to alter the constitution, if possible, by remedies adapted to each disposition, with a view to alter the actions of the parts arising from such dispositions, and reduce the disease to its simple form. If the constitution cannot be altered, we can only allow the action to wear itself out.

When the inflammation has considerably abated, and the disease only remains in a mild form, its cure may be attempted either by internal remedies, or local applications. If local means are used, violence is still to be avoided, because it may bring back the irritation. At this period (continues Mr. Hunter), gentle astringents may be applied with a prospect of success; or, if the disease has begun mildly, and there are no signs of an inflammatory disposition, either of the common, or irritable kind, an irritating injection may be used, in order to get rid of the specific mode of action quickly. Such application will increase the symptoms for a time; but, when it is left off, they will frequently abate, or wholly disappear. In such a state of parts, astringents may be used for the only thing to be done, is to procure a cessation of the discharge, which is now the principal feature.

When the itching, pain, &c., are felt for some time before the discharge appears, Mr. Hunter rather prefers the footling to the irritating plan of treatment. He suspected, that thus the coming out of the discharge would be promoted, which occurrence he conceived was the first step towards a resolution of the irritation. He believed that, at all events, in this case, the employment of astringents would be bad practice, as, by preventing the discharge from taking place, they might prolong the inflammation, and protract the cure. Also, in cases of ulcers, and of disceded tinctures, he is adverse to the use of astringents; for, says he, while the discharge lasts, both the other complaints are relieved.

The internal remedies commonly recommended in a gonorrhœa, may be divided into evacuants and astringents. The evacuants (says Mr. Hunter), are principally of the purgative, or diuretic kind, and these are not confined to any particular medicine, every practitioner supposing that he is in possession of the best. Some use mercurial evacuants; whilst others carefully avoid mercury in every form. The neutral
neutral faults have been given from the idea of their being cooling. Some of the profession have chiefly kept to diuretics, perhaps with two views: first, as evacutaries acting mechanically upon the urinary passages, so as to wash away the matter; secondly, as specific. For this purpose, nitre has been given, a medicine which has always been thought to have great effect in lessening inflammation, though Mr. Hunter has doubts concerning the truth of the opinion. Under every mode of treatment the patients always get well, and the cures are ascribed by each practitioner to his own favourite method.

Mr. Hunter remarks, that "to keep the body open in most cases, even when the patient is in other respects in health, mull, no doubt, be proper; but what idea can we form of an irritation, produced all along the intestinal canal, curing a specific inflammation in the urethra? Yet there are cases where a brisk purge has been of service, and even in some has performed a cure. But I suspect, that, in such cases, the disease had been continued by habit only, and that this practice would not have succeeded in the beginning. A gentleman had a gonorrhœa, all the symptoms of which continued after the third and fourth days, when about two grains of belladonna, purged him most violently, he was immediately cured. The calomel could not have acted specifically, but by a kind of derivation, that is, an irritation produced in one part, cured one that subsisted in another; but even if it should be granted, that in some constitutions purges have the power of making the solids less susceptible of this irritation, it cannot be supposed they will have this effect in every case: in some constitutions, they might debilitate, increase irritability, and of course increase the symptoms. These contrary effects must take place in different constitutions, in which a medicine has no specific action. On the supposition of the cure being promoted by an evacuation from the blood, what service can purging out some of the blood, in the form of a secretion from one part, do to an inflammation of another part? On such a supposition would not a sweat, or an incrustation of the surface, by chewing tobacco, or stimulating the nose by snuff, all tend equally to cure a gonorrhœa? But humourus having been considered as the universal cause of every disease, especially those in which purgation had the effect of discharging poison, and purging having been supposed to be the cure for humourous putrid constipation, all of course made use of in this disease; and as the patients have always been cured, the practice became generally established.

Those who recommended mercury in this form of the disease, did it most probably from the opinion, that this medicine was specific for the venereal disease in all its forms. On this supposition, we can see some reason for their practice, as it would be absorbed from the intestines, circulate through the inflamed vessels of the urethra, and thereby destroy the venereal irritation. Here we can only suppose it to act by its specific virtue; but I doubt very much of mercury having any specific virtue in this species of disease; for I find, that it is as soon cured without mercury as with it; and where this medicine is only used as a purge, or purged off the next day, and therefore allowed to act merely upon the bowels, I cannot conceive that it could have any more effect upon the venereal inflammation in the urethra, than an irritation in the bowels arising from any other purgative. So little effect, indeed, has this medicine upon a gonorrhœa, that I have known a gonorrhœa take place whilst under a course of mercury sufficient for the cure of a chancre. Whether the gonorrhœa arose from the same infection that produced the chancre I cannot say; nor can it be easily determined in such cases. Men have also been known to contract a gonorrhœa when loaded with mercury for the cure of a venereal; the gonorrhœa, nevertheless, has been as difficult of cure as in ordinary cases." P. 72, &c.

With respect to diuretics, considered as evacutaries, Mr. Hunter observes, that they may have the same general remarks made on them as have been offered in regard to purgatives. It is possible, says he, that specific medicines, taken into the constitution (if we had such), and passing off by the urine, might act upon the urethra in their passage through it. The ballasts and turpientes pass off in this way, and become specific for many irritations in the urinary passages; but how far medicines which have the power of affecting particular parts when found, or when under diseases peculiar to those parts, have also the powers of affecting a specific irritation in them, Mr. Hunter was uncertain. He conceived, however, that they might be capable of removing any attending irritation, though not the specific one. He thought, that diuretics did good inasmuch as they increased the quantity of urine; but he believed simple water was best for this purpose, or water joined with such things as encourage the patient to drink a good deal, as with tea, capiliaries, ipecacuanha, &c.

Allirgants have frequently been preferred, though without the approbation of the generality of regular practitioners. It was Mr. Hunter's opinion, that, such medicines did not lessen the inflammation, but that they often lessened the discharge.

With regard to local applications, they may be either internal to the urethra, or external to the penis. In many cases both kinds are proper. One would suppose, that what is applied to the urethra, must be the most likely to effect a cure, by coming immediately into contact with the diseased parts.

Local applications to the urethra may be either in a solid or fluid form, each of which has its advantages and disadvantages. A fluid (says Mr. Hunter) is only a temporary application, and that of very short duration.

The solid applications may remain a long time, and, in this respect, would seem to be better than fluid ones; but in general they create irritation. They must be used in the form of a poultice, which Mr. Hunter imagined was comparatively injurious, when the parts were in an inflamed state, though the effect, in cold medicines, that he never saw any harm from it in any case, when employed with caution.

Fluid applications to the inside of the urethra are usually called injections, and, like the internal remedies, are without number. However, as the inflammation is frequently removed under the use of injections of various kinds, have we not, (as Mr. Hunter notices) a long corroborating circumstance in favour of an opinion, that every such complaint will in time cure itself? This eminent surgeon thought, however, that practice evinced, that an injection often has almost an immediate effect upon the symptoms, and, therefore, that it must have some powers, though the injection, which would have the greatest specific effect, he believed, was not yet known. If an injection has no specific powers, it must be very uncertain in its effects, and can only be of service as far as it may be adapted to a peculiarity of constitution, or parts. As injections are only temporary applications, it becomes necessary to use them often, especially in cases where they are found to be of service. They should therefore be applied as often as convenient, perhaps every hour, or even oftener; but Mr. Hunter adds, that this must be regulated in some measure by the kind of injection; for, if it be irritating, it will not be proper to use it to oftens, as it may be productive of bad consequences.

The same author observes, that many injections remove
the symptoms immediately, or soon after the application, and prevent the formation of matter, which has given rise to the notion of their flushing up the disease and driving it into the constitution; but this supposition cannot be true, since the matter is the only fluid in which the poison is contained, and the formation of the poison is inseparable from the formation of matter. Therefore, if we can prevent the one, the other cannot take place, and, of course, there can be no room for absorption; so that there can be neither any power of infecting the constitution in the same person, nor of communicating the infection to others.

Mr. Hunter divided injections into four kinds, namely, the irritating, sedative, emollient, and astringent. He believed that we are not acquainted with any specific one, although a mercurial injection, of some sort or another, is frequently fancied to have such a quality.

All irritating injections act upon the principle of producing an irritation of another kind, which ought to be greater than that of the gonorrhoea, by which means the fust is destroyed, and the disease cured, although the pain and discharge may still be kept up by the application.

These symptoms will soon go off, as soon as the injection is laid aside, because they only arise from its irritating qualities. In this way bongues, as well as any minor injections, may be supped; to perform a cure, and although they increase the symptoms for a time, they never can increase the disease itself; any more (says Mr. Hunter) than the same injection, which would produce the same symptoms, if applied to the urethra of a found man, can communicate the disease. Most of the irritating injections have an astringent effect, and, when mild, prove simply astringents; their irritating quality depending chiefly upon their strength.

Mr. Hunter was not able to determine absolutely the kind of caifes in which irritating injections might be used with advantage. He thought, however, that such applications should never be used when there is already much inflammation, especially in constitutions which cannot bear a great deal of irritation, as a previous knowledge of the disease in the same person sometimes teaches us. Neither should these injections be used when the irritation has spread beyond the specific distance; when the teledicis are tender, or when they have become more upon a sudden diminution of the discharge; when the perineum is very susceptible of inflammation, and particularly if it should have been formerly fuppurated.

Irritating injections also ought not to be employed when there is a tendency in the bladder to irritation, which is known from the patient having had, for some time, a frequency in making water. In all the preceding caises they do no good, and often do mischief: Mr. Hunter thought he had seen abscusses in the perineum brought on by their employment.

In mild cases, and in constitutions which are not irritable, such injections often succeed, and remove the disease almost immediately. The practice, however, as the foregoing writer remarks, ought to be attempted with caution, and not, perhaps, till milder methods have failed. Two grains of corrosive sublimate (hydrargryus muriatus), dissolved in eight ounces of distilled water, are an eligible injection of this kind; but an injection of only half this strength may be used, when it is not the design to attempt a very sudden cure. If, however, the injection that weakened should give considerable pain, or occasion a great increase of, foreshots in making water, it must be still more diluted.

Sedative injections, according to Mr. Hunter, will always be of service in cases where the inflammation is considerable, not by lessening the disease itself, but by lessening the diseased action, which always allows the natural actions of the part more readily to take place. They are likewise very useful in relieving the painful feelings of the patient. Perhaps, says this celebrated surgeon, the best sedative which we have is opium, as when given by the mouth or anus, as when applied to the part affected in the form of an injection. But even opium will not agree, nor act as a sedative in all constitutions or parts. On the contrary, it has often opposite effects, producing great irritability. Lead may be reckoned a sedative, so far as it abates inflammation, while, at the same time, it may act as a gentle astringent. Fourteen grains of faccharum saturni (acette of lead), dissolved in eight ounces of distilled water, make a good sedative astringent injection.

Mr. Hunter next remarks, that the drinking freely of diluting liquors may, perhaps, be considered as having a sedative effect, as it in part removes some of the causes of irritation, rendering the urine less stimulating, either to the bladder, when the irritation is there, or to the urethra in its passage through it; and the plan may possibly lessen the susceptibility of irritation. The vegetable mucilages of certain seeds and plants, and the emollient genus, are recommended for impregnating the patient’s drink. Such substances pass off with the urine, and render the evacuation of that fluid less painful. It is proper to notice, however, that Mr. Hunter does not appear to have a high opinion of the utility of this practice.

When the inflammation is very great, Mr. Hunter believed, that emollient injections are the most proper applications. It seems probable, that they act first by simply washing away the matter, and then leaving a soft application to the part, in which way, says this eminent writer, they can be of singular service by lessening the irritating effects of the urine. A solution of gum arabic, milk and water, or sweet oil, will frequently lessen the pain and other symptoms, when the more active injections have done nothing, or seemed to do harm.

When great irritation and foreshots prevail at the mouth of the urethra, the point of the syringe cannot be introduced, and no attempt to use an injection ought to be made before the inflammation abates. Emollients may be used externally in the form of fomentation.

The astringent injections, observes Mr. Hunter, can only act by lessening the discharge. They can have no specific effect upon the inflammation. They should only be used towards the latter end of the disease, when it has become mild and the parts begin to itch. However, if the discharge should begin mildly, they may be used at the very beginning; for, by gradually lessening the discharge, without increasing the inflammation, we complete the cure, and prevent a continuation of the discharge called gleet. If the astringent injections be strong, they will be irritating, and frequently increase the discharge, instead of diminishing it. When weaker, they often stop the running, without halting, however, the cure in all cases; for the inflammation may still continue even longer than it would have done, had the tendency to secretion not been removed. But sometimes an astringent injection will cure a slight irritation in a very few days. Mr. Hunter never found one astringent more efficacious than another. The astringent genus, as dragon’s blood, the balm, and the turpintines, dissolved in water; the juices of medicinal vegetables, as oak bark, Peruvian bark, tormentil root, and, perhaps, all the metallic salts, as green, blue, and white vitriol; the salts of mercury, and also alum; probably all act much in the same way. Mr. Hunter, however, owns that they do not act equally well in every gonorrhoea,
GONORRHOEA.

Gonorrhea, and that changing the injection will often succeed,
when a long perseverance in a previous one would not.

We have to observe, that the astringent injection, which is most generally approved of by practitioners, is that containing white vitriol (zincum vitriolatum), about half a scruple of which, dissolved in eight ounces of water, is a very good application to begin with. The strength may be increased or diminished, however, as the patient's feelings may require.

Poultices and fomentations have been used as external applications in cases of gonorrhea; but, says Mr. Hunter, they can be of little service, except when the prepuce, glans, and orifice of the urethra are inflamed. It is now more common, in the inflammatory stage of the complaint, to surround the penis with linen kept continually wet with the fuiturne lotion.

When any of the glands of the urethra remain in an indurated state, after the subsidence of the inflammation, the hardnels may be removed by frictions with camphorated mercurial ointment.

It is remarked by Mr. Hunter, that in women, the mode of curing the gonorrhea is nearly the same as in men; but the effects of the principal symptoms is more numerous in females. Hence the cure is more simple.

When the disease is confined to the vagina, it may be easily cured by means of injections, taking care also to wash the external parts with the application. The patient cannot, however, apply an injection to the meatus urinarius, when that passage is affected.

The same kinds of injections are proper for women as are prescribed for men; but they may be made doubly strong, as the parts in women are not nearly so irritable as the common foot of this disease in the other sex.

When the inflammation runs along the ducts of the glands, either of the mouth of the vagina, or of the urethra, or where it affects the glands themselves, the case claims the same treatment as in men. The mercurial ointment should be freely applied to the indurated parts. When the ducts and glands suppurate and form abscesses, these should be opened and dressed like a sore. The ulcer, however, is not regarded as venereal. Though Mr. Hunter entertained such a sentiment, and directed a corresponding treatment.

In the astringent treatments, the symptoms are frequently violent, attended with a strong propensity to the inflammatory fever. The inflammation, however, does not extend beyond the specific disease. Many medicines, which might be of service in another constitution, here do harm, and increase the symptoms which they were intended to relieve. Mr. Hunter has seen opiate glysters after at first doing good, bring on fever and an exacerbation of all the symptoms. He has seen the balsam capivi render the inflammation worse. The treatment of such a constitution, when affected with this disease, should chiefly consist in bleeding and gentle purging. It is proper also for the patient to live sparingly, and use little exercise.

In the weak and irritable constitution, as Mr. Hunter observes, the symptoms are frequently very violent, and often extend beyond the specific disease, the inflammation running along the urethra, and even affecting the bladder. In this instance the foregoing author was of opinion, that a strengthening plan should be adopted.

Sometimes gonorrhea is so capricious in its cure, that the accesion of an accidental fever stops the discharge, removes the pain in making water, and the disorder is permanently cured. Sometimes the symptoms cease on the commencement of the fever, and return when the latter complaint is well. In other examples a gonorrhoea may begin mildly; but a severe fever coming on and continuing for several days, the symptoms of the first disorder are rendered much worse, and, on the fever going off, the gonorrhea likewise disappears. Mr. Hunter remarks, that although a fever does not always cure a gonorrhoea, yet, as it possibly may, nothing should be done while the fever lasts; and if the local complaint should continue after the fever is gone, it is then to be treated according to the symptoms.

The name writer represents, that, unfortunately, there are cases in which no known method lessens the symptoms: evacuations, a strengthening plan, sedatives and emollients, all prove useless, and time alone seems to bring about the cure.

In these instances, Mr. Hunter thought the poisoning plan of treatment the most advisable, and was against the employment of astringents. Neither had he much opinion of the capivi and Cananda balsams, nor of turpentsine in general, though they might diminish the discharge.

A gonorrhoea is also considerably affected by the patient's way of life, during the inflammatory stage. Most things which hurry or increase the circulation, aggravate the symptoms, such as violent exercise, drinking strong liquors, eating strong indigestible food, taking peppers, spices, spirits, etc.

When the complaint begins mildly, or after the violent symptoms have subsided, we may prescribe medicines which will affit the above local remedies, in checking the discharge.

Mr. Hunter thought the turpentine the most efficacious. Cantharides, elliprium vitriolatum, acetate of lead, and alum, have also been recommended.

The reader is already aware, that Mr. Hunter regarded gonorrhoea as a disease arising from the venereal poison, and believed that the matter from the urethra, it introduced into the circulation, would occasion a febrile fever. In order to guard against the effects of absorption, he was an advocate for exhibiting small doses of mercury at an early period of the malady, and for continuing them even for some time after the formation of matter is an end. He advised a grain of the hydrargyrum calcinatus to be taken every night, or every evening and morning; but frictions, with the mercurial ointment, when mercury disaffixed with the fomach and bowels. Most practitioners at this day are strongly addicted to the system of prescribing a grain or two of calomel every day during the treatment of a gonorrhoea, and deem it unsafe to abstain altogether from the use of mercury, in some form or another. Others give calomel with a view of its acting as an alterative and purgative. We never have seen any reason, however, for exhibiting either the hydrargyrum calcinatus, or calomel, or for employing mercury in any mode whatsoever.

Before closing the present article, it only remains for us to say a few words respecting some complaints, which are occasionally attendant on gonorrhea.

When the inflammation is violent, or spreads along the urethra, there is frequently a discharge of blood from the vessels of that part. Mr. Hunter states, that in such cases the balsam capivi has been found serviceable; but that he did not observe any good result from the use of astringent injections.

Opium alone, or joined with camphor, is the best medicine for the prevention of painful erections. Cicuta is also said to prove useful for the same purpose.

With regard to the treatment of chordee, Mr. Hunter remarks, that in the beginning of this complaint bleeding from the arm is often of service, but that it is more immediately useful to take away blood from the part itself by leeches. Great benefit often follows the accidental buming of a vesicle, and a profuse hemorrhage. Relief is often ob-

3 M

ailed
tained from exposing the penis to the steam of warm water. Poultices and fomentations, especially such as contain camphor, are frequently productive of benefit by removing the inflammation. Opium given internally is of singular service, and is still more beneficial when joined with camphor. It lessens the pain and prevents erections, which are the immediate cause of the complaint.

When the chordee continues after all the other symptoms are gone, the only remaining object is to promote the absorption of the extravasated coagulable lymph, by friction with mercurial ointment on the parts. Mr. Hunter informs us, that in one case considerable benefit seemed to result from giving cicutia, after the common methods had failed. Electricity, he says, may also be of service. A chordee is often longer in disappearing than either the running or pain; but, like most of the consequences of inflammation, its declension is gradual and uniform.

Mr. Hunter has seen the kind of chordee, which seems to depend on spasm, relieved by bark.

When the glands of the urethra suppurate, Mr. Hunter advises the use of mercury, just as if the case were a chancre; but this practice is not deemed necessary by the most judicious surgeons of the present day. It is proper to make an early opening into the abscesses, when Cowper's glands suppurate, in order to prevent the matter from making its way into the urethra or scrotum.

When the bladder is affected with irritation, in consequence of gonorrhœa, opiate elettes, the warm bath, and copious bleeding, are the chief means of relief. Leeches applied to the perineum have also good effects. Bleeding, however, in certain conditions, is hurtful, and should always be resorted to with caution. When the complaint lasts very long, resorting ordinary methods, Mr. Hunter fuggles the trial of an opiate plaster on the pubes, or small of the back; or a small blister on the perineum.

The mode of treating a swelling of the testicle, we shall consider under the head, Hernia, Herniaemulosis.

The decline of a gonorrhœa is generally known by the pain becoming less, or changing into an itching, similar to what is often felt in the beginning of the complaint, and which at length goes away altogether. The fonic of weariness about the hips, hips, testicles, and scrotum is no longer felt; and the cherry-like appearance of the glans penis gradually subsides. The running diminishes, or at all events becomes white, then paler, and by degrees assumes a more flaky consistence, in proportion as it becomes more like the natural secretion, which is designed to lubricate the urethra.

Recurrences of the disease every now and then are met with, after the pain, discharge, &c. have quite ceased. Standard-pipes, however, are more common in women than men, and the complaint is usually in a milder form than before.

GONARA, in Geography, a town of Hindoostan, in Bandeland; 20 miles N. of Calingen.

GONS, a town of Hungary; 22 miles S.S.W. of Zatmar.

GONALFO, Hernandez De Cordova, in Biography, an eminent Spanish commander, was born in 1443; and brought up from a very early age to the profession of arms. He signalized himself in a war against Portugal, and under the reign of the celebrated Ferdinand and Isabella he served in the conquest of Grenada. He was afterwards employed to succour Ferdinand king of Naples against Charles VIII. of France, and by his assistance the whole of that kingdom was recovered from the French. Kings, however, are not always consistent in their projects, and the monarch of Spain who had defended and saved one king of Naples, formed a project of supplanting his succedeur, and making a partition of the country with Lewis XII. of France, and Gonalfo was employed to execute the attempt. The warrior was completely successful, and made Alphonso, son of the king of Naples, his captive. Elated with his success, and willing to shew his moderation, Gonalfo swore upon the holy sacrament, a wretched abuse of a religious rite, that the young prince should enjoy his liberty; but after the surrender was complete, and the time was come when he could execute his promise, he pretended that he had received new orders from his own sovereign, which obliged him to send Alphonso, a prisoner into Spain. Without partitioning powers from disfigured among themselves, and the French, being in a greater state of preparation, attacked, defeated, and expelled the Spaniards from most of the places which they possessed. Gonalfo was now compelled to retire with his army, deflute of money, provisions, and ammunition. He retired, however, only to recruit himself, which he had an opportunity of doing among the Venetians, when he rallied, drove the French before him, and entered Naples in triumph. Ferdinand, in the mean time, doubtful of the event, had negotiated a treaty with Lewis, confirming their former partition; but upon the intelligence of the great success of Gonalfo, such was "Spanish honour," that he refused to sign it, and the French were, by the efforts of Gonalfo, obliged entirely to evacuate the kingdom of Naples. For these and other eminent services, he not only obtained the title of the "Great Captain," but was rewarded by his sovereign with many valuable as well as honourable marks of honour. He was made confidant of the kingdom of Naples, raised to the dukedom of Terranova, St. Angelo, and other estates. He at length fell under the suspicion of his sovereign, who sent letters to recall him, which the general repeatedly declined upon different pretences. The king determined to go to Naples, and was met at Genoa by Gonalfo. They entered Naples together in apparent harmony, and the king conferred an additional dukedom on his "Great Captain," but Ferdinand thought it prudent, in the following year, when he left Naples, to take his general with him. At Savosa they had an interview with Lewis XII. who showed his esteem for Gonalfo, by decorating him with a gold chain taken from his own neck, and causing him to sip at the same table with himself. At Venice also he received some magnificent presents. On his arrival in Spain, he was commanded to retire to his own estate at Grenada, where he died in 1513, at the age of seventy-two. Gonalfo is distinguished as a firm disciplinarian, a great master of the art of war, but as one who was never distinguished for generosity of sentiment. Unier. Hist. Mexic.

GONALFO, S., in Geography, a town of Brazil, in the government of St. Salvador; 40 miles W. of Serpique.

GONTAPILLY, a town of Hindoostan, in the circuit of Cacocela; 25 miles s. of Coambique.

By Lourieiro's description of his only species, G. amorifum, a shrub with pinemat ferrated hairy leaves, and by his reference to Rumphi. Amboin. Append. t. 15, it should seem to be allied to Fagara, though the description of the pithil and fruit does not exactly answer. It agrees perhaps better with Brunus, Jaff. 373, both in botanical characteristics and medical properties; see that article. Lourieiro says his plant is found in the woods of China and Cochinchina, and that
the virtues of the root and fruit are diaphoretic, alestetric, antifebrile, and antihelminic. He adds, that "it seems to be the fame drug which the Portuguese call radix de Solar, because it grows in the island of Solar, as well as in Timor, and which is in great use in India." Is the Beraco, after all, an Indian plant? 

GONWA, in Geography, a town of Hindostan, in Gujarat; 20 miles N.W. of Aamood.

GONYALGIA, of qui, koe, ak'te, pair, a term used by some authors to express a violent pain in the knee.

GONZALEZ, Luceria, in Biography, daughter of Pirro Gonzaga, lord of Gazvola, was distinguished as a literary lady in the sixteenth century. The celebrated Bandello was one of her mallers; by him she was introduced to the knowledge of the Greek tragedies. She married, at the age of fourteen, Gianpaola Manfroni of Ferrara, which proved an unfortunate union, since her husband, on account of a plot against the life of duke Hercules II., was unjustly condemned in 1546. The duke did not caufe the sentence to be executed, but was contented with keeping him in perpetual imprisonment, under which he died in 1552. His faithful spouse, Lucretia, employed all her powers to obtain his liberation: she is said to have addressed letters to almost all the powers in Europe, imploring their intercession, and one to the grand seignior, inveigling him to make an attack upon the fortresses where her husband was confined. It must be observed, that these letters have been imputed to Ortenfia Landi; it cannot, however, be doubted, that this lady had acquired a considerable literary reputation by being suppos'd capable of such productions. She was, indeed, panegyrized by most of the learned in Italy in her time, among the rest by Julius Cesar Scaliger, and a volume of poems in her praise was published in Bologna in 1565. Several of her works were printed, one of which was a small volume of poems. She remained single after the death of her husband, and placed her two daughters in a convent. She died at Mantua in 1576. Moreri.

GONZALEZ, Scipio, born in 1542, was son of Charles, count of St. Martino, of the branch of the Gonzaga, dukes of Sabbionetta. He was carefully instructed in letters, and sent to Padua to complete his studies, where he greatly distinguished himself in classical literature. He afterwards acquired considerable reputation for his knowledge in theology and philosophy. Murcius, in 1571, dedicated to him the first volume of his Orations, with a high panegyric: and Guzman submitted to his criticism his "PaiTor Fido." He was created cardinal in 1587, and died at Mantua in the year 1593, leaving behind him commentaries of his own life, written in elegant Latin. Moreri.

GONZALEZ, Venetiam, duke of Sabbionetta, born in 1531, is celebrated as a commander in the service of Charles V. and Philip II., but he is still more distinguished as a splendid promoter of the arts and sciences. He built from the ground up the city of Sabbionetta, which, for the neatness and regularity of the streets, the architecture of the private houses, the beauty of the churches, and the elegance of the public buildings, has excited universal admiration. He also founded in it a public school for the learned languages, to which he invited as a professor Mario Nizzoli, one of the most learned men of the age. His palace was always full of men of knowledge and science, of whom he was the liberal patron. Gonzaga employed Scamozzi in the creation of a very fine theatre, for the performance of dramatic pieces, and he is himself recorded as an elegant Italian poet. He is mentioned with high respect and applause by Tasso, and other literary characters, and he is noticed as a collector of books.

GONZALEZ, in Geography, a town of Italy, in the department of the Mincio; 16 miles S. of Mantua.

GONZAGA, St., a town of Peru, in the audience of Quito; 60 miles N.W. of St. Josaf of Huasas.

GONZALES, Bartolome, in Biography, a painter, born at Valladolid in the year 1564. He frequented the school of Patricio Caxes at Madrid; in the sequel painted much for Philip III. at Burgos, Valladolid, Lerma, in the Pardo and Escorial, till 1617, when he was made painter to the court, in the place of Fabricio Castello. His portraits are admirable, especially the six whole lengths with the date 1621, poiffided by the baron of Casa Davallillo. In hifory, his style was ornamental; his drapery, a varied imitation of Iifa, by its illusion captivated the vulgar, while it destroyed the dignity, simplicity, and generally the confluence of the subject. He died in 1627, not, as Palomino states, in 1611. Fufeli's Pilkington.

GOOBER, in Geography, a country of Africa, S. of Wangara, between 10 and 12 N. lat. and 15° and 20° E. long. The mountains of Kuiru, so called by Abulfeda, commence in this territory.

GOOCHLAND, a county of Virginia, in America, surrounded by Louisa, Flavonna, Hanrico, Hanover, and Powhatan counties; about 40 miles long and 14 broad, and containing 4,693 free inhabitants, and 4,925 slaves.

GOOD, or GOODNESS, denotes whatever tends or conduces to preserve or improve human nature or society; in opposition to evil, which tends to destroy, injure, or impair the fame.

Hence good is divided by the philosophers into 1. Bona fuo, private good; which is that whereby a thing tends to preserve, &c. itself, under which comes that popular division of goods of body, mind, and fortune.

2. Bona communitatis, whatever promotes the interest and welfare of society; as all the civil offices, &c.

Good, in Metaphysics, or Metaphysical Good, called also absolute or real good, and good for its, is the effential perfection or integrity of a thing whereby it has every thing that belongs to its nature.

In this sense, all things are good, inasmuch as they have the perfections naturally belonging to things of their kind. Thus, a thinking subsistence is good, or perfect, as it has all the effential attributes of thought; so an extended subsistence is good, as it possesses all the parts necessary to constitute it such.

In effect, as it is absurd to imagine a being without its essence, so is it to imagine a being without the requisites of its essence: so that it appears an error in some philosophers, who divided beings into good or perfect, and evil or imperfect. See Essence.

Others define metaphysical, or transcendental goodnes, by congruency with the divine will, which they say, constitutes the measure of all real goodnes.

Goo, Physical or Natural, is that whereby a thing possesses all things necessary to its be and eff, i.e. its well being, or second perfection, and to the performance of its functions and uses.

In this sense, physical goodnes coincides with physical perfection.

To this are required the several powers and faculties, in their proper degree; a due situation, figure, and proportion of parts, &c.

Note, before absolute physical goodnes, there may be a relative one; as in foods, which is to one, are salutary, to another poison, &c. To this head also belong the things good pro tempore, or according to circumstances; as the amputation of a mortified limb, &c.

Natural
Natural good may be otherwise defined to be that which makes or denominates a being happy, or prepares him for happiness; or, at least, prevents or removes his misery: accordingly, good is either objective or formal; objective good is that which makes us happy: formal good, or the pleasure resulting from the application of the faculty to the object, is that which denominates us happy.

Gourn, Moral or Ethical, is the agreement of a thinking, reasonable being, and of the habits, acts, and inclinations of such a being with the dictates of right reason, and the will of the Creator, as discovered by natural light. See Virtue.

In order to this, it is not enough that a thing done, said, thought, defired, be just and good; but it must be done, thought, &c. well; i.e. from good principles, and to good ends.

Others define moral good more largely. Moral, which they also call relative good, according to them, is something that is good to another, or that tends some way to the perfection thereof. In this sense they divide it into three kinds, bonum, jactandum, and utilic.

The first, bonum bonitum, is what agrees with right reason, and is desirable for itself; as all things virtuous; e. g. to love God, respect our parents, &c. It is considered without any regard to pleasure; not but there is sincere pleasure annexed to it. Zeno and the Stoics allow of no other goods; those of the body, &c. they call commoda, convenienciae, not goods.

Bonum jactandum is that which is good, as it tends to give us pleasure, and is desired on that account; but without any regard to virtue or right reason; as music to the ears, painting to the eyes, &c.

Bonum utilic, or commandum, is that which is good on account of something else for which it is desired; as money, riches, &c.

Goop, chief, sovereign, or supreme, summan bonum, is that, the enjoyment of which renders men truly and completely happy. The school distinguish this chief good of man into that which is simply and adequately fo, and beyond which there can be no other; and an inferior, subordinated kind, which is, in some measure, attainable in this imperfect state. This last they call felicis vivorum, and the former felicis comprehendorum. The chief or sovereign good, according to the idea collected of it from the original, natural, and universal preconceptions of all mankind, is something agreeable to our nature, conducive to well-being, accommodated to all places and times, durable, self-derived, and inestimable; and this consists, says Mr. Harris, in rectangle of conduct, or in living perpetually delighting, as far as possible, what is congruous to nature, and rejecting what is contrary, making our end that deciding and rejecting only. Three Treaties. &c. 1755, p. 121, &c. 205, &c.

Philosophers are divided as to what the chief good of man consists in: whether in the goods of fortune, of body, or of mind. Some hold riches and honours the supreme good; others, as Aristippus and the Cynic school, bodily pleasures; and others, as Zeno and the Stoics, virtue, or living according to nature. The Peripatetics agreed with the Stoics in maintaining that virtue is the summan bonum: but the Stoics affected farther, that virtue was the only good: whilst the Peripatetics denied, with reason, that virtue was felt different, and therefore required several other things as auxiliaries, such as health, prosperity, friends, &c. which are to the virtuous man in the nature of ingredients or ornaments to his felicity. An excellent writer lays down the following criteria or characteristics of the summan bonum, or chief good, which reason can demonstrate to be actually designed for man: it is something which all men, if not wanting to themselves, may be possessed of; it is one and the same to all mankind: and while in itself fitted to make the possessor happy, it is not prevented in its operation by some other thing which keeps him from enjoying it: and as to the highest good which it is possible for man to enjoy, it must be referred to no other, but all others must be embraced for the sake of this: and it must be sufficient to furnish a happiness adequate to the capacities of human nature, and equal duration; i.e. it must be not only perfect whilst it lasts, but everlasting. According to these characters we may infer, that neither the goods of fortune, nor those of the body, nor even virtue itself, constitute the chief good. Virtue, rightly understood, is the perfection of human nature; it is the influence of obtaining happiness: but this alone will not make a man happy: it is farther necessary that he be perfect as to life, or happy in the circumstances of his being: and, therefore, natural reason demonstrates, that the favour of God, secured by virtue, is properly man's supreme good. Grove's System of Moral Philosophy, vol. i. part. i. paffim. See Epicurians, Peripatetics, and Stoics.

Goodwill. See Benevolence.

Good Works. See Merit and Supererogation.

Good Abusing, bona gesta, in a Low Sense, is particularly used for an exact carriage or behaviour of a subject towards the king and his liege people; to which some men, upon their misbehaviour, are bound.

The judges are empowered by 24 Edw. III. cap. 1. to bind in this manner all them that be not of good fame; under which general expression, it is held that a man may be bound to his good behaviour for causes of scandal, contra bona mori, as well as contra poenam; as, for haunting bawdy-houses; for keeping bad women in his own house; or for words tending to scandalize the government; or in abuse of the officers of justice, especially in the execution of their office: a justice may also bind over all night-walkers, eaves-droppers, such as keep foppish company, or are reported to be pilferers or robbers, common drunkards, whore-masters, the putative fathers of bastards, cheats, idle vagabonds, and any other persons, whose misbehaviour may reasonably bring them within the general words of the statute. Persons of this description may be bound, with one or more furtices, in a recognition or obligation to the king, entered on record, and taken in some court, or by some judicial officer, whereby the party acknowledges themselves to be indebted to the crown in the sum required, i.e. 10s. with condition to be void on non-performance, provided that they behave themselves well, either generally or specially, for the time therein limited; as for one or more years, or for life. This recognition, if taken by a justice of the peace, must be certified to the next sessions, by 3 Hen.VII. cap. 1. and if the condition of it be broken, the recognition becomes forfeited or absolute; and being eflactuated or extracted, (i.e. taken out from among the other records) and sent up to the exchequer, the party and his furtices are become the king's debtors, and are sued for the several sums in which they are bound. All persons under the king's protection may obtain such security, upon due caufle shown; and the justice may be compelled to grant it by a mandatory writ, called suspensio: but this writ is seldom used, for, when application is made to the superior courts, they usually take the recognizances there, under the direction of the statute 21 Jac. I. cap. 8. A recognition may be discharged, either by the demise of the king, or by the death of the principal party bound thereby, or by order of the court to which it is certified by the judge: He that is bound to this, Lumbard says, is more strictly bound than to the peace;

Good Confederation. See Consideration.

Good Fortune, or Para, in Geography, an island in the East Indian sea, near the W. coast of Sumatra, about 36 miles long and six broad. S. lat. 1° 5'. E. long. 98° 30'.

Good Taste. See Tast.

GOODALORE, in Geography, a town of Hindostan, in the cirec of Dindigul; 10 miles S. of Ootampanam.

GOODenia, in Botany, so named by the writer of the present article in honour of the Right Rev. Samuel Goodenough, lord bishop of Carlisle, F.R.S. and a vice-president of the Linnean Society, author of a most valuable paper on British Carices, in the second volume of the Linne Society's Transactions, and of one on British Fuci, in conjunction with Mr. Woodward, in the third. The name was contructed after the example of Tournefort, who, as he tells us, not without much consideration, contrived to form Gou- denia out of Gauden/sel/omer. It did not occur to us at the time that Goodenia might have come nearer to the original, and have been equally unexceptionable. It is now too late to make any such alteration. Linnaeus named Richardia after Dr. Richardson, Silliguria after Mr. Silligueri, and these are sufficient precedents. Sm. Tr. of Linn. Soc. v. 2. 346. Brown. Prodr. Nov. Holl. v. 1. 374. Wild. Sp. Pl. v. 1. 954. Mart. Mill. Diet. v. 2. Claws and order, Pentamia Monogynia. Nat. Ord. Campanaceae, Linn. Campanaceae, Juff. Goodeniana, Brown.

Gen. Ch. Cal. Perianth superior, of five, nearly equal, linear leaves, permanent. Cor. of one petal, much longer than the calyx, irregular; tube slit from top to bottom at the back; limb of five deep, firm, lanceolate segments, with thin dilated longitudinal borders, turned moat to one side, forming one lip, or generally two. Stam. Filaments five, shorter than the tube, often projecting through its fissure, capillary, equal; anthers vertical, oblong, of two lobes. Pét. Germen inferior, oblong, crowned with the calyx-leaves, which run down its sides and form ribs; style taper at the base, swelling upwards, undivided, nearly as long as the tube; stigma large, firm, obtuse, enveloped with a cup-shaped cover, more or less two-lipped, its margin fringed with dense upright hairs. Perig. Capsule oblong or elliptical, of two valves separating at the top, and two (rarely four) cells, the partition flat, parallel to the valves. Seeds numerous, imbricated, compressed.

Eff. Ch. Corolla of one petal, slit longitudinally at the back; limb in five deep segments turned one way. Anthers separate, bearded. Stigma with a cup-shaped fringed integument. Capsule inferior, of two or four cells, with a parallel partition. Seeds numerous, imbricated.

Obs. Mr. Brown has remarked, in some species, a small bag of honey attached to the germe, opposite to the fissure in the corolla.

Eight species of this very curious genus were originally defined in the Linnean Society's Transactions, three of which, having been described without a knowledge of their fruit, are now, on more full examination, removed by Carvanilles and Brown to other genera. There are the albidus, fritha, and ramosissimus; the latter, which, like the albidus, is a Scrophulus, may be seen in Sm. Bot. of N. Holl. t. 5. The fritha belongs to Mr. Brown's Dauceiras. But on the other hand the discoveries of this indefatigable collector and accurate botanist have increased Goodenia to 32 species, all natives of New Holland or of Van Diemen's land. Of these the first 28 have a two-lipped corolla, and the first 25 of them have yellow flowers, the red blue or purple. Of the remaining four, two have a single-lipped corolla, and the others are doubtful in this respect, it being doubtful whether these have properly belong to the genus. One of them is Sellera radiata, Cavan. L. t. 474. I. 2. Gooden- ia repens; Billard. Nov. Holl. t. 76.

Satisfactory examples of the genus are, G. paniculata. Sm. n. 2. Cavan. L. t. 507. This has yellow flowers in terminal panicles. Leaves mostly radical, strongly toothed. Herbage hairy.

G. rota. Sm. n. 1. Cavan. L. t. 526. Andr. Repof. t. 68. The first species that bloomed in England, and from which the genus was described. This has rather shrubby stems, ovate nearly serrated smooth leaves, and axillary forked flalks, bearing elegant yellow flowers. It is a desirable ornament for a greenhouse, and not difficult of culture.

G. grandiflora. Sims in Curt. Mag. t. 390. Differs from the last in being downy, with laurate leaves and larger flowers, whose tube is split into four segments, andingularly rough or bearded within.

GOODENOVIUM, a natural order of plants recently established by Mr. Brown. Prodr. Nov. Holl. v. 1. 573, being separated by him from the Campanulaceae of Sullivans, and essentially distinguished by a peculiar cup-shaped integument, either undivided or two-lobebed, which contains the stigma, and has hitherto been described by botanists as the stigma itself. See Campanulaceae.

Mr. Brown describes his new order as follows:

Calyx superior or half superior, rarely inferior, five-leafed, sometimes in five or three deep divisions, sometimes five-leafed, undivided, and occasionally obflate; its segments equal, rarely unequal, permanent.

Corolla of one petal, more or less irregular, deciduous or withering. Tube split longitudinally, sometimes separable into five portions, while the calyx is merely attached to the base of the germen. Limbs in five deep segments, composing one lip or two, their disk lanceolate, flat, their sides, or wings, of a thinner texture, elevated, folded inwards when young, rarely oblate or obtuse.

 Stamina five, unconnected with either corolla or stamens, and alternate with the divisions of the former. Filaments distinct. Anthers either separate or coherent, linear, vertical, attached by their base, undivided, two-celled, the cells opening lengthwise. Pollen simple, rarely compound.

Germen of two or four cells, rarely of one only; the seed-masses of the seeds either indefinite or definite, erect; sometimes bearing a gland between the two anterior filaments. Style one, simple, very rarely divided. Stigma lobate, oblate, either undivided or two-lobed, encompassed from beneath with a somewhat membranous, cup-shaped, entire or two-lobed integument, the great peculiarity of the order.

Pericarp, when the number of the seeds is indefinite, a capsule of two cells, rarely four, or sometimes, from the shortness of the partition, of scarcely more than one. Partition mostly parallel, rarely contrary, to the valves, which are either undivided or cleft, bearing the seeds on its margin. When the number of the seeds is definite, one being in each cell, the pericarp is a drupa or a nut, rarely an utriculus (or membranous undividing capsule), bearing the feed from its base.

Seeds often with a thickish coat, sometimes with a hard shell.
clown. Albumen flabby, shaped like the seed, seldom wanting.

Embryos straight, as long as the albumen. Cotyledons of a middling size, often leafy. Plumbago inconspicuous.

These plants are either herbaceous or shrubby, not milky, chiefly found in the southern hemisphere, rarely within the northern tropic. Their paleness when pressed is generally simple, sometimes glandular, rarely tattered. Leaves scattered, without stipules, simple, mostly undivided, sometimes lobed, often toothed. Inflorescence terminal or axillary, various. Flowers dimorphic, very rarely aggregate, yellow, blue or purplish, seldom reddish.

The first section, with indeffinite seeds, contains six genera:

*Goodenia*, *Galago*, *Fortunella*, *Vellina* of Smith, *Lechenaultia* and *Ambition*: the second, with definite seeds, three genera: *Scaevola* of Limnace, much augmented, *Diaspia* and *Ampela*: the third, section, with a single-seeded *utricularia*, is contrived to admit the *Brunnula*, named after the worthy and intelligent author, by Dr. Smith in the tenth volume of the Linnaean Society’s Transactions not yet published. The place of this genus in a natural series is extremely difficult to determine. It agrees with the *Goodeniae* chiefly in having an integument to the stigmas, but in habit, aggregate flowers, four distinct bracts, and some other marks, agrees with the *Dipsosea* of Jaffeur, to which it is referred, not without doubt, in the Linnean Transactions. It consists of two species, *Brunnula fricii*, and *australis*, herbaceous plants, with the aspect of simple-leaved *Scaevola*.

**GOODEROE**, in *Geography*, a town of Abyssinia; 24 miles S.S.E. of Mience.

**GOOD HOPE, or HOPE ISLAND**, an island in the S. Pacific ocean, discovered by Le Maire and Schouten in 1616. The land is mountainous, not very high, and abounds with cocoa-nut trees; the coast affords no anchorage. S lat. 16° E. long. 174° 15′. — Alfo, the name of a Danish colony in West Greenland. N lat. 64°.

**Good Hope, Cape of.** See Cape.

**GOODIA**, in *Botany*, in memory of Mr. Peir Good, an industrious gardener, employed in collecting seeds in New South Wales for the Kew garden. He died, some years since, in that remote country, and Mr. Brown has always been so sensible of his merits, that he has long defined a genus to his honour. — Salif. Parad. Lond. t. 41. Sims in Curt. Mag. t. 598.—Chaff and order, *Diadelphus Decandria*. Nat. Ord. Papilionaceae, Linn. Leguminoseae, Jaff.

Eff. Ch. Calyx two-lobed; the upper cleft, broad and short. Legume flat, compressed, flat at the upper edge, of one cell. Seeds two.

ObBiz. This genus, as Dr. Sims observes, ought to be placed next to *Bojetia*, Tr. of Linn Soc. v. 9, 302; from which it differs essentially in its legume, which has no dilated thickened edges, nor is it internally fleshy nor many-celled. The flowers are truly diad. In which it differs from *Crotalaria*, as also in not having an inflated legume, though its habit comes nearest to that genus.

Two species are known.

1. *G. lobifolia*. Curt. Mag. t. 958.—Leaflets smooth, as well as the branches and flower-stalks.—Native of Van Diemen’s land. One of the first New Holland plants raised in this country, and very hardy in the green-house, possibly able to bear our climate. Mr. Aiton favoured us with specimens from Kew in 1796. It is a delicate smooth *fruab*, with tarmate somewhat glaucous leaves, and terminal clusters of numerous yellow flowers, the bafe of whole standard, and part of the wings, are flamed with crimson, as in many New Holland flowers of this family. The legume is somewhat ovate, with a taper base, smooth, but marked with numerous, transverse, parallel, reticulate veins. One seed only is usually perfect.

2. *G. pulchella*. Curt. Mag. t. 1332.—Leaflets downy, as well as the branches and flower-stalks.—Very like the former, and brought from the same country. It flowered at Mr. Lodige’s at Hackney. We think with Dr. Sims it has sufficiently the aspect of a distinct species, thought it downy, often a variable circumstance, affords the only specific character. The leaflets in the plate do not answer to its definition of obcordate, and we believe they vary in shape, as in many leguminous plants.

**GOODIANELLI, in Geography, a town of Hindoostan, in Myfore; 19 miles N. of Seringapatam.**

**GOODMANELLE, a town of Hindoostan, in My- forest 20 miles W. of Bangalore.**

**GOODLICK BAY, a small bay in the strait of Magellan, entirely surrounded by rocks. This bay supplies a little wood, and plenty of good water, but it is very difficult of access. S lat. 53° 23′; W. long. 74° 33′; Variation two points easterly.**

**GOODNESS, in Theology, expresses one of the attributes of the Deity, sometimes denominated Benevolence. (See Attributes and Benevolence.) Dr. Paley, in his “Natural Theology,” illustrates and proves the divine goodness by two propositions, which may be evinced by observations drawn from the appearances of nature. The first of these propositions is, that in a vast plurality of instances in which contrivance is perceived, the design of the contrivance is beneficent. No productions of nature display contrivance so manifestly as the parts of animals, and all these parts have a real, and with very few exceptions, a known and intelligible subserviency to the use of the animal. Nor is the benevolent design of the creator abortive. The world, made with this design, is a happy world. The air, the earth, the water, teem with delighted existence. This argument is stated by the author in his “Moral Philosophy” in the following manner; “Contrivance proves design; and the predominant tendency of the contrivance indicates the disposition of the designer. The world abounds with contrivances, and all the contrivances which we are acquainted with are directed to beneficial purposes. Evil no doubt exists; but is never, that we can perceive, the object of contrivance. Teeth are contrived to eat, not to ache; their aching now and then is incidental to the contrivance, perhaps inseparable from it; or even, if you will, let it be called a defect in the contrivance; but it is not the object of it. This is a distinction which well deserves to be attended to. In describing improvements of husbandry, you would hardly lay your finger on the sickle, that it is made to cut the reaper’s hand, though, from the contruction of the instrument, and the manner of using it, this mischief often follows. But if you had occasion to describe
GOO

describe the instruments of torture or execution, this engine, you would say, is to extend the fines; this to dislocate the joints; this to break the bones; this to scourch the soles of the feet. Here pain and misery are the very objects of the contrivance. Now, nothing of this sort is to be found in the works of nature. We never discover a train of contrivance to bring about an evil purpose. No anatomist ever discovered a system of organization, calculated to produce pain and disable; or in explaining the parts of the human body, ever said, this is to irritate; this to inflame; this duct is to convey the gravel to the kidneys; this gland to produce the sweat; this organ, if by chance, he come at a part of which he knows not the use, the moat he can say is, that it is useless; no one ever suspects that it is put there to incommode, to annoy, or to torment."

Our author's second proposition is, "that the Deity has added pleasure to animal sensations, beyond what was necessary for any other purpose, or when the purpose, so far as it was necessary, might have been effected by the operation of pain." There is a class of properties, pertaining to animals, which may be said to be superadded from an intention expressly directed to happiness; an intention to give a happy existence distinct from the general intention of providing the means of existence, with which other capacities are connected; and that is, of capacities for pleasure, in cases, wherein, so far as the conservation of the individual, or of the species, is concerned, they were not wanted, or wherein the purpose might have been secured by the operation of pain.

The provision which is made of a variety of objects, not necessary to life, and administering only to our pleasures; and the properties given to the necessities of life themselves, by which they contribute to pleasures as well as to preservation; shew a farther design than that of giving existence. This observation is illustrated by our ingenious author in a variety of familiar instances, deduced from the senses of taste, hearing, smell, and sight. The senses appear to be specific gifts, ministering not only to preservation, but to pleasure.

But the senses, as they are usually called, are far from being the only vehicle of enjoyment, or the whole of our constitution, which is calculated for the purpose. We have many internal sensations of the most agreable kind, hardly referable to any of the five senses. Besides these there are exercises of the understanding in volition, &c. of the imagination, and of other faculties of the mind, which furnish unmix'd gratifications, without any counterbalancing pains. Whilst the above-mentioned propositions can be maintained, we are authorized to ascribe to the Deity the character of benevolence; and what is benevolence at all, null in him be infinite benevolence, by reason of the infinite, that is to say, the inexcusably great, number of objects, upon which it is exercised. But besides the evidences of divine goodnes that are furnished by a survey of the creation of the world, and especially of mankind; the same attribute is evinced in the providential government of the universe, and in the extraordinary means which the Deity has soled and pursued for mitigating the present condition of the human race, for recovering mankind from the degeneracy and misery that have prevailed in consequence of their own folly and vice, and for conducting them to the perfection of knowledge and virtue, and a happy immortality in a future world.

The character and undertaking of Jesus Christ, and all the benefits that redound to mankind from his mission and mediation, reflect peculiar luster on the benevolence of the Deity.

GOODOR, in Geography, a town of Hindoostan, in Coelonda; 35 miles S.E. of Warangole. — Also, a town of Hindoostan, in the circle of Adoni; 15 miles N.N.E. of Condumore.

GOODS, in Mining, signify, in Derbyshire, the large and sizable lumps of lead ore, otherwise called binding or potter's ore.

GOODS, among public brewers, denote the malt or grains and liquor in their muth-tun.

GOODS, bona, in Law, and particularly the Civil Law, include all kinds of effects, riches, lands, possessions, &c. There are two kinds of goods; moveable, re movenles, or mobiles; and immovable, called res non movenles, or immobiles.

It is a maxim in the civil jurisprudence, that he who confounds the body, confects the goods; meaning, that all the effects of a person condemned to a capital punishment, or perpetual banishment, are forfeited to the king.

A man is said to bind himself body and goods; meaning, that besides his goods, he obliges his person, and submits to remain in prison, provided he do not execute his promise.

Goods, again, are divided into, 1. Proper, patrimonial, hereditary; 2. Acquired or acquit; also quin bera; ditatis juris acqinlit, and, 3. Conquella; vero & uxoria familia acquisita.

Goods, again, are divided into real and personal. (See Chattels and Estate.) And, lastly, into noble or free, and servile or base.

Goods belonging to the domain of the crown, ad ferae speciulit, cannot be alienated for ever, unless it be done by way of exchange; they may be sold under the faculty of perpetual redemption.

Goods, Adjuvutia, adventitia, are those which arise otherwise than by succession, from father or mother; or from direct ancestor to descendant. See Adventitious.

Goods, Dotal, dowina, those accruing from a dowry, and which the husband is not allowed to alienate. See Dowry.

Goods, Fugitive. See Fugitive.

Goods, Paraphernalia. See Paraphernalia.

Goods, Prohibited. See Prohibited.

Goods, Presumptuous, profistititius, are those arising by direct succession.

Goods, Receiptments, were those which the wife might receive the full property of to herself, and enjoy them independently of her husband; so called, in distinction from dotal and paraphernal goods.

Goods, Patrimo, or patrimo, are those abandoned, or left at large, either because the heir renounces them, or that the default has no heir. See Bona.

Goods, Alloting. See Alloting.

Goods, Consequent. See Consequent.

Goods, Running. See Running.

GOODWIN, John, in Biography, a learned divine in the seventeenth century, who is said to have made more noise in the world than any other person of his age, rank, and profession. He was born in 1595, and received his academical education, at Queen's College, Cambridge; he was immediately after he was admitted to orders, he was much admired for the erudition and elegance which distinguished his pulpit compositions. In 1633 he was induced to the living of St. Stephen, Coleman Street, London, from which he was ejected in 1645, because he refused to baptize the children of his parishioners promiscuously, and to administer the sacrament to his whole parish. He embraced the Armenian doctrines, and eagerly pleaded their cause in his sermons and writings, he adopted and maintained the independent form of church government.
government, and he was reckoned to be exceedingly faithful and courageous in attacking or repelling those who opposed him. His tenets were not those generally embraced, and at one period he is characterized as a man by himself; as being against every man, and having almost every man against him. He had a clear head, a fluent tongue, a penetrating spirit, and a marvellous faculty in debating on scripture. In politics he was a decided and strenuous republican, and, being eager in whatever he engaged, distingushed himself by his discourses and writings to promote, and afterwards to justify, the condemnation of the king. He lived, however, long enough to feel the weight of government directed against himself and his writings. He was obliged to abdicate for a season, and one of his pieces was burnt by the common hangman, and in the same fire which executed his commission on the "Defenso pro populo Anglicano," by John Milton of immortal memory. The friends which his Arminian principles had procured him, found means to pacify the people in power, and to allure themselves that Goodwin should not be prosecuted for the part which he had taken in the late reign.

He returned from solitude, and became minister of a private congregation in the neighbourhood of Coleman street, and, disapproving of the act of uniformity afterwards passed, continued a dissentier from the established church of the Independent denomination, till his death in 1665, in the seventy-second year of his age. His works, which are chiefly theological, are very numerous, among which the following may be mentioned; "Redemption Redeemed," in folio. "The divine Authority of the Scriptures," 4to. "An Exposition of the ninth Chapter of the Epistle of St. Paul to the Romans," 4to. Neal's Hist. of the Puritans, &c.

Goodwin, Thomas, who is styled by Anthony Wood "One of the Attalies and patriarchs of independency," was born in the year 1600 at Redby in Norfolk. Having received the elements of a grammatical learning, he was sent, when he was thirteen years old, to Christ-church college, Cambridge, where he applied himself with so much diligence to his studies, as to secure the esteem of his teachers, and to attract much notice in the university. In 1629 he was removed to Trinity Hall, of which he became a fellow. He soon felt a decided inclination to the views and sentiments of those who were denominated Puritans, and taking them as his models, he prepared himself for the office of a Christian minister. It is not known when he took orders, but he was elected lecturer of Trinity church, in Cambridge, in the year 1628, and in 1632 he was presented by the king to the vicarage of the same church. In these employments he was greatly admired and followed by the Puritans, who began to look up to him as a leader, but becoming dissatisfied with the terms of conformity, he relinquished his preferments, and quitted the university in the year 1634. In 1639 he was elected as an object of persecution by the episcopal consistory, and to enjoy liberty of conscience he fled to Holland, where he was chosen pastor to an independent congregation at Arnhem. During the sittings of the Long Parliament he returned to London and became pastor of a church there, and also a member of the assembly of divines. His conduct, in their various meetings, and his zealous support of the Presbyterian, contributed to render him a favourite with Cromwell, through whose influence he was, in 1650, made one of the commissioners for the approbation of public preachers, and also appointed president of Magdalen college, Oxford. Here he formed a church upon the independent plan, and was exceedingly diligent in promoting the interests of learning and piety. His public duties as a preacher did not prevent him from those studies which enabled him to become distinguished as a writer. He attended Cromwell upon his death-bed, and was overheard to express himself boldly and enthuastically confident of the protector's recovery; and it is affirmed that when the event proved him mistaken, he exclaimed in a subfrequent address to God "thou hast deceived us, and we are deceived." After the restoration he was dismissed from his presidency, when he retired to London, where, however, he was permitted to continue in the exercise of the ministry till his death in 1679, when he had attained to his eightieth year.

He was a considerable scholar, and a learned and eminent divine. In the common register at Oxford he is described "in scriptis in re theologicae quam plurimos Orbi notus." He was a high Calvinist, but while zealously endeavoring what he conceived to be the doctrines of Christianity, he did not forget to enforce by every incitement in his power the necessity of pure moral conduct. He was author of numerous pious and controvertical pieces, sermons, expositions, &c. some of which were printed during his life time, and inserted, after his death, in a collection of his works published in five volumes folio, which continue to be read and quoted by Calvinites of the present day. Neal's Hist of Puritans, by Toulmin.

Neal's Hist of Puritans, by Toulmin.

Googoo, in Geography, inhabitants of the inland territory of the island of Sumatra, covered with long hair, and little superior to the orangs outangs of Borneo. See Sumatra.

Googoor, a town of Hindooilan, in Sanore; 25 miles N. N.W. of Sanore.

Googul, a river of Hindooilan, which rises near Burwany, and runs into the Tapty, 8 miles S. of Chaprah.

Goot, signifies a ditch or trench for water; called also a goit, gurt, lunt, &c.

Gooole, a breach in a sea-bank or wall; or a passage worn by the flux and reflux of the sea. Vide 16 and 17 Car. II. cap. 11.

The word comes from the French, goilet, the gullet or neck.

Goolunge, in Geography, a town of Hindooilan, in the cireer of Chanderce; 25 miles E. of Chanderce.

Goolah, a small cireer or province of Bengal, situated E. of Coor-Beyhar.

Goomah, a town of Bengal, 45 miles N. of Ramgar, N. lat. 24° 25'. E. long. 85° 34'.—Allo, a town of Hindooilan, in Bahar; 40 miles N.E. of Chittara.

Gombo, a town of Africa, in Cambara. N. lat. 15° 31'. W. long. 5° 10'.

Gomboano, a town of Africa, in Kaflan. N. lat. 14° 20'. W. long. 8° 50'.

Goomong, a town of Hindooilan, in Berar; 12 miles S. of Nagpur.

Gomerfun, a town of Hindooilan, in Oude; 16 miles S.W. of Azimgur.

Gompinna, a town of Hindooilan, in Colconda; 20 miles N. E. of Cullor.

Goomrepor, a town of Hindooilan, in Alaha-bad; 20 miles E. N. E. of Jumport.

Goomty, a river of Aifs, which rises in the moun-
tains of Kededon, and crossing the country of Oude, enters the Ganges, about 15 miles N. of Benares.

GOOUGANGAY, a small island in the East Indian sea, near the N. E. coast of Cutch. S. lat. 8° 10' E. long. 110° 24'.

GOONDWHANAH, the ancient name of the province of Nagepore, which also—Allo, mountains of Hindooftan, called "Kummnah." situated in the S. E. part of the country of Malwa, extending from Huffingabad to Munderah, about 170 miles long. N. lat. 22° 40', to 23° 1 E. long. 78° to 81°.

GOOPAMOW, a town of Hindooftan, in Oude; 20 miles W. of Kairabed.

GOOPIJUNGE, a town of Hindooftan; 32 miles W. of Benares.—Allo, a town of Hindooftan, in the four-bah of Agra. N. lat. 26° 24'. E. long. 79° 18'.

GOORACKPOUR, a province of Oude, bounded on the N. by Thibet, on the E. by Bettish and Sarum, on the S. by Gazypore, and on the W. by Oude proper and Bahrait, about 60 miles long and 50 broad. The capital of the same name is situated 65 miles E. of Pysabad. N. lat. 26° 44'. E. long. 83° 30'.

GOORAH, the name of two towns of Hindooftan; one in Oude and another in Allahabad.

GOORUNTY, a town of Hindooftan, in the circur of Cicaole; 17 miles S.W. of Ganjam.

GOOS, a town of Nubia. N. lat 18'. E. long. 34° 18'.

GOOSANDER, in Ornithology. See MERGUS MERGANFER.

GOOSE, Anser, forms an order of birds in the Linnean system. (See ANSEREN.) The several species of geese belong to the genus of anas or duck under this order. See DUCK.

Goose, a well-known bird, which, in many situations, may be highly beneficial to the farmer, as, where there are large waters and commons, and where the flubbles are abundant. It is valuable both for its flesh, fat, and feathers.

The varieties of geese are numerous, but the large common kinds are probably the best for the uses of the farmer.

GOOSE, Ember. See COLUMBUS EMMER.

GOOS, Selan or Solan, sometimes called goamer, the English name of a large water-fowl, called by authors Alector Bifflanus, and by LINNÆUS PELICANUS Bifflanus, which see.

Goos. Crest, in Geography, a river of New Jersey, which runs into the Atlantic, N. lat. 39° 53'. W. long. 74° 16'.—Allo, a river of Kentucky, which runs into the Ohio, N. lat. 38° 16'. W. long. 86° 3'.—Allo, a river of North Carolina, which runs into the Atlantic, N. lat. 34° 40'. W. long. 77° 21'.—Allo, a river which falls into the Potowmac, about a mile S. E. of Thorp's, in Fairfax county, Virginia.

GOOS, ding, in Agriculture and Medicine. See DING and CHEMOPHYTA.

GOOS, gorse, or Wild Garuge, or Good Henry, in Botany. See CHEMOPHYTA.

GOOS-graps, the common name of a troublesome weed that is frequently met with on chalky soils. It is best destroyed by cutting it in the summer, and keeping the land under the plough in good condition. See Galium aparine.

GOOS-graps, Great. See ASPERAGO.

GOOSE Island, in Geography, a small island in the gulf of St. Lawrence, near the coast of Labrador. N. lat. 50° 52'.

GOOSE Lake, a lake of North America. N. lat. 62° 57'. W. long. 94° 45'.—Allo, a lake of North America. N. lat. 54° 30'. W. long. 101° 21'.

GOOS-necked, in Sea Language, is a sort of iron hook fitted into the inner end of a boom, and introduced into a clamp of iron or eye-bolt, which encircles the mast, or is fitted to some other place in the ship, so that it may be unholed at pleasure.

Goose River, in Geography, a river of America, which runs into the Mississippi. N. lat. 43° 14'. W. long. 93° 56'.—Allo, a river of Carolina, which runs into Cooper's river. N. lat. 33° 2'. W. long. 79° 57'.

GOOS, weaving of a sail, in Sea Language, denote the lower corners of a ship's main-sail, or fore-sail, when the middle part is unfurled or tied up to the yard.

Gose-coing, at Sea, a certain manner of fitting a sail, when there is a bed of light earth wind before a wind, or with a quarter-wind, and in a fresh gale, the kaimen sometimes, to make the more bails, unpair the mizen-yard, and then they launch out both yard and yard over the quarter on the lee-side, fitting guyes at the farther end, to keep the yard steady with the boom, and this booms out the mizen-sail. This they do to give the ship the way more, which otherwise, with these winds, the mizen-sail could not do; and this sail, so fitted, is called a goos-coing, and sometimes a fludding-sail.

GOOSEBERRY Bush, Grossularia, in Botany, is a species of the ribs in the Linnean system. See Ribes.

The gooseberry-bush is propagated either by suckers or cuttings, but the latter way is preferable, as the roots are less subject to shoot out suckers afterwards.

The bell Axion for planting the cuttings is in autumn, just before the leaves begin to fall; observing always to take the handiomed shoots, and to pick them from such branches as produce the greatest quantity of fruit. The cuttings should be about six or eight inches long, and should be planted in a bed of light earth exposed to the morning sun; they must be planted about three inches deep, and watered to help their taking root. The shoots should be rubbed off from these plants as they put out, except those at the top, that there may be a regular stem. In the October following, they should be removed to a bed of fine light earth, and planted in rows at three feet distance, and one foot afiinder in the rows. They should remain here one year, and the rows branches at times be cut off, as also the lower ones, so as to keep a clean stem about a foot above the ground. They will be then fit to plant out where they are to stand, which should be in a light sandy loam. They should be kept from the shade of other trees; and to have the fruit in its utmost perfection, should be set in an exposed place in rows of eight feet afiinder, and each of the irhabi six feet from the others in the rows. The bell time for transplanting them is in October, when the leaves begin to decay. Miller.

GOOSEBERRY, in Agriculture, is a plant that may sometimes be employed in the forming of hedge-fences, especially that forl noted in the North by the title of Ironmugger.

GOOSEBERRY Caterpillar, in Gardening, the common name of a very destructive insect to the gooseberry and some other plants. Many different methods of destroying it have been proposed, but with little success.

GOOSEBERRY of Barbados. See CACTUS.

GOOSEBERRY Tree. See MELASTOMA.

GOOSEBERRY-galls, in Natural History, the name given by
authors to a species of protuberances of the gall kind, found very frequently on the oak. They are of a roundish figure, and sometimes adhere to the tree by a short pedicle, but more frequently by a part of their spheric surface. They are usually found on the under side of the leaves of the oak, but sometimes on the young shoots, and sometimes on the pedicles of the leaves.

They are most frequent in spring, but they are found at all times when the leaves are upon the trees. These galls are green at first, and afterwards become yellowish, and finally red, in which last state they very much resemble the small red gooseberry. They are very soft to the touch, and when opened are found to contain a juicy substance, with a cavity in the middle, in which there is lodged a single insect. This, according to the time in which the gall is opened, is found in the form of a white worm, or else of a white chrysalis, or finally of a small short-bodied four-winged fly of a black colour; for the creature does not leave the gall to go through any of its changes, but passes all its states in it. The gall, in all these cases, is found whole and unruptured; but if only is opened in which there is a hole pierced, this is sure to be found empty, that being the palliation by which the fly has made its way out. Reaum. Hift. Inf. vol. vi. p. 214.

Goosberry Islands, in Geography, small islands near the E. coast of Newfoundland; 24 miles N. W. of Cape Bonavista.

Goosberry Rocks, dangerous rocks lying on the coast of East county, in the state of Massachusetts.

GOTTA, a town of Hindostan, in Goomnawah; 10 miles S. of Nagpour.

GOTTO, a town of Hindostan, in the c circuit of Ruttunpour; 5 miles S. of Ruttunpour.

GOTY, or GUTI, a town and fortress of Hindostan, the capital of a district in Myfor; 170 miles N. of Seringapatam. It is situated on a hill beyond the river Penjar, or Penaur, and towards Adoni; and was formerly the seat of government of a Mahattia prince; but at the death of Tippoo, the town and district were alligned to the Nizam. N. lat. 15° 15'. E. long. 77° 48'.

GO-OUT, in Mining, is sometimes used to express the appearance of the edge of a frature at the surface; otherwise called the fault, crop, out-going, or out-burst of that frature; and such fractures are said to go-out, burst-out, run-out, head-out, want-cover, &c.

When the ore in a vein suddenly ends in the dead or gangue, it is said to go-out; also, when a frature of coal ends abruptly against a fault, or wall of gravel filling a fault, or fault under a heap of gravel, as is not uncommon in the south of Derbyshire, it is said to go-out, and so of the irregular or feather-edge marks which are sometimes met within the frature accidentally, or without being continuous like all the regular frature, however thin.

GOPALCHITY, in Geography, a town of Hindostan, in Cimbetore; 18 miles N.W. of Erroad.

GOPALPUNGE, a town of Bootan; 58 miles N. of Dinageproy.

GOPALNAGUR, the name of two towns in Bengal; one 25 miles S.S.E. of Kithenagur, and another 30 miles E.S.E. of Dacee.

GOPALPROO, the name of several towns in Hindostan, one 8 miles N. of Hurdah, a second, 12 miles N. of Goragot, a third, 15 miles N. of Garrah, a fourth, 23 miles S. of Bahar, a fifth, 20 miles N.W. of Nara, a sixth, 20 miles S. of Gourackpore, a seventh, 28 miles S. of Fyzabad, an eighth, 25 miles N. of Amidea-bad.

GOPALDROOG, a furtrel of Mylore; 36 miles E. of Seringapatam.

GOPAULGUNGE, a town of Bengal. N. lat. 23° 2'. E. long. 89° 56'.

GOPALNAGUR, a town of Bengal, 42 miles S. of Hurdah. N. lat. 22° 31'. E. long. 88°.

GOPBER, a town of Bengal; 15 miles N.E. of Ramgar.

GOPERAPILLY, a town of Golconda; 20 miles E.S.E. of Hyderabad.

GOPHNA, GOPNITHI, or Gopnath, in Ancient Geography, a town of Paleafide, and chief place of one of the ten toparchies of Judah. Esnuffles places it fifteen miles from Jerusalem, towards Sichem.

GOPLO, in Geography, a lake of Poland, in the palmatinne of Brzece, 16 miles long, and four wide.

GOPPINGEN, a town of the kingdom of Wurtemberg, situated on the Vils, in a fertile country, having considerabler woodlen manufactures, and near it a medicinal spring; 20 miles N.W. of Ulm. N. lat. 48° 47'. E. long. 9° 47'.

GOR, a town of Persia, in the province of Farifik; 57 miles N.W. of Schiras.—Also, a town of Italy, in the department of the Nela; 8 miles S. of Brescia.

Gos, a name given by some writers to a very lofty tree, which bears a fruit like the chestnut; it grows principally on the banks of the river Niger, and that not near the sea, but far up the country.

Gor-cock, in Ornithology, the name of a gallinaceous kind, called by authors the lagopus altera, and by many the moor-cock, or red game; it is of the shape of the partridge, but is half as large again. See Grous and Tetrao Lago.

GORA, in Geography, a town of Hindostan, in the circuit of Chundal; 20 miles W. of Saipur.

GORACALLY, a town of Bengal; 12 miles S.S.W. of Mahmudough.

GORAGOT, a province of Bengal, bounded on the N. by Rungpur, on the E. by Radjochow, Patladah, and Ulimabad, on the S. by Bettorish and Pargamun, and on the W. by Dinagepore; about 55 miles long, and from 12 to 30 broad. Its capital, Goragot, is distant 80 miles N.E. from Meerchandabad. N. lat. 25° 14'. E. long. 89° 22'.

GORAI, a town of Poland, in Galicia.

GORAM, a small island, being one of the Maluccas, in the East Indian sea. S.E. of Ceram; reputed the most eastern boundary of M.antomatan. It has thirteen mouths. S. lat. 3° 42'. E. long. 121° 36'.

GORANTO, a town of Atalic Turkey, in Caramanin; 80 miles S.W. of Satalia.

GORAPARI, a town of Brazil, at the mouth of a river of the same name, which runs into the Atlantic. S. lat. 25° 20'.

GORARA, a town of Coreia; 8 miles N.E. of Calvi.

GORBATA, a town of Africa, in Bleedelgerid, anciently "Obitha"; 12 miles S.W. of Gafsa.

GORBATOV, a town of Russia, in the government of Novgorod. N. lat. 50° 3'. E. long. 43° 14'.

GORCA, See Gorahit.

GORCE, or Gour, denotes a weir. By flat. 25 Edw. III. cap. 4 it is ordained, that all gorges, mills, weirs, &c. leved or let up, whereby the king's shaps and boats are disturbed, and cannot pass in any river, shall be utterly pulled down, without being renewed. Sir Edward Coke derives this word from gurget, a deep pit of water, and calls it
it a gurz, or gulf; but this seems to be a mislake, for in
Doomday it is called gurt and gurt, the old French word for
a weir.

GORCHWICH, in Geography, a town of Saxon, in the
Vogtland, 18 miles S.S.W. of Gera. N. lat. 50° 22'.
E. long. 11° 53'.

GORMAN, probably a corruption of Gerichen, a

town of Holland, situated on the river Linge, at its union
with the Wahle. From the Steele of the principal church
may be seen 22 walled cities, besides a great number of
towns and villages; before the revolution it had one paroch-

cchurch, and three religious houses; 12 miles E. of Dort.
N. lat. 51° 52'. E. long. 4° 50'.

GORDENE', in Ancient Geography, a country of the
Greater Armenia, according to Ptolemy; which country is
called "Gordyene" by Strabo and by Plutarch in his life of
Lucullus.

GORDES, in Geography, a town of France, in the de-
partment of Vaucluse, and chief place of a canton in the
district of Apt; 9 miles W. of Apt. The place contains
2812, and the canton 6450 inhabitants, on a territory
of 1671, kilometres, in 8 communes.

GORDENWEAR POINT, a cape of Hindooflan, on
the coast of Rajamundry, at the mouth of the Godavery.
N. lat. 16° 42'. E. long. 82° 28'.

GORDIÆUS Monx, in Ancient Geography, a mountain of
the Greater Armenia. Ptol.

GORDIANI, M. ANTONIVS-GORDIANUS, in Biography,
Roman emperor, born A.D. 157, was son of Mucius Ma-
runnus, a senator descended from the Grachi, by Ulpia
Gordiana, of the family of the emperor Trajan. He became
possessed of a great estate, with which he lived in a style of
magnificence, but without puffing the bounds of moderation.
He was a patron of literature and literary men, and a pro-
ficient in eloquence and poetry. He wrote a poem in thirty
books, to celebrate the reigns of Titus and M. Aurelius An-
tonium. When he served the office of edile, he enter-
tained the people with a splendour which no private peron
had for a long time exhibited, and his shows were exhibited
every month in the year W. 1 he was in office. There is,
however, no reason for supposing that he was over ambitious
of coming forwards into public life, for it was not till his
fifty-fifth year that he was elected consul in conjunction with
the emperor Caracalla. He might, perhaps, be unwilling
to rife the safety of his person in those turbulent times;
and it has been thought extraordinary that under so jealous a
tyrant he should venture upon the profuse expences which
distinguished his conduct not only in the imperial city, but
in various parts of Italy also. He enjoyed the fame honour
a second time in the reign of Alexander Severus, who ex-
pressed his high esteem for him by confirming his nomination
to the government of Africa as proconsul. In this impor-
tant post he displayed so much equity and beneficence, that he
was more beloved in the province than any of his predecessors.
Under the emperor Maximin, in the year 237, a sedition
was excited against the capacity of an officer in the government
of Africa, and the perpetrators, to avoid the vengeance of a
cruel and incensed sovereign, appeared in open rebellion
and inflamed upon Gordian's inflaming the purple. He re-
monstrated with the conspirators, but their resolution was
formed, and at the age of forty-four he was forced to ap-
pear in a character, after which he had never aspired. They
associated with him, to alleviate his cares, the younger Gor-
dian, a man of voluptuous habits, but who was of a mild
disposition, and attached to letters. A library of sixty-thou-
sand volumes, bestowed him by his tutor Serenus Sammon-
nicus, gave him reputation in the literary world, which he
maintained by writing both in prose and verse. This young
man had been elevated to the office of quaesitor by the defd-
cable Heliogabalus; nevertheless, the confidence placed in
his integrity, and knowledge of the laws, by Alexander,
who created him prefect of Rome, and who always paid
great deference to his advice, was much in his praise. He
shone in the elevation of his father, and they were declared
joint emperors. The Gordians removed to Carthage, whence
they sent letters to Rome, announcing their election. Maxi-
min was at that time absent, and the senate willingly func-
tioned the choice of the Africans, and declared Maximin a
public enemy. In the mean time, a change took place in
Africa, which annulled all their projects. Capelanium, go-

governor of Mauritania, who had been always upon ill terms
with Gordian, assembled a body of veterans, declared for
the reigning emperor, and marched to Carthage. The youn-
ger Gordian falled out to oppose him with his guards,
but he was soon defeated and slain. Capelanium entered the
city, which so much alarmed the elder Gordian, that to
prevent his falling into the hands of his enemy, he strangled
himself in his apartment with his girdle. This event hap-
pened in June 237, and within a few weeks of his assuming
the office of emperor. Gibbon.

GORDIAN III., Roman emperor, grandson of the elder
Gordian, was but thirteen years old when he was chosen
emperor, in connection with Maximins and Balbinus. He
was created Caesar, and assumed the family name. His two
colleagues were in a few months murdered by the Pretorian
bands, and the youthful Gordian remained sole emperor.
His person and manners excited universal favour, and the
senate, people, and army united in giving him the endearing
appellation of their son. In the commencement of his
reign he was governed by his mother's counsellors, who abdied
his authority, and let the honour and offices of the empire fall to
sole. He was, however, happily rescued from this disgraceful
condition by Mithridates, a man of learning, to whom he was
also indebted for literary instruction and advice. In the
year 234 he married the daughter of Mithridates; and rais-
ing his father-in-law to the poel of prefect-praetorio; com-
mitted him to the principal direction of public affairs. It
proved himself worthy of the important trust confided in him,
and discharged the duties of a statesman and general, as well
as he had maintained those of a more private station. By
his persuasion, the young emperor accompanied him in 242, in
an expedition to the East, for the purpose of repelling an
invasion from Sapor king of Persia. Under his guidance, Gor-
dian relieved Antioch, crossed the Euphrates, defeated Sa-
por, and recovered the whole of Mesopotamia. The young
emperor did not assume the glory of the deeds, but, in a
letter to the senate, announcing the success, he modestly
acquits them to the conduct, the experience, and wisdom of
Mithridates, who shortly after died. During the whole ex-
pedition Mithridates had watched over the safety and discipline
of the army, while he prevented their murmurs by maintain-
ing a regular period in the camp, and by establishing ample
magazines of vinegar, bacon, flour, barley and wheat, in
all the cities of the frontier. The prosperity of the em-
peror expired with Mithridates; he was succeeded in the office
of prefect by Philip, an Arab by birth, and consequently, as
Gibbon, in the earlier part of his life, a robber by profession.
He was a man of considerable military talents, but ambi-
tious, and delinquent of true moral principle. His energy
and boldness prompted him to aspire to the throne, and his
abilities were employed to supplant, not to serve his indul-
gent master. By his arts discontent was fomented among
the
the troops, which induced them to demand that his minister Philip should be associated with Gordian as partner in the empire. This was not sufficient to satisfy his ambitious views; the young emperor was sacrificed at his instigation; he was put to death near the banks of the Euphrates, in March 244, after a reign of five years and eight months. A sepulchral monument was erected to his memory on the spot where he was killed. Gibbon.

**Gordian**, a term in *History*. Gordian knot was a knot made in the leaves or barks of the chariot of Gordius, king of Phrygia, and father of Midas; so very intricate, that there was no finding where it began or ended.

The inhabitants had a tradition, that the oracle had declared, that he should be master of Asia who could untie this knot. Alexander having undertaken it, and fearing that, if he should not be able to effect it, it would be deemed an ill augury, and prove a check in the way of his conquests, cut it afurden with his sword; and thus, say Quintus Curtius, either accomplished the oracle, or eluded it. But Arribolius gives a different account of this matter. See Arrian, lib. iii. cap. 20. and Plut. in Vit. Alex.

Some will have the phrase derived from Gordius who tied the fatal knot; others from Gordium, a city in Phrygia, where the knot was made.

**Gordium**, in *Geography*, a town of Asia, in Phrygia, situated on the river Sangar; afterwards called Julopolis.

**Gordius**, in *Zoology*, a genus of Vermes, the essential character of which consists in the body being round, filiform, naked or smooth, and of equal thickness throughout.

Linnæus, and after his example the French naturalist Bureau, has placed the animals of this genus among the intestinal vermes, an order of beings to which, from their general structure, they seem to bear no very remote alliance; and this similitude is still more strongly evinced in the habits of those species which occasionally penetrate into the flesh of men and animals, and therein for a while derive their subsistence from the blood and other fluids. Notwithstanding this analogy, under such circumstances we cannot but agree with Lamarck that it is impossible to consider them as internal vermes with propriety, since they only occasionally infest the bodies of animals as before mentioned, and in their habits and manners of life at other periods differ much essentially: they are literally aquatic animals, with carnivorous appetites; though for a certain length of time they can habituate like the true intestinal vermes, when by any accidental circumstance they happen to infest themselves into the flesh of a living animal.

At the head of this tribe we may justly place the species *Acrocephalus*, or hair worm of the Indians, a pernicious creature, referred to the genus Gordias by Linnæus in the latest edition of his *Syst. Nat.* but from which it was afterwards removed by his editor Gmelin to that of Filaria. This removal we deem unnecessary, and under this persuasion with to restore the species to its former situation in the genus Gordius.

**Species.**

This very remarkable creature is often from ten to twelve or even fifteen feet in length, and in thickness not exceeding a horse-hair. It is well known by its diaphanous effects as an inhabitant of both the Indies, where it lives in marshy places, and is frequently observed on the ground in the morning dew. In this situation it easily creeps up, and enwraps itself round the naked legs of the negro slaves, or animals, and penetrating the skin, buries itself speedily in the flesh, where it causes the most violent pains, accompanied with troublesome itchings, and oftentimes inflammation and fever. The most certain means of extricating the worm is to make an incision in the part of the flesh at which its entrance was effected, so as to obtain secure hold of either of the extremities, or the head if possible, and this being made fall to a small flick by means of a piece of silk, the animal may be gradually drawn out of the wound by turning the stick round a little each day. The utmost circumspection is requisite in performing this operation, for if by being too much strained the worm should break, the part remaining within the flesh grows with increased vigour, gangrene appears almost immediately, and death itself ensues very shortly.

This so entirely resembles a hair of from four to six inches in length, that except by its motions it could be in no manner distinguished from a substance of that kind by the casual observer; its internal structure is equally remarkable for its simplicity, consisting merely, as it appears, of a canal extending from one end to the other, and both the mouth and vent are the most simple possible, since a small vent constitutes the head, and a groove or hollow the latter. Its ordinary places of residence are stagnant waters; in pools and ditches, or in very tranquil rivers, as the agitation of turbulent waters would destroy its tender frame. During winter it remains buried deep in the clay, from whence it emerges in spring, and is found in the water during the summer months, where it is frequently observed, and from its appearance is vulgarly imagined to be the offspring of hair, dropped by accident into the water. It twists itself into various contortions; and it is affirmed that its bite will occasion the complaint called a whistow. A fact still more extraordinary, and which appears in some measure to be authenticated with tolerable accuracy, is the retentive power of animation, which this creature possesses in a very superior degree, though not by any means to the extent that certain naturalists conceive. Some writers affirm, indeed, that it has been known to recover the free exercise of its vital functions upon being steeped for a short space of time in water, after having remained in a dried state for weeks, months, and even years, and when of course it might be naturally conceived the most latent spark of life must be extinct. If these latter assurances have not arisen from the result of some very superficial experiments, they are at least to be received with caution, since their observers seem to believe that these animals partook also in some measure of the reproductive properties of the polype, and which more recent observations prove to be erroneous; we cannot, therefore, upon the whole, avoid concluding that although the animals of this kind are extremely tenacious of life, there is no foundation in truth for the very extraordinary assertions above related.

**Archilacus.** Body uniformly yellowish. Linn. *Vitulus aquaticus*.

Very much resembles the hair, and like that species is found in the clay at the bottom of stagnant waters.

**Filium.** Body filiform and whitish. Mull. Extremely slender, tapering at one end, and hyaline. Found in the bark of old wooden pipes which had been placed in the ground for the conveyance of water.

**Lacteus.** Body uniformly white and opaque. Mull. Occurs in myriads in stagnant water from the month of July till September. When touched, this species contracts itself in a moment, and then again expands immediately.

**Armillarius.** Pulvus and obtuse. Mull.

Inhabit
GORDON, Bernard, in "Biography," a French physician of the thirteenth century, is said to have conferred honour on the medical faculty of Montpellier, where he began to teach in the year 1215. As was the custom of the time, he took his surname from the place of his birth, (Gordon in Rouergue,) and called himself Bernardes de Gordon, and not Gordonius, as it is commonly written. According to the accounts of some writers, who place the death of this physician in 1305, he taught at Montpellier only twenty years; but Renen affirms, that he was living in 1318. He left a considerable number of treatises, which were published together at Ferrara in 1487, at Venice in 1494, at Paris in 1542, and at Lyons in 1550. Elyot. Dict. Hist.

Gordon, Mr., in the year 1744 played the first violin in Drury-lane play-house. He was a young man, born in Norfolk, who had travelled to Italy for improvement. He was very near-sighted, and always played in spectacles. He succeeded Charke, who had a strong hand, good tone, and was well fitted to his situation. He generally played a concerto in the second music, as was then the practice, which was very attractive. He was brother to the subject of the following article.

Gordon, ———, an eminent performer on the violoncello, the son of a clergyman in Norfolk, and many years the first violoncello at the opera. He was remarkable for the fulness of his tone, and perfect execution of whatever he undertook, though far surpassed by subsequent players in the use of the bow, and knowledge of the finger-board. He lived reputedly, had many powerful friends, and realised a competence by his profession.

In 1765, Mfrs. Gordon, Vincent, and Crawford, undertook the opera regiment in the Haymarket. The two first were experienced professors, and the third had been many years treasurer under different managers. Gordon, an excellent performer on the violoncello; and Vincent, a scholar of the celebrated Martini, long a favourite on the hautbois. His father was a balloon player in the Guards, and his brother, James Vincent, who died young, was joint organist of the Temple with Stanley, and a brilliant performer. Mr. T. Vincent, the impresario, had been in great favour with the late prince of Wales, father to his present majesty; had acquired a considerable sum of money in his profession, which he augmented by marriage. However, the ambition of command, though of so forward a family as an opera, vocal, and instrumental band, turned his head and his purse infide out; in short, he soon became a bankrupt, sunk into indigence during the eft of his life; and his colleagues, though they cleared utter ruin, were not enriched by the connection.

Gordon, Alexander, a learned writer of the eighteenth century, was a native of Scotland. He was well acquainted with the Greek and Latin languages, and being a good draughtsman, he was enabled to derive pecuniary advantages from a long residence in Italy, and from his travels in other parts of Europe. He was engaged as secretary to the society for the encouragement of learning; and to the Egyptian club, and to the Antiquarian society. He afterwards accompanied governor Glen to Carolina, where he occupied various posts in the province, and received a handsome grant of land. Here he died, leaving a good estate to his family.

He was author of "Itinerarium Septentrionale," or a journey through most parts of Scotland, illustrated with copper plates. This was published in 1726, and in 1732 he gave additions and corrections to it, containing an account of Roman antiquities in Scotland, and ancient monuments in the north of England. He wrote likewise "The Lives of Pope Alexander VI, and his Son Caesar Borgia," "A complete History of ancient Amphitheatres, translated from the Italian." "An Essay towards explaining the hieroglyphical Figures on the Coffin of a Mummy," "Twenty-five Plates of all the Egyptian Mummies in England, and other Egyptian Antiquities." Gen. Biog.

Gordon, Andrew, was born in 1712 near Aberdeen. He was sent to Ratibon, where he applied himself to polite literature. In 1731 he made a tour through Austria, Italy, and France, and on his return in the following year entered into the order of the Benedictines in the Scots monastery, where he applied to philosophy, and was ordained priest. In 1735, he went to Salzburg to study the law, and he attended the theological lectures till he was invited, in 1737, to be professor of philosophy at Erfurt. His discoveries in electricity made his name known to the philosophers in Holland, France, Italy, and England, and he is mentioned by Dr. Priestley as the first person who used a cylinder instead of a globe in electric experiments. His first work on this subject was entitled "Phenomena Elec^tricitatis Exposita," 1744; and in the following year he published in 3 vols. 8vo. "Philosophia ultima et jucunda." He was author of an "Impartial Account of the Origin of the present War in Great Britain," and of "Physica Experimentalis Elementa." Gen. Biog.

Gordon, James, a Scotch Jesuit, was born in the year 1543. He left his native country, and came to Rome, where he entered the society of Jesus, in 1563. He became distinguished for deep and extensive learning, and was sent on religious missions into Germany, Denmark, and the British Isles, where he is said to have suffered much on account of his attachment to the Catholic faith. He died at Paris in 1625, leaving behind him a work in two volumes 8vo, entitled "Controversiarum Christianae Fidelis Epitome.

There was another Scotch Jesuit of the same name, and contemporary with the above, who wrote a commentary on the whole bible, which he published at Paris, in three volumes folio, under the title of "Biblia sacra, cum Commentariis ad ejusam Literae, et explicationum Temporum, Locorum, Rerumque omnium quae in facris Codicibus habent obscuritatem; mona cum Textu Bibliico." This work is well spoken of by Dupin. He was author likewise of a work on Chronology; and of "A System of moral Theology," etc. Moreni.

Gordon, Thomas, a native of Kirkcudbright, in Scotland, after having received an academic education in his own country, came to London, and maintained himself by teaching the learned languages. His talents were made known to people of consequence, and he was employed by the earl of Oxford in queen Anne's reign as a political writer. He wrote in defence of bishop Hoadley in the Bangorian controversy, and became the amiable and partner of Mr. Trenchard, in his literary undertakings. They published, in conjunction, a series of papers, entitled "Cato's Letters," and the "Independent Whig," which Mr. Gordon continued alone after the death of Trenchard. When this event took place, sir Robert Walpole engaged Gordon as one of the writers in defence of his interests, and procured him a place, which he held as long as he lived. Mr. Gordon made himself known by translations of Tacitus and Sallust, as well as by his political pieces. Of these translations he prefixed discourses relative to subjects of each original author. He died in 1756, at the age of sixty-six. Some of his polemical tracts appeared in two works, entitled "A Cordial for Low Spirits," and "The Pillars of Prescifraft and Orthodoxy shaken," etc. He was a distinguished writer in favour of civil and religious liberty, and is highly esteemed.
GORDONNA, in Geography, a town of Naples, in the county of Molife; six miles S.W. of Molife.

Gen. Ch. Cal. Perianth fimple, inferior, of five roundish, concave leaves. Cor. Petals five, large, obovate, or obcordate, concave, cohering at their base, somewhat unequal. Stam. Filaments very numerous, thread-shaped, united at their base into a thick cup-shaped body; anthers oval, erect. Pist. German superior, ovate or nearly globose; style short, columnar, obtusely five-fidged, sometimes five-fidged; stigma five, acute, horizontal. Peric. Capsule ovate or globose, of five cells and five valves, the partitions from the middle of the valves, which are deeply cleft at their base. Seeds in two rows in each cell, angular, winged, inserted into a five-angled central column.

1. G. Lacinatus. Linn. Mant. 176. Curt. Mag. t. 668. Cavan. Diff. t. 161. (Hyperiunum Lacinatus; Linn. Sp. Pl. v. 3. 1101. Alecrora floridana quinqucapellaria, &c.; Plbk. Amell. t. 352. f. 3.) Lobolly Bay.—Flower-talks elongated. Leaves coriaceous, smooth. Capsules ovate.—Native of swamps in South Carolina, where it forms a very handsome tree, but is with great difficulty cultivated in England. It blooms in August and September. We have seen this plant flowering in great perfection at Kew 25 years ago. The leaves are feddar, on short stalks, elliptic-lanceolate, three to five inches long, bluntish, with numerous shallow ferratures, veiny, smooth on both sides, of a fine shining green, like those of Prunus Lauro-cerasus above, paler beneath. Stipes none. Flowers solitary, on leafy axillary inflorescences, twice as long as the footstalks, as large as a moderate rose, white with yellow stamens, very handsome but inodorous. A pair of deciduous fringed bracts, a little below the flower, are called by Cavanilles an outer calyx. Authors have differed about the clafs of this plant in the Linnaean system, the filaments cohering imperfectly and irregularly together in par- als, besides being connected by one common fifieh base. If this base be called a nectary, for which there is no good rea- son, the flower is polyphelous, but we think, with Dr. Sims, and most others, that it is monadelphous.

2. G. Heemskerckiana. Swartz. Ind. Occ. 1190.—Blood- red Wood Tree.—Flower-talks very short. Leaves elliptic-lanceolate, pointed, serrated, smooth. Petals inwardly heart-shaped. Style deep five-fidged. Native of dry woody places on lofty mountains, in the west side of Jamaica; Dr. Swartz, from whom we have specimens. This tree, whose ftem is from twelve to sixteen feet high, with a smooth greyish black, and round fnder flat compound leafy branches, Leaves two or three inches long, scattered, on footstalks, elliptic-lanceolate, tapering at both ends, with a blunff, recurved point, smooth on both sides, less coriaceous than in the former, their margin somewhat revolute, with numerous shallow ferratures. Flowers from the bosoms of the upper leaves, solitary, on very short footstalks, not fo long as the foot- stalks, bearing one or two unequal bracteae; their petals pale flesh-coloured, unequal, deeply lobed, fearfly large as those of G. Lacinatus, but flatter and more spreading. Germin filky, furrowed. Style, according to Dr. Swartz, divided into two, Caffule oblong, rather pointed. Seeds two in each cell, with an abrupt point. This tree was omitted by Dr. Swartz in his Prodromus, and is little known to botanists, having never yet been brought to Europe. It flowers in February and March. The wood is hard and of a blood-red, valued in Jamaica for making ornamental fur- niture, but as yet not known, or not distinguished by Eu- ropean workmen. The peculiar structure of the style does not constitute any generic differentiation here, any more than in the neighbouring genus Stauria. See Sm. Exot. Bot. v. 2. 101.

3. G. palafera. L'Herit. Stirp. Nov. 156. Cavan. Diff. t. 162. Vent. Jard. de la Malmaifon. t. 1. — Flowers nearly fesse. Leaves downy beneath. Capsules globose.—Native of South Carolina, now not uncommon in green-houses, flowering in autumn. A handsome shrub, whole branches, calyx, and the back of its leaves, are clothed with fine white depressede down. The flowers most remarkable those of the fift species, but one petal is considerably more concave than the reft, shorter, and downy, approaching to the nature of the calyx. The flower-stalks are extremely short and thick. Leaves ovato-lanceolate, acute, with shallow ferratures, smooth and of a fine green above. Ventenat's figure, drawn by Redouté, the first in the splendid Jardin de la Malmaifon, is one of the finest representations of a plant that can any where be seen, except that the French mode of printing in colours gives indifferently an idea of a downy surface, so that in this case both fides of the leaves look alike.

4. G. Franklinii. L'Herit. Stirp. Nov. 156. (Franklinia Alata; Marhl. Arb. 49,)— Flowers fesse. Leaves smooth. Capsules globose.—Native of South Carolina. Flowers fesse, solitary, large, white, very much admired in their native country, but we have not heard of their being produced in Europe, nor have we seen even a dried specimen. The caflules, according to L'Heri- tier, is globose and umbilicated. Seeds numerous in each cell, imbricated in two rows, sliefly angular, much like those of the Cyprers, the angles somewhat bordered. Leaves alternate, on short footstalks, oblong, toothed, attenuated at the base, and smooth.—Marshall and Botram say the flowers smell like a china orange, and are often five inches in diameter, the lower petal hollow, enfolding the reft till thy expand, as in G. palafera. It was first observed by Mr. John Bartram in 1762, on the borders of the Alatamaha river, in Georgia.

GORDYONG, in Geography, a town of Hindoosfan, in Vifnapur; 22 miles N.E. of Poonat.

GORE, in Heraldry, denotes one of the regular abate- ments, used, according to Guillim, to denote a coward. It conffils of two arches or curve lines, drawn, one from the mitter chief, the other from the mitter base, and meeting in an acute angle in the middle of the fee-point.

GOREL, or GORE, in Geography, an iland in the German ocean, near the mouth of the Meiife, about 120 miles in circuit; two miles N. of Schoven. N. lat. 41 450

E. long
E. long. 3° 35'.—also, a sea-port town of this island, near the E. coast, on a canal communicating with the Meuse; formerly carrying on a considerable trade, but the harbour is now choked with sand; 6 miles W. of Helvoetfluyts.

Gorse, a small island in the Atlantic, within cannon-shot of the coast of Africa, about two miles in circumference. The air is cool and temperate, being refreshed by alternate breezes from the land and sea. It is almost inaccessible on account of its surrounding rocks; but it has two bays, and a fort with several new buildings constructed by a late director M. de St. Jean, who has also rendered it a very strong place. By means of the inundation of fresh water, many of the vegetables and fruit trees have been discovered; so that the island, once barren and desolate, is now made one of the most fertile, pleasant, and important settlements in Africa. Gorse was ceded to the Dutch in 1617 by a king of Cape Verde, and by them fortified. The Dutch were driven out by admiral Holmes in 1663, and the island was garrisoned by the English. It was two years after taken by De Ruyter, and its fortifications augmented by the Dutch; but in 1667 a French squadron compelled the Dutch to abandon Orange fort, and retire to fort Nassau; but here, incapable of defending themselves, they were obliged to surrender at discretion. Upon the arrival of M. du Caffre, the island was formally taken possession of in the name of the Senegal company, and a treaty was concluded with the king and negroes of the neighbouring country on the same conditions with those by which the Dutch had pollied the island. The conquest was secured to the company by the treaty of Nimegen. The French immediately repaired the forts, and changed their names, calling the lower fort "Vermandois," and the higher "St. Michael." In 1750 Gorse was taken by the English. By the treaty of 1763 Gorse and its dependencies were left to the French. In 1778 it was taken by the English. N. lat. 14° 40'. W. long. 17° 30'.

Goree, a small island on the coast of Brazil, at the mouth of the Rio dos Reves Magros. S. lat. 19° 10'.

GOREING, or GORING, is said of a fall when cut planting, so that it is broader at the clew than at the earing, as all top-falls and top-gallant-falls are.

GOREL, a name or title given to the prince of Georgia. The gertil is always a Mahometan. The sophy of Peria obliges him to observe the religion of the Alcoran, in order to preserve the dignity of goret in his family.

GORES'S Bay, in Geography, a bay on the S. W. coast of the island of Tavay-Poomannoo. S. lat. 43° 12'. W. long. 16° 36'.

GORE'S Island, an island in the N. Pacific ocean, so named by captain Cook in the year 1778. This is a narrow island, particularly at the low necks of lands which form a junction between the hills; it is about 30 miles long from N. to S.E.; and it appeared barren and unhabited. Some settlements were seen. N. lat. 60° 40'. W. long. 172° 30'.

GORESBIDGE, a small town of the county of Kilkenny, Ireland, 51 miles S. from Dublin, on the road to Waterford.

GORLY, a small town of the county of Wexford, Ireland, also called New Borough, which, before the Union, was represented in parliament. It is 45° 1 miles S. from Dublin, and 21 N. from Wexford.

Gorvymountains of Ireland, in the county of Donegal, near Raphoe.

GORG, a town of Mingrelia, on the Black sea; 30 miles S. of Anagrih—also, a river of Naples, which runs into the Liban, in Calabria Citra.

Gorge, in Falconry, is the uppermost bag or remach of a hawk or falcon, being that which receives the food the first.

The gorge, inglialis, is the fame, in birds of prey, with what we call the crop or crop. When the bird is fed, he is said to be gorged.

Gorge, in Architecture, denotes a sort of concave moulding, wider but not so deep as a festoon; used chiefly in frames, chimneypieces, &c.

Gorge of a Chimney, is that part between the chimney and the crowning of the mantle. Of this there are divers forms; straight, perpendicular, in form of a bell, &c.

Gorges is sometimes also used for a moulding that is concave in the upper part, and convex at bottom; more properly called gola and cynatism.

Gorge is also used for the neck of a column; more properly called colamin and gorgerin.

Gorge, in Fortification, the entrance of a Bastion, or of a Ravelin, or other Outwork. See each article.

The Gorge of a Bastion is what remains of the sides of the polygon of a place, after retrenching the curtains; in which case it makes an angle in the centre of the bastion.

In flat bastions, the gorge is a right line on the curtain, reaching between the two flanks.

Gorge of a Half moon, or Ravelin, is the space between the two ends of their faces next the place.

Gorge of the other out-works is the interval betwixt their sides next the ditch.

All the gorges are to be made defillete of parapets; otherwise the besiegers, having taken possession of a work, might make use thereof to defend themselves from the flat of the place: so that they are only fortified with palisades, to prevent a surprize.

Gorex, Half the Gorge, demigorge, that part of the polygon between the flats and the centre of the bastion.

GORGED, in Heraldry, is when a crown, coronet, or the like thing, is borne: about the neck of a lion, a swan, &c. In that case they say, the lion or cygnet is gorged with a ducal coronet, &c.

Gorged is also used when the gorge or neck of a peacock, swan, or the like bird, is of a different colour or metal from the rest.

Gorged, among Farrières, &c. signifies as much as swelled. In which sense they say, the legs of an horse are gorged; the patina-point is gorged; you must wait him out, to digorse his shoulder.

Gorged, in Rural Economy, a term which is sometimes applied to signify being beseen by fresh luxuriant green food, and relates to cattle, &c.

GORGÉRIN, a part of the ancient armour, being that which covered the throat or neck of a peron armed at all points.

Gorgis, or Gorge, in Architecture, the little freeze in the Doric capital, between the aitragal, at the top of the shaft of the column, and the annulet.

Some call it collarine. Vitruvius gives it the name hypo-

Gorget, in Military Affairs, a piece of brass or silver, worn by the officers of foot upon their breasts when on duty. The gorget hangs round the neck by a ribbon; they are sometimes gilded, and have commonly some device engraved on them, as the sovereign's, or even the colonel's coat of arms, crest, or cypher.

Gorget, an instrument used in Surgery, for the purpose of cutting an opening into the bladder, to as to enable the operator to introduce the pair of forceps and extract the stone.
It is impossible to give the reader a proper notion of the form and manner of using the gorgets, without presenting him with engravings of the instrument, and entering into a description of the operation of lithotomy. Hence, we must at present content ourselves with referring to the surgical plates, and the article LITHOTOMY.

Besides cutting gorgets, constructed for the above design, there are also blunt ones, intended to be introduced into the wound, when their concavity serves as a guide for the forceps into the bladder.

The employment of gorgets for the performance of lithotomy has been objected to by several eminent surgeons of the present day, particularly by Mr. John Bell of Edinburgh. (See his Principles of Surgery, vol. 2.) We have seen the operation most easily executed by means of a common scalpel. Mr. Atley Cooper uses, instead of a gorget, a common scalpel with a beak, which slides along the groove of the flaff into the bladder. Several other knives and instru-
ments have been at different times invented to supersede the gorget. The principal ones will be represented in the surgical plates, and due notice will be taken of them in the article LITHOTOMY.

GORGIAS, son of Aesilaus, born at Leontium in Sicily, from whence he derived his second name, was a celebrated orator and learned sophist, who flourished in the fifth century before the Christian era. He was a disciple of Empedocles, and is reckoned one of the earliest writers on the art of rhetoric. He is thought to have introduced numbers into prose, treated of common places, and thwed the use of them for the invention of arguments. Hence Plato gave the name of Gorgias to his ele-
phant dialogue on this subject, which is still extant. He was so great an orator, that in public assemblies he would undergo to declaim extempore upon any subject proposed to him. In the war between Syracuse and Leontium, the ci-
tizens of the latter applied to the Athenians for succour, and employed Gorgias and Tisias as their ambassadors, the former of whom was peculiarly qualified to influence popular assemblies by his bold and perulusive eloquence. On their arrival at Athens about the year 447 B.C., Gorgias made an oration to the people on the grievances which their countrymen suffered from the people of Syracuse, and the advantages which would accrue to them from sending a powerful army into Sicily, by which he persuaded them to rush headlong into a war, that proved in the end more fatal to them than any in which they had engaged. Afterwards he made a display of his eloquence at the Olympic and Pythian games, on account of which a golden statuette was erected to his honour at Delphi. He is said to have lived to the great age of 107 or 108.

GORGOGLIONE, in Geography, a town of Naples, in the Bafilicata; 15 miles E. of Veneda.

GORCONTA, an island of small extent and of a circular form, in the Mediterranean, about 16 miles from the coast of Etruria. The mountains, says Somnini, seem to be of the same nature with those of the continent. This island is famous for the anchovy fishery on its coasts. N. lat. 43° 22'. E. long. 9° 56'.—Allo, an island in the Pacific ocean, about 18 miles from the coast of Peru, about 16 miles in circumference. N. lat. 3° 36'. W. long. 75° 52'.

GORONIA, in Zoology, a genus of Zoophytes, the stem of which is coriaceous, woody, corky, horny, or somewhat bony, and in general flexible; the texture glairy, fibrous, or like flume, friated, tapering, fixed at the base, which is dilated, and covered with vascular or cellular fleis, or bark of a spongy and friable nature in a dried state; the mouths or cells covering the surface of the stem and bearing polyps.

These marine productions were regarded by the ancients as a class of plants, and described as such by their botanists; nor was this idea, however remote from truth, exploded till fo late a period as the eighteenth century, when the discovery of Porifonea upon the nature of coral, published in 1727, and those of Trembley on the hydra (or polype) about fourteen years after, contributed to demonstrate, in a very explicit manner, that the gorgonix in common with other zoophytes (as these particular bodies are now denominated), do not appertain to the vegetable, but animal kingdom, or are at least the fabrication and genuine habitations of animals.

Among the various observers of this curious order of animal productions, few, if any, have pursued their investigations with greater discrimination and success than Procco Volans, or our own countryman Ellis, and his friend Dr. Solander; nor indeed can we hesitate to confess that our knowledge of the gorgonix tribe has been enlarged only in a very inconsiderable degree by any of the sub-
quent authors on this subject. The latest observations tend principally to confirm the accuracy of those writers who had before assured us the gorgonix are the habitations of various kinds of polypiferous animals, each of which refides in a distinct cell; that they lie in general dormant or contracted during winter, and, like the blossoms of plants, put forth buds, and expand in their proper season, which is commonly in summer. The stem and branches of the gorgonix, which are most commonly of a somewhat horny and flexible nature, may be considered as the true skeleton of these cells of habitations, being covered with a flathy or pulpy substance, the exterior surface of which is porous. These pores are the mouths or openings of the cells in which the polypes are lodged, and it is the number, disposition, and varied structure of these, in addition to the general aspect of the plant-like cell of habitations, that constitute the most material differences by which the various species are distinguished; the figure of the animal, when it can be ascertained, forming the secondary or least important character. It may be lastly ob-
erved, that the gorgonix differ exceedingly in size, being from one to two, or perhaps three feet in height, while other species in deep bays, and similar situations of the sea, are less favourable to their growth and increase, attain to the gigantic height of ten or twelve feet, and from their number as well as magnitude; their remarkable ramose, and foliated or flabelliform appearance; interwoven structure, and coral-like texture, form a conspicuous portion of those vast submarine "groves of coral" that are sometimes seen by navigators in the hotter regions of the globe.

Species.

LEPÆDIFERA. Dichotomous, with crowded, imbricated, reflected, campanulated flores. Mill. "Gorgonia rædifta." Pal-

Native of the Norway seas, from eighteen inches to two feet high; flath pale, with whitish skin or scales; flum white, with a flomy bafe and cartilaginous branches.

From two to three feet high; flum brittle and white, with flexible branches. Native of the Mediterranean and North seas.

Placoem.
**GORGONIA.**

Height two feet; stem erect, woody, and yellow, scarlet or reddish cinereous. Inhabits the Indian and European seas.

MOLLIS.Coriaceous, dichotomous, with perpendicular tubular florets. Pallas.

Native of the Mediterranean, and about eighteen inches in height, the colour brown violet; stem brown; branches long and slender.

EXserta. Round, amber-colour, dichotomous, rigid, the stem covered with tuberous gaping florets. A very rare species, the native place of which is unknown; it is only six inches high, the stem tesselaceous.

AMERICANA. Branched and sub-divided, the divisions nearly opposite, compressed, with rows of polypterous cells on each margin; flesh yellowish, within pale purple; bone horny. Gmel. *Gorgonia pinnata, Soland. and Ellis.*

Native of the West Indies; flesh purplish or yellowish.

PATULA. Compressed, with flexuous sub-pinnate branches, crimson, with two rows of florets each side, each surrounded with a whitish ring; bone brownish, horny. Soland.

Height two feet; branches long, slender, and white; polypies with many feelers and exerted. Inhabits the West Indies.

CERATOPHYTA. Branched, with divericate erect sub-divisions, each marked with two furrows; florets white, in irregular rows; flesh purple; bone black and horny. *Gorgonia ceratophyta, Soland. Corallina fruticosa purpurea, C. Baur. Lithobyon etc. Genta. Corallina fruticosa erecta, Cateby.*

Found in the Mediterranean, Atlantic, and South American seas; height twelve inches; flesh bright purple.

JUNCEA. Stem simple, round, and tapering both ways; bone dusky, horny; flesh orange-colour, with two furrows; florets longish. Soland. &c. *Juncis lapides, Plin. Palmatuncus albus, Rumph.*

Inhabits the flores of the American islands adhering to stones; height about three feet, and very flexible when alive.

FLAMMEA. Compressed, branched, and sub-pinnated; bone flat and horny; flesh bright red, with minute florets. Soland. and Ellis.

A beautiful species, of a fiery red or flame-colour when recent; this kind inhabits the African coast, and appears to be found in most abundance near the Cape of Good Hope.

UMBRACULUM. Fan-shaped, and somewhat resculptured; branches numerous, divergent and round; flesh reddish, warted or covered with florets. Soland. and Ellis.

Native of the Indian sea; stem short, rising from a broad base, divided into about two or three branches, the smaller ones rising from which are numerous, and so intimately connected as to form a kind of net-work.

PURPUREA. Somewhat dichotomous, with divaricately slender branches; flesh violet and sub-verrucosel. Pallas.

Round, smooth and blackish, with the extremities of the branches yellow. A South American species.

**SAEPPO.** Sub-dichotomous, round, with divaricated slender branches; flesh red, with numerous hairy florets. Pallas. *Acorbana saeppe, virga fungina, Rumph.*

About twelve inches in length, the texture horny, and colour black. The branches are frequently adhering to this species.

**PALMA.** Flat, with numerous very long and simple divisions; flesh smooth, sprinkled with spongy pores. Pallas. *Chamaeripha peregrina, Chius.*

Grows to the height of five feet, though more commonly not exceeding two or three feet; the substance horny, covered with a calcareous coating, and flexible. Inhabits the Indian ocean.

**RADIATA.** Very much branched, and corky; with minute scattered pores, and many-leafed at the base. Pallas, Seba, &c.

Native of the African seas; sub-dichotomous, grey, with branched trunk, and in substance resembling cork.

**SUBEROSA.** Woody, very much branched, diffuse, the branches compressed and grooved, and covered with tuberculated scattered pores. Pallas.

Height three feet; flesh red, spongy; bone pale red and corky; branches long, round, and erect. Found in the Indian and African seas.

**CORALLOIDES.** Woody, erect, sub-dichotomous, and variously formed; flesh tuberous, with elevated tuberculated florets. Pallas. *Corallina ligna incrusta, Bocci.*

Native of the Mediterranean; length one foot, very tough, pale grey; with yellow florets.

**ELONGATA.** Dichotomous, divaricate, with the flesh red, and covered with papilliferous sub-incrustated pores. Gmel. &c.

Pole and brittle, with square branches with pores at the angles; grows to the height of four feet, and inhabits the Atlantic.

**SCIREEA.** Very simple, straight, with a decomposit leafy base, and soft tuberculated flesh. Pallas.

Fuscous, tapering towards the tip; the flesh cinereous when dry; inhabits the Indian seas.

**SETACEA.** Simple, rigid, with calcareous white sub-tuberculated flesh. Pallas. *Ifidae placumum, Mercat.*

Native of the American ocean.

**VIMINALIS.** Very long, depressed, branched, with erect sub-divisions; flesh yellow; florets seated along each margin of the branches, and rather prominent. Pallas. *Ifidae placumum., &c. Mercat.*

Height eight inches; branches long and slender; bone blackish and horny; florets white; the polypies furnished with eight feelers or claws. Native of the Atlantic and Mediterranean.

**MELICATA.** Round, with depressed sub-divided branches; flesh thick; pores cylindrical and spinous. Pallas, Ellis, etc. *Epectoralia, &c. Petiv. Lithophrones, Tournef.*

Native of the American islands; height from two to three feet; coriaceous, horny, with a whitish medullary nerve.

Inhabits the West Indian, Mediterranean, and rarely the British seas, adhering by the broad base of the principal trunk to the rocks, and rising to the height of twelve or fifteen
fifteen inches, and sometimes rather more, in a fan-like form; colour when dry greyish-white; bone of a texture between horn and wood.

Grows to the height of two feet, and inhabits the Indian and Mediterranean seas. This is the black coral of the fleet.

Novae-Hollandiae. Dichotomous, the branches somewhat tapering; flesh red, slippery, and soft; the surface speckled with numerous eight-valved, conic, and rather elevated, irregularly disposed pores; bone bright red, striated, and slightly punctured externally. Soland. and Ellis, Corallum nodosum, Linn. Synt. Nat. X. Meduspara rubra, Linn. Synt. Nat. X. Pallas. Corallum rubrum, Donast. Red coral, Ellis.

The bone of this species constitutes that beautiful and much esteemed marine production, the red, or true coral of the jewellers. The coral is a general inhabitant of the Mediterranean, Adriatic, and Red seas, and appears to be no where more abundant than in the sea about Marseille, Corfes, Sicily, and the coast of Africa; in the vicinity of Barley, the coral fisheries in those parts being carried on with great spirit, and proving highly lucrative. From the observations of Donast, an author who has devoted much attention to this curious subject of enquiry, we understand that the flesh or exterior covering of the coral is of a red colour, varying from bright to paler hues, the tint of which is uniformly less brilliant than that of the bone of the coral itself. The most prevalent colour of the bone is red, exhibiting all the tints from a pale rose colour to fiery scarlet, and sometimes inclining to yellowish or fine fialen. The coral grows in a shrubby form, and not infrequently in an inverted form, to the height of a foot or eighteen inches, which latter it rarely exceeds, nor is the circumference of the largest branches more than one inch. Externally the surface is frizzled, more or less nodulous or warted, and the substance when broken appearing composed of a number of concentric layers. The coral of this species is equal in hardness and durability to the most compact marble, and of material qualities, in addition to its beautiful texture or grain, and colour, have contributed to render it valuable in the embellishment of the world from the earlier ages, as we learn from Pliny, and other writers of remote antiquity. At this day the true coral bears a considerable price throughout the East as well as in Europe; its supposed medicinal virtues have, however, fewer vatrates at present than formerly. The polyps, by which the cells are occupied, are furnished each with eight arms or tentacula, in the centre of which the mouth is situated; these arms are retractile, contract immediately on being touched; the cells or pores are filled with a white liquor, and the polyps are likewise white.

Inhabits the American seas, and some of the European seas; height nearly two feet; bone roundish, tapering to the ends, and violet when recent.

Crasa. Round, dichotomous, with long, thick, divaricated, erect branches; flesh thick, violet, with small prominent, approximate, equidistant pores; bone dark brown and horny. Soland. and Ellis.

Native of the American seas.

Pinnata. Rather compressed and pinnated, with very simple compressed branches; flesh red with oblong pores. Linn. Palma pelagica, Theophr. Lithophyton, Breyn.

Grows to the height of from one to four feet; the texture horny and brown. the branches yellowish. Native of the African and North seas.

Sanguinolenta. Depressed, very ramose, and pinnated; flesh yellow, with purple pores in double rows. Pallas. Lithophyton sanguinolentum, Tournef.

Native of the Atlantic and Mediterranean seas; height one foot.

Vulcania. Rather depressed, with pinnated branches; flesh violet; nearly square, with somewhat prominent pores. Gmel. Phorusrum, Theophr.

Inhabits the American seas, above a foot long, and horny.

Grows to the height of two feet; very upright, and inhabits the Mediterranean and American seas.

Native place unknown; bone horny, black, with amber-coloured ramifications.

Ptyconata. Round, with parallel ascended simple branches; flesh red, with gibbous scattered pores; bone white, hard, and brittle. Gmel.

Very rare, white, with red flesh; found in the Indian ocean.

Adpressa. Ramose pinnated; flesh yellow, with rows of purple florets each side; bone horny and yellowish. Soland. and Ellis.

Native of the African seas, and seldom exceeds a foot in height.

Calyculata. Dichotomous and subdivided, with creft thick ramifications covered with truncate papillae; flesh cinereous, with purplish; cells large and cup-shaped; bone dark brown and horny. Ellis.

Inhabits the American seas.

Brilareus. Subramose, round, thick; flesh pale or white within, externally cinereous; bone composed of small purple glossy needles, irregularly and closely disposed longitudinally. Soland. and Ellis.

Cells large, prominent, numerous, and irregularly disposed; the species inhabits the West Indies.

Black or brown; the species inhabits the Indian ocean.

Reticulatum. Reticulated, branches with very close ret and round ramifications, and red tuberculated bark.

Very ponderous, of a grey colour, and inhabits the Indian ocean.

Clathrus. Reticulated, woody; with round ramifications; flesh smooth with simple pores. Pallas.

Native place unknown; about eight or ten inches in height, pale, with a thin reddish-grey flesh.

The bone is black, horny, and slightly filariated on the larger branches.

Found adhering to various substances, and varying in colour.
colour from yellow to purple: this species inhabits moist
fens.

**GORGONIUM**, in *Botany*, a name given by some
authors to the common eryngium or eryngo, the roots of
which we use candied.

**GORGONS**, in *Antiquity and Mythology*. Authors are
not agreed in the account they give of the Gorgons. The
poets represent them as three sisters, whose names were
Stelena, Eurystyle, and Medusa, the daughters of Pheorus
by Ceto; the latter of whom was mortal; and having been
decked over by Neptune, was killed by Perseus: the two
former were subject neither to age nor death. They are
described with wings on their shoulders, with serpents round
their heads, their hands were of brass, and their teeth of a
prodigious size; so that they were objects of terror to
mankind. Æschylus, in his Prometheus, adds, that they had
but one eye and one tooth among all the three, which they
made use of one after the other, and that they killed men
with a single glance of the eye.

Pindar (Pyth. 12.) improves upon Æschylus, and
heightens the fable by these circumstances, unknown to his
predecessors. The first is, that the Gorgons turned those
into flame whom they looked upon, and that it was by this
kind of death that Perseus, in presenting Medusa's head,
debated the island of Seriphus, whose inhabitants he petrified,
together with their king. The second is, that Minerva,
who aided Perseus while he was struggling with Medusa,
being surprized with the melody of the Gorgons' sigis,
together with the evils of their serpents, felt certain charms
in that mixed composition of dreadful accents; and to renew
the idea of the harmony, she invented a flute in imitation
of it, which she imparted to men; and in allusion to its
first model she called the various sounds it produced "a
Harmony with many heads." The third is, that Phorcys,
whom Hesiod represents as having taken flight to the
mountain of the gods, was afterwards broke by Minerva,
and given to Belcherphon, who mounted him to combat the
Chimæra; but that hero having attempted to ascend to
heaven on the wings of that horse, was thrown down to the
cave, and Phorcys placed among the stars. (Pindar's *Ol. in.
Pyth. vii.*) The Latin poets, though faithful copies of the
Greek ones, have yet altered the fable of the Gorgons
with new circumstances. Homer had said, that the Gorgon's
head was engraved upon the tremendous *Egis* of Minerva.
Virgil adds, and upon her entrails too, in the place which
covered the goddess's breast:—

"Iphamque in pectore Dire
Gorgon detecto vertament humma colo." *An. l. viii.*

After the death of Medusa, her sisters, according to
Virgil, were appointed to keep the gate of the palace of
Pluto:

"Multaque preterea varianum monstra ferarum—
Gorgones, Harpeaque—" *An. l. vi.*

Ovid of all the poets has more enlarged upon the fable
of the Gorgons, and added several particulars which are only
found in his Metamorphoses, 1. iv. and v.

Diodorus Siculus will have the Gorgons and Amazonis to
have been two warlike nations of women, who inhabited
that part of Lybia which lay on the lake Tritonis. The
extermination of these female nations was not effected till
Hercules undertook and performed it.

Paulinus says, the Gorgons were the daughters of Phor-
bus, probably by mistake for Pheorus; after whose death,
Medusa his daughter reigned over the people dwelling near
the lake Tritonis. The queen was particularly fond of
hunting and war, so that she laid the neighbouring countries
quite waste. At last, Perseus having made war on them,
and killed the queen herself, when he came to take a view
of the field of battle, found the queen's corpse to extremely
beautiful, that he ordered her head to be cut off, which he
carried with him to show his countrymen, the Greeks, who
could not behold it without being struck with astonish-
ment.

Others represent them as a kind of monstrous women,
covered with hair, who lived in woods and forests. Others,
again, make them animals, resembling wild sheep, whose
eyes had a poisonous and fatal influence.

Xenophon of Lamprocus, who is followed by Pliny and
Solinus, was of opinion, that the Gorgons were female va-
vages, who inhabited the islands Gorgades. Hanno, the
Carthaginian general, penetrated as far as these islands, where
he found women, who, in twain, outran the flight of birds.
Gerard Vofius, in his "Origin and Progress of Idolatry," is
perceived, that the fable of the Gorgons took its rise from the
relation of Hanno the Carthaginian general, above cited,
from Xenophon of Lamprocus. Le Chere, on the contrary,
in his notes upon Hesiod, takes them for the nays of Ly-
bria, which the Phoenicians in a voyage to Africa had taken
away. Bunier (Mythol. vol. iii.) is of opinion that the Gor-
gons dwelt in that part of Libya which was afterwards
called Cyreneum; and that Phorcys, their father, had con-
quered Ithaca, which was not far from the coast of Africa,
where he refided. It is not incredible that this prince would
employ his fleet in carrying on an advantageous trade, and
that Polydeuces, king of Seriphus, in order to get rid of
Perseus, gave him some ships for the purpose of pirating on
the coasts of Africa. Perseus accordingly, thus equipped,
failed from the isle of Seriphus for the coast of Lybia, and
having fallen in with the fleet of Phorcys, made himself
master of some of his ships and a part of his riches. These
ships, it is said, bore the names of Medusa, Stheno, and
Euryle. They were loaded with the teeth of elephants, the
horns of felines, and the eyes of hyenas, which Phorcys bar-
tered for other goods. This, it is said, is the mystery of
the tooth, horn, and eye, which the Gorgons borrowed by
turns; that is, the ships, when arrived in the port, took
each of them goods proper for the place to which they were
bound. The other fables that accompany this history,
says the author now cited, will explain themselves.

A further account of them, p. 72, seq. See Medusa caput.

**GORGONZUOLI**, in *Geography*, a town in Italy, in
the department of the Olt, 10 miles N.E. of Milan.

**GORGORA**, an island of Abyssinia, in the lake Deobes
(which see), where a palace was built, which is the usual
residence of the emperor in winter.

**GORHAM**, a port town of America, in Cumberland
county and state of Maine, on the N.E. side of Saco river,
130 miles N.E. from Boston; incorporated in 1704, and
containing 2053 inhabitants.

**GORIO, ANTONY FRANCIS**, in *Biography*, a learned
antiquary of the eighteenth century, a native of Florence,
was author of the following works, *viz.* "Museo Floren-
titum," or a description of the cabinet of the Grand Duke,
eleven volumes folio, with a great number of plates:

**GORTIZ, or GUNEZ**, in *Geography*, a county of Ger-
many, in the circle of Austria; bounded to the N.E. and S.
by the duchy of Carniola, and on the W. by the Venetian
states. The chief produce of the country consists of wine
and fruit, with some corn and silk; the horses and oxen are

502, few,
few, but the goats are numerous. The language of the country is Schlesische, and the religion Roman Catholic.

**GORLIA** or **Gooralia**, a town of Germany, situated in the above-mentioned country, and divided into Upper and Lower towns. The former is ancient, seated on a mountain, and defended by a castle; the latter is situated on a plain on the river Limaz. Besides the church, since the year 1784, not of the metropolis, it has seven convents, nine chapels, and a college. In 1797 it was taken by the French: 20 miles N.N.W. of Trieste. N. lat. 46° 5'. E. long. 13° 35'.

**GORE**, a town of Brandenburg, in the New Mark, seated on the Oder, formerly the metropolis of the circle of Leading.

**GORKA**, a town of Hoithoofdan, in Meck.; 12 miles S.S.W. of Cottibah.

**GORKALL**, a town of Asia, situated in the N.E. part of the island so called, on the borders of Napaul; 35 miles N.W. of Cantamun. N. lat. 28° 25'. E. long. 84° 36'. The country lies between the province of, Oude and Tibet, and is governed by a rajah dependent of Tibet. — Alto, a town of the duchy of Warfaw; 40 miles S. of Posen.

**GORLEUS, ABRAHAM**, in *Biography*, a celebrated medallist, was born at Antwerp in 1550. He devoted himself entirely to the collection of ancient medals, seals, rings, and other curiosities. He died at Delft, where he spent the greatest part of his life, in the year 1629. His works are entitled *Dactyloheza ferr Asseborum Sigmorique*, &c. Ferro, Argento, atque Auro Promptuum. "The Laurus Numismatum Familiarum Rom. ("Paralipomena Numismatum.") His works are highly valued by those who are addicted to these studies. — Moreri.

**GORT, Z.,** in *Geography*, a town of Upper Lusatia, situated on the river Neisse, and the first town in the county with regard to size, population, and wealth. Within the walls it has three churches, and as many without. The principal trade is brewing, with woollen and linen manufactures. 50 miles E. of Dresden. N. lat. 51° 9'. E. long. 15° 31'.

**GOROCHOVETZ, a town of Russia, in the government of Vladimir; 72 miles E. of Vladimir. N. lat. 50° 10'. E. long. 42° 34'.

**GORDITSCHE** or **Goritsche**, a town of Russia, in the government of Penza; 32 miles E.S.E. of Penza. N. lat. 53° 20'. E. long. 49° 34'. — Alto, a town in the government of Kiev, 112 miles S.E. of Kiev. N. lat. 49° 3'. E. long. 34° 16'. — Alto, a town in the government of Tobolsk, 20 miles E.S.E. of Enibolk.

**GORODNIA**, a town of Russia, in the government of Tver, on the Volga, 23 miles E. of Tver.

**GORODNITZSK, a town of Russia, in the government of Tchernigof, on the Sow; 32 miles N.N.E. of Tchernigof.

**GORODOK**, a town of Russia, in the government of Polotsk; 36 miles E. of Polotsk. N. lat. 55° 36'. E. long. 29° 54'.

**GORON, a town of France, in the department of Mayenne, and chief place of a canton, in the district of Mayenne; 9 miles N.W. of Mayenne. The place contains 1860, and the canton 12,733 inhabitants, on a territory of 200 kilometres, in 11 communes.

**GORONGO, a small island in the East Indian sea; 20 miles S. of Gilolo. S. lat. 1° 8'. E. long. 128° 35'.

**GORONPALE, or Gorontano, a town on the E. coast of the island of Celebes.

**GORPET, a town of Hindoostan, in Birar; 24 miles W. of Chunar.

**GORSE, JOHN D.,** in *Biography*, was born at Paris in the year 1805. He took the degree of doctor of physic in that city about 1540, and was appointed dean of the faculty in 1548. He is said to have performed both the learning and fertility requisite to form an accomplished physician, and to have practiced with great humanity and success. His works contributed to support this reputation. The greater part of them consists of commentaries on different portions of the writings of Hippocrates, Galen, and Nicander. During the civil war, which was fatal to numerous men of letters, John de Gorse was stopped by a party of soldiers, when on his journey to Melsbu to visit the bishop of Paris, and the fright which he sustained is said to have deprived him of his reason. This occurred in 1561, and he lived many years in this deplorable condition, having died at Paris in 1577, at the age of 72.

His father, also John de Gorse, was a physician at Bourges, attained considerable eminence, and left two works, one on the general "practice of medicine," dated 1555; the other, a "collection of formulas," 1568, both in Latin.

**Elyo Dict. Hist.**

**GORRITLI, in Geography, a small island in the river La Plata.**

**GOSA, a small island near the S. coast of Cuba. N. lat. 21° 43'. W. long. 81° 21'.

**GORME.** See *Furme* and *Ulrex.*

**GORSIO, in Geography, a town of Sweden, in Hellingland; 8 miles W. of Hadingwickswal.**

**GORT, a small town of Ireland, in the county of Galway. It stands on an eminence, and is a dirty straggling town, but can boast of a few good houses. Adjoining to it are the ruins of a castle, and near it is Kilmadeagu, the seat of a bishop. Gort is 98 miles W. from Dublin.**

**GORTER, JOHN D., in Biography, a physician, who, after having been a disciple of the celebrated Boehmave, became a distinguished teacher of medicine at Hardwick, his native place; in consequence of which he was elected a member of the academies of Peterburgh, Rome, and Haelere, and obtained the title of physician to Elisabeth, empress of all the Russias. He was the author of several works, which are written with excellent method, and contain many interesting and original observations. He died on the 11th of September, 1762, at the age of 72.—His works, the titles of which are enumerated by Elyo, relate to physiological and practical subjects, as well as to the practice of the ancients. Elyo Dict. Hist.**

Gen. Ch. *Common calyx* of one leaf, imbricated with spiny scales, the innermost gradually longer, straight, bristle-shaped, rigid. *Cor.* compound, radiated. Flores of the disk numerous, perfect, with a funnel-shaped five-cleft corolla: those of the radius fewer, female, with a ligulate lacinolate one. *Stam.* (in the perfect florets only) Filaments five, short; stamens united into a cylindrical tube. *Pis.* (of the perfect florets) German hairy; filiform thread-shaped, the length of its own little corolla; stigma clavate. In the female florets the germen is oblique and abortive; style none; stigma none. *Peric.* none, except the calyx, falling.
off entire. Seeds to the perfect florets only, solitary, roundish. Down simple or woolly. Receptacle naked. E.T.C. Receptacle naked. Down simple or woolly. Florets of the radius ligulate. Calyx of one leaf, clothed with imbricated scales. All the plants ranged under this genus are natives of the Cape of Good Hope. In the 2d edition of Linnaeus's Species Plantarum, where it first appears, are five: *perfonata, Jacq.* Coll. v. 4, t. 21. f. 1; *rigida, Curt. Mag. t. 92; squarrosa, citrina, and fruticosa.* The latter is the same plant as *G. alicivale, Linn.* Suppl. 381, but different from *Arzidias oppositifolia,* under which it is quoted in Synth. Veg. ed. 12 735. To the above are added, in the Manilla, p. 287, *G. fistula;* and in the Suppl. iuxta mixere more, *herbaea, bispicata, frutesco, corona, uniflora,* and *bordota.* Of these the *bordota* is there suspected, to be a mere variety of *rigida.* The genus thus understood undoubtedly forms a very minute and elegant tribe of flowering plants. *Linnaeus having chiefly considered the simple-leaved *cucumis* of the *Geraniaceae* family, remarked. Wilder, accordingly, has but seven *Gortynia,* the *perfonata, rigida,* and *corona* of *Linnaeus,* with *squamia, integri folia,* and *blattis* of *Thunberg.* Others are lent to his genera of *Mug- *ficus,* *Cnidosocium,* *Cygnum,* and *Zygophyllum,* whose receptacles are villosa, and feed-down, formed of simple hairs; and *Drege's* whole receptacle and feed-down are chaffy. Among the Later are the beautiful and truly wonderful *G. citrina,* and the *fusca.* the latter figured in Jacq. Hort. Schonbr. t. 572. This is doubtless a great improvement, but it seems to us that the genus maia, after all, chiefly depend on *G. perfonata,* which is an annual plant, of no beauty, with many spreading *flora,* about a foot high. *Leaves* alternate, spatulate, revolute, pinatitudine undivided; very white and corymbaceous beneath; and green and bristly, like the *flora,* above. *Flowers* solitary, terminal, small, yellow, with numerous prominent spines to the calyx. The *flora* are crowned with wood, but have no proper *pappos* or *feed-down.* The leaves of *G. rigida* bear some analogy with this, but the large orange blossoms, unarmed calyx, and long simple feed-down, urge the propriety of separating it. The latter is *Lamarck's Gortynia* above quoted.

**GORTYNA, or GORTYN, in Ancient Geography, an inland city of Crete, being, according to Strabo, near 93 furlongs distant from the African sea, or that part of the Mediterranean which bordered the southern part of the island. Its origina is obscure, some ascribing it to Gortyn, the son of Rhadamantus, and others to Taurus, who carried off Europa. In process of time, however, it eclipsed all the other cities of Crete, especially after the island was reduced by the Romans. Of its ancient splendour and magnificence we may form some judgment from its ruins, which are still visible about six miles from mount Ida; though many of them have been carried away by the Turks. In ancient times it was famous for the temples of Apollo, Diana, and Jupiter Hecatombus, so called because Memnon there sacrificed to Jupiter 100 oxen, when he received information of Helen's flight. Its walls were washed by the river Lethe. Theophrastus, Varro, and Pliny speak of a plane tree near Gortyn, which never lost its old leaves till new ones sprout forth.**

**GORTYNA, a town of Greece, in the northern part of Macedonia.**

**GORVAY, in Geography, a town of Hindookept, in Balh, 62 miles W.S.W. of Balk.*

**GORZ, a town of Georgia, in the province of Carduel, on the Kura; 45 miles W. of Teltis. N. lat. 41° 55'; E. long. 44° 30'.**

**GORZE, a town of France, in the department of the Meuse, and chief place of a canton, in the district of Meus,* 7 miles S.W. of Metz. N. lat. 49° 3'; E. long. 6° 4'. The place contains 15,355, and the canton 14,278 inhabitants, on a territory of 330 kilometres, in 31 communes.**

**GORZEGNO, a town of France, in the department of the Savoy, on the Rhone; 13 miles S.E. of Alba. N. lat. 44° 28'; E. long. 8° 7'.
The word is Saxon, and of the same form with the Latin term evangelium, or the Greek εὐαγγέλιον, which signifies glad tidings, or good news; the history of our Saviour being the best history ever published to mankind. This history is contained in the writings of St. Matthew, St. Mark, St. Luke, and St. John, from thence are called Evangelists. (See each of these articles.) The Christian church never acknowledged any more than these four gospels as canonical; notwithstanding which, several apocryphal gospels are handed down to us, and they are entirely false. We shall here refer in the titles of some of the principal of apocryphal gospels, as we find them in Jones’s Canon, and Lardner’s Works, with remarks that will serve to enable us to distinguish them from our four gospels, the authenticity of which is excused under other articles in this work. (See Bible, Canon, and Testament.) Several of these spurious gospels are mentioned in the decree, ascribed to pope Gelasius, in the council of Rome, A.D. 494, which pronounced them to be apocryphal. The gospel of “Andrew the Apostle” is only mentioned in this decree. No fragments of it are extant, nor are there any testimonies concerning it. The gospel of “Apelles” is not mentioned by any writer before Jerom, who places it among the apocryphal pieces of the New Testament. Apelles was a disciple of Marcellus, bishop about the year of Christ 180, and is supposed to have formed this gospel out of the true and genuine gospels for the use of his followers at the close of the second century. The gospel, “according to the twelve apostles,” is mentioned by Origen, Ambrose, and Jerom, but they unanimously come to this conclusion, and in expressly affirming that the church received only these four gospels. Jerom supposes this to have been the same with the gospel according to the Nazarenes. The gospel “according to St. Barnabas” is not noticed by any of the Christian writers of the first four centuries; nor do there seem to be any fragments extant, that unquestionably belong to it. Mr. Jones apprehends that this was merely some interpolated corrupted gospel of St. Matthew. The gospel of “Bartholomew” is mentioned by Jerom as apocryphal, and Jones, for reasons which he alleges, inclines to think, that it was the same with the gospel of St. Matthew, used by the Hebrews or Nazarenes. M. Daille is of opinion that it was forged but a very little time after Gelasius. The gospel of “Ballilides” is named by Origen, Ambrose, and Jerom, among the apocryphal books of the New Testament; but no fragments of it remain. The gospel of “Corinthus” is mentioned only by Epiphanius in connection with an exposition of the first words of St. Luke’s gospel, as many other Christian writers notice the apocryphal books; and it seems probable, from the similarity of the opinions adopted by Corinthus and the Ebionites, that the gospel of Corinthus and his followers was no other than the Ebionite or Nazarene gospel, i. e. the gospel of St. Matthew corrupted and interpolated, in Hebrew. The gospel “according to the Egyptians,” was one of the most celebrated apocryphal books, and supputed even by several modern critics to have been a faithful compendium of some Catholic Christians in Egypt, before either of the four canonical gospels now received. The first Christian writer who cites it is Clement Alexander, who, however, rejects it, though some have supposed that a passage in the second epistle of Clement Romanus to the Corinthians is taken from this gospel. It is mentioned by Origen, Jeron, and Epiphanius among apocryphal books. Many modern writers, as Abaris, Grolius, Grotius, Mill, suppose, that it is referred to in the introduction to St. Luke’s gospel, and therefore that it was prior to his; andDupin and P. Simon think, that though it is not of the same authority with the four canonical gospels, it ought not to be rejected. Mr. Jones is of opinion, that it was composed by some very early heretics to support their doctrines of celibacy and abstinence, and very probably by those of Egypt; and Dr. Lardner thinks that it was not written before the third century. The gospel of the “Ebionites” was either altogether, or very nearly, the gospel of the Nazarenes. The gospel of the “Encratics” has been mentioned by Fabricius and some others, but there is reason for doubting whether any gospel was ever called by this name. The gospel of “Eve” has been mentioned by several modern writers, but only by Epiphanius among the ancients; it was, without doubt, a forgery of the Gnostics. The gospel of the “Hebrews” was the fame with that of the Nazarenes. The gospels of “Hesychis” were some interpolated copies of our received gospels. The gospel of “Iudas Icariot” is mentioned by Irenaeus and Epiphanius as peculiar to one of the most monstrous and inconsistent sects that ever affumed the Christian name. The false gospels of “Lucius,” who was a famous scribe and martyr under Diocletian, were, like the half-mentioned, corrupted, interpolated copies of our present gospels. The gospel of “Matthius,” of which there are now no remains, is mentioned by several of the most celebrated writers among the ancients, e. g. Origen, Eusebius, Ambrose, and Jerom; but they all represent it as apocryphal. The gospel of “Marcion” is taken notice of by Tertullian and Epiphanius, but it appears to have been one of our own gospels, mutilated and altered; probably that of St. Luke, from which he took away entirely the two first chapters, and many other parts, inverting many things of his own, with a view to favour the opinions he had adopted. The gospel of the “Nazarenes” or “Hebrews” is the most famous of all the ancient gospels. Some have supposed that St. Paul refers to this gospel, Gal. i. 6. It is cited by Iginatius, as some have supposed, by Clemens Alexander, by Origen, by Eusebius, by Epiphanius, by Jerom; and it is mentioned by Bede, Sixtus S Ensifis, Baronius, Caelianus, Grotius, F. Simon, Dupin, Grab, Toland, Nye, Richard Mill, Fabricius, Manger, and other modern writers. However it is alleged, that this gospel was never received by any primitive writer as canonical, nor was it cited or appealed to, as of any authority, by any one writer of the first four centuries; and moreover that it was composed out of St. Matthew’s and the other authentic gospels, with additions of some other things received by oral tradition. It is allowed, that it was an early compendium, and Mr. Jones says, that it was undoubtedly extant in the beginning of the second century, and seems to have been made by some converted Jews, to favour their notion of blending judaism and christianity together. “As many mistakes,” says Dr. Lardner, “have been entertained about the gospel according to the Hebrews,” it may not be unbecoming to observe here, that probably it was an Hebrew translation of St. Matthew’s original Greek gospel, with additions from the other gospels; to which possibly might be added some few particulars received by tradition from the early Jewish believers.”
believers." (See Ebionites and Nazarenes.) This excellent writer elsewhere observes, it is not necessary for us to suppute, that the ancient fathers who mention other gospels, thought, "that all, if any of these gospels, were written before St. Luke's, or that he spoke of them; for Balaides and Apelles could not write gospels before the second century: and they might suppute, that several, if not all the others, mentioned by them, were written after St. Luke's. The meaning of what the ancient writers say is, that the church receives four gospels only. There were many others. But to them may be applied the words of St. Luke; they only took in hand, or attempted. They did not perform, as Matthew, and Mark, and Luke, and John did. And they might express themselves in that manner concerning gospels written after St. Luke's, as well as before it."

The gospel of "Peter" has been taken notice of by many of the ancient writers, as Sera-phon, Tertullian, Origia, Eut- fcbius, and Jerom. Some have supputed, that this was the gospel of St. Mark, who was the companion of Peter, and wrote the gospel now extant under his name. But there is reason for believing that the gospel of Peter was different from that of St. Mark. It is not very certain by whom it was forged. Dr. Grabe, and after him, Dr. Mill, suppute it to have been made by Luccius, whom they reckon to have been a heretic of the second century; but Luccius did not live till the latter end of the third, or the beginning of the fourth century; whereas this gospel appears to have been extant in the second century, as we may infer from the account of it by Sera-phon, who was bishop of Antioch in the 11th year of the emperor Commodus, i.e. A.D. 190. Mr. Jones apprehends, that this gospel was composed by those ancient heretics in the second century, called Docet (see that article); and he conjectures that the gospel of Balaides above-mentioned, was either wholly, or in a great measure, the same with this apocryphal gospel under the name of Peter. The gospel of "Perfection" was one of the numer- ous forgeries of the Gnostics, who pretended to a greater perfection in knowledge and virtue than all others, and hence took their name. (See Gnostics.) The gospel of "Philip" was another forgery of the same perfons. The gospel of "Scythianus" was composed by him who was the fource and author of the Manichean hereby. The gospel of "Tatian" was no other but a harmony of four gospels, or a fort of epitomes of the whole history contained in our four gospels. The gospel of "Thaddaeus" is merely mentioned in the decree of pope Gelasius. The gospel of "Thomas" or the gospel of the "Infancy of our Saviour," is mentioned by Origen, Eut- fcbius, Cyril, Ambrose, Athanasius, and Jeron, and is unquestionably apocryphal; though this is different from the gospel of Thomas, one of the followers of Manes, the head of the Manichees, for Origen, who mentions the former, lived a considerable time before the Mani- chean hereby was divulged. The gospel of "Truth" was a forgery of the Valentians in the second century. This is suppted by some to be the same with the gospel of "Valentine," but others are of opinion that he had a gospel of his own, different from that called the gospel of Truth used by his followers. For further particulars we refer to Jones's Caxon and Lardner's Works.

GOSPINI, in Geography, a town of the island of Sar- dina; 24 miles S. of Orifagni.

GOSPORT, is a sea-port town of Hampshire, England. In the time of king Henry VIII., when Leland visited this part of the island, Gosport was only a poor village inhabited by fishermen; but it has gradually become a town of con- siderable extent and importance; and of late years has been regularly fortified on the land side by a line of battions, re- douts, countercarps, &c. that extends from Wobul to Stoke, or more properly, Alverstoke. Within the works on the Wobul side, are the king's brewery and cooperage, with an immense range of florehouses for wine, malt, hops, &c. This place communicates with the sea by means of a large basin and canal, with extensive quays, where vessels of considerable burthen can take in their stores. Many small boats belonging to Wobul are employed in the conveyance of wine, beer, and water, to the ships in the harbour. On the Wobul side are also the new barracks, an extensive range of buildings, with every convenience for a great number of soldiers. Gosport, considered as a sea-port, is handsomely built, and the police well regulated. The town is a chapelry to the neighbouring village of Alverstoke, the chapel is a spacious edifice, standing in a large well- planted cemetery, to the south of the town; the interior is neat, and dappled into a middle and two side aisles. The workhouse for the poor is a large, airy, and commodious building. Here are also several charity-schools; and some almshouses for distressed widows. The markets are held three days weekly, and are much frequented, and vegetables are sold in great abundance; the latter being brought, not only from a considerable distance inland, but also from the Isle of Wight. Two fairs are held annually. Several breweries are established; and a very extensive iron foundery, where numerous articles are manufactured for government. Gosport is 73 miles distant from London; the population of the parishes of Alverstoke, including the inhabitants of this town, was returned, under the act of 1821, at 11,295; the number of houses being 1926. The connection between Gosport and Portsmouth is preferred by numerous ferryboats that ply across the harbour, which is this place is about three quarters of a mile in width.

At a small distance south of Gosport, is the Royal Hospital of Hauler, built between the years 1746 and 1762, for the reception of sick and wounded seamen, on the earnest recommendation of the late earl of Sandwich. It is situated within 400 yards of the extremity of the point of land which bounds the west side of the entrance to Portsmouth harbour; and consists of an extensive front, and two wings, each comprising two distinct ranges of buildings. In this hospital upwards of 2000 patients can be accommodated; the regular expense of the establishment in salaries, &c. is above 5000l. annually.

Nearly a mile south-west from Hauler hospital is Fort Monkton, a modern and regular fortification, exceedingly strong, and defended by thirty-two pieces of heavy ordnance; to the westward, ranges a strong redoubt; and this, together with the fort, effectually protects this part of the coast. On the shore, to the easterly, a high and massive stone wall has been erected, to preserve the land from the ravages of the sea.

Near the extremity of the neck of land which terminates the entrance of the harbour on the east side, is the Block house, a very strong fort, defended by a formidable battery. Beauties of England and Wales, vol. vi.

GOSFORT, formerly called Appleford, is a fishing town of America, on Star island, belonging to Rockingham county, New Hampshire, containing 85 inhabitants; about 12 miles E.S.E. of Piscataqua harbour.

GOSS, in Rural Economy, a term occasionally applied to the common whin in different places, and which is sometimes written goose. See Flax.

GOSSAINGUNE, in Geography, a town of Hin- donhouse, in Oude; 15 miles S.E. of Lucknow.

GOSSAMER is the name of a fine filzy substance, like web.
cobwebs, which is keen to float in the air, in clear days in autumn, and is more observable in flubbed-fields, and upon furze and other low bushes. This is probably formed by the flying spider, which, in traversing the air for food, floats out these threads from its anus, which are borne down by the dew, &c.

GOSSEMPINUS, a name given by Pliny and the ancients to a tree growing in the East Indies, which produced a fort of cotton, the threads of which were too short to be spun or carded; so that it served only for the fillings of beds and the like, for which it was very proper, being very light and soft. It was in some esteem in medicine also, to recall the heat and spirits into parts to which it was applied. It is called by Piño arbó fiber lincérea, the wool-tree, and had its ancient name from the words gypsun, cotton, and pinus, the pine-tree, being somehow like the pine in external appearance, yet bearing a fort of cotton.

GOSSE-ABDIALI, in Geography, a town of Nuba, on the Tenezé; 90 miles S. of Jazan.

GOSSEC, M. in Biography, a voluminous French musical composer of the old school, almost the only linear descendant of L'Alfi and Rameau. He had force, fire, and knowledge; but his style was not of that of the present day, either in Italy or Germany, nor could his friend, M. Laborde, persuade us, that "true genius is in need of no school or model. In whatever nation a man of genius may be born, he will make himself known, and not march with his firmens, though without a guide, in the road to glory. Celebrated schools cannot give genius, that is the boon of nature, and nature wants no school." Essais sur la Mus.

Unluckily, nature alone has never made an artist. A good painter, poet, or musician can never be made without education, study, and models. Ingenious works have been produced by the dyes of genius, but never faultlessly. The awkwardness of self-teaching will always appear; and taste, elegance, facility, grace, and often learning, will be wanting to render them perfect.

GOSSEINS, in Geography, a town of Thibet, on the Dwesh. N. lat. 30° 30'. E. long. 81° 24'.

GOSSELIES, a town of France, in the department of Jemmap, and chief place of a canton, in the district of Chalkroy. The place contains 28,722, and the canton 12,894 inhabitants, on a territory of 100 kilometres, in 17 communes.

GOSPIUM. See GOSPIUM.

GOSPLAR, in Geography, a town of the kingdom of Oehom, on the Gohe, which runs near this place into the Okear. It was a free and imperial town, having on one side the lake of Hildesheim, and on the other the principality of Wolframburg. It was founded in the year 922, by Henry the Fowler, and part of it re-built after being destroyed by fire in 1728. It has four parish churches, two chappels, and two Lutheran convents. Its principal trade arises from the mines of iron and lead in the Okear mountain near it; 30 miles S. of Brunswick. N. lat. 51° 55'. E. long. 10° 26'.

GOSSUM, a swelling of the thyroid gland. See Broscholle.

GOSSEWSTEIN, or GOSMANSTEIN, in Geography, a town of the bisphoric of Bamberg, on the Puthach; 20 miles E. S. E. of Bamberg. N. lat. 49° 45'. E. long. 11° 19'.

GOS-SPYUM, in Botany, the Cotton plant. The name is by supposition by the learned to be of Egyptian origin, and if so, is akin to Cotonus, or Cryptocotis, the evident source of our word Cotton, which is given as the Egyptian appellation of the plant in Alpinus, de Plaetis

Gen. Ch. Cal. Perianth double: the outer of one leaf, three-leaf, flat, largest; inner of one leaf, cup-shaped, with five blunt notches. Cor. Petals five, inwardly heart-shaped, flat, spreading, attached to the tube of the flaminas by their base. Stan. Filaments numerous, connected in their lower part into a tube, separate and lax above, inserted into the corolla; anthers kidney-shaped. Pist. German superior, roundish; style columnar, as long as the flaminas; stigma three or four, oblong, thickish. Peric. Capsule roundish, pointed, with three or four cells and as many valves, with contrary partitions. Seeds numerous, oval, fringed and enveloped in wool.

Eff. Ch. Calyx double; the outer three-leaf. Capsule with three or four cells. Seeds enveloped in wool.

The species of Cotton, like those of all plants cultivated from the most remote antiquity, in all countries, for chemical purposes, are extremely difficult to define, and obscured by numerous varieties.

Linnaeus in Sp. Pl. ed. 1, defines three species only,

1. G. herbeocam. Camer. Epist. 203. Cavan. t. 164. f. 2, supposed to be a native of the Levant, East Indies, and Africa, and generally cultivated in those countries for its produce.—Leaves five-lobed, pointed, with one gland beneath. Stem herbaceous, nearly smooth.—This is annual, with a bulky, branched, often zig-zag stem, smooth or only slightly downy. Leaves cut half-way down into three principal, and two smaller lateral, pointed rounded lobes. The mid-rib bears one gland at its back, about half an inch from the flank. Flowers yellow, purple at the base. Capsule the size of a walnut, enveloped in the calyx like a sifter.

2. G. herbaceus, taken up from Plukenet, t. 158. f. 1. Leaves three-lobed, entire, with three glands beneath.—Supposed to be a native of Barbadoes. It is at least one of those cultivated in the West Indies. The plant is in all its parts larger than the foregoing; lobes of the leaves not near to the mid-rib.

3. G. arborcum. Cavan. t. 165. Plub. t. 158. f. 3. (Cuda-pariti; Rhode Hort. Mal. v. 1. 55. t. 31.)—Leaves palmate, five-lobed; lobes lanceolate. Stem shrubby.—Native of the East Indies in a sandy soil. The woody perennial stem, and deep-cut long-lobed leaves, whose mid-rib bears one gland, distinguish this. The flowers are reddish. The cotton is used in manufactures. Willdenow erroneously quotes Alpinus here.

His Cotunisgar is in the Plant. Egypt. t. 71, not his Exot. t. 38, and does not agree with the East Indian plant.

To these is added in Sp. Pl. ed. 2. 975;

4. G. hierfum. Cavan. t. 167. Leaves with three or five acute lobes. Stem branched, hairy.—The synonym of Tournefort is wrong. This is said to come from America. It appears to us a hasty variety of the frill, for the gland on the mid-rib, which Linnaeus thought an exclusive mark of hierfum, is found in both.

What Linnaeus intended by G. religiosum, Syl. Nat. ed. 12. v. 2. 462, is rather doubtful. He defines it—Leaves thrice-lobed, acute, with one gland beneath. Branches dotted with black."—We have an East Indian plant which answers to this definition, but it does not exactly agree.
agree with what he has marked "religion" in his own herbarium, which appears to us barbarous; though it may be what he had in his garden.

With the "religion" of Murray, Comm. Gota, for 1756, t. 1, we are unacquainted.—Cavallini figures and describes several more species, especially G. "religion" t. 166, a noble plant, from Commerson's herbarium, gathered in the Mauritius.—Widénan, adopting these, reckons ten species in all, but the synonymy of the whole genus requires revision.

GOSTAST, Jotifsrud, or Jofopcheid, in Geography, a town of Saxony, in the circle of Erzgebirg; 23 miles S. of Chemnitz. N. lat. 50° 26'. E. long. 13° 2'.

GOSLIN, a town of the duchy of Wurzawl; 43 miles N.N.W. of Rava.

GOSTULLA, a town of Bengal; 22 miles E. of Kithaenge.

GOTARA, a town of Hindoostan, in Dahr; 57 miles S.S.W. of Patna.

GOTTEROT, a valley of Switzerland, in the canton of Friburgh, on the N.W. of the town of Friburgh, near the bridge leading to Bern, takes its name from the Goterom, a small rivulet; it is extremely narrow, and above two miles in length, and is bounded on each side by overhanging rocks of sandstone. Vernet, the celebrated landscape painter, flumed these rocks with great attention, and frequently declared that, excepting those of Tivoli, he never saw any where varying tints had a more pleasing and harmonious effect. The valley contains several mills, an iron foundery, where the ore brought from Franch Comte is forged, and a manufacture of linen and cotton, established by some merchants of Neuchatel, under the protection and encouragement of government.

GOTH, STEPHEN, in Biography, archbishop of Upsal, in Sweden, in the 16th century, concurred in the measures adopted by king John, to restore and re-establish popery in that kingdom. With this view he functioned a new liturgy, which, under the presence of bringing the Lutheran church nearer to the simplicity of the earlier ages of the gospel, artfully affronted the doctrines and ceremonies of worship to those of Rome, with the omission of some particular forms and expressions which would have too plainly divided the object in view. This liturgy was ordered to be used in all the churches. The king's brother Charles, and the clergy within his jurisdiction, were alarmed at this attempt, and they so effectually roused the jealousy and excited the fears of the people, and of the states, that after repeated efforts to carry his point, which introduced great confusion into the kingdom, and had nearly produced a civil war, the king was obliged to relinquish his scheme, and the liturgy was suppressed. It has long since become an object of curiosity among collectors, and is entitled "Liturgia Suecana Ecclesiae cum praefatione et notis Laurentii Upfalensis Episcopi," 1576. Univer. Hitt.

GOTHA, in Geography, a principality of Germany, in the circle of Upper Saxony, bounded on the N. by the electorate of Saxony, on the E. by the duchy of Weimar, on the S. by the county of Heussberg, and on the W. by the principality of Elersbach. The duchy contains 12 towns, and more than 200 churches; it abounds in grain and fruit, and the southern division contains part of the forest of Thuringia, and some mine works. The flate consists of three classes, viz. counts, nobility, and some barons, convoked by the prince. The reigning duke maintains a guard of 150 men, two regiments, each of which is composed of 800 men, and a corps of artillery. The chief rivers are the Leine and the Neisse.

The capital of the principality of the same name is seated on an eminence near the Leine, which supplies the town with water, conveyed by stone-canal, and is among the noble and handomest towns in Thuringia. It has an hospital for the fathers, two schools for their children, and barracks, in which the military art is taught; it has likewise a foundry for cannon, balls, &c. and two churches, a good academy, a house of correction, an hospital for widows, and another for orphans. The inhabitants carry on a considerable trade in wool and woollen manufactures, and beer; and they derive benefit, not only from the agriculture of the vicinity, but from the passengers that traverse it from Leipsick to Upper Germany. The residence of the duke, called Friedenstein, stands on a hill above the town, and contains an armoury, a valuable library, a museum of natural curiosities, and an excellent cabinet of medals: 13 miles S.W. of Erfurt. N. lat. 50° 37'. E. long. 10° 40'.

GOTH, a river of Sweden, which rises from the southern extremity of the lake Wenner, near Wennerborg, and after a course of 70 miles, falls into the sea near Gothenburg. In most places this river flows with a gentle current and in a narrow channel, and is navigable only in some parts of its course for small craft of 20 tons burden. If it could be rendered navigable through its whole course, the Wenner lake might be joined with the German ocean; but as numerous shoals and cataracts intervene, the communication has been attempted by the Carlgraf canal, the canal of Tralhassa, and the sluices of Akerflasa and Edes. About 10 miles from Gothenburg the river Gota divides into three branches: two unite again after encircling a small rocky island, crowned with the fort of Bolus, formerly deemed impregnable; the stream formed by the union of the two branches is called the Northern river, and falls into the sea after a course of 10 miles. The third branch retains the original name of Gota; and the space included between the Northern river and the Gota is named the island of Hillingen.

GÖTHARD, Sr., a town of Hungary, near which the Turks were defeated by the Chirilians, in the year 1663; 21 miles W. of St. Crois.

GÖTHARD, St., a chain of mountains of Swisserland, in the canton of Uri, the summit of which rises above the sea 9075 feet, though some have estimated its height to much greater. The particular parts of this chain are called by different names; of which the principal are the Salla, Prun, and Surecha, to the east; the Feudo, the Patuma, and the Locendo, to the west; to the north, the Urfino; and to the south, the ridge of naked and pitted rocks of the Val-Magdia. Of these, the Feudo is the highest. There are five parishes on the neighbouring heights, on which are fed 200 cows, 150 goats, and 30 hordes. The river Téno has three principal forces in the chain of St. Gothard; the first is a spring near the foot of the Prun, the second is the lake of La Salla, in another part of the eastern chain, and the third is furnished by the streams of mount Feudo. Three torrents uniting with another branch, that flows from the Furca, through the valley of Bedneto, form one great torrent, which takes its course towards the south, enters the lake of Locerno, and traversing part of the Mensano, falls into the Po. The course of the Reuse is the lake of Locendo, an oblong piece of water, about three miles in circumference, stretching between the mountains of Patuma and Locendo, and almost entirely supplied by the immense glaciers which crown the summit of the Locendo. The stream issuing from this lake rushes down the valley of St. Gothard, and joining in the vale of Urfeno, the two branches which come from the Furca on one side, and from the Grison mountains on the other, flow towards the north into the lake of Luc,
The valley of St. Gothard is exceedingly dreary. It does not contain a single field, nor produce a single tree; and the sides of the mountains are barely sprinkled with short herbage.

Mount St. Gothard affords one of the best Alpine passages from Germany and Switzerland to Italy. The Romans were acquainted only with that over the Great Bernhard and September. The Gothard was called by them sometimes Adula, sometimes the High and Lepentine Alps. The present road over this mountain begins at the village Hospitall, in the Urner valley, and terminates on the same side, at Airolo; its breadth is from ten to twelve feet, and it is covered with large pieces of granite.

The first attempt of passing over the Gothard in a traveling carriage, was successfully made in the month of July, 1775; by the late Mr. Greville, the gentleman to whose early exertion in collecting and in employing persons well qualified to assist him, we owe very great variety in their mixtures of minerals lately purchased by government for the British museum.

Though, in the high Gothard valley, the temperature is seldom below 19° of Reaumur, yet, on the N. side of the mountain, the climate is sufficiently rough to make the growth of trees cease at the height of 4,566 feet. Among a vast number of plants common to the Alps in general, we find here, as peculiar to mount Gothard, the Viola minima, and Campanula patula.

But most interesting is this mountain in regard to its mineral substances, and its geognostic structure in general: for, respecting the former, it may be said, that there is scarcely any where a tract of country known, that, within the same extent of space, affords so considerable a variety of them. This is not the place for enumerating all these fossils; we should, however, not omit mentioning, that the tremolite, which has received its name from the valley of Tremola, is, according to Ebel, not found there, but deeper down the mountain, in the Leventine valley. See Tremolite.

The St. Gothard consists entirely of primitive rocks, which, however, display, to the best advantage, their general and district characters. On the N. side veined granite, gneiss, mica-slate; in the plain of the rocky valley, where the Hospitall flanks, granite of large grain, traversed by veins of veined granite and mica-slate; from the summit downwards, on the S. side, mafic granite of large and small grain alternately, veined granite, mica-slate; in the Tremola valley, on the Flunio and Sorecina, hornblende-slate concretions, mingled with some patches of dike granular quartz, in others with feldspar, and lower down with fine reddish-brown, dolcicatal calcrete; with a surrounding rock the road winds, through the Piosella forest, down to Airolo. On the N. side, in the Urner valley, among the few mentioned rocks, runs pot stone on the S.S.E. part of the valley, and on the N. W.N.W. primitive horn-bone and clay-slate; while the S. side in the Leventine, Canaria, and Piora valleys, exhibits primitive horn-bone and gypseous.

All rocks of the Gothard are disposed in strata, having a direction from F.N.E. to W.S.W., and from N.E. to S.W., which is best observed between Hospitall and Airolo, where the road makes a transversal section, almost through the whole of the central chain. The regularity of the stratification of the granite is most striking in the neighbourhood of the Rudent bridge; the strata are from three to four inches thick, and have their direction from N.E. to S.W. Likewise, on the Piusa and Flunio, and southward from Hospitall down the valley of Tremola, the primitive horn-bone and gypseous, paws on the S. side of the mountain through the Leventine, Canaria, and Piora valleys, and the horn-bone, clay-slate, and pot-slate, lean on its N. side, in the Urner valley, are the continuations of the same formations that range through the whole of the Pays de Vand.

The ridges of mountains constituting the Gothard are exceedingly broken, and near the marks of causes the most destructive; nor is it improbable that they were infinitely higher in ancient times, and that, at the period of the Romans, they were not unaptly called the High Alps. The upper rocky valley, where the Hospitall is situated, is covered with numberless pieces of rocks, which are all precipitated from the surrounding peaks. The great proportion of a small grained granite, among the rocks of the Gothard, are the probable causes of this extraordinary devastation. The upper, nearly circular, rocky valley, was in former times completely flat on all sides; the remains of the rocks that formerly filled the chasms are still distinctly seen on the N. side, near the bridge over the Rudent, where the Reins forms a beautiful fall; and on the S. side, below the Hospitall, the rocks approach each other so closely, that the violent action which, and grained to the Caumizlii, is sufficiently evident. Before that revolution happened, it is highly probable that this considerable valley formed a deep lake; nor is it left for, that the Urner-valley, before the Devil's mountain was broken through, and the upper Leventine valley, before the Platier, near Dacezo Grande, was rent asunder, represented deep seas of considerable extent.

GOTHEBORG, a town of Sweden, in West Gothland, distinguished by a commodious port, and standing near the site of Lodef, a town built by Gustauus Vasa, which, being endowed with singular privileges, soon became the great emporium for the trade of the western provinces. Charles IX., when duke of Gothland, having, in 1604, laid the foundations of a new town in the island of Visingen, not far from Lodz, called it Gotheborg, in honour of his duchy. On his accession to the throne, he erected in his new town a trading company; drew thither many foreigners, particularly the Dutch, to whom he allowed an exemption from all duties of export and import during twenty years; established a corps of English and Scots troops, and granted to the Caumizlii a free exercice of their religion, the first place in Sweden where this toleration was permitted. By these means Gotheborg soon became a flourishing port, and, next to Stockholm, the most commercial town in Sweden. In 1611 it was reduced to ashes by the Danes, and afterwards rebuilt in the reign of Gustavus Adolphus on the present site, and obtained a confirmation of its ancient rights, with a grant of several new privileges. Gotheborg is built in a singular situation. At a small distance from the sea is a marshy plain, not more than half a mile in breadth, watered by the rivers Göta and Moldal, and almost included with high ridges of bare and rugged rocks. Gottheborg stands partly on the ridge, and partly in the plain, and is divided into the upper and lower town. The latter is entirely level, intersected by several canals, and the houses are constructed on piles: the upper part hangs on the ditches, and rows of buildings rise one above the other like the tents of an amphitheatre. The whole is regularly fortified; and the circumference is near three miles, exclusive of the suburbs, called "Haga," which lies towards the harbour. The streets are uniformly straight; some few of the houses are of brick, but most of them are constructed of wood, painted red. The harbour, formed by two chains of rocks, is about a quarter of a mile in breadth; and the entrance is defended by the fortress of New Efelfborg, which stands on a small rocky island, and contains a garrison of 250 men.

A royal society of sciences and literature has been lately established.
established in this town, on the plan of that of Upsal. The acts, written in the Swedish tongue, and printed in 8vo., contain dissertations on various subjects, in the several branches of science, natural history, antiquities, history, and similar letters. The population amounts to 150,000 persons, in consequence of an increase, occasioned by the extension of its commerce, particularly on account of the East India company, and the success of the herring fishery. The East India company was established in 1731, and, on account of the ice, which closes the port of Stockholm, in the gulf of Bothnia, at the proper season of the departure of ships for the East Indies, the company carries on its commerce from Gothenburg, whose harbour, lying in the German ocean, is more open. In 1749, the herrings, which had not hitherto usually approached the western shore of Sweden, flocking in shoals, the inhabitants of Gothenburg established a fishery, which has been very lucrative. The fishery begins in November, and though it continues fearfully three weeks, it supplies the fishermen of Gothenburg with not less than 600,000 barrels. Of these, 250,000 are salted, and the oil is drawn from them; fifteen barrels of herring yield one of oil, which is principally exported to Holland and Spain. One barrel of salt, procured from Spain, covers three barrels of herrings: the average exportation of salted herrings may be estimated, and the inland consumption of Sweden at 50,000 barrels. An English consul and factory reside at Gothenburg; and a chapel, with a regular chaplain, is appropriated for their use. The fortifications of Gothenburg are so weak, that in the year 1788 it must have fallen into the hands of the Danes, if foreign powers had not interfered. N. lat. 57° 40'. E. long. 11° 44'. Coox's Travels in Sweden.

GOTHIC, or GOTTICK, something that has a relation to the Goths, an ancient people, originally inhabiting that part of Sweden called Gothland; whence they spread themselves over Greece, Dalmatia, Bulgaria, Italy, Spain, &c. See Gothics.

Gothic Architecture, a term of approbation to denote one or more kinds of architecture which prevailed during the middle ages. It seems to have been invented by the reformers of the Grecian orders in Italy, about the middle of the 16th century, to dignify every preceding species of European architecture not conformable to them, and it was imported into England by Christopher Wren, though the latter appears sometimes to confine the term to the pointed style, in which particular he is followed by the greater part of late writers. Mr. Evelyn, quoted by Sir Christopher Wren, in his "Parentalia," says: "Gothic architecture is a conglomeration of heavy, dark, melancholy, monkish piles." In the same sense, Sir Christopher himself, speaking generally of what he terms Gothic architecture, calls it "Mountains of stone; vast, gigantic buildings, but not worthy the name of architecture. This we now call the Gothic manner: so the Italians called what was not after the Roman style." In opposition to the idea which this eminent architect gives of the architecture in question, he, in another part of his Parentalia, describes the inventors of it as "setting up slender and misshapen pillars, or rather bundles of slates and other incongruous props, to support ponderous arched roofs without entailure." In conformity with this latter notion of Sir Christopher, Mr. Rous, a professional writer, says: "Modern Gothic is distinguished by the lightness of its work, the exquisite boldness of its elevations and of its sections, by the delicacy, profusion, and extravagant fancy of its ornaments." The fame confusion of language, if not of ideas, prevails amongst the admirers of the Gothic style, so called, as amongst the declared foes of it. The late poet laureat, Thomas Warton, who has written a great deal on the subject, and who had planned a "History of Gothic Architecture," speaking of Salisbury cathedral, expressly denies that it is in the Gothic style, while two other celebrated writers in the same line, the Rev. James Benthall and Capt. Groats, as positively affirm that this cathedral is "entirely in the Gothic style." The perplexity and uncertainty of an ordinary reader must necessarily be increased by the different senses in which the terms, ancient architecture, modern architecture, Saxo-Celtic architecture, Norman architecture, and English architecture, are now used by different writers. To clear up this confusion, and to present distinct and clear ideas on these much agitated subjects, it seems best, to treat them in an historical manner.

It is demonstrable that the regular orders of Grecian architecture were upon the decline throughout the Roman empire after the reign of the Caesars, and fall more so after that of Constatine the Great. A century later the Ostrogoths overran and subdued Italy, the Visigoths, Spain, the Huns, Germany, the Vandals, the Roman provinces of Africa, the Franks, France, and the Saxons, Britain. These fierce barbarians destroyed innumerable monuments of all architecture, and the other arts, but they did not introduce a style of building different from that which they found professed in the conquered countries. They did not infect the ancient inhabitants to build in a new manner; on the contrary, they learnt of them so much of the art as they actually acquired. But the art itself being vastly degraded in the fifth and sixth centuries, and those warlike hordes not being very apt scholars, no wonder their first structures were executed in a rude and heavy style. Still nothing is more groundless than to speak of Gothic architecture in the manner of Mr. Evelyn and Sir Christopher Wren, as of a style of building invented or introduced by the Goths. The fact is, the heavy circular manner of building which prevailed throughout Christendom, from the fall of the Roman empire, in the fifth century, down to the twelfth century, was the Roman, or, what is the same thing, the Grecian style, incorrectly and rudely executed. Amongst us it is called the Saxon style, because it prevailed during what is called the Saxon period or dynasty in South Britain; but the first teachers and the models of it were both of them of the time of Gregory the Great. On the first introduction of Christianity amongst the Saxons, at the conclusion of the fifth century, they consecrated many of the existing Pagan temples to the Christian worship, according to the instructions which they received to this effect from pope Gregory the Great, and they ran up other temporary oratories of wood or wattles, as we learn from Bede, and other original historians. Very soon, however, the Saxon millionaires, who converted them, taught them to build churches of stone after the Roman manner; for this denomination of it, the Roman manner, (more Romans,) is always mentioned by the aforesaid historians. The first archbishop of the Northumbrians, Paulinus, who was a Roman monk, appears to have been the chief architect amongst the English Saxons at the beginning of the seventh century. He built churches of stone at York, Lincoln, and other places. His next successor but one, Willfrid, was an Englishman, who not only equalled but greatly surpassed his master in architecture. For the churches which he built at Rippon and at Hexham were long celebrated for being the finest buildings of their kind north of the Alps; but this is expressly recorded, both of him, and his rival in architecture, Benedict Biscop, abbot and founder of the church and monastery of Were-
mound, that they made different journeys to Rome, and studied the architecture of the church of St. Peter's and other churches there, and that they even hired workmen from thence to execute their works in England. Thus it evidently appears, that the style of architecture, which is called the Saxon style, was not the invention of our ancestors, but was imported from Italy in the seventh century; and it is equally evident, from various monuments, that the Italians in the and the subsequent ages built in the same heavy manner, and made use of the same members and ornaments, that the English Saxons did. Still the architecture of our ancestors, previously to the conquest, though very heavy and rude, has been too much depreciated by many English writers. The Rev. Mr. Bonham, in his "History of the Church of England," or rather the post-Grey, who drew up its architectural part of that work, refrains from, Staveley, and other authors, who deny that the Saxon builders made use of stone for their buildings, or knew how to turn an arch; but then this very writer fails to do them the justice due to them, where he signifies that they were unacquainted with the use of towers, bells, and transepts, previously to the tenth century. It would have been strange if they had not imported these amongst other ecclesiastical inventions from Italy during the preceding centuries; but we have otherwise sufficient proofs that they had adopted each of them long before the tenth century.

During a great part of the ninth and tenth centuries, England and France were as much harassed by invasions of the Northern barbarians, as their former inhabitants, the Gauls and Britons, had been in the fifth century, by the ancestors of the now civilized Saxons and French. These turbulent invaders, who were indifferently called Danes or Normans, were guilty of much greater devastation upon the existing religious monuments, at least, than the Goths and Vandals had committed; because the latter were Christians, though Arians, when they over-ran the civilized world; whereas the Danes and Normans, when they invaded England and France, were persecuting Pagans. So great was the dread of their violence throughout the half mentioned country, that the following petition was there added to the litany: "From the fury of the Normans, O Lord deliver us." In fact, the Almighty was pleased to deliver first France and then England, from the scourge which had so long and so forcibly afflicted them; but in a very different manner from what the Christian inhabitants expected. Instead of witnessing the extermination or subjugation of their barbarous enemies, they saw them bend their necks to the yoke of Christ, and become models of piety and morality to themselves and the other Christian nations. Such a feat was the cause of the Northern men, who settled in that part of France, which from them has since been called Normandy. A falling peace and tranquillity being, through this happy event, restored to the French provinces, its princes and nobles began to rebuild their demolished churches, and to erect others with incredible diligence. But no people flowed so much zeal in this undertaking as the newly converted Normans. The reader will be convinced of this, when he is given to understand that William the Conqueror, during the few years that he reigned in Normandy, I previouly to his invasion of England, built two noble churches and abbeys, and his nobles, not fewer than thirty-eight, each of them availing with the rest, to make his building the most magnificent and splendid. Such were the Normans, the bravest, most industrious, and most religious people, and the most addicted, in particular, to ecclesiastical architecture of all Christian people, when William, his prince, with the flower of his nobles, his army, and his ecclesiastics, came to settle in England soon after the middle of the eleventh century. It is to be observed, that the most celebrated schools of

Gothic Architecture.

Literature and the arts, and more particularly of architecture in Europe, at this period, were the abbeys of Bec and Caen in Normandy, the former of which produced those three great architects, Lanfranc and Anselm, successively archbishops of Canterbury, and Gaundolph, bishop of Rochester. But indeed all the Norman prelates and abbots appear to have been able architects; for there was hardly a cathedral or abbey church in England which was not rebuilt by one or other of them, in the course of thirty or forty years after the conquest. The characters which they aimed at in their structures were evidently the sublime and beautiful. To produce the former effect, they built their churches as long and as lofty as possible; to produce the latter effect, they not only built in a much more neat and perfect manner than the Saxons had done, but also they made use of certain new invented ornaments in their structures. Of these the most offensively and ordinary was the arcade or series of arches which, in one or other of its various forms, is to be met with in all the existing Norman churches. From the continued efforts of these indefatigable and ingenious architects, to make their churches as awful and as beautiful as possible before the middle of the twelfth century, a new style of building was produced, called "the Pointed Style." It certainly appeared, for the first time, either in England or in France; nevertheless, the fact ascertained influence of which has hitherto been produced, claims the honour of the invention for this country. But before we proceed to give a more particular account of the rise and progress of this singular style of building, it will be proper to detail the various other systems which have been published respecting it.

It has been seen above, that Mr. Evelyn and Mr. Christopher Wren describe the architecture of the middle ages, in general, whether circular or pointed, under the opprobrious term of Gothic, as being the real invention of the Goths and other barbarians. The former of these writers, as quoted with approbation by the latter, says, in his "Parentalia": "The Goths and Vandals having demolished the Greek and Roman architecture, introduced, in its stead, a certain fantastical and inventions manner of building, which we have since called modern Gothic, of the greatest industry and expensive carving, full of fret and lamentable impiety, sparing neither pains nor cost." We see that the writer here speaks of the light pointed ornamental style of our ancestors no less clearly than he does in another passage, quoted above, of the plain heavy circular style, called the Saxon; and that he supposes the former no less than the latter to have been really introduced into the countries, which had formed the Roman empire, by the Goths and Vandals, who subdued them. How little reason there is for ascribing the Saxon style to these barbarians has been shown above; and, with respect to the pointed style, it is sufficient to observe that this appeared in no part of Christendom before the twelfth century; whereas the Goths and Vandals committed whatever depredations on the monuments of Roman art, which they did commit, in the fifth century, and that their power was everywhere crushed, and their very name extinguished in the course of the sixth century, except, indeed, in Spain, where the name of Gothic remained attached to the reigning family, till the beginning of the eighth century and no longer. So groundless and absurd, in every respect, is the term Gothic, as applied to pointed architecture!

At the same time that Mr. Christopher commends the system of his friend Mr. Evelyn, he himself departs from it, since he prefers the word Spiracentic to denote the pointed style. "What we now vulgarly call the Gothic," he says, "ought properly and truly to be named Saracentic architecture, refined by the Christians, which first of all began in the East, after the
the fall of the Greek empire. The holy war gave the Christians who had been there an idea of the Saracen works, which were afterwards imitated by them in the West."

This system concerning the pointed style, namely, that it originated with the Saracens, has, out of mere respect to the name of its author, Sir Christopher Wren, been followed by bishop Lowth, in his life of Wyclam, by Kious, by Marton, by Grose, and, in short, by the generality of modern writers who have had occasion to enter upon the subject. In refutation, however, of this system, we have to remark that the first, or Grand Crusade, in which the conqueror's son, Robert, and many other Normans and Englishmen embarked, making part of above a million of persons, who were engaged in it, began in 1096, and terminated by the capture of Jerusalem in 1099. Now it is certain from history that the cathedrals of Exeter, Rocheller, and Chicheller, with many abbey churches, were built wholly in the circular style after the last-mentioned year. Amongst these the influence which is most to the present purpose is that of Rocheller cathedral, which was built by that greatest architect of his age, Gundulph, formerly a monk of Bec abbey, then bishop of Rocheller, as well as the castle of that city, the chapel in the white tower of London, &c. without the leaf mixture of the pointed style. The reason of this, because Gundulph had travelled through the East on a pilgrimage to Jerusalem, a little before the crusade took place, when he had an opportunity of surveying the churches and other buildings of those countries at his leisure. Again, it has been remarked by Grose, Beatham, and other writers on the subject, that in all the descriptions and drawings of buildings in the Holy Land and other parts of the East, given us by Pecock, Norden, Shaw, Le Bruyn, &c. there is but one church, namely, that of St. John d'Acro, in the proper pointed style (which church the writer of this article has discovered to have been built by William, an Englishman, at the time when our Richard I. made himself master of that city); and that very rarely such a thing as a pointed arch is represented as existing in those countries. It is true a late writer, the Rev. Mr. Whittington, in his "Survey of the Ecclesiastical Antiquities of France," has proposed to discover from these and other drawings pointed architecture in every part of the East, from the Euxine sea to Egypt; but then it appears that he calls the mis-shapen obelisks and minarets of the Mahomedan mosques pointed architecture. He has another argument for his position, namely, that "it is improbable the dark ages of the West should have given a model of architecture to the East." If there is any force in this argument, it would follow that the mathematical scale of belfies, optical glasses, the mariner's compass, gun-powder, and print were discovered in the East instead of the West, contrary to the known facts.

Mr. Murphy, to whom the admirers of pointed architecture are indebted for his elegant views of the church of Batalla in Portugal, conjectures that this style was borrowed from the pyramids, and that of course Egypt was its native soil. But is almost every country and age men have built their habitations with sloping roofs to carry off the falling rain; hence they must have been the figure of a triangle at the gable ends of them, no less than the Egyptians did in their pyramids. Denon's, Meyer's, and other views of ancient buildings in Egypt, are by no means favourable to Mr. Murphy's system. There is indeed an ancient hall in the castle of Cairo, called Joseph's Hall, which is a great deal in the pointed manner, and which is supported by the vigors to have been built by the patriarch of that name; but Niebuhr and lord Valentia give sufficient reason to believe that it was built by Saladin, the enemy of our Richard I., whose true name was Joseph. In fact, it is in the style of that period. According to this supposition, we are warranted in believing that this hall was the workmanship of Christian prisoners, or fugitives, after the third crusade. Mr. Murphy's theory is equally delusive of historical grounds and moral probability.

Bishop Warburton, in his "Notes on Pope's Epistles," endeavours to unite together two of the above-mentioned refined systems, that which derives pointed architecture from the Northern Goths, and that which brings it from the Eastern Saracens, at the same time that he assigns the western peninsula of Europe for the real place of its birth. The following is an abridgment of his account. "When the Goths had conquered Spain, and the religion of the old (Christian) inhabitants had inflamed their piety, they struck out a new species of architecture unknown to Greece and Rome. For this northern people having been accustomed, during the gloom of Paganism, to worship the Deity in groves, when their new religion required covered edifices, they ingeniously projected to make them resemble groves; at once indulging their old prejudices, and providing for their present conveniences by a cool receptacle in a sultry climate, with the assistance of Saracen architects, whose exotic style of building suited their purpose." All this is mere reverie.

The Goths and Vandals entered Spain in the year 409. They did not, however, acquire there a new religion from the old inhabitants, for they were already Christians, and habituated to the use of churches. On the other hand, the Moorish Saracens did not enter Spain till three hundred years afterwards, namely, till the year 712, when having crossed up the Christians in the mountains of Afturias, there continued ever afterwards the most relentless warfare between the two people. It is impossible to conceive more monstrous ideas than that the Christian Goths should have brought with them into Spain a partiality for the Pagan worship which they had practised in the forests of Germany, and that they should have retained it for the space of three hundred years afterwards, till they had the means of employing their implacable enemies, the Mahomedan Moors, to build Christian churches for their use; and that when this was effected, they should have kept the secret of pointed architecture to themselves for the space of 400 years longer! Were all this possible, or were it a fact that this style had been imported into our country from any other, where it had been practised for a considerable time before, it would have made its appearance amongst us at once, with its several striking characters; contrary to what we actually find was the fact. After all, if the aisle of an ancient cathedral resembles an avenue of trees in some respects, it differs from it in many others, which are obvious to the sight.

Having followed different guides, north, east, and west, in search of the original pointed architecture, we have latterly been invited by an ingenious artist to accompany him to the south, namely, into Italy, the cradle of modern arts, with a promise that he will there point out to us much earlier specimens of this style than are to be met with in this northern climate. In the year 1805 Mr. Simirczian, jun., returned from Italy, laid before the Society of Antiquaries a certain drawing, since engraved in the "Archaeologia," vol. xvi., of the dressings of a window belonging to the cathedral of Modena, in the richest style of the third pointed order, being such as we have no example of in this country before the middle of the 15th century. These dressings he would have us believe are coeval with the cathedral itself, which was built by the Norman chiefstain Roger, earl of Sic-
GOTHIC ARCHITECTURE.

ly, in the eleventh century. He presented another drawing, published by the society as aforesaid, which appeared to be much more for his purpose, because of the known dates of the original. This drawing represents a portion of the outside of the baptistery of the cathedral church at Pisa, which baptistery was certainly built by Diotisalvi in 1152. The drawing exhibits what we should call Roman and Saxon work, with intermixed crocketed pediments and pinnacles, such as we were unacquainted with for more than a hundred years afterwards. Lastly, this gentleman viewed a view of the cloister of Campo Santo, adjoining the altar mentioned cathedral, built in 1278. Here we see the richest tracery multitudes under semi-circular arches, the whole of which he considered as being the same original work. These specimens gained many converts to his system, that of Italy being the parent country of pointed architecture.

But there is no error which we have to guard against in studying architectural antiquity as the confounding of false-quaint alterations with the original work. There are few adepts in this science who would not flate at the first sight of Mr. Smirke's drawings, and who would not pronounce the works they represent an incoherent mixture of the architecture of different ages; but it was reserved for Sir Henry Englefield's profound knowledge of the subject and critical acumen to detect and exhibit in detail the pointed enrichments with which later architects had decorated the plain circular works of their predecessors. To the justice of this learned antiquary's remarks the accurate history of the cathedral of Pisa, written by Martini a canon of that church, bears ample testimony. In a word, all the specimens which Mr. Smirke has produced in favour of Italy's claim to the invention of pointed architecture, as well as all the other buildings, tombs, and altars at Rome, and in every other part of Italy, demonstrate its great inferiority both in date and in execution, to England, France, and Germany, with respect to this particular style.

Allied, in one respect to the system of Bishop Warburton, is that of Sir James Hall, bart., who, in "An Essay on Gothic Architecture," now published, endeavors to show that the pointed style was borrowed from the idea of upright pinnacles surrounded with ornamental work, the heads of which are to meet like those of trees in an avenue. But the utmost that the ingenious baronet proves is that basket-work may be made to resemble pointed architecture, not that pointed architecture was borrowed from existing models of basket-work. Lord Orford, heretofore Sir Horace Walpole, in his "Observations on English Architecture," says, that the architecture in question was copied from frame-work; just as if the making of boxes preceded the building of houses! After all, this is only placing the tortoise under the elephant; for where did artists learn to fashion their frises in the pointed style? Lastly, Mr. Payne Knight derives this style from all the three parts of the world, heretofore known, Europe, Asia and Africa, where he decides, in his "Principles of Taste," that "the style of architecture which we call cathedral or monastic, is manifestly a corruption of the sacred architecture of the Greeks or Romans, by a mixture of the Moorish or Saracenic, which is formed out of a combination of the Egyptian, Persian, and Hindoo."

But why should we wander into every remote corner of the world, and even into the regions of fancy in search of an invention which belongs to our own climate? And for what purpose should we take so much pains to prove a plant to be an imported exotic which we have seen sprouting up, and attaining its full growth in our own garden? Let us now go back to the point from which we started in pursuit of various false sysleds. We have seen above that the greatest people, without dispute, of the eleventh and twelfth centuries, namely, the Normans, the conquerors of England, France, Italy, Sicily, and various regions in the East, were at the same time a most industrious and ingenious people, and puffed of the most ardent passion for ecclesiastical architecture of any people we read of, and that they were guided by each other in the grandeur and beauty of their respective structures. To produce the effect of grandeur, as it has been before observed, they gave the greatest possible length and height to their churches; for that of beauty they devised several architectural ornaments; the most common of which was the arcade or series of small round arches, which appear on some part or other of all their churches built in this country subsequent to their conquest of it, and which sometimes cover the whole of them over, as we see on the outside of St. Botolph's priory, and St. Olyth's abbey in Essex, and in the balustrade story of the inside of Durham cathedral. Thefe arcades the architects diversified in a great variety of ways, as may be seen upon the tower of St. Augustine's monastery in Canterbury, built by the Norman abbot Scotandius in 1080. One of the varieties consisted in making the circular arches intersect each other. The portion thus intersected formed a new kind of arch, more graceful in its appearance, and far better calculated to give an idea of height than the round one, which, however, had hitherto been adopted by all nations, whether Egyptians, Greeks, Romans, or Saxons. In fact, every one must be sensible that a pyramid or obelisk, from its aspiring form, appears to be taller than a semi-circular arch, the diameter of which is equal in height to it. Thence plain and intersecting arcades were sometimes irregularly intermixed, as in Carlepio's and Flambard's work on the north side of Durham cathedral; and sometimes placed in alternate rows, as in that of Remigius on the façade of his church at Lincoln. The pointed arch thus formed appeared first in mere bifo refces, as in the above mentioned inlances, amongst several others; but soon it was likewise seen in alto relievo over niches and recesses, in the walls of churches, as in the remains of archbishop Lanfranc's work in Canterbury cathedral, and in the abbeys of Gloucester and Ramsey. It is probable that some of the first, if not quite the first open arches in the pointed style now existing, are the twenty windows in the intersected portions of such crossing arches in the choir of St. Crois near Winchester, made by that great encourager of the arts, and particularly of architecture, bishop Henry de Blois, king Stephen's brother. The date of this work is 1132, according to Godwin, Grose, and others, or 1135, according to bishop Louth, who had examined the records of this foundation, and Rudborne, the monk of Winchester, in his "Historia Major Wintoniensis." Most probably the choir was begun in the former year, and finished in the latter. As the prelate proceeded in his work, from the choir to the transept and tower of his church, he made several other pointed arches without any intersecting circles over them, notwithstanding the greater part of his work, as still appears, was the circular Saxon. In 1138, as we are assured by the above-mentioned monk of Winchester, and another monk who wrote the "Annales Wintonienses," bishop De Blois rebuilt his episcopal mansion of Farnham in Surrey, where his successors still ordinarily reside. Now in the ancient part of this building, we see at the present day pointed arches resting upon circular Saxon columns, just as we do at St. Crois; and no architectural critic, with these documents before him, will hesi-
GOTHIC ARCHITECTURE.

rate a moment in pronouncing them part of the work in question, executed by De Blois in 1138. As the same prelate restored the abbatial church at Rumsey, where his niece Mary was a nun, and as he himself had been abbot of Chaltonbury, before he was bishop of Winchester, we may safely attribute the pointed arches, intermixed with the circular ones in these two structures, to his direction, some time in the latter end of the reign of his cousin Henry I.

After all, it would be rash to pronounce absolutely that bishop De Blois of Winchester was the author of pointed architecture, since we have convincing evidence, that churches were built by other architects about this period, in the same mixed style of pointed and circular work. We must, however, incidentally observe, that before the conclusion of this twelfth century, the circular style was entirely laid aside, as well with respect to columns as to arches. We have evidence, for example, in the annals both of St. Wulfran's abbey Chelles, and of Peterborough abbey, quoted by Dugdale, that Bishop was abbey in Shropshire, where the seven pointed arches of the nave, surmounted by small circular arches, in the upper story, are still seen, was founded either in 1136 or 1139; probably it was begun in the former year, and finished in the latter. We might argue in the same manner from the dates and actual state of Kirkthorpe abbey, Lantony abbey, and several other ancient structures. If we may give implicit credit to the testimony and the plates of Captain Groke, the Scotch architects were not long in adopting the style of their English neighbours. It is remarkable that the ecclesiastical buildings erected by David king of Scotland, and his nobles, before he came into England in order to command the armies of his niece, the empress Maud, were purely in the Saxon style; whereas those founded there, after that event, present the same mixture of circular and pointed architecture which prevailed at that period in England.

A late writer, the Rev. Mr. Whittington, whose professed object it was to transfer the credit of the discovery in question from the Norman English and English to the French, which credit the latter seem disposed, from traditionary accounts, to attribute to our countrymen, has asserted that examples of pointed arches, of a more ancient date than any existing in England, are to be met with at the abbey church of St. Denis near Paris, which church was finished in 1144. It appears, however, that this writer was unequipped with the historical evidence on which the above-mentioned early influences of the pointed arch in England rest, and that he was even at a loss to determine which of the works at St. Denis really belonged to the period he has assigned. If we examine the pointed windows of this abbey, exhibiting different transitions of the first cruciform in Montfaucon's "Monarchie Françoise," which windows are said by this great antiquary to have been executed by abbots Sager in 1140, we shall not find the appearance of a pointed arch in any of them. It may be added, that in the famous transept of Parma, representing the conquest of England, and said to have been wrought by the conqueror's mother, there is no appearance either of a pointed, or so much as of an intersected arch, in the several churches, shrines, and other architectural works there displayed. In a word, throughout the whole of Montfaucon's plates, we every where find the French pointed architecture much inferior to that of a corresponding date in our own country.

To return to the subject of intersecting arches: we observe these sometimes to consist of plain semicircles crossing each other, as on the outside of the south transept of Wal-ke lyn's work at Winchester, and on the north transept of Warwiclt's work at Exeter, forming in the interections simple pointed arches; and sometimes we remark that the interections roll upon pillars, each of them being surmount- ed with a capital, or at least with an abacus, as on the north transept of Durham, and the west front of Lincoln cathedrals. In the latter case, we have the appearance of pointed arches with lateral points, or cusps within the heads of them, as Sir James Hall has very aptly termed them. This addition to the pointed arch was occasionally used in the first period or order of pointed architecture, but afterwards it became universal. The addition of another cusp on each side of the pointed arch turned its trefoil head into a cinque foil. In like manner, four of these cusps being placed at equal distances within that circle or "L'Œil de Bœuf," within the Roman and Saxon architects had been in the habit of placing in the tympanum of their pediments, turned it into an elegant quatrefoil or cross. By means of additional cusps, and circles within circles, the Katharine wheel, or Marygold window, as it is called in England, or "La Rose du Portail," as the French call it, was easily produced. In all the works executed during the middle and latter part of the twelfth century, a confused heterogeneous mixture of styles is everywhere discernible, as might be expected where secular fashion began to be left off, and the pointed one to be used instead of it.

In a general way, the arches were altered before the columns. Hence nothing is so common as to find in the structures erected between 1140 and 1150, arches of the flump point, reeding on circular Saxon pillars of the greatest circumference. It could not, however, long escape the observation of our indefatigable architects, that such heavy supporters ill accorded with the lightness of the aspiring arch. Accordingly, towards the latter end of this twelfth century, in some instances the circular Saxon columns began to be shaped like the Arabic numerical figure 8, so as to retain its former strength, and to appear gracefully slender; and whereas columns were made use of more for decoration than for strength, as for example to support ornamental arcades, or the arches of windows or doors, very thin detached columns were employed, and these for the most part made of Parbeck or Purbeck marble. We have a striking and most interesting example of these and other improvements which took place in the pointed style, towards the latter part of the twelfth century, in the east end of Canterbury cathedral. Persons who cannot see the original, will find it accurately represented in Mr. Carter's treasury of original specimens, called "The Ancient Architecture of England." This portion of our Metropolitan church was rebuilt, after an accidental fire had destroyed the upper part, and weakened the remainder of it, between the years 1175 and 1180. As we have the incomparable advantage of possessing a circumstantial account of this building, and of the differences between it and the former structure, raised a hundred years before by Bishop Lanfranc, which account is drawn up by the intelligent monk Geofrey of Canterbury, who was an eyewitness of what he relates, we shall find some of the most material parts of it; he tells us how, that the pillars of the new choir were of the same form and thickness with those of the old choir, but that they were twelve feet longer; that the former capitals were plain, while the latter were delicately carved; that there were no marble columns in Lanfranc's work, but that there was an incredible number of them in the work of the two Williams; that the stones which formed the ancient arches were cut with an axe, but those of new arches with a chisel.
that the vaulting of the side aisles of the choir was plain; whilst that of the new choir was groined and fixed with key-flouens; that the former choir had a flat ceiling ornamental'ly pointed; but that the succeeding choir was elegantly vaulted with hard stone for its ribs, and light topi flouen for the interstices; finally, that there was only one triforium, or gallery, round the ancient choir, whilst there were two such in the modern choir. The east end of this venerable cathedral, as it is seen at the present day, and as it is represented by Mr. Carter, exactly corresponds in thee and in other particulars with this description of it, given 600 years ago. It is all in the first order of the pointed style, except the main pillars, which are (to the eye round); with a furt of Corinthian capital, and except the arches springing from these pillars, which are also circular as far as the colonn abscissa or altar end, these being point ed, as likewise with the exception of certain blockings and mouldings, where the Saxon billet ornament is still seen.

The improved architecture of this, the most dignified church in the island, could not fail of being adopted in our other churches, when there was occasion for rebuilding or repairing them. Lincoln cathedral seems to have led the way in this particular about the year 1195, under the di rection of its bishop St. Hugh, who was not less renowned for his skill in architecture than for the sanctity of his life. This prelate undertook to rebuild the whole of his vast cathedral, and he was fo intent upon the work, that, as Matthew Paris tells us, he carried mortar and stones on his own shoulders for the use of the masons. The building was so far advanced at the time of his death, which happened in the year 1200, that he is considered and called its founder, though his work was not finished till about fifty years afterwards, in the episcopacy of Robert Grofetice. Excepting the west front, which is almost all the work of the Norman prelate Remigius, and the towers, the groining, the screens, and certain other decorations added in the fourteenth century, the whole vast pile of St. Mary's church and Chapter house at Lincoln is in the siple style of the first or lanceal order of pointed architecture; but awful and beauteous beyond the conception of those who have not seen it, and greatly superior to any church of the fame order and period to be found in France. In 1202, the rich and powerful bishop Godfrey de Lucy, amongst his other great works, began to rebuild the eastern part of his cathedral at Winchell, where he executed in the style of the Metropolitan choir, but without the least mixture of the Saxon. His extensive work is still to be seen there, consisting of long narrow sharp-pointed windows and other arches, detached pillars of Purbeck marble, quatre-foil mouldings, and light groining of simple interlacing ribs. And, whereas, it became very uulaf, for the sake of gracefulheads and the like, where they were used as windows, to place two or more crook arches close together under another pointed arch; the greater width, in consequence of which a vacant space occurred between their heads; a trefoil, quatrefoil, or circular arch was frequently introduced, with the happiest effect, to fill up this space. In 1227, archbishop Walter de Cantilupe began to rebuild the northern Metropolitan church, and the prevailing style, and he actually finished the work during his lifetime as it is now seen. The same kind of work was carried on at this time at Worcester, Salisbury, and other abbey churches. The late-mentioned church, which had an entire new foundation, begun by bishop De Puteulis in 1225, and finished by bishop Bridport in 1258, exhibits in its front and other parts, the double lancet arch, the intermediate quatrefoil, and all the other cha tracters described above. There being occasion, however, to place three lancet arches together in the windows of the upper story, the head of the middle one was gracefully raised above the other two, an improvement which was soon adopted in many other churches. A full more striking im provement which took place, if not at Salisbury for the first time, at least about the time of its completion, was the elevation of the cornice, pediment, or canopy which had hitherto adhered, or at least had been near to the architrave of the arch. This was now raised, like the two sides of a triangle, to a considerable height above it. The jambs of the pediment were at first rather short, not reaching, by any means, to low as the springing of the arch, and generally rolling on some small flower or other flight ornament.

The point of the canopy always terminated in a trefoil or other graceful ornament, but was not, as yet, adorned with crockets or foliage down the jambs. Bishop De Pove, being translated to Durham, began to ornament the east end of his present cathedral in the style which he had introduced into the one he had left. Whilst the work at Salisbury was drawing towards a conclusion, that at Westminister abbey, was beginning, namely, in the year 1245. The north transept, and part of the adjoining nave of the church, remain in almost the same state they were left in by their founder Henry 111. The windows of the last-mentioned portion of the abbey, together with the corresponding aisle, are larger and better proportioned than any which had hitherto been seen in this island. Here also we meet with the cinquefoil rofe between the heads of the two lights; while the exterior windows of the triforium or gallery consist entirely of a triple cinquefoil under a pointed arch. These two models for the upper part of church windows were long followed. On the other hand, the arches and windows of the transept, being placed in a regular square and very narrow, presented an appearance of those large mullioned windows which, in the succeeding period of this style, came into fashion. In this part also of the abbey church, namely, the inside of the transept, we begin to meet with good flatuay.

During the reign of Henry's son, Edward I., which began in 1252, the architecture of this country, through the ingenuity and industry of its artists, acquired a new character, and may be said to have grown into a new order of the pointed style. The first and distinguishing feature of this was the general adoption of the well proportioned and well turned alstephing arch. The arches which had hitherto been constructed, though sometimes accidentally perfect, were, for the most part, too acute. But the arches built at the latter end of the thirteenth century generally approached to the perfect proportion. This proportion, according to the best judges, is when an equilateral triangle can be inscribed within the crown and imposts of the arch. The arches also were gracefully turned. Besides all this, they were now invariably ornamented in their heads with cusps, so as to form trefoils, cinquefoils, or sepofts. In like manner the pediments or canopies over the arches were universally purplied, that is to say, adorned with the representation of foliage called crockets, from the corbel on which they rested up to the rich flower or other elaborate finial in which they terminated. These corbels or brackets now corresponded in height with the springing of the arch, and mosty exhibited bulbs of the founders or other benefactors of the establishment. Pinnacles, which hitherto had been both very simple and very rare, were, in this improved order, placed at the sides of almost every arch, and on the top of almost every buttress, being invariably purplied and sur mounted with rich finials. A pinnacle of a proportionable
size being placed on a tower, instead of a buttress, became a broach or spire. Accordingly the use of spires became almost general in the fourteenth century. We even read of a new built tower being pulled down, because it was unequal to bear the weight of this grand ornament, when a new one was built, which, with its spire, was as high as the church was long. In the same spirit of ornamental grandeur, the buttresses, supporting the upper part of the nave, instead of being concealed in the roofs of the side aisles, were brought into view with suitable decorations, and made to stretch over the tops of those aisles, in which are called flying buttresses. The window no longer confined of an arch divided by a simple mullion, and furnished with a single or a triple roll, but was henceforward, in all grand churches, portioned out by mullions into three, four, five, six, and sometimes into nine different bays or days, as the separate lights in a window were then called; and these again were frequently subdivided by one or more transtoms running across them. Their heads also were varied by tracery work to a variety of architectural design, and sometimes, as at the west end of York, into the form of a beautiful flower. The plain nitches of the thirteenth century became, in the fourteenth, gorgeous tabernacles, in which as much architectural skill was often displayed as in the whole church to which they belonged. These tabernacles, as well as various other parts of the faceted edifice, were filled with statues, which frequently showed equal spirit in the design and art in the execution. Finally, the ribs supporting the groined ceiling were no longer simple intersecting arches; but they branched out into tracery work, still richer and more elegant than that in the grand windows of this period; and wherever the ribs met, they were tied together by an architectural knot or boss, which generally exhibited some instructive device. It must not be forgotten, that during the latter part of this period, the pediments which before had been upright, began to humour the sweep of the arch, by which means they became less plain and more graceful.

We have instances of these improvements, or rather of this new order of the pointed style, in the three remaining architectural crosses, erected by Edward I. thes of Norbridge, Geddington, and Waltham, to the memory of his queen Eleanor, who died in 1290; likewise in the magnificent tomb of his brother Edmund Crouchback in Welfinlbury abbey, which departed this life in 1296. But the most complete specimen of the whole detail of these improvements is York Minster, the nave of which, as it stands, was built between the years 1299 and 1330, and the choir some thirty years after the latter period. If any similar structure in the same style, but upon a smaller scale, could, in its time, have vied with this in beauty and grandeur, it was St. Stephen's chapel, Wellminister, now the house of commons, which Edward III. began to erect in 1348. Of the innumerable beauties of the latter erection, only a few scattered vestiges remain, to show the architectural antiquity which it was in its glory. There are few, if any, of our cathedrals and remaining abbey churches which were not rebuilt or restored in some considerable part or other of them, according to this improved order. Before 1321, bishop Langton had added the Lady chapel to his cathedral of Litchfield, had groined the nave and choir, and had erected the magnificent western façade. About the same time the greater part of the nave of Wellminster abbey church was rebuilt. Between the years 1237 and 1340, Exeter cathedral was groined, and its heavy Norman arches and pillars were changed into light and graceful pointed arches and clouter-columns, by its munificent prelate Grandison. During the pontificate of archbishop Courtenay, which began in 1381, and that of his successor Arundel, the nave of Canterbury cathedral was rebuilt. During the same period that eminent prelate and architect, William of Wykeham, was employed in performing the same difficult transmutation of the nave of Winchester cathedral, which had been performed in that of Exeter. The circular columns and arches were not taken down, as has been generally supposed, but the former were caled and the latter reduced to a point. This may be ascertained by an attentive examination of the work within the roofs of those structures; and without this trouble, by simply looking at the nave of Gloucester, St. Albans, or Romley great church, where the operation here described will appear to have been performed, on two or three of the circular pillars and arches at the west end, and to have been left off with respect to the other pillars and arches. The taste for these improvements defended even to country parish churches, few of which did not sooner or later exchange their ancient windows, at least, for those of the pointed style.

But human arts, like the human body, when they have attained to the perfection of their state, tend towards their decline. This was the case with that angular invention, pointed architecture. Its rise, progress, and decline, occupy little more in the chronology of the world than four centuries. As its characteristic perfection confined in the due elevation of the arch, its decline commenced by an undue depression of it. This new style, or third order of pointed architecture, took place in the latter part of the fifteenth century, and its be born in the royal chapels of St. George, Windor, of King's college, Cambridge, and of Henry VII., Welfinlbury. It cannot be denied, that the builders of these splendid and justly admired structures displayed more art and more professional science than even their predecessors had done; but then they dis played this at the expense of the whole work, which they cultivated, and of the awful and devout impressions which this style was invented to excite. The spectator was now amazed to see huge masses of stone, called pendent capitals, each one of more than a ton weight, hanging in the air, which, instead of supporting the vast groins they were fixed in, were supported by them; the consequence of this, however, was to bring the flat arches of the ceiling still nearer to the eye, so that their curvature was henceforward discernible at their springing rather than at their point. Finally, ingenuity was at this period much more affected than awfulness; hence these royal chapels, and several mortuary ones built in Winchelster, Peterborough, and our other grand churches, during the time of the two last Henrys, are been covered over with tracery, and loaded in their groins and friezes with bulls, armeal bearings, and retables, beyond all due proportion, so that, however elegant the design, and exquisite the execution of them generally is, a judicious spectator, after adoring them, fails not to prefer to them the chapel-grandeur of York Minster, or even the unadorned majesty of Salisbury cathedral. The church-windows of this period were too multiplied and enlarged, as to become what a late writer, Mr. Whittington, proffestes to admire "all window," but which they certainly could not become without great detriment to the character of awfulness in the church itself. The face depression of the pointed arch took place on the outside as in the inside of the buildings of this period. Instead of the tapering pinacles and lofty spires which had hitherto adorned the towers of churches, these structures were now generally covered with round cupols, and the portals, instead of being forgiowed with corombed pediments and graceful pinacles,
were generally enclosed within square architraves, the chief ornaments of which were seen in the spandrels. All this, however, is to be understood with some exceptions. For example, bishop Oliver King erected his church at Bath, about the year 1160, in a veryimple fasion of pointed architecture, and bishop Fox repaired the prebendary and chancel of Winchester cathedral with a chaste and tasteful elegance.

But the downfall of pointed architecture in this kingdom became inevitable from various causes, chiefly, however, from the loss of its characters of majesty and awfulness, the necessary consequence of the depredation of its fulminating and graceful arch. The declension of it was complete at the beginning of the reign of Edward VI., from which period, till the introduction of the pure Grecian style in the reign of Charles I., a real Gothic, or at least a truly barbacian style took place, confounding a confused medley of all the known styles and orders of styles, intermixed with globes, triangles, pyramids, obelisks, frets, and other whimsical and ugly devices, as may still be seen in the sepulchral and other monuments of the period in question.

From what has been said, it appears that the term Gothic architecture is an improper one, as applied to any species of architecture whatsoever; that the mode of building which prevailed amongst our ancestors before the conquest, called the Saxon style, consisting of round pillars with rude capitals and bases, and of circular arches, was strictly Roman, being copied, even to its minute ornaments, from coeval originals at Rome, and having been first taught and practised in this island by Roman masters; that this style was succeeded, before the middle of the twelfth century, by a style of architecture perfectly new, the essential character of which is the pointed arch, from which, by a natural process, the slender column, the aspiring cornice or pediment, the crocketed pinnacle and lofty spire, with other ornaments mentioned above, actually grew; that this style was not borrowed from Northern Goths, or Eastern Saracens, or Western Normans, or Southern Italians (for in this style the Italians themselves were but novices, and not very apt ones), but that it was discovered in this climate, most probably by the English Normans, the greatest people of the 12th age, and the fondest of ecclesiastical architecture that ever existed; that the style was improved by the joint efforts of the Normans, English, and French, at a time when our kings were masters of the fairest provinces of France, and brought to its perfection, chiefly by the ingenuity and industry of the English, during a period in which England was in prosperity by her conquests, and France in declination from her defects; that there are three distinct orders in this style, the members and proportions of which can be distinctly pointed out by professional men, (such as the author of the "Ancient Architecture of England") with almost as much accuracy as those of the five Grecian orders; on which subject it may be observed, that the five Grecian orders were practised long before their members and proportions were accurately laid down, that the characteristic of the first order is the acute arch, and that the period of its duration may, in a general way, be said to have last from the middle of the twelfth to the end of the thirteenth century: of this order, Lincoln, Beverley, and Salisbury churches are examples; that the chief characteristic of the second order, is the perfect or equilateral arch, the reign of which was from the end of the thirteenth, till after the middle of the fifteenth century, to which order York Minster, and the naves of Winchester and Canterbury cathedrals belong; and that finally, the characteristic of the third order is the obtuse arch, which grew into fashion about the half-mentioned period, and lated to the downfall of pointed architecture itself in the middle of the sixteenth century. The finest specimens of this, doubtless, are the above-mentioned royal chapels. With respect to the proper denomination of this style, some of the learned, as well as the vulgar in general, still call it the Gothic, others the Saracenic, a third class, the Norman, a fourth, the English, and a fifth, the pointed. From the whole of what has been said above, it will be readily concluded, that the present writer conceives the last of these terms to be the best adapted to the style, as being the most strictly descriptive of its characteristic quality.

This article is the abridgment of a much longer treatise on pointed architecture, which is shortly expected to appear from the pens of Mr. Taylor's Architectural Library; in which treatise many historical documents in support of the present system, and certain plates to illustrate it, will be seen.

M.

Gothic Bible. See Bible, and Argenteum Codex.

Gothic Character, or Writing, is a character or manner of writing, which, in the main, is the same with the Roman, only that it is very full of angles, turns, and bendings, especially at the beginning and ending of each letter.

The manuscripts in Gothic character are not very ancient. Ulphilas, bishop of the Goths, was the first inventor of the Gothic characters, or the first who composed the Gothic alphabet, in imitation of the Greek, and the first that translated the Bible into the Gothic tongue.

The letters used in the Gothic gospels are twenty-five in number, and formed, with slight variations, from the capitals of the Greek and Latin alphabet. As these characters, in which the Codex Argenteus, or Gothic version of the Bible, was written by Ulphilas, their inventor, were derived partly from the Greek and partly from the Latin, Michaelis (Introduct., to the N. T.) thinks it natural to ascribe the said version not to the Franks or Germans, but to the Goths, who lived on the borders of the Danube; or in Wallachia, where they at that time reposed, the Latin was spoken, and their nearest neighbours were the Greeks. A mixed alphabet, such as that which is found in the Codex Argenteus, is such as might reasonably be expected. Some of the words in this version are still used in the Leffer Tartary, the ancient seat of the Goths; e.g. vctian, of the, from saecula, age, a word that is quoted by Butbeck, from the language of the Crim Tartars. In this version, many words are adopted immediately from the Greek; vec, sove, atta, father; unc, water, &c. Hence it is inferred, that the dialect, in which such words occur, was that of a nation that lived in the neighbourhood of the Greeks. This version has also Selavonian words, such as sun, a matter, which prove it to have been written in the dialect of a nation that bordered on Sarmania. The name may be said of many Latin words: such as annuntian, to announce, to fit at table, militundium, militantes, foldiers, aghiti, water, &c. This argument is the more decisive, when we consider, that the Goths, in the time of Ulphilas (see his biographical article) lived in Wallachia, a country in which Roman colonies had been planted, and where a corrupt Latin is spoken at this very day. Ulphilas himself lived in Wallachia, and had it in his power at least to make use of Latin letters, as well as those of the Greeks, with whom he had continual intercourse. See Gothic Language.

The Runic characters are also frequently called Gothic characters. See Mokieus, De Re Diplomatic. lib. i. cap. 2.
But they who take the Gothic characters to be the same language as the Runic, are mistaken; as is shewn by Ol. Wormius, Junius in his preface to the Gospels written in Gothic letters, and Dr. Hicks on the Runic Tongue.

Gothic Column is any round pillar in a Gothic building, either too thick or too small for its height.

There are some found even twenty diameters high, without either diminution or swelling.

Gothic Language, the language of the Goths. This language, as the acknowledged parent of the English, is of considerable importance; while its remote antiquity, the facility of its records, and the circumstance of its having been ruined only by few among the learned, have rendered it a matter of great uncertainty as to its character and origin. The question respecting its antiquity and genus is resolvable into those in regard to the people who used it. Mons. Mallet, in his "Northern Antiquities," supposes that the ancient Galls and Germans, the Britons and the Saxons, were all originally one and the same people: and thus he makes the Gothic the same language as the Celtic tongue. This opinion, which was first taken up by Clavirius in his "German Antiquities," has been since adopted by Keyser in his "Northern and Celtic Antiquities," and Pelbottier in his "History of the Celts," and maintained by them with uncommon erudition. According to these writers, the ancient original inhabitants of Europe consisted of two distinct races of men, viz. the Celts and Sarmatians; and from one or other of these, but chiefly from the former, all the ancient nations of Europe are descended. The Sarmatians, or Sauromatae, were the ancestors of all the Seluvian tribes, viz. the Poles, Ruffians, Bohemians, Wallachians, &c. who continue to this day a distinct and separate people, extremely different in their character, manners, laws, and language from the other race, which was that of the Celts; from whom, as they suppose, were descended the old inhabitants of Gaul, Germany, Scandinavia, Britain, and Spain, who were all included by the ancients under the general name of Hyperboreans, Scythians, and Celts, being all originally of one race and nation, and having all the same common language, religion, laws, customs, and manners.

This opinion, though supported with an uncommon display of deep erudition and a great variety of specious arguments, is controverted by the late learned and ingenious Dr. Percy, in a preface to Mons. Mallet's "Northern Antiquities," which he has translated and enriched with notes. This profound antiquarian, in opposition to the French writers, states that ancient Germany, Scandinavia, Gaul, and Britain, were not inhabited by the descendents of one single race; but, on the contrary, divided between two very different people; the one of whom he calls with most of the Roman authors, Celtic, who were the ancestors of the Galls, Britons, and Irish; the other Gothic or Teutonic, from whom the Germans, Belgians, Saxons, and Scandinavians derived their origin; and that these were the original two distinct people, very unlike in their manners, customs, religion, and laws.

The Gothic, then, is radically different from the Celtic according to Dr. Percy, who, in the preface of his "Institutions Grammaticales Anglosaxoniæ," gives the following genealogy of the two languages. Gothic is the parent of 1. Old Saxon, or Anglo-Saxon; 2. Francic or Franco-Theotic; 3. Cimbri, or Old Icelandic. From the first, viz. the Anglo-Saxon, are again derived English, Broads Scotch, Belgs, or Low Dutch, and Frile. From the Francic, are derived German, or High Dutch, German of Swabia, and Swiss; while the Cimbri, in its turn, gave birth to the Teutonic, Norwegian or Norfe, Danish, and Swedish. On the other hand, the Gothic is represented by the name writer as the parent of the ancient Gaul, the ancient Britons (ramified into the Cornith, Armorican, or Bas-Bretagne, and Welsh,) and the ancient Trifon, which was subdivided into Marks, or language of the Isle of Man, into Erle, or Highland Scotch, and Irish. To the old mother tongue of all the Gothic dialects, it has been usual to give the name of Teutonic, not as much as Dr. Percy affirms from its being the language of Tufts, the great father and deity of the German tribe, as from the Teutones, the people who used it: the same probably with the Cambrics, or as the Greeks called them Lygions, who inhabited the northern regions, and more particularly the Danish islands. Now, in opposition to this writer, we are free to affirm, there is no ground for believing that this mother tongue, whether called Gothic or Teutonic, was in its primitive form different from the Celtic. And this proposition we shall endeavour to make manifest from the very specimens by which Dr. Percy has attempted to shew their essential difference. But before we enter on this question, it is necessary to remark, that learned men, in their enquiries concerning the origin of nations, have not sufficiently attended to the consideration which we learn from the Mosaic history, that all nations originated in a common family, and at first spoke a common language. Let us suppose that some members or descendants of this family, (as we read of Gomer,) emigrated from Asia to Europe. If they settled in Greece, they introduced with them the primitive customs, and language, though somewhat corrupted, no doubt from its original purity. Others, actuated by the same spirit of emigration, would soon follow; and, if more powerful, would displace their predecessors, who had no other resource but to seek new habitations in remote regions.

As these wanderers multiplied, they advanced, till, in the course of years, all the countries on the north and west, as well as on the east of Europe, were completely peopled. But this population of course could not take place before they had been divided into independent tribes, and distinguished by correspondent difference in dialects and manners. But still a very great resemblance must have as yet been visible among them in both these respects, however separated from each other: for in the earlier periods of society, language, though widely used, must long have continued the same, with little variations, it being corrupted and diversified into distinct tongues only by the progress of civilization; by the refinements of literature, by improvements in art and in government, and by those political convulsions which the love of conquest, inspired by conscious superiority in the arts, produces. All the nations of Europe, therefore, in the ruder and more early ages, may be considered as using only the same great primordial speech, grown indeed into distinct branches, and affixing in one country the appearance of being independent of, and unconnected with those used in other countries. Now, if we suppose that the Celtæ were the first emigrants from Asia, who, pervading Europe, settled in Gaul, Old Spain, Britain and Ireland; while their brethren, under the names of Cætæ (Goths), Scythæ, Cimbri, &c. directing their course to the North, occupied Thrace, Scandinavia, and other northern territories; it would follow, that these tribes, however remote, used at first either the same language, or languages which had a close affinity from their relation to the common primal tongue. "Nor would there be material difference in this conclusion, though we should suppose, with many learned men, that the inhabitants of the North of Europe came, not from the East but from the
the North of Asia, as they must still have been descendants of the same primitive family, which, according to Moses, peopled the world. Thus the Celtic and the Gothic or Teutonic must have been, in their origin, the same or sister tongues.

But further, while the ancient Celts and Goths continued in the darkness for which they became proverbial, the inhabitants of Greece rapidly improved in laws and the arts of life. In this improved state, Greece became, in regard to the favoured inhabitants of the North and West, what Asia had hitherto been in respect to Greece, a fresh source of civilization and letters. Its language, growing more copious and refined with the people, diffused itself with the blessings of knowledge and society, which their example or instruction imparted to the Northern and Western inhabitants of Europe. Thus Greek, with the arts of Greece imported into Italy, gave birth to the Latin tongue; and this at a later period necessarily affected the Celtic language, in consequence of the victories which the Roman arms achieved in Gaul and in Britain. This revolution greatly widened the line of distinction which for ages had been extending between the Celtic and the Gothic tongues; the former being assimilated to the Latin, the latter to the Greek, by a copious influx of new terms. It were indeed matter of great curiosity if some records of the Celtic and Gothic tongues had been preferred before they were yet modified by the ascendant languages of Greece and Rome; but no such records unfortunately have survived the wrecks of time. And we can judge of the ancient Celtic only from the Welsh, its acknowledged daughter; while we are left to form our judgment of the primeval Gothic from the remains of a version of the New Testament, effected by Ulphilas, into the dialect used by the Goths in Masna, and hence called Merovingian.

Having made this preface to shew that the Celtic and Gothic had one common basis, viz. the primordial tongue imported from Asia, we proceed to prove, as far as we are able from their respective offsprings, that they had in common many Asiatic words, and were modified by a great portion of Latin and Greek terms; and that from these two causes they essentially resembled each other. The Lord's prayer is thus rendered in the ancient Gothic of Ulphilas:

LITERAL TRANSLATION:

1. Attā unfar thu in himnam
2. Velihni name thein
3. Quinah thudindus theins
4. Vairalh Vilga theins fæ in himnam, gah anu airthai
5. Hlaif unferana thana fin timan gis uns himmordag
6. Gah afeit uns theae feu lans figaima, fia fæ gah wis ailetam than feu lam unferons
7. Gah ni bringais uns in fæthilbogai
8. Ak lufei uns athamma
9. The following is a specimen of the Celtic, as existing in the Welsh tongue:

1. Ein Taed, yr lwan wyt yn y Nefoeth
2. Santeiddler dy enw
3. Dewed dy deyrnas
4. Bydded dy Ewlylys ar y ddaear meigis y maen yn y neveth
5. Dyro i ni neidrwy ein bara bymfyddi
6. A maddi Ani ein Dyledion fel y maddeun ni ein dyledwy
7. Ag ma arquin ni i brefodegaeth

We propose next to lay before our readers a brief analysis of the first two specimens, which it is prefixed will shew that the two languages in question have much nearer resemblance to each other, than Dr. Percy, or any person who has not a thorough knowledge of both, could possibly imagine. The Hebrew יִתֵּר, thad, pronounced with an initial and closing vowel, is adda, and signifies beloved, and this is the source of the Gothic atta, and the Greek αὐτός, with the udmth propriety applied to a parent as the dearest object of love. The same word in Hebrew is written יִתֵּר, dood, and is other than the Celic atta, under a difference of character. In the Cornish it is taw, in the Frisic katas, in the Landb at, and the old Cantabrian or Bifeykan atta, father. Unfer is the Greek ἀντίς, thus strangely corrupted, ἀντός, untar, unfer; and hence the English our. In the same manner, argaes: has degenerated into unis, wis, ws, us. The Celtic ni is the Hebrew and Arabic pronoun N,N., ani, which, founded with only the closing vowel, is ni, ws, and with only the initial ein, our. The Gothic in and the Welsh ysa have originated in the Greek ης, or the Latin in; but it is observable that both these languages use this preposition as it is used in Latin, when followed by an accusative noun in the sense of into, untar, or to: thus in freistafhagai, into temptation; inni, or i ni, to us. The Welsh language is remarkable for the attention paid to harmony in the arrangement of its terms. To produce this effect the termination of a preceding word, in order to coincide with the faceeceeding one, is somewhat changed, and thus made to unite both into one. Thus urine is yr hwan, the one, where y or ei (aspirated after the manner of the Greek ἕμι), is prefixed to ein, the Latin unus, or the Anglo-Saxon an. Ysa, moreover, is a coalition of any y, air thow, or thou art; by being the substative Greek verb εἰς, whence the Goths derived their in, and the English our on. The Greek γίνεσαι, to partake of, from the Latin innus, or the Anglo-Saxon ann, is, with the ablative case ysa, or ysa, in which the Goths derived their in, and the English our on. The Greek γίνεσαι, to partake of, from the Latin innus, or the Anglo-Saxon ann, is, with the ablative case ysa, or ysa, in which the Goths derived their in, and the English our on.
Gothic Language.

Ae is the same with the Gothic thu, and no other than the Latin tu, or the Gothic tu, or the English thou. The Gothic thian, it is obvious, has given birth to the English form of the. Nouns, whence our name, retains the Persian character of nana, though perhaps it is more immediately derived from noman, and is a kindred noun with the Welsh cans, which probably degenerated from *cans, by dropping the last syllable.

3. The Arabic ܐܢܛܝܢ, quoum, lega, has given birth to the Gothic quomin, to uso the legs, i.e. to come, and to the Anglo-Saxon cynman, and our can. The same word has been imported into the Celtic in the shape of canmn, signifying to hop or hop. The same word exists in the Skanfur, quomun, to go. The corresponding Welsh lefn when you walk, is the Greek κανή, κανα, or κανον, to stretch to an object, which was defended from the Arabic ܐܢܛܝܢ, ana, by dropping the initial vowel. The same verb exists in Welsh, under the different figure of thyen or thygyn, and is no other than the English to conduct. The Gothic thulmam, a kingdom, seems originally to have meant the emperor of a federal nation, from the Greek τυράννον, and τυραννίς, or τραγάνον, as the offspring of the former exists in this tongue, theoyn, gen., popularis. On the other hand, the Welsh dyfon is the Greek ἴσων, corrupted, by the transposition of b, into thesos or dyes. Our English throne, conforms to the original in sound and sense. In the Anglo-Saxon the corresponding word is reo, which still exists in such English compositions, as kiboric, i.e. the dominion of a bishop. In the Great Indian language abovementioned, this term suffices under the character of ryo, meaning wealth, and which is nearly the same in sound and sense with the Anglo-Saxon reo, or our riches, and the Latin rex, property.

4. As light or air is the chief medium of existence, the Hebrew term אָרָא, aer, gave birth to the Latin exam, air, and the Gothic avari or ovirban, to be, to become. The Welsh eddlyd, which exists also in the form of llyd, and which is the same with the Greek ἀέρ, and the Latin vind, defended from the Perisan badan, to be, and šen in Arabic, or volo, with ga annexed, by an analogy common in the Gothic tongue. The Welsh eddlyf, or with a prefixed, caddlyf, has flowed from the same source; and under the former of these forms is nearly allied to the English will. Sue is our so, or the Greek is reverend, a fate very common with monophyllals in the ancient languages. Gab came from gab, and ana from aer, which, in composition, means up, and has given birth to the Gothic sense of upon. Airhat is the Arabic arad, from the Hebrew ܣܢܪ, arees, while the Welsh daur, or as it is otherwise written, aw, originated in tana. The Hebrew ܐܢܛܝܢ, abor, the parent of *e in Greek, of or in German, ofer in Gothic, and over in English, has contracted in Celtic into ar, in the sense of upon.

5. The Arabic ܐܢܛܝܢ, abedh, food, is the origin of the Gothic blys, and the English loaf. Thaxan, or iban, is the accumulative article in. Sinimine is formed from the noun feish, significat, change, which is no other than the Hebrew אָנָשׁ אָנָשׁ, feish, that change or period of time called a year; hence sinimine came to signify continual, or perpetual. Our Lord, we believe, by the clause πάντα ἐν ἀμώθων, meant not, as it is generally rendered, daily bread; but the bread belonging to us, and essential to us as immortal beings, namely, the bread of the soul. (See 'Mr. Jones's Illustrations of the Four Gospels,' p. 123.) In this sense the clause was understood by the early commentators, and by the Gothic translator, who has rendered it blis thana sinimine, the eternal bread. In Hebrew, Arabic, and Persian, ܢܡ, keph, denotes the palm of the hand; hence it came to signify the action of the hand, which confines either in imparting or receiving. In the former sense it gave birth to the Gothic ges, and in the latter to the Latin capio. Hinnid is means this day; biusma, or as we write it, bien, being the personal pronoun used definatively, and diog or dogt, according to the Anglo-Saxon, being the Latin dies; his day for this day, which is more common in the plural form among the vulgar them days.

The Welsh dyro, in the same verse, is the Greek ἴσος, a gift, converted into a verb. Hedyso is a distinguished form of bodhi, which last is only a contraction of tene die, this day. Bars is a word which exists in all languages. Its origin is the Hebrew בָּרֶז, phobos, fruit; and hence τερίς in Greek, far, and paris in Latin, brod in Cimbri, brot in Francic, broade in German, broada in North, broad in English, broad in Danith, and broac in Frisic. Brnydydd, rendered daily, appears to be composed of bymn, a top or summit, and yddhel, the Latin dies advertised, and means a top of each day, or a head of each day, i.e. daily. The words is also used brnydylah, being a corruption of pen, a head. The Welsh word for the plural of this expression, and have a phraste, poby dyth or y pen, each day on his head, meaning every day in succession.

6. After us, i.e. of let, or it self, diffuses to us. That is a corruption of the Greek ὑπὸ, this or that thing, and is thus the parent of the English that; hence the reasonableness of the explanation which the celebrated Mr. Tooke has given of such phrases—remit us to that thing, vis. falsum sigcima, we are debtors. Seulans were persons under command, under obligation or debt, from the Greek εὐκλαύσιν, to labour; hence appears to have been derived our seulion, a mean domicil servant. In ancient times labourers usually paid their rents in kind from the products of their fields; hence, in Greek, the tenant was called χρυσόμακας. On the same principle, in Gothic, the word signifying to labour, came to signify to owe, or to be in debt. Sigcima is only the Latin fiasm corrupted by the inlocation of gen, a particle of frequent use in Gothic. The Welsh a mabath, or as it may be written, ammadheus, is a composite of ag maddy, and remit, the first being the Latin conjunction as, the second the Greek αὐτῆς, the same with *αὐτῆς, to signify or remit. Dydek, the plural of dykel, is the Latin delecta, things to be enjoyed, or to be cancelled by being paid, i.e. debts. The noun sun, or the plural sun, which in this tongue is so often added to the name of a thing, is but the Latin vin—dydegyn, debsmen or debtors.

7. The Goths and Anglo-Saxons corrupted *vas into byvan and bringan, and hence our to bear, and to bring—ni bringan, do not bring us. The Latin nē in Gothic is ni, in Anglo-Saxon and English no, in Welsh na or nog. Fraytun, is the corresponding noun of frajtin, to tempt, and appears to have been borrowed from the Latin praefectus, and therefore primarily meant praefectus, praetextus. The Welsh arawin is the French ren with the vowel π prefixed, and is the same with our rin: its proper sense is to lead a horse with a bridle. The French, in deriving words from the Latin, generally reject the guttural in the middle or at the end; and on this principle the root of ren is ren, to rule, direct. Preflected strictly denotes experience, and its origin is the Latin probe, which last is itself taken from the Greek κτισθ, puiwre, or the corresponding verb κτισθε, to taste or chew.

8. The Gothic ak is the Latin ac, though used by the latter in a conjunctive, by the former in a disjunctive sense—but. The root is παρ, or the whence derived augs, whence the Gothic auges: and ak, conformably to the form of this
GOTHIC LANGUAGE.

The corresponding Welsh word is eithir, derived from *eitres, another. The explanation of it is this—lead us not into trial; another thing, i.e. do another thing, namely, deliver us from evil; on this principle the conjunction *axa, *bat, originated in *æxox. *Launf, which has given birth to various words in Anglo-Saxon and in English, and among the number to *laufs, left, *lauffs, releafs, let, is apparently the offspring of the Hebrew *לוּף, *lôof, *doeds, *redoeds; to deliver from evil is but to caude to escape from evil, and thus launf corresponds in form as well as in sound to the original. A bove character is a character freed or loosened from the rules of sobriety and justice, and this deviation from rectitude is implied in the original *לוּף; while the compound releafs comes close to the Gothic signification of launf, to deliver. The Welsh which answers to this is *gweard, and is no other than the Latin gero, (properly pronounced gero,) to manage, to carry. The Arabic *جدل, *jedal, is the origin of our word *free, its primary sense. Being thence applied to men, it came to signify those who were the heads of families, or who went before them: hence it was used to convey the more general and abstract ideas of precedence or beginning; in this sense it is the origin of *ψλλ in Greek, *pre in Latin *free or from in Gothic, *flua in Cumbric. In the Anglo-Saxon *we is annexed, and hence our word from, though the Scotch use it in the original purity of senses. The corresponding Welsh *ebeg, which means *fair, *distance, has retained with great exactness the found and sense of *ψλλ, *ebak, its Hebrew original. The Gothic *abai, German *ebel, Anglo-Saxon *ifas, and English evil, is the Perian and Arabic *ṣbl, *balba, with a vowel prefixed. The Perian *tawil, is the parent of the English dark: and as darkness was the symbol of evil, or of the suppos'd demon which created it, the Celts received it to express evil under the form of *drag; and it is remarkable that the same word with *αλ*πετριτυμιν is used by the Greeks to denote a contrary sense—*ψαλλων, *not dark, ingenuus, *finer, *true. In the same language *ψαλλω means an *impoñor, which the lexicographers, misled by mere similarity of sound, have erroneously referred to *ψελλω, to eat.

From this analysis, which we hope is worthy the attention of the learned, we shall draw a few conclusions respecting the Gothic tongue. First, it appears to resemble the Celtic, in having a common primitive basis, and in containing a copious influx of Greek and Latin words. As the two languages were not essentially different, there is no foundation for supposing, with Dr. Percy, that the Celts and the Goths were originally distinct races of men. And here we cannot help specifying a feature in these tongues, which, in a remarkable manner, bespeaks their original identity, or their immediate descent from a common parent.

The Gothic, with its offspring the Anglo-Saxon and the German, uses the particle *ga or *ge prefixed to words, and especially to verbs. The Gothic sometimes inflects *g in the middle of words, and frequently before the infinitive termination of verbs: *gæa, or *agere, is *wæppian, and *gæon to deride, *blægian, to laugh. In consequence of this analogy, words borrowed from Greek and Latin are remarkably disguised, and they must be stripped of this peculiarity before they can be traced to their true origin. The Celt, if we may judge from the Welsh, was distinguished among the former characteristic feature; thus, the Latin war is *gær; *gæm, *gæm, *gægen, *gæg; &c. On this principle *fæs, *fæs, *af, in Welsh is *megs, which bears the sense of the original. The identity or similarity of the two languages will account for the Goths and Celts being called by the common name of Cimmerians or Cimbri, which the true Britons, the undoubted descendants of the Celts, still inherit under the name of Cymri.

Sir W. Jones, in his sixth discourse delivered to the Society at Calcutta on the antiquities of Asia, has the following passage well worthy of our attention, as tending to confirm, in a remarkable manner, the result of the preceding inquiry. The passage is this: "It has been proved by clear evidence and plain reasoning, that a powerful monarchy was established in Tartary long before the Affyrian government; that it was in truth a Hindoo monarchy, though, if any chief to call it Cyclic, Cadinean, or Scythian, we shall not enter into a debate on mere names; that it sublimed many centuries, and that its history has been ingrafted on that of the Hindoos, who founded the monarchies of Ayodya and Indrapratha; that the language of the first Persian empire was the mother of the Sanscrit, and, consequently, of the Zend and Parth, as well as of Greek, Latin, and Gothic; that the language of the Affyrians was the parent of Chaldæan and Pahlavi, and that the primary Tartarian language also had been current in the same empire; although, as the Tartars had no books, or even letters, we cannot, with certainty, trace their unpolished and variable idioms. We discover, therefore, in Peria, at the earliest dawn of history, the three distinct races of men, whom we described on former occasions as possessors of India, Arabis, and Tartary; and whether they were collected in India from distant regions, or diverged from it, as from a common centre, we shall easily determine from the following considerations. Let us observe, in the first place, the central position of Iran, which is bounded by Arabia, by Tartary, and by India; whilst Arabia lies contiguous to Iran only, but is remote from Tartary, and divided even from the shores of India by a considerable gulf. No country, therefore, but Peria seems likely to have sent forth its colonies to all the kingdoms of Asia; the Brahmins could never have migrated from India to Iran, because they are expressly forbidden by their oldest existing laws to leave the region, which they inhabit at this day; the Arabs have not even a tradition of an emigration into Peria before Mohammed; nor had they, indeed, any inducement to quit their beautiful and extensive domains; and as to the Tartars, we have no trace in history of their departure from their plains and forests till the invasion of the Medes, who, according to etymologists, were the sons of Medes, and even they were conducted by princes of an Affyrian family. The three races, therefore, whom we have already mentioned, (and more than three we have not yet found,) migrated from Iran, as from their common country; and thus the Saxon Chronicle, I presume on good authority, brings the first inhabitants of Britain from Armenia; while a late very learned writer concludes, after all his labours and researches, that the Goths or Scythians came from Peria; and another contends, with great force, that both the Irish and Old Britons proceeded severally from the borders of the Cæpians; a coincidence of conclusions from different media, by persons wholly unconnected, which could scarce have happened, if they were not grounded on solid principles.

We may, therefore, hold this proposition firmly established, that Iran or Peria, in its largest sense, was the centre of population, of knowledge, of languages, and of arts; which, instead of travelling westward only, as it has been fanciously supposed, or eastward, as with equal reason might have been asserted, expanded in all directions to all the regions of the world." Here we see it stated, as the result of Sir William Jones's inquiry, that the Goths, the Irish, and the Old Britons, or the Celts, were originally the same people, and
and of Asiatic origin; that they used the same language derived from the primitive language of Asia; and this he gives not merely as the consequence of his own investigation, but as a coincidence of conclusions, through different media, by persons wholly unconnected. "We know not whether this great man was aware of the great similitude subsisting between the Gothic and the Celtic tongues. From his silence we may conclude that he did not; and if he had been specimens of them, analyzed similar to that above, he would have deemed the resemblance a surprising confirmation of his theory.

We conclude, in the second place, from the above analysis, that the Gothic had a close affinity to the Greek and Latin. And Sir William Jones gives it as his opinion, that the Greek, Latin, and Gothic originated in one and the same language; namely, the ancient language of Peræa. These three languages, therefore, originally resembled each other, not merely because they borrowed some words from one to the other, but because they had the same words, phrases, and even consonation, in consequence of having derived them from a common tongue. And here we cannot help mentioning one feature in which the ancient Gothic bore a very singular resemblance to the Greek in the time of Homer, or that dialect of the Greek (namely, the Æolic), from which the Latin was principally derived: we mean the much disputed Æolic digamma. In the Oriental languages gutturals abounded; these, by degrees, softened into a mere aspirate; and for this aspirate, in very numerous instances, substi-
tuted a labial letter $v$ or $w$, or $f$, or $z$. Thus $vóizó$, a king, degenerated into $hóizó$, and being introduced into Greek in the form of $\omega πίζο$, or $\omega μποξά$, was pronounced $\omega υίζο$, $\omega μποξά$. While the oral Greek was thus corrupted, the written retained the aspirate; and as the works of Homer became the subject of universal study, the true orthography triumphed over the caprice of oral sounds. But the Latins had no such monument of genius as the Iliad to study; the corruptions of pronunciation, therefore, prevailed, and the digamma was universally sublimated for the aspirate. Thus $\váxy$, $\válbh$, $\véxy$, $\vélbh$. The digamma was also pre-
fixed to a broader open vowel, and always inserted between a diphthong, as $\vá$, pronounced $\váα$, $\vá οι$, $\vá οο$, $\vá υυ$, $\vá οιο$, $\vá υυο$. Now, this same digamma runs through the Gothic language, which shows that a great part of it, through some channel or other, was derived from the Greek; about the early age in which the Latin separated into a distinct dialect. We shall give a few examples of this fact. The Greek αφεξ, in Gothic, is written conversa-
tially to the corrupt pronunciation of $\omega ραξ$, $\váαξ$; $\váαξ$, $\váαξ$, is $\váαξ$, $\váαξ$, $\váαξ$; $\váαξ$, (which is equivalent to $\váαξ$) is $\váαξ$, $\váαξ$, $\váαξ$; hence the English, to work.

But though the Greek may have the same form and bals with the Gothic; and though by some communications, now unknown, it may have enriched the Gothic with its own early improvements, yet the dialect dignified with this name is only the remains of the Gothic tongue, debased by a strong mixture of Greek and Latin terms, a century or two after the commencement of the Christian era. The Goths who used it lived in Wallachia, a country in which</p>
GOTHLAND, a country of Sweden, bounded on the N. by Sweden Proper, on the E. and S. by the Baltic, and on the W., by the Sound, the German ocean, and Norway. This country is inhabited by a people, who derived their origin from the Gotte, or Tartars of the Crimea. The Goths had kings of their own, till the year 1132, when they were united to Sweden. The country is pleasant and fertile, confiding of pasture and arable land; and abounding in lakes and rivers plentifully stored with fish, and also with forests and mines. It contains 48 towns, and is divided into East, West, and South Gothland.

East Gothland is bounded on the N. by the provinces of Nericia or Nerike, and Sodermanland, on the E. by the Baltic, on the S. by Smoland or Småland, and on the W. by the Wetter lake, which separates it from West Gothland. It is about 80 miles long, and 70 broad. It produces wheat, rye, barley, oats, peas, &c. in such abundance as to supply the neighbouring provinces. It has likewise many fine orchards, with meadows, pastures, lakes, and rivers abounding with fish, extensive forests, iron-mines and foundaries, and quarries of stone and marble. The inhabitants are occupied in husbandry, hunting, and fishing, and also in some places in the mines. The chief towns of this province are Nordkoping, Soderkoping, Linkoping, and Vadstena, which are respectively.

South Gothland is divided into three provinces, viz. Schonen or Skone, Halland, and Blekingen, which have at busy times changed their masters, till at length Charles Gustavus annexed them for perpetuity to the Swedish dominions, by the treaty of Roschild, in the year 1658.

West Gothland is bounded on the N. by Warmeland, on the E. by Nericia, the Wetter Lake, and Småland, on the S. by Småland and Halland, and on the W. by the Scuggerac. It is about 115 miles long, and 15 broad; like East Gothland it was under the administration of its own kings and laws. The soil produces corn, vegetables, and fruit; and affords excellent pastures, which enable the occupiers to supply other provinces with butter and cheese. The rivers, lakes, and sea-coast abound with fish; and in several places are erected iron-forges, alum-works, paper mills. The inhabitants are chiefly employed in agriculture and fishing. The chief towns are Gothenborg, Wenneborg, Lidkoping, and Falikoping, which are respectively.

Gothland, or Gotland, an island belonging to Sweden, situated in the Baltic, between 56° 54', and 57° 56', and E. long. 18° 6', and 19° 6'; about 70 miles long and 23 in its greatest breadth. It was formerly an independent kingdom, but is now subject to the supreme court of justice at Stockholm. Its situation has gained for it the appropriate denomination of the "Eye of the Baltic." The soil is fertile, and affords fine woods of oak and pine, and good pastures; and its breed of sheep is accounted excellent. It has large quarries of stone, which is exported to Stockholm and other places, and some curious species of stone and marbles, cancellas, agates, and beautiful petrifications. It furnishes likewise good lime-dones, tar, and deal-boards. Although it is not infested with bears or wolves, it abounds with foxes, deer, and hares. The inhabitants gain their subsistence by tilling the ground, grazing, fishing, working in the quarries, burning lime, and other sorts of mechanic trades, and navigation. The peasants are in a state of absolute dependence on the burglers, who supply them with necessaries, and with money for paying their taxes, and to whom they surrender the whole produce of their industry, without stipulating any price. This island was at first subject to the crown of Sweden, and afterwards to the Dane for near two centuries, till the year 1625, when by the treaty of Bromebro, it was restored to Sweden. The capital of the island is Wisby, on the western coast.

Goths, a people, who came originally, according to Jornandes (Reg. Get.) who abridges the Gothic history of the learned Cæsariodes, comprised in 12 books, from the vail island, or rather peninsula, called Scandinavia, and including the present Sweden, Norway, Lapland, and Finnmark. The learned Grotius, and after him Sheringham, and most of the northern writers, maintain by arguments, which, as many conceive, have not been refuted, but which are not convincing to others, that the Cimbrians (see Cimbris, Getes (see Gete.)), and Gotes, were the same nation; that Scandinavia was first peopled by them; and that from thence they detached colonies into the islands in the Baltic, the Chermonus, and the adjacent places, yet deficient of inhabitants. Many vellages, which cannot be ascribed to the arts of popular vanity, attest the ancient residence of the Goths in the countries beyond the Baltic. From the time of the geographer Prolemy, the southern part of Sweden seems to have continued in the possession of the left enterprizing remnant of the nation, and a large territory is even at present divided into East and West Gothland. (See Gotland.) The time when the Goths first settled in Scandinavia, and the period at which they first populated their colonies the islands, the Chermonus, and the neighbouring places, have not been ascertained. Some have said, that their first settlement was conducted by Eric, contemporary with Sarah, grandfather of Abraham. However this be, the peopling of the islands in the Baltic sea, of the Chermonus, and of the adjacent places on the continent, is called by the Northern writers, the first emigration of the Goths or Getes. The attempt to cross the Baltic was natural and easy. The inhabitants of Sweden (as we learn from Tacitus) were masters of a sufficient number of large vessels with oars; and the distance is little more than 100 miles from Carlseroon to the nearest ports of Pomerania and Prussia. At least as early as the Christian era, and as late as the age of the Antonines, the Goths were established towards the mouth of the St. Petai, and in that fertile province, where the commercial cities of Thorn, Elbing, Koningsberg, and Dantzig were long afterwards founded. Westward of the Goths, the numerous tribes of the Vandalus were spread along the banks of the Oder, and the sea-coast of Pomerania and Mecklenburg. A striking resemblance of manners, complexion, religion, and language, seemed to indicate that the Vandals and Goths were originally one great people. (See Vandali.) In the age of the Antonines the Goths were still seated in Prussia. About the reign of Alexander Severus, they made frequent and destructive inroads into the Roman province of Dacia. In this interval, therefore, of about seventy years, we must place the first emigration of the Goths, from the Baltic to the Euxine. To what cause this was owing is matter of mere conjecture. Perhaps a pestilence or a famine, a victory or a defeat, an oracle of the gods, or the eloquence of a daring leader, were sufficient to impel the Gothic arms on the milder climates of the south. Besides the influence of a martial religion, the number and spirit of the Goths were equal to the most hazardous adventures. The use of round bucklers and short swords rendered them formidable in a close engagement; the main body of the men, who yielded to hereditary kings gave uncommon union and stability to their councils; and the renowned Amahl, the hero of that age, and the tenth ancestor of Theodoric, king of Italy, enforced, by the ascendancy of personal merit, the prerogative of
of his birth, which he derived from the anfes, or demigods of the Gothic nation.

Whatever was the motive of their migration, they took their route eaitward, entered Scythia, advanced to the Cimmerian Bosphorus, and, driving out the Cimmereans, settled in the neighbourhood of the Maeotian lake. There, in process of time, they sent out numerous colonies into Thrace, Dacia, Moesia, or Italy, and latily into the countries bordering on the Euxine sea, forcing everywhere the ancient inhabitants to abandon their native abodes. Such is the account given by Jornandes, and Ablavius, a celebrated writer among the Goths, who lived long before him. In the vicinity of the Maeotian lake, they had, it is said, Filiimir for their king, who was a warlike prince; in Thrace, Maxia, and Dacia, Xenakiis, a great philosopher; and in the countries on the Euxine sea, princes of the illustrious families of the Balthi and the Amali, the Visigoths being subjéct to the former, and the Ostrogoths to the latter. In all these countries they were the same people, though subjected to different princes, and known by various appellations. As for the denominations of Weltrgoths, softened by the Latins into that of Vifigoths, and Ostrogoths, they were distinguished by the names before they left Scandinavia, being called Weidrogoths and Ostrogoths, or western and eastern Goths, from their situation to the west and east, the former inhabiting that part of Scandinavia which borders on Denmark, and the latter the more eastern parts, near the Baltic. The information we derive from Jornandes concerning the various migrations and settlements of the Goths is conformable to the accounts that are given by the ancient Greek and Latin authors with respect to the different colonies and settlements of the Getes. That the Goths and Getes were the same people, is supposed by all the writers who flourished in or near the times in which both empires were overrun by them. Those authors, without doubt well acquainted with their origin, call them sometimes Goths, sometimes Getes, and sometimes Scythians; and several authors tell us, that the Getes and Goths had been long known to the Romans, and also to the Greeks by the former names, but not by the latter, till their invasions into the empire.

When the Goths greatly increased in Scythia, they resolved to seek new settlements; and accordingly, purposing their route eaitward, and travelling through several countries, they returned at length into Germany. Their leader in this migration was the celebrated Woden or Odin, of whom many strange things are related. It is said by the northern writers, that he was king of the Afdarians, supposed to be the same people with the Afdurians mentioned by Tolemy and Strabo. Afdaria and Afdurgia are said to be a common name of their city, situated, according to Strabo, near Bosphorus Cimmerius; and Afdurgia was the metropolis of a country which Strabo calls Afa; hence Woden and his followers are styled by the ancient Gothic writers Afe, Afani, and Afae. The kings of Afdurgia are represented as being masters of all that part of Scythia that lay west of mount Imaus, and which the Latins called "Scythia intra Imaum," or Scythia within mount Imaus. Of this Afdaria or Afdurgia, Woden is said to have been king; and hence he emigrated with a great multitude of his followers in quest of new settlements; or, as some say, with the great design of forming in Sweden, considered as the inaccessible retreat of freedom, a religion and a people, which, in some remote age, might be subservient to his purposes; when his invincible Goths, armed with martial fanaticism, should issue in numerous swarms from the vicinity of the Polar circle to chastise the oppressors of mankind. Having passed through different countries, and performed a variety of exploits, he at length arrived in Sweden, where he was allowed to settle, and where he reigned till his death. His name became so famous that the northern nations ranked him among the gods, and worshipped him with divine honours. He is supposed to have brought with him out of Asia the Russian characters (see Rusie), and to have taught the northern nations the art of poetry; whence he is said to be the father of the Scaldi or Scaldur. See Scald.

That the Goths, under the conduct of Woden, came from Scythia into the northern parts of Germany, is a received opinion among the northern writers, and, as they allege, confirmed by an immemorial tradition, by the ancient chronicles of those countries, and by many monuments and inscriptions in Runic characters, some of which are still to be seen in Sweden, Denmark, and the neighbouring islands. That there were such migrations can hardly be questioned, since we find the same names common to the inhabitants of Scandinavia and Asiatic Scythia, and likewise the same language, as Grotius, and after him Sheringham, have shown. The ancient language of the Goths is now spoken by the Tartars of Precopus, whence, and from other collateral circumstances, it has been concluded that the Scandinavian Goths and Asiatic Scythians had once and the same original. As to the time of this migration of Saxians under Woden into the northern parts of Germany, those who maintain it have been at least to determine. Some refer it to a period about 244 years B.C; for at that time, they say, Pompey laid waste Syria, and great part of Asia, and marched the north with ferocity. After all, this wonderful expedition of Woden or Odin is admitted with great hesitation, or indeed fearfully admitted at all by many, into authentic history. According to the obvious sense of the Edda (see Edda), and the interpretation of the most skilful critics, in-ward, instead of denoting a real city of the Asiatic Sarmatia, is the fictitious appellation of the mythic abode of the gods, the Olympus of Scandinavia; from whence the prophet was supposed to descend, when he announced his new religion to the Gothic nations, who were already seated in the southern parts of Sweden.

Before we proceed with our brief abstract of the history of the Goths, we shall give some account of their character, customs, laws, and religion, before they embraced Christianity. With regard to their general dispositions and character, they were celebrated for their hospitality and kindness to strangers; and it is said that they derived their name from their being eminently good; the name of Gotli being derived, according to Grotius and other writers, from the German word got, signifying good. They encouraged, says Dio, the study of philosophy more than any other barbarous or foreign nation, and often selected their kings from among their philosophers. Polygamy was not only allowed, but encouraged, and every one was respected according to the number of his wives, and of course his children. Adultery with them was a capital crime, and invariably punished with death. This severity, and likewise polygamy, prevailed among them, when they were known to the Greeks and Romans only by the name of Getes, as appears from the poet Menander, who was himself a Gete, and from Horace (l. iii, col. 24.), who bewails great encomiums on the virtue and chastity of their women. Of their laws we shall have occasion to speak in the sequel of this article. Their government was monarchical. Their religion seems to have been the same with that of the ancient inhabitants of Scandinavia and Saxony; which see respectively. Till the end of the eleventh century, a celebrated temple subsisted at Upsal, the most considerable town of the Swedes and Goths. This temple was enriched with the gold which the Scandinavians had acquired...
in their piratical adventures, and fanctified by the uncouth representations of the three principal deities, the god of war, the goddess of generation, and the god of thunder. In the general festival that was solemnized every ninth year, nine animals of every species (without excepting the human) were sacrificed, and their bleeding bodies flung over the sacred grove adjacent to the temple. The only traces that now subsist of this barbaric superstition are contained in the Tiber, which see. See also Opus.

Caracalla was the first Roman emperor who quarrelled with the Goths, and marched against them into that part of Dacia, north of the Danube, of which they had taken possession; but the advantages which he seems to have gained over them in a few skirmishes were very inconsiderable. It appears, that the Romans were alarmed at an early period by the progress of this warlike nation; for in the reign of Alexander, which began in 222, considerable sums of money were lent to them from Rome, in order to prevent their disturbing the peace of the empire. Notwithstanding these bribes, as soon as they heard of the affaillusion of the emperor Maximin, who was of Gothic extraction, they resolved to revenge it, and accordingly entering Moesia, they totally laid waste that province. Not long after they made themselves masters of Thrace, from which they were driven by Gordian. Under Philip, his successor, they committed dreadful ravages both in Thrace and Moesia. Soon after their retreat from the siege of Marcelluspolis, the capital of the second Moesia, and after having compelled the inhabitants to ransom their lives and property, they passed the Danube a second time, under the command of their king, Cuiva, with a more considerable force; and having obliged Darius the son of the Roman emperor, to save himself by flight, they were opposed by the emperor himself. Darius, having compelled them to raise the siege of Nicopolis, they retired towards Philopappis, took it by storm, and massacred, as is said, 100,000 persons in the sack of that city. The time, however, which was consumed in this tedious siege, enabled Darius to revive the courage, restore the discipline, and recruit the number of his troops, after the defeat they had sustained in their pursuit of the Goths. Thus recovered, the emperor exerted his utmost vigilance to oppose either the progress or the retreat of the barbarians. The Goths were now, on every side, surrounded and persecuted, for by the Roman army, and exhausted by the long siege of Philopappis, they would gladly have purchased, by the surrender of all their booty and prisoners, the permission of an undisturbed retreat. The emperor, confident of victory, refused to listen to any terms of accommodation; and the high-spirited barbarians preferred death to slavery. The two armies, therefore, prepared for an engagement. The conflict was severe; two lines of the Gothic army were thrown into disorder; and the third only remained entire, prepared to dispute the passage of a morass, which was imprudently attempted by the Roman troops. Here the fortune of the day assumed a new aspect. In this morass the Roman army, borne down by the weight of their armour, after an intellectual struggle, was irrecoverably lost; nor could the body of the emperor ever be found. Upon the election of Gallus A.D. 231, the first object of his attention was to deliver the Illyrian provinces from the intolerable weight of the victorious Goths. He offered them every inducement: in his power to withdraw their forces; and he even promised to pay them annually a large sum of gold, on condition they should never afterwards infest the Roman territories by their incursions. This tribute, however, though granted at the expense of the honour of the Romans, was insufficient to secure their permanent repose.

New swarms of barbarians, encouraged by the successes, and conceiving themselves not bound by the obligation of their brethren, spread devastation through the Illyrian provinces, and terror as far as the gates of Rome. In this period of alarm and discord, Aninius, governor of Pannonia and Moesia, rallied the scattered forces of the empire; and the barbarians were unexpectedly attacked, routed, chased, and pursued beyond the Danube. Under the reigns of Valerian and Gallienus, the frontier of the last-mentioned river was perpetually infested by the inroads of the Germans and Sarmatians; but it was defended by the Romans with more than usual firmness and success. Nevertheless, the great stream of the Gothic hordes was diverted into a very different channel. The Goths, in their new settlement of the Ukraine, soon became masters of the northern coast of the Euxine; to the south of that inland sea were situated the wealthy provinces of Asia Minor, which possessed all that could attract, and nothing that could repel, a barbarian conqueror. The little kingdom of Bosphorus, whose capital was situated on the straits, through which the Maotis communicates itself to the Euxine, was composed of degenerate Greeks, and half-civilized barbarians. In this small kingdom, domestic factions, and the fear, or interest, of obnoxious usurpers, who feigned on the vacant throne, admitted the Goths into the heart of Bosphorus.

Here they acquired a naval force sufficient to transport their troops to the coast of Asia. For this purpose, they constructed a fort of flat-bottomed boats, called "Camara," framed of timber only, without any iron, and occasionally covered with a shewing roof, on the appearance of a tempest. With this kind of fleet, they first appeared before Pityus, at the utmost limit of the Roman provinces, with a convenient port, and fortified with a strong wall. Their first attack was repulsed; but, renewing their attempts, they destroyed this city. Then circling round the eastern extremity of the Euxine sea, their navigation from Pityus to Trebifond was a course of about 350 miles. This city was large and populous, defended by a double inclosure of walls, and had its usual garrison strengthened by a reinforcement of 10,000 men. But this numerous garrison was dissolved in riot and luxury, and thus rendered careless in guarding their inexpressible fortifications. The Goths, availing themselves of the supine negligence of the besiegers, erected a lofty pile of fagaces, ascended the walls in the silence of the night, entered the defended city, sword in hand, massacred the inhabitants, destroyed the temples and splendid edifices, and gained an immense booty. With the rich spoils of the city they filled a great fleet of ships, which they found in the port, and, satisfied with the success of their first naval expedition, returned in triumph to their new establishments in the kingdom of the Bosphorus. In their second naval expedition, possessed of greater powers both of men and ships, they took a new course, followed the western coast of the Euxine, passed before the wide mouth of the Borythones, the Niter, and the Danube; and increasing their fleet by a great number of fishing boats, they approached the narrow outlet through which the Euxine sea pours its waters into the Mediterranean. In this expedition they plundered the cities of Bithynia, Chalcedon, Nice, Prum, Apamea, Cius, and Nicomedia. From the recent attack of Prum, the Goths advanced within 18 miles of Cyzicus; but their progress was stopped by the small river Rhynsacus, which issues from the lake Apollinates, and which was then swelled into a broad and rapid stream. Their retreat to the maritime city of Hercules, where their fleet was probably stationed, was attended by a long train of waggons, laden with the spoils of Bithynia, and
and was marked by the flames of Nice and Nicomedia, which they wantonly burnt. The third naval expedition of the Goths consisted of 500 sail of transports, containing about 15,000 warriors. They now steered their destructive course from the Chersonian to the Thracian Bosphorus; and were carried to the lake of the Propontis. Their landing on the little island of Cyzicus was followed by the ruin of that ancient and noble city. They then passed through the narrow passage of the Hellespont, and purged their winding navigation amidst the numerous islands scattered over the Archipelago, or Aegean sea. At length the Gothic fleet anchored in the port of Piraeus, five miles from Athens, ravaged Greece, and caused the rage of war, both by land and sea, to spread from the extremity of Samos, to the western coast of Epirus, advancing within sight of Italy. The insatiable Galliuns was routed; the emperors appeared in arms; and his presence contributed to check the despair of the enemy. Some of the numerous Gothic boat broke into Mysia, for the purpose of forcing their way up the Danube to their settlements in the Ukraine. Others returned on board their vessels, and retracing their course through the Hellespont and the Bosphorus, and finding themselves secure within the bason of the Euxine, landed at Anchialus, in Thrace, near the foot of mount Hauma, and refashioned themselves by the use of those pleasant and salutary hot-baths. Amidst their devastations, we may select the destruction of the famous temple of Diana at Ephesus, which they burnt in their third naval invasion. It is also said, that they threatened to destroy all the libraries of Athens, but were prevented from executing their menace by the profound observation of one of their chiefs, that as long as the Greeks were addicted to the study of books, they would never apply themselves to the exercise of arms. Under the reign of Claudius, A. D. 269, the Goths collected an armament more formidable than any that had yet issued from the Euxine. On the banks of the Nielder they constructed a fleet of 2000, or even of 6000 vessels, which, in their piaffage through the Bosphorus, encountered various difficulties. However, they made several defeats on the coasts, both of Europe and Asia. But discontent and division arose in the fleet, and some of their chiefs deserted them, and failed away towards Crete and Cyprus: the main body, nevertheless, pursued their course, anchored at the foot of mount Athos, and assaulted the city of Thessalonica. Their attacks were soon interrupted by the rapid approach of Claudius. The Goths, eager for a general engagement, relinquished the siege of Thessalonica; and with this view, leaving their navy at the foot of mount Athos, traversed the hills of Macedonia. Claudius was defeated, but at the same time firm and determined. The event exceeded even his own expectations, as well as those of the world; and having gained signal victories, and diverted the empire from this host of barbarians, he was distinguished by politeness under the glorious appellation of the Gothic Claudius. The decisive battle was fought near Naissus, a city of Dardania. The war was afterwards diffused over the provinces of Mysia, Thrace, and Macedonia, and the superior talents of the emperor generally enabled the successes of his arms. The Goths suffered to such a degree, that a feebler body of their youth was received among the Imperial troops, the remainder was fold into servitude, and the female captives were innumerable, that every soldier appropriated to himself two or three women. To complete the disasters of the Goths, their fleet was either taken or sunk, so that their retreat was thus intercepted. Aurelian, the successor of Claudius, distinguished himself during the Gothic war, and, at last, put an end to it by a lading and beneficial treaty. The Gothic nation engaged to supply the armies of Rome with a body of 2500 auxiliaries, consisting entirely of cavalry, and, in return, stipulated an undisturbed retreat, with a regular market as far as the Danube, provided by the emperor's care, but at their own expense. But the most important condition of peace was understood rather than expressed in the treaty. Aurelian withdrew the Roman forces from Dacia, and tacitly relinquished that great province to the Goths and Vandals. This proved, in the event: a wise measure; for, after Dacia became an independent state, it formed as the firmest barrier of the empire against the invasions of the haggers of the North.

About the year 273, the second of the reign of Probus, the Goths entered Thrace, and advanced as far as Illyricum, having wasted the country with fire and sword; but as soon as they heard that the emperor was marching against them, they retreated and left their booty behind them. In Illyricum, Probus was met by deputies from the Gothic nations, suing for peace, and submitting to his power. No further mention is made of the Goths till the year 289, at which time Diocletian is said to have gained a complete victory over them. From this victory Diocletian assumed the name of "Sarmatian," as appears from several ancient coins and inscriptions. From this year to the 15th of Constance, the Goths gave no disturbance to the empire, being engaged in wars with the neighboring nations. As soon as the Goths were disengaged from other wars, they invaded the Roman empire; but they were overcome by Constantine in several battles, fought at Campania, in Panonia, and at Margus and Bononia, in Upper Media. The emperor determined to chastise as well as to repulse the infidel barbarians who had dared to attack the territories of Rome, passed the Danube, and penetrated into the midst of the Gothic camps; and when he had inflicted a severe reverse, he condescended to give peace to the suppliant Goths, on condition that as often as they were required, they should supply his army with a body of 50,000 soldiers. In the year 331, a war broke out between the Goths and Sarmatians; on which occasion the latter had recourse to Constantine, who was glad to embrace an opportunity of humbling that ferocious nation. In the first action the barbarians gained the advantage; but the event of a second and more successful action, in April 352, retrieved the honour of the Roman name. Near 100,000 of the enemy were either put to the sword, or perished after the battle with hunger and cold; and this defeat was so signal, as to oblige Abaric, king of the Goths, to sue for peace, and to deliver hostages to the emperor, one of whom was his own son. The Goths not only continued quiet, but served the Romans with great fidelity, during the remaining part of Constantine's reign; and in the reigns of Conclusions, Julian, Trajan, and Valentinian I. But in the first of Valens, they made inroads into Thrace; and had wasted that province. The emperor purchased their retreat for a sum of money. In the following year news was brought him to Bithynia, that the Goths were again ready to break into Thrace. When Procopius revolted, and assumed the title of emperor, the Goths expelled his cause, and sent a body of troops to his assistance; but before their arrival, he was defeated and put to death. They, however, continued in the territories of the empire, committing great ravages in Thrace and Media. Valens sent a strong detachment against them, and, in their retreat being cut off, they were obliged to lay down their arms, and yield themselves prisoners. After hostilities which lasted three years from 366 to 369, the barbarians submitted, and thus appeased the resentment of Valens. After the ratification of the treaty, Valens returned in triumph to Con-
Goths.

The Goths remained in a state of tranquility about six years; till they were violently impelled against the Roman empire by an innumerable host of Scythians, who appeared to issue from the frozen regions of the North. In the year 375 the Huns invaded the territories of the Goths, and agreed among them for a general confederation, and thus they fell upon the Roman dominions. Valens listened to their supplications, and granted them protection. The liberality of the emperor, however, was accompanied with too harsh and rigorous conditions. Before they passed the Danube, they were required to deliver their arms; and it was intimated that their children should be taken from them, and dispersed through the provinces of Asia; where they might be civilized by the arts of education, and serve as hostages to secure the fidelity of their parents. A probable testimony has fixed the number of the Gothic warriors at 200,000 men; and if we can venture to add the full proportion of women, of children, and of slaves, the whole mass of people which composed this formidable emigration must have amounted to near a million of persons, of both sexes and of all ages. The Goths, fully provoked at the cruel treatment they met with from the Roman officers, who were furnished with provisions, had fiercely entered Thrace, under the conditions imposed upon them, when they began to mutiny and plunder the country. This occasioned a long and bloody war between them and the Romans. They were joined by the Huns, Alani, Taifakes, and other swarms of their countrymen. In the battle of Hadrianople, A.D. 378, the Roman cavalry fled; and the infantry was abandoned, surrounded, and cut in pieces; and though the Goths were obliged to raise the siege of Hadrianople, the tide of the Gothic inundation rolled from the walls of this city to the suburbs of Constantinople; and the Roman provinces were ravaged by the barbarians. At this time a suffusion prevailed, that the Goths of Asia had formed a secret and dangerous conspiracy against the public safety. An order was promulgated that, on a fixed day, the Gothic youth should assemble in the capital cities of their respective provinces; and as a report was industriously circulated, that they were summoned to receive a liberal gift of land and money, the pleading hope allayed the fury of their resentment, and perhaps lulled the motions of the conspiracy. On the appointed day, the unarmed crowd of the Gothic youth assembled in the square, or forum; the streets and avenues were occupied by the Roman troops; and the roofs of the houses were covered with archers and slingers. At the same time in all the cities of the East, the signal was given of indiscriminate slaughter; and the provinces of Asia were delivered by the cruel prudence of Julius, who was master-general of the troops, from a domestic enemy, who, in a few months, might have carried fire and sword from the Hellespont to the Euphrates. At length the Goths submitted to Theodosius I., and were allowed by him to settle in Thrace and Macedonia, which two provinces had been almost depopulated by the frequent incursions of the neighbouring barbarians, and the late destructive war. A numerous colony of the Vitighots was settled in Thrace; the remains of the Ofrorothots were planted in Phrygia and Lydia; their immediate wants were supplied by a distribution of corn and cattle; and their future industry was encouraged by an exemption from tribute for a certain number of years. Hopes were entertained that the manners of the barbarians would in time be civilized, and that their potterv would be indubitably blended with the body of the Roman people. Notwithstanding these flattering expectations, it was apparent to every discerning eye, that the Goths would long remain the enemies, and might soon become the conquerors of the Roman empire. As the impotent Goths could only be restrained by the firm and temperate character of Theodosius, the public safety seemed to depend on the life and abilities of a single man. He died in the month of January A.D. 395; and before the end of the winter of the same year, the Gothic nation was in arms. The interception of the harvest in the province of the Pireus, Corinth, Argos, and Sparta yielded without resistance to the arms of the Goths. From Thermopylae to Sparta, the leader of the Goths purged his victorious march, without encountering any mortal antagonists; and the Christian faith, which he had devoutly embraced, taught him to despise the imaginary deities of Rome and Athens. In 397 Stilicho, the general of the West, advanced to chastise the invaders of Greece. The skill and perseverance of the Roman at length prevailed; and the Goths, after fulfilling a considerable loss by defection and desertion, gradually retreated to the lofty mountains of Phocoe, near the sources of the Peneus, and on the frontiers of Ely; a sacred country, which had formerly been exempted from the calamities of war. Their camp was immediately besieged; and reduced to great distress by thirst and hunger. A strong line of circumvallation was formed to prevent their escape. Alaric was secret, prudent, and rapid in his operations; he immediately negotiated a treaty with the ministers of Constantine; and Stilicho was compelled to retire from the dominions of Arcadius; and he respected, in the enemy of Rome, the honourable character of the ally and servant of the emperor of the East. Alaric is declared master-general of the Eastern Illyricum; and the ufe to which he applied his new command distinguishes the firm and judicious character of his policy. He lies his orders to the four magazines of offensive and defensive arms, Margus, Ratiana, Naufius, and Thebafalia, to provide his troops with an extraordinary supply of shields, helmets, swords, and spears. With the unanimous consent of the barbarian chieftains, the master-general of Illyricum was elevated, according to ancient custom, on a shield, and solemnly proclaimed king of the Vitighots. Thus armed with double power, and feated on the verge of the two empires, he aspired to quell the two emperors Arcadius and Honorius, till he declared and executed his resolution of invading the dominions of the West. He was tempted by the fame, the beauty, and the wealth of Italy, which he had twice visited; and he secretly aspired to plant the Gothic standard on the walls of Rome, and to enrich his army with the accumulated spoils of three hundred triumphs. Alaric lyes no time in executing his purpose of invading Italy, and advances, against much opposition, towards the capital of the empire. It was in the year 400 that he first entered Italy, making dreadful ravages in his progress. His march, probably from Thebafalia, through the warlike and hostile country of Pannonia, as far as the foot of the Julian Alps; his passage of those mountains, which were strongly guarded by troops and entrenchments; the siege of Aquileia, and the conquest of the provinces of Illyria and Venetia, appear to have employed a considerable time. In the year 403, Alaric approached Milan, and the emperor Honorius, dreadimg his arrival, fled to Ravenna. Stilicho, however, prepared to march against the enemy, whom he found encamped at Pollentia, on the Tamaro, in Piedmont. While the Christian
Goths.

Christian Goths were devoutly celebrating Easter, they were attacked by Sulich, and after a very severe engagement, they retreated from the field of battle, after the total defeat of the infantry, with their cavalry entire, under the command of Alaric, who poisted a mind, that was invincible and superior to misfortune, and that derived new resources from adversity. The Gothic sovereign, wishing to distinguish his retreat by some illustrious exploit, attacked Verona, but in the battle that ensued he suffered a defeat so great as to separate him from that at Pollentia. In the year 428 Alaric marched again towards Rome; with bold and rapid marches he passed the Alps and the Po; hastily pillaged the cities of Aquitania, Alba, Concordia, and Cremona; increased his forces by the accession of 75,000 auxiliaries; and, without meeting a single enemy in the field, advanced as far as the edge of the mora, which protected the impenetrable residence of the emperor of the West. He soon after pitched his camp under the walls of Rome. A ransom having being offered and accepted, he raises the siege.

A.D. 429. Alaric's next attack was directed against the port of Ocitia, one of the boldest and most stupendous works of Roman magnificence; and as soon as he was in possession of this important place, he summoned the city to surrender at discretion; but he contented himself with superfluous Honorius, and believing the purple on Atalattus, prefect of the city. Atalattus was soon after degraded, and his degradation was followed by the third siege and sack of Rome, Aug. 24, A.D. 410. At the hour of midnight the Sabine gate was silently opened, and the inhabitants were awakened by the tremendous sound of the Gothic trumpet. Eleven hundred and sixty-three years after the foundation of Rome, the Imperial city, which had fabled and civilized for a considerable part of mankind, was delivered to the licentious fury of the tribes of Germany and Scythia. After six days' pillage and devastation, the victorious Goths evacuated Rome, and their intrepid leader advanced into Campania, and having ravaged that and the neighbouring provinces of Lucania, Samnium, Apulia, and Calabria, he approached the limits of Sicily, with a design to pass over into that island, and thence into Africa; but he was seized in the neighbourhood of Rhegium with a fit of illness, of which he died in a few days. (See ALARIC.)

He was succeeded in the Gothic throne by his brother-in-law Atalattus, or Adolphus, who concluded a peace with the empire, and marched into Gaul A.D. 452. Being driven out of Gaul A.D. 451, he retired to Spain, where he was soon after assailed. Jingeric, his successor on the Gothic throne, shared the same fate. After his death the free choice of the nation bestowed the Gothic sceptre on Valia or Wallia, who concluded a peace with the Romans, and commenced a faugumary, but successful war with the barbarians, who had settled in Spain. His victorious Goths, A.D. 459, forty-three years after they had passed the Danube, were enfeoffed, according to the faith of treaties, in the possession of the second Aquitain, a maritime province between the Garonne and the Loire, under the civil and ecclesiastical jurisdiction of Bourdeaux. The Gothic limits were afterwards enlarged by the additional grant of some neighbouring dioceses; and the successors of Alaric fixed their royal residence at Thoiloufe. Thus, about the same time, in the latter year of the reign of Honorius, the Goths, the Burgundians, and the Franks, obtained a permanent seat and dominion in the provinces of Gaul. Wallia was succeeded by Theodoric, who first made war with the Romans, and gained several places in Gaul belonging to them; and afterwards concluded a peace with them. The Goths continued quiet in the countries that had been allotted them in Gaul for the space of ten years, or till the year 456, when, the Romans being engaged in a war with the Burgundians, Theodoric availed himself of that opportunity to enlarge his dominions. At length the Gothic king made peace with the Romans; and in the year 453 engaged by an alliance with them to affiit them against the Huns, who had entered Gaul. Theodoric, his son and successor, breaks with the Romans; but his brother Theodore, who next occupied the Gothic throne, and who was eminently distinguished by his talents and attainments, cultivated the friendship of the Romans, and contributed by his martial exploits to the support of the Roman empire. Theodoric entered Spain with a large army of Goths and Burgundians; and having almost reduced the Suevians in Galicia, A.D. 457, he passed from thence into Lusitania, and reduced several places. Upon his return to Gaul, he took several cities belonging to the Romans, but was at length checked in his career and defeated by Agisidius, commander in chief of the Roman forces in that country.

In Spain the Goths were more successful than they were in Gaul, and became masters of the greater part of the country. Under Euric, who ascended the throne A.D. 466, the Goths drove the Romans out of Spain; and all the provinces, except Galicia, and part of Lusitania, which were subject to the Suevians, acknowledged him as their king, who residing at Thoulofs, governed them by his lieutenants. Euric, having also made himself master of the breadth of Gaul, comprising the whole tract between the Rhone and the Loire, and of the greatest part of Spain, was full of designs of reducing the remaining parts of both countries, when his death at Arles, A.D. 483, put a stop to his great designs. Euric is said to have been the first who gave written laws to the Goths, for till his reign they had been governed by customs only; and for this purpose he employed Leo, his prime minister, one of the most learned men, and best citizens of that period. These laws were called the "Theodorian" laws; and were obtruded by Euric upon the people of Gaul and Spain, who had been long accustomed to the Roman laws; but Alaric, his son and successor, restored the Roman laws to their former authority, and caused them to be observed throughout his dominions. About this period the king of the Vifgoths in Gaul terminated; and they, being driven from thence, fixed their royal seat at Toledo, in Spain. (See VISIGOTHS.) For the history of the Ostrogoths, see OSTROGOTHS. Under Theodoric, who, A.D. 493, caused himself to be proclaimed by his Gothic king of Italy, and was acknowledged as such by the emperor Anastasius, the successor of Zeno, Theodoric secured his new kingdom by alliances with neighbouring powers: he quarreled all his Goths in the cities and strong holds, with their officers who were to command them in time of war, and govern them in time of peace; he retained the Roman laws, the same form of government, the same distribution of provinces, the same magistrates and dignities; and, besides, according to the custom of the Goths, he appointed for each city inferior judges, distinguished by the title of counts, who were to administer justice, and decide all disputes; and in this respect he followed the policy of the Goths, as Goths observes, far excelled that of the Romans. Thus Italy, from the dominion of the Romans, fell under that of the Goths, almost without any perceptible change. See THEODORIC.

At subsequent periods attempts were made to recover the country from subjection to their government; particularly in the reign of Jutamin. Under the weak reign of Theodatas, the Gothic king of Italy, Belisarius invaded Italy, entered Rome A.D. 536, and reduced Naples A.D. 537. He defended Rome against the whole army of the Goths.
Goths, who besieged it A.D. 537, and continued it above a year till their final departure. During this siege, which was raised in March, A.D. 538, one-third of their enormous host was destroyed in frequent and bloody combats under the walls of the city, and the evils of famine and pestilence were aggravated by their own licentiousness, and the unfriendly disposition of the country. Vitiges, their king, retired for shelter within the walls and moraines of Ravenna. At length Belisarius besieged the city, and took it in the latter end of the year 539. The feoffation of the capital was imitated in the towns and villages of Italy; and the independent Goths who remained in arms at Pavia and Verona, were ambitious only to become the subjects of Belisarius. But his inflexible loyalty rejected, except as the substitute of Justinian, their oath of allegiance. In the year 540, the Goths revolted, and Totila, the nephew of their late king, undertook the restitution of the kingdom of Italy. His first movements were rapid and successful; and after reducing by force, or treaty, the towns of inferior note in the midland provinces of Italy, Totila proceeded, A.D. 546, to encompass Rome, and to harry its inhabitants. Famine had relaxed the strength and discipline of the garrison, and Rome was taken by the Goths in December, A.D. 546. After the departure of Totila, it was recovered by Belisarius in February, A.D. 547. (See Belisarius.) When Totila returned to avenge the injury and disgrace, the Goths were three repulsed; they lost the flower of their troops; the royal standard had almost fallen into the hands of the enemy, and the fame of Totila funk, as it had fallen, with the fortune of his arms. Rome was again taken by the Goths, A.D. 549. Justinian made great preparations for the Gothic war, the conduct of which was committed to Narses, who defeated Totila in a bloody engagement, July, A.D. 552, and Totila himself was struck through the body with a lance. Narses then proceeded to the conquest of Rome; and Justinian once more received the keys of the imperial city, which, under his reign, had been five times taken and recovered. The last king of the Goths was Teias, who was unanimously chosen to succeed and revenge their departed hero, March, A.D. 553: Sixty days were consumed in diffuse and fruitless combats, between the Gothic and Roman armies, but at length, after an engagement of many hours, Teias fell, and his head, exalted on a spear, proclaimed to the nations, that the Gothic kingdom was no more. After a reign of 50 years, the throne of the Gothic kings was filled by the exarch of Ravenna (see Exarch); and the remains of the Gothic nation evacuated the country or mingled with the people. (Anc. Un. Hist. vol. xiv. Gibbon's Hist. vol. vii. par. 13.)

The Goths spread themselves very widely in their various migrations, and formed part of the population of the several nations of Europe. In England the Celtic population was succeeded by the Gothic, and about two-thirds of England were peopled by the Belgic Goths. (See Belgae and England.) About the time that the Belgae feigned on the south of England, it appears that a hundred Gothic tribes passed to the south of Ireland. (See Ireland.) In France, or Gaul, the Goths, or warlike German tribes, under the denomination of Belgae, feigned on a third part of the country into which they introduced the Gothic language and manners. (See Belgae and Gaul.) The original population of the Netherlands was Celtic; but it was afterwards peopled by the Belgae. (See Belgae and Netherlands.) In Germany, the Scythians or Goths, proceeding either from Scandinavia, or, as others say, from their original seats on the Euxine, expelled the Cimbri and Jines, and thence, intermixed with the German nations, destroyed the Roman empire in the west. (See Germany, and the preceding part of this article.) Prussia appears to have been peopled by the Pechini and Jellis, Gothic tribes bordering on the Venedi, who were Slavonians. (See Prussia.) The Vandals, who conquered Spain in the fifth century, were subdued by the Visigoths under Euric, who founded the modern kingdom of Spain. (See Spain.) The original population of Turkey in Europe chiefly sprung from the ancient Scythians on the Euxine, the progenitors of the Dacians, Thracians, &c. and even of the Greeks. The regions of Turkey in Asia were peopled by Scythic nations, intermixed with a few Assyrians from the south. (See Turkey.) The Batavi of Holland were the most northern people of Belgic Gaul, and without doubt a German or Gothic people. (See Batavi, Gaul, and England.) The Cimbri or northern Celts, who originally peopled Denmark, were expelled by the Goths, if they were not, as some conceive, tribes of the same name; and the Fins or Laps of Norway, which, with Sweden, constitutes the ancient Scandinavia, were driven to the northern extremities by the Gothic invasion. (See Denmark, Norway, Scandinavia, and Sweden.) The Helvetians, or original Swifts, are supposed by some writers to have been Celts; but others, with greater probability, consider them as a Gothic race, or very ancient colony of Germans.

It has been a general opinion, tenaciously maintained by Cluverius and Pelloutier, and adopted by Mallet in his "Northern Antiquities," that the Gothic and Celtic nations were the same; but the ingenious English translator of Mr. Mallet's "Northern Antiquities" has produced a variety of testimonies from ancient authors, to prove that the Celtic and Teutonic or Gothic nations were, ab origine, distinct, and that they differed considerably in person, manners, laws, religion, and language. The former were the ancestors of the Britons of Gaul, Britons of Britain, Saxons, and Scandinavians derived their origin from the latter. The Celtic tribes were probably the first that travelled westward; and the Goths, or Getz of the ancients, who emigrated at different times from the eastern countries after them, might borrow some of their opinions and practices, which will account for the resemblance that has been observed between them, without admitting that they were descents from them, or that they should be considered as the same people. In the same way we may account for those relics both of Celtic and Gothic superstitions, which are discernible in Gaul and Britain, and many other countries, the inhabitants of which derive their descent equally from the Celts and Goths, who were at different times mailers of thefe kingdoms, and whose descendants are now blended together; thus, the first inhabitants of Gaul and Britain being of Celtic race, followed the Druidical superstition. The ancient Germans, Scandinavians, &c. being of Gothic race, professed that heaven of polytheism which was afterwards delivered in the Edda; and the Franks and Saxons, who afterwards settled in Gaul and Britain, being of Gothic race, introduced the polytheism of their own nation, which was in general the fame that prevailed among all the other Gothic or Teutonic people. See, however, the article Gothic language, where the original identity of the Celts and Goths is maintained partly by general reasoning, and partly by etymological investigation.

GOTLUNDA, in Geography, a town of Sweden, in Nericy; nine miles N. E. of Orebro.

GOTOMB, a town of Poland, in the palatinate of Lublins; 29 miles N. W. of Lublin.

GO-TON, a town of China, in the province of Se-tchuen; 48 miles N.W. of Ou-mung.
GOTSEELA, a town of Bengal; 48 miles W. of Midnapour.

GOTTA, or Gotto Island, a cluster of small Japanese islands. N. lat. 30° 40'. E. long. 131° 40'.

GOTTALU, a town of Bengal; 33 miles S. of Burdwan. N. lat. 22° 42'. E. long. 88° 5'.

GOTTESBERG, a town of Silesia, in the principality of Schweinitz, near which are two mines, one of gold, not now worked, and another of coal. The manufacture of this town consists of knit worsted stockings. It contains two churches; 12 miles S. W. of Schweinitz. N. lat. 50° 35'. E. long. 15° 54'.

GOTTESGRAB, a town of Bohemia, in the circle of Saaz. N. lat. 30° 22'. E. long. 12° 54'.

GOTHE, Vincent Lewy, in Biographie, was born at Bologa, in the year 1642. At sixteen years of age he embraced the ecclesiastical life among the Dominican monks, and when he had completed his course of philosophy at Bologa, he was sent to study theology for four years at Salamanca in Spain. Upon his return to Italy in 1688, he was appointed professor of philosophy in the university of Bologna; and soon recommended himself by his talents and virtues to the poits of prior and provincial of his order. In 1728, pope Benedict XIII. raised him to the dignity of the purple; and three years afterwards appointed him member of the congregation for examining bishops. So highly was he esteemed, that in the last conclave, which was held during his time, he had the suffrages of a great number of the college for his being raised to the papal throne. He died at Rome in 1742, in his 79th year. His works, which are much valued by the Catholics, particularly by those in Italy, display considerable erudition and abilities. Of these the principal are "De vera Christi Ecclesia," in three volumes; "Theologia Scholastico-dogmatica, juxta Methem divi Thomae Aquinatis, &c." in six volumes 4to.; "Colloquii Theologi-Politici, in tres clavis distribuit, &c." in 12 volumes. He was employed at the time of his death in writing "A Commentary on the book of Genesis." Moreri.

GOTTIGNIES, Giles-Francois, was born at Brusseis in the year 1639, and entered into the order of the Jesuits at Mechlin in 1653, whence he was sent to Rome, to pursue his theological studies; here he spent the rest of his life employed in teaching the mathematics, and writing different works in that science. He died in 1689, when he was about sixty years of age. He was a considerable mathematician; a great lover of pure geometry, and had a dexterity in the algebraic method of resolving problems; his works are very numerous, and have been highly commended for the perspicuity and precision. They relate to arithmetic and geometry; and to the various parts of astronomy, and other branches of speculative and practical mathematics. Moreri.

GOTTINGEN, or Goettingen, in Geographie, a town of the kingdom of Welfphalia, and principal place of a district, named from it, is situated in a spacious, pleasant, fertile valley, on a canal, branching from the river Leine, and dividing the town into the New town and March. The number of houses is about 1500, containing about 8000 persons; the streets are large and paved; it has five parish churches, and one for Calvinists; the Roman Catholics perform their religious service in a private house. The town is governed by a provost, named by the sovereign, burgomasters, and a syndic chosen by the regency, appointed by a council. The university of Göttingen claims peculiar notice; it was founded in 1734 by George II, king of England, and consecrated on the 17th of September 1737, and by the attention of its first curator, baron Menchehusen, it has since to distinguished reputation. It has a splendid church, with its own pastor; and it is accommodated with a flately edifice of stone, the ground-floor of which serves as a hall for public lectures, and the upper apartments are appropriated to the library, council-chamber, and other necessary purposes. Its library is very large and valuable, and it is called the "Bulowean," from a collection of about 10,000 volumes, with which it originated, bequeathed by baron Bulow for public use, and granted by his heirs to the university. A royal society of sciences, founded in 1751, and a royal German society, form part of the university. It has likewise a fine observatory, erected on a tower on the ramparts, with a phyic garden, anatomical theatre, &c. The territory belonging to the town is very considerable; 22 miles N. E. of Callic. N. lat. 51° 47'. E. long. 9° 52'.

GOTTO, a country, in Africa, situated to the south of Jimbali and Trombeto, and the rivier Niger or Joliba, about 15° N. lat., and from o to 2° E. long. It was formerly divided into several petty states, under their own chiefs, but it is now under the government of a king. Its chief town is called Moooffedawo, from the name of their first monarch.

GOTTOLENGO, a town of Italy, in the department of the Mela; 15 miles S. of Brescia.

GOTTORP. See Schlwig.

GOTTSCHHE, a town of Middle Carniola; 20 miles S.S.E. of Laybach. N. lat. 45° 53'. E. long. 14° 48'.

GOTZEL, a town of Bavaria; 36 miles E. of Rathbon.

GOVAN, a town of Scotland, in Lasarkhire; the population of which, in 1801, was 6070, of which 1314 were employed in trade and manufactures; four miles W. of Glasgow.

GOVANDORE, a bay on the coast of Chili.

GOUANA, in Botany, was named by Jacquin in honour of Anthony Gouna, a physician and celebrated botanist of Montpellier, where he was also medical chaplain, and, as far as we know, is still living, though at a very advanced age. He was the friend and correspondent of Linnaeus, and is the author of a Flora Montpeliensia, arranged according to what he himself calls a hybrid system, the outlines being on the principles of Tournefort, the subordinate sections taken from the Linnaean sexual system. This work appeared in 1765. He had previously, in 1762, published a Hortus Montpelienfis according to the last-mentioned system. Each work forms an octavo volume. They are chiefly remarkable for the secondary generic characters, taken from the habit, subjoined to the essential ones which are founded on the fruitification. Professor Gouna published also a folio volume of Observations Botaniques, with plates, illustrative of the plants of his neighbourhood; as well as a quarto volume in Latin and French on the methodical arrangement, and generic characters at length, of filices.—Jacqu. Amer. 263. Liv. Gen. 547. Schreb. 33. Mart. Mill. Dict. v. 2. Jaff. 581. Linn. Illustr. t. 854.—Chais and order, Polygonum Monnaea, or rather Pensusa Monogyna, Nat. Ord. Duftp. Linn. Rhanni, Jull.

Gen. Ch. Cal. Perianthi of one leaf, superior, funnel-shaped, five-leaf; tube permanent; segments of the limb ovate, acute, spreading, deciduous. Cor. Petals five, opposite to the stamens, hood-shaped, chalice. Stam. Filaments five, awl-shaped, the length of the segments of the calyx, and alternate with them, inserted into the tube; anthers roundish, incumbent, sheltered by the petals. Fil. German inferior, roundish; style awl-shaped, divided half-way down
GOU

Down into three segments; stigmas obtuse. *Peric.* Capsule with three angles, separable into three parts, of one cell each, not bursting. *Seeds* solitary, ovate, compressed, polished.—There are some male flowers, furnished with a style, but without of stigmas and stigma.

Jacquin originally described two species, of which Linnaeus adopted but one. Lamarck has added three more, all in our post-filion, to which we are enabled to furnish three non-descript species, making eight in all.

2. *G. tenentofa.* Jacq. Amer. 263. Linii MSS. in Sp. Pl. (G. crenata; Lamarck Dict. v. 3, 5.)—Leaves ovate, crenated, downy.—Native of woods in Hispaniola, climbing to the tops of lofty trees. Jacquin. Of this we have seen no specimen. Jacquin says the leaves are four inches long. *Seeds* black and shining. Lamarck supposes his plant to be the same on account of the great size of its leaves, and he says it is distinguished from all others by its crenatures. Jacquin describes it as lightly crenate.

3. *G. vescerocarp.*—Leaves elliptic-oblong, pointed, oblongely ferrured, roughish, naked on both sides. Wings of the fruit narrow, orbicular.—Native, we believe, of the West Indies. The very young *flowers* and *leaves* only are fylim and furrugineous. The full-grown leaves are near three inches long and one broad. The fimbriate ovate, ferrured entire, or furnished with fllfudant ferratures, and a fllfudant entire blunt point; they are green and quite naked on both sides, but hard to the touch on the upper surface. Veins diffuse. *Flowers* fimbriate, *stipulas* hairy. *Flowers* somewhat fllfudant. *Fruits* orbicular at each side, each wing forming a hemisphere, and not being much dilated.

4. *G. denticula.*—Leaves ovate, pale and downy beneath, entire, with a finely toothed point.—Gathered by the late Mr. Christopher Smith in the island of Honinoma, East Indies.—The *leaves* are about an inch and half long, with fimbriate veins, connected by numerous minute reticulations, and are remarkable for the numerous little sharp teeth which border their upper part and terminal point, while the rest of their margin is entire. Their upper fide is roughish to the touch, but green and naked; while the lower is hoary with very dense short down, the veins only being naked. *Stipulas* small and deciduous. A fimple curved tendril terminates each lateral branch, as in all the foregoing. *Flowers* in axillary downy clusters, with lanceolate deciduous bracteas. The fruit we have not fended.

5. *G. murriana* Lam. Lamarck Dict. v. 3, 5.—Leaves ovate, pointed, variously ferrured, downy on both sides.—Native of the heights called the Goli, in the desert, of the Isle de Bourbon, where it was gathered by Commeron, and sent to the botanical garden at Paris. The *leaves* are the size of the leaf, but green and clothed with fllfudant down on both sides. Their figure is ovate, rarely somewhat cordate, often unequal, sharp-pointed, their margin singularly variable, being sometimes nearly entire, having only furred shallow ferratures, sometimes very deeply and doubly ferrated, not unlike the Roman nettle, *Urtica pilafisfera.* *Stipulas* ovate, acute, clothed with shining reddish fllfudant hairs, as well as the young twigs and tendrils. The frutification is wanting in our specimens. Lamarck says the *capsules* have rounded thin and membranous wings.

6. *G. tllifolius.* Lamarck Dict. v. 3, 5. (G. Stedmanni; Willem. Herb. Maurit. 58.)—Leaves heart-shaped, bluntly pointed, smooth on both sides, bluntly and fllfudant ferrured. Native of the Isle de Bourbon, near la Villette. *Flowers* much branched and divided, smooth, except the very young florets. *Leaves* an inch or inch and half long, and nearly as broad, heart-shaped, with shallow ferratures and a short blunt point. They are light green and naked on both sides, smooth above; minutely chaffed beneath. *Stipulas* glandular. *Flowers* fally fllfudant and downy. The *tendrils* become very thick and strong by age.

7. *G. integrifolia.* Lamarck Dict. v. 3, 5.—Leaves ovate, bluntish, entire, smooth on both sides. *Stipulas* awl-shaped. Long cultivated in the Paris garden, but its native country is not remembered. We have a specimen from thence, definite of *flowers* and fruts, yet we readily agree with Lamarck that there can be no doubt respecting its genus. The habit, *fem* and *tendrils,* folded young leaves, and their pale parallel veins, all indicate *Gerania,* for no genus can be more natural than this. The *leaves* are usually about an inch long, exactly ovate, (not oval) without any elongated point, though tipped with a gland; their margin quite entire, their midribs sometimes fllfudant hairy at the back. *Stipulas* awl-shaped, deciduous. *Flowers* hairy only while young.

8. *G. miliaena.*—Leaves heart-shaped, minutely ferrured, acute, somewhat hairy. *Stipulas* awl-shaped. *Flowers* umbellated, scarcely so long as the leaves. Brought by the late Sir G. L. Staunton, Birt, we believe from the Bahamas. The zig-zag branches, with small heart-shaped *leaves,* and numerous axillary umbels of *flowers,* give it the aspect of a *Smilax.* The *tendrils* grow from the first joint of each branch, and are elegantly spiral; fally and hairy, like the *flowery-flakes* and *callys.* The principal *leaves* are usually about an inch long, green on both sides, their ribs and veins always very hairy, their surface more or less so. *Stipulas* awl-shaped, hairy.

GOUAREC, in *Geography,* a town of France, in the department of the North Coasts, and chief place of a canton, in the district of Loudené, 124 miles S.W. of St. Brieuc. The place contains 678, and the canton 6,693 inhabitants, on a territory of 2073 kilometres, in 5 communes.

GOUD, or Gaul. See Wulp.

Gouda, or Ter Gouw, in Geography, a city of Holland, seated on a branch of the Rhine, called *Isel,* where it receives the *Gouw,* from which it derives its name. The great church of this town is one of the largest and handsomest in the country, and is particularly famous for its painted glass windows, which were executed principally by Theodore and Walter Ceraebach of this town, and which are carefully preserved. The town is advantageously situated, on account of the fllfudant and canals, which are running streams, and its convenient port, the *Isel.* It has five gates, and is so circumfanced by reeds for the *fllfudants,* which may inundate the adjacent country, the breadth and depth of its fllfudants,
and the strong fortifications on the banks of the Ijssel, that it cannot easily be besieged. Its chief trade consists in cordage, cheese, and tobacco-pipes; and it has a regular communication by boats with Amsterdam, the Hague, Rotterdam, Utrecht, &c.; 22 miles S. of Amsterdam. N. lat. 52° 1'. E. long. 4° 36'.

GOUDHURST, a port-town of England, in the county of Kent, containing 1782 inhabitants; 11 miles S. of Maidstone, and 44 S.E. of London.

GOUDOZ, a town of Atilic Turkey, in Natolia; 72 miles E.N.E. of Kütajta.

GOUDIMEL, Claude, in Biography, one of the early and most celebrated composers of music to the metrical French translations of the psalms for the use of the Calvinists. He was a native of Franche-Comté, who seems to have loft his life at Lyons, on the day of the massacre of Paris, for having fet down, in the psalms of Clement Marot. Goudimel has been much celebrated by the Calvinists in France for this music, which was never used in the church of Geneva, and by the Catholics in Italy for instructing Palestrina in the art of composition, though it is doubtful whether this great harmonist and Goudimel had ever the least acquaintance or intercourse together. He set the "Chansons Spirituelles" of the celebrated Marc-Ant. De Muret, in four parts, which were printed at Paris, 1555. We may suppose Goudimel, at this time, to have been a Catholic, as the learned Muret is never ranked among heretics by French biographers. Ten years after, when he set the psalms of Clement Marot, this version was still regarded with less horror by the Catholics than in later times; for the music which Goudimel had set to it was printed at Paris by Adrian Le Roy, and Robert Ballard, with a privilege, 1565. It was reprinted in Holland, in 1607, for the use of the Calvinists, but seems to have been too difficult; for we are told by the editor of the psalms of Claude le Jeune, which were printed at Leyden, 1633, and dedicated to the States-General, that in publishing the psalms in parts, he had preferred the music of Claude le Jeune to that of Goudimel; for as the counterpoint was simply note for note, the most ignorant in music, if possessed of a voice, and acquainted with the psalm-tune, might join in the performance of any one of them; which is impracticable in the compositions of Goudimel, many of whose psalms being composed in fugue, can only be performed by persons well skilled in music.

The works of Goudimel, who was certainly the greatest musician in France, during the reign of Charles IX., are become so scarce, that his name and reputation are preferred by Protestant historians, more in pity of his misfortunes, than by any knowledge of their excellence. With respect to his having been the master of Palestrina, that point will be discussed elsewhere.

The earliest mention of Goudimel, as a composer, that we have been able to discover, is in a work entitled "Libro quatuor Ecclesiasticarum Cantionum quatuor vocum vulgo Motet' vacant," printed at Antwerp, by Sufato, 1554, eighteen years before his death. On fearing several of these motets, we found the harmony pure and correct, but constructed entirely on the principles of the ecclesiastical tones; probably before he became a disciple of Calvin. The title of all his compositions may be seen in Draudius, Bibl. Class. and Bibl. Exot. (See Franc, Claude le Jeune, and Palestrina.) The motets of Goudimel, in four parts, resemble in gravity of style, simplicity in the subjects of fugue, and purity of harmony, the ecclesiastical compositions of our venerable countryman Bird.

Vol. XVI.

GOODSWAARTE, in Geography, a small island at the mouth of the Meuse, S. of the island of Putzer.

GOUEGA, a town of Africa, in Whidah; 10 miles W.S.W. of Sabi.

GOVENDING, a town of Bengal; 32 miles E. of Calcutta.

GOVERDAN, a town of Hindooftan, in Mewat; 10 miles E.S.E. of Digm.—Also, a town in Ouda, near the De- wah; 20 miles N. of Azimgur.

GOVERDUNPOUR, a town of Hindooftan; 44 miles N. of Allahabad.

GOVERNDUNGURRY, a town of Hindooftan, in Canara; 14 miles S.E. of Onore.

GOVERNMENT, a quality or office which gives a man power or right to command or rule over a place, a city, a province, a kingdom, or the like, either supremely or by deputation.

Government is either general and supreme, as that of a whole kingdom, empire, sovereign state, &c. or particular and subordinate, which, again, is subdivided into civil, military, and ecclesiastical.

Our cities, corporations, and boroughs, are usually governed by mayors, with aldermen and common-councillors.

Government is also used for the country, city, or place to which the power of governing or commanding is extended.

Government, again, is used for the manner or form of governing, i.e. for the police of a country, state, &c.

In this sense the various forms of government have generally received their denominations from the number of persons to whom the supreme power has been entrusted. If it be in one person, it is called a monarchy, especially if the chief magistrate lies under considerable restrictions, or governs by fixed and established laws; whereas, if this single person lies under fewer restraints, or directs everything by his own will and caprice, the government is called despotic. If the supreme power be lodged in a limited number of persons, the government is called oligarchy, or aristocracy; and if all the citizens have an equal vote in making laws, and appointing magistrates, or the supreme power is lodged in the whole body of the people, it is called a democracy or republic. See these several articles.

Civil government and society originate in the wants and fears of individuals, who, being naturally free, equal, and independent, associate together, either by express or tacit consent, for the mutual preservation of their lives, liberties, and estates, on this fundamental principle, that the whole should protect all its parts, and that every part should pay obedience to the will of the whole. However the several forms of government, that now exist, actually begun, there is and must be in all of them a supreme, irresistible, absolute, unconstrained authority, in which the jura summi imperii, or the rights of sovereignty, reside; and this authority is placed in those hands, wherein, according to the opinion of the founders of such respective states, either expressly given, or collected from their tacit approbation, the qualities requisite for supremacy, viz. wisdom, goodness, and power, are the most likely to be found.

Individuals unite for mutual protection and benefit; and, therefore, the legislative and executive authority of government, originally derived from themselves, should be invariably directed to no other end but their safety and welfare; and that form of government is most eligible, which is best adapted to these purposes. Cicero declares himself of opinion, in his fragments De Rep. lib. ii. « elle optimum condit.
GOVERNMENT.

Ritusam rempublicam, que ex tribus generibus illis, regular, optimo et populari, fit modice condita. Of this kind is the British constitution, which lodges the executive power of the laws in a single person, and the legislative in three distinct powers, entirely independent of each other; viz. the king; the lords spiritual and temporal, forming an arithocratical assembly; and the house of commons, freely chosen by the people, which renders it a kind of democracy; and each branch of this aggregate body, actuated by different views, and attentive to different interests, is armed with a negative power, sufficient to repel any innovation which it shall think inexpedient or dangerous. Nothing can endanger or hurt the constitutional government of Britain, but destroying the equilibrium of power between one branch of the legislature and the rest: for if ever it should happen that the independence of any one of the three should be lost, or that it should become subservient to the views of the other two, there would soon be an end of our constitution: the legislature would be changed from that which was originally set up by the general consent and fundamental act of the society; and such a change, however effected, is, according to Mr. Locke, at once an entire dissolution of the bands of government, and the people are thereby reduced to a state of anarchy, with liberty to constitute to themselves a new legislative power. Locke on Government, book ii. chap. 19. Blackill. Com. vol. i. Introd.

Another excellent writer gives a different account of the origin of civil government from that which has been above stated. Accordingly, he observes, that government, at first, was either patriarchal or military; that of a parent over his family, or of a commander over his fellow-warriors. Paternal authority, and the order of domestic life, says Dr. Paley, (Moral Philosophy, vol. ii.) supplied the foundation of civil government. The condition of human infancy prepares men for society, by combining individuals into small communities, and by placing them from the beginning under direction and control. A family contains the rudiments of an empire. The authority of one over many, and the disposition to govern and to be governed, are in this way incidental to the very nature, and consoled, no doubt, with the existence of the human species. Besides, a parent would retain a considerable part of his authority after his children were grown up, and had formed families of their own. This is the second stage in the progress of dominion. The first was that of a parent over his young children; this that of an ancestor preying over his adult descendants. The association, thus formed, would naturally be continued after the death of the original progenitor; and the members of it, accustomed to the benefits resulting from it, might be induced to supply his place by a formal choice of a successor, or they might voluntarily, and almost imperceptibly, transfer their obedience to one of the family, which had claimed their respect and confidence; or, again, they might receive with due deference a successor, appointed by the first ancestor. Thus we have a tribe or clan, incorporated under one chief, and fulfilling the purposes of civil union, without any other or more regular convention, constitution, or form of government than what has now been described. Two or three of these clans would frequently, by marriage, conquest, mutual defence, common dislike, or some other accidental circumstances, be united into a society of larger extent. Another source of personal authority, which might extend, or supersede, the patriarchal, is that which results from military arrangement. A popular and successful leader, in every action of aggression or defence, would gain a powerful and permanent influence among his followers. This advan-
tage, added to the authority of the patriarchal chief, or favoured by any previous distinction of ancestry, would enable the person who possessed it to acquire the almost absolute direction of the affairs of the community; more especially if he took care to associate to himself principal auxiliaries, and to gratify or remove those who opposed his pretensions.

The causes which have contributed to introduce hereditary dominion, are principally the influence of association, which communicates to the son a portion of the respect that was paid to the virtues or flattery of the father, the mutual jealousy of other competitors, the greater envy with which all behold the exaltation of an equal, than the continuance of an acknowledged superiority, and the number of adherents left by a reigning prince, who prefers their own importance, merely by supporting the succession of his children, and the apprehension of calamities that are incidental to contested elections. The ancient state of society in most countries, says our author, and the modern condition of some uncivilized parts of the world, exhibit that appearance, which this account of the original of civil government would lead us to expect. The earliest histories of Palestine, Greece, Italy, Gaul, and Britain, inform us that those countries were occupied by many small independent nations, resembling those which are now found among the savage inhabitants of North America, and upon the coast of Africa. This theory, it is added, affords a presumption, that the earliest governments were monarchies, because the government of families, and of armies, from which, according to the preceding statement, civil government derived its institution, and probably its form, is universally monarchical.

Our readers will observe that this theory is very different from that of Robert Filmer's patriarchal scheme, now, indeed, almost forgotten and scarcely deserving to be recorded; the refutation of which constitutes the first part of the admirable Treatise on Government. According to this scheme, all government is absolute monarchy, which the author founds on this previous principle, that no man is born free. The absolute sovereignty of Adam was the result of a divine appointment and donation, and this sovereignty has been regularly conveyed by a divine hereditary right to all succeeding monarchs. The notion, that kings reign by a divine right, independently of the designation of the people, and not accountable to them for the exercise of their power, absurd as it will now very generally be thought, was, however, for a long time not only admitted, but prevalent even in this country. It is strongly inculcated in the Homilies of our established church, and was strenuously maintained by several of its respectable divines. Dr. Tillotson, enlightened and excellent as he was in other respects, could not, in the middle part of his life, emancipate himself from the idea, that it was sinful to revolt government, as is evident from his letter to Lord Rufford. That power originates with the people was condemned as an abominable tenet by the famous Oxford decree of 1683; but this is a topic on which it is needless to enlarge.

In the most popular forms of government, says Dr. Paley, the physical strength resides in the governed; and it therefore becomes an inquiry of considerable importance, among politicians, what motives induce the many to submit to the few. In the discussion of this question our author distinguishes the subjects of a state into three different classes, viz. 1. Those who obey from prejudice, or who are determined by an opinion of right in their governors, which opinion is founded upon prescription; this preceptive title, in hereditary monarchies, is corroborated, and its influence considerably augmented, by an accession of religious sentiments, and by that force which Dr. Paley calls the social virtue. 2. Those who obey from respect for the power, in the national sense, of the commune: a power which supports the government, in the present age of society, with an additional strength, is the influence of civil opinion, or the judicious administration of the administration. 3. Those who obey from respect for the integrity of the persons, who are esteemed the agents of the government. This is the principle of a sort of domestic government. The subject-matter of this inquiry is treated at length in the last volume of Paley's Moral and Political Philosophy.
GOVERNMENT.

That which men are apt to ascribe to the perfons of princes. 2. Those who obey from reafon, by a cenferation of the neceffity of some government or other, and of the certain mischief of civil commotions. 3. Those who obey from felf-interest, and who are kept in order by a variety of confequences that immediately affect themfelves.

Concerning the moral obligation of fubmiffion to civil government, thofe who adopt the principles of Mr. Locke, and many other political writers, allege a compact between the citizen and the state, as the ground of the relation between them; and this compact binding the parties, like private contracts, refolves the duty of fubmiffion into the universal obligation of fidelity in the performance of promises. This compact is either, 1. Exprefs, on the part of the primitive founders of the state, who are fuppofed to have met together for the declared purpofe of fetting the terms of their political union, and a future confitution of government. The whole body is fuppofed to have unanimously confefted to be bound by the refolutions of the majority; and that majority is fuppofed to have fixed certain fundamental regulations, and thus to have confifted, either in one perfon, or in an asfembly, a flanding legiflature, to which, under thefe pre-éstablifhed reftrictions, the government of the state was thenceforward committed, and whose laws the feveral members of the convention were, by their firft undertaking, thus perfonally engaged to obey.—This tranfaction is fometimes called the "Social compact," and these fuppofed original regulations compofe what are meant by the "confitution," the "fundamental laws of the confitution;" and form, on one fide, the "inherent indefeafible prerogative of the crown;" and, on the other, the unalienable "birth-right" of the subject: i.e. a tacit or implied compact by all fucceeding members of the state, who, by accepting its protection, confeft to be bound by its laws. "This account of the fubject," fays Dr. Paley, "although fpecious, and patronized by names the moft respectable, appears to labour under the following objections; that it is founded upon a fuppofition fake in fact; and leading to dangerous confquences." No fuch focial compact was ever really made, nor any fuch original convention of the people ever actually held, or could be held in any country, antecedent to the eftablitement of civil government in that country. It is to fuppofe it poifible to call favages out of caves and defarts, to deliberate and vote upon topics, which the experience, and studies, and refinements of civil life, alone fuggrefs; therefore no government in the univerfe began from this original. At a Revolution fome imitation of a focial compact may have taken place. The eftabliment of the United States of North America bears the neareft refeemblance of it. Should it be faid, that the original compact is not propofed as a fact, but as a fiction, for the commodious explication of the mutual rights and duties of Sovereigns and Subjects; to this representa- tion it may be replied, that the original compact, if it be not a fact, is nothing; it can confer no actual authority upon laws or magiftrates, nor afford any foundation to rights, which are fuppofed to be real and exifling. But in the books, and ali in the apprehenfion of thofe who deduce our civil rights and obligations à patria, the original convention is appoited to, and treated of, as a reality.

Moreover, it is alleged, that the theory of government, which affirms the exiflence and the obligation of a focial compact, leads to conclusions unfavourable to the improvement, and to the peace, of human fociety. Upon this theory it may be premifed that many points, called "fundamentals" of the confitution, were fet down by a convention of the people, anterior to the eftabliment of the fuflifing

legifature, and which the legislature has no right to alter, or interfere with. This circumstance affords a dangerous pre- frence for disputing the authority of the laws. Hence arose the doubt, which to much agitated the minds of men in the reign of Charles II., whether an act of parliament could of right alter or limit the fucceflion of the crown. Besides, if it be by virtue of a compact that the subject owes obedience to civil government, he ought to abide by the power of government which he finds eftablifhed, however abfur or inconvenient it may be. Moreover, every violation of the compact on the part of the governor relieves the subject from his allegiance, and difolves the government.

Dr. Paley, rejecting the intervention of a compact, as unfounded in its principle, and dangerous in the application, aligns for the only ground of the fubject's obligation, "the will of God as collected from expediency." Accordingly the author reasons in the following manner. It is the will of God that the happiness of human life be promoted; civil fociety conduces to that end; civil focieties cannot be upheld, unless in each, the interest of the whole fociety be binding upon every part and member of it; and this ftep of the argument conducts us to the conclusion, namely, that as long as there is an interefl of the whole fociety requires it, that is, as long as the eftablitement of government cannot be refilled or changed without public inconvenience, it is the will of God (which will universally determines our duty) that the eftablitement of government be obeyed; and no longer. This princiile being admitted, the juftice of every particular cafe of refiilance is reduced to a computation of the quantity of the danger and grievance on the one fide, and of the probability and expence of redifting it on the other. If it be asked, who shall judge of this? the an- fwer is, "Every man for himself." In contenotions between the Sovereign and the fubject, the parties acknowledge no common arbitrator; and it would be abfurp to refer the decision to thofe whose whole conduct has provoked the question, and whose own interefl, authority, and fate, are immediately concerned in it. From the refolution of "public expediency" into the place of all implied compacts, promises, or conventions whatever, our author infers, 1. That it may be as much a duty at one time to refiil government as to obey it, yea, when more advantage will in our opinion accrue to the community from refiilance, than mischief. 2. That the lawfulnefs of refiilance, or the lawfulnefs of a revolt, does not depend alone upon the grievance which is fuffred or found, but also upon the probable expence and event of the conteft. Hence thofe who concenred the revolution in England were juftifiable in their counfels. 3. That irregularity in the firft foundation of a flat, or fubfequent violence, fraud, or injustice in getting poifition of the fupreme power, are not fufficient reafons for refiilance, after the government is once peaceably fettled. 4. That refiilance is not justified by every infraction of the fubject's rights, or liberty, or of the confitution; by every breach of promife, or of oath; by every fretch of prerogative, abuse of power, or neglect of duty on the part of the chief magiftrate; unless these crimes draw after them public confidences of fufficient magnitude to outweigh the evils of civil disturbance. 5. That no age, law, or authority whatever, is fo binding, that it need not be continued, when it may be changed with advantage to the community. 6. As all civil obligation is refolved into expediency, what, it may be asked, is the dif- ference between the obligation of an Englishman and a Frenchman, or why is a Frenchman bound in confience to bear any thing from his king, which an Englishman would
not be bound to bear, since the obligation of both is founded in the same reason? Although their conditions may differ, their rights should seem to be equal; and yet we are accustomed to speak of the rights as well as the happiness of a free people, compared with what belong to the subjects of absolute monarchies; and how, it may be reasonably inferred, can this comparison be explained, unless we refer to a difference in the compacts by which they are respectively bound? In order to obviate this difficulty, it is allowed that a Frenchman is in confidence bound to endure many things from his prince, to which an Englishman would not be bound to submit for the following reasons; viz., because the same act of the prince is not the same grievance where it is agreeable to the constitution, and where it infringes it; and because redress in the two cases is not equally attainable. The duty of obedience is defined by different boundaries, and the point of justifiable resistance is placed at different parts of the scale of suffering—all which is sufficiently intelligible without a social compact. 7. The interest of the whole society is binding upon every part of it. If we appeal to the Christian scriptures with regard to the duty of civil obedience or the extent of our civil rights and obligations, Christianity hath left us where the found us; she has neither altered, nor ascertained it. The two passages to which writers have generally referred in their investigation of this subject are Romans xiii. 1—7, and 1 Peter ii. 13—18. In order to comprehend the proper import of the instructions contained in these passages, there are two questions relating to the subject of civil obedience, which should be considered, viz., whether to obey government be a moral duty and obligation upon the confidence at all, and how far, and to what cases, that obedience ought to extend? These passages, it may be observed, inculcate the duty; but they do not describe the extent of it. The due consideration of this distinction is sufficient to vindicate these passages of scripture from any explanation of them that shall favour an unlimited passive obedience. But admitting what many commentators have stated, that an opinion was privately cherished by the first Christians, which led them to conceive, that their conversion to Christianity entitled them to new immunities, to an exemption as of rights (however they might give way to necessity) from the authority of the Roman sovereign; we are furnished with a full and satisfactory interpretation of the Apostle's words. The two passages apply with great propriety to the refutation of this error. Little need be added in explanation of particular clauses. St. Paul has said, "wheresoever resisteth the power, resisteth the ordinance of God." This phrase, "the ordinance of God," is by many so interpreted as to authorize the most exalted and supercilious ideas of the regal character. But surely such interpreters have sacrificed truth to adulation. For, in the first place, the expression, as used by St. Paul, is just as applicable to one kind of government, and to one kind of succession, as to another—to the elective magistrates of a pure republic, as to an absolute hereditary monarch. In the next place, it is not affirmed of the supreme magistrate exclusively, that he be the ordinance of God; the title, whatever it imports, belongs to every inferior officer of the state as much as to the highest. The divine right of kings is, like the divine right of popes, in the law of the land, or even actual and quiet possession of their office; a right ratified, we humbly presume, by the divine approbation, so long as obedience to their authority appears to be necessary or conducive to the common welfare. Princes are ordained of God by virtue only of that general decreed, by which he asents, and adds the function of his will, to every law of society, which promotes his own purpose, the communication of human happiness: according to which idea of their origin and constitution, and without any repugnancy to the words of St. Paul, they are by St. Peter denominated the "ordnance of men." Paley, ubi supra. See King, Law, Liberty, Magna Charta, Parliament, Passive obedience, &c.

Government, in Grammar, is understood of that construction of nouns and verbs, wherein they require some alteration to be made in others joined or constructed with them.

Construction is divided into two parts; that of concur, and that of government, called also regimen. See Concord, and Regimen.

GOVERNOI.O, in Geography, a town of Italy, in the department of the Maine; 12 miles S. E. of Mantua.

GOVERNOR, an officer upheld by a king, or sovereign prince, with the command and administration of a province, place, &c.

A governor represents the king; and not only commands the garrison, troops, &c. but the citizens, &c. A governor of a fortified place was anciently required to hold out three attacks, before he surrendered.

Governor is also frequently used for a president or superintendant.

Thus we say, the governor of the bank; the governor and directors of the South Sea company; the governor of an hospital, &c.

GOVER, in Geography, a town of Hindooftan, in the cirec of Rajamundry; 10 miles W. N. W. of Rajamundry.

GOUGE. See GOLF.

GOUFRE, in Geography, a town of Canada, in the river St. Lawrence; 50 miles E. of Quebec.

GOUGAN-BANNA, a lake of Ireland, in the county of Cork, not far from Inishgeele. The river Lee rises in a mountain above this lake, through which it flows. It was formerly the residence of St. Fin-Bar, and is visited by great numbers of pilgrims, whilst its romantic beauties attract a few travellers, notwithstanding the ruggedness of the road.

GOUFRÉ, William, in Biography, who flourished in the former part of the seventeenth century, was born in the parish of Bow, in the year 1575. He was educated partly at St. Paul's school, and partly at Eton, and, in 1595, he was elected to King's college, Cambridge. Here, in due time, he performed with much applause all the exercises required by the statutes, and took his degrees. In 1607, he was admitted into orders, and in the following year obtained the rectory of Blackfriars, London. In this situation he continued during the remainder of his life, discharging the parochial functions with great diligence and fidelity, and setting before his parishioners an example worthy of imitation. The zeal with which he performed the duties of his office, led him to establish a weekly lecture, which was frequented not only by his own people but by many of the London clergy, the members of the Inns of Court, and the more respectable and serious citizens. In 1628, he was admitted to the degree of doctor of divinity, and about the same period he became one of the trustees of the society that had united for the purpose of buying up improprations, to bellow them on such unpatronized clergymen as were distinguished for piety and other ministerial qualifications, which occasioned his being prosecuted in the Star-chamber. In 1651, he was nominated one of the assembly of divines, and was held in such reputation by that body, that he was often called to fill the moderator's chair during
GOU

during his absence. He was selected as a proper person to write notes on the bible, and took, for his share of the work, from the beginning of the first book of Kings to that of Job. He died in the year 1653, soon after he had completed his 75th year. He had, for several years, been esteemed the father of the London miníters. In his departinent, he was modest, humble, and affable; he had a pious and benevolent spirit, and continued to preach as long as he had strength to walk into the pulpit. Besides the "Annotations" already referred to, Dr. Gouge published many other theological pieces, as "A Commentary on the Epistle to the Hebrews;" "An Exposition of the Lord's Prayer;" "The Whole Armour of God, &c.

GOUGE, THOMAS, son of the preceding, was born at Bow, in the year 1605; and, having, in his academical course, followed the steps of his father, he was first chosen fellow of his college, and afterwards preferred with a living at Colfden, near Croydon, in Surrey, where he continued but a short time; and, in 1638, he undertook the more important charge of St. Sepulchre's parish, London. During a period of twenty-four years he discharged the duties of his profession with the most exemplary zeal. Besides preaching twice every Sunday, and often on week days, he visited his flock, catechized their children, enquired into and relieved the wants of the poor, and devised plans for their employment. He is said to have given the hint which produced the humane and benevolent institutions of Mr. Firmin, which have been referred to in the memoir of that excellent citizen. When the act of Uniformity took place, he was too conscientious to sacrifice his principles on the throne of power, and was ejected from his living. His time was now zealously devoted to acts of beneficence and charity. He employed his own fortune, which was considerable, in relieving the wants of his poorer brethren, who, on account of their non-conformity, were deprived of their means of subsistence; and he was a useful agent in the rich, from whom he received large sums, which were applied to that humane purpose. In the year 1671, he set about a plan for introducing knowledge and religion into the different parts of Wales, which at that period were in the most deplorable darkness. He established schools in different towns where the poor were willing that their children should be taught the elements of learning, and he undertook to pay all the expenses which were incurred in the outfit of the buffins. By degrees these schools amounted to between three and four hundred, and they were all annually visited by Mr. Gouge, when he carefully enquired into the progress made by the young people, before whom he occasionally preached in a style adapted to their age and circumstances in life, until he was obliged to desist by prosecutions carried on against him in the ecclesiastical courts. With the affilliance of his friends, whose purses were ever open at his command, he printed eight thousand copies of the Bible in the Welsh language, a thousand of which were distributed freely among those who could not afford to purchase them, and the rest were sent to the cities and chief towns in the principality, to be sold at reasonable rates. He procured likewise the church catechism, and other practical pieces, to be printed in the Welsh language, and distributed among the poor. To these and such like charitable undertakings did Mr. Gouge devote his time, his talents, and his fortune, when precluded by the intolerance of the laws from officiating in the capacity of a preacher. He was accustomed to say with pleasure, that he had two livings, which he would not exchange for two of the greatest in England. These were Wales, where he travelled every year to diffuse the principles of knowledge, piety, and charity; and Chrift's Hospital, where he catechized and instructed the children in the fundamental principles of religion. He died suddenly in 1687, in the seventy-seventh year of his age. His death was regarded as a public loss. A funeral sermon was preached on the occasion by Dr. Tillotson, afterwards archbishop of Canterbury; who, at the conclusion of an animated eulogium on his piety and virtue, observes, that "all things considered, there have not, since the primitive times of Christianity, been many among the sons of men, to whom that glorious character of the son of God might be better applied, than he went about doing good." And Mr. Baxter, in his Narrative of his own Life and Times, says of Mr. Gouge, "I never heard any one person, of whatever rank, fort, or sect foever, speak one word to his dishonour, or name any fault that they charged on his life or doctrine; no, not the pretentioufes themselves, fave only that he conformed not to their impositions; and that he did so much good with fo much industry." This eminent Christian divinity published a few practical pieces, of which the following may be mentioned; "The Principles of Religion Explained:" "A Word to Sinners:" "Christian Directions to walk with God:" "The Sureft and safest Way of Thriving, viz. by Charity to the Poor;" "The Young Man's Guide through the Wildernefs of this World." Gen. Biog. Neil's Hist. of the Puritans.

GOUGE, an instrument used by divers artificers; being a fort of round, hollow chisell; serving to cut holes, channels, grooves, &c. in wood, flone, &c.

GOUGEON, JOHN, in Biography, a French sculptor and architect in the reign of Francis I. and his successors, is reckoned the first who introduced a true taste for sculpture in France, and freed it from the barbarism of former times. He was employed in many of the public works with which Paris began to be decorated in the reign of Francis I. Of these the most considerable is the fountain of the Nymphs, called the Innocents, finished in the year 1550. Among the other remains of his workmanship is a tribune in the hall des Cent-Suiffes, at the Louvre, enriched with sculptures, and supported by four gigantic Caryatides. He was an able medalist, and truck several pieces for Catharine de Medicis, which are fought by the curious. He generally worked in small, and there are no detached figures or groups by his hand. His reliefs are executed with taste, his drapery is light and elegant, his figures graceful and flexible, but their attitudes somewhat forced. He was a Huguenot, and was shot as he was working on a scaffold, on the infamous St. Bartholomew's day, 1570. Gen. Biog.

GOUH'S ISLAND, in Geography, a small island in the Southern Atlantic ocean, discovered by captain Gough in 1715. It is very high land, in S. lat. 40° 15' W. long. 81° 57'. Some doubt being entertained with respect to its true longitude, it was recommended to M. de la Perouze to ascertain its true position, as it lies in the way of ships going directly to India, or China, early in the season, without touching at the Cape.

GOUJET, CLAUDE PEIER, in Biography, was born at Paris in 1597. His father, a tailor by trade, in vain opposed his inclination for a studious life. He was educated among the Jesuits, and, having taken orders, became a canon of the church of St. Jacques l'Hôpital in Paris. He was an associate of several academies in France, and was generally esteemed for his learning, and also on account of the mildness of his temper and the purity of his morals. He died in 1767, and had collected a library of ten thousand well chosen volumes, which was the basis of his numerous works. Of these, the following may be mentioned, "Vies des
des Saints," in two vols. 4to. "Supplement to Morer's Dictionnary," two vol. 8vo. "Bibliothèque des Écrivains Éclectiques," three vol. 8vo. "Différents de l'Université des Études depuis le xiv siècle." "Du L'Etat des Sciences en France depuis la Mort de Charlemagne jusqu'à celle du Roi Robert." This dissertation obtained for the author the prize of the Academy of Belles Lettres, and he was complimented by a deputation from that body, deferring permission to nominate him to the vacant place of the deceased abbé Vertot. Goujet was likewise author of "Bibliothèque François, ou Histoire de la Littérature François," 18 volumes 12mo, which is reckoned his most valuable work. Moreri.

GOJIN, in Geography, a town of Portugal, in the province of Beira; 12 miles S. W. of St. João de Pefquire.

GOJINPOUR, a town of Hindoostan, in Bahar; 26 miles S. of Bahar.—Also, a town of Bengal; 10 miles W. of Nakhingah.

GOULAMCOKDA, a town of Hindoostan, in the Mysore; 9 miles S. of Cooy.

GOULART, Simon, in Biography, a French Protestant divine, was born at Seulim in 1543. He began his studies late in life, but by persevering industry, he made a great proficiency in the learned languages, and was chosen pastor of the church which Calvin had been minister. Here he discharged the duties of his office with much diligence and success, till within a few years of his death, which took place in 1628, when he was about 85 years of age. He edited many works, performing at the same time the business of a commentator. Among these were the "Works of Plutarch;" "St. Cyriac's Works;" "Seneca's Works," &c. He made a collection of "Remarkable Histories" in 2 vols. 4to., and wrote several pieces relating to the history of his own times. The most interesting and curious of the latter description is his "Collection of the most memorable events which occurred during the League, with notes and original documents," in 8 vols. 4to. Many of his pieces were anonymous, but to these he usually prefixed the initials S. G. S. signifying "Simon Goulart Soulluifien." He had such an extensive acquaintance with the literature of his time, and knew so well to whom different publications, that were printed without the writer's name, were to be attributed, that Henry III. of France, being deficient of knowing who was the author of a piece published under the assumed name of Stephanus Junius Brutus, and intended to propagate republican doctrines, sent a perfon to Geneva to enquire into the matter of Goulart, but the latter refused to communicate the fact, for fear of exposing the author to ferior injury. Moreri Bayle.

GOULDSBOROUGH HARBOUR, in Geography, a harbour of the United States of America, in the district of Maine. N. lat. 44° 25'. W. long. 67° 53'.

GOULHERAUTF, a town of Thibet; 28 miles S. of Deoprag.

GOULOUR, a town of Hindoostan, in the circuit of Senare; 18 miles N. of Senare.

GOULSTON, Theodore, in Biography, was the son of William, rector of Wymondham, and was born in Northamptonshire. He became probationer fellow of Merton college, Oxford, in 1569; and, after applying himself to the study of physic in this university, he practised for a time with considerable reputation at Wymondham and its neighbourhood. At length, after taking his doctor's degree in 1576, he removed to London, and became a fellow of the College of Physicians, and afterwards senhor. He resided in the parish of St. Martin's, near Ludgate, and was in great esteem, as well for classical learning and theology, as for the practice of his profession. He died in the year 1612; and by an article in his will testified such regard to the interests of medicine, as entitles him to grateful commemoration. This was a bequest of 200 pounds, to purchase a rent charge for the maintenance of an annual pathological lecture within the College of Physicians, to be read by one of the young doctors of the College. The public has been indebted on several occasions to this institution for ingenious dissertations, delivered as Gulifonian Lectures; as those of Dr. Murgrew; Dr. Fordyce's Treatise on Digestion; &c.

GOUMEL, in Geography, a town of Africa, and capital of the country of the Foulahs, and residence of the Sarkitik. N. lat. 16° 16'. W. long. 11° 32'.

GOUNDA, a town of Hindoostan, in Oude; 32 miles E. N. E. of Manickpaur.

GOUPIL, James, in Biography, a physician of the sixteenth century, was born in the province of Poitou. He acquired a considerable knowledge of the ancient languages, and afterwards directed his studies to medicine, in the schools of Paris, where he graduated in 1547. His talents attracted the attention of the court, and he was appointed by Henry II. to the professorship of medicine in the royal college, in 1555, a vacancy being occasioned by the death of Sylvis. He is principally known as an editor and annotator of the writings of Diocedes, Alexander Trallian, Actarius, and some other Greek writers: and he was engaged in the fame labour, in respect to some of the writings of Hipocrates, when his studies were terminated by death, in 1568.

Eloy.

GOUR, called also Lucknow, in Geography, the ancient capital of Bengal, supposed to be the "Ganga Regia" of Ptolemy, which stood on the left bank of the Ganges, about 25 miles below Rajenmul. N. lat. 24° 53'. E. long. 88° 14'. It was the capital of Bengal 750 years B. C. and was repaired and beautified by Achbar, A. D. 1575, who gave it the name of "Jennuteabad," which same part of the circus in which it was situated still bears. It was deserted, as it is said, on account of the unhealthiness of its air. Taking the extent of the ruins of Gour at the most reasonable calculation, it is not less than 15 miles in length, along the old bank of the Ganges, and from two to three in breadth. Several villages stand on part of its site; the remainder is either covered with thick forests, the habitations of tygers and other beasts of prey, or become arable land, whose foil is chiefly composed of brick-dust. The principal ruins are a mosque lined with black marble, elaborately wrought; and two gates of the citadel, which are grand and lofty. The bricks, which continue to be an article of merchandise, are of a peculiarly folid and durable texture.

GOURA, or GURA, a town of the duchy of Wallack on the Verna; 12 miles from Warfaw.

GOURA, a town of Perifin, in the province of Irak; 35 miles E. of Izphahan.

GOURAY, a cape on the E. coast of the island of Jersey; 4 miles E. of St. Helen.—Also, a town of France,
GOUD, in Bata. See CECCUBITA.

GOURD, Biter. See COLCUS.

Gourd, Indian tree. See CRESCENTIA.

Gourd, Smur. See BAOAR.

Gourd, zoom. The English name of a species of worm found in the intestines of several animals. It has this name from its resembling the seed of the gourd in figure.

GOURDON, in Geography, a town of France, in the department of the Lot, and principal place of a district, 16 miles N. of Cahors. N. lat. 46° 44'. E. long. 1° 28'. The place contains 1703, and the canton 12,115 inhabitants, on a territory of 1725 kilometres, in 15 communes.

GOURDY, Legs of Horse. See GREASE.

GOURKEY, in Geography, a town of Hindoostan, in Oude; 10 miles N. W. of Lucknow.

GOURGONG, a town of Hindoostan, in Allahabad; 10 miles N. of Corah.

GOURGON'TY, a town of Hindoostan, in Golconda; 36 miles W. S. W. of Rachore.

GOURK, a town of France, in the department of the Morbihan, and chief place of a canton, in the district of Pontivy, 12 miles N. W. of Pontivy. The place contains 374, and the canton 11,819 inhabitants, on a territory of 2424 kilometres, in five communes.

GOURMA, a town of Abyssinia, on the coast of the Red Sea. N. lat. 14° 52'.

GOURMUNGUL, a town of Hindoostan, in Golconda; 12 miles S.W. of Mallar.

GOURMELEN, Etienne, in Biography, was a native of Brittany, and was sent at an early age to Paris, where he studied surgery, and afterwards medicine; in the latter of which he took the degree of doctor in the year 1559, and was elected dean of the faculty in November, 1574. Surgery, however, continued to be the favourite object of his attention, and he was appointed by Henry III. professor of surgery in the Royal College in the year 1588. But he did not long fill his chair, for he died in 1594. His writings, which were valuable in their day, have now left their interest, in consequence of the great improvements of modern surgery; they consist of a Synopsis Chirurgica, printed in 1566, and afterwards translated into French; a Latin translation of Hippocrates De Alimentis, with a commentary; and a treatise, entitled Chirurgia Artis ex Hippocratis et Veterum decretis ad rationem norman reddita, Libri tres, 1580. Elyot, Dict. Hist.

GOURNAY, Le Jars de, Mary, was born at Paris in 1506. She was, while very young, deprived of her father, and acquired an adoptive one in the celebrated Michel Montagne, who became the object of her enthusiastic admiration. After the death of Montagne she became heiress of his writings, and published an edition of his Effays, dedicated to Cardinal Richelieu. She had well improved the leons of youth, and was intimately acquainted with the learned languages. She maintained a correspondence with many of the most eminent literary characters of the age, by some of whom she was honoured with the title of "Tenth Muse," by others she was denominated the "French Siren;" it is not, however, improbable, that the uncommonness of female learning at that time in France, rather than the intrinsic merit of her writings, excited admiration. In her own language she wrote a style and awkward style, and her taste in reading was usually turned to the compilations and commentaries of past ages. She passed her life in celibacy, contented with a small pension from the court, and much esteemed by her particular friends, some of whom were persons of high rank. She died at Paris in 1615, in her 57th year, and was honoured with many epistles from literary characters. Her works were collected in a quarto volume, under the title of "Les Avis ou les prelins de la Demoiselle de Gournay." Her temper was apt to be violent, and she was very retentive of real or supposed injuries; by these means she made herself many enemies, who attacked her in their writings, in which neither her person, nor the defects in her character were spared. Bayle. Moreiri.

GOURNAY, in Geography, a town of France, in the department of the Lower Seine, and chief place of a canton in the district of Nenfis-l-tel, 24 miles E. of Rouen. N. lat. 49° 29'. E. long. 1° 47'. The place contains 3543, and the canton 11,301 inhabitants, on a territory of 183 kilometres, in 19 communes.

GOURNEI, a town of Egypt, on the site of the ancient Thbes.

GOURPE, See GREENOCK.

GOURRI, a town of Abyssinia; 35 miles S.W. of Affaf.

GOURVILLE, John Herould de, in Biography, born at Rochefoucauld in 1615, was taken by the celebrated duke of that title into his service as valet de chambre, but in a short time he became his confidential friend. He was patronized by the great Condé, and was employed by the supernardent Fouquet, in public business. So well did he approve himself to his employers for political talents and integrity that he was proposed to the king as successor to Colbert in the ministery. He died in 1705, leaving behind him Memoirs of his Life from 1642 to 1668, in two volumes 12mo. These memoirs are written with frankness and simplicity, in a lively, though incorrect style, and they contain many curious and well-authenticated anecdotes of the ministers and principal persons of his time, of which, it is said, Voltaire made much use. Moreiri.

GOURY PASHEM, in Natural History, a name given by the people of the East Indies to a kind of orpiment of a deep yellow colour, veined with red in several places, and in some with white. It is found principally at the bottoms of mountains. They calcine it several times, and afterwards give it internally after intermitting fevers, and use it externally in ointments for the itch.

GOUSSET, James, in Biography, was born at Blois in the year 1635. He was educated for the ministeriy, and was chosen pastor of the Protestant church at Poitiers in the year 1662. He was thrice invited to undertake the professorship of divinity at Saumur, but refused to quit his flock till compelled to become a fugitive from the kingdom, in consequence of the revocation of the edict of Nantes. On this occasion he took refuge in Holland, and afterwards was setted, as French minister, at Groningen, where he likewise exercised the offices of professor of divinity, and of the Hebrew language in the university of that city. He died there in 1704, in his sixty-ninth year. His principal works were Differtations in Controversy with the Jews, 1699. Commentarius Linguar Hebrew, 1702, which form a valuable Hebrew dictionary, of which the bell edition was published at Leipsic in 1743. Differtations in Epitola Pauli ad Hebræos, &c. 1712. At his death he left behind him numerous MSS., among which are commentaries upon the whole of the sacred scriptures. Moreiri.

GOU'T, Gour, a French term, for what the Italians call giogo, and we tayle.

GOUT, in Medicine, a disease principally characterized by inflammatory attacks of the joints, more especially of the
foot, which return at intervals, and are connected with derangement of the digestive organs. The term, however, includes such a variety of morbid affections, in its extended sense, that it is not easy to give a concise definition of it; and we must have recourse to a more ample description of those affections, in order to convey a just notion of its signification.

The ancient physicians included all the varieties of inflammation, that are liable to occur in the joints, under the general term, *Aristitis* (from αίρητος, a joint, with the termination ἕται, denoting inflammation,) for the distinctions, made by modern physicians, between the two modifications of inflammation in the joints, now denominated gout and rheumatism, had not then been attended to. The term *Aristitis*, however, was used both as a generic and specific term, and signified, not only inflammation of the joints generally, but the ordinary form of gout by way of excellence. But the Greeks also gave specific names to the varieties of arthritis, according to the particular joints which the disease occupied: thus, for the ordinary form of gout in the foot the term ποσεγγα, podagra, was employed, which also became a generic title; for gout in the hand, the word γυνιγγα, chiragra; and for gout in the knee, γυνιγγα, gonagra; and so on. Among the species of arthritis was also included the *ijchia, staictica, or hip-gout*, which is now deemed a species of rheumatism. These terms the Romans adopted; and they are still retained in medical language. Our vernacular term *gout*, which came to us probably through the French, *la goutte*, originated in the dark ages among the humoral physicians, who considered the disease as arising from the flow of a morbid humour, *guttain*, as it were, upon the joints; hence, the name *gutta*, or *drop*, was applied to the disease. This term, according to Du Cange, was used by Sallustius, a Dominican of the 13th century, who writes, "cum *gutta*, quam podagram vel arthriticam vacant, frequentem vexaretur." Milagroire de Arthritide.

In consequence of the various forms which gout assumes, physicians have divided it under two heads, *regular* and *irregular* gout, or, as some have termed it, *tonic* and *atonic* gout; the former occurring in the earlier periods of life, while the strength or tone of the system remains unbroken; the latter, after a certain degree of weakness, or atony of the constitution, has been produced by the frequent attacks of the disease, advanced age, or other causes. We shall first describe the symptoms by which these forms of the disease are characterized, and afterwards state the canons and method of treatment, together with the speculations of pathologists, respecting the nature of the disease, beginning with an account of the paroxysm of gout.

*Regular Gout.*—It is an inflammatory affection of the joints of the foot, which constitutes what is called a fit or paroxysm of the regular gout. This sometimes comes on suddenly, without any warning of its approach; but it is generally preceded by several symptoms, especially by those of indigestion, as heart-burn, flatulence, and heaviness after meals, with eructations of acid or bitter matters, and some degree of languor and torpor of the body; but immediately before the fit the appetite is sometimes unusually sharp. There is also often an unusual coldness of the feet and legs for a few days preceding the fit, with the cessation of the perspiration about the former; a frequent numbness, alternating with a sense of pricking, along the whole of the lower extremities; occasional cramps of the muscles of the legs; and an unusual turgescence of the veins, are occasionally observed.

The attack is sometimes felt in the evening, but more commonly about two or three o'clock in the morning; when the patient is awakened from a quiet sleep by a pain affecting one foot, generally the ball or first joint of the great toe, but sometimes the other parts of the foot, or the ankle. This pain is accompanied with more or less of chilliness and shivering, which, as the pain increases, gradually ceases, and are succeeded by a hot race of pyrexia, or symptomatic fever, which continues during the same time as the pain. The pain becomes by degrees more and more violent; at first it is attended with a sensation, as if warm water were poured upon the membranes affected, and is said to resemble the pain of a dislocated joint; as it becomes severe it is sometimes described as resembling the pain of a tenion, or laceration of the ligaments, sometimes as like that from the grazing of a dog, and sometimes as a feeling of weight and conflagration of the membranes of the part, which becomes so exquisitely tender, as not to endure the weight of the bed-clothes, nor even the shaking of the room from a person walking briskly in it. Hence, great restlessness of the whole body, and especially of the part affected, always accompanies the fit; the patient confiantly changing his posture, with a view to ease the pain, which, nevertheless, continues severe all the following day, until mid-night, after which it gradually remits; and about two or three in the morning, that is, after twenty-four hours from the first attack, it commonly ceases almost entirely; and this freedom, with the breaking out of a free perspiration, allows the patient to fall asleep. On waking, he finds the pain slight, and the part affected with some redness and swelling.

When a paroxysm has thus come on, although the violent pain, after the period of twenty-four hours, be considerably diminished, yet the patient is not entirely without pain. For some days he has a return every evening of pain and fever, which continue, with more or less violence, till morning. After continuing in this manner for several days, the disease sometimes goes off entirely, not to return till after a long interval; and in such cases it generally leaves the person in very perfect health, enjoying greater ease and alacrity in the functions both of body and mind, than he had for a long time before experienced.

It often happens, however, that the disease does not thus speedily quit the patient, especially when he has previously suffered considerably from its attacks. For, instead of ceasing altogether after a few days, it seizes the other foot in the same manner as it did the former, both in respect to the vehemence and duration of the pain. Most commonly the foot first affected becomes quite easy, in such a cafe, and even as strong and healthy as if it had not been diseased; but sometimes both feet are affected together, and with equal violence. When this happens, the succeeding exacerbations, as Sydenham remarks, are less regular both, as to the time of coming on, and as to their continuance; but the pain always increases in the evening and remits in the morning; and what is called a fit of the gout, which goes off sooner or later, according to the age and constitution of the patient, is made up of a number of these little fits. For when this disease lasts two or three months, it is not to be esteemed one continued fit, but rather a series of small fits, the last of which proves milder and shorter, until the whole is terminated. In strong constitutions, and such as have the gout feilum, the attack is commonly finished in fourteen days; but in those of advanced life, or who have frequent returns of the disease, these series of fits will continue for two months; and in such persons as are more debilitated, either by age or the long continuance of the disorder, it will not...
G O U T.

go off till the summer advances, (beginning, as is most common, in January, or early in February,) which seems to drive it away.

When the fit is going off, a violent itching seizes the foot, especially between the toes, and the cuticle peels off. The appetite and strength return sooner or later, according to the greater or less severity of the preceding fit, and the interval of health between the paroxysms is generally nearly in the same ratio; i.e. longer in proportion to the greater violence of the last fit. At the beginning of the disease, Dr. Cullen observes, the returns of it are sometimes only once in three or four years; but after some time the intervals become shorter, and the attacks become annual: afterwards they come twice each year, and at length recur several times during the whole course of autumn, winter, and spring; and as it happens that, when the fits are frequent, the paroxysms become also longer, so, in the advanced state of the disease, the patient is hardly ever tolerably free from it, except, perhaps, for two or three months in summer.

Before the disease becomes thus inveterate, however, it has gradually assumed other appearances, and attacked other parts of the body. At first it commonly affects one foot only; but afterwards every paroxysm affects both feet, the one after the other, and then both together; and its changes of place, as it continues to recur, are not only from one foot to the other, but also from the feet into other joints, as the hands, wrists, elbows, knees, &c.; so that there is scarcely a joint in the body that is not, on one or other occasion, affected. It sometimes feizes on two different joints at the same time; but more commonly it is severe in a single joint only, and pallies successively from one joint to another; so that the patient's affliction is often protracted for a long time. The pains, indeed, are commonly less violent, in this state of the disease, than they were at first; but, in addition to them, loss of appetite, sickness, and other symptoms of the atomic gout, now afflicts him. Besides, in the intervals between the first paroxysms of the disorder, the joints which had been affected were entirely restored to their former suppleness and strength, and were free from pain or uneasiness, and all the functions of life were well performed. But in this protracted condition of the disease, the joints remain not only weak and flabby, after the termination of the fit, but they become at length so contracted and disabled, that although the patient can stand, and perhaps walk a little, yet it is very slowly, and with great lameness and difficulty, so that he is scarcely able to move from room to room; and sometimes the joints lose their motion altogether.

In many persons, though not in all, when the disease has frequently recurred, this immobility of the joints is farther increased by the formation of concretions, of a chalky appearance, upon the outside of them, and for the most part immediately under the skin. The formation or deposition of this matter is characteristic of the disease, being the consequence of gouty inflammation alone. It seems to be deposited at first in a fluid form, but afterwards becomes dry and firm; in which state the concretions have the appearance of a friable earthy sub stance, and have been called chalk-stones (which see). From the investigations of Dr. Wallon, however, and other modern chemists, it has been ascertained that they contain no calcareous or earthy matter, but consist of a neutral salt, formed by the combination of the lithic or uric acid, with the fixed alkali, soda,—constituting a nitrate or urate of soda. These concretions form principally about the joints of the toes and fingers, in little nodules, which Sydenham compares to crab's eyes; but sometimes they appear about the larger joints, as the elbow and knee, occasioning a whirling swelling almost as large as an egg, which becomes gradually incised and red. Mr. Watton has related an example of a very extensive deposition of urate of soda, in a gouty man, who was a martyr to the disease. Chalk-stones not only enveloped the joints of his great toes, formed tumours upon his legs, and, being mixed with the synovia of the large joints, rendered this fluid as thick as cream; but "the joints of the fingers were swelled and knotty, every knot being a lump of chalk; and I was told," he adds, "that when he played at cards, he needed frequently to score up the game with his knuckles." (See Medical Communications, vol. i. art. 3.—See also Parkinson's Obs. on the Nature and Cure of Gout, p. 5.)

Such is the progress of gout, as it affects the joints, and while it may, therefore, be called regular gout. Sydenham, indeed, and some other writers, confine the appellation of regular to gout in the feet only; and consider it as irregular, when it attacks the hands or other joints. But Dr. Cullen, Warner, and the physicians of the present day, in general, agree in calling the disease, when it affects only one inflammatory affection of the joints, the regular gout; "as," says Dr. Cullen observed, "whatever symptoms we can perceive to be connected with, or to depend upon, the disposition which produces that inflammatory affection, but without its taking place, or being present at the same time, we name the irregular gout." First Lines, § 518.

Irregular gout, anomalous, internal or atomic gout, as it has been also called, consists of various symptoms of disorder in the internal organs of the body, which do not differ from the symptoms affecting the same organs under other circumstances; it is, therefore, suspected that these symptoms are of gouty origin, when they occur in persons bearing the marks of a gouty diathesis or disposition: and especially when, in such habits, either a manifold tendency to the inflammatory affection of the joints has formerly appeared, or when the symptoms alluded to are intermixed with, and are relieved by, some degree of the inflammatory affection. The morbid symptoms which appear, in such cases, and are considered as signs of atomic gout, are principally affections of the stomach; such as loss of appetite, indigestion, and its various concomitants of sickness, nausea, vomiting, flatulence, acid eructations, and pains in the region of the stomach. These symptoms are frequently accompanied with pains and cramps in the upper extremities of the body, which are relieved by the discharge of wind from the stomach. Together with these affections of the stomach, colic pains also commonly occur; but sometimes a hoarseness with colic pains. These affections of the alimentary canal are often attended with all the symptoms of hypochondriasis; as desolation of mind, a confendant and anxious attention to the slightest feelings, an imaginary aggravation of these, and an apprehension of danger from them. In the same atomic gout, the viscera of the thorax are also sometimes affected, and palpitations, faintness, and ahuma occur. And the head also is often disordered, with pains, giddiness, somnolence, and even apoplectic and paralytic affections. (Cullen. See also Mulgrave "De Arthritis Atonam," where these various modifications of irregular gout are described at length; and Warner’s "Full and Plain Account of the Gout," where his observations are translated, pp. 70—90, second edit.)

We may here remark, in passing, that many errors have probably been committed, in considering almost every species of indisposition, that occurs in gouty habits, as arising...
GOUT.

from the gouty diathesis. We remember to have heard this point fireaneously insisted upon by the able professor of ph ysics, in the university of Edinburgh, Dr. Gregory. Many of the symptoms above enumerated are obviously connected with the impaired functions of the stomach, and occur in dyspepsia, or indigestion, in habits not gouty; such are the various hystchondriac faliactions; the palpitations of the heart, often arising from over-distention of the stomach with flatus, by which the heart is mechanically pressed upwards: the cramps in different parts of the body, which are often relieved by a discharge of wind from the stomach; the difficulty of breathing, often occasioned by great distension of the stomach, which impedes the descent of the diaphragm; and the head-ache, giddiness, &c., which are daily observed to be connected with impaired digestion. On the other hand, inflammatory disorders of the lungs and other viscera, congections in the head, inducing headache, faintness, vertigo, &c., and ultimately various degrees of paralytic and apoplectic disease, not essentially different, in any respect, from the same affections in habits not tainted with gout, have probably been suffered to go on, and to prove fatal, under a notion that they were gouty, and the proper remedies have been therefore neglected.

The irregular gout occurs in a less equivocal form, when the inflammatory state of the joints has come on in the usual manner, but when, without arising to the ordinary degree, or at least without continuing for the usual time, and receding gradually, as is common, the pain and inflammation suddenly and entirely cease, while some internal part becomes disordered. This has been called the retrocedent or refelled gout. When the gout is thus retrocedent, the same internal parts are attacked, and the same disorders produced, as in the irregular or atomic gout, where no previous imperfect attack upon the joints had been itself. The stomach is for the most part commonly affected, whence violent pain, ficknefs, vomiting, anxiety, &c.; the heart and lungs are also occasionally attacked; and sometimes the occurrence of apoplexy, palsy, or delirium, mark the head as the seat of the retrocedent disease.

Another variety of irregular gout has been denominated misplaced gout: namely, when, instead of the joints of the extremities, the stomach, brain, lungs, intestines, kidneys, or bladder, become affected with symptoms of inflammation, which give way upon the appearance of the inflammation in the extremities, when that takes place. This inflammation of the internal organs, however, is indicated by the same symptoms which accompany inflammation of the same parts, arising under other circumstances, and in constitutions not gouty: and it has probably been sometimes supposed to be of gouty origin, when it arose from the ordinary cause. Dr. Cullen affirms, that he never met with any instances of misplaced gout in his practice, and that no case has been distinctly made out by medical writers, except that of pulmonary inflammation. But he had known two varieties of internal disease alternate with external gouty inflammation: viz. the one an affection of the neck of the bladder, producing pain, strangury, and catarrh with eflac; the other an affection of the rectum, sometimes marked by pain alone in that part, and sometimes by hemorrhoidal swellings.

Such are the phenomena, by which the various forms of regular and irregular gout are chiefly characterized. The next object of our inquiry will be the

Causes of Gout.—Among the prevailing causes of gout, an original peculiarity of constitution, often transmitted from the parent to the offspring, appears to be the most common. In other words, the disease is said to be hereditary. This position, indeed, has been controverted, especially by Dr. Cadogan (see his Diff. on the Gout, and all Chronic Dis- eases, p. 7.) but the discussion has turned upon a mere dispute about words. For it is admitted, on all hands, that the predisposition of the constitution to be affected by gout is transmitted from father to son, like other peculiarities of habit; like the family-likeness, for instance, in features, in voice, complexion, &c. It is true, indeed, as Dr. Cadogan contends, that some persons acquire this gouty disposition, who have it not by hereditary transmission; and, on the other hand, that the hereditary predisposition may be constituted by various causes, but particularly by certain modes of life, so that the disease itself shall never appear. Yet it is equally true, that the same occasional causes, which will excite the disease in those who are hereditarily predisposed to it, will not produce it in others, although applied in greater force; and, therefore, the existence of an original constitutional predisposition must necessarily be inferred. The middle and advanced periods of life are also more disposed to gout, than the early periods: thus it does not commonly attack men until after the age of thirty-five, and generally not till a little later period. When the gout does appear, in more early life, of which there are instances, it seems to be in those in whom the hereditary disposition is very strong, and to whom the exciting causes have been applied in a considerable degree. Hippocrates remarks, that cunachs are not liable to be affected by gout, nor boys previous to venery: but the temptation included in the remark is probably unfounded; since, with respect to the latter, the disease, as we have already stated, is almost peculiar to an advanced period of life, and the cunachs, who, in the time of Hippocrates, were chiefly Persian slaves, were doubtless confined to the strict discipline and the frugal and temperate life, which the rigorous laws enjoined to all, and therefore not exposed to the most active causes of gout. For Galen, in his commentary upon this observation of Hippocrates, observes that, in his time, the remark was no longer true, "owing to too much indulgence on their part in an indolent, as well as intemperate mode of life," and the remark is confirmed by modern experience. (Van Swieten, loc. cit.)

It has been fully ascertained, indeed, that the principal source of the gouty habit consists of high feeding and indulgence conjoined. Sydenham (who, upon the subject of gout, stands unrivalled in accuracy of observation, and the model of all succeeding writers, many of whom have done little more than copy his history of it) begins his account of the disease with these remarks. "The gout generally attacks those elderly persons who have formed the greater part of their lives in ease and indulgence, both in the use of high feeding and of wine, or other spirits and fermented liquors; and who, in conformance of the flagellants of advanced life, have ceased from all those exercises to which they were accustomed in their youth. The gout, however," he adds, "does not always wait till an advanced age; it sometimes attacks those who are in the prime of life. But these persons have unfortunately received the seeds of the disease from their parents; or, if not, they have indulged in premature and excessive venery, or left off entirely those exercises which they had previously used with great activity, and have been belied most indulgent to the appetite, and drank to excesses of wines and spirituous liquors, afterwards suddenly turning to those that are cold and cold." (Sydenham, Tractatus de Pedegrn.) These facts have been long known. There is a Greek etymology Etcdly signifying "Bacchus and Venus'" or "Bacchus and Venus' charming Egyptian" Yoshis is born a daughter, the limb-relieving Gout." And a similar observation is contained in the adapte, "Bacchus pater, Venus mater, et Ira oblitentica Athletus." While this fact is confirmed,
confirmed, on the one hand, by the testimony of ages in the affirmative, it is corroborated also, on the other hand, by observation in the negative. Dr. Cullen remarks that gout seldom attacks those who are engaged in bodily labour, or who live much upon vegetable aliment, or those who make no use of wine or other fermented liquors. Indeed, the gout is said to be altogether unknown where these liquors are not used, as among the common people of Turkey. Among the lower orders of people, even in this country, the disease is very rare, and still more rare in Scotland and Ireland, where animal food and strong ale and beer are less used. Van Swieten observes, that some people who, from comfortable circumstances, have been reduced to labour for their subsistence, and to exchange a luxurious table and indulgence for a frugal diet and activity, have lost their gout. He mentions particularly the instance of a certain priest, who enjoyed a rich living, and had been an old and constant sufferer from the gout; but happening to be taken by the pirates of Barbary, he was kept constantly at work in the galleys for the space of two years: "which had this good effect, that afterwards, when he was ransomed from captivity, leaving off all his trouble-some and monitory fatness, he never once had a fit, though he lived several years after the event." (Van Swieten, Comment. ad Aph. 1255.) Several anecdotes of a similar nature are related by the indubious Schenckius. (Obs. Med. Rurico. Bb. v. p. 657. edit. 1644.) In a word, much exercise, which will often counteract the influence of intemperance, will, when combined with temperance, counteract even the hereditary disposition to the disease.

The effect of full living and indulgence, in producing the gouty diathesis, is also manifested from the form and temperament of the persons in whom it occurs. These are especially men of robust and large bodies with large heads, and of full and corpulent habit. They have commonly also a crosser skin; and if, with the ancient, we might denote the tempers of men by certain terms, we should say that the gout especially afflicts men of a chal nic-fangarine temperament, and seldom attacks the purely fanguine or melancholic.

Women are not very liable to the gout, probably from their less temperate mode of life, in general, than that of men: but those females whom it attacks are generally of robust and full habits. It is said not to occur in them commonly till after the cessation of menstruation; which perhaps only implies that it is a disease of advanced life. For as Dr. Cullen justly remarks, "it often happens to such the robust body..." before the menstrual evacuation has ceased," and he had "found it occurring in several females, whose menstrual evacuations were more abundant than usual." (Fifth Lincs, § 494.) A fact, which we may explain, with Dr. Gregory, by observing, that those women who indulge much in vinous and fermented liquors, are more liable to menstruation than others.

It is obvious, then, that the experience of all ages concurs in affirming intemperance and indulgence as the principal causes of that habit of body, in which the gout is liable to occur. This habit, or predisposition, seems to be sufficient, in many cases, to produce the disease itself, or at least to require the application of slight and imperceptible exciting causes to bring it forth. The disease, indeed, depends to much upon predisposition, that it is difficult to assign the occasional causes; the same agents appear to be sometimes the generators of a predisposition to it only, and at other times actually to excite the disease.

The exciting causes, which often suddenly bring on a fit of the gout, in those who are predisposed to it, are, in the first place, those circumstances which induce a sudden debility, especially of the stomach. The concurrence of indigestion, and the local inflammation in gout, is one of the characteristics of the disease; and, as we have already stated, the latter is usually preceded for some time by the former. Hence whatever suddenly depresses the digestive power, is liable to induce the local and constitutional disease. Thus a paroxysm of gout has frequently been excited by an occasional excess in the use of wine or spirits; by overloading the stomach with food, or by eating such as is not easily digestible in its nature; by the copious use of vegetable acids or aseptic matter, especially by weak aseptic wines, punch, &c., all of which tend to debilitate the digestive organs either directly or indirectly. In the same way, excess of venery, which powerfully influences the stomach, (Van Swieten, Aph. § 86, and 1255.) has often brought on a fit. This seems to have been universally understood by the ancients. We have already noticed the observation of Hippocrates; and Aëtion, in recounting the general causes of gout, says, there are, "abounding eructations, frequent drunkenness, and, above all, an immediate use of venery." (Sermon xii. Cap. 6.) Sydenham and Van Swieten add their testimony to the fact. Intense study, night-watching, excessive anxiety and attention to business, all of which greatly depress the power of the body in general, and of the stomach in particular, destroying the appetite, and producing a sene of uneasiness, fasting, or weight about the region of the stomach, are likewise enumerated among the occasional causes of the gouty paroxysm. The same is true with respect to the violent motions and passions of the mind, more particularly of anger. "In obstruxar arcaestis" is part of the adage above quoted: and the three causes of gout, inflected on by Dr. Cadogan, are intemperance, indulgence, and overeat. The influence of violent mental emotions on the functions of the body is, indeed, very manifest, and more especially on the function of digestion; the disturbance of which, we have already observed, is exceedingly instrumental in the production of gout. "The first immediate effect of violent grief or vexation," says Dr Cadogan, "is to take off the action of the stomach entirely. Let us suppose a man in the best health, the highest good humour and spirits, as well as good stomach, sitting down to dinner with his friends, receives suddenly some very affecting news. Instinctly his appetite is gone, and he can neither eat nor swallow a morsel. Let the same thing happen after he has made a hearty cheerful meal, as suddenly the action of his stomach, the whole power of digestion is cut off totally, as if it were become paralytic, and what he has eaten lies a most oppressive load. Perhaps as the excess of weakness is often conviction, it may be rejected by a violent vomit, or do greater mischief: for which reason such brokes of diatheses are les hurtful received upon an empty than a full stomach." &c. (Loc. cit. p. 55.) The gouty habit, indeed, is often an irritable habit; and Sydenham observes, that a fit of gout may be called a fit of anger. (See also Van Swieten, § 1258.)

Among other exciting causes of gout, the sudden ceasing from the customary exercises and Labour is commonly mentioned, and its principal effect is probably upon the function of digestion, which is much under the influence of exercise. Indolence, in general, as contributing to induce the gouty disposition, is well understood; and the sudden cessation of activity, like all others sudden changes, is apt to produce a sudden accession of the paroxysm, in those who are predisposed to the disease. In a similar manner, a sudden change in the mode of living, the opposite to exercise, namely, from high feeding to a very spare and abstemious diet, is liable to induce the paroxysm of gout. That such a sudden abstraction of the powerful stimulus of a copious supply of food and strong liquors, must necessarily induce a considerable

3 T 2
direct debility in the organs of digestion, is well understood by those who are acquainted with the laws of stimulants on the animal body. (See Debility and Excitability.) This fact, however, although sometimes deduced as an argument against the advantages of an abstinence regimen, in preventing the gout, affords no such legitimate inference. It is too obvious, indeed, to require an elaborate discussion, that all extremes, hastily adopted, are liable to derange the animal economy; and that habit alone can render extreme moderation invariably beneficial, on the one hand, and enable us to bear excess with a considerable degree of impunity on the other. Another mode of debilitating the fluid, which sometimes brings the paroxysm of gout, is excessive evacuation of any kind; such as by hemorrhage, brisk purging, vomiting, &c.; especially in aged persons, whose constitutions are already much broken down by the disease.

Sudden vicissitudes of weather, especially when connected with moisture, as from mild to cold, or from severe cold to damp and mild weather, often excite the gout; hence, Sydenham remarked, that the most frequent occurrence of the gouty paroxysm takes place in the latter end of January, and in the beginning of February. The fit may be produced either by the local application of cold and moisture to the feet, or by a general exposure to it; for such exposure, which in most people will occasion rheumatism, a catarrh, or a sore throat, will, in a gouty subject, excite a fit of the gout. In like manner, bruises or sprains of the leg or foot, or mere over-exercise of the muscles and ligaments of those parts, as in long walking, will sometimes bring on a paroxysm.

There is another alleged cause of the gout, which it would not now be necessary to mention, were it not noticed by Boerhaave, Van Swieten, and others, viz. contagion. Van Swieten considers the disease as analogous to dysestheny and other maladies, which, although originating from very obvious causes, nevertheless propagate themselves afterwards by contagion. But the stories, by which this doctrine is supported, are somewhat ridiculous: such as this, that a dog living at his master's feet during a paroxysm of the gout, suddenly ran bowling and barking round the room, Expressing the pain which he had caught from his master, whose torture at the same time became greatly alleviated, &c. (Swieten Com. ad § 155.)

Of the Diagnoses.—The attack of the regular gout is readily distinguishable from the only disease which resembles it, viz. acute rheumatism, if all the symptoms are taken into consideration. In the first place, gout is commonly a disease of advanced life; acute rheumatism is most frequent from the age of 18 to 30. Nor does rheumatism, like the gout, feize the feet in preference to the other joints, or remain for a considerable time in the same joint; but at the first attack it often attacks every joint of the body in succession, and sometimes continues for several months. The colour of the skin of the part affected in rheumatism, if it be changed, is only slightly red, whereas it becomes of a deep bright red in the gout. The pain in the rheumatism is not extremely acute, while the part is at rest, but becomes violent when it is moved only; which is not the case in the gout. And the symptoms of indigestion and disordered stomach, which precede the paroxysm of the gout, together with the marks of distention just mentioned, will serve particularly to determine the nature of the paroxysm. It must be admitted, however, there are instances of the combination of the symptoms of the two diseases, which renders it difficult to decide to which of them the individual examples belong. (Hecbergen, Comment. de Morb. p. 58.) Again, the symptoms which the irregular gout presents, are extremely numerous and proteiform, appearing frequently as dyspepsia, hydria, hypochondriasis, asthma, palpitation, syncope, vertigo, apoplexy, paralysis, &c. according to the original or acquired tendency of the constitution to those diseases. Hence the differentiation between these modifications of gout, and the disease which it mimics, is occasionally very difficult.

Of the nature or proximate cause of Gout.—This is a part of the subject upon which, if we were to confine ourselves to the communication of actual and useful knowledge, we should be altogether silent, or say but a few words. The observation, indeed, will apply to many other diseases, as well as to gout; but as gout is an affection almost exclusively occurring in the higher classes of society, among the wealthy and intelligent, it has claimed a more general attention, and become the object of more general discussion. It is greatly to be lamented, however, that the most mistaken notions have prevailed, from the earliest times, in regard to the nature and extent of the infirmity, which we are capable of obtaining, into the operations of the animal economy; and to the means by which we can obtain it. Indeed opinions as to the cause of the phenomena of health and disease, faithfully recording these phenomena, and arranging them according to their most obvious analogies, physicians have been busy in searching after their hidden causes; and, fancying a resemblance between the most dissimilar things, have succedingly called to aid the analogies of every human science, as it advanced in cultivation, to explain the phenomena of animal life. The ancient doctrines of numbers and elements, and their qualities, and the modern discoveries and suppositions of the chemical, mathematical, and mechanical philosophers, have in turn been assumed as affording the most perfect elucidation of the operations of the living body; and, as they have, of course, been in turn exploded, we need not recur to any other argument in proof of their want of foundation. By these remarks we would only to shew the futility of reasoning on the subject of proximate causes of disease, which, as we are and must remain entirely ignorant of the proximate cause of health and life, must be equally inapplicable. "Nam quae demum causa," as Celsus justly observes, "vel feudum valetudinis en praecedent, vel morbos excitant, &c. ne capiatem quidem professorum, scientia comprehensur, sed conjecturale proierentur" (De Med. Praef. lib. i.) The inquiry respecting the proximate cause of diseases is as futile as the speculations of the Cartesians to explain the essence of gravitation, and have as little to do with the advancement of true medical science, as the hypothesis of an ether affjicted Newton in his observations and calculations respecting the phenomena of that agent.

If these observations should not be sufficiently intelligible to the general reader, a brief enumeration of the hypotheses, which have been invented by medical writers, in order to explain the essential nature of gout, will probably be sufficient to prove the absurdity of such attempts. Most of the Greek and Roman physicians, with the exception of the methodists, considered the presence of a corrupted humour in the small vessels as the essential cause of gout. Hippocrates believed this humour to conflit of bile and phlegm, which flowed upon the joints. Galen followed him in supposing the defluxion upon the joints to be chiefly pituitous or phlegm, or bile mixed with phlegm. Paulus Egineta attributed the disease to a redundancy of blood, black bile, and phlegm. Trallian and Celsius imagined, that it arose from the blood itself being forced into the joints; and Ortibus affirmed that the blood in gouty people was vitiated, according to their nature of the subject.
refsembling melted glass, which remaining in the joints, produced the cretaceous matter. Arcturus, one of the most able of the Greek writers, is the only one who passés over the essential cause of the disease, a knowledge of which he allıgned to the gods alone; the evident causes, he says, are apparent to man. Themidon, Celcimus Aurellanus, and the medical fects, attributed guilt to relaxation or irritation of the parts; some, however, imputed it to the one frate, and others to the opposite. The Ancients followed closely in the path of their matters, and taught that one or other of the humours was predominant, or that they were variously combined, in cases of gout. So luminous and instructive were the doctrines of the ancients.

In the dawn of modern science, the humours were almost banished by the hypotheses of the chemists; but although we hear little more of bile, phlegm, and melancholy, or black bile, all disease was nevertheless attributed to a morbid or peculiar matter, and fakes, earth, or tarar, were deemed the immediate cause of gout and other maladies; and Paracelsus, Van Helmont, and others, are very ablrive of the ancients for promulgating fo many absurd doctrines! When the mathematical and mechanical physicians arose, they took up the hypothetical doctrines of their predecessors, and reasoned concerning the action of these supposititious humours, fakes, &c. upon mechanical principles; the chemical doctrines predominated, however, over the ancient hypotheses. Thus, to use the words of Dr. Warner, "according to Sydenham the arthritic matter consists of the putrefying heat and acidity of indigested juices: Boerhaave gives it the appellation of an acrimony or over-toughness of the liquid which waters the nervous parts: Liller makes it to be a crude and vitious forum become tchorous and corrosive: Bonnet defines it an acrimony that is invariably of the putrid, volatile: alkaline nature: Quincy says that it consists of rigid particles, such as approach near to the faline, of the nature of tartar, and not much unlike that which forms itself into concretions in the urinary passages: Cheyne in one place calls it tartarous, urinous, or other fakes: Ingram will have it to be a coagulation made by a mixture of saline particles with the oil of the adipose membrane. As every one of these writers makes the gouty matter to be an acrimony taken in with our aliment, which they call either putrid, vitious, corrosive, saline, urinous, or tartarous, so Dr. James, bane whole name needs no addition, disagreeing with them all, hath judged this acrimony to be earthy."

(See Warner on the Gout, p. 91. -- See also a feasible and learned disquisition on this topic, in "An Historical, Critical, and Practical Treatise of the Gout," by Thomas Thomson, M.D. Lond. 1742.) But such hypotheses did not die with Dr. James; for in a treatise on the gout, published in 1805, we find the following statement: "The proximate cause of gout appears to be, a peculiar saline acrimony exiiting in the blood, in such a proportion, as to irritate and excite to morbid action, the minute terminations of the arteries, in certain parts of the body." (See Observations on the Nature and Cure of Gout, &c. by James Parkinson.) a statement, which is equally indefinable, hypothetical, and practically useless, with those that have preceded it.

On reviewing these opinions of men, who have been deftively esteemed the ornament of their profession, some readers may express their surprise that such an extraordinary difference should be found among them, and that so much error (for of opposite opinions one half at least must be wrong) should exist in the science. But the only rational ground for wonder is, that so many men of sound understanding should have employed themselves in inquiries beyond the reach of their faculties, and should have imagined that, in framing hypothetical suppositions, they had acquired any actual knowledge, or had advanced one step in the practical improvement of their art. If a number of philosophers were engaged in investigating the nature of light and heat, and should not only execute a series of experiments on the reflection, refraction, and divisibility of the one, and on the properties of expansion, inflammation, vaporization, &c. of bodies, which belong to the other; but should likewise think it necessary to form conjectures relative to the nature and qualities of the sun, which is the cause or proximate cause of both; these conjectures, like the medical hypotheses just quoted, however they might amuse us, would add not a little to our knowledge, nor would the want of them be any diminution of our information, or of our practical powers.

The great source of these hypotheses, respecting the existence of a morbid humour in the gouty habit, is, no doubt, the appearance of a palpable matter, of a peculiar nature, in the joints diseased. This chalk-like matter, however, will be found to afford no ground for such a conclusion, if the circumstances are duly examined. In the first place, the production of this morbid matter may be the effect of the disease; and that it is so, is apparent from its not occurring in all cases of gout, and from its seldom or never accompanying the first attacks of the disease, but only appearing after repeated paroxysms. Nor have we any direct evidence, from experiment or observation, of the smallest difference in the blood or other humours of gouty people, from those of other persons. On the other hand, we know that the vessels in particular parts acquire the power of secreting or otherwise producing new fluids, when inflammation is induced. Thus a blow in a fleshy or membranous part shall occasion inflammation, and a considerable quantity of pus shall afterwards be accumulated or discharged, as in a common abscess; yet no one supposes that this pus was contained in the mafs of the circulating blood, any more than he supposes that urine and bile are contained in that mafs, and not elaborated by the kidneys and liver. The appearance of the chalky matter, or urate of soda, in the parts attacked by gouty inflammation, is therefore to be considered as the result of that inflammation, and not as its cause. If the general mafs of blood were contaminated with this morbid matter, or any peculiar acrimony tending to produce it, why is it never deposited on the vifera and other internal parts? Yet no such deposition was ever observed: those parts remain invariably free from it in the most inveterate forms of the gout, and the appearance of chalk-dolmes is confined exclusively to the membranous and ligamentous parts which exhibit inflammation externally. In the next place, the frequent and sudden translation of the disease from one part to another is not consistent with the supposition of its dependence on the presence of a morbid matter: but analogous changes or modifications of other inflammations, in which no peculiar matter is produced, are exceedingly common. Besides, upon the supposition of such a translation of morbid matter, its operation should be similar on every part, whereas it seems to be very different, being stimulant and exciting inflammation in the joints, but sedative and destroying the tone or energy of the stomach. Further, as Dr. Cullen justly observes, "the supposition of a morbid matter is quite superfluous; for it explains nothing, without supposing that matter to produce a change in the state of the moving powers; and a change in the state of the moving powers, produced by other causes, explains every circumstance, without the supposition of a morbid matter: and to this purpose it may be observed, that many of the causes exciting gout do not operate upon the state of
of the fluids, but directly and solely upon that of the moving powers." Dr. Cullen likewise remarks, that the supposition of a morbid humour being the cause of gout has been hitherto udesles, since it has not suggested any successful method of cure; but, on the contrary, that particular suppositions have often corrupted the practice, and have frequently led from those views, which might be useful, and from that practice which experience had approved. (First Lines, pt. 530.)

Having failed to explain the phenomena of the disease, on the supposition of a morbid condition of the fluids of the body; we might take up the doctrine of the nervous pathologists, and attempt an explanation of the symptoms, upon the notion of a derangement of the living fluid, or moving fibre, as Dr. Cullen has done. (Loc. cit. § 533–6.) But it is sufficient to peruse the account given by that celebrated physician, to be convinced that it is a mere repetition of the phenomena of the different varieties of the disease, couched in a new pharosology; and therefore that it is practically as udesle as that which he controverts. It cannot be questioned, we apprehend, in the present state of our physiological knowledge, that the prime agents in the operations of the living body, whether in health or disease, are the fluid, irritable, and moving parts; and that by these the fluids or humours are chiefly elaborated and modified: but it is likewise obvious, that the solids derive their powers from certain conditions of the circulating fluids, which are varied by respiration, nutrition, &c. Therefore the disputes between these who confine the origin of gout to the one or other part of the sytem exclusively, will be deemed frivolous. Our knowledge is necessarily limited to the phenomena of the disease, and the order in which they occur, and to the effects of physical agents upon them, as taught us by observation and experiment. "Nulla tamen adhibit oblivieux curiosi effe," says Dr. Heberden, "quam que veratur de hujus morbi causis, effectibusque, et remedii." (Comment. de Mort. Cap. 9.) But we cannot doubt that these numerous hypotheses, which have at once diverted the minds of physicians from the labour of observation, and have perverted their views of facts, have rendered the subject more obscure than it would otherwise probably have been.

Before we come to the method of treatment, there is another question to be noticed, upon which much discussion has taken place, and which has perhaps been popularly settled with considerable incorrectness: we mean the question, whether regular fits of the gout are fatalary; i.e. whether they altogether remove or prevent other complaints. The affirmative is generally maintained; and this opinion has arisen partly from observation, and partly from the hypothesis, that a paroxysm of gout confids in an effort of the constitution, by which the morbid matter is thrown off through the part affected. In a number of instances, beyond a doubt, the various symptoms of indigestion, whether affecting the stomach and bowels only, or the lungs and heart by vicinity, and the head by synpathy, are relieved or altogether carried off by the complete fit. Perhaps Dr. Heberden is scarcely correct, when he considers this relief as either, in a great measure imaginary, like that which many invalids invariably obtain from a change of their physician, or from a new medicine; or as not more frequent than similar relief from light indisposition after other violent diseases: he appeals, however, to an ample experience in support of his opinion. He thus writes: (we translate from the Latin ed. iv.) "There are some complaints in which the fit is a very frequent disease, and there this eruption is deemed fatalary. Even an ague was formerly considered by the majority of physicians as a wholesome affection, and is still so considered by some persons; its occurrence was therefore a subject of congratulation both with the patients and their friends, and every precaution was taken not to get rid of it too soon. But these notions are almost exploded in this country; and if we shall discover a remedy equally effectual for the gout, as with which we cure the diseases just mentioned, we shall at length learn with what perfect safety and advantage the gout may likewise be eradicated."—"I confes," he adds, "that I have seen some persons who rejoiced on the first attack of the gout, as if it allured to them all future happiness, and who, dreaming only of the most perfect health to come, easily persuaded themselves that this first fit had been wonderfully beneficial. This is a common disposition with mankind, as often as they have recourse to new physicians, or to remedies not before tried. But, passing by such persons, let us inquire the opinion of those, who have suffered under long and frequent paroxysms, and who are better acquainted with the disease. Of a very great number of patients whom I have seen, and whose cases I have committed to writing, more than twice as many, to say the least, have found no relief whatever from their previous complaints, in consequence of the regular fit, or have even suffered an increase of them, as have seemed to derive any benefit: and, in my opinion, the evils which were attributed to the disease, more certainly originated from that source, than the supposed advantages. Occasionally, indeed, we find that other complaints have ceased on the suppression of the gout; but the same thing also happens after acute fevers, after palsy, althama, small-pox, and inflammation, of all which I have witnessed many examples; yet no one will call these diseases fatalary. On the other hand, gout frequently occurs to persons affected with vertigo, althama, indigestion, and melancholy; where, far from alleviating these disorders, it produces a considerable aggravation of their symptoms. Besides, in some patients, all these complaints constantly accompany the paroxysm of gout, and continue during the whole of its course." (Loc. cit. p. 56.)

At all events, if we look at the life of the gouty in general, we find ultimately but little ground for congratulation. In some, it is true, the disease occurs at distant intervals, and from goes off, and therefore occasions very little, if any, obvious injury. Even epilepsy itself, when its attacks are rare, does not prevent the patient from reaching old age. But this is far from being the case frequently with either disease. In many persons whom the gout attacks, the health suffers from the time of the first fit, and gradually grows worse, until it is greatly broken, or fails altogether. It may possibly be doubted, in such cases, whether the gout caused these evils; but we are very certain that it has not been the remedy for them, nor in any way salutary.

We may justly wonder, therefore, with Dr. Heberden, how it has come to pass, that the gout is held in so much honour in England; unless it be that it is a disease, which several great men have suffered, and which chiefly attacks those happy persons who enjoy leisure and affluence, and all the good things of life. Louis XIV. of France happened to labour under a filament in the anus, and the fugitives of that time were contentedly called in by his fashionable subjects to administer relief to imaginary filament; which royal disease they persuaded themselves had attacked them: and it is probable, as Dr. Heberden observes, that in these cases of medicated waters in France, capable of producing filent, they would have been visited with the same anxiety to which our countrymen are liable to with Bathy, in the hope of returning with the gout.
GOUT.

Of the Cure.—Perhaps this may be deemed an improper term for the treatment of a disease, which, on the one hand, has been affirmed to be incurable by medicine, and called the opprobrium of physicians; and, on the other, has been considered so fatal, that it ought not to be cured, and could not be cured without the most imminent danger to the patient. Nay, farther, as much trouble has been taken to produce and excite the gout, as to relieve or cure it; and all the evils which arthritis suffers, are not supposed to arise from a superabundance of gout, but because they have not had enough. It would be only justice, however, as the intelligent writer just quoted remarks, to the art of physic, no longer to call the disease its opprobrium, until the patients lay aside their prejudices and fears, and have a disposition to be cured. "Utinnam," he adds, "tam in promptu effe ineunre, quam tatum adhibere, podagre remedium." (Comment. p. 43.)

The treatment is, it is obvious, must be necessarily very different according to the different forms of the disease, the different periods of life, and the state of strength of the patient, &c. We shall first speak of the practice necessary to be pursued in the regular gout; which will resolve itself into the treatment requisite during the fit, and that which is proper during the interval.

Treatmet of the Regular Fit.—All active measures, during the occurrence of a regular paroxysm of gout, have been prescribed by writers in general since the days of Sydenham. This physician remarked, that the more violent the pain and inflammation ion, the shorter in general will be the fit, the recovery most perfect, and the interval between this and the succeeding paroxysm the longer. If this opinion were admitted as just, it would suggest the prohibition of any remedies which might moderate the inflammation. But against this doctrine another has been advanced by Dr. Cullen, which is at least equally plausible, and better supported by analogy, if not by fact; namely, that the violence of the inflammation may weaken the tone of the parts, and while it renders them less liable to similar violent attacks, and the consequent more perfect recovery, may, by that very debility, invite a return of the disease. On the whole, the indications of practice generally pursued at present, are to moderate the violence of the inflammation and febile action, when it is severe, without applying any active remedies to the foot itself. After enumerating the various external applications, such as poultices, fomentations, blisters, infusions, caustics, and stimulating substances, which have been occasionally recommended, Dr. Cullen concludes, that from any of them there is danger of rendering the gout retrograde; "and that therefore the common practice of committing the person to patience and flannel alone, is established upon the bell foundation." As there is no danger from the fit of gout, when regular, in a constitution not much broken, this method may be pursued with a certain degree of impunity; but it cannot be questioned, that the loads of flannel, which are sometimes useful, often augment the necessity for a supply of patience, by increasing the inflammation and pain in the foot. It is true, that the parts thus swelled and painful, are more acutely sensible to cold, as well as to other irritations, than in health; but no covering beyond what is sufficient to prevent a troublesome fenation of cold, if that should occur, can be necessary. (Haberden.) All poultices, fomentations, and warm bathing during the inflammatory stage are pernicious.

It is more than probable, that considerable errors have been committed, upon the hypothetical notion of keeping the gout in the extremities, at least in the younger subjects of gout, by deviations from the antiphlogistic regimen. In such fulgeæ sinuos and fermented liquors should be altogether abstained from during the fit; and the diet should consist of light aqueous and vegetable matters, or thin animal broths. The bowels should be kept open by laxative medicines, and the skin moist by diaphoretics of the neutral sorts. This is at least a palliative system, and the prejudices of men in general are averse to any more active interference with the disease. But in cases the inflammation is extremely violent, in young and hale men, Sydenham, Cullen, Huxham, and other able authorities, concur in recommending the employment of blood-letting from the arm. This, however, they do not recommend to be often repeated, on account of the debility which may ensue; and as the part affected is not an organ important to life, and the inflammation is purely local, there does not appear to be any good reason for recurring to this remedy, except in cases of extraordinary violence, in very peltorrhic habits, in which the symptomatic fever itself might prove hurtful. Local blood-letting, by means of leeches applied to the foot itself, promises more advantage, and experience itself has proved the efficacy and safety of the practice. (See Cullen, First Lines, par. 563.—Mugrave de Arbrict, regulari, cap. 8. § 4.) Cupping and scarifying the neighbouring parts have also been found beneficial. (Mugrave.)

We are persuaded that hypothesis has had much more influence than observation and experience, in exciting the general fears about interfering with the progress of the gouty inflammation, and of the danger of its being driven to some internal part by such interference. When it was believed, that a quantity of morbid matter existed in the inflamed part, it was inferred, of course, that it could only be removed by expulsion or by repulsion, in which last case it must fall upon some other organ. We know very well, that the fame hypothesis, and the same fears prevailed no long time ago with respect to cooling the skin in fevers, and especially in eruptive fevers, such as scarlet fever and small-pox. "The perspiration will be checked," said the theorist, "if you allow the skin to be cooled, and the present matter must therefore be thrown back upon the bowels, or the lungs, or the brain, and the effect may be fatal." But ample, and unvarying experience has now demonstrated, not only that such danger was altogether imaginary, but that walking the skin with cold water, even under the full eruption of scarlatina, and in the eruptive fever of small-pox, affords the most grateful relief to the patient, and is the most effectual moderator of his disease. (See Cold, effects of as a remedy.) Nor is a considerable experience of the safety and efficacy of a familiar practice, in subduing the inflammation of gout, wanting. The great Dr. Harvey himself, whose name is immortalized by the discovery of the circulation of the blood, was in the habit of immersing his foot in cold water, as soon as he perceived the approach of the gout, and thus removed the disorder; he lived to the age of eighty. Van Swieten mentions an officer of infantry, who was induced to take his gouty feet into snow, and afterwards, emboldened by successes, walked a little way barefoot upon the snow, and returned quite free from pain; the interval before another fit was also lengthened by this practice. Similar observations were likewise made by the ancients. Actius informs us, that he had been a perfon labouring under what he calls a bilious gout, "who obtained extraordinary relief from immersing and keeping his feet some time in cold water." And it is an apologium of Hippocrates, that "cold water, copiously poured upon dwellings of the joints, painful ulcers, gouty disorders, and con- vulsed limbs, lessens and removes the pain." (Aph. 25, feo. 5.—See also Haberden Comment. p. 45.—Van Swieten, Com. ad Aph. 1273.) But the most extensive evidence
of the efficacy of this practice, in curing the paroxysm of gout, has been adduced by Dr. Kinglake, (see a Difcipline on Gout, &c. Lond. 1824,) who brought forward about thirty cafes, in which the application of cold water to the inflamed part, during the gouty paroxysm, was immediately and most happily effectual in relieving the pain and removing the diseaee, without any untoward circumstance ensuing. Dr. Kinglake maintains, that the inflammation of gout is to be treated upon the same principles as other local inflammations, and yields to the same treatment. That this proposition is correct, while the constitution remains unbroken, we fully believe; but to what extent the principle will hold, in those whose health is greatly debilitated and decayed, as well by age as by frequent and protracted disease, remains as yet undetermined by experience. With the diminished strength of the patient, the paroxysms become diminished in violence, and active remedies are, therefore, the less required; but from what we have detailed above, it appears at least highly probable that, in the first attacks of gout, the application of cold, judiciously employed, so as to remove the morbid heat and no longer, would always be safe, and would contribute as well to shorten the paroxysm in the suffering of the patient, and to prevent the joints from the injury, which protracted inflammation and morbid effusions necessarily occasion.

The operation of purgatives, which is known to be essentially useful in other inflammations, has been considered as beneficial in the gout by some physicians, but has more commonly been altogether forbidden. Sydenham expresses himself very strongly in prohibition of purging, at any period of the fit, or even in the interval of health. Had he expressed his conviction upon this point simply as the result of experience, we should have been disposed to bow to his authority; but his theory appears to have had at least an equal share in producing this conviction; and unfortunately this theory involves the most gross contradiction. In the beginning of the paroxysm, we are told that there is great danger lest purgatives should drive the inflammation of the foot, "by throwing back into the mafs of blood that pessant matter, which nature was protruding to the extreme parts." (Tractat. de Podagra.) But after the termination of the fit, there is extreme danger, "lest a new paroxysm in the foot, equal severe with the former, should be produced by a purgative." (Ibid.) So that this theory blows hot and cold, like the fayre in the fable; and these dangerous purgatives drive the pessant matter out of the foot, when it happens to be in, and are the most effectual means of throwing it into the foot after it has been driven out not only from the foot, but from the whole body (according to the hypothesis) by nature!

Sydenham, however, lived long enough to retract, in part, his opinion respecting the injurious influence of purgatives in the gout, especially if the milder ones are used, and an apology given after the operation. (Dillert. de Mictu Sanguineo, &c. 1666.) Van Swieten observes, "many physicians are of opinion, that part of the gouty matter may be carried off by purgatives, and the fit rendered much more mild, especially if it be occasioned from errors in diet;" and he quotes Hofmann, who recommends gentle purgatives in all cases of local pain, and has mentioned an instance in his own person of the most striking benefit derived from a purgative taken immediately before the fit of gout. An instance has been related to us, in which the gout was completely banished, during a space of nearly twenty years, by the use of a brisk purgative, taken when the first symptoms of the fit began to appear; the medicine employed in this instance consisted principally of fennel, in the dose of about fifteen grains. We have seen this medicine used in a few cafes, with some relief, in smaller doses, and without any untoward consequences. That purgatives, as well as cold applications, may be referred to with advantage in the beginning of the paroxysm of gout, wherever the constitution is unimpaired, we consider as tolerably well established on the grounds of observation; although we do not doubt that many of the cafes of repelled gout, which have been attributed to such causes, may have really occurred, under circumstances of broken and feebile constitution, or of peculiar idiosyncrasy. But the accidents arising from a careless or injudicious abuse of any practice, afford no just argument against the rational and cautious use of it.

We apprehend, however, that many disorders have been very erroneously attributed to repulsion of the gout, which might be more correctly explained upon other grounds. For every inflammatory disease that occurred, even at the dilution of several months from the effusion of the fit, has been considered as the result of the premature cure of the gout: whereas, it is next to impossible that so long an interval could have taken place between the cause and its effect; and, on the other hand, as gout is most frequent in plethoric habits, which are also most liable to inflammatory diseases, the occurrence of pleurisy or apoplexy, in such cafes, is double to be attributed to the plethuses, and not to the previous gout. Dr. Cullen mentioned that he had known about twenty persons die suddenly, more than half of whom were of gouty habits.

The violence of the pain, in the paroxysm of gout, would naturally suggest the use of opiates; but experience has shown that opium, in any form, when administered in the beginning of any inflammatory disease, with which much heat of fkin and great fublimate excitement are connccted, generally fails to give relief; on the contrary, that it tends to increase the heat, fever, and reliefs, and, with them, the pain likewise. When, however, the violence of the paroxysm is somewhat abated, yet continues to return, so as to occasion painful and restlefs nights, opiates may then be given with safety and with advantage, especially in the cafe of persons advanced in life, and who have been often affected with the disease. The hypothetical objection to the use of opiates, that they tend "to lock up the morbid matter," is altogether groundlefs. Dr. Warner speaks with delight of the soothing influence of opium in the fits of gout, which he suffered in the latter periods of his life. (P. 135—136.)

Hitherto we have seen that the practice, generally purgative in the paroxysm of gout, is merely palliative; an actual cure being deemed a deiferitatum by molt persons, and a thing impnper to be attempted by others. Of late, however, a medicine has been introduced into this country from France, which is said to poiffes a specific power over the gouty paroxysm, which it removes "cito, tuto, et juuninde." The composition of this medicine is at present unknown, but it has been aecertained that it is a vegetable matter, and it is said by the inventor to be a plant heretofore not used in medicine. It is called "au medicinale d'Hufian." It has appeared, in many instances in which it has been employed in this country, and that in persons of the first rank and character, to poiffes the power of removing the paroxysm of gout in the course of twenty-four hours, leaving the patient in a state of good health, and in possession of the fame ufe of his limbs which he enjoyed before the fit. It is said that, in general, it increases the various excreitions considerably, if taken in the full dose, producing several loose motions from the bowels, a free perspiration, and an increased di-
GOUT.

charge of urine. But the influence of the medicine on the gouty paroxysm is not attributed to these evacuations; since, in some instances, in which a smaller dose was taken, a similar relief to the gout was procured, without any increase of the excretions. No untoward circumstance whatever has yet occurred, in confinence of the speedy removal of the paroxysm: but farther experience will be requisite to enable us to form a satisfactory estimate of its properties. (See an Account of the Eau Medicinale d’Hauin, by Edwin G. Jones, M. D. Lond. 1810.)

Treatment in the Interval.—Whatever method is adopted in the treatment of the fit of gout, whether it be merely palliative, or to actuate as to shorten the attack, the constitution retains its predisposition, and is equally liable to suffer a return of the disease. It is not yet ascertained, we believe, whether the fits, when warded off by the eau medicinale, do not recur more frequently. It is the treatment of the patient in the interval of health, by which alone the disease can be cured, i.e., the paroxysms prevented from returning, and the gouty diathesis eradicated. How this is to be effected, we cannot learn from a view of the proximate cause, or essential nature of the disease; for upon this point we have no actual knowledge: but, as we possess some knowledge of the existing causes of the disease, or of the circumstances which generate or foster the predisposition to its attacks; so, by removing these, we may hope to prevent the production of that predisposition, or to diminish it, if not to remove it altogether. Now, we have seen that intemperance and indolence are the parents of the gouty diathesis, where it is not hereditary, and are the chief agents in exciting it to activity, when it is. The inference, then, is obvious: by temperance and activity, and not by medicine, the return of the gouty paroxysms is principally to be prevented.

There is, perhaps, no subject, on which Englishmen in general entertain so many unfounded prejudices, or listen to argument with so little attention or conviction, as that of temperance. It is conceived that physicians, in inculcating the advantages of it, only talk idly about it, in the way of their profession; and that what is called good living, when not carried to actual debauchery, is favourable to the support and health of the body. It is, indeed, so universally the practice, in this country, to indulge an artificial appetite, beyond the actual wants of nature, that temperance is a thing, as Dr. Cadogan observes, of which an Englishman can acquire no idea at home. It is, however, altogether comparative with respect to individual constitution; for some persons will become plethoric to a morbid degree, upon a diet which is barely sufficient to support life in others. Perhaps Dr. Cadogan’s tale is correct. “As long as a man eats and drinks no more than his stomach calls for;” (i.e. when unexcited by variety of dishes, by sauces and condiments, or by interpolating liquor of any kind;) “and will bear without the least pain, disfellation, or uneasiness of any kind, &c. he may be said to live in a very prudent well-regulated state of temperance, that will probably preserve him in health and spirits to great old age.”

(On the Gout, p. 31.)

We know too well, however, the general want of power or inclination to refit the pleasures of the table, with that degree of perseverance and to the requisite extent, to expect that many cures of the gout will be effected in this way; but this we may assert, that the only influences of the eradication of the disease, which are known, have been accomplished by rigid and persevering temperance. Dr. James Gregory, the present professor of medicine in the uni-

versity of Edinburgh, is a remarkable example of the perfect cure of the gout by such means. Born of gouty parents, he was attacked severely when young, and suffered several paroxysms, which, after being banished by abstinence living, recurred on a short indulgence in revisiting Oxford; but he has since that time entirely kept the fast at a distance for about thirty years, by extreme temperance and much exercise, and is now hale and strong, though advanced several years beyond the age at which his father died, broken down by the gout. This he repeats annually to his pupils with no small exultation. His diet has been chiefly broth, or a sparing quantity of plain animal food, with little or no wine. Dr. Cadogan affords another instance of the benefit of rigid temperance, in his own person, “having not only got rid of the gout,” he says, “of which I had severe fits in my younger days, but also emerged from the hallowed ebb of life, that a man could possibly be reduced to by coffee, jaundice, and a complication of complaints, and recovered to perfect health, which I have now uninterruptedly enjoyed above ten years.” (Loc. cit. p. 83.)

Dr. Heberden likewise observes, that although complete cures of the gout are extremely rare, yet he has known more than one instance in which, by a total abstinence from animal food and wine, the patients were relieved from a state of extreme debility and misery, to such a degree of health and strength, as rendered their life no longer unsatisfactory to others, nor painful to themselves. Comm. p. 44.

It can scarcely be doubted, indeed, that a complete cure of the disease might, by a rigid plan of life, be accomplished in most cases, when the patients are not above the age of 30 or 35 years, even if they should have already experienced two or three paroxysms. In older habits, where the disease is of longer standing, a complete cure cannot be so confidently expected; but experience has shown that the feverity and the consequent evils of the disease may be actually mitigated by temperance, even under such circumstances. It is a milder, less distressing, and a more disease of the body to indulge an artificial appetite, beyond the actual wants of nature, that temperance is a thing, as Dr. Cadogan observes, of which an Englishman can acquire no idea at home. It is, however, altogether comparative with respect to individual constitution; for some persons will become plethoric to a morbid degree, upon a diet which is barely sufficient to support life in others. Perhaps Dr. Cadogan’s tale is correct. “As long as a man eats and drinks no more than his stomach calls for;” (i.e. when unexcited by variety of dishes, by sauces and condiments, or by interpolating liquor of any kind;) “and will bear without the least pain, disfellation, or uneasiness of any kind, &c. he may be said to live in a very prudent well-regulated state of temperance, that will probably preserve him in health and spirits to great old age.”

(On the Gout, p. 31.)

We know too well, however, the general want of power or inclination to refit the pleasures of the table, with that degree of perseverance and to the requisite extent, to expect that many cures of the gout will be effected in this way; but this we may assert, that the only influences of the eradication of the disease, which are known, have been accomplished by rigid and persevering temperance. Dr. James Gregory, the present professor of medicine in the uni-

Vol. XVI.
both by the assistance of others, which may be given him in the following manner: let a handy active servant or two be employed to rub him all over, as he lies in bed, with flannels, or flannel gloves, fumigated with gums and frises, which will contribute greatly to brace and strengthen his nerves and fibres, and move his blood without any fatigue to himself. This may take up from five to ten minutes at first, but must be repeated five or six times a day, supposing him totally unable to help himself. But if he can walk a hundred yards only, it will forward him greatly to walk those hundred yards every two hours; and if he can bear a carriage, let him go out in it every day, till he begins to be tired. The first day or two all this may disturb and fatigue him a little; but if he has patience to persevere to the fourth, I dare promise him some amendment and increase of strength; which he must employ, as young merchants do a little money, to get a little more. Thus he must go on rubbing, walking, and riding a little more and more every day, slopping always on the first sensation of weariness to rest a little, till he be able to walk two or three miles at a stretch, or ride ten without any weariness at all. He must ever remember that the habit of body is only to be corrected by habitual measures; and perseverance, therefore, must be his motto in regard to exercise, not less than with respect to temperance. But it must be observed, in general, that the exercise should not be violent; for if violent, it cannot be long continued, and must always endanger the production of atony and debility in proportion to the degree of violence. It must be moderate;" to use the words of Dr. Cullen, "but at the same time coniant, and continued through life."

It has been supposed by some persons, that an abstemious and active mode of life for a limited time, as for instance, an abstinence from animal food and fermented liquors, and a diet of milk and farinaceous matters alone, for the space of one year, might be sufficient for a radical cure of the gout. Such an opinion was expressed by Celsus, who says that "sine, by cleaning themselves thoroughly by drinking saes' milk, have for ever nulplied the disease; and others, by abstinence, during a whole year, from wine, mulik, and venery, have obtained a security from it for the remainder of their lives." (De Medicina, lib. ii. cap. 22.) In a few cafes, the plan possibly have succeeded; but it is well known that many persons, who, by entering on an abstemious course, had been delivered from the gout, have, on returning to their former mode of living, had the disease return with at least equal violence.

While an abstemious regimen, combined with exercise, will tend to correct the gouty habit, if steadily pursued; it will be at the same time advisable to avoid as much as possible some of those circumstances, which we have mentioned above as among the frequent exciting causes of the disease; more especially when the gouty habit has been established by a repetition of the fits, or is hereditary in its origin. In such cases, the measures, which we have proposed, are not easily pursued to the requisite extent, and are commonly attempted even with reluctance; men, therefore, have been very desirous to find a medicine which might answer the purpose, without requiring a restraint on their manner of living. Of this there are many empirical and self-interested pretended physicians have taken advantage, and have been induced either to abuse the gouty, in fact, or have rashly employed those of the most pernicious tendency. It is unnecessary for us to inquire into the nature of those alleged mustard, etc., nostrums, which, after being for some time in vogue, were neglected or exploded, as their inutility or injurious qualities were thus acknowledged. But after promising that we are much disposed, with Dr. Cullen and others, to believe the impossibility of curing the gouty habit by medicines, we shall notice one or two known medicines, which have been in vogue so long time ago. If the gouty constitution is created by a series of high-fevering and indolence, how is it to be expected that medicine can change that constitution, especially while the cause continues to operate?

The Portland powder is a medicine which obtained considerable reputation, as a cure for the gout, about the middle of the last century. This powder derived its name from the duke of Portland, who received so much relief from it, that he ordered the formula to be printed, and delivered to all who should ask for it. It was brought from Switzerland by a friend of the duke's. The powder consists of the roots of arctiologia rotundata and gentian, and of the tops and leaves of germander, ground-plum, and consinry, well dried and powdered, equal weights. This powder was ordered to be taken for a year or two, at first in the dose of a dram daily, but afterwards in smaller quantities. (See Weisse, p. 17.) In the work just referred to, Dr. Ckphere has shown that a similar compositon was used by the ancients for the cure of gout. Such a formula is given by Galen, in his treatise De Antidotis, lib. ii. cap. 15., which he says he had used himself. Celsus Aurelianus speaks of similar medicines, under the denomination of annella medicinae, from their being taken for the space of a year. Actius gives, among other gout medicines, an "antidotus podagrica ex doubius cantarese generiosis," which differs from the Portland powder in one ingredient only. But several of the ancients concerned the long uninterrupted use of these medicines as dangerous; and allure us that they are extremely hurtful in the hot and bilious, and are only proper in cold and phlegmatic constitutions. The Portland powder has fallen into neglect, under a notion that it was ultimately prejudicial. "In every instance," says Dr. Cullen, "which I have known of its exhibition for the length of time prescribed, the persons who had taken it were indeed afterwards free from any inflammatory affection of the joints but they were affected with many symptoms of the atomic gout; and after some time finishing their course of medicine, have been attacked with apoplexy, atheroma, or dropsy, which proved fatal." (First Lines, par. 557.) Dr. Heberden, however, is of opinion, that the popular prejudices against this medicine at present are as far beyond the truth, as they formerly were in its favour. (Comment. p. 48.) He attributed to it considerable powers of alleviating the difeafe, by strengthening the stomach and supporting the function of digestion; and believes that many of the evils (which, because they followed its exhibition, were imputed to its operation,) were in reality the consequences of the difeafe, and not of the remedy. That those cafes, however, of apoplexy, &c., which it is admitted, occur in gouty habits, would be probably accelerated, if not occasioned, by the use of a hemorrhagic powder, while the full diet was continued, appears to be extremely probable; for the plethora must have been increased in proportion to the artificial increase of the digestive powers. We should, therefore, be disposed to conclude, that the constant use of such a medicine must be pernicious, unless it were combined with temperance in eating and drinking; and that, with such a regimen, it would in all probability be highly beneficial, if taken whenever the symptoms of indigestion should appear.

Another class of remedies has been employed in the interval between the paroxysms of gout, and in many instances with considerable alleviation to the disease, rendering the
the fits milder, and the intervals between them longer; we allude to the antacids; such as the alkalis, and absorbent earths. The nature of the chalky matter, produced in invertebrate gout, which is an acid, and denominated lithic or uric acid, (being the same which is found in the urine and urinary concretions,) has led to the theory, that this acid, or its elements, is the specific humour of the gouty; and therefore naturally suggested the idea of using alkaline medicines as remedies for the disease. And as accentuant drugs are found to increase the gouty diathesis, and to increase the disordered state of the digestive organs; to alkaline medicines we have been made to relieve the symptoms of indigestion, and at the same time to lessen the disposition to gout. Thus the caustic alkalis have been found beneficial; but not more so, we believe, than the mild or carbonated alkalis, especially potash; and the absorbent or alkaline earths have likewise afforded relief; and sometimes speedily removed some of the urgent symptoms of disordered stomatch; especially the preparations of chalk, lime-water, and magnesia. The magnesia is perhaps one of the best medicines of this fort for the gouty, as it not only corrects the acidity of the stomatch, but at the same time is laxative to the bowels, and thus contributes to obviate phlethora. When these antacids do not sufficiently open the bowels, or do not prevent colic, a little rhubarb, aloe, or some other aromatic purgative should be added. Thus, Mr. Home and Mr. Brande, in experiments made on the Philosophical Transactions, (Part I. for 1810) that magnesia has a much more powerful influence in preventing the formation of the uric acid, in the urine, than of the alkalis; it is probable, therefore, that they may be more beneficial in the gout. As a warm laxative the tincture of guaiacum was much recommended, and as it combines a stimulant with an evacuant property, it may be serviceable in some conditions.

Care of the irregular Gout.—We have already remarked, that false theory has led to much false alarm, and doubled to many mistakes in practice, especially relative to the atomic gout; all the various symptoms of dysepspsia, and hypochoonrialists being often supposed to be gouty, when no actual gout had ever appeared. Hence fomentations, blisters, rubefacients, and other local stimulants to the extremities, the Bath waters, hot podlavia, &c. have been employed to bring on the gout in the foot, instead of relying on the remedies which might rectify the functions of the digestive organs. The Bath waters are certainly to be recommended in those cases, as they are possessed of considerable powers in restoring the healthful condition of the stomatch, especially when it has been disordered by irregular and intemperate living; and of relieving those wandering pains, which are deemed gouty, but which, as Dr. Heberden observes, are the common accompaniments of declining years and a broken constitution.

In these cases of atomic or wandering gout, as it is called, all the means usually employed to strengthen the habit in general, and the stomatch in particular, are to be resorted to. Moderate, but frequent and regular exercise on horseback, or walking, must be pursued; the diet should be a little more generous, and some wine may be necessary; but both food and drink of the accepet kind must be measured, and if wine, of whatever sort, must be found to increase the acidity of the stomach, spirits much diluted with water should be administered. At the same time, for the purpose of supporting the tone of the stomach, preparations of iron, the Peruvian bark, bitters, and aromatics in moderation may be resorted to; and laxatives, employed only so as to prevent colic, must be taken. The propriety of frequent gastric vomits, where the indigestion is troublesome, is more than questionable; for, while they give a temporary relief, by removing a load of undigested food, they tend to debilitate the organ, and thus to increase the evil which they were intended to remove. At the same time, all the causes of debility formerly mentioned, must be snuffed, and exposure to cold especially must be carefully avoided: the most certain means of doing this is by repairing to a warm climate during the winter season.

Care of misplaced or retrocedent Gout.—These, like the atomic gout, are in a considerable degree the fruits of medi- cal speculation, more especially the misplaced gout; they do, we believe, occasionally occur in cases of old and inver- terate gout, but certainly much more rarely than is generally believed. This opinion Dr. Heberden rates from his own experience. (Comment p. 41.—See also "Letters on the Caufe and Treatment of Gout," by Dr. Robert Hamilton, Lynn, 1820.) The last-mentioned physician, who had employed bleeding and other antiphlogistic remedies, both upon himself and several of his friends for eighteen years, never saw any thing like a retrocedence of gout; and Dr. Gulien never saw an influence of misplaced gout.

When the gout has disappeared in the extremities, the stomatch and bowels are sometimes attacked with most acute pains, which is of a spasmatic nature, and to be relieved by thirst, and the employment of strong, diluting, and antacids, fluids, such as wine, or even opium in full doses. Opiums are doubtless the most effectual antiphlogistic medicines; but their operation will be aided by combining with them the others, volatile alkali, the free use of strong wines, and aromatics, given warm, or ardent spirits, if there be not effectual. Camphor, mufk, asafetida, and other strong smelling substanccs, may be employed as adjuvants, especially in lef violent cases. External heat to the region of the stomatch, hot podlavia, or the warm bath, will contribute by their stimulant powers to overcome the spasm, and pain. If the stomatch is known to be loaded, as by a previous repast, its contents may be evacuated upwards, by draughts of warm water, with wine, or of chamomile tea, or downwards by means of some of the cathartic tinctures, as of fennel, or rhubarb.

As those persons, who are subject to paroxysms of the gout, are generally pellitory in their habits, so they are liable to inflammatory diatheses; and it cannot be doubted, that ordinary attacks of inflammation of the lungs, of palsy, and apoplexy, have been deemed gouty, and have proved fatal from the omission of blood-letting. When the symptoms of pleurisy, or periiuemousness, or the acute pains of head, vertigo, somnolency, threatening apoplexy, or the actual symptoms of apoplexy and palsy occur; we ought not to delay the exhibition of the usual remedies for those diatheses, or be induced to be sparing in the use of the lancet, because we apprehend a gouty diathesis; for death may be produced in a few minutes. And, as Dr. Heberden judiciously observes, "where the danger is imminent, from the violence of the symptoms, and we are doubtful whether they be gouty or inflammatory, we incur much greater risk by omitting blood-letting in a diathesis arising from inflammation, than by drawing blood in a disease arising from gout." Indeed those very physicians, who condemn bleeding and other evacuations in gout, in the extremities gravely prescribe the prompt administration of those remedies, when the lungs, head, or other viscera are attacked with it. In a word, when the internal viscera are affected with unequal or violent symptoms of inflammation, the same treatment by local and general evacuation, blistering, &c. must be resorted to; and in all other cases of inflammation, regard being had at the same time (an ob- servation, indeed, which applies to the practice of medicine universally)
universally) to the peculiar circumstances of the patient's age, strength, and constitution.

GOUT, in Botany. See Angelica.

GOUTIER, Gouye, or Goutre, terms in Surgery, applied to a chronic enlargement of the thyroid gland. See Bronchocele and Goitre.

GOUTY-LAND, in Agriculture, a term used by the farmers to denote a hollow fuzzy black earth, with little springs, that have no free outlet, and therefore swell and elevate the surface in many places.

GOUVEA, in Geography, a town of Portugal, in Estremadura; 20 miles S.E. of Viseu.

GOUX DE LA BOULAYE, Francis E.B., in Biography, a celebrated traveller, was born in the province of Anjou about the year 1616. Little is known of his early life, but that he felt a strong propensity for rambling into foreign countries; he employed ten years successively in traversing various parts of the globe. He seems to have been willing to become all things to all men, in order to obtain his wishes in safety. In Africa and many parts of Asia he passed for a Mahometan, and in Europe he was a good Catholic. On his return, he published an account of his travels, under the title of "Les Voyages des Observations de François de la Boulaye le Goux, en divers Pays, d'Europe, d'Asie, et d'Amérique, jusqu'à l'année 1650." This work was published in 1650 and illustrated and adorned with engravings. The style is incorrect, but the facts, as far as they are borne out with truth, are said to be very curious. He was so much altered in his person during his absence from France, that his mother even, either could not, or would not recognize him, and he was obliged to institute a law-suit to establish his rights as heir in the family. In 1658 he was appointed ambassador to the Porte and the great Mogul, by Lewis XIV, and was very dilettante in renewing his commerce with the East. Le Boulaye died in Perou of a fever before he had executed this mission. Morel.

GOUYE, Thomas, was born at Dieppe in the year 1650. He was brought up among the Jefuits, and was at an early period distinguished by an ardent love for mathematical and scientific pursuits. In 1699 he was elected a member of the Royal Academy of Sciences at Paris, of which body he became an affluential attendant, and was highly esteemed for the useful contributions which he made to their memoirs. He died at Paris in 1723, leaving behind him, as memorials of his learning and industry, "Physical and Mathematical Observations tending to the Improvement of Astronomy and Geography, sent from Siam to the Academy of Sciences at Paris, by the Jefuit Missionaries, with Reflections and Notes, in two volumes." The first volume was published in 1688, the second in 1692, and both have been added to the seventh volume of the collections of the Academy. Morel.

GOW, in Geography, a town of Hindoostan, in Bahar; 40 miles S.S.W. of Bahar. N. lat. 25°; E. long. 83° 48'.

GOWER, John, in Biography, an ancient English poet of the fourteenth century, is said to have been descended from a family at Sittemham in Yorkshire. He had the best education which the times afforded, and at a proper age became a member of the Society of the Inner Temple, where he attained to a high degree of respectability in the profession of the law, and where he became acquainted with Chaucer. Some writers affirm that, in the course of his professional duties he was appointed chief justice of the court of Common Pleas, though others think the judge was another person of the same name who was a contemporary with the poet. Gower attached himself to the duke of Gloucester, uncle to Richard II., and was much noticed by the king himself, at whose desire he wrote his principal work. He had, however, a pliable mind, and could turn his pen to different interests; for on the accession of Henry IV. he not only wrote in adulatory terms to the new king, but even reflected on the misgovernment of the one who had been deposed, and who had been his patron. His circumstances were such as to put him beyond the fear of want, for he appears to have been a liberal contributor to the rebuilding of the church of St. Mary Overy in Southwark. During the first year of Henry's reign, our poet had the misfortune to be deprived of his sight, an affliction which he did not long survive. He died in the year 1422, at a very advanced age. Gower, says his biographer, is entitled to a place among English writers only relatively to the time in which he flourished; for though well versed in learning, and a successful cultivator of his native language, he has not the least pretensions to genius or invention. He is characterized by his friend Chaucer, as the "moral Gower;" he was uniformly grave, even upon topics that might inspire vivacity. He was author of three volumes, entitled "Speculum Meditationis;" " Vox Clamantis;" and "Confessio Amantis." Of these, the first is a moral tract, and relates to conjugal duties; the second is a metrical chronicle concerning the insurrection of the people under Richard II., in Latin elegiac verse; the third, or "Lover's Confections," relates to the morals and metaphysics of love. This is the only one that has been printed, and it was among the earliest products of the English press, by Caxton in 1483. It seems, says Mr. Warton, to have been his object to crowd all his erudition into this elaborate performance. The most interesting part of the work is a variety of stories added as moral examples, and taken from authors most in vogue, ancient and modern. The language is periphrastic, and the verification frequently harmonious. Biog. Brit. Warton.

GOWER, in Geography, a district of W.Wes, in the south-western extremity of Glamorganshire, below the town of Swansea, and bounded by the Irish sea and the Bristol channel.

GOWER, Cape, a cape on the E. coast of China, lying in the track from the southward to the gulf of Pekin. A reef of rocks runs out from a neck of land near this cape, which appeared to have a compact harbour. The entrance to it was between the cape and the reef just mentioned. When the perils concerned in the embay to China passed this cape, a considerable number of vessels were lost in the harbour, and a pretty large town behind it. N. lat. 36° 57'. E. long. 122° 15'.

GOWER'S ISLAND, a small, flat, low island, in the Pacific ocean, so called by captain Carteret, who passed it in Aug. 1767; he found no anchorage, and could only obtain a few cocoa-nuts in exchange for nails; the inhabitants resented the theft of Egmont isle. S. lat. 7° 50'. E. long. 158° 50'.

GOWER'S HARBOUR, a bay on the S. W. coast of New Ireland; 2 miles N. of Cape St. George. M. Bougainville calls this "Prafalin Bay," and by Dampier it is called "St. George's bay." S. lat. 4° 50'. E. long. 150° 48'.

GOWGAT, a town of Hindoostan; 12 miles W. of Agra.

GOWGATCHY, a town of Bengal; 12 miles N. of Calcutta.

GOWN, Rone, a long upper garment, worn by ladies, divines, and other graduates, who are hence called gownsman of the gown, or gown-man.

The gowne is an ample sort of garment, worn over the ordinary
ordinary clothes, hanging down to the feet. It is fashioned differently for ecclesiastics, and for laymen.

At Rome, they give the name virile gown, togas viriles, to a plain kind of gown, which their youth affumed when arrived at puberty. This they particularly denominated pluvius.

In some universities, physicians wear the scarlet gown. In the Sorbonne, the doctors are always in gowns and caps.

Beadles, &c. wear gowns of two colours.

Among the French officers, &c. they distinguish those of the short gown, or robe, which are such as have not been regularly examined. They have also barbers of the short gown, who are such as are obliged to pluck in an inferior way to barbers, or those of the long robe, in the general, for the civil magistrature, or the profession opposite to that of arms.

In this sense it was that Cicero said, "Cedant arma togae."

GOWRAH, in Geography, a town of Bengal; 27 miles S. S. E. of Dacca.—Also, a town of Hindostan; 5 miles N. E. of Benares.

GOWRAN, a poilt town of Ireland, in the county of Kilkenny. It is a place at present of no importance, but was a borough before the Union, and there are some ruins which seem to intimate its former importance. It is 52 miles S. from Dublin.

GOWREY, a town of Hindostan, in Oude; 53 miles W. of Kaisarabad.

GOWRY-Bray, in Ornithology, a name given by Edwards to the Loma sanctuloria.

GOWRYPOUR, in Geography, a town of Bengal; 26 miles S. E. of Dacca.

GOWT, in Engineering, or go-out, is a name applied to the finnish ridge, or valley used when embankments next the bank in rivers, is allowed for, to lower the land-waters when the tide is out, and preventing the ingreets of salt-water. Some of the gowns in the feast of Lincolnshire and Cambridgeshire are very large works, and cofl immense sums of money.

GÖY, in Geography. See ASCO.

GOYANCES, a town of Spain, in Galicia, on the sea-coast; 25 miles S. W. of Santiago. N. lat. 42° 32'. W. long. 8° 50'.

GOYAS, GOJAS, or GOYES, a town and government of Brazil, extending from 42 to 54° W. long. and from 6° 30' to 19 S. lat. the inhabitants of which are estimated at 89,530 whites, 29,659 Indians, and 34,100 negroes, who are employed in searching for gold in the mines, which were discovered in the year 1726.

GOYAVA, a town on the W. coast of the island of Grenada. N. lat. 12° 13'. W. long. 61° 31'.

GOYAVES, a town of the island of Guadaloupe, giving name to a bay in which it is situated.

GOYEN, JOHNS VAN, in Biography, a painter, born at Leyden, 1596, who studied successfully the practice of landscape-painting under several masters, and having an uncommon readiness and skilfulness of hand, he produced a great many works of a light agreeable kind; with much character of nature, but no great relish of art; which, in their time, however, were very highly esteemed and widely spread over Europe.

Views of he scenes on the banks of the canals and rivers of the Low Countries were his favourite studies; sometimes he emerged to the sea shore, or sunk into the interior of the country, and sketched the villages that presented themselves to his tatte in the one, or the harbours, &c. of the other; but all are touched by the same kind of pencilling, and generally in the same hue of colour, when he came to work them up into pictures. Certainly, they have much merit of a peculiar kind, such as lightness in the handling, and freedom in their effect; but frequently they are rapid and flimsy, and by no means justify the high value and reputation affixed to them. It is said that the grey tone, too frequently found in his pictures, arose from the use he made of Haerlem blue, which is apt to fade into that tint, and therefore no longer in use. It may be so; but that grey is not the predominant defect in his pictures; it is the evident fault with which they are wrought, and their consequent imperfection of imitation, that induces us thus to condemn what the world have too long estimated in a high ratio, which ought only to be given to works completed with the skill and purity of talle of a Caracci or a Claude. He died in 1656, aged 60.

GOZ, or GOZEN, in Geography, a sea-port town of Morocco, on the coast of the Atlantic, in the vicinity of Mogador.

GOZO, an island of the Mediterranean, situated N. W. of Malta, and at a little distance from it. This island is about 25 miles in circumference, rather fertile, and containing about 5000 inhabitants.

Gozzi, or Gajda, a small island in the Mediterranean, about 27 miles from the S. W. coast of Carthaca; anciently "Clauda," near which St. Paul sailed in his voyage to Rome. Some biblical writers suppose that the Gozo near the site of Malta is the Cladus of the Book of Acts. It is occupied by about 30 families; who have a Greek church, and is occasionally visited by vessels for a supply of water and provisions. At a small distance to the west is a very little island called "Pulo Gozo," or Little Goz. N. lat. 34° 48'. E. long. 23° 46'. See GOZZANO.

GOZZANO, a town of Italy, in the department of the Guglia; 18 miles N. of Novara.

GOZZOLI, BENOZZO, in Biography, one of the early practitioners of the art of painting on its revival. He was a Florentine, and disciple of Fra Angelico; but subsequently imitated with very great success the style of Masaccio, his contemporary. Valfari speaks of him with great esteem under the name of Bonozo, and relates histories of his many productions at Florence, Volterra, Rome, and Pisa; at which latter place are his most conspicuous labours, both in history and portraits, which indeed at that time were usually introduced in historical pictures. At Pisa he died in 1478, aged 78, and a monument, with a Latin epitaph, is placed near his principal work in the Campo-Santo; a monument of his powers, and the esteem in which they were held.

GRAAF, REINIER DE, an excellent physician, was born at Schoonhoven, a town in Holland, where his father was an eminent architect; on the 30th of July, 1641. He studied physic at Leyden, where he made great progress, and at the age of 22, published his treatise "De Sterco Pandreatico," which gained him considerable reputation. In 1665, he went to France, and received the degree of M. D. at Angers, but he returned to Holland in the following year, and settled at Delft, where his great success in practice excited the envy of his professional brethren. He married in 1673, and died in Augst, 1673, when he was only 32 years of age. He published three dissertations relative to the organs of generation in both sexes, upon which he had a controversy with Swammerdam. His works were published in 1668. At Leyden, in 1667 and 1705; they were also translated into Flemish, and published at Amsterdam in 1686. Houtchinson, Biol. Med. Eloy.

GRAAF KEYSET, in Geography, a district of southern Africa,
Africa, in the colony of the Cape of Good Hope, extending to the easterly extremity of the colony. On the E. it is divided from the Kafris by the Great Fish river, the Turky, the Bamburgh, and the Zuureberg; on the W. from the districts of Zwentendam and Stellenhof by the Cangoos river, the Gunka or Lion’s river, and Nieuwland mountains; on the N. from the Bosjesman Hottonutos by Plattnberg Landmark, the great Table mountain, and the Karreeberg; and on the S. it is terminated by the peace; the whole length and breadth of this district may be about 250 by 100 miles, making an area of 150,000 square miles, which is peopled by about 750 families, each family commanding about 57 square miles of territory. Great part of it has been occasionally abandoned on account of the incursions of the Kafris and Bosjesmen. The inhabitants are a sort of Nomades, who would long ago have penetrated with their flocks and herds far beyond the present boundaries of the colony, if they had not been resisted by the Kafris. The hours of this district are graziers; and it is entirely composed of sheep-farms, which were grants made to the original settlers of certain portions of land to be held on reasonable yearly leases, on condition of paying to government an annual rent of 24 rix-dollars. Barrow’s Travels in S. Africa, vol. ii. 1 GRAAT, or GRAAF BARENT, in Biography, an historical painter, whose name is remembered principally upon account of his close imitation of the works of Bambocci, and of his having founded an academy at Amsterdam, where he was born, to which the best artists of his time resorted to study after living models; by which means much improvement was obtained, and spread among those who cultivated taste and science in the arts. He died in 1709, aged 81. 2 GRAB, in Geography, a town of Bohemia, in the circle of Leitmeritz; 17 miles W. N. W. of Leitmeritz. 3 GRABARCIJ, GRABERT, in Church Antiquity, such persons as deferred the receiving of baptism till the hour of death; or who did not receive it till they were dangerously ill, and out of hopes of life; from an opinion, that baptism absolutely washed away all former sins. The word is formed of grafa, bed; and that from the Greek ἱππα, a hanging bed, of κύπευ, I suspend; such as was the bed of slaves, poor people, Cynic philosophers, &c. who are enemies of luxury and ease. 4 GRABAU, in Geography, a town of the duchy of Warsaw; 12 miles S. of Kalisz. 5 GRABAW, a town of Austrian Poland, in the palatinate of Belz; 28 miles N. W. of Belz. 6 GRABE, JOHN ERNST, in Biography, a learned divine, and editor of the Alexandrian manuscript, in the Royal Library at London, was born at Konningberg, in Prussia, in the year 1666. Here he received his education, and in due time took his degree of M. A. applying himself with all diligence to the study of divinity, and the pavement of the fathers. He had been brought up in the Lutheran principles, but having imbibed some notions inconsistent with the commonly received faith, respecting the uninterrupted succession of bishops being essential to the existence of the true church, he was summoned before his superiors and imprisoned. Upon his release, after a few months, he chose rather to quit the church than abandon his opinion, and determined to become a member of the Catholic religion. He delivered, in a memorial to the ecclesiastical college at Sambia, in Prussia, in 1679, containing the reasons for his change, and then left Konningberg, that he might be at liberty to carry his plan into execution, in some place where he should be beyond the reach of the Prussian jurisdiction. While he was on the road to Erfurt, through which he meant to pass to a Catholic country, the elector of Brandenburg sent three tracts to him in answer to his memorial, by three Prussian divines, written by order of the elector. This great attention of his sovereign claimed the respect of Grabe, who not only read them with care, but felt defects of disfiguring the question more closely before he formed his ultimate determination of abandoning the religion in which he had been educated. He accordingly wrote to one of the persons that had answered his memorial, intimating a design with to return to Berlin, that he might enjoy the benefit of a conference with him. This privilege was obtained for him; M. Grabe returned and was soon prevailed on to relinquish his purpose of joining the papal communion, but still he maintained the obstinate tenet for which he had suffered imprisonment. Finding him insurmountable on this point, his friend advised him to remove to England, where, said he, “you will find the outward and uninterrupted succession which you want; take then your route thither: this step will cause less uneasiness to your friends, and, at the same time, equally satisfy your scruples.” He gladly complied with the advice, and was strongly recommended to King William, who immediately granted him a pension of 100l. per ann. to enable him to pursue his studies. From this time he considered England as his country, because he conceived that its ecclesiastical constitution approached nearer on the whole, than that of any other, to the primitive pattern. He showed his gratitude for the liberal patronage which he received by the publication of several learned works. Having formed a design of printing some curious and scarce pieces of the fathers, in defence of his own opinions, he obtained access to the university of Oxford, to examine the treasures of the Bodleian library; and, in 1698, he published “Scripturum S. S. Patrum, &c.” vol. i. and in the following year, the second volume of the same work appeared. Shortly after this, he was ordained a deacon of the church of England, and was appointed chaplain of Christ-church, Oxford. This promotion he accepted, in order that he might be entitled to the emoluments without being required to discharge the duties of the appointment, for he had refrained, on his ordination, to receive the sacrament, on account of the omission of the prayer in the communion service, mentioning the sacrifice, before the elements were distributed, which had been inserted in the first common-prayer book of King Edward VI, and he ever afterwards continued a non-conformist in this particular. In the same year in which he took orders, Mr. Grabe published “S. Iustini Philosophi et Martyris Apologia Prima pro Christianis, &c.” illustrated with the notes of several learned men, and additional remarks of his own; and in 1702 he published “S. Ioannis Episcopi Lugdunensis contra omnes Harectos Libri quinque, &c.” with preface and notes. On the accession of Queen Anne to the throne, Mr. Grabe’s pension was continued, and her majesty was advised to employ him in printing the Alexandrian MS. in the royal library, of the Septuagint translation of the Old Testament. The queen took the opportunity of informing him of the appointment herself, and at the same time made him a handsome present as an encouragement to his exertions. In 1705, he published proposals for printing that work by subscription, setting so fair a superior value of this copy to the Vatican MS.; he also gave three specimens, containing so many different methods for the projected edition, in the final choice of which he was to be determined by the learned world. As a testimony of their approbation of the design, the university of Oxford pre-
fected him with the degree of doctor of divinity. His proposals met with a very favourable reception on the continent as well as in England, and he received a handsome present from his own sovereign, the king of Prussia, and liberal subscriptions from the principal nobility, clergy, and gentry of all parts. In 1707, he gave to the public his first volume, under the title of "Vetus Testamenti latina Septuaginta ab Appii Apollonii Septuaginta," which was published in 1709. This volume contains the Pentateuch, and the three following books. In the expectation of an accession of additional MSS. he deferred the second and third volumes, and published the fourth volume in the year 1709. This contained the book of Psalms, of Job, of the three books of Solomon, &c.; and in the following year he published a Latin dissertation, giving a particular account of the reasons why he had departed from the usual order of publication, and of the help which he expected to receive in order to perfect his plan. These were, a Syriac MS. of the historical books of the Old Testament, with Origen's remarks upon them, and two MSS. one belonging to cardinal Chigi, and the other to the college of Lewis XIV. When he received these MSS. and had collated them, he prepared a volume of annotations on the whole work, and collected materials for the Prolegomena. The time which these objects took, caused a material delay in the publication of the second and third volumes, which did not, in fact, appear till after the author's death. This event took place in 1712, when he was in the forty-fifth year of his age. He had previously to this published "An Essay upon the Arabic MSS. in the Bodleian library, and that ancient book, called the Doctrine of the Apollonius, which is said to be extant in them, wherein Mr. Whitton's mistakes about both are plainly proved." The third volume of his great work was published in 1719, and the fourth in 1720. On his deathbed he was attended by Dr. Smallridge, by whose means he declared that the public might be informed that he died in the faith and communion of the church of England, though he considered its constitution to be defective in some points, in which he thought the nonjuror clergy adhered more closely to the apostolical doctrine and discipline. Of his talents there were different opinions, but of his industry and learning no one could harbour a doubt. Dr. Thirlby says, in the dedication of his edition of Julian's Apology, "he was a good man, and not unlearned, and well versed in the writings of the fathers. But he was no critic, nor could be one, since he was not furnished with genius or judgment, or, to speak the truth, in learning was only sufficient for the purpose." In this opinion Le Clerc coincides, and adds, that his books gained him the character of a laborious person rather than that of a great critic. He was the author of many other works besides those which have been mentioned, and was editor of an elegant edition of bishop Bull's works; he likewise assisted in preparing for the prebend archdeacon Gregory's edition of the New Testament in Greek; and he left behind him many MSS. some of which have been published. Biog. Brit.

GRABEN, in Geography, a town of Croatia; 12 miles S. of Varazdin.

GRABO, a town of Sweden, in East Gothland; 11 miles S.E. Linköping.

GRABON, a town of the duchy of Mecklenburg, on the Elbe; 80 miles N.W. of Berlin. N. lat. 53° 23'. E. long. 11° 44'.

GRABUSA, an island of the Mediterranean, near the N.W. coast of the island of Candy, confirmed to the Turks by the peace of Carlowitz, and generally garrisoned with 1000 men. N. lat. 58° 40'. E. long. 23° 33'.

GRABUT, in Geography, an obscure French musical composer, whose name is not to be found in the annals of the art. He was brought into England to flatter the partiality of Charles II. for the music of France; and employed by Dryden to set his political opera of "Albin and Albanus," though Purcell had already given indisputable proofs of his superior genius, and was rapidly rising into fame and national favour.

This drama, written under the auspices of king Charles II., was reprinted several times, as the author informs us in his preface, before his majesty, "so had publicly declared, more than once, that the compositions and choruses were more full and more beautiful than any he had heard in England." We believe this prince was not very skilful in music, nor very sensible to the charms of any species of it but that of France, of the gayest kind; however, royal approbation is flattering and extensive in its influence. Unfortunately for the poet and musician, his majesty died before it was brought on the stage; and when it did appear, the successes feem not to have been very considerable. Upon a perusal of this drama, it seems hardly possible, so near a revolution, that it should have escaped condemnation upon party principles; as, under obvious allegations, Dryden has lathed the city of London, democracy, fanaticism, and whatever he thought obnoxious to the spirit of the government at that period. Had Orphius himself not only composed the poem and the music, but performed the principal part, his powers would have been too feeble to charm such unwilling hearers.

GRAÇAY, in Geography, a town of France, in the department of the Clercy, and chief place of a canton, in the district of Bourges; 9 miles S.W. of Vierzon. The place contains 2264, and the canton 5459 inhabitants, on a territory of 145 kilometres, in 9 communes.

GRACCHURIS, an ancient town of Hispании Tarraconensis, mentioned by Livy, Antonine, and Ptolemy, and said to be built by the proconsul Titus Gracchus Sempronius, after having conquered the Celtiberians. Others suppose that it existed before Sempronius, under the name of "Hericius," and that he only repaired it. It is now called Arr Soldier.

GRACCHUS, Tiberius Sempronius, in Geography, a person very memorable in the history of Rome, was the son of a father of the same name, a distinguished commander, and excellent citizen, who, from the Plebeian ranks, arrived at distinguished honours, and the highest offices in the state, having been master of the horse to the dictator, Junius, after the celebrated battle of Cannae, afterwards consul, and, at length, to complete his glory, he was slain while fighting for his country. The mother of the subject of this article was Cornelia, daughter of Scipio Africanus, whose character has been illustrated in the proper place. Tiberius received every advantage of education that the pious affection of a wise parent could bestow, and his natural disposition seconded the efforts of his instructors. He was modest, and remarkably mild in his temper; and became, at a very early age, distinguished for eloquence, sobriety, and political knowledge; and his reputation was fed by an admixture into the venerable college of augurs. It is mentioned, as a proof of the high character which he fulfilled, that Claudius Appius, one of the most illustrious perfons in Rome, and president of the senate, offered him, spontaneously, his daughter in marriage, which he thankfully accepted. When Appius informed his wife what he had done, she replied, "Why so suddenly, you might have taken
taken time, even if Tiberius Gracchus were the man.” In
conformity with the Roman custom, Tiberius paid his
youth in military service; first in Africa, under his brother-
in-law, the younger Scipio, where he obtained great credit
in the army, being equally beloved by those above and those
below him. He was made quæstor, in the Numantian war,
to the consul C. Hollius Mancinus. This was in the year
B. C. 137: the campaign was unfortunate, and the Roman
general was under the necessity of negotiating a treaty of
peace with the enemy.

The Numantines, who had been betrayed in a former treaty by the Romans, refused to nego-
ciate, unless it were with Tiberius Gracchus, with whose
character for probity and strict honour they were well ac-
quainted. This being admitted, a peace was immediately
concluded. The treaty, though as favourable as possible,
circumstances, could be expected, was received by the
Romans with great indignation; they determined to annul
it, and to deliver those, who had been instrumental in making
it, into the hands of the Numantines. The confuion
was accordingly given up to them, naked and in chains, and it
is probable that Tiberius Gracchus would have shared the
same fate had not a powerful intercess been excited in his
favour. A sense of the injustice of the Senate on this occa-
sion, and resentnent of the dithour they had thrown upon
his treaty, was supposed to be a principal cause of the sub-
sequent hostilities in which he engaged against that body.

The condition of the Romans, at this period, afforded a
good opportunity for the exertions of patriotism; for the
great mass of the lower classes of citizens were in a state of
absolute poverty. Lucius the Wife, the friend of Scipio,
had attempted to introduce some remedy for this evil, but
the serious opposition of men in power had deterred him
from the execution of his plan. Tiberius Gracchus resolved to
take up the cause. He was accordingly elected a tribune of
the people, and proposed a revival of the Lexian law, with
certain modifications, which greatly fastened its operations.

(See Agrarian Law.) It offered a full compensation
out of the treasurers for all the land above the 500 acres
allowed, which any one might be obliged to resign to the
public, and permitted every child of a family to hold 250
acres above the 500 held in the father’s name. This proposal
was received, as it might be expected, by the superior orders,
whose rights and properties were to be affected by it; they
were determined to stand by another one in refuting the
innovation. On the other hand, Gracchus felt no time in
rushing the people to a knowledge and affront of their
claims as men and members of society. His speeches
were addrefed to their interests and their feelings; his
arguments were specious and highly dangerous to the peace
of those whose wealth was become the object of popular
diffusion. In one of his harangues, he exclaimed, “The
wild beasts have their caves and dens, but the brave men
who shed their blood in the cause of their country have
nothing free but the air and the light. It is a mere mockery

when their generals exhort them to fight for their fucphulces
and household gods, when, perhaps, not a man among them
is poiffessed of a domestic altar, or fuscphule, of his ancestors.
The private men bleed and die to secure the luxuries of the
great, and they are denominated the masters of the world,
while they are not owners of a foot of ground.” At length,
after much tumult in the fenate, the Agrarian law was paifed,
and Appius Claudius, Tiberius Gracchus, and his younger
brother Caufus, were appointed commissioners to carry its
provisions into execution. In his progress in the bufi-
ness he was embaffied with many obflacles; and, on his
part, he took measufes effectually to thwart the purposes of
the great; and, by new laws which he got enacted, he ren-
dered the property of all the old families infecure. The
difficulties which occurred in carrying the new law into
effect were fupplied by the death of Attalus, king of
Pergamus, who was one of the friends of Gracchus. A
law was enacted for the distribution of his treasures
among the poorer citizens, and for the dispofal of the rev-
ue of Pergamus, not by the Senate, but by the assembly
of the people. These meafures gave him a great degree
of influence among the citizens, and he conceived the design
of securing the powers of which he felt confiderv possessed,
by raifing his father-in-law to the confulate, his brother to the
tribunifhip, and continuing to himself the fame office
another year. He also planned other regulations for abridg-
ing the authority of the patriots, and throwing more weight
into the popular fcale. The day of election was approaching,
and the fentiors resolved to make a fand againft the
innovations which he proposed, and a conspiracy was openly
formed to take away the life of Tiberius Gracchus. Of this
he was informed by a friendly fentior, as he was proceeding
to the capitol. He, nevertheless, advanced, and his party
prepared to repel force by force. In the uproar, he at-
tempted to pfeak, but his voice could not be heard. He
made figns to his friends, by making signs to the people, to
fave him. This signal was instantly interpreted by his enemies as a demand of the regal crown,
and Scipio Nafica, the invenior of enemy of Gracchus, cried
out “Since we are betrayed by our confual, let thieves
who love the republic follow me.” A general content now
commenced. The adherents of Gracchus were quickly dis-
perfanded, and himself was dispatched with a thousand blows.

Not few than 350 persons were slain in this commotion, and
the bodies of the dead, even that of Gracchus himfelf, were
ignominiously thrown into the Tiber. Several of his friends
were afterwards banifhed, and not a few put to death, with-
out the form even of trial, and the Senate passed an act of
indemnity for all thieves who were concerned in the mafiace.
The people, however, indignant againft his enemies, drove
Nafica from Italy, and would never permit him to return.

With respect to Tiberius Gracchus, his character has been
celebrated either as that of a martyr to liberty, or as a
victim to lawless ambition, according to the different prin-
ciples of those who have commented on his actions. Many
have thrown on his memory reflections as unanswerable as
they are unfounded. It seems to be acknowledged on all hands that
he possessed great talents, and was eminently qualified for his
private worth. That he was a man of ambition none will deny,
and it may be that a love of popularity suggested the great
meafures which he proposed; nevertheless, the historian
may be safely followed, who fays, that he was actuated by
the best intentions, but that he proceeded with too
much violence.

Gracchus Caufus, brother to Tiberius, but his junior
by nine years, enjoyed the fame advantages of education
with his brother, which he so well improved as to be-
come one of the ablest orators of his time. Cicero fays of
him, that he knows not if he had his equal in eloquence,
and recommends his compositions, though unfiftendid, to the
study of youth. After the tragical end of his brother,
Caufus pafled some time in retreat, cultivating his rhetori-
cal talents, and secretly preparing to act his part on the theatre
of the public. In the year 125 B. C. he accompanied the
confual A. Aurelius Orellus to Sardina as his courier, and ob-
tained great applause, as well for his humanity and temper-
ance, as for a strict attention to the duties of his office.
The Senate shewed evident signs of jealousy on account of
the
the popularity of which he acquired, and retained him as pro-
quellor in Sardinia in order to keep him at a distance from the Roman forum. Perceiving their intentions, he ventured, in defiance of their orders, to quit the island without leave of his commander, and suddenly made his appearance at Rome. He was called to account for this breach of military discipline, but was readily acquitted. Soon after he became a candidate for the tribune-shaip, and such was the zeal of the people in his favour, that the Campus Martius was not able to contain the multitude who flocked from the Italian towns to support his election, and many gave their votes from the tops of the adjacent houses. Cais had not forgotten the enemies of Tiberius, and would have purged them to their destruction, but was probably dissuaded from it by his mother. His speeches were calculated to revive the indignation of the people against the senators for their conduct towards Tiberius, and he proposed and carried motions for confirming his brother's laws, and the passing of others still more obnoxious to the patricians. He was appointed commissioneer for the division of lands among the poor citizens and allies, and in his progress through Italy he employed his talents and wealth in repairing roads, building bridges, and in other works equally useful and important. He established public granaries in Rome, from which the citizens were to have their monthly distributions of corn at a low price, the expenses of which were to be defrayed by duties laid on goods imported into the dominions of the late king Attalus. By these, and other acts of a like kind, he ingratiated himself with the people, that he was chosen a second time tribune. Triumphing in his success, he proposed a law for transferring from the senators to the knights the cognizance of all private causes. When he had obtained his purpose he exclaimed, "at length I have humbled the senate." He now felt himself the arbiter of the republic, and treated the patricians with contempt. This behaviour hardened his ruin. There is a point, beyond which the most successful man, whatever be his pretensions, cannot go with safety. Cais had transgressed this boundary, and his enemies were perpetually on the watch for opportunities to check his power, and to introduce rivals who might, by the appearance of more liberality, depress his reputation and influence in the state. During his absence in Africa his enemies were ever on the alert to injure his fair fame, and to ascribe unworthy and base motives to all that he did or proposed to do; and in the tumult which accompanied the discussion of some of his laws after his return, he fled to the temple of Diana, and, unwilling to fafferve either himself or his adherents to popular fury, he proposed terms of accommodation. These were rejected by the arts of Opimius the conful, and a price was instantly put upon the heads of Gracchus and his friend Fulvius. A formal battle ensued, in which multitudes were slain on both siles, and the populac without hesitation deserted their friends: Fulvius concealed himself, but, being discovered, was instantly killed. Gracchus, having solemnly impetrated upon the heads of the Roman people perpetual flavery for the base defecion of the caufe, left the city and passed across the bridge named Sublicius. His retreat was favoured by two faithful friends, who defended the bridge till they fell covered with wounds. In the mean time Gracchus reached a grove faced to the furics, where it is said a flave, by his order, flri dischanched him, and then put an end to his own life. Others have, however, given a different account of the matter; they say that he was over-taken by his enemies, and had them killed. His head was cut off and nailed to the caufe for its weight in gold. The body was thrown into the Tyber, but afterwards being taken from the water it was delivered to his affiduci mother for burial. This catastrophe, in which three thousand persons perished, happened in the year 121 B.C., and the senate immediately proceeded to aboish all the laws of the Gracchi. Their names, however, were still fondly cherished by the people, statues were erected to their memory, and the places in which they were killed were consecrated, by religious rites, to their names. Cais has been generally considered as less pure in his intentions, and less moderate in his plans, than Tiberius. From the evidence of history it should be seen, that the disturbance of the public tranquility was rather owing to his opposers than to him; "so that," says the historian, "instead of calling the tumult of that period the "sedition of the Gracchi," we should rather call them the sedition of the senate against the Gracchi, since the efforts of the latter were made in vindication of a law, to which the former had assented, and as the designs of the former were supported by an armed power from the country that had never before interfered in the business of legislation, and the introduction of which gave a moat irrecoverable blow to the constitution. Cais in his person was graceful, his action was strong and impressive, his voice of great compass and melodious when the vehemence of his pleading did not raise it to too high a key; to correct this defect he was accustomed to place a judicious person behind him with a pitch-pipe, by which he was enabled to regulate his tone. In temper he was warmer than Tiberius, nor was he distinguished by frugality of manners, though in this respect he might be advantageously compared to the Roman youth in general. Plutarch. Unier. Hist.

GRAC, GRATIA, 299, in Theology, denotes in general any gift or favour, which God freely bestows upon mankind; whether such gift pertains to the present or future life; but as those which relate to the improvement of their temper, and their fitness for final happiness, were favours of the greatest importance, this term is by way of eminence applied to them. The proper figurition of the word grace is favour;—favour in such a sense as denotes mercy and goodnes in a superior, either remitting somewhat of his own right, or conferring somewhat benefical upon others, freely and without any obligation of debt. And because this may be done in various modes and in a great diversity of instances, hence the word grace in scripture is accordingly applied in a corresponding diversity of figurations. Sometimes it signifies those extraordinary gifts and favours of the Holy Ghost, by which the apostles were enabled to demonstrate the truth of their commission, to teach the church with authority, to convince gained persons with evidence, and to govern the churches by a proper distribution of different truths and offices. The gifts or powers, by which the apostles were enabled to do all these things with extraordinary efficacy and succe, are therefore called grace, because they are not at all natural acquisitions but free gifts of God; distributed to every one, not according to the will of man, but at such times, and in such proportions, and to such persons, and for such purposes as God himself pleaseth. See Rom. i. 5. Ephes. iv. 7. 11.

In other passages, the fame word is used to signify that extraordinary aflaince and support which God has been pleased sometimes to afford to his servants under extraordinary difficulties and trials; and this is called grace, because it is considered as given particularly and gratuitously upon extraordinary occasions over and above the general supports arising from the confiderations of reason, and from the promises and motives of the gospel in general. See 2 Cor. xii. 9.

A third sense, in which the word grace sometimes occurs in the New Testament, is to express such moral virtues as are the effects of men being influenced by the spiritual
motives of the gospel, and the practice of which prefers men in the favour of God, and recommends them to his gracious acceptance. (See Eph. iv. 29. 2 Pet. iii. 18. 2 Cor. viii. 1, 6.) Moral virtues are plainly for this reason distinguished by the denomination of grace, because they proceed from and are founded on a regard to God in general, and in particular to his will revealed under the gracious dispensation of the gospel of Christ.

Another signification of the word grace in Scripture is to express the merciful acceptance of repentance and amendment, by which God is pleased, not out of any obligation of justice, but in gracious goodness, to restore men to favour. In this sense Paul says (1 Cor. xv. 9.) "By the grace of God I am what I am;" to John, i. 17., the doctrine of Christ is styled "grace and truth." The Apostles' preaching is by St. Luke (Acts, xiv. 3.) called "the word," or declaration "of God's grace: " to which St. Paul declares (Rom. iii. 24.) that repeating sinners are "justified freely by grace," and blaming those "who continue in sin, that grace may abound." The word grace in all these passages signifies that merciful and compassionate disposition of the divine nature, by which God freely remits of his right of punishment, and receives penitent sinners, upon more gracious terms, and to greater degree of his favour, than he was bound to do by any obligations of justice.

Hence it is, that the gospel itself, as being the great and standing declaration of God's mercy and goodness towards men, shown forth in the free pardon and forgiveness of sin upon the gracious terms of repentance and amendment, is in the New Testament very frequently meant by the phrase, "the grace of God." (Clarke's Serm. vol. ii. p. 265-257. 8vo. fol. ed. vol. i. p. 180, &c.) Bishop Pearce (Comm. on p. 259.) renders υπὸ τῆς ὁμοθυματίας, in 1 Cor. x. 3. Thanksgiving, and not grace, as it is in our version; and he observes that the sense of the word υπὸ τῆς ὁμοθυματίας is too frequent in St. Paul's writings to require a proof of it. He adds that υπὸ τῆς ὁμοθυματίας in the latter part of the verse confirms this sense.

Some divines define grace to be any degree of divine influence on the mind, inclining it to believe in Christ, and to practice virtue; and those divine influences, which are not effectual in producing saving faith and sincere obedience, they call common grace, in contradistinction to special grace, the operation of which is completely efficient and saving; and those influences which introduce special grace, though they do not actually amount to it, are with respect to that introduction sometimes called preparatory. It is disputed among theologians whether special grace, which they suppose is never on the whole finally rejected, so as to fail of working faith in those who are the happy objects of it, be in the nature of its operations upon the human mind irremissible or not; and it is also questioned, whether common grace be sufficient. Whether the mind be entirely poftive in the first moment of its conversion, or whether there be any cooperation of our own; together with the influences of Divine grace upon the heart, is a question, which has been also very much disputed amongst divines of a particular description; and another question, to the subject of controversy, is similar to the former, and that is, whether the work of regeneration and conversion be accomplished in an infant. But we should far exceed our preferred limits if we were to state the arguments pro and con on questions of this nature.

Grace, in Law, is sometimes used for a faculty, licence, or dispensation; but this seems to be only in a case where the matter proceeded, as it were, ex gratia, of grace and favour; and not where the licence or dispensation is granted of course or of necessity.

Grace is also a term in the formula of all patents, &c., which begin, George, by the grace of God, king of Great Britain, &c. The Roman bishops frequently began their mandates in the like manner: such a one, by the grace of God, and the holy see, bishop of, &c.

The English archbishops say, by divine grace, or divine providence. See Archbishop.

All sovereigns use the phrase grace of God; as emperors, kings, princes, &c. Anciently dukes, counts, and even lords, talked in the same style. In the new collection of Father Martene we meet with a mere seigneur, or lord, qualified by the grace of God seigneur de Comborn. Louis XI. forbade the duke of Brittany to style himself by the grace of God.

Grace is also a title of dignity, attributed to princes of inferior rank, and who are not qualified for that of highness.

In former times the kings of England were addressed under the title of grace, as they are now under that of majesty. See King.

Our English dukes and archbishops are still addressed under the title of grace. But that title is most frequent in Upper Germany, and particularly Austria, where it is borne by the barons, as being inferior to that of excellence.

Grace is also applied to persons, and various kinds of performances, to denote a quality, or rather the result of a combination of qualities, which attracts peculiar notice, and affords peculiar pleasure.

Grace is also used for a short prayer offered before and after meat. This practice is very ancient, and has very generally obtained both in the heathen and Christian world; and hence grace-cup is used by some of our poets for the cup or health drank after grace.

Grace, in the arts of Painting and Sculpture, is used to signify a peculiar quality which heightens the effect that beauty of form is calculated to produce, and renders it still more engaging.

We have already, in the article Beauty, slightly touched upon this subject, and there mentioned the origin of the term among the Greeks; who gave to the Charities or Graces, whom they deified, the presidency over whatever was amiable and engaging in the actions or sentiments of mankind. By the undistinguished nudes of which they always represented these deities, to whom they gave the names of Aglaia, Thalia, and Emphymone; they allegorized the pure fincerity and simplicity in which acts of kindness should always be wrought. By the union of these perfections, which are generally holding each other by the hands, or with their arms round each other's necks, they marked the union of spirit which dictates acts of benevolence and social intercourse; and by devoting them to the service of Venus, exemplified the necessity of uniting the virtues of humanity to the beauties of person, in order to become truly engaging.

This allegory of the ancient Greeks leads us to the just conception of the meaning of the word grace when applied to the arts. Whatever can lend to beauty, increase of interest upon the beholder, is entitled to be called graceful, or at least elegant. (See Elegance, in Painting.) As the heart of man, when inclined to good, is to his mental, so is grace to his personal accomplishments; that, which gives the most delightful gratification to those with whom he associates. Without it, art is nothing, compared with the values it acquires by its presence. Independent of all which confitutes mere beauty of form, it is absolutely necessary to give it its full force, its greater effect, viz. that which beauty
beauty acquires by motion, wherein alone grace is visible.

Poets as well as painters and sculptors acknowledge the value of this quality; and the bell have constantly applied it to the objects of their adulation when moving. Milton says of Eve, "Grace was in all her legs." Ariosto adds it to all the beauties of his Alcina; when he says,

"Avea in ogni parte un lascio teso
O pari, o ride, o cantar, o passa nova."

The graces, lurking about the mouth and the eyes of a beautiful person when in motion, are the most constant theme of poets, and as constantly the source of emulation to the painter and sculptor to imitate; and when the artist has by his ingenuity discovered and represented truly those minute variations of form which take place both in figure and features, when the mind is excited by some amiable emotion; he has obtained the ultimatum of his art; no power can go beyond it. Apelles, the ancient Greek artist of most repute, declared of his contemporaries, that their several works professed every beauty but the perfection which grace alone can give; in this he found himself unrivalled. Ancient sculpture is fraught with it; their figures, whether in action or repose, profess it; and when we lay that it may be found in figures reposing, we do not militate against the sentiment that action is the basis of grace; a previous motion being supposed to have taken place, to produce the graceful polishing. No figure, standing, sitting, or lying down, can be graceful, however beautiful it may be, whose parts or members are presented altogether straight and full to the eye. Without some varying turn being given to the head, the body, the arms, or the legs, it will be in vain to look for grace; and it is their being arrested in the action they may assume, at the most agreeable and expressive point of view, which gives the consummation of this invaluable quality to them. Then, if fixed for ever, they will be for ever graceful; and the delight which the contemplation of their mere beauty of form and proportion conveyed, will be heightened to the summit of that gratification which art is enabled to afford.

Wherein then lies this source of perfection? How, with certainty, may we express it in our works? is the hitherto unanswered query of the artist; or answered but in part and unsatisfactorily. All writers on painting have touched upon grace, and gone have attempted to give information of the principles whereon it rests. Lomazzo, in his Trattato della Pittura, says, that Michael Angelo gave the following precept to Marcus de Sirena, his pupil. "That he should always make a figure pyramidal, serpent-like, and multiplied by one, two, three!" In which precept (Lomazzo continues) in mine opinion the whole mystery of the art confilits. For the greatest grace and life a picture can have, is, that it expres motion. Now there is no form so fit to express motion as that of flame of fire." This text is again repeated by Du Freynoy, and thus has Dryden translated the passage: "Large flowing gliding lines, which are in waves, give not only a grace to the part, but to the whole body, as we see in the Antinous, and in many other of the antique figures. A fine figure, and its parts, ought always to have a serpent-like and flaming form; naturally, these forms of lines have I know not what of life and seeming motion in them; which very much resembles the activity of the flame and of the serpent."

On these two remarks our own industrious and skilful Hogarth has built a system, which, if it be not altogether complete, has yet much capacity and utility in it, and which he has given to the world in his Analysis of Beauty. He therein adopts the serpentine line, (which he illustrates by supposing a wire drawn spirally round a cone from its base to its apex), as the basis of grace, with much apparent truth; and he is most certainly supported by all those fine works wherein gracefulness is acknowledged to reside. The Torso of the Belvidere, the Venus de Medicis, the Apollo Belvidere, the Laocoon, who, in the midst of the violent anguish he suffereth, still possessest grace. All that is and indeed all others, which have any pretensions of the like kind, have the serpentine line for the base of their composition, in a greater or less degree. Who shall laugh at a system upheld by such authority? Walpole attempts to ridicule it, as well as others, because Hogarth was not equal to put it in practice. The futility of such an argument needs no illustration. To conceive a thing in the imagination, and not be able to exemplify it by practice, is by no means an uncommon occurrence among artists, or among men; yet the propriety of the conception may be unquestionable, taken on general grounds. Hogarth's mistake appears to have been, having fixed the boundary of grace; in giving where he said it lays the present line of it; whereas, all the antique figures mentioned above are graceful, while each varies from the other in the quantum of curve which its action contains of. Hence arises, that he too narrowed the sphere wherein grace was observable, which in nature is found to be so widely extended, that, without just confusion, his ingenuity was regarded as the ravings of excess; whilst no good arguments were adduced to disprove the general principle, which appears to us to be just. How to employ it, is another question. And here we fear no rules will suffice to guide the practitioner in art. As we said of elegance, we repeat of grace: he that is endowed by nature with a power to feel its beauties, and display its effects, may, by cultivation, improve his original stock; but he that requires to be taught what grace is, will, in vain, seek to obtain the power of painting it; if he ever arrives at the knowledge of it, or the power of feeling it, in nature or in art. A constant observation upon the actions, in figure and feature, of those who are by nature graceful, is the best school in which to study it, and the readiest mode to discern wherein it lies.

Grace is not, or rather ought not, to be confined to the figures in a composition. Every part of the picture should have a conjunctive effect to produce grace in the whole. Contrast of form will aid the beauty of the principal parts, but that contrast should never force itself into notice, the artifice would then become apparent, and the eye would not be led to the beautiful parts, but, on the contrary, be detainted from them. The painter therefore who has conceived a graceful figure, should either paint it singly, or be careful to support it, by proper accompanying lines and objects, that its beauty be not lost in the mass, and its effect overpowered by other forms of less value becoming obtrusive to the observer. And great care should be taken to prevent every attempt to produce grace in the action of figures, from degenerating into affectation. Where that begins, grace ends; and detestation or ridicule, instead of admiration, becomes the meed of the artifize! No vice in art is so odious as affectation! If the bell executed work imaginable were unhappily tainted with it, few minds of an elegant or graceful turn of feeling will bear to dwell upon it. Those artists who allow their minds to be imposed with the passion or emulation they wish to convey in their figures, and hence conceive the action of them, are not so liable to fall into this error, as those whose ideas are more intent on making an agreeable picture, and think of the actions, before they have considered the passions of their figures. Raphael is an instance of the former; Correggio and Parmigianino, of the latter.
GRACIAN, Balthasar, in Biography, an eminent Spanish writer, was born in 1603. He entered among the Jesuits at the age of sixteen, and became a teacher in their society;
GRA

Leiety, of the belles-lettres, of philosophy, and of theology. He likewise exercised the duties of a preacher, and was at length rector of the Jesuits' college of Tarragona, where he died in the year 1658. He was a much esteemed author, and most of his works have been translated into French and other foreign languages. The principal of these are "The Hero;" "Reflections on the political Conduct of Ferdinand the Catholic;" "A Treatise on the different Kinds of witty Conceptions." A work treating of the errors to which man is liable, and a collection of meditations on taking the holy communion. Morevi.

GRACIAS a Dios, in Geography, a town of Mexico, in the province of Honduras, and abode of Guatimala, situated at the mouth of a river, which communicates with the bay of Honduras. It has some gold mines in its neighbourhood. N. lat. 14° 30'. W. long. 90° 6'.—Alfo, a cape on the N. coast discovered by Columbus. N. lat. 15'. E. long. 132° 50'.—Alfo, a cape, called "Falce Cape Gracias a Dios," on the coast of Nicaragua, 63 miles from the other. N. lat. 13° 36'.

GRACILIS, in Anatomy, a muscle of the leg, thus called from its slender shape.

It arises partly tendinous, and partly fleshy, from the os pubis internally, between the first and second heads of the triceps; and in its descent on the side of the thigh, grows narrow, and becomes tendinous, a little below the bartorius, and is thus inserted into the tibia. It affords in bringing the thigh and leg forwards.

GRACILIS Retinu, a name given by Riolan to one of the muscles of the leg, called by Winflov the rectus cruris anterior, and by Couper the rectus femoris. Albius calls it the rectus cruris.

GRACULA, in Ornithology, a genus of the order Pige, having the bill convex and acute at the edges, the base rather naked; tongue entire, sharipifi, and feistiy; and the feet formed for walking. The genus gracula corresponds with the mainate of Brifon, from whom it appears to have been adopted by Linneus under the former term. Some of the species of this natural tribe were known to Ray, who refers them to the crows; and also to Wullughby, who considers them as of the flare or flaring kind. The species of gracula, described in the Gmelinian Systema Naturae, amount to twelve; and this number is increased to fourteen in the work entitled "Index Ornithologiseus" of Dr. Latham, by the addition of the new species lteropes, and the introduction of the Limmian Paradisifne trills, which latter the author of the writer has deemed it requisite to remove to this place. As a secondarily to the essential or generic character above described, it may be proper to observe that the birds of this kind have the bill thick, and compressed at the sides; the nostrils small, at the base of the bill and sometimes situated near the edge; the toes three forward and one behind, the middle toe connected at the base to the outer one, and the claws hooked and sharp. Their principal food consists of fruits and insects.

Species.

The length of this bird is ten inches and a half, its bulk equal to that of the black-bird: the bill an inch and a half long, of an orange colour tipped with yellow; the legs tawny or orange; feathers of the head, except the middle ones, very short and silky; and the naked band reaching nearly to the neck. This species is found in many parts of India, and not unfrequently in a tame or domesticated state, being naturally of a familiar disposition, and capable of being taught to whistle, sing, and imitate the articulations of the human voice with greater precision than any of the parrot tribe. In the islands of Sumatra and Java it is called by the natives bill-menaya, and in China, whether it is imported from the latter place, its common name is Teoong. Several supposed varieties of this bird are described by writers, the most remarkable of which is that called the greater minor grakle, le grand mainate of Brifon; this entirely corresponds with the ordinary kind, except in size, which it materially exceeds, being in this respect not inferior to the jackdaw; it inhabits the isle of Hainan, in Asia.

Size of the black-bird, with the head and cheeks bare of feathers and flesh-coloured, except a narrow lift of short brown feathers, extending from the base of the bill to the back of the head; the naked part becoming of a deep red when the bird is irritated: the general colour above is silvery-ash, beneath grey-brown, bill and legs brown. These birds build their nest in the hollows of trees, especially preferring those of the cocoa-nut: it is represented as a noisy flittering bird, of voracious appetite, and as living principally on fruit. Found in the Philippine islands.

FESTIVA. Black; exterior part of the quill-feathers blueish; band round the neck naked. Linn.

Native of America, in size resembling the magpie: the head with erect, short, silky feathers; nostrils oval and naked; tongue sharp; and tail even at the tip.

BARL. Somewhat grey; shoulders blue; quill-feathers at the outer edge green. Linn. Menula tota nigra, Ray. Boat-tailed grakles, Lath.

Size of the cuckow: the bill shortish, rather black, paler beneath and naked at the base; the plumage black, inclining to grey, and glossed with purple; tail rounded, concave when folded, and becoming flat on being expanded; legs and claws black. The species inhabits the AntiUy islands and North America. It feeds on insects and fruits.

CRITATELLA. Black, the first quill-feathers at the base, and tail-feathers at the tip white; bill yellow. Gmel. Merula jenevis cristata, Briff. Merle beouf de la Chine, Buff. Chinese flaring or black-bird, Edwards.

A species rather larger than the black-bird; the plumage inclining to blue, with a crest of feathers on the head which it can raise and depress at pleasure; greater quill-feathers from the base to the middle white, the remaining part deep blue; tail-feathers, except the two in the middle, tipped with white; legs dull yellow. The crested grakle fings and talks like the species religiosa, but with inferior distinctness; and is frequently kept in cages in China, which country it inhabits in a wild state; its principal food is rice, worms, and insects.

Native of Bengal. Size of the Miffel thrush, with the head, neck, breast, back, rump and upper tail-coverts black; belly, sides, thighs, and under tail-coverts white; tail even at the end, black above, and white beneath. The female differs in being black instead of brown on the fore-
part of the neck and breast, and in the white being mere obscure.

Native of the West Indies, and the warmer parts of America, and the West Indies; sings finely, builds on trees, is destructive to plantations, but useful in destroying the noxious insects that infest them. The skill is black and unavory. Its fize is about that of the black-bird, the male a little exceeding the female in bulk; the bill and legs are black; tail long and cuneated, and with the wings purple; the female entirely dusky.

**Bullock.** Greenish-blue; belly rufisy; legs blood-red. Linn. *Corrus Egyptius,* Haffele. *Egyptian grackle,* Lath. Size of a duck, and is putpowed by Hailfiequit to feed on insects, the remains of centipedes and scorpions being found in the stomach. The bill is black; neck with a longitudinal rufiy line each side, and the claws black.

**Longirostra.** Brown, beneath ochre-yellow; head and neck black; band round the neck naked and wrinkled; area of the wings white; tail cuneated, black, and at the tip white. Pallas, &c. Native of South America; length eight inches. This appears to be the same species as that described by Sornini under the name of melus des Savannes.

**Sturnina.** Hoary; spot on the crown and back between the wings violet-black; tail and wings with a tinge of green, the latter with a double white stripe. Pallas.

Inhabits the Ozie banks of Daumur; the nest and eggs resemble those of the thrush; the plumage of the female is dirty ash, with the back brown; and the wings and tail deep black.

**Icterops.** Black; band on the wings and body beneath white; the region of the eyes naked and wrinkled. Lath. *Le mainatp a face jaune,* Vieill. *Yellow faced gackle.*

Length seven inches and a half; bill compressed; nostrils oval; legs yellow and wrinkled. Native of New Holland.

**Cayanas.** Striated; above tawny, beneath yellowish; head of chin varied with tawny and white; tail wedged, fith and with the wings tawny. Gmel. *Chinking gackle.*

Inhabits the interior parts of Guiana; is about ten inches in length, and remarkable for climbing trees; the bill is black; about two inches long, and a little curved; the legs are also black.

**Caruncula.** Cinereous; tail and quill-feathers black; crown and chin with warty excrescences. Gmel.

Length six inches; and supposed to inhabit the Cape of Good Hope.

**Melanophon.** Head black, front white; back, tail, and wing-cover white; the bill with a transverse white line near the extremity. Don. *Graculus melanophthalus,* Lath. *Le mainatp a tete noire,* Vieill. *Black-headed gackle.*

A species recently discovered in New South Wales; its height is about eight inches; the bill yellow, a little bent, and formed at the base like that of the Turtls, or thrush tribe; the tail three inches long; the legs very long in proportion of a pale yellow ochre-colour, and armed with strong blackish claws.

**Virdis.** Dull green; throat above brown and blackish varied; under parts of the plumage white, with some blackish streaks; wings blackish, edged with white; tail blackish, with white tip. Don. *Graculus viridis,* Lath. *Le mainatp vert,* Vieill. *Green gackle.*

Lately found; the species inhabits New Holland, and appears to be very rare; the bill is strong, somewhat inclining at the base, and the colour of horn; the legs blackish.

**Cyanotes.** Space about the eyes bare of feathers and bright blue; head black, with a white cres in the hind part; upper part of the body, neck, upper, wings, and tail yellowish-green; breast lead-colour; plumage beneath white. Don. *Graculus cyanotis,* Lath. *Le mainatp a oreillet bleue,* Vieill. *Blue eared grackle.*

Length twelve times a half; bill black; legs blue black, with very hooked black claws. Native of New South Wales.

**Picata.** Greater part of the head, neck; transverse band on the breast, back, border of the wings, and tail above nearly to the tip black; throat, breast, wing-cover, body beneath, and under surface of the tail-feathers white. Don. *Graculus pecta,* Lath. *Le mainatp pecta,* Vieill. *Pie grackle.*

Rather larger than the black-headed gackle, and like that species inhabits the regions of Australasia; the general colour black and white, the former partially glided with purple; bill yellow, and corresponding in form with that of the black-headed gackle; and the legs lead colour.

**Graculus,** the Shagge, a species of *Pelecanus;* which fee. — Also, a species of *Corvus;* which fee.

**Gradation.** The act of ascending, step by step, to any pitch or eminence; from the Latin *gradus,* degree, step.

**Gradation,** in Architecture, signifies an artful disposition of parts, rising, as it were, by steps or degrees, after the manner of an amphitheatre; so that those placed before do no difference, but rather service, to those behind.

The painters also use the word gradation for an insensible change of colour, by the diminution of the tints and shades. See below.

**Gradation,** in Chemistry, is a kind of procés belonging to metals. It consists in gradually raising, or exciting them to a higher degree of purity and goodness, so as to increase their weight, colour, confidence, &c.

**Gradation,** in Logic, is an argumentation, consisting of four or more propositions, so disposed as that the attribute of the first is the subject of the second; and the attribute of the second is the subject of the third; and so on, till the last attribute come to be predicated of the subject of the first proposition. As in Porphyry’s tree; man is an animal; an animal is a living thing; a living thing is a body; a body is a substance; therefore man is a substance.

An argument of this kind is liable to many fallacies; both from the ambiguity of words and things; &c. Peter is a man; man is an animal; animal is a genus; genus is an universal; therefore Peter is an universal.

**Gradation,** in Painting, relates both to chiaroscuro and to colour; that is, all the different degrees in which light and dark, and colour may be modified, are comprehended in it.

An object receding from the light, and gradually losing it, becomes at its farthest extremity obscurely defined. A coloured body, pure or bright in tint, under the same circumstances, gradually diminishes in clearness of hue through out its receding parts, and becomes dull and dark. By fixing the scale of gradation in both these particulars, effects of great force or great simplicity may be produced. The scale of defcent being made rapid, great force will enue, from the strong oppositions it promotes; and the reverse will take place when the degrees of descent are prolonged, and lets contral thereby effected. The nature of the subj
The gradation of colour includes not only what is mentioned above, viz., the different degrees of purity, or brilliancy of the same colour, but also the approximations of each colour to its neighbour, necessary to produce harmony; and also the art of gradually losing the local colour in obscurity, and yet maintaining the character of it in the object; which is extremely difficult and of great importance in the art of painting.

Gradation, in Rhetoric, is when a series of considerations or proofs is brought rising by degrees, and improving each on the other. See Climax.

Such is that in Cicero to Herennius: "Africanus induit duæ virtutes, virtutis gloriae, virtutis omnium comparativit."

Gradus, Italian degrees. Every ecclesiastical mode, and every key in regular music, has its gradus, its scale; no note of which can be changed by an accidental flat, sharp, or natural, without changing the key. As in the key of F major with one flat at the clef, annul that flat by a natural, and the key is changed to C, and another flat and it modulates into B B.

Gradisca, or Gradisca, in Geography, a town of Germany, and capital of a small county, annexed with Goritz to the dominions of Austria, seated on the Lison, built in the year 1473 to stop the incursions of the Turks, additionally fortified in 1764, and erected into a bishopric in 1784; taken by the French in 1797: 5 miles S. of Goritz. N. lat. 46° 2'. E. long. 13° 27'.—Alla, a town of Schalonia, on the river Save, near the borders of Croatia, well peopled and fortified; 132 miles W. of Belgrade. N. lat. 45° 10'. E. long. 17° 50'.

Gradiello, a town of Italy, in the department of the Adda and Oglio; 8 miles S. of Brescia.

Gradista, a town of European Turkey, in Bulgaria, on the borders of Servia; 40 miles S. of Volumn.

Gradisze, a town of Walachia; 48 miles N.E. of Galatz. N. lat. 45° 23'. E. long. 27° 19'.

Graditz, a town of Bohemia, in the circle of Konigigratz; burnt by Ziska; 12 miles N. of Konigigratz.

Gradou, a small island in the gulf of Venice, near the coast of Friuli, with a town which was the first see of the Venetian patriarch. N. lat. 45°. E. long. 13° 17'.

Gradual, Gradual, was an anciently a church-book, containing divers prayers, rehearsed, or sung, after the epistle; called in some of our ancient writers gradile, graduale, graille, &c.

After reading the epistle, the chantor ascended the ambo with his gradual, and rehearsed the prayers, &c. therein; being answered by the choir; whence the name gradual, on account of the steps or degrees of the ambo.

The gradual or graille, which the provincial constitutions of archbishop Winchelsea, made at Merton, A. D. 1305, required to be in every church, was a book containing all that was to be sung by the choir at high mass; the tracts, sequences, alleluias; the creed, offertory, triumfum, and also the office for sprinkling the holy water. "Gradale fæ dictum, a gradualibus in tali libro contenti\-

It is sometimes taken for a mass-book, or part of it, instituted by pope Celestine, anno 430. See flat. 37 Hen. VI. cap. 32.

In the Romish church, gradual is an appellation still given to a verse which they sing after an epistle, and which was anciently rehearsed on the steps of the altar: though Ugutio gives us another account, and says it took its denomination gradual because sung in the gradual accent from note to note. Magri speaks differently still, and will have it to have taken its name because sung while the deacons went up the stairs to the pulpit, to sing the Gospel.

Gradual, Graduale, is also applied to the fifteen psalms, sung among the Hebrews, on the fifteen steps of the temple. Others are rather of opinion that they were thus denominated because the fingers raised their voice by degrees, from the first to the last.

Cardinal Bona, in his treatise of Divine Psalmody, says, the fifteen gradual psalms are intended to represent to the mind, that we only arrive at the perfection of good news, or holiness, by degrees. He goes on to lay down the fifteen degrees of virtue, corresponding to the fifteen psalms: five of them are for beginners; five for proficient; and the rest for the perfect.

Graduate, a person who has the degrees of any faculty: a graduate in physic, in divinity, in music, &c. See Degree, Doctor, &c.

This privilege of graduates is no older than the fifteenth century; it being observed, that men of learning were much neglected by the colleges, and patrons of churches; complaint, therefore, was made to the council of Balsh, where this decree was made; which was afterwards confirmed by the Pragmatic Sanction, and again by the Concord.

Graduation of Astronomical Instruments, is the dividing of a circle, or of some aliquot part thereof, into degrees and its sub-divisions, on the limb of any instrument that is used for measuring angles with a great degree of accuracy. (See the article Degree.) When the instrument to be graduated is of a portable size, admitting of only a small radius of curvature for the limb that is to be divided, the operation is very readily as well as accurately performed by an engine, such as Ramden's or Troughton's, the former of which we have described under the article Engine for dividing Circles, &c. but when the radius of the instrument is too large to admit of division by an engine, the task of graduat- ing, by the determination and adoption of original dividing points or lines, requires no ordinary portion of skill, manual dexterity, and perseverance to be united. Before the esta- blishment of the Royal Observatory at Greenwich, the art of graduating was in a rude state, but a desire to have this institution furnished with superior instruments of observation has stimulated the different astronomers royal, successively, to encourage the talents of superior artists from time to time, till at length such perfection is attained, that little more can now be hoped for in the improvement of our best English instruments. The history of the art of graduating astronomical instruments, and the gradual development of the most convenient and most accurate modes of proceeding, together with the difficulties to be surmounted in the various lags of progress towards perfection, will be best explained by a concise detail of each successive method of dividing, that has been practiced, agreeably to the order of time; and by remarks arising out of each detail, as they most naturally occur.

We know not sufficient of the afroaholios of Hipparchus and Ptolemy to enable us to give satisfactory account of the nature and accuracy of their divisions and sub-divisions, though it is probable that the graduated circles on them contained each 360°, agreeably to the Egyptian mode of dividing the circle. Neither can we give a very perfect de-
GRADUATION.

scription of the manner in which Copernicus, long afterwards, had his astrolabe and meridian quadrant graduated, though we have shown under our article CIRCLE that his parallactical instrument, with which his altitudes were chiefly taken, had its limb divided by equal divisions that were the subtenes of $\frac{1}{3}^\circ$. 176 each.

Tycho Brahe's instruments had the advantage of a long radius, which rendered any inequalities that might exist in his divisions of left value than they would have been in instruments of short radius: the smallest sub-divisions into which he professed to mark his spaces were to each, and the single minutes and portions of a minute, even to 15" and 10", were indicated by triangular diagonals; but with what degree of precision the sub-divisions were effected, and what dependence could be placed on his diagonals, as to accuracy, at this distance of time, it is not an easy matter to ascertain: it is recorded, however, that the operation of graduating his instruments was performed by his own manual labour.

And what we have here said of the instruments of Tycho Brahe, is equally true of the machina celestis of Hevelius; whatever accuracy his apparatus possessed, was the result of his own perceiving industry, but we are not aware that his methods of proceeding have been particularly detailed.

In Dr. Hook's Animadversions on the Machina Celestis of Hevelius, 1674, this very ingenious mechanist has published an account of his method of racking the exterior edge of the limb of his quadrant, as performed by Tampion, which method, he says, "does not at all depend upon the care and diligence of the instrument-maker, in dividing, graving, or numbering the divisions, for the same screw makes it from end to end." But, as Smeaton has very properly observed, this inventive contriver has not given his reader any precautions or particular directions how the perfection of the screw is to be ensured, or how the notches of the rack work are to be rendered perfectly equal among themselves, notwithstanding the unequal densities, and hardness of different portions of the metal to racked. The difficulties alluded to here, were acknowledged by the due de Chaun. in a memoir of the Royal Academy of Sciences at Paris, published in the year 1765. The doctor called the account of his method, "an explanation of the new way of dividing," and as an original invention that may probably be called his own, though the want of a perfect screw, with intervals exactly proportioned to the effective radius of his quadrant, was a source of error, that posterior contrivances were required to remedy. See Engine (by Ramdten) for cutting the screws of the circular dividing engine.

The use of Dr. Hook's screw for racking the limb of an astronomical instrument was not, however, abandoned, without a fair trial of its accuracy in reading the quantity of the angles so measured; for Flamsteed, or (Flamsteed), on his appointment to the Royal Observatory in 1676, employed Tampion to construct him a sextant of six feet nine and a quarter inches radius, at the expense of Jonas Moore, with an endless screw of seventeen threads per inch, acting on the racked edge of the limb, and with telescopic sights, which had not been before used: the result of this trial was, that some shake took place in the notches, that were worn by the screw, and frequently an error of a whole minute in reading another observation was unavoidably produced thereby. To remedy this evil, in the following year degree spaces, with diagonal divisions to read to the accuracy of 16", were added as a check on the measures of the screw, and a column, to contain the check angle by diagonal lines, was filled up from the 11th of September of the year 1677. These additions, it appears, from the Prolegomena of the Historia Celestis, were inferred by Flamsteed himself, and a companion of the screw with the diagonals proved that an error of as much as one minute was frequently the result of the reading by the screw. In an observation of the moon, taken on the 9th of June 1677, Smeaton says, that on looking over the observations, he detected an error of 55', which, upon a radius of six feet nine inches, he calculated amounts to more than $\frac{1}{3}$ th part of an inch. The screw, however, was useful for giving a regular flow motion to the telescopic sights, and though an accurate measure of a large arc, was soon abandoned in astronomical instruments, it has been retained as an excellent mode of producing a flow motion, by the aid of a tapped clamping piece, and has been applied with great success to the limb of a dividing engine, which, being a complete circle, admits of equalization of the contiguous notches, by a long continued simultaneous action of several threads of a very perfect screw, carried many times all round the circle, when the exact situations of distant notches have been asured by the checks afforded by accurate divisions, previously made on its plane.

Notwithstanding what we have above said of the imperfect measurement of an angle by the screw, it was not relinquished without another trial in Flamsteed's time, by Abraham Sharp, his amanuensis, to whose skill and dexterity in manual operations of a mechanical nature both Flamsteed and Smeaton have borne ample testimony: the letter of which Sharp says, "I look upon Mr. Sharp to have been the first perfom that cut accurate and delicate divisions upon astronomical instruments." The instrument at which Sharp laboured, and to which he applied the screw in conjunction with the diagonals of the divided spaces, in 1689, was the mural arc at Greenwich, of which the radius is six feet seven inches and a half. "But yet," says Smeaton, in his paper on this subject, read November 17, 1785, at the Royal Society's room, "whoever compares the different parts of the tables for conversion of the revolutions, and parts of the screw belonging to the mural arc into degrees, minutes, and seconds, with each other, at the same distance from the zenith on different sides, and with their halves, quarters, &c. will find as notable a disagreement of the screw-work from the hand-divisions, as had appeared before in the work of Mr. Tomson, and hence we may conclude, that the method of Dr. Hook, being executed by two such masterly hands as Tampion and Sharp, and found defective, is in reality not to be depended on in nice matters."

This inference of Smeaton obviously implies, that what he calls the hand-divisions of the mural arc, are more accurate than the readings by the screw alone; but, as he has given no other test of the accuracy of these hand-divisions, nor has explained by what process they were inferred, the more legitimate inference would have been, that either the screw, or the hand-divisions may be faulty, or both may be so in their respective degrees. It is to be regretted that Sharp, who was a mathematician as well as a mechanist, has not published the method he adopted of marking out and cutting his dividing lines, which is more immediately the subject of our present article. Had he made his hand-divisions first, and checked his notches, made by the screw, thereby, as Ramden did with his engine afterwards, his measures by the screw would have been more perfect, though the centre-work might have been liable to be called by too much pressure of the screw against the notched edge of the instrument, when frequently used.

Nearly about the time that the mural arc was fixed at Greenwich, Olaus Roemer, the Danish astronomer, supplied his domestic observatory with an instrument that had divisions and telescopic sights moving in the meridian, by means of a long axis, common to both the divided arc and telecope, which
which therefore admitted of better adjustment for the vertical motion than the mural arc was capable of; and which may be considered as the first transit instrument that properly deserves such a name. In dividing his arc, Mr. Roemer dis-regarded the total length, with respect to an exact number of degrees, and looked more particularly to the equality of the divisions, which were convertible into degrees and minutes, by a table calculated for this purpose. The method he made choice of, for rendering his divisions equal, was to begin at one end of his arc, and to proceed by flipp ing, and by marking the dividing points with a proper prefix at each step, till the whole arc was finished; for this purpose he did not depend on a pair of dividers, however strong their legs were, but two line pointed pieces of strong tempered steel were tied, or otherwise fixed together in such a way, that the distance between the two points was 4th or 5th of an inch, and the radius of the arc to be divided was so proportioned, from 2½ to 3 feet, that this distance made a space very nearly equal to 1°; whether exactly so, or not, did not signify, as the difference was allowed for by the calculated table, when an angle had been read by the divided spaces as numbered. It is easy to conceive that this mode of measuring an angle would be as accurate as any other, after the due allowance was made, provided the spaces were perfectly equal to each other; but the theory of this method is more perfect than the practice; for none of the mixed metals is so perfectly uniform in its density, and so free from hard particles, occasionally met with in the flipp ing points, as to ensure the perfect equality of the divided spaces, however carefully the flipp ing points are prefixed in a vertical direction; the smallest deviation on making the first impulsion becomes greater by prehure, and an attempt to rectify any erroneous points can never be depended upon: but, what is worst, every individual deviation from perfect equality is charged on the whole arc, which therefore will be either longer or shorter than the true length, by the aggregate of all the positive, or negative quantities, that predominate in the inequalities of the individual spaces thus divided; and the longer the arc is from the first point, when any angle is measured, the greater is the error of the measurement in all probability, because the greater is the probable aggregate of the deviations from perfect equality in the spaces. The total arc thus divided was about 75°, but Roemer applied no correction to the errors of the distant divisions of this arc, no dependence could be placed on the result of the readings, even when converted into degrees and minutes by his table, which supposed the arc perfectly divided.

The next ingenious artizan who distinguished himself in the art of graduating almanacical instruments, was the celebrated Graham. At the appointment of Dr. Halley to the Royal Observatory of Greenwich, Flamstead's instruments were removed by his executors, and in the year 1725, Graham undertook the construction of a new mural quadrant, which remains as a flaiming proof of his skill, to this day, in the said observatory. This artizan availed himself of every contrivance that had been practised by his predecessors, and invented such a strong, and, at the same time, light method of contriving the frame-work of the iron quadrant, constructed by Jonathan Sisson, as evinced his superior knowledge of mechanics, as well as Sisson's precision in the workmanship. The diagonals were now rejected, as being incapable of being read by a fiducial edge with requisite exactness, and the vernier scale was substituted as much preferable in this respect, and the beam-compas, with equal advantage, was substituted for the rule and dividing knife, which were liable to considerable parallax, notwithstanding the greatest precaution taken in drawing the dividing lines, or in marking the dividing points. The screw for slow motion was also used for dividing the vernier scale in a proper way, after its value was ascertained; and its perfection was insured, with respect to the due inclination of its thread all round, as well as to the equality of their spaces: and hereby, in order that the advantage of continual division might be introduced as a check on the degree spaces, the quadrant was divided in 56 spaces, with sub-divisions, in a separate arc; and the readings from the 96th arc were a constant check of the readings by the 90°, when converted into degrees and minutes by calculation, or by a table used for that purpose.

As it is not our intention to describe here the structure of Graham's quadrant, but merely to describe his method of graduating the limb of French, which was laid over the iron frame, we shall satisfy ourselves by stating that two separate arches were struck by a beam-compas, secured from bending by several brassing pieces; the respective radii of which were 96.85, and 95.84 inches. The inner arch was divided into exact degrees, and twelfth parts of a degree, or spaces; but the outer one was divided, as we have said, into 55 equal parts, and each of these again sub-divided into 16 equal parts, so that the sub-divisions were to each other as 1082: 1536, or in smaller number, as 25: 32. To convey to the reader an idea how the arcs were divided, suppose the quadrant to be represented by fig. 1, of Plate XVIII. of Astronomical Instruments, and that the occult line a b d be required to be divided into degrees by points inferred thereon, as centres for cutting the dividing lines from; the known property of the circle, that the chord of sixty degrees is always equal to the radius, afforded the means of laying down the total arc of 90° in the first place; thus, from the point a, or zero of the arc, the point b was marked by measurement of the fame points of the beam-compas unaltered, that struck the occult line; and this arc of 60° was bisected at c by an extent nearly equal to the chord of 30° from the points a and b respectively; the extent, however, being a trifle less than the chord of 30°, the two sweeps did not intersect each other, but approached so nearly together, that the small space between the sweeping lines was bisected by a point put in by hand, by the assistance of a magnificent eye-glass: the distance of this point c from a or from b being the chord of 30°, was laid along the limb from b to d, the extreme point of the whole arc of 90° and when this operation was so carefully performed, that the arcs a c, c b, and b d were precisely of the same length, when compared with each other, the total arc might safely be depended on, as being of its true dimensions. During this nice operation, it was prejudiced, that the length of the dividing beam had not altered by any variation of temperature. The next step was to bisect each of those three arcs of 30° into fix of 15° each, in the same manner as a b, the arc of 60° was bisected into c and c b: but the arc of 15° were not divisible into a lower number than three parts of each 5°; in order to tripurate each arc of 15°, a separate arc was used, as an arc of trial, defribed from the original radius unaltered, and 15° were transferred to it, and divided by trial till one-third of it was ascertained to measure exactly the distance between the two points of the compas; this distance was then laid off each way from each of the foregoing points of the arcs of 15°, and the second space of each being found equal to their contiguous first and third spaces thus measured, the whole arc was sub-divided into 18 equal arcs of 5° each; in the same manner, a fifth part of one of the arcs of 5°, first transferred upon another part of the arc of trial, was ascertained by repeated adjustments and examinations, and then inserted within the divisions of the arc.
divided arc, by turning the points over twice each way, from every point already laid down, and then the middle space of each five being found equal to the extreme as well as contiguous spaces respectively, the whole arc was subdivided into points of one degree of distance from each other. But to ensure a perfect equality among these spaces required great steadiness of hand, as well as observation of the eye, and caution, to preserve the regular distances of the points, unaltered during the operation. Of course, the marking point was required to be fine, and at the same time well tempered, as well as strong enough to bear pressure, which preface was also necessary to be made in a perpendicular direction on the face of the limb. The sub-divisions of the degree spaces into 12 parts of 5' each, were done first by trisecting, and then by bisection, or \( \text{vide vero} \), in the manner we have already described; and the delity of these operations, on so small a scale, required extraordinary attention and care to ensure perfect equality among the smallest sub-divisions, which were now in a plate to be transferred by lines tending to the centre of the arc to be graduated. This was an operation that could not be done well by the straight edge of the scale, and a marking point, or dividing knife that would be liable to deviate a little, notwithstanding the greatest care; here another, but smaller beam-compasses was sublitted for the ruler, probably for the first time, for the purpose of transferring the graduated points from the occult arc into the arc to be graduated, in the following manner: suppose the points \( g \) and \( h \) to be intended to be transferred; because the lines to be cut, as the dividing lines, are required to be in a direction tending directly towards the centre \( o \) of the concentric arcs, described on the limb; the distance of the cutting point, from the stationary point of the compasses, was taken of such a length, that the cutting point crossed the arc to be cut at right angles; or, in other words, the beam was so situated, as to become a tangent to the arc to be cut; therefore the distance of the two points of the beam was regulated by the distance of the occult line of dots \( a, b, d \), from the arc to be graduated by the straight lines, or rather by the curved lines, which in fact were subdivided, and which passed without sensible error, for straight lines, when the tangent line in question was long. From the point or dot \( g \), the curve \( h \) was drawn, and from the dot \( g \) the curve \( j \) was drawn, but in such a way that a small portion only of each, that lies between the curvilinear lines, was cut on the face of the instrument. In the same manner all the other dots were successively transferred, while each representative of the numerals 5, 10, 15, &c., were made longer than their intermediate lines of division, and the sub-dividing lines were again still shorter. The vernier carried by the telescope, when nicely and accurately divided, would detect any inaccuracy in the sub-divisions thus transferred, by the aid of a magnifier properly adjusted.

The arc of 96 divisions, with their sub-divisions, was not, properly speaking, graduated, but divided and sub-division into portions of smaller value than degrees, and 5' spaces; but as the number chosen is divisible continually by the number two, it was completed by continual bifections, which method therefore requires no further explanation. We are told by Dr. Smith (in his Optics) that these two arcs were never found to differ from each other more than 5" or 6' on any part of the limb, but that when there is such difference, the preference ought to be given to the bifected arc of 96 divisions.

To prove that the spaces obtained by the lines of transfer are equal to those between the corresponding dots or points, let \( e f \) and \( g b \) be joined, also \( e f, o b, o e, \) and \( o g \); and the triangles \( e f, o b, \) will be very nearly similar, and equal to each other; therefore, if the common angle \( e o b \) be taken away from the equal angles \( e o f, g o b, \) the angles \( e o g \) and \( o e b \), that remain, will also be equal to each other.

It does not appear that Graham took any measures to guard against, or even to detect the errors that his method of dividing is liable to, from variations of temperature in his quadrant and beam, during the time that the operation is going on, and from the corresponding variations of length in the metals, according to their respective expansibilities: nor is it quite certain that he was aware of the probable extent of such errors, seeing he constructed the frame-work of his instruments of iron, and had his circle to be divided of brafs. In Dr. Bradley’s zenith sector made by Graham, Dr. Mathewson has caused an iron limb to be subdivided for the original brafs one, and has laid the points of division inferted on itsd of gold, to avoid the errors that arose from the unequal expansibility of the different metals.

We might here mention Mr. H. Hindley’s plan of dividing a circle by a toothed circular plate and endlets ferew in form of an engine, about the year 1746, but that we think his method of dividing and drilling the holes of his plate, by heading a straight flinder bar of brafs into a circle and transferring the holes therfrom, cannot be depended on where much accuracy is required in the divisions of a circle. It was originally intended, and is much better calculated, for dividing and cutting the notches between the teeth of a wheel; but the reader may see the plan described, and some improvements on it propoed by Smewton, in his paper already mentioned, as contained in the Philosophical Transactions of London, in the year 1785.

Jeremiah, the son of Jonathan Sifton, was of Graham’s school of dividing, and did nearly as much justice to the method he adopted, as Graham himself, probably; and his nice care, and persevering almosity, have chiefly him among the few dividers of his time; but we are not aware that he was the inventor of any original contrivance, except, perhaps, that he applied a triple index to some of his instruments, one of which had the vernier, and each of the others had a single line or frorke drawn at onethird of a circle from each other, and from zero of the vernier, which might act as a check on the eccentricity of the circle, as well as on the inequality of its divisions; though it does not appear certain that this was the original intention, as the three props of his vernier-bar in his theodolites required it to be triple; but in his circular indexes one frorke only was made, and that opposive the vernier: the importance of a triple vernier has not been noticed particularly by any one, previously to the time of Mr. Ed. Troughton’s introduction of the triple vernier into his circular instruments. Mr. Ludlam, however, says, that Sifton very early rejected the method of trisecting, and that of fpleving too. Having (by means of the radius and infinituons only) divided his quadrant into three arches of 30 each, he let off in each of these arches the chord of 21° 25', or 25° times five minutes. This chord was taken off 5 a scale of equal parts, and was checked by the chord of 8° 45', both chords together filling up the arch of 30°. The arch of 21° 25' was divided by continual bifections into arches of five minutes each. This description, says Mr. Ludlam, in a note to page 4, of his Introduction and Notes on Mr. Bird’s method of dividing, was given by Jeremiah Sifton, in a private letter dated May 20, 1766; and according to the same letter it appears also, that Sifton placed the fixed or central point of his compass in a blank tangent line, as hereafter described by Bird, during the operation of transferring the divided points into linear divisions; but as Bird has in the year 1767 published these proceedes as originally his own, and as he worked for the Siffons previously to 1766, we are disposed to consider Bird, and not
either of the Siflons, as the real contriver of the methods here adverted to. Siflon (the younger) rejected the arc of 96, as being only a help to a bad divider; but Bird used to retort on him, by saying, that good dividing was not afraid of such a tell of its accuracy.

It is the characteristic of a great genius in mechanics, not to tread too closely in the steps of his predecessor, but, availing himself of any hints that may have been presented to him, to mark out a more direct and even path for himself, that shall throw in his way fewer obstacles to impede his progress. This was the case with Mr. Bird, who, having been brought up a cloth-weaver in the county of Durham, and having noticed some very coarse divisions on the face of a clock that fell in his way, immediately set about dividing one himself, in a much neater manner, and was so pleased with his success, that in the year 1740 he came to London, and was in business for himself as an instrument-maker, only five years afterwards. After having made himself acquainted with the methods at that time in use of dividing a circle, he saw that no one had guarded against the errors produced by the effects of variable temperature on the beam of the compass, as well as on the metal of the scales and circles to be divided; he also saw that bisection of an arc had so much advantage over trisection, or qua
division. That he abandoned the latter modes of dividing altogether, and was the first probably to compute chordlines, to be taken from a good vernier (what he calls numinous) scale, by the beam-compasses, in order to determine such points in an arc of 90°, as may enable a division by continual bisection to be adopted, and at the same time such may be laid down without loss of time, or, in other words, without sensible change of atmospheric temperature.

We cannot better describe Mr. Bird's method of dividing astronomical instruments than by using his own words. "The re
quiftions," says he, "for the performance of this work are as follow: A scale of equal parts, by which the radius may be measured to 0.001 of an inch must be provided. My scale is 90 inches long, each inch divided into 10, contiguous to which are numinous (verniers) divisions, viz. 10.1 inches divided into 100 equal parts, having 0.001 of an inch, and by the assistance of a magnifying glafs, of one inch focal length, a third of 0.001 may be taken off by estimation. "Provide fine beam-compasses, to which magnifying glafes of not more than one inch focal length should be applied. Let the longest beam be sufficient to draw the arcs, and measure the radius; the 2d to measure the chord of 42° 40'; the 3d to measure the chord of 30°; the 4th, 10° 20'; the 5th, 4° 40'; and if a sixth, to measure 1°, be made use of, so much the better. "The radius of the arc of 90° at the points is equal to 95.938 inches, from which the following numbers were computed, viz. 49.605 inches = chord of 30°; 25.6343 inches = chord of 15°; 12.70947 inches = chord of 10° 20'; 7.81866 inches = chord of 4° 40'; and 69.80318 inches = chord of 42° 40'. Having drawn the several arcs, between which the divisions were to be cut, the radius and the lengths of the above chords were taken by the beam-compasses, which, together with the scale, were laid upon the quadrant, where they remained till the next morni
g; during which time the door of the room was kept locked. Before sun-rise I re-measured the radius, which required some correction; the beam being of white fir, and the scale of brass, which probably contracted, while the beam remained unaltered: the other beam-compasses also required correction. Now the quadrant and scale being of the same temperate, the faint arc b d (fig. 2, of Plate XVIII. of Astronomical Instruments,) was struck, and with a very fine prick-punch (pointil) the point a was made; with the same beam-compasses unaltered I laid off from a to r the chord of 60°, making also a fine point: with the chord of 30° a was bisefted in r. Now one point of the beam-compasses containing 60° was fixed in r, and with the other was marked the point r or 90° a mean; with the beam-compasses containing 15°, was bisefted e in a or 75°; from a was laid off the chord of 10° 20'; and from r, 4° 40'; which two last chords joined exactly in g, being the point of 85° 20': now each degree being to be divided into 10 parts, or every 5'; therefore, 85 X 12 + 4 = 1024, a number divisible by continual bisections. The last chord computed was 42° 40', with which a g was bisefted in a; o a g were bisefted by trials: but, whoever undertakes to divide a large quadrant, will do well to compute also the chord of 21° 20'; but for this chord any of the beam-compasses already provided, which will take in the length, may be used. The point g, being formed as above, I proceeded, by continual bisections, till I had the number required, viz. 1024. To fill up the space between g and r, containing 56 divisions, the chord of 64 divisions was laid off from g towards d, and divided like the rest by continual bisections; as was also from a towards b. The points 52°, 69°, 75°, and 90°, fell in without any sensible inequality. "The method which will suffice for giving a general idea of Bird's proceedings, in dividing his aстрonomical instruments; but his method of transferring the divided points into dividing lines was equally original, and guardian also against errors that might arise from the handling of the beam during the operation, by variable temperature; before, however, we proceed to detail this process, it may be proper to observe, that the points made on the faint circle were infected by a pointil, or piece of steel-wire, with a conical point made fall into a piece of cylindrical bras rounded at the upper end: the fleel part was 1/4 of an inch thick, and 2/3d of an inch long, and the bras part 2 3/10 long, and 3/8 of an inch in diameter. The angle of the steel conical point was from 20° to 25°, and the point somewhat above a spring temper, fo that the point made in the circle did not exceed 0.001 of an inch; as it was sharpened on an oil-bone while turning round, and while drawn in a direction outwards from the point itself, the surface partook of the nature of a counter-funk, and, as it were, drilled a diminutive hole of a conical shape when gently pressed on, as it revolved in the point of bisection, which point, by reason of the four angular bars made by the intersecting lines, could be felt as well as seen. The points of the beam-compasses were never made to approach nearer to each other than two or three inches, but at the ends of the arcs spring dividers, with conical points, were substituted to measure small arcs. Another precaution was, that in all bisections, the place to be pointed was laid off from left to right, and then from right to left, from the respective central points. "As the maxim, "that an arc may be bisefted, but not practically trifected or qua\ndisected with certainty," was the maxim adopted by Bird, when he introduced the use of his scale for measuring the chords, so the maxim, "that a right line cannot be cut on bras, so accurately as to pass through two given points, but that a circle may be described from any centre, to pass accurately through a given point," was taken up by him when he adopted the beam-compasses, as Graham and Siflon had done, for cutting the small portions of a circle, instead of perfectly straight lines, as boundaries of the divisions. His plan of doing this, however, was new, as it may be seen from his own words. "The next step," says he, "is to cut the linear divisions from
from the points: the best instrument for this purpose is the beam-compas, having both its points conical and very sharp. Draw a tangent to the arc $bd$, suppose at $r$, it will intercept the arc $xy$ in $g$, this will be the distance between the points of the beam-compas to cut the divisions (nearly) at right angles to the arc $bd$. Lodge that point of the beam-compas next your right hand, in the point $r$, let the other fall freely into the arc $xy$; press gently with your finger upon the fcrew-head that takes the socket (and that is convex), and with the point towards the right hand cut the divisions. In this manner you must proceed with the rest."

The intention of transferring the central or settings point of the compas into a blank tangential line, instead of sufferling the faid point to reft in the respective points made in the faint arc, is, that in the former case shou'd any alteration take place in the length of the beam, during the operation of cutting, no error is charged on the divisions cut, but the alteration is compensated by the distance of the newly made point in the tangential line from the cutting point; that is, each division is charged only with such a minute error, if any, as arises from temperature during the act of cutting a single froke, and if one of the points should break, another may be replaced without inconvenience; whereas, by the method of Graham, a broken point produces considerable difficulty; and the whole error arising from temperature, during the whole process of cutting all the divisions, is charged not only on the total arc, but likewise in a certain undefined degree on each of the whole divisions. This idea of getting quit of the effects of temperature is ingenious, but has been objected to as liable to the ill effects of flapping in a certain degree, inasmuch as that a hard particle, lying under the point of the froke, may cause a little deviation in the divisions before the froke is cut. This objection, however, was not allowed to be realized by Bird, who no doubt must have obviated it by some other plan, had he found any real inconvenience arising from it. Great care, notwithstanding, must have been taken in fettling down, and prefing on the point at the froke in a perpendicular direction. Another objection applied to Mr. Bird's scale, from which the chord-lines were measured, inasmuch as the scale itself might be erroneous in fome places, and would impart its errors to the arcs measured from the computed chords taken therefrom.

Besides the arc of 90°, the mural arc by Bird had an arc of 90° divifions, like Graham's, divided by continual bifects, till each of the 90° divifions had 16 sub-divifions, as a check on the accuracy of the arc of degrees; but subsequent divifors of astronomical instruments have found this superfluous, as being in the opinion of others, as well as Jeremiah Sifton, a check only on bad dividing, and as rendering the reduction of observations troublesome, when made thereby.

The vernier was retained by Bird as the best method he knew of sub-dividing the 5′ spaces into quantities of 30″ each, which was the smallest angle he profefled to measure; and to effect his purpose he made ten divisions on his vernier equal to eleven on the limb of the instrument, firit by computing the chord of thirty-two parts, and then by taking ten out of those parts, when bifected, as the proper divifors for the vernier; there, being made in points, were also transferred by a tangential line into linear divifions by the beam-compas, as before deferibed; but great care was taken, that the froke zero on the vernier was drawn from the quadrant's centre, precifely parallel to the line of collimation of the telecope. Mr. Ludlam fays, that the cutting-point which Sifton used was flat in the knife-edge form, but that Bird's was a triangular prism, with a flope ground down to a point at one of the angles; which formed the cutting-point.

At the requell of the commiffioners of the Board of Longitude, Mr. Bird, in the year 1767, published his method of dividing in a quarto pamphlet, for which they rewarded him with 500L. besides 65L. for his plates, after having bound them to confull an expenditure of five years in the art of constructing and dividing astronomical instruments.

Mr. Sweaton is of opinion that Bird's method of dividing may be improved in one repect, and expresses himfelf on the fubjeft thus: "I muft here obferve that I apprehend no quadrant, that has ever undergone a severe examination, has been found to form a perfect arch of 90°, nor is it at all neceffary it should; the perfect equality of the divifions throughout the whole is the firft and primary consideration; as the proportion of error, when ascertained by proper obfervations, can be as easily and readily applied when the whole error of the rectangle is fifteen feconds, as when it is but five. In this view, from the radius taken, I would compute the chord of 16′ only. If I had an excellent plain fcale, I would ufe it, because I fhould expect the deviation from the right angle to be lefs than if taken from a fcale of more moderate accuracy; but if not, the equality of the divifions would not be afcertained, though taken from any common diagonal fcale. This chord, so prepared, I would lay off five times in succession, from the primary point of 0 given, which would compleat 90°; I would then bifect each of thoae arches of 16′, as prefcribed by Mr. Bird, and laying off one of them beyond the 80th, would give the 88th degree, proceeding then by bifection, till I came to an arch of 2′, laying that off from the 88th degree, would give the point of 90°. Proceeding still by bifection, till I had reduced the degrees into quarters of 15′ each, I would there flop, as from experience I know that when divifions are over clofe, the accuracy of them, even by bifects, cannot be fo well attained, as where they are moderately large. If a space of 2′ths of an inch, which is a quarter of a degree, upon an eight feet radius, is thought too large an interval to draw the index over by the micro-meter fcrew, this may be shortened by placing another line, at the divifion of one-third of a division on each side of the index line, in which cafe the fcrew will never have to move the index plate more than one-third of a division, or 5′, and the perfect equality of thofe index lines from the index line may be obferved, and adjusted to 5′ precisely, by putting each of the fide lines upon a little plate, capable of adjufment to its true divifion from the middle one, by an adjufing fcrew. The above hint is not confined to the chord of 16′, which prohibits the sub-divifion going lower than 15′; for if it be required to have divifions equivalent to 5′ upon the limb itself, then I would compute the chord of 21 20′ only; and laying it off four times from the primary point, the limit would mark out the divifion 85′ 20′; pointed out by Mr. Bird, supplying the remainder to a quadrant from the bifected divifions as they arise, and not by the application of other computed chords." Mr. Sweaton, fufficiently, however, that this method of laying 16 five times over, or 21 20′ four times over, may be objected to, as liable to the errors of biflapping, arising from Römer's method, afterwards proposed to lay down the chord of 64′, or of 85′ 20′, from computation all at once, and then to bifect, and complete the quadrant from the bifected divifions, which Mr. Bird himfelf prefcribed as a good method for Hadley's extants and octants. But thefe plans are nowuperfeded for instruments of small radius by the dividing engines, which performs the work with great expedition, as well as accuracy, and the original methods of dividing the circle are only useful for the larger
larger instruments, and for the finishing of the dividing engines themselves.

In the year after Mr. Bird had published an account of his method of dividing astronomical instruments, the duc de Chaumnes printed in French a folio work, entitled "Nouvelle methode pour diviser les instrumens de Mathematique et d'Astronomie," and also a work proper to be bound with the former, called "Description d'un Microscope et de differens Micrometres determines a mesurer des parties circulaire du droites avec la plus grande precision." The former of these pamphlets contains 15 plates, and the latter fix, which exhibit plans and drawings in different points of view of all the apparatus, both in pieces and together; these are not necessary to be copied by us, but we will desribe them as far as they fall within our present purpoise. This new method of dividing is performed by the affillance of compound microscopes, with crofs hairs in the focus of the eye-glafs of each, to be fixed to the circle to be divided in any given situation, and of moveable pieces of brafs with fine dividing lines marked thereon, which may be so fixed with wax, as to be adjustable to the point of interfection in the focus of any of the microscopes, and when duly adjusted, a dividing pointil, moving in a complex frame of brafs, cuts the line, on the circle to be divided, that shall correspond to the point of the circle where the adjustable division is fixed; though the line cut is not in the fame part of the circle. As this method may be considered as the ground-work of Rawlifs method of dividing a large circle, and has not, that we know of, been translated into our language, we will give the substance of that part of the work which more immediately relates to our present subjeft, without following the author through all his minute details. The circle, which the duc de Chaumnes proposes to divide by his original method, is the table of his dividing engine, but as it is equally applicable to any circle that may be fixed concentrically on it, we will fuppole it an astronomical circle for altitudes or azimuths that is to be divided by his method. In the firft place, he propofes to have from 30 to 40 thin pieces of smooth brafs about one-third of an inch long, and one-sixth broad, having each a fine stroke drawn acrofs, perpendicular to the long fides and just deep enough to be been; and secondly, three compound microscopes are to be provided, one to be fixed diametrically oppofite the pointil, or cutting point, that is carried in and out, i.e. towards and from the centre of the circle by an adjustable frame, and the other two are adjustable to any given points along the plane of the circle to be divided. When the circular lines are struck on, the adjustable microscopes, which we will call A and B, are placed as oppofite to each other, in a diametrical line, as can be gufed, or roughly measured by any of the ordinary means, and a moveable division on a piece of brafs already defcribed, is put by means of wax under each of the two microscopes, and moved by hand, till the lines, which must be in a radial direction, fall respectively under the centres or interfection points of the fields of view; these microscopes, it muft be understood, are fixed, not on the table which bears the circle, and which is made fo as to re- volve on a long vertical axis, but on a fixed or stationary frame, that is unconnected with the table itself, when the table is at liberty to revolve; suppose now the table and circle on it to be carried half round, while the microscopes remain fixed, in such a way that the moveable division which was under the microscope A, falls under the centre of microscope B; in this situation, if the moveable division falls under the centre of A, the circle is truly bi-fected; but as this is not likely to be the cafe at the firft trial, the quantity that is over or short must be adjusted, one half by the moveable division, and the other by the mi croscope, and the operation of reverting muft be repeated, and the refifitions made, till the circle is found to be truly bi fectioned, both backwards and forwards, by the coincidence of the divisions with the interfection points in each focus of the microscopes. The two microscopes A and B may now be removed, and the third or fixed microscope must be made fast over one of thefe two dividing strokes, after the pointil has been brought precisely to occupy the place of the other, in which situation the pointil and the fixed microscope will f品格 to diametrically oppofite each other, that whenever an available line is brought to bi-fect the field of view of this microscope, the pointil will be ready to cut a line on the opposite fide of the circle, and whenever a fet of adjuilable divisions are properly placed, by the wax, on one femi-circle, the lines in the other femi-circle, directly oppofite thefe re- spectively, can be permanently cut, before the moveable pieces are taken off, and afterwards the faid lines for cut may be brought fuccefsively under the fixed microscope, in order that their oppofites, where the moveable pieces were ftruck on, may, in like manner, be cut; fo that one-half of the circle will be fufficient to be divided and sub-divided by the adjustable pieces, feeing that each of its divisions and sub-divisions, brought in fucceffion under the fixed microscope, may be ini- niately transferred by the pointil, into the oppofite femi-circle, and also thefe in their turn transferred back again. Let us now fee how the femi-circle is divided and sub-divided by means of the two microscopes A and the fixed one, B being no longer wanted; the furf operation is the tritction of it into arcs of each 60°; for this purpoife, while the pointil remains at T, (fig. 3. of Plate XVII.) one of the points cut, viz. at 180°, and the fixed microscope rests at Z, or zero, i.e. the firft point of the circle, to be f变得 0 or 360°; two moveable pieces are ftracted on at C and D reprefeftively, fo as to tritect the femi-circle Z B T very nearly, and the microfcope A is placed directly over C, fo as to view it; stroke or line at the point of interfection in the focus of the eye-glafs; there it is made falt for the prefent; the line C is now brought under the fixed microfcope at zero, by making the circle revolve, and fuffered to remain; the piece D has its stroke put under the microfcope A, as before was the cafe with piece C, now at zero; the circle is again made to re- volve till the froke of D is under the fixed microfcope at zero; in this situation the point T, or 180°, will have been brought forward 120°, or 60° twice over; provided the pieces C and D were truly placed, and in this cafe an eye, looking into the microfcope A, will fée this dividing line bi-fect the field of view; but as this is not likely to happen at the firl trial, the microfcope must be moved one third of the error now fiewn, and each of the pieces C and D another third, accordingly as the portions of the femi-circles Z C, C D, and D T taken together, are found to be more or lefs than an exact femi-circle. The operation we have defcribed is repeated again and again, till the three equidiftant arcs amount to an exact femi-circle; after which they are rendered permanent, by strokes made fucceffively on the oppofite femi-circle, at the points z and l/, which trit- fect the femi-circle T A Z, when the adjuilable strokes C and D are in fucceffion exactly fixed in the centre of the field of view of the fixed microfcope. The distance between the two microscopes, which is here 60°, is called the opening of the microscopes, which are considered as the two points of a pair of dividers, and the arc between them is therefore denominated accordingly.

The next step is to bi-fect the arcs of 60° each, into two of 30°, by an opening of 30°; to do this one moveable piece, ftruck at the middle of each arc of 60°, will be requisite, and the
the two halves, to the right and left of each piece, may be examined and adjusted till the bisections are complete, and in a flate to be transferred into the opposite semi-circle; for instance, suppose the arc of 60° from Z to C to be biseected, put a moveable stroke at 30°, more or less, and place the microscope A over it; make the table and circle revolve till this stroke 30° falls under the fixed microscope B; in that situation, the whole space ought to be biseected the field of view of microscope A, and whatever the deviation may be, plus or minus, it must be adjusted by trial, partly by moving the microscope A, and partly by moving the piece with the stroke on at 30°, when brought back again under the microscope A. In the same way, any other bisection may be made within the possible opening of the microscopes. Again, the arcs of 30° are trisected, as before described, into arcs of 10°, which are all transferred into the opposite semi-circle in succession.

With respect to the division of the arcs into smaller quantities than those of 10°, where the microscopes approach too near together to admit of the necessary adjustments, an ingenious mode of sub-dividing is adopted by a property of the number 9, thus: having all the arcs of 10° in the semi-circle laid down, the points 90° and 108° are of course among them, and these are divisible by 9, an opening of nine degrees is taken by trial, which repeated ten times, by means of the moveable strokes, will reach from 0 to 90°, when properly adjusted; besides the 10°, 20°, 30°, &c. there will now be 9°, 18°, 27°, &c. up to 90°, and also 99°, 108°, 117°, &c. up to 180°, and the differences of spaces left as the divisions obtained from 10°, and those from 9° repeated, will be respectively 1°, 3°, 5°, &c. up to 9°; now, if the points 9°, 18°, 27°, &c. which numbers decrease by unity in the units place, be made in succession points of commencement, for the arc of 10° to be repeated from, they will from 9° produce 19°, 29°, 39°, &c.; from 18° they will give 28°, 38°, 48°, &c.; and from 27° they will give 37°, 47°, 57°, &c. and so on, till all the single degrees are put on by the arc of 10° thus applied from the points derived from 9° and its multiples. The work is performed thus: make the opening of the microscopes again 10°, by fixing the one called A at the tenth degree when zero is at the fixed one, then turn the table and superimposed circle to be divided till the stroke 9° comes to zero, then a moveable piece flack properly under A will be 19°, bring this to the fixed microscope, and the place for 29° will be had for the next stroke, under A again; and in like manner every individual degree may be marked in succession, by taking stroke ending with 8, after stroke ending with 9 have gone through; and after that, stroke ending with 7, with 6, with 5, &c. till all the numerals are included. If the circle is large enough to admit of division to 5° by the opening of the microscopes, the numbers 4 and 5 may be substituted with advantage for 9 and 10, and then the opening may be 20° for inserting them, instead of 10°, as in the mode we have described. When half degrees are required to be inserted 15° may be biseected, and the line obtained will be in the middle between 7 and 8°, from which stroke, with an opening of 15°, all the other half degrees may be marked as before, by the aid of the adjustable marks to be transferred afterwards into the opposite semi-circle, and all the strokes in that semi-circle may then be transferred back again permanently, so as to complete the circle.

The use of the numerals nine and ten, or of the four and five, is evidently borrowed from Clausius the Jesuit, whose problem for thus dividing a right line, or arc of a circle, was published in 1611.

Another method of sub-dividing the circle, when marked into degrees, as above described, is also proposed as being less tedious, and capable of carrying the sub-divisions to a lower denomination; thus, a socket is made to fit the arbor of the revolving table that carries the circle to be divided, so tight, that it will revolve with the said arbor, or without it, as the case may be. When the socket a telescope is fixed with a vertical hair in the focus of its eyepiece, that may bifect any distant mark to which it may be directed, then a long ruler, of six or seven feet in length, is divided, for instance, into twelve equal parts, so that it may be read distinctly; the distance of this ruler is so adjusted from the telescope, that when placed at right angles to the line of collimation, it may just subtend one degree, which may be first calculated nearly, and then adjusted by trial, till the run of the telescope over the twelve marks of the ruler be exactly corresponding to the run of one degree of the circle under one of the microscopes. In this situation of things, the divisions of the ruler, as seen through the telescope, are, with great care and steadiness, transferred in succession, not to one of the degree spaces itself on the circle, but to a pattern-piece of bracps, which may be afterwards fitted with the object lens of the fixed microscope, fo as to be applied in succession to each separate degree, as the circle is made to revolve, during the operation of transferring these five minute spaces, to the opposite parts of the circle, by means of the pointillr. In strictness, the ruler, viewed through the telescope, ought to be a portion of a circle; but the arc and the chord of one degree are so nearly alike, that one may be substituted for the other, without sensible error. When small circles, or parts of a circle, were propounded by the due de Chaulnes to be divided, they were fixed on the revolving arbor of the table, and the microscopes and cutting point were so arranged, that the divisions of a large divided circle were transferred to the small one in succession, and the whole apparatus, as arranged, constituted an engine for dividing; but the work could not be performed with such expedition as with our modern engines, where stops are substituted for the microscopes, and where the touch has greatly the advantage over the sight. With respect to the accuracy of the work performed by the due de Chaulnes, we are greatly inclined to believe, that the sliding mechanism of the cutting-point would not secure the strokes from having a deviating direction sometimes, arising from the necessity that the sliding parts must have had to admit of free motion, unless, indeed, the parts of action were fitted with extreme nicety.

Lastly, the vernier scale was retained by the author before us, as the belt sub-divider of the 5° spaces, or other small divisions; but he has not conceived it necessary to explain, in detail, how he proportioned it to the divisions of his circle, though it is easy to conceive how this may be done by the help of microscopes and the cutting-point. Our remark on this original method of dividing is, that it shows great ingenuity; but we conceive, that making an equality in the divided and sub-divided arcs will not always ensure perfection in the Angular measures, because the axis of motion may be out of the centre of the divided circle, and the eccentricity will neither be detected by this method, nor allowed for in the divisions and sub-divisions, unless, indeed, two or three equidistant verniers were used for taking an average of the readings from different sides of the circle. It is somewhat remarkable that the same thought that introduced the microscopes for measuring the arcs to be divided, did not substitute them for the vernier, in reading off small quantities of a sub-division when an instrument was finished; which practice was left for Mr. Ramsden afterwards to adopt. The second semi-circle, being only the copy of a
copy, renders this method of dividing less worthy of imitation, as an original method, than it would have been if the imperfections of the first portion of the circle had not been necessarily transferred to the other, and from that back again. In short, we think the wax-work might have been better employed.

The elder Troughton (Jolin) whose dividing was acknowledged to be equal to that of any of his predecessors, or contemporaries, used the beam-compasses, like Bird, but rejected the computation of chords, and the measures taken from scales, as being liable to uncertainty in determining the primary points from which the bifections were to proceed. After having described his circle, or rather quadrantal arc to be divided, he determined the point 60' with the radius, as Graham and Bird had previously done; and, having bifected it at 90°, let off 30' in addition to the 60° to complete the arc of 90°; he then bifected till he had arcs of 15°, and again till he had 75° in each division: the two marks nearest to 90° were now 82° 30' and 86° 15'; but the point 85° 20', or limit of the largest bifacional arc, lay between these two, and could not be obtained by further bifections; the space between the two marks in question was therefore trifected, and the more forward of the two new points was 85° 8'; again, the space between this mark of 85° 8' and that of 86° 15' was trifected; from which came 85° 25', as denoted by the more backward of the two new marks; and lastly, a fifth part of one of the sub-divided arcs was let backwards from 85° 25', to 85° 20', the point from which the 1024 divisions were incepted from 0 entirely by bifections. The quadrantal arc was then completed from the sub-divisions thus obtained. It may be necessary, however, to observe, that the marks at first made by the radius, bifections, triflections, &c. were none of them permitted to be permanent, being of no further use than to ascertain the individual point 85° 20', from which the subseuent biflections were to commence. This method is considered as being preferable to Bird's method of computing the chords and using the scale, inasmuch as it does not depend on secondary or auxiliary means of ascertaining the primary point in the bifacional arc. It has uniformity of means to recommend it in preference to those mixed methods that depend partly upon computation, and partly upon the extended radius.

The method of dividing a large circle, commonly known by the appellation of Ramflclin's method, or the method of drawing, confits of Bird's method, and of that proposed by the duc de Chaunlnes united: the circle is first divided by the beam-companiss into primary points; and the true situation of each of these points is ascertained by opposite microscopes, as the work proceeds, and is rectified accordingly, by pulling the points forward or backward a tripe, till they are in their true places. This method, now generally prac-
tified by all the best dividers, except the present Mr. Troughton, has not, that we know of, been very particularly described, with references to drawings, &c. though it is capable of considerable accuracy in the hands of a good workman, who has perseverance en Ens to do justice to it. The great number of points that will require to be rectified, will, notwithstanding the utmost precaution, render the work irregular in its appearance, and a circular line must necessarily pass through the centre of all the points or conical holes, to render them concentric; besides, the bifecional arcs deform the conical shape of the points, by passing through them, and the subflequent erasures must leave an unevenness in the metal that cannot but offend a nice eye.

Sir George Sluckburgh, in his paper on the equatorial, calls the points that have been enlarged by rectification, and burnished level again, "doubtful or bad points;" and these bear a considerable proportion to the whole. "It would," says Mr. Troughton, "be a great improvement of this method to divide the whole by hand at once, and afterwards to correct the whole; for a dot, forced to its place, as above, will seldom allow the compass-point to rest in the centre of its apparent area; therefore, other dots made from those will scarcely ever be found in their true places. This improvement also prevents the corrected dots from being injured or moved by the future application of the compasses, no such application being necessary."

The circle that is divided by this method is placed horizontally to have its first points made, after it has had its circle described from a revolution on its own axis, and then it is placed vertically in a frame, in which it revolves, and which carries the microscopes with micrometers, that subdivide, and read to the accuracy of one second, in order that the semi-circles, taken from any given opposite points, may have their equality ascertained, or their deviation therefrom determined previously to final rectification. In these operations great attention is paid to the temperature of the whole of the metallic parts employed in the work.

Mr. Ed. Troughton has deviated from the beaten track of his predecessors, and made a road for himself, (probably before Ramflsl's plan was adopted,) that he has trodden with great success, and which he has fully described in a paper of the Philosophical Transactions of the year 1819, which gained him Copley's medal. The reason that caused him to think for himself on this subject, as he has done successfully on many others, seems to have been this: "With as steady a hand, and as good an eye," says he, "as young men generally have, I was much disappointed at finding, that after having made two points, neat and small to my liking, I could not bifect the distance between them without enlarging, displacing, or deforming them with the points of the compasses."

This discovery led to the abandonment of the beam-compasses and ironing-dividers, and, the art of turning appearing to have approached the nearness to perfection of any of the mechanical arts, a roller was thought of, which by its revolutions might sub-divide the circumference of a circle rolled over, after the ratio of their respective diameters was ascertained and properly adjusted. When this speculation was first attempted to be realized, some circumstances occurred which could not be certainly inferred from reasoning, a priori, from known data, but of which a perfect knowledge was necessary for the consummation of the project; in the first place, it was found on trial, that however smooth the surfaces of the circle and roller were made, there was no slippery action, as might have been expected, but the points of contact acted with each other in an apparatus like that hereafter to be described, as the teeth of wheel-work of indefinitely small dimensions; the certainty of this kind of action was an indispensable condition; secondly, notwithstanding this flabbyness in the motion of the roller, it was found to measure different portions of the metallic circle with different degrees of accuracy, some of the measures being a tripe plus, and others minus, with respect to the truth: this want of accuracy, which, as we have said, did not depend on any sliding of the roller, was expected to take place previously, in a certain undefined degree, by reason of the unequal density of hammered materials, and of their consequent unequal porosity; but thirdly, though there was found to be a deviation from true measurement in indivi-

dual
dual portions of the circle; yet, when the roller was properly adjusted to measure the whole circle without a remainder, it was found to possess the desirable property of accommodating itself to the same track again, as often as the circuit was repeated, and consequently arriving at the point zero again without the least sensible deviation. This circumstance, which may be considered as a phenomenon in mechanics, reproduced the hope of success, which the want of perfect regularity in measuring the intermediate portions of the circle was calculated to discourage; and a remedy, hereafter described, was successfully employed to equalize the measurements, nay, so exactly was the course of the roller found to be identical in the same point in every part of its circuit, that, when duly adjusted for diameter, the deviation at any individual point, from the first measure, would not exceed a second. This uniformity in the mode of the roller's travelling furnished the means of correcting its own inaccuracies of measurement, seeing that these inaccuracies, once ascertained, always remained the same at the same points of the circle, provided that zero of the roller started from zero of the circle, at the commencement of its first circuit. We cannot convey an adequate conception of the mechanical application of a roller to the division and sub-division of a circular instrument, without a reference to drawings of the apparatus actually used; nor can we describe that apparatus better than in the words of the author himself. The instrument, of which he has described the graduation, is a four feet meridian circle, at present the property of Stephen Greenbridge, esq. of Blackburn.

"The surface of the circle, which is to receive the divisions," says Mr. Troughton, "as well as its inner and outer edges, but especially the latter, should be turned in the most exact and careful manner; the reason for which will be better understood when we come to describe the mode of applying the roller: and as no projection can be admitted beyond the limb, if the telecope, as is generally the case, be longer than the diameter, those parts which extend further must be so applied, that they may be removed during the operation of dividing." Plates XIX. and XX. of Astronomical Instruments exhibit the principal parts of the apparatus; fig. 1 shows the plan, and fig. 4, the elevation of the revolving parts of the mechanism, in both of which the name letters of reference are affixed to corresponding parts, and both are drawn to a scale of half dimensions. A A is a part of the circle, the surface of which is seen in the plan, and the edge in the elevation. B B B is the main plate of the apparatus, reposing with its four feet A A A A, upon the surface of the arc; these feet, being fixed, may be adjusted so as to take equal shares of the weight, and then are flattened by nuts below the plates, as shown in fig. 4. C C and D D are two similar plates, each attached to the main plate, one above, and the other below, by four pillars; and in them are centered the ends of the axis of the roller E. F F and G G are two friction wheels, the latter firmly fastened to B, but the former is fixed in an adjustable frame, by means of which adjustment these wheels and the roller E may be made to prefs, the former on the interior, and the latter on the exterior edge of the circle, with an equal and convenient force; namely, by the bending of the pillars of the secondary frame, and of the axis of the roller. At the extremities of the axis of the roller, and attached to the middle of the plates C and D, are two bridges, having a screw in each, by means of which an adjustment is procured for raising or lowering the roller respecting the edge of the circle, whereby the former having its diameter at the upper edge about .001 of an inch greater than at the lower edge, on account of its being a little conical, may easily be brought to the position where it will measure the proper portion of the circle.

Much experience and thought upon the subject have taught me, that the roller should be equal to one-sixteenth part of the circle to be divided, or that it should revolve once in 22° 30', and that the roller itself should be divided into sixteen parts, no matter whether with absolute truth, for accuracy is not at all essential here. Each of such divisions of the roller will correspond with an angle of 1° 24' 22', or 1/16th part of the circle. This number of principal divisions was chosen, on account of its being capable of continual bifects, but they do not fail in with the ultimate divisions of the circle, which are intended to be equal to 5 each.

The next thing to be considered is, how to make the roller measure the circle. As two microscopes are here necessary, and those which I use are very simple, I will in this place give a description of them. Fig. 3 is a section of the full size, and sufficiently explains their construction, and the position of the glasses; but the micrometer part, and manner of mounting it, are better shewn at H in figs. 1 and 4. The micrometer part consists of an oblong square frame, which is folded into a slit, cut at right angles in the main tube; another similar piece, nicely fitted into the former, and having a small motion at right angles to the axis of the microscope, has at one end a cylindrical guide-pin, and at the other a micrometer scale; a spring of steel wire is also applied, as seen in the section, to prevent play, by keeping the head of the micrometer in close contact with the fixed frame. This head is divided into one hundred parts, which are numbered each way to fifty; the use of which will be shewn hereafter. A fine wire is stretched across the moveable frame, for the purpose of bifecting fine dots. Two of these microscopes are necessary; also a third, which needs not have the divided head, and which must have in the moveable frame two wires crossing each other at an angle of about 30°; this microscope is shewn at 1, fig. 1. In the two first micrometers a division of the head is of the value of about .0".2, and the power and distinctness such, that when great care is taken, a much greater error than to the amount of one of these divisions cannot well be committed in setting the wire across the image of a well-made dot. The double eye-glasses has a motion by hand, for producing distinct vision of the wire; and distinct vision of the dots is procured by a similar adjustment of the whole microscope. The first step towards fixing the roller is to compute its diameter according to the measure of the circle, and to reduce it agreeably thence, care being taken to leave it a small quantity too large. The second step is, after having brought the roller into its place in the plate B B, to make a mark upon the surface of the circle, near the edge, and a similar one upon the roller, exactly opposite each other; then carry the apparatus forward with a steady hand, until the roller has made sixteen revolutions; if now the mark upon the roller, by having over-reached the one upon the circle, shews it to be much too large, take it out of the frame, and reduce it by turning accordingly; when, by repeating this, it is found to be very near, it may be turned about .001 of an inch smaller on the lower edge, and so far its preparation is completed. The third and final step is the use and adaptation of the two microscopes; one of these must take its position at H in fig. 1, viewing a small well-defined dot made for the purpose on the circle; the other, not represented in the figure, must also be fixed to the main plate of fig. 1, as near to the former as possible, but viewing one of the divisions on the roller with a due attention to each microscope, it will now be seen to the
the greatest exactness, when, by raising or depressing the roller, its commensurate diameter is found. 

Fig. 5. is a representation of the apparatus for transferring the divisions of the roller to the circle. It consists of two slender bars, which, being seen edgewise in the figure, have only the appearance of narrow lines; but looked at from above, they resemble the letter A. They are fastened to the main frame, as at W and Z, by short pillars, having also the off leg of the angle secured in the same manner; Y is a fine conical feeler point for making the dots, and X is a roller, whereby the point Y may be preffed down with an uniform force, which force may be adjusted, by bending the end of the bar jutt above the point, so as to make the dots of the proper size. The point Y yields most readily to a perpen dicular action, but is amply secured against any eccentric or lateral deviation.

The apparatus so far described, is complete for laying the foundation, i.e. for making 256 primary dots; no matter whether with perfect truth or not, as was said respecting the divisions of the roller; precision in either is not to be expected, nor wished for; but it is of some importance that they should be all of the same size, concentric, small, and round. They should occupy a position very near the extreme border of the circle, as well to give the greatest radius possible, as that there should be room for the stationery microscope, and other mechanism to be described hereafter.

It must be noticed that there is a clamp and adjusting screw attached to the main plate of fig. 1, by which it is placed in no respect from the usual contrivances for quick and slow motion (see Circle), it has been judged unnecessary to incumber the drawing with it.

Now the roller having been adjusted, with one microscope H upon its proper dot on the circle, and the other microscope at the first division on the roller, place the apparatus of fig. 5, so that the dotting point Y may fland directly over the place which is designed for the beginning of the divisions. In this position of things, let the feeder X be preffed down, until its lower end comes in contact with the circle; this will carry down the point, and make the first impression, or primary dot, upon the circle; unclamp the apparatus, and carry it forwards by hand, until another division of the roller comes near the wire of the microscope; then clamp it, and with the screw-motion make the con centric dot, proceed in this manner until the whole round is completed.

From these 256 erroneous divisions, by a certain course of examination, and by computation, to ascertain their absolute and individual errors, and to form these errors into convenient tables, is the next part of the process, and makes a very important branch of my method of dividing.

The apparatus must now be taken off, and the circle mounted in the same manner, that it will be in the observatory. The two microscopes, which have divided heads, must also be firmly fixed to the support of the instrument, on opposite sides, and then wires brought to the point first dot, and the one which should be 180° different. Now the microscopes remaining fixed, turn the circle half round, or until the first microscope coincides with the opposite dot; and if the other microscope be exactly at the other dot, it is obvious that these dots are 180° apart, or in the true diameter of the circle; and, if they disagree, it is obvious that half the quantity by which they disagree, as measured by the divisions of the micrometer head, is the error of the opposite division; for the quantity measured is that by which the greater portion of the circle exceeds the less. It is convenient to note these errors + or -, as the dots are found to forward or too backward, according to the numbering of the degrees; and, for the purpose of distinguishing the + and - errors, the heads, as mentioned before, are numbered backwards and forwards to fifty. One of the microscopes remaining as before, remove the other to a position at right angles; and, considering for the present both the former dots to be true, examine the others by them; i.e. as before, try by the micrometer how many divisions of the head the greater half of the semi-circle exceeds the less, and note half the quantity + or - as before, and do the fame for the other semi-circle. One of the micrometers must now be set at an angle of 45° with the other, and half the differences of the two parts of each of the four quadrants registered with their respective signs. When the circle is a vertical one, as in the present instance, it is much the best to proceed so far in the examination with it in that position, for fear of any general bending or spring of the figure; but for the examination of smaller arcs than 45°, it will be perfectly safe and more convenient to have it horizontal; because the dividing apparatus will then carry the micrometers, several perceptions being made in the plate B for the limb to be seen through at proper intervals. The micrometers must now be placed at a distance of 2°, 3°, and the half differences of the parts of the all of the arc of 45° measured and noted as before; thus deducing by bincctions to it 15°, 30°, and 45°. Half this half quantity is too small to allow the micrometers to be brought near enough; but it will have the desired effect if they are placed at that quantity and its half, i.e. 4° 1' 37° 57°, in which case the examination, instead of being made at the next, will take place at the next division but one, to that which is the subject of trial. During the whole of the time that the examination is made, all the dots, except the one under examination, are for the present supped to be in their true places; and the only thing in this most important part of the business, from first to last, is to ascertain with the utmost care, in divisions of the micro scope head, how much one of the parts of the interval under examination exceeds the other, and carefully to tabulate the half of their difference.

I will suppose that every one who attempts to divide a large astronomical instrument, will have it engraved first. Dividing is a most delicate operation, and every coarser one should precede it. Besides its being numbered in a particular useful to distinguish one dot from another; thus in the two annexed tables of errors, the side columns give significant names to every dot in terms of its value to the nearest tenth of a degree, and the misplacing of one for another is rendered nearly impossible.

The foregoing examination furnishes materials for the construction of the table of half differences, or apparent errors. The first line of this table consists of two varieties; i.e. the micrometers were at 180° distance for obtaining the numbers which fill the columns of the first and third quadrants; and at 90° for those of the second and fourth quadrants. The third variety makes one line, and was obtained with a distance of 45°; the fourth consists of two lines, with a distance of 2° 30°; the fifth of four lines, with a distance of 1° 18'; the sixth of eight lines, with a distance of 5° 37° 50°; the seventh of sixteen lines, with a distance of 2° 48° 44°; and the eighth and last variety, being the remainder of the table, consists of thirty-two lines, and was obtained with a distance of 4° 15° 27°.

The table of apparent errors or half differences, just explained, furnishes data for computing the table of real errors. The rule is this: Let a be the real error of the preceding dot, and b that of the following one, and e the apparent error,
error, taken from the table of half differences, of the dot
under investigation; then is \( a + b + c = \) its real error.

But as this simple expression may not be so generally
understood by workmen as I would wish, it may be necessary to
say the same thing less conically. If the real errors of the preceding
dot and following dots are both + or both - , take
half their sum, and prefix thereto their common sign; but if
one of them is + and the other -, take half their differ-
ence, prefixing the sign of the greater quantity; again, if
the apparent error of the dot under investigation has the
same sign of the quantity found above, give to their sum the
common sign for the real error; but if their signs are con-
trary, give to their difference the sign of the greater for the
real error. I add a few examples.

**Example 1.**

For the first point of the second quadrant.

| Real error of the first point of the quadrant | 0.0 |
| Real error of the first point of the third quadrant | - 6.9 |
| Half sum or difference | - 3.4 |
| Apparent error of the dot under trial | + 12.2 |
| Real error | + 8.8 |

**Example 2.**

For the point 45° of the second quadrant.

| Real error of the first point of the quadrant | + 8.8 |
| Real error of the last point of the quadrant | - 6.9 |
| Half difference | 0.9 |
| Apparent error of the dot under trial | - 8.9 |
| Real error | - 8.8 |

**Example 3.**

Point 88° 6', or last point of the third quadrant.

| Real error of the point 84° 4' of the third quadrant | - 21.0 |
| Real error of the point 25° 8' of the fourth qua-
drant | - 2.9 |
| Half sum | - 11.9 |
| Apparent error of the dot under trial | - 4.0 |
| Real error | 15.9 |

**Example 4.**

Point 88° 6', or last of the fourth quadrant.

| Real error of the point 84° 4' of the fourth qua-
drant | - 21.6 |
| Real error of the point 25° 8' of the first quadrant | - 10.2 |
| Half sum | - 15.9 |
| Apparent error of the dot under trial | + 9.5 |
| Real error | - 6.4 |

It is convenient, in the formation of the table of real
errors, that they should be inserted in the order of the num-
bering of the degrees on their respective quadrants; although
their computation necessarily took place in the order in which
the examination was carried on, or according to the arrange-
ment in the table of apparent errors. The first dot of the
first quadrant having been assumed to be in its true place,
the first of the third quadrant will err by just half the dif-
ference found by the examination; therefore these are alike
in both tables. The real error of the first dot of the second
quadrant comes out in the first example; that of the fourth
was found in like manner, and completes the first line. It
is convenient to put the error of the division 90° of each
quadrant at the bottom of each column, although it is the
same as the point 0° on the following quadrant. The line
of 45° is next filled up; the second example shews this; but
there is no occasion to dwell longer upon this explanation,
for every one, who is at all fit for such pursuits, will think
what has already been said fully sufficient for his purpose.
However, I will just mention that there can be no danger in
the formation of this table, of taking from a wrong line the
real errors which are to be the criterion for finding that of
the one under trial; because they are in the line next to it; the
others which intervene in the full table not being yet in-
ferted. The last course of all is, however, an exception;
for, as the examining microscopes could not be brought near
enough to bisect the angle 2° 48' 45'', recourse was had to
that quantity and its half; on which account the examination
is prosecuted by using errors at two lines distance, as is shewn
in the two last examples.

When the table of real errors is constructed, the other
errors, although it is of no further use, should not be thrown
away; for, if any material mistake has been committed, it
will be discovered as the operation of dividing is carried on;
and in that case the table of apparent errors must be had re-
course to, indeed not a figure should be destroyed until the
work is done. Respecting the angular value of the num-
ers in these tables, it may be worth mentioning, that it is
not of the least importance; 100 of them being comprised
in one revolution of the micrometer screw; and in the in-
finiteness before we 5 6 of them made no more than a fecond,
but it is not pretended that one of these parts was seen beyond a
doubt a degree of an inch, much less the tenths, as exhibited in the tables; but as they were visible
upon the micrometer heads, it was judged best to take them
into the account.

Having now completed the two first sections of my
method of dividing; namely, the first which consists of making
256 small round dots; and the second in finding the errors of
these dots, and forming them into a table; I come now to the
third and last part, which consists in using the erroneous
dots in comparison with the calculated errors, so as ultimately
to make from them the true divisions.

It will here be necessary to complete the description of
the remaining part of the apparatus. And first a little instru-
ment which I denominate a sub-dividing sector presents itself
to notice. From all that has hitherto been said, it must
have been supposed that the roller itself will point out, upon
the limb of the instrument to be divided, spaces corre-
sponding to others previously divided upon itself, as was done
in setting off the 256 points; but, to obviate the difficulty
of dividing the roller with sufficient exactness, recourse
was had to this sector; which also serves the equally im-
portant purpose of reducing the bisectonal points to the
final division of the circle. This sector is represented in
full dimensions by fig. 2; it is formed of thin brasses, and
centered upon the axis at A, in contact with the upper sur-
face of the roller; it is capable of being moved round by
hand; but by its friction upon the axis, and its prefigure upon
the roller, it is sufficiently prevented from being disturbed by
accident. An internal frame B-B, to which the arc C C
is attached, moves freely in the outer one, and by a spring D
is pushed outwards, while the screw E, whose point touches
the frame B, confines the arc to its proper radius. The
arc of this sector is of about four times greater radius than
the roller, and upon it are divided the spaces, which must be
transferred to the instrument, as represented on a magnified
scale by fig. 6. Now the angle of one of the spaces of the
circle will be measured by sixteen times its angular value
upon the sectorial arc, or 22° 30'; but this does not repre-

---

**GRADUATION.**
feet any number of equal parts upon the instrument, whose subdivisions are to be 5' each; for \( \frac{1^2}{2^2} \times 5 \) is exactly \( 16\frac{2}{5} \), therefore so many divisions are exactly equal to a mean space between the dots, whose errors have been tabulated. Let therefore the arc of the sector be divided into 16 spaces, of 1° 20' each, and let a similar space at each end be subdivided into eight parts of 50' each, as in fig. 6; we shall then have a scale, which furnishes the means for making the true divisions, and an intermediate examination at every bisectional point.

I have always divided the sector from the engine, because that is the readiest method, and inferior to none in point of accuracy, where the radius is very short; but as it is more liable than any other to centrical error, the adjustment of the arc by the screw E becomes necessary; by that adjustment also any undue run in the action of the roller may be reduced to an infensible quantity.

When the utmost degree of accuracy is required, I give the preference to dividing by lines, because they are made with a less forcible effort than dots are, and also, because if any small defect in the contexture of the metal causes the cutter to deviate, it will, after passing the defective part, proceed again in its proper course, and a partial crookedness in the line will be the only consequence; whereas a dot, under similar circumstances, would be altogether displaced.

But, on the contrary, where accuracy has been out of the question, and only nomenclatures required, I have used dots; and I have done so, because I know that when a dot, and the wire which is to bisection, are in due proportion to each other, the wire covering about two-thirds of the dot, the nicety of comparison possible may be obtained. It may be further observed, that division by lines is complete in itself; whereas that by dots requires lines to dilute the value.

On the upper side of fig. 1, is represented the apparatus for cutting the divisions. It consists of three pieces, J, K, L, jointed together, so as to give to the cutter an easy motion for drawing lines directly radiating from the centre, but inflexible with respect to lateral pressure; d, d, are its handles. The cutting point is hidden below the microscope H; it is of a conical form, and were it used as a dotting point, it would make a puncture of an elliptic shape, whose longer diameter would point towards the centre. This beautiful contrivance, now well known, we owe to the ingenuity of the late Mr. Hindley of York; it was borrowed by Mr. Ramden, (see Engine for Drawing,) and applied with the best effect to his dividing engine.

Previously to cutting the divisions, the parts now described must be adjusted. The cutting apparatus must be placed with the dividing point exactly at the place where the first line is intended to be drawn, and clamped, so that the adjusting screw may be able to run it through a whole interval. The microscope H must be firmly fixed by its two pillars A, B, to the main frame, with its micrometer head at ccr; and with its only wire in the line of the radius, bisecting the first of the 256 dots. And it should be observed that the cutting frame and this must not vary respecting each other, during the time that the divisions are cut; for any motion that took place in either would go undiminished to the account of error. The microscope I is also fastened to the main frame, but it is only required to keep its position unvaried, while the divisions of the sector pass once under its notice, for it must have its wires adjusted afeid to these divisions at every distinct course. The microscope I has two wires, crossing each other at an angle of about 40°, and these are to be placed so as to make equal angles with the divisions of the sector, which are not dots but lines. The sectorial arc must also be adjusted to its proper radius by the screw E, fig. 2, i. e. while the main frame has been carried along the circle through a mean interval drawn by H, the sector must have moved through exactly 16\( \frac{2}{5} \) of its divisions, as indicated by I.

Things being in this position, after having given the parts time to settle, and having also sufficiently proved the permanence of the micrometer H, and the cutting frame, with respect to each other, the first division may be made; then, by means of the screw for flow motion, carry the apparatus forward, until the next line upon the sector comes to the cross wires of I; you then cut another division, and thus proceed until the 16th division is cut = 1° 20': now the apparatus wants to be carried further, to the amount of 3ths of a division, before an interval is complete, but at this last point to division is to be made; we are here only to compare the division on the sector with the corresponding dot upon the instrument; this interval, however, upon the circle will not be exactly measured by the corresponding line of the sector, which has been adjusted to the mean interval, for the situation of the dot 1.4 is too far back, as appears by the table of real errors, by -4.8 divisions of the circle per head. The place of the screw for flow motion must now be restored, the cross wires of H set back to -4.8 divisions, and the sector moved back by hand, not to the division 0 where it began before; for, as it left off in the first interval at 3ths of a division, it has to go forwards 1\( \frac{1}{2} \)th more before it will arrive at the spot where the 17th division of the instrument 1° 25' is to be made, so that in this second course it must begin at 3rd of 0; go through this interval as before, making a division upon the circle at every one of the sixteen great divisions of the sector; and H should now reach the third dot, allowing for a tabular error of -10.2, when the division 5ths of the sector reaches the cross wires of I. It would be tedious to lead the reader through all the variety of the sector, which consists of eight courses; and it may be sufficient to observe, that at the commencement of every course, it must be put back to the same fraction of a division which terminated its former one; and that the wire of the micrometer H must always be set to the tabular error belonging to every dot, when we end one interval and begin another. The eight courses of the sector will have carried us through 3\( \frac{2}{3} \) part of the circle 1° 15', and during this time the roller will have proceeded through half-a-revolution; for its close contact with the limb of the circle does not allow it to return with the sector when the latter is set back at every course. Having in this manner proceeded from one interval to another, through the whole circle, the micrometer at last will be found with its wire at ccr, on the dot from which it set out; and the sector, with its 16th division, coinciding with the wires of its microscope.

</table>
We might have quoted several other parts of Mr. Troughton's paper, for the advantage of the reader, but instead thereof, we recommend the perusal of the whole to such persons as are interested in this subject, and shall conclude our account of the present method of dividing by remarking, that it requires not more than one-fourth of the time that Bird's method does, and not much more than one-twelfth that Ramfden's demands, and is applicable to a quadrat or sextant, &c.; that it may be performed by night, by the aid of an appropriate lamp, as well as by day; that the work is, as it were, magnified by the sector; that any erroneous action of the roller, when verified at every interval, does not extend its influence to any distant divisions; that the divisions of the sector very conveniently convert the 256 points into degrees and parts of a degree, while the micrometer head allows for their errors of position; that all tools liable to vary their dimensions by change of temperature are here abandoned; and lastly, that eisfen alone is employed in ascertaining the measures of the arc divided; on which account this method is called dividing by the eye; which appellation, indeed, might have been given to the due de Chaunuel's method; a method which, we understand, Mr. Troughton was not acquainted with till lately, and from which it will be perceived his differs very essentially. We have no hesitation in asserting, that this far excels every other method of graduating large circles that we are acquainted with.

Soon after Mr. Troughton's paper was read at the Royal Society's room, the late Henry Cavendish, esq. F.R.S., whose death is an irreparable loss to the scientific world, contrived a new method of using the beam-compas, with a view of avoiding the difficulties of pointing the exact middle of a small space between two scratches, and of using that point again without altering its critical figure. As these difficulties had led to Mr. Troughton's new contrivances, Mr. Cavendish presumed that a removal of them would render the beam-compas unobjectionable; and that future dividers might continue the use of an instrument which long habit has rendered familiar. The method proposed, but which probably has not been adopted, if tried at all, is, to unite a micrometer that has got a micrometer, with the beam-compas, in such a way, that no dots may be necessary at all in dividing or sub-divisioning any arc of a circle, but that bisection, trisection, and quinquesection, may all be performed by eisfen before the dividing strokes are made on the circle to be divided; we say circle, because this method is not intended to apply to a quadrant, or any other aliquot part of a circle. We will endeavour to explain the method now before us as concisely as possible. Let C, C, C, in fig. 4, of Plate XVIII. of Aeronautical Instruments, be the circle to be divided, in which we will retain the original letters of reference, and B B a frame resting on its plane so readily as to be without flake, but notwithstanding to have the power of sliding smoothly round the circumference to any given point, to which it may be adjusted by a slow motion, and there clamped; let d be a beam-compas, having its cutting point adjustable near b, and let m be a micrometer with two parallel hairs, one fixed, and the other moveable by the micrometer, made so as to slide along the beam of the compas into any required situation. Let a point d on the frame be so chosen, that the line d m may lie in the direction of the chord of half the arc to be bisected, when bisection is used, in which case the whole length from d to m must be very nearly equal to the whole chord of the said arc, and then both the centre of the field of view of m, and also the point d, will fall in the circle to be divided. It is not said how the fixed or central point d is to be supported, and kept perfectly steady, but as its distance from the centre of the circle must necessarily depend on the length of the chord d, it is proposed that the piece of metal that constitutes the support should be adjustable by a sliding motion of some sort, and that the beam near d should rest on a prop to guard the cutting point, when demitwed low enough to make a stroke. Suppose now F and f to be the extreme points of an arc to be bisectioned somewhere near d; after having placed the microscope at or near the middle of the beam, with respect to the two points d and e, and fixed the point on the reeling place of d, slide the frame till the fixed hair in the center, which must be exactly perpendicular to the line d, interferes the circle at F; then, lowering the point d from its prop, make a faint scratch in the next place turn the beam-compas a little raised at the end 2, round its centre d, till f is found over the circle, at the other side at D, where it must rest on a prop for a time; slide now the frame forwards, and adjust till the fixed hair cuts the point f, and there fix it; the second scratch must now be made, which will be over, or short of the first, accordingly as the microscope has been beyond or short of the middle of the distance d. It is not proposed to make a dot between these two strokes, but to bisect the space between the hair, by the eye, or, if necessary, by the moveable hair of the micrometer, after it has measured the whole of this space; the bisection line being now the true place of z, which we suppose brought back to the microscope at m, this intersection is the extreme point of the bisectional arc F z or f z, which must be bisectioned successively in like manner, when the point s has been adjusted. When the arc becomes small, a crooked point is proposed to be used at s, that it may lie in the way of the micrometer, or other, if that plan will not succeed, to adopt what he calls Mr. Troughton's method of bisecting an odd number of contiguous divisions, which was also done, as we have seen, by the due de Chaunuel and others. In cutting the lines of division, the microscope and point d are proposed to be very near together, and, if possible, so near at one side of another, that the stroke cut may coincide with the fixed hair, when the beam has an angular motion given, as a check on the stability of the microscope; and lastly, the point d must be so taken that the line d 2 may now be a tangent to the circle at the cutting point.

If the whole circle could be graduated by continual bisecton, this account is all that would be necessary for explaining the method of dividing here proposed, but, as trisection and quinquesection are necessarily introduced, either before or after bisection, where the computation of chords is rejected, we must give again an account of these processes, which we believe are original. Suppose the arc a s, in fig. 5, to be projected for quinquesection, the equal measures a f, f s, e d, d b, and b u, are laid down in succession, by bringing a to the microscope, and making f nearly one-fifth of the whole, then by bringing up f, the microscope, and marking s, &c. in the same way, beginning at a, the points 2, 4, 1, and 7, are made with the same extent, which it appears was with too small an opening. Now the true point of the first quinquesection from a will be between 2 and 4, and distant from 2 just one-fifth of the differential space 2 b, and the second point will be two-fifths of 4 from 3, and so on for the rest; therefore, in cutting the dividing strokes, the micrometer must measure the whole differential space, and then allow for the due proportion, after which it must be brought into the place of the fixed hair, to bisect the scratch before covered by it, and then the dividing line may be cut: in the same way allowance may be made for 3ths of the small space 3 d, before a second dividing stroke is made; or,
or, which gives less trouble, when the first quinquefecting line is truly laid down, it may be transferred forward by using the fixed hair with it first, and then with the second, while the third is cutting, and so forth till they are all measured and cut in succession from the first measure repeated. This method is, however, acknowledged to be liable to the double error, which may arise, first, from placing the intermediate point, and again, of sub-dividing from it. A third method for quinquefected or trisections is lastly proposed, but is considered inferior to the former plans, and therefore may be passed over in silence.

We must confess there is something specious in the theory of Mr. Cavendish's proposed method of dividing, but our opinion, that it would not answer well in practice, has been confirmed by the assertion of a practical artist, whose judgment in this art we estimate much more highly than our own. Supposing the point $d$ on the frame not to be altered in shape or position by the large sweep of the beam from right to left, and vice versa, alternately, nor yet the point injured, there must necessarily be a change of position in the hands of the operator, as well as in his whole body, at every backward and forward change of the beam, to the right and left, which circumstance will be not only unfavourable to expedition, but also to accuracy; in fact, the operator must be both right-handed and left-handed to succeed with an alternation of operations that require the greatest nicety of management, and in which the hands, the eye, and the diversified attitudes of the body, have all an equal share, and where a false stroke once made cannot be well rectified. The bisected arcs will not be more affected by change of temperature probably than by Bird's method, but the quinquefected arcs may be sensibly affected, as some time must necessarily be taken up in ascertaining the measures by vignon, while the operator breathes on the beam during the inspection of the microscope, and is also handling it in two places during the whole time of obtaining the line points, or rather bars, in question.

Soon after Mr. Cavendish's paper on the manner of dividing astronomical instruments had been read before the members of the Royal Society, the Rev. William Lax, A.M., R.S., Lowndes's professor of astronomy in the University of Cambridge, addressed a paper on the astronomer royal, which was also read and printed in part 2. of the year 1809, immediately after Mr. Cavendish's paper. This paper, as well as Mr. Cavendish's, was probably brought forward in consequence of Troughton's paper, printed in part 1. of the same year.

The method of examination made use of by professor Lax may be familiarly explained thus, without entering into any mathematical formula to mark the value of particular explications, that might puzzle the ordinary reader: two microscopes were adapted by frame-work, so as to be capable of adjustment to any given points of the circle to be examined, and one of them, having a micrometer attached to it, was capable of measuring minute differences between a given arc of 60, 62, or 45, &c. and any of the following multiples of that arc taken in succession; consequently, if all the said differences marked $+\, -$ as the case might be, balanced one another exactly, when the whole circle was gone through, the measure of the first arc was a standard measure, or the exact fraction of the whole that it ought to be; if not, a proportional part of the balance of errors would belong to it, and must be allowed for accordingly. It is not necessary to be more minute in explaining the principle of examination before us, as it is of no use in graduating a circle, but is only intended as a correction on bad graduation, like the French repeating principle, to which it bears some analogy. The author's idea of ascertaining the fractional value of each division in his instrument successively, which he calculates will cost him an expenditure of 98 hours, is founded on an opinion that astronomical instruments in general do not possess that degree of accuracy in their divisions that the makers of them affirm; but he does not appear to be aware that as rigid an examination as his own is practised by all the best instrument-makers in the final adjustment of the divisions, and that too by means of micrometrical microscopes; so that, if a posterior examination is found necessary, it must, generally speaking, be necessary in consequence of some change of figure that the instrument has undergone from carriage, accident, or temperature; in any of which cases the professor's mode of examination will be very desirable. But any one who proposes to take the trouble of making a table of all the positive and negative errors in the divisions of an indifferent instrument, will do well to have the whole of the original paper before him at the time, by which every step in the process will be pointed out as it is wanted. Without meaning to discourage any attempt of this nature, for the proposal of which astronomers are much indebted to the learned professor, we profess a belief that three or four readings of any individual observation by as many microscopes properly arranged round the divided circle, in stationary situations, will answer every purpose of accuracy, and correct all the usual sources of error that exist at the time of making the observation; for when any table of errors is completed with the greatest care, it ought only to apply to observations made while the instrument remains in the same predicament as it was when the table was constructed. Mr. Troughton, who is engaged with the construction of his six-foot circle for the Royal Observatory, intends, we understand, to adopt the use of four microscopical readings, two opposite each other, which will correct for eccentricity simply corrected, and two at 120° distance from one of the former ones, which will check the bisectional dividing, and correct the inaccuracies of division, if any, as well as the effects of any change of figure in the circle by unequal temperature, in the room where it may be used. This proposal, coming from so skilful and experienced an artist as Mr. Troughton, we consider as a strong argument in favour of our opinion, which we expressed in favour of three readings in our article Circles, before the paper in question was published, or known to us.

"I find," says Mr. Lax, "that I can read off, to a certainty, within less than three-fourths of a second, and hence I conclude that I could examine the divisions of my circle (of one foot radius) without being liable to a greater error than 9 63 seconds." This is illud on calculation to be the extreme limit; which, according to the doctrine of chances, can very seldom happen, but if one-half of this error is likely to happen in any one division of the whole circle, as read off by the microscopes, the result will be, that the errors of the table may be as great as those of a well-divided instrument, supposing it to preserve its figure unaltered after examination. In another part of the paper before us, the author says, "we may likewise observe that by this examination we shall not only beolicited against the errors of division, but against those which arise from bowing centres, and from the imperfect figure of the circle, and which in general are of too great a magnitude to be neglected." From this observation we must necessarily conclude, that the distance between the microscope and micrometer, used in measuring, was not the measure of the included arc, but of the angular quantity at the centre opposite that arc; for it must be evident, that, in case the axis of motion is not precisely the centre.
of the divided circle, the arc, simply considered, will not be the true measure of the angle, being one side of the circle will be farther from the centre than the other. For instance, if we suppose the line that passes from zero to the centre of the divided circle, should also pass through the centre of motion, placed a small quantity out of the centre of the graduated circle, in this case the angles subtended by the first and fourth quadrantals will be greater than those subtended by the second and third; but if the line from 90 to the centre of motion should pass through the centre of the divided circle, then the angles subtended by the first and second quadrantals will be greater than those subtended by the third and fourth. When, however, the microscope have a miles hair, as well as a radial one, the length of the radius as well as of the arc may be measured, and consequently the true quantity of the subtended angle.

The great familiarity with the due de la Cour's method of dividing a circle, and of professor Lax's method of examining one when divided, cannot but strike the reader; they both use microscopes, one with a micrometer attached, and both take multiples of the arc under consideration; but one corrects the errors by adjustment during the act of dividing, and the other calculates and tabulates them for subsequent corrections.

Neither will the likenesses pass unnoticed between the apparatus employed by Mr. Lax, and that for the purpose of examining standard measures, described by Sir Geo. Bentinck (Phil. Trans. 1798); but Mr. Troughton, we know, acquires the learned professor of borrowing anything from him.

In the spring of 1810, Mr. James Allan, of Blewitt's Buildings, Peter Lane, London, received the gold medal from the Society of Arts, at the Adelphi, for a new method of equalizing the teeth on the edge of an engine plate for dividing sextants, &c., which would have been described more properly under the article ENGINE, but as it was not then made known, we will take some notice of it in this place, though the Society's account is not yet published. The professed improvement of Mr. Allan's method of packing, consists in its enabling a bad divider of a circle to correct his divisions, by what he calls a self-correcting process. The contrivance is this: the usual wheel or circular plate that is racked, has a brass rim of about two inches breadth, and of the same diameter and thickness as the wheel, rubbed over it, so as to appear a part of the same wheel; four leaden pins, at the exact distance of a quadrant from each other, keep the rim in its place by the aid of several equal-distant screws, and the rim will therefore admit of four positions on the wheel. When the wheel and rim together have been faintly racked in the usual way (see ENGINE by Ransden) one of the other positions is given to the rim, suppose the opposite one, and then the operation of racking by the screw is resumed; when the teeth are a little formed, another position is given to the rim, and the racking resumed as before to a certain extent, and, after several changes have been gone through, it is presumed that the teeth become nearly equalized, and are exactly equal to one another at the conclusion. How far this will be precisely the case we will not pretend to assert. We conceive it to be a very nice operation to drill four holes in the wheel and rim so exactly equidistant and concentric, that a reversed position shall not affect their relative fittings, and if there is the least deviation in this respect, it will be charged as an error on the divisions. The screws also profess to be placed so as to admit of reverting in position, and unless the lead pins fill their holes completely, these pins will, in all probability, be drawn aside by the fixing screws in some of the positions. If the wheel is truly racked in the first instance by a careful divider, and the lead pins placed with precision, the reverting of the rim will not disturb the coincidence of the two rows of teeth all round, which is the thing ultimately desired; but if the original division was bad, and had both negative and positive deviations from true division, in different parts of the circle, then we have a doubt whether the rim will produce the defined effect of equalizing them: a good screw will of itself equalize contiguous teeth, when fifteen teeth or upwards are acted on at the same time; but it will not equalize distant teeth, which the rim professes to do. In order, however, to answer the purpose of a self-corrector, the rim must be competent to meet all cases of bad division that are liable to occur; let us suppose, in the first place, that whenever large teeth are made by the divider on one side of the wheel, teeth corresponding in small ways are to be met with at the opposite side, in this case, which is the most favourable to the operation of the rim, the errors being opposed to each other, by an opposite position of the rim, will correct each other, provided they are of similar quantity, and the rim will produce its defined effect; but, secondly, if equal errors happen to be in the same direction they will not be corrected at all; and, thirdly, if unequal errors be in the same direction, they will be corrected by only half their difference; nay, arcs of the wheel, that are true at first, will, we conceive, be vitiated, unless they fall in with arcs of the rim that are also true. How far a change of temperature will affect this long process we will not affirm; but we hesitate not to give it as our opinion, that an upper plate, or wheel, revolving on the same centre as the wheel itself, would be less liable to central error than the rim with leady pins, however carefully fixed; for leady pins could not then cause any sensible eccentricity in fixing at the different positions.

It would have been desirable if Mr. Allan had given with his account of the racking, his method of making a perfect screw, which is essential in a dividing engine. We lately had an opportunity of examining one of his engine-divided reflecting circles, and found, however, the opposite verniers very well corresponding with each other all round the circumference.

Graduation of a Circle geometrically. After the description we have given in our preceding article of the various practical methods of graduating astronomical instruments, it may, perhaps, seem superfluous to give a further account of the methods that geometerians have proposed for graduating a circle theoretically; but which have been of little or no use in the practical division of circles, or circular arcs, on instruments. It is not sufficient for the purpose of the instrument-maker, that a problem be true merely, but that the means necessary for its adoption in practice be not subject to the introduction of error. The ancient geometry implies the possibility of making a straight line in practice through two given points, which cannot be effected with certainty by a ruler and pointed tool, however carefully applied, while the modern geometry of Mascheroni, the Italian, rejects the use of lines altogether, and substitutes the compasses only in the division of a circle. We will gratify the curiosity of the reader with a few specimens of each method in succession.

In Adam's geometrical and graphical essays are the following problems, which imply the practicability of drawing a straight line through two given points.
GRADUATION.

Problem I.

"To cut off from any given arc of a circle a third, a fifth, a seventh, &c., odd parts, and thence to divide that arc into any number of equal parts."

Example 1.—To divide the arc $AB$ into three equal parts. $A$ being the radius, and $C$ the centre of the arc. Biseect $AB$, fig. 1, of Plate XXI. of Astronomical Instrumants, in $K$, draw the two radii $C K$, $C B$, and the chord $A B$; produce $A B$ at pleasure, and make $B L = A B$; biseect $A C$ at $G$; then a rule on $G$ and $L$ will cut $C L$ in $E$, and $B E$ will be $\frac{1}{3}$, and $C E$ $\frac{2}{3}$ of the radius $C B$; on $C B$ with $C E$, describe the arc $E e d$, lastly, set off the extent $E e$ or $D e$ from $B$ to $a$, and from $a$ to $h$, and the arc $A K B$ will be divided into three equal parts.

Corollary.—Hence, having a sextant, quadrant, &c. accurately divided, $\frac{1}{6}$ the chord of any arch set upon any other arc of $\frac{1}{6}$ that radius will cut off an arch similar to the first, and containing the same number of degrees. Alto, $\frac{1}{6}$, $\frac{1}{4}$th, $\frac{1}{3}$th, &c. of a larger chord will constantly cut similar arcs on a circle whose radius is $\frac{1}{6}$, $\frac{1}{4}$th, $\frac{1}{3}$th, &c. of the radius of the first arc.

Example 2.—Let it be required to divide the arc $A B C$, of the same figure, into five equal parts, or to find $\frac{1}{5}$ of the arc $A B$. Having bisected the given arc $A B$ in $K$, and drawn the three radii $C A$, $C K$, $C B$, with radius $C I$ describe the arc $I m N$, which will be bisected in $n$ by the line $C K$; then take the extent $I n$, or its equal $M a$, and set it off twice from $A$ to $B$; that is, first from $A$ to $a$, and then from $a$ to $o$, and $O B$ will be $\frac{1}{5}$ of the arc $A B$. Again, set off the same extent from $B$ to $m$, and from $m$ to $o$, and the arc $A B C$ will be accurately divided into five equal parts.

Example 3.—To divide the given arc $A B$ into seven equal parts. $A B$ being bisected as before, and the radii $C A$, $C K$, $C B$, drawn, find (by a problem referred to) the seventh part $P B$ of the radius $C B$, and with the radius $C P$ describe the arc $P R N$; then set off the extent of $P R$ twice from $A$ to $3$, and from $3$ to $6$, and $6 B$ will be the seventh part of the given arc $A B$; the compasses being kept to the fame opening $P R$, set it from $B$ to $4$, and from $4$ to $1$; then the extent $A 1$ will biseect $1$ into $2$, and $2$ into $3$; and thus divide the given arc into seven equal parts.

It is obvious, that this method of dividing any portion of a circle, into an odd number of equal parts, is subject to three sources of error in practice; 1st, the variation of the compass from expansion; 2d, the uncertainty of getting the exact points of intersection where the angles are acute; and 3dly, the probable deviation of the points in stepping; to fay nothing of the errors arising from drawing the right lines, which would, in all probability, exceed all the other errors put together, even before they are doubled and trebled, &c. by stepping.

Problem II.

"To divide a given arc of a circle into any number of equal parts by the help of a pair of beam, or other compasses, the distance of whose points shall not be nearer to each other than the given chord," (by Clavius).

Let $A B$, fig. 2, of Plate XXI. be the given circular arc to be divided into a number of equal parts. Produce the arc at pleasure; then take the extent $A B$, and set it off, on the prolonged arc, as many times as the given small arc is to be divided into smaller parts, namely, to the points $C$, $D$, $E$, $F$, and $G$. Divide now the whole line $A C$ into as many equal parts as are required in $A B$, as $G, H, I, K, L, M$, and the same extent, or the same parts, as are required in $A G$; therefore, since $A G$ contains $A F$, and $4t$ of $A B$, $B L$ is 4th side of $A B$. Then, as $G H$ contains $A B$, plus $F H$, which is $4t$ of $A B$, $K L$ will be the $4t$ of $A B$, $D$ $K$, the 4th side of $A B$. Therefore, if we set off the interval $G H$ from $F$ and $H$, we obtain two parts between $F$ and $I$; the fame interval, or extent, set off from these two points near I, gives three parts between $D$ and $K$; when set off from the points from $D$ to $K$, it gives four parts in $C L$; and the next transfer will, from these points, give five parts from $B$ to $A$; so that, by and by, the same extent will give in the remaining divisions in succession from those between $B$ and $C$.

This method is liable to some of the same errors of error as the preceding method, when compasses alone are dependent on; but it is useful, according to the due of Chaulne's mode of proceeding, and may be serviceable in Ramfden's method of dividing, where the points are refiled by opposite microscopes. In all probability the verier scale owes its origin to this problem of Clavius, which problem may be variously diversified, to prevent the necessity of small extents; but whenever small spaces are marked out on an arc by a differential plan of this fort, it is requisite that the extent began with should not alter during the whole process, and also that the points, once marked, should be capable of being referred with certainty at the subsequent transfer. When, however, an error is made in any divided space by a hard particle, or otherwise, this error will recur at every multiple of the extent measured therefrom.

This problem of Clavius, it will be remarked, implies the given arc $A B$ to be measured, or otherwise known previously to the proposed subdivision.

When an entire circle is proposed to be divided into degrees, the radius, which is equal to the chord of $60^\circ$, affords the means of making fix equal arches; and these arcs may be subdivided to arcs of $15^\circ$ each by bisection only; but to reduce the equal arcs to a still lower denomination, recourse must be had to either trisection, quinquesection, computation of the chords, or the differential method originally proposed by Clavius, all which have been already described.

The method of dividing a circle, proposed by L. Mascheroni, is translated into French by A. M. Cauette, 1798, and is contained in the second book of his "Géometrie du Compas." This method rejects not only the drawing of lines, but all measurement from scales, and bisections of an arc by trial, as well as trisections, quinquesections, &c., but admits of stepping, and supposes the extent of a pair of compasses, once taken, to be afterwards invariable. The radius of the circle is the basis of all the other extents, which are very few in number, considering the various divisions that may be made therewith, and three points determined, or without and two within the circle, afford the mensurations of obtaining all the measurements, instead of a scale; consequently, any circle divided by this method must necessarily have its plane extended considerably beyond and within the circular space to be divided, which is seldom the case in a large instrument, where a ring or rim is attached to radial bars, to form a wheel for the body of the instrument, which construction contributes equally to strength and lightness; a
new put from and neceffary within and divided as succeed to the into which thtfo and A 12, take circle 30', or the appren
division ner of this will the kind of this is from the radius, will be kept unaltered, or the chord B F of 90°; all of the arc E F, of E F, and of F B; the circle is now divided into four quadrants at the points B, E, F, and G. To obtain an eighth part of the circumference, let A B, by the compa N° 1, from the point a, out of the circle, to C and H in the arc on each side; then the semi-circle is divided into four, and the points g and a, in the other semi-circle, may be transferred from G to g, and from H to b, with the compa N° 3, or chord of 90°, and the whole circle will now be divided into eight equal arcs by the points B, G, F, H, E, b, f, g.

To gain twelve equal arcs of the circle, with N° 1, or extent equal to radius, from P as the first point turn over to N, and a, in succession one way, and to O and o in succe
cssion the other; and the whole circle will be divided into twelve equal arcs by the points B, N, C, F, D, O, E, a, o, f, e, n. To double this number of equal arcs, begin at G with the same extent of radius, and from L and M one way, and to k and i the other; also from H with the same extent of radius, and from m and l the other way, which points will bisect the former twelve arcs, and make the whole 24.

Hitherto we have had occasion for no other point but a for determining the 24 arcs, and it is some
tewhat remarkable, that the three extents a, e, and f, the radius, the chord of 90°, and the chord of 120°, are to each other in the simple ratio of the square roots of 1, 2, and 3 respectively. In order to sub-divide without trial, the 24 arcs into 48, another point e within the circle is necessary; with a fourth compass take the extent a N, and find the point e by intersection from B and its opposite point E; then N 1, or radius, will cut the circumference from this point e in the points g and h; so shall K e, e N, M 1, and O be each equal to the 48th part of the whole circumference. To divide the circumference into five equal parts, a third point b within the circle, and in the same diameter with c, but at the opposite side of the centre, will be necessary; to avoid confusion from further sub-division, we will take another fig. (4) with similar letters of reference as the preceding one. With N° 3, or extent a A of 90°, intersect at the point b from the points N and O, then with a fifth extent B b set off from B to Q, and the arc B Q will be the fifth part of the circumference. To bisect these five large arcs, take the fifth extent A b and set it from B to P, which will be equal to the arc P Q, and, consequently, will be a tenth part of the circumference. Again, without any further operation, the small arc Q 1, already marked, will be the 120th part of the circumference; and to obtain 6th part of the same, in the quadrant B V F, the extent B F, set off from F to V, will have the arc B V equal to this quantity. And lastly, to procure 240 equal arcs, take the extent c 1, and let it over from a to g, and from g to i, so shall the arc P g be the 48th part of the circumference; but to subdivide all the circumference by the small arc P g of 1° 30', the arc N G of 15 must first be divided into five parts of 3° each, without quinquesection; thus, with the extent A b = B P, step from B to the points P, Q, R, S, and it will fall next in E already marked; then with A b, as before, begin at L and put in the points q and p successively; also from I put in r, and from O put in t, by stepping the points q, s, r, and t; thus shall the points p P r and c sub-divide the arc N G into five equal arcs, and e will be found equal to p, or 1/120th part of the whole. After having obtained these five sub-divisions of 3° and 1° 30', the first may be transferred, with the extent N G for instance, into other arcs of 15 in succession, beginning with G C first, and using the points N, P, G, C, and so on, till the whole is gone through, after which the small arcs thus trans-
ferred may be bisected by an extent c N, going a second time over the fame points in succession as before. Thus will the whole circumference be sub-divided into 240 parts of each 1° 30'..

The eleventh or last problem on this subject, is to divide any arc BC (fig. 4) into two equal parts in G. To do this, with radius A B, which has described the arc BC to be divided, and from the centres B and C, the two exten-
ties of the arc, let the arcs A D and A E be described; let A D and A E be made equal to BC; then from the points D and E, as centres, and with radius D C or E B, find by interjection the point F, lastly, with the radius A F, and from the centres D and E, let the point G be intersected, which will fall in the circumference, if the operation is truly performed, and will also bisect the arc BC as was required.

By the help of the three remarkable points a, e, and b, in our fig. 4, the author of the Geometry of the Compa, has laid down in his twelfth and last book a dozen equa-
tions, some one of which may be applied to determine, by approximation, almost any small arc of a circle that shall cut off a given quantity. It would be tedious to enter here minutely into his various calculations, but, for the sake of amusing the reader, we will select the solutions of a few problems, without the annexed demonstrations, which would enlarge our article too much.

Problem 1.

To find the arc of one degree without the error of half a second.

Solution.—Let the arc B A, below B, be 55° 50', (in the circle which has been divided into 240 parts of each 1° 30'), take the distance b s, and from the point e, as a centre, de-
scribe an arc to cut the circumference in some point Z, and the arc B Z, above B, will be 52° 39' 15", or 52° 39' within about 25"; then in the divisions between B and F is the divi-
division $\frac{3}{4}$, or $\frac{3}{8}$ of the whole circle; there will therefore be $\frac{3}{4} - \frac{3}{8} = \frac{1}{8}$ by approximation within the required degree of accuracy.

Solution 2. Let the arc $AB$ be taken as $10^\circ$ to $30^\circ$, (by the divisions existing) from the centre $a$, and with the distance $b$ as radius, cross the circumference in the said point $Z' = 29^\circ$ to $30^\circ$; or $29^\circ$ to $30^\circ$ without an error of half a second; then look for $28^\circ$ to $30^\circ$ in the existing divisions, viz., $\frac{3}{8}$ of the circle, and the difference will be very nearly as before $= 1^\circ$. This solution is less accurate than the former by about $4''$; the error being $29''$.

**Problem II.**

To find an arc of $15^\circ$ without an error of $1^\circ$.

Solution. Take the arc $BZ$ as $12^\circ$ below $B$, the distance $eB$ will be the chord of $87^\circ$ to $15^\circ$; with a radius of this extent, and from $B$, as a centre, cut the arc $BF$ above, in the point $Z'$, and the arc $BZ'$ will be $87^\circ$ to $15^\circ$; but among the existing divisions of the arc is $87^\circ$, or $\frac{7}{36}$th of the circumference; therefore, the difference of the two arcs is $= 15^\circ$.

**Problem III.**

To find an arc of $10^\circ$ without an error of $10''$.

Solution. Take the arc $BZ$ downward as $49^\circ$ to $30^\circ$, and the distance $eB$ will be the chord of $38^\circ$ to $50^\circ$, without an error of $10''$; then, the division $39^\circ$, or $\frac{3}{8}$, being found already, their difference on the circumference taken from $B$ upwards, will be an arc of $10^\circ$.

**Problem IV.**

To find an arc of $6^\circ$ within $15''$.

Solution. Take the chord of $45^\circ$ from $B$ to $G$ above, and from the point $b$ cut the circumference above $= z$, which will be at $45^\circ$ to $6^\circ$, downwards from $B$, without an error of $15''$, but $40^\circ$ counted downwards already exits, therefore the small arc between is $6^\circ$.

**Problem V.**

To find an arc of $1^\circ$ within $22''$.

Solution. Let $BZ$ downwards be $= 22^\circ$; from the point $e$ as a centre with radius $bZ$, cut the circumference above at $Z$; and the arc $BZ$ will be $29^\circ$ to $39^\circ$, with an excess of $22''$; therefore, the arc $BN$ being $30^\circ$, the arc $ZN$ will be $1^\circ$ within $22''$.

By such means as these an arc of $9^\circ$ within $7''$ is determined; also, an arc of $20^\circ$ within $1''$; an arc of $12^\circ$ within $15''$; an arc of $10^\circ$ within $15''$; and an arc of $5^\circ$ within $2''$; but these last arcs are too minute in all ordinary circles, that we omit the solutions, as being of no utility.

We have hitherto supposed the circle divided into $360^\circ$ with their sub-divisions, but the French have proposed a centesimal division of the circle to be subdivided, where each quadrant has $100$ instead of $90$, making $400$ in the whole circle, with each degree sub-divided by hundreds, &c. This mode of dividing has been exemplified by L. Mafcheroni, in his Geometry of the Compasses; and Mr. Troughton has described the method of graduating a circle in this way by his method, if it should ever prevail in England; but, as there appears to be no advantage to the divisor in affording bisections lower than $25^\circ$, and as our tables of logarithms, as well as astronomical tables, are adapted to the existing mode of dividing the circle, we are unwilling to lead our aid to the introduction of useless innovations, by entering more minutely into the subject.

L. Mafcheroni is the Italian geometrical, we are informed, who taught Bouzaptie some problems, when in one of his campaigns in Italy, with one of which he puzzled the French mathematicians, and gained the reputation of being an adept in mathematics.

**Graduation, in Mineralogy.** When a mineral is discovered which is intermediate between other known species, and in different specimens, or parts of the same specimen, approaches very near to such known minerals, it is said to have the character, from its structure, and the fashion which the earth is more or less compatible in common with some known one, the chert bands in them. More frequently, each stratum is separated by a thin layer or way-board of pulverulent matter, which occasions the strata to part freely; and often, in such cases, the parts of the strata in contact with each way-boards differ nothing from the general mass of each stratum, or there is no graduation between one stratum and the next in succession.

**Graduation of Saline Liquors, in Chemistry.** Is a method of concentrating weak saline solutions, by pouring them through a heap of pebbles and exposing them in this divided rate to a free current of air. See Murals of Soda.

**Gradus Gemonic.** See Gemonic.

**Graecia, Persia, a name used by the old Greek writers for the wrinkled pellicle which arises upon milk in the boiling state. It was also used in a figurative sense for the wrinkles in the skin of old people.

**Grecia, the Greeks, in Ancient Geography.** A country of considerable extent, forming, as it were, the boundary or frontier between Europe and Asia, and comprehending a great number of different states and kingdoms. We have various opinions as to the etymology of the appellations Graeci and Graecia. The most prevalent opinion traces the origin of these terms to Graecus or Graecus, the father, as former, but, according to others, the son of Theffalus, who gave its name to Theffaly. Salamanus supposes the name Graecus to be derived from Ragus or Rau, the son of Pelag, the fourth in descent from Shen, the son of Noah, by the transposition of a letter in order to soften the sound. Pezon deduces it from Graia, signifying in Celtic ancient, and applicable to the Greeks by way of contradiction to more modern people. But it has been objected to this etymology, that the Pelagii and Hellenes were a more ancient people than the Greeks. M. de Gebelin supposes the origin of the appellation to have been the word rhus, or rhe, denoting a sudden or momentary reference to the sea which terminated the Adriatic gulf, on the borders of which the Greeks migrated southwards, whence he forms Rhaeus, signifying this sea, and by prefixing the guttural G to the last root, Graecus. The Greeks were also called Achaeans, Hellenes, and Pelagii. The first of these appellations is supposed to have been derived from Acheus, the son of Xuthus, the son of Hellen, and father of Ion; the second from Hellen, just mentioned, the son of Deucalion, and father of Dorus, from whom sprung the Dorians; and the third, from a pretended founder Pelagus, who, taking possession of the Peloponnesus, occasioned its being denominated Pelagia. Grothus, Salamanus, and Stillingfleet.
names of considerable authority in disquisitions of this nature, suppose that the descendants of Peleg, the fourth in descent from them, the son of Noah, whom they suppose to have been the father of the Scythians, were the first who peopled Greece; and that they only softened the name of Peleg, or Phileg, their progenitor, and called them Pelasgians. But Bochart (in his "Phileg") shows, that both Phileg and Ragau, and their descendants, remained in the confines of Media and Armenia; and that the Scythians were the descendants of Magog, and not of Peleg or Ragau. Some have asserted that the most ancient name of all is that of Ion, which the Greeks themselves derive from Xuthus, grandson of Deucalion. Jofephus affirms (Ant. l. i. c. 7.) that their original is of much older date; and that Javan, the son of Japhet, and grandson of Noah, and his descendants, were the first who peopled these countries; and in proof of this position the learned Bochart has alleged several strong presumptive arguments. He first addsuces the authority of Jofephus, just cited; he then appeals to the name of the patriarch, "Javan," which, without the points, sounds more properly Ion than Javan; he next alleges the authority of Moses, who says (Gen. x. 5.) that "by these" (the sons of Japhet) "were the fifies of the Gentiles divided;" which, according to the genius of the Hebrew, mean, not islands properly so called, but all maritime countries, at any distance from Palæstine, especially those which are along the Mediterranean; and he also refers to the prophets (Is. cap. ult. v. 19. Dan. viii. 21. x. 20) who call Greece by the name "Ion," Ion, or Javan, and hence the Jews have always called the Greek tongue "Ionic," Javanic. To these arguments he adds that the clear remains of Eilitha, Javan's eldest son, are still to be found in that of Elis, one of the ancient kingdoms of the Peloponnesus.

Greece, or Ancient Greece, Geography of. Exclusively of the provinces of Epirus and Macedon, which long remained barbarous and uncultivated, the continental possessions of the Greeks (says Dr. Gillies,) were nearly equal to Scotland in extent. In its length, comprehended between the 36th and 41st degrees of N. latitude, the whole country is almost equally divided by two opposite gulsps, comprising between them a mountainous neck of land, to the breadth of only five miles, into the peninsula of Peloponnesus, and the territory extending northward, from the extremity of the Corinthian isthmus to the southern frontier of Macedonia. The Peloponnesus, 160 miles in length, and scarcely 100 in breadth, is everywhere intersected by mountains, particularly the towering ridges of Zarex and Taygetus. During the flourishing ages of Greece, this small peninsula contained seven independent communities of unequal power and fame, which ranked in the following order: the comparatively large, and highly diversified, territory of Laconia; the fruitful vale of Argos; the extensive coast of Achaia; the narrow but commercial isthmus of Corinth; the central and mountainous region of Arcadia; together with the more level countries of Elis and Meffenia, which are throughout better adapted to tillage, than any other provinces of the Peloponnesus. The Grecian polities beyond the isthmus of Corinth were more comfortable, extending above 200 miles from east to west, and 150 from north to south. They were naturally divided by the long and intricate ridges of Olympus, Pindus, Oeta, and Ossa, into nine separate provinces; which, during the celebrated ages of Grecian freedom, were occupied by nine independent republics. They comprehended the extensive and fertile plains of Thessaly and Bocotia, both of which were, in early times, much exposed to inundations, and the latter, abounding in subterranean caverns, was peculiarly subject to earthquakes; the less fertile, but more secure territory of Attica; the western provinces of Aetolia and Acarnania, encompassed on one side by dangerous seas, and confined on the other by almost impassable mountains; and the four small rocky districts of Phocis, Doris, Locris, and Megara.

These names and divisions (says the above cited historian) which remained to the latest times, are pretty accurately marked by Homer, whose poems continued, through succeeding ages, to be the approved standard and legal code, to which neighbouring communities adhered, in adjudging their disputed boundaries. This qualification, however, must be admitted with two exceptions. During the Trojan war, the extensive province of Thessaly sent forth above a fourth part of the whole Grecian strength, and was divided among many warlike leaders. But when commerce, navigation, and the mechanic arts, enriched and adorned the middle and southern divisions of Greece, the northern district of Thessaly lost its ancient pre-emience. The other exception arose from the extensive power of the house of Pelops, which, had, by fortunate marriages and rich successions, acquired dominion over the northern and eastern parts of the Peloponnesus, formerly containing several independent principalities, and, after the misfortunes of Agamemnon and his family, again divided into the immortal republics of Sparta, Argos, Corinth, and Achaia. The following table will exhibit at one view the principal flates of Greece, with some of their towns and rivers, referring to each article for a further account, and observing that we have admitted into it Macedonia, though it was not properly a province of Greece till after the reign of Philip, or rather that of Alexander, and also Epirus and Illyria.

T essentially.
The ancient authors, who are to be consulted with regard to the different periods of the geography of Greece, are Homer, for the more remote times, in his account of the forces collected for the siege and capture of Troy; Strabo, who avails himself of ample materials to which he had access; Pausanias, who details the results of his own travels and observations; and Ptolemy, who furnishes an useful nomenclature of the cities and chief towns, with their latitudes and longitudes.

Greece, or Ancient Greece, briefly of. The traditions of the Greeks (savs the learned historian, Dr. Gillies,) agree with the authentic records of sacred history in representing the countries afterwards known by the names of Thrace, Macedon, and Greece, as peopled at an earlier period than any other portion of the western world. The southern corner of Europe, comprehended between the 26th and 41st degrees of latitude, bordering upon Epirus and Macedonia towards the north, and on other sides surrounded by the sea, was inhabited, above 18 centuries before the Christian era, by many small tribes of hunters and shepherds, among whom the Pelasgi and the Hellenes were the most numerous and powerful. The barbarous Pelasgi venerated Inachus, as their founder; and, for a similar reason, the more humane Hellenes respected Deucalion. From his son Hellen, they derived their general appellation, which originally denoted a small tribe in Thessaly, and from Dorus, Eolus, and Ion, his three remote descendants, they were differentiated by the names of Dorians, Eoithians, and Ionians. The Dorians took possession of that mountainous district of Greece, afterwards called Doris; the Ionians, whose name was gradually lost in the more illustrious appellation of Athenians, settled in the left barren parts of Attica; and the Eoithians peopled Elis and Arcado, the western and inland regions of the Peloponnesus. Notwithstanding many partial emigrations, these three original divisions of the Hellenes generally entertained an affection for the establishments which had been preferred by the wisdom or caprice of their respective ancestors; a circumstance which remarkably distinguished the Hellenic from the Pelasgic race. While the former discovered a degree of attachment to their native land, seldom found in barbarians, who live by hunting or pastoral life, the latter, disdaining fixed habitations, wandered in large bodies over Greece, or transported themselves into the neighboring islands, and the most considerable portion of them gradually removing to the coasts of Italy and Thrace, those that remained melted away into the Doric and Ionic tribes. At the distance of 12 centuries, obscure traces of the Pelasgi occurred in several Grecian cities; a district of Thessaly always retained their name; and their colonies continued, in the fifth century B.C., to inhabit the southern coast of Italy, and the shores of the Hellespont; and in those widely separated countries, their ancient affinity was recognized in the uniformity of their rude dialect and barbarous manners, extremely dissimilar to the customs and language of their Grecian neighbours. Such is the account of the first settlers in Greece, given by Dr. Gillies on the cited authorities of Herodotus, Dionysius Halicarn., Pausanias, Thucydides, Diodorus Siculus, and Strabo. Modern authors, however, have entertained different opinions on this subject. Some have supposed that the Pelasgi succeeded the Hellenes, and others have considered them as the same people under different denominations. According to M. de Gebelin, Moses, the Jewish legislator, has given us the primitive origin of the Greeks. In tracing the genealogy of the descendants of Noah he says that Japhet, one of the sons of Noah, had seven sons: that the fourth was called Ion, and that he was the father of Eoith, Tharsis or Thracis, Ketim, and Dodanim; this Ion was the father of the Greeks, and M. de Gebelin labours to find among the Greeks four nations formed by his four sons. With this view, he says, that Pelasgia comprehended the whole territory between the Danube and the sea of Peloponnesus; and here we may discover, as he conceives, the respective situation of each of Ion's four sons. Thrace acknowledges Tharsis or Thrasius for its founder; Ketim possessed the country of the Getæ, N. of Macedonia, and Macedonia itself; Dodanim had the country that lay between Macedonia and the Peloponnesus, inhabited by the Dorian; and Elfa designated the inhabitants of the Peloponnesus. This author, in no small degree indulging his imagination, and yet exercising a very considerable degree of ingenuity and attention to facts, observes, that the history of Deucalion is the foundation of the Greek chronology and history; this Deucalion is distinguished by his deluge, his ark, and his being the father of the Greeks or Hellenes. All these circumstances afford a presumption that Deucalion and Noah were the same person. He also says, that the fable of the Argonauts and their voyage to Colchis is a copy of the navigation of Noah. Phryxus, or the "man faved," in the Grecian mythology, is Noah. He discovers also other coincidences, which lead him to conclude, not only that Noah and Deucalion, but that Ion and Hellen, the reputed father of the Greeks, were the same person; and that the Hellenes and Pelasgi were the same people. According to this writer, the Pelasgi were the sole poecloflos of the whole country which extended itself from the banks of the Danube, to the sea of the Peloponnesus; they peopled Thrace, Getæ, Macedonia, Illyria, Epirus, Thessaly, the Phocidea, Attica, and the Peloponnesus; they sent colonies to the ile of Crete, to Etruria, and to the south of Italy; and others crossed the Dardanelles, and were denominated Dacians and Getæ. Greece was in this flat, says M. de Gebelin, when some colonies of strangers arrived on its coasts, as Cecrops at Athens, Danaus at Argos, and Cadmus in Boeotia. Thence, he says, came not from Egypt, but from Phoenicia, a neighbouring country. The first inhabitants of Greece, nevertheless they came, were, in a very considerable degree, like the ancestors of other people, barbarous and savage; and the Hellenes, whose manners were mild and gentle, contributed in some measure to civilize them; but their efforts produced effect very slowly. At length, however, the happy position of their country, forming a kind of frontier between Europe and Asia, and divided only by a narrow sea from Egypt and Syria, and not far remote from those-easter regions which were anciently most populous and flourishing, invited strangers hither to visit, and afterwards to dwell among them. The Greeks were not infensible of their obligations to strangers for the most important discoveries, not only in religion, but in agriculture and the arts; but as they advanced to superiority in arts and arms, above surrounding nations, they vainly fancied that their infancy was reared by the gods; and to the gods they transferred the merit of many useful inventions, that had been communicated to them or their progenitors by their ancient visitants; and it must be acknowledged, that the worship of several divinities was introduced at the same time, and by the same perfons, who made known to them the arts most subfervient to the purposes of human life.

From the middle of the 15th to the middle of the 14th century, B.C. an inundation of Egyptians, Phrygians, and Phrygians overflowed the Hellenic coasts. The principal colonies were conducted by Cecrops and Danaus, Egyptians, who respectively settled in Athens and Argos; Cadmus, a Phoenician, who founded Thebes in Bœotia; and Pe-
Europe. indulged They journey, infomuch, Paleallnie, fancy, fulcli from their well formed Greeks. opinions with three and undertake' the their knowledge in the operations of agriculture; they multiplied the rites of religion; discovered to them several uses of the metals; and, in return, adopted the Greekian language, and generally conformed to the Greek customs and institutions. By the Phoenicians they were taught and encouraged to brave the dangers of the sea, and to maintain a commercial intercourse with each other, as well as with foreign nations. Their country, indeed, was peculiarly advantageous for this purpose; three sides of it being washed by the sea, and being surrounded by numerous islands, and abounding in excellent harbours. Greece, however, was slow in availing itself of the advantages it enjoyed; and in making improvements in commerce, as well as in agriculture, and other useful arts. Many circumstances concurred to retard its improvement. The inhabitants of different parts of the country were unconnected on account of the creeds and rivers, as well as the mountains and promontories, that rendered Greece different from any other part of Europe. The Greekian states were small; each city was at war with its neighbour, and wanted union and mutual concurrence prevented the advancement in science, and the arts. Besides, their coasts were ravaged by pirates, and the metals, instead of being formed into useful implements of agriculture, were converted into instruments of destruction, partly for hostility and partly for self-defence; and the inland country was invaded by Thracians, Amazonians, and other northern savages. But these invasions and ravages of the barbarians occasioned the instituting of the Amphictyonic council, which restored some degree of present tranquillity to Greece, and laid the foundation of its future grandeur. This council produced, after a considerable interval of time, and in the year 1263 B.C. the Argonautic expedition, an undertaking which was attended with a beneficial effect on the manners and character of the Greeks. (See Argonautic.) In the progress of the Greeks towards civilization, they perceived the advantages of political confederacy, before they became sensible of the benefits of civil union; and accordingly a federal association between different communities was formed before the members of any one state had been sufficiently united in the system of domestic policy. In order to cement such disorderly communities by laws and governments, they had recourse to the wise institutions and examples of the Cretans, which are represented not only as the most ancient, but as the best regulations that ever were established in any portion of the Grecian territory. (See Cretes.) Thebæus communicated the Cretan improvements to the Athenians; from Athens they were diffused through Attica, and in process of time through the neighbouring provinces of Greece; inasmuch, that at the commencement of the Trojan war, in 1193 B.C. all the Greekian states had adopted one uniform system of government, uniting the independent spirit of European freedom with the respectful veneration of Egyptian and Atlantic superstition.

Of the mythology and manners of the Greeks in the heroic ages, as well as their geography and history, Homer, whilist he has indulged his fancy, has given us an accurate delineation; and such as was conformable to the system of opinions and belief which prevailed among his countrymen. The religion, or mythology of the Greeks, was adapted to the melioration of their condition, and to the improvement of civil society. Unlike that of the rude inhabitants of ancient Germany, among whom the offices of priest and king were administered by different persons, the foepitre, which denoted the connection of civil power with sacred protection, was conferred, among the Greeks, on those who, while they continued the humble minister of the gods, were appointed to be the chief, but accountable guardians of the people. The same voice (says Dr. Gillies), that smothered the warriors to adventure, and decided, in time of peace, their domestic connections, conducted the order of their religious worship, and presided in the prayers and hymns addressed to the divinity. These prayers and hymns, together with the important rite of sacrifice (which was likewise performed by royal hands), formed the ceremonial part of the Grecian religion. The moral was far more extensively acceptable to the stern god of war; but the virtues of charity and hospitality were still more pleasing to the more amiable divinities. To this purpose Homer says (Od. xiv. 56.) _" all strangers and beggars come from love."_ The submission of subjects to their prince, the duty of a prince to preserve inviolate the rights of his subjects (Il. xvi. 385.), the obedience of children to their parents, the respect for the young for the aged, the sacred laws of truth, justice, honour, and decency, were inculcated and maintained by the awful authority of religion. Even the most ordinary transgressions of private life were congratulated by the pity of the Greeks. They ventured not to undertake a voyage, or a journey, without soliciting the propitious aid of their heavenly protectors. Every meal (and they had three in a day, _v. i. iexa, leiphe, leixo_), was accompanied with a sacrifice and libation. The common form of petitions, the customary duties of civility, were not decided by the varying fates of individuals, but defined by the precise voice of the gods. The laws of religion were guarded and enforced by corresponding sanctions. The dreaded vengeance of imaginary powers was established in the Grecian creed; and it appears from the writings of Homer throughout, that every important event, prosperous or adverse, which happened either to individuals or to nations, appeared to the Greeks, as the reward of their religion and virtue, or the punishment of their irreligion and vice. The principles above stated are confirmed not only by the writings of Homer and Hesiod, but by almost every page of Herodotus, of Pindar, as well as of the Greek tragedies and historians.

The origin of the gods of Greece has afforded a subject of elaborate discussion; and many learned writers have traced it to Palestine, Egypt, and other nations, whence the first settlers or future emigrants sprang. By the dim light of etymology and tradition (lays the ingenious historian of Greece), and the deceitful glare of legend and fable, inquisitive men have endeavoured to trace the corrupt endreams of Pagan worship to the pure fountain of the Jewish dispensation; and it must be acknowledged, that the general doctrine of providence, the rebellion in heaven, the state of innocence, the fall of man, atonement by sacrifice, and a future state of retribution, for which the present life is only preparatory, are tenets, all, or some of which, are found in
the traditions of all nations, Greeks and Barbarians. (See Hefiod, Oper. and Di. v. i. 165. Theog. v. 220. 725.)

But our authority proceeds, that the majesty of Jehovah is very feebly represented by the united power of Homer's divinities; and that the mythology of the Greeks is of such a peculiar texture, that, whenever originally derived, it must have undergone a particular modification in the Grecian soil; nor (he says) is it easy to concur with the opinion of writers who bring it immediately from Egypt, Chaldæa, or Leiffer Afia, when we consider that there is not the smallest vestige in Homer of the judicial astrology which prevailed so much in the two first countries, (Diod. Sic. i. ii. Exod. ch. vi. Psil. i. xxxv.) or of the worshipping of idols, which almost universally prevailed in the last. (Old Testament, paffim.) Dr. Gillies traces the origin of the Grecian faith and worship in the natural passions of the human heart, the hopes, the fears, the wants, the misery of man, which in all ages rendered him a prey to the terrours of superstition.

The great pillar of superstition, raised by the anxious passions of men, was fortified in Greece by a peculiar facility of character, which exerts itself in the exercise of social affection, and strengthens, by a variety of associations, their belief of invisible and intelligent powers. The nature, the character, and the occupations of the gods, were suggested by the lively feelings of an ardent, rather than by the regular invention of a cultivated mind. These celestial beings were subject to the blind passions which govern unhappily mortals: their wants, and their desires, were similar to those of man. But what was wanting in the dignity and perfection, was supplied by the number of the gods. Homer only describes the principal and reigning divinities; but Hefiod, who gives the genealogical history of this fanciful hierarchy, makes the whole number amount to 30,000. Every virtue had its protector, every quality of extensive power in human life had its patron, and every grove, mountain, and river its favourite inhabitants. (See Gons.) The religious creed of the Greeks, composed of materials, in great measure created by fancy, formed by poetry into beauty, and improved into use by policy, became the happiest antidote against the furious renfement, the savage cruelty, and the fierce spirit of wild independence, which usually characterized the ancient and venerable sages of barbarians. The whole system of the Greeks was distinguished above most other false religions, by the uncommon merit of doing much good, without seemingly occasioning any considerable harm to society. The Grecian tenets, while they inculated profound respect to the gods, had no tendency to break the spirit or to repress the courage of their warlike votaries. In order to avert the calamities threatened by the anger of their divinities, they did not recur to the infliction of tortures on themselves, but they repaired the wrongs which they had committed against their fellow-citizens, or compensated, by new attentions, for the neglect shewn to the ceremonies of their national worship. In their estimation, the doing of injury to men, and the omission of prayer to the gods, were the principal causes of the divine displeasure, which they were anxious to avert by a diligent practice of moral duties. The dangerous power of oracles, the abused privileges of asylum, the wild raptures of prophetic enthusiasm, the abominable ceremonies of the Bacchanalia, and the horrid practices of human sacrifice, all which are circumstances that cover with disgrace and infamy the latter periods of Paganism, were unknown to the good influence and purity of the heroic ages; nor is there to be discovered the smallest vestige of any of these wild or wicked inventions, either in the writings of Homer, or of his contemporary Hefiod. Their religious syste

G R E C I A.

In examining the political states of the Greeks, during the heroic age, we shall find that they deserve the title of republics, rather than that of monarchies. The soldiers of any warlike tribe fought and conquered, in their attack of a more fertile territory than their own woods and mountains, not for their leaders, but for themselves; and the land acquired by their united valour was considered as a common property. No disjunction was known among them, but that which was occasioned by the difference of personal merit and abilities. This difference raised a chief or leader to the head of each society; and his superior usefulness in this station, was rewarded by the gratitude of his tribe with a valuable portion of ground, separated from the common property. (II. xii. 310.) This perfec, who commanded in the field, became the arbiter and judge of their civil differences, and he was invested with the honourable office of presiding in their religious ceremonies. The important functions of priest, judge, and general, conferred on the chief and bravest in each particular tribe, were conferred, upon the union of several tribes into one state or nation, on the chief and bravest of all the different leaders. The various states of Greece formed a general confederacy, in which the council of princes regulated the resolutions of the monarch, and the voice of the assembly ruled that of the council; and so likewise in each particular kingdom, the decisions of the senate prevailed over the will of the prince, and the acknowledged majesty of the people controlled the decisions of the senate. The fame distribution of power took place in every particular village.

The civil rights of the Greeks were maintained by the fame simplicity which regulated the political system. As the price of submitting to the restraints of society, a man was secured in the enjoyment of his life and property: his moveables were equally divided, at his death, among his descendants; and the unnatural right of primogeniture, which, in order to enrich the eldest son, reduces the rest of the family to want and misery, was altogether unknown to the equal spirit of the Greek institutions. Causes respecting property were decided by the first magistrate, or by judges of delegated authority. The prosecution of murderers belonged to the relations of the deceased, who might accept a compensation in money for the loss which the family had sustained; but in defect of this composition, all the members of the tribe concurred with the aggrieved, in either punishing the murderer by death, or compelling him to leave the society.

The history of the heroic ages of Greece prefers the most interesting picture of conjugal love, parental affection, and filial duty. The institution of marriage was ascribed to the gods; and it was celebrated with all the pomp of religious festivity. Adultery was held in the greatest detestation, and always mentioned with the same horror as murder. The guilty person might purchase immunity, but more frequently escaped death by voluntary servitude. It has been erroneously said, that, in ancient Greece, wives, as well as concubines, were the slaves of their husbands, and that they were purchased by them. The attention of women was chiefly confined to domestic care and occupations, which did not require any great degree of strength, courage, or wisdom. Weaving and embroidery, which were employments of females, were practised by ladies of the highest rank, and even by queens; and they were also entrusted...
tried with the education of their children. They were permitted to join in the celebration of religious rites and ceremonies, and many of them were consecrated to the service of particular deities.

War, being the principal employment of the Greeks in the heroic ages, they supplied by courage what they wanted in skill. They marched to the field in a deep phalanx, rushed impetuously to the attack, and bravely closed with their enemies. Their principal weapon was the spear; and when the use of this failed, they drew their swords, and rushed impetuously on the foe. The Greeks had also bows, flings, and darts which were chiefly used in their military pacifics. Their defensive armour was complete: a light helmet, adorned with plumes, covered the head and face, a fine coriell defended the breast, groves of brais defended to the feet, and an ample shield, lightly attached to the shoulders, turned in all directions, and opposed its firm resistance to every hostile assault. Their close combat battles served to excite the most furious passions, and to embitter national animosity by personal hatred and revenge. Before any war could be undertaken, it was necessary to dispatch ambassadors, who explained the injury that had been done, demanded satisfaction, and if this were refused, denounced the resolution of their community to prosecute its claim by force of arms. After the commencement of war, the characters of heralds were equally respected by friends and foes; and they travelled in safety through the midst of embattled hosts. The use of poisoned weapons was forbidden, under pain of the divine displeasure. The will of the gods required that life should be spared, when a sufficient ransom was promised; and when a treaty of peace was concluded, without any ratification but the honour of the contracting parties, the peridious wretches who betrayed the faulty of their engagements were devoted, amidst libations and sacrifices, to the fury of the terrible goddesses.

(II. 1.)

From the practice of war we may now turn our attention to the arts of peace. Pallagage and agriculture supplied the Greeks with food and clothing; but their implements for preparing these articles were very imperfect. The principal produce of their fields was barley, which supplied the ordinary food of men as well as horses. Mills were the steam, and the grain was bruised between two large stones with the hand. They cultivated the olive, but knew not how to extract the oil; and though their soil was favourable to the grape, the juice was obtained by a tedious and operose process, which rendered wine scarce and dear. Of the mechanic arts, weaving was but little understood; and the hatchet, wimble, plane, and level, are the tools mentioned by Homer, who seems to have been unacquainted with the saw, the square, and the compasses. Homer does not mention the orders of architecture; and pillars are the only ornaments adjoined to the edifices which he describes. The roofs of the houses, consisting of two floors, and surrounded by a wall, were flat. The invention of enamelled metals had been cultivated with peculiar felicities; and though painting, properly so called, was rude and unformed during the age of Homer, the genius of the divine poet has described the rudiments of his kindred art with such grace as would adorn its most refined state of perfection. Music was much practiced among the early Greeks. (See Music of the Greeks.) The sciences were in a low and imperfect state. For arithmetic they had little occasion; by means of their astronomy they were enabled to observe the eccentricals which directed the adventurous course of the mariner; but their navigation was so imperfect, that they seldom abandoned the coasts. The only stars mentioned by Homer are the Great and Little Bear, the Pleiades, the Hyades, Orion, and the Dog-star. Of their games, we give an account under Games and Gymnastics. As to their general character, we shall transfer the two or three paragraphs from the first volume of Dr. Gillies's History of Ancient Greece, to which we have been indebted in the compilation of this article. "The Greeks, says Dr. G., had advanced beyond that uniform idleness of deportment, that fallen ferocity of manners, and that hardened insensibility of heart, which universally characterizes the savage state. They still policed, however, that patient intrepidity, that noble spirit of independence, that ardent attachment to their friends, and that generous contempt of pain, danger, and death, which render the description of the wild tribes of America so interesting to a philosophic mind. Of two principal en-joyments of life, study and conversation, they were little acquainted, indeed, with the confolations and pleasures of the first, the want of which was compensated by the finery, the confidence, the charms of the second. Their social affections were left comprehensive in their objects, but more powerful in their effects than those of polished nations. A generous chief rushes to certain death to revenge the cause of his friend; yet refuses to the prayers of an aged parent the melancholy consolation of interring the remains of his favourite son, till the corresponding image of his own father arise in his mind, and at once melts him to pity. (Iliad, xxiv.) The imaginary wanton and artificial passions which are so necessary to urge the hand of industry, and to vary the pursuits of men, in improved commercial societies, were supplied to the Greeks by that excessive sensibility, which interested them so deeply in the affairs of their community, their tribe, their family, and their friends, and which connected them by the feelings of gratitude even with the immate objects of nature. As they were not acquainted with the fame diversity of employments, so neither were they fatigued with the same giddy round of dissipat pleasures which augment the splendid misery of later times. Though ignorant of innumerable acts which adorn the present age, they had discovered one of ineffable value, to render the great duties of life the most entertaining amusements. It will not, perhaps, be easy to point out a nation which united a more complete subordination to established authority with a higher degree of personal independence, and a more respectful regard to the dictates of religion with a more ardent spirit of martial enterprise. The generous quality of their principal establishments, and their fancied intercourse with the gods, conspired to raise them to a certain elevation of character which will be for ever remembered and admired. This character was rendered permanent in Sparta, by the famous laws commonly ascribed to the invention of Lycurgus, but which will appear (under that article) to have been "almost exact copies of the customs and institutions that universally prevailed in Greece during the heroic ages." The character of the Greeks in subsequent periods will appear in the account of the several states, provinces, or kingdoms, which they occupied.

The general history of Greece may be divided into four periods, marked by as many memorable epochs. The first extends to the siege of Troy in the year 1 184 B.C.; the era of its commencing is not precisely ascertained; but if we date it with the foundation of the kingdom of Sicily by Anaximander in the year 2670 B.C., it lasted 905 years. This was properly the infancy of Greece; and comprehended the establishment of the kingdoms of Sicily, of Argos, 1376 B.C., of Athens, 1556 B.C. of Troy, 1546 B.C. of Thebes, 1493 B.C., of Mycenae, 1444 B.C.; the deluge of Ogyges, 1764 B.C. and that of Deucalion, 1503 B.C. \[4B\]
the murder committed by the daughters of Danaus on their husbands, 1485 B.C.; the introduction of the Phoenician letters into Greece, 1493 B.C.; the legislation of Minos in Crete, 1426 B.C.; the Argonautic expedition, 1265 B.C.; the exploits of Theseus, 1234 B.C.; the war of the seven heroes against Theseus, 1225 B.C., &c. &c.

The second period begins with the siege of Troy, and terminates with the battle of Marathon, 490 B.C., including about 694 years. In the year 1104 B.C., 86 years after the taking of Troy, the Heracleida, or descendants of Hercules, conducted the Dorians to the eastern coast of Peloponnesus, and having landed their followers without opposition, subdued the dodecarchies, territories, to which they had long laid claim, comprehending the whole Peninsula, except the central province of Arcadia, and the maritime district of Achaia. The five other provinces were conquered at the same time, though by different means. Laconia was betrayed to the invaders; Argos acknowledged their authority; Corinth, Elis, and Messenia submitted to their arms. The revolution was complete, and effected with little bloodshed; but not without great oppression of the ancient inhabitants, many of whom emigrated, and many were reduced to slavery. The Heracleida divided their new acquisitions by lot. Upon the division of Peloponnesus the kingdom of Laconia commenced, 1102 B.C. In the year 1056 B.C., or 88 years after the taking of Troy, the Eolians, having traversed the northern parts of Greece in quest of new settlements, crossed the Hellespont, and established themselves along the shore of the ancient kingdom of Priam. They gradually diffused their colonies from Cyzicus on the Propontis to the mouth of the river Hermus; which delightful country, together with the isle of Lesbos, from this time received the name of Eolis or Eolia, denoting that its inhabitants belonged to the Eolian branch of the Hellenic race. In the year 1070 B.C. royalty terminated in Athens upon the death of Codrus, and the Athenians were afterwards governed by Archons. In the year 1044 B.C., 63 years after the return of the Heracleida, the Ionians, blended with other emigrants, having seized the central and most beautiful part of the Aeolic coast, gradually diffused their colonies from the banks of the Hermus to the promontory of Paphion, and afterwards took possession of Chios and Samos; and all these countries were united in the year above-mentioned by the name of Ionia, intimating that the Ionians composed the most numerous division of the colony. (See Ionia.) The Doric migration took place in the year B.C. 944 (See Dorians.)

During the heroic ages we have seen, in the preceding part of this article, that the authority of kings was founded on religion, supported by gratitude, and confirmed by utility. While they approved themselves worthy ministers of heaven, they were entitled to due and hereditary honours; but they were bound to respect the rights, the sentiments, and even the prejudices of their subjects. But at length, inced by ambition and avarice, they transgressed the prescribed limits, and trampled on those laws which their predecessors had held sacred. The minute division of property, which had taken place, not only in Peloponnesus, but in the northern provinces of Greece, rendered the nobles and people more liable to their approaches, and induced them to repeat their oppression. The more independent and illustrious citizens, who from the earliest times had been accustomed to come armed to the council or assembly, communicated their grievances, and adopted proper means for removing them. Miltiades, the fourth Argive prince in succession to Temenus, to whom Argos fell on the Heraclidaan distribution, was condemned to death for usurping absolute power. In Attica monarchy more honourably expired; it perished with more disgracefully in Arcadia; but was gradually abolished in every province of Greece, except Sparta, from the southern extremity of Peloponnesus to the northern frontier of Thessaly. The consequence of the abolition of monarchy was the introduction of accumulated evils. These, however, were removed, or at least alleviated, by the authority of the Amphictyonic council, and by that of the oracles, particularly that of Delphi. This latter oracle confirmed by its awful function the Olympic games and Spartan laws, which had been respectively established, the former by Iphitus, and the latter by Lycurgus in the same year, viz. 884 B.C.; and which served to the safety of their respective territories, though in different ways; the Olympic games by rendering Elia the most pacific, and the laws of Lycurgus by making Sparta the most warlike, of all the Grecian communities. Greece, even under its kings, was divided into many independent states; and under the republican form of government it was still more subdivided; and hence wars became more frequent, and battles more bloody and more obdurate. But the long and spirited contest between the Lacedaemonians and Meffennians was the only war of that age which produced permanent effects. Of Laconia and Meffenia we shall give an account under their respective articles. We shall here observe, that they were both governed by kings of the family of Hercules, and inhabited by subjects of the Doric race, and yet this kind of mutual affinity and connection was not sufficient to counteract other causes, which produced hostilities among them. Urged by reciprocal provocations which we cannot here detail, the Spartans invade the Meffennian frontier and attack the small town of Amycla; and thus in the year 743 B.C. began the first war between the Meffennians and Lacedaemonians, which lasted 19 years, and terminated with the surrender of Ithome, their capital, to the Lacedaemonians, and the dispersion of its inhabitants. In the year 685 B.C. the Meffennians prepare to revolt, and a second war commences, which continued 14 years, and ended with the capture of Itra, or Eira, by the Lacedaemonians, after a siege of 11 years. The conquest of Meffenia rendered Sparta the most considerable power in Greece, as its subjects occupied two-fifths of the Peloponnesus. In the year B.C. 600 commenced the first "Sacred War," occasioned by an injury committed against the oracle of Delphi, and undertaken by order of the Amphictyons, and terminated by the total destruction of the cities accused of sacrilegIOUS outrage. On occasion of the happy termination of this war the Pythian games were re-established 591 B.C. The battle of Marathon, which closes this second period of the Grecian history, terminated, after a very severe contest, in the total defeat of the Persians, and triumph of the Athenians under their commander Miltiades.

The third period of the history of Greece comprehends an interval of 167 years, that elapsed between the battle of Marathon and the death of Alexander, 323 B.C. The Athenians, in compliance with the advice of Themistocles, augment their navy; and under his command they defeat the fleets of Xerxes and Corecyra. Themistocles, instead of allowing the Athenians to indulge themselves in security after the advantages they had gained, exhorted them to be always ready for action. In consequence of this judicious counsel, they were enabled to oppose the immense armaments of Xerxes. The Athenian fleet proved the safe-guard of Greece, and prevented a country, from which the knowledge of laws, learning, and civility was diffused over Europe, from becoming a province of the Persian empire, and being confounded with the masts of barbarous nations. Xerxes was provided
GRACIA.

provided with 1200 ships of war, and 3000 ships of bur- 
than, for his intended expedition: and his army consisted of 
eventeen hundred thousand infantry, and four hundred thou-
sand cavalry, and these, joined to those who manned his 
flattened, to near two millions of fighting men. In the year 480 B.C. he passed the 
Hellepont, and the wondrous monarch had the pleasure of reviewing the whole 
flotilla and army near Doricus, a city of Thrace, at the 
mouth of the river Hebrus. In the mean while those Greci- 
ans, who, unmoved by the terrors of invasion, obeyed the 
voice of liberty and their country, had sent deputies to the 
ithmus of Corinth, to deliberate about the common safety. 
A general union prevailed, and the general danger seemed to 
harmonize the most discordant members of the common 
council. The Grecian fleet failed to Artemision, patient- 
ly expecting the arrival of the barbarians. The fleets of 
Thermopylae, 15 miles distant from the flotilla of the Greci- 
ian fleet at Artemision, and deemed the gate or entrance into Greece, was guarded by troops, consisting chiefly of 
Persepolitanians, under the command of Leonidas, the 
Spartan king. Xerxes having made his previous arrange- 
ments, sent messengers to treat with the Spartans, and to de- 
ter them to lay down their arms; to which they replied, 
"Let him come and take them." The messengers then of-
tered them lands, on condition of their becoming allies to the 
great king, but they answered: "That it was the custom of 
their republic, to conquer lands by valour, not to acquire 
them by treachery." Xerxes waited four days after the 
return of the messengers, expecting the Grecians to retreat 
into their own country, or surrender their arms. On the 
fifth day he determined to chastise their insolent opposition. 
The attack was ordered, and the Persians were repelled: it 
was renewed the next day with the like result. 

The Greeks, however, were betrayed by Epialtes, a per- 
fidious wretch of their own nation, who conducted a body of 
twenty thousand Persians through a passage in the moun-
tains of Ossa, several miles to the west of that guarded by 
Leonidas. The Athenian general had prudently guarded this 
important but unknown path, which, as he conceived, chance 
or treachery might discover to the Persians. A body of 
1000 Phocians had been appointed to this service; upon 
the approach of the Persians they instantaneously flew to their arms, 
and determined to resist the progres of the enemy or to die 
in the attempt. Expecting to be pursued, they retired to the 
heighted part of the mountain; but the Persians, declining to 
follow them, feized the passage which they had aban-
doned, and marched down the mountain in order to accom-
plish the design which had been preconcerted by the traitor 
Epialtes. Leonidas, apprized of this act of treachery, called 
a council of war; when all the confederates of Persepolis, 
except the Spartans, determined to abandon a post which they 
deemed to be untenable. Leonidas, however, with 700 
Thebians, 400 Thiscans, and 300 Spartans, remained in the 
poll of danger and of glory. In the dawn of night, the 
Spartans, headed by Leonidas, marched in close battalion 
towards the Persian camp, with resentment heightened by 
depair. The conflict was ardent and destructive, whilst the 
Greeks were favoured in their attack by the darkness of the 
night; but at the approach of day the Persians, who had 
previously fled, discovered that their fears had multiplied the 
number of the enemy; and therefore rallying their scattered 
forces, Xerxes gave orders to pursue the Greeks, who had 
retreated in close order to the fronds of Thermopylae. 
The shock was dreadful; and the battle was maintained on the 
tide of the Greeks with persevering intrepidity and def-
perate valour. At length a barbarian dart pierced the heart 
of Leonidas; nevertheless the Laccestrians and Thebians, 
though ingloriously defeated by the Thebans, maintained 
their firmness to the last; and they were finally not defrayed 
or conquered, but buried under a trophy of Persian arms. 
(See LEONIDAS and THERMOPYLAE.) During the military 
operations at Thermopylae, the Grecian fleet was stationed 
in the harbour of Artemision, the northern promontory of 
Euboea, and the numerous one of the Persians had an-
chored on the road that extends between the city of Caifanza 
and the promontory of Sepias, on the coast of Thebaly. 
Here it suffered calamities, of which Xerxes had been fore-
warned, but which he disregarded. Themistocles, by his 
address, prevailed on the Athenian commander to remain at 
Artemision; and as soon as the Persians recovered from the 
terrors of the storm, the effects of which they had suffered, 
both sides prepared for a battle, for the refult of which see 
ARTENIUM, The Persians were again totally defeated near 
Salamis (which fee); upon which Xerxes determined to 
leave Greece. Of the conduct of Themistocles on this 
occasion, see his article; and for an account of the battle of 
Plataea, see PLATAEA. The event of this bloody engage-
ment not only delivered the Grecians from the danger of fer-
ducy, but gave them possession of greater wealth than they 
could ever have expected to posses. In his precipitate re-
trart from Greece, Xerxes left behind him all his riches 
and magnificence. The battle of Plataea was succeeded by that of 
Myical, in which the Greeks were again victorious. 
About 40,000 Persians perished in the field, many fell in the 
pursuit, and the remainder fled in disorder, nor thought them-
elves secure till they had reached the walls of Sardis. 
Their ships, their camp, the freedom of Ionía, and the undisturbed 
possession of the Asiatic coast, formed the inestimable prize 
of the victors; and thus the expedition of Xerxes, under-
taken with a view to enslave Europe, restored liberty to the 
fairest portion of Asia. The beginning of the 5th century 
B.C. forms the most glorious era in the history of Greece. 
It is, however, the peculiar glory of the Athenians that, 
during their rapid career of military and naval triumphs, 
they cultivated, with a generous enthusiasm, the arts which 
adorn peace as well as war. It is observable that in the sin-
gle life-time of Pericles, the republic of Athens produced 
those inestimable models of poetry, eloquence, and philo-
 sophy, which, in every succeeding age, the enlightened por-
tion of mankind hath invariably regarded as the lofti-
standards, not merely of composition and style, but of 
taste and reason. The name of Greek seemed thenceforth 
to be funk in that of Athenian. (See ATHENS, and 
SPARTA.) For an abstract of the further history of this 
period of Alexander's history and exploits, we have given a 
brief sketch under his article; we shall here observe, with 
Dr. Gillies, that during the latter years of his reign the 
Greeks, deprived of the honour and delivered also from the 
cares of independent sovereignty, and undisturbed by those 
continual and often bloody dilisions, which deformed the 
nation under their turbulent condition, indulged their natural 
propensity to the social embellishments of life; a propensity 
by which they were honourably distinguished above all other 
nations of antiquity. Their innumerable shows, festivals, 
and dramatic entertainments, were exhibited with more pomp 
than at any former period. The schools of philosophers and 
rhetoricians were frequented by all descriptions of men. 
Painting and statuary were cultivated with equal ardour and 
succes. Many improvements were made in the sciences, and 
the Greeks, particularly the Athenians, still rivalled the 
taste and genius, though not the spirit and virtue, of their 
ancestors. Yet even in this degenerate state, when patriotic 
and true valour were extinct, and those vanquished republi-
cans had neither liberties to love, nor country to defend, their 
martial
martial honours were revived, and brightened by an associa-
tion with the renown of their conqueror. Under Alexander, their
exploits, though directed to very different purposes, equaled, per-
haps excelled, the bejewelled trophies of Marath-
on and Plata. 1 By a singularity peculiar to their fortune, the
era of their political disgrace coincides with the most
splendid period of their military glory. Alexander was him-
self a Greek; his kingdom had been founded by a Grecian
colony; and to revenge the wrongs of his nation, he under-
took and accomplished the most extraordinary enterpris-
res recorded in the history of the world.

The fourth period of the history of Greece, commencing
with the death of Alexander, 323 B.C. and terminating
146 B.C. when the Achaean league was dissolved, and
Greece became a Roman province, under the name of
Achaia, comprehends an interval of 177 years. After various
changes and revolutions, for an account of which, see
ACHAEANS AND ATTI.

Greece, Magna, a name given to the southern part of
Italy, comprehending Apulia, Lucania, and the country of
the Buri, and also to Sicily and several of the adjacent
islands. The name of Greece was derived from the Greek
colonies, which migrated hither at different periods, and the
epitaph Magna, or great, was derived from mere osten-
sation, as Pliny informs us (I. iii. c. 1.). This migration and settle-
ment took place at a very early period, about 1055 years
B.C. The most numerous colonies, the migration of which
was occasioned by intestine faction, foreign invasion, or the
reflex of spirit of adventure and rapine, occupied the isles of
the Ionian and Egean seas, the southern coast of Italy almost
interfected by the former, and the wooring shores of Asia
Minor so beautifully diversified by the latter. The larger
islands of Sicily, Sardinia, and Cyprus were very anciently
planted by Greeks.

Whoevers has observed the defective barbarity of Calabria,
or reflected on the narrow extent and present weaknesses of
Sicily, will scarcely believe, that five centuries B. C. those
countries contained above 20 warlike communities, several
of whom could feed into the field 100 thousand fighting
men. In order to account for this wonderful population,
we must look back to the period above mentioned in the
heroic ages; and consider likewise that the greater number
of Greek colonies in those parts were planted during the
eighth century before the Christian era, and chiefly, 1. By the
Euboeans, whose principal city Chalcis, usually furnishing
the conductor of the colony, gave the epithet of Chal-
cidian to the new settlements; 2. By the Achaeans of Pel-
opomeii, who were of the Eolian tongue and images; and 3.
By the Dorian states of that peninsula, especially Corinth.
Besides these powerful colonies in Corcyra, Locres, Amat-
torium, Ambracia, whose transactions form such an im-
portant part of the history of ancient Greece, the Corin-
thians founded Syracuse, which soon became, and long
continued, the capital of Sicily; and in the sixth century
B. C. the Syracusians had extended their settlements over
all the southern coast of the island. By means of these and
similar establishments of a powerful kind, the Dorians ac-
quired, and always maintained, an ascendant in Sicily; but
the Achaean colonies, who were of the Eolian blood and
language, commanded the Italian shore. Crotona, the most
considerable city of the Achaeans, and of all Italy in ancient
times, was built 710 years B. C. Sybaris, its rival, was
founded about the same time. The former sent colonies to
Tirins, Cephalaoria, and Pandória; the latter built Lapis,
Metapontum, and Polidonia, or Paedum, whose admired
ruins attest the ancient wealth and grandeur of the Greek
cities of Italy. We may here remark, that the Ionians,
who came from Euboea, and settled chiefly near the eastern
shore of Sicily, never rivaled the power and fame of their
Dorian and Achaean neighbours, but fell short of those
notions in Magna Graecia, as much as they surpassed them
in the shores and islands of Asia. In order to account for
the flourishing situation of Magna Graecia about the year
500 B. C., many causes may be assigned, besides those of
a physical and moral nature, which usually contribute to the
rapid growth of newly-established colonies. We might
mention the natural fertility of Magna Graecia, and partic-
ularly of Sicily, which in many places produced an hundred
fold; and in this connection observe, that the Greeks who
failed thither from Peloponnesus, carried with them the
knowledge and practice of agriculture, which had early
attained a high degree of perfection in their peninsula; and
that the exuberant soil of Sicily, improved by cultivation,
soon exhibited a picture of that rich abundance, which, in
later times, made that beautiful island be entitled the gra-
mary of Rome. Besides, the peculiar situation of the
Achaeans and Dorians, from whom chiefly the colonies in
Magna Graecia derived their origin, had a considerable in-
fluence in accelerating the population and grandeur of their
new establishments. The impartial and generous spirit of
the Achaean laws early compensated the natural defects of
their territory, which was a long, but narrow, strip of
ground, not more fertile than extensive, along the Corinthian
gulf. They, however, were the first, and long the only
republic of Greece, who admitted strangers into their com-
unity on equal terms with the ancient citizens. The
equitable and generous policy, which they transported with
them into Magna Graecia, could not fail to promote the
happiness and prosperity of that delightful country.
The condition of the Dorians, at the time when they planted
colonies in Italy and Sicily, is not less worthy of considera-
tion. The Dorian states of Peloponnesus were then uni-
versally subject to the gentle government of limited but
hereditary princes, or to magistrates chosen from the
defendants of their ancient royal families; and who, thus
adorned by birth, were sometimes still more ennobled by
wifenomt and virtue. Moreover, the colonies in Magna
Graecia, enjoying a wide extent of territory before them,
were not retarded in their advancement by intercourse of
interest on the part of neighbouring states, but they found
sufficient employment in subduing the original inhabitants
of that country, without commencing hostilities either
against their neighbours or against each other. The kings
or nobility of Magna Graecia, secure of their own pre-em-
nence, felt nothing of the republican jealousies which
prevailed in the mother country. They received with pleasure
new citizens, or rather subjects, from whatsoever quarter they
might come. The states of Italy and Sicily, thus increasing
by degrees, could soon boast, the former of Crotona, Ta-
rentum, Sybaris, Rhegium; the latter of Syracusae, Agrig-
etum, Messena, Himera, and several other cities, which
rivalled or surpassed the wealth of Athens or Corinth, and
the populous cities of Thesee, Argos, or Sparta. The wars,
conquests, or oppressions, and, above all, the civil dissections,
in which the fifth century B.C. disturbed and deformed the
coast of Ionia, and the other Grecian colonies in the islands
and continent of Asia, brought frequent excursions of inhab-

tants to the shores of Magna Graecia. Nevertheless, the
Ionians, along with their poetry, music, and painting,
communicated also their diffusive and artificial appetites to the
Greeks of Italy and Sicily. It is a fact, however, that
Magna Graecia, having obtained opulence by industry,
dilapidated it in idleness and licentiousness: inform us that the
Greek cities of Italy, and particularly Sybaris and Crotona,
cava, for a prey to the most dangerous errors and vices, when Pythagoras came to their relief about 550 years before the Christian era. His philosophy and legislation reformed and improved the manners and policy of Magna Graecia, and contributed, in an eminent degree, not only to the quiet and happiness, but to the industry, power, and splendour of that celebrated country. (See Pythagoras.) The concurrence of historians affirms us, that the school of Pythagoras flourished about 40 years to the unprofitable benefit of Magna Graecia, when a war arose between Crotona and Syracuse, the latter of which had over contemptuously rejected the Pythagorean institutions.

Having traced the progress towards prosperity and renown of Magna Graecia, it is natural to relate the causes of its decay. In Italy, the citizens of Crotona had too soon reason for lamenting their ill-luck against their magnates, and the dereliction of the discipline of Pythagoras. The other Greek cities of Italy, which are said to have imitated the fatal example of Crotona, were harassed by wars against each other, or against their barbarous neighbours. In 60 years after the death of Pythagoras, an attempt was made to revive his institutions; but in less than 40 years a new persecution entirely drove the Pythagoreans from Italy, and completed, according to Polybius (i. 423.) the confusion and misery of that once happy country. Gilles's Hist. of Greece, vol. ii.

GRAFF, from the French graveur, i.e. sculter, a skulter, or painter. It is used in the flat. 5 Hen. VIII. cap. 1.

GRAFFIGNY, FRANCOIS D'ISSEMBROUG D'APPON-OURT DE, in Biography, a literary lady, daughter of a major of the gendarmerie of the duke of Lorraine, was born at Nancy about the year 1624. She married de Graffigny, chamberlain to the duke, a man of violent passions and most brutal disposition, from whom she obtained, after living with him many years, a legal separation. She now went to Paris with mademoiselle de Guiche, who was espoused to marquis Richelieu, and soon made her merit known to the worth of the capital. In 1745 she was announced as the author of a Spanish novel. This was followed by the "Lettres d'Une Peruvienne," in two vols. 12mo., which were much read and admired, though defective in point of style, and in the metaphorical manner of treating of the passion of love. One of her best pieces was entitled "Conic," a drama in five acts, which was written in prose. She wrote another, which was entitled "La Fille d'Aritside," and which obtained a much less share of public approbation. This lady was of a truly estimable character in private life, and had many respectable friends, even in the highest ranks of society. The emperor and empress honoured her with particular notice, and made her frequent presents. She was an associate of the academy of Florence; and died at Paris in 1758, at the age of sixty-four. Gen. Biog.

GRAFFIO, or GRAVIO, in our Old Writts, denotes a landgrave or earl. "Nec princeps nec grafio, hanc alienationem promoverat." Graft, in Gardening, a name applied to the shoot or scion that is to be inserted into the stock or branch of the tree, in the operation of grafting. It has occasionally the vulgar term of graft given it by gardeners. The word is formed of the French graffe, which signifies the same thing; and greffe, in this sense, is supposed to have been derived from the resemblance the shoot bears to the point of a penknife, which was anciently called greffe. Du Cange goes farther, and derives the ancient greffe from græ/fo/ium: Menage, from graphem, a Latin word, signifying a little fleye, or iron boeldin, one end whereof was pointed, and forced to write on waxen tablets; and the other flat, serving to efface or rub out what was written.

There are several circumstances to be attended to in choosing the graft. The shoots or scions that are to be employed in this way, should be selected and cut in the manner that will be directed in speaking of grafting; but they should never be taken from such as have too little firmament growth, or are in the least degree infected with disfigure of any kind. See Grafting.

In the conducting of this process, though the vessels of the stock and those of the shoot or graft are, in some measure,
GRAFTING.

Sure, brought into contact and thereby united, as well as those of the latter supplied with nutritious matters from the former, yet their economy remains still the same. Mr. Bradley has considered it as a sort of planting; the shoot or scion rather taking root in the stock or tree into which it is inferted, than uniting itself with it, as is seen by its preserving its natural purity and utility, although fed and supported merely by a crab-stock; which it is supposed depends upon some difference in the vellets of the shoot or scion from those of the stock or tree.

GRAFTING, the act of inferring a shoot or scion taken from one tree, into the stem or some other part of another, in such a manner as to unite and constitute a perfect plant of the same kind as that from which the branch was taken.

It is by this practice that particular sorts of curious fruit-trees of different kinds are capable of being raised with a certainty of their being the same, or not degenerating. It has been observed, that though the plants raised from seed are liable to run from their kinds, and afford such fruits as are not worth the trouble of cultivation; those procured from shoots taken from such trees as produce good fruit, never alter from their kind, whatever the stock or tree on which they are grafted may be; as well as the scions receive their nourishment from the stocks, their varieties are never altered by them, but continue to produce the same kind of fruit as the tree from which they were taken; the only alteration which they undergo is, that when the shoots on which they are grafted do not grow so fast, and afford a sufficient supply of nourishment to the grafts, they do not make so great a progres as they otherwise would do, nor is the fruit they produce so fair, or sometimes so well flavoured, or so large.

This process has the advantage, probably from the supply of nutritious matter being not only abundant but more regular, of rendering the plants or trees which are thus raised more quick in their arriving at the state of maturity, or that of bearing.

It is on tbe different accounts that the practice of grafting is principally had recourse to, in raising different sorts of fruit-trees, as well as some particular sorts of ornamental plants of the tree and flower kinds. It also affords the means of producing different kinds of fruits and flowers of the same kind, in the same stock or tree, as several varieties of pears and apples, &c.

There are different methods of performing this operation, and which are distinguished by different terms or names, as below.

Rind, Shoulder, or Crown Grafting.—This is that mode in which the grafts are let in a fort of circle or crown, upon the top of the cut-off stem or branch.

It is chiefly practised on large trees, when either the head or the large branches are cut off horizontally, and two or more shoots or scions put in, according to the size of the branch or stem; in performing which, the scions are cut flat on one side, with a shoulder to rest upon the crown of the stock; then the rind of the stock is raised up, to admit them between the wood and the bark of the stock, which must be inferted about two inches, so as that the shoulders may meet, and closely join the crown of the stock; and after the whole of the shoots or scions are inferted, all the crown of the stock should be well chayed over, leaving two eyes of them uncovered with it, which will be sufficient for shooting.

It is a method of grafting that was much more in practice formerly than at present, owing to the bad success with which it has been attended; for, as the scions are placed between the rind of the stock and the wood, they are frequently blown out by strong winds after they have made large shoots, sometimes after five or six years growth. Where this method is practised, there should therefore always be some stakes fixed, so as to support the scions until they have almost covered the stock or branch. It is usual to perform the operation in this mode of grafting about the beginning of April, or sometimes a little later.

Stock, Chie, or Slit-Grafting.—This is a mode which is practised upon stocks, trees, or branches, of a smaller size, as from one to two inches in diameter, and may be used with success where the rind of the stock is not too thick, by which the inner bark of the scion will be prevented from joining to that of the stock. In performing it the head of the stock or branch must be cut off with a knife, and a slit made the contrary way, in the top of the stock, deep enough to receive the scion, which should be cut slanting like a wedge, so as to fit the slit made in the stock; care being then taken to leave that side of the wedge which is to be placed outward, much thicker than the other, and in putting the scion into the slit of the stock, great care must be taken to join the rind of the scion exactly to that of the stock; for if these do not unite perfectly, the grafts will not succeed; when this method of grafting is used to stocks that are not strong, it will be proper to make a ligature of bafs, to prevent the slit of the stock from opening; after which the whole should be chayed over, to prevent the air from penetrating the slit, so as to destroy the grafts, only leaving two eyes of the scion above the clay for shooting. It is usually performed about the beginning of March, or sometimes a little later.

Whip, or Tongue-Grafting.—This is most generally practised by nursery-men, especially for small stocks, or branches of an inch, half an inch, or less, as the scions much sooner cover the stocks in this method, than in the other. It is performed by cutting off the heads of the stocks flopping; then making a notch in the flope towards the upper part downwards, a little more than half an inch deep, to receive the scion, which must be cut with the flope upward, and a slit made in this flope like a tongue, which tongue must be inferted into the slit made in the flope of the stock, and the scion be placed on one side of the flope, so as that the two rinds of the scion and flope may be equal, and join together exactly; after which, there should be a ligature of bafs put round to fall the scion, so as that it may not be easily displaced, the whole being afterwards chayed over as in the former methods. It may be performed in the early spring months, with most success.

There are besides the above, some other modes of performing the busines.

Grafting by Approach, or Inarch-Grafting.—This is sometimes called ablation. It is performed where the stocks that are designed to be grafted, and the trees from which the graft is to be taken, stand far together, as that their branches may be bent and united. It is most commonly practised on tender exotic plants, and some other sorts, which do not succeed in any of the other methods. In performing the work, a sort of the stock or branch is cut off about two inches in length, a smooth part of the stock being always chosen for the purpose; and then a small notch is made in this slit downward, in the same manner as directed for whip-grafting; the branch of the tree designed to be inarched having a part slit off in the same manner as the stock, and a slit made upward in it, so as to leave a tongue, which tongue should be inferted into the slit of the stock, joining their rinds equally, that they may unite well together; after which a ligature of bafs should be made, so as to keep them exactly in their situation, and afterwards this part of the stock chayed over to keep out the air. In this method of grafting, the scion is not separated from the tree until
until it is firmly united with the stock, nor is the head of the stalk or branch, which is grafted, cut off till the same time, and only half the wood pared off with a flake, about three inches in length, and the flake of the scion or graft. But in this method of grafting, the operation is not performed fo early in the season as the others; it being done in the month of May or June, when the sap is flowing, at which time the flake and stalk will join together, and unite much sooner than at any other season or period of the year. It is principally employed in raising jasmines, oranges, and other exotic trees of the hardier kinds.

By experience it has been found, that the walnut, fig, and mulberry will take by this method of grafting, while neither of them succeed in any of the other modes. Several sorts of evergreens may likewise be propagated by this method of grafting; but all the trees that are grafted in this way are weaker, and never grow to the size of those which are grafted in the other methods; therefore it is rarely practiced, except on such sorts of trees as will not take by the other methods of performing the operation.

Root-grafting. — This, which is a late improved mode, is performed by cutting the clean smooth roots of the stalks in pieces of five or six inches long, and as large, or a little larger, than the scion; then they are whip-grafted, and tied together very closely, so as to prevent the water from flowing the wounded parts, planting them so deep as that the graft, which should be four or five inches long, may be about half buried. In this way, the grafts themselves will root, and a nearer similitude be preserved to the tree, whence the grafts are taken; and after two or three years, the stalk may be cut quite away, and the graft left to maintain itself. In practicing this method, the grafts should be an inch or two longer than the others.

Season of Grafting. — The period or season for grafting should always be regulated by the state of the weather. From the climate being so uncertain in the spring, it is better to defer it till the circulation of the sap is brisk, and the buds of the stalks begin to break into leaves; attention being had that the weak shoots of tender trees will not admit of being so long cut as the more hardy, and that the operation should never be performed while it actually freezes or rains, or there is snow upon the ground.

Proper Grafts. — In providing these, care should be taken that they are shoots of the former year, as when they are older they never succeed well; that they be always taken from healthy fruitful trees, as when the trees are sickly from whence they are taken, the grafts often partake of so much of the distemper, as not to get the better of it, at least for some years; that they be not taken from young luxuriant trees, whose vessels are generally large, continuing to produce luxuriant shoots, and seldom proving fruitful; and that they be taken from the lateral or horizontal shoots, rather than the perpendicular ones. They should be cut off from the stalks before their buds be in full swell, which is mostly three weeks or a month before the season for grafting; consequently when they are cut off, they should be laid in the ground, with the cut part downwards, burying them half their length, and covering their tops with dry litter, to prevent their drying; if a small joint of the former year's wood be cut off with the bud, it will preserve it the better, and when they are grafted, this may be cut off; for, at the same time, the scions must be cut to a proper length before they are inserted in the stalks; but, till then, the stalks should remain of their full length, as they were taken from the stalk, which will better preserve them from shrinking; when the scions are to be carried to a considerable distance, it will be proper to put their ends into a lump of clay, and to wrap them up in moss, which will preserve them fresh for a month or longer: but these should be cut off from the trees earlier than those which are to be grafted near the place where the trees are growing. It is, however, always the best practice to cut the stalks as near the time of their being inserted into the stalks as possible, as by that means they succeed with much more certainty.

Stocks proper for Grafting upon. — The stalks are the trees or plants for grafting upon; which are either such old trees as are already growing where they are to remain, but the fruit of which is intended to be changed; or such young trees as have been raised in the nursery as a supply to the garden. In the former case, there is no other choice than that of the branches, which should be such as are young, healthy, well-situated, and have a smooth bark. Where these trees are growing against walls or epaphers, it will be proper to graft six, eight, or ten branches, according to the size of the tree, by which they will be much sooner furnissed with branches again, than when a left number of shoots or scions are put in; but in standard trees, four, or at most six scions will be sufficient for the purpose.

In choosing young stalks for grafting upon, such as have been raised from the seed, and that have been once or twice transplanted, should always be fixed upon for the purpose.

After these, those stalks which have been raised from cuttings or layers should confidentially be preferred; but those which are suckers from the roots of other stalks should be rejected, as they are never so well rooted as the others, and confidentially put out a great number of suckers from the roots, by which the borders and walks of the garden will be always pestered during the summer season. Thee, besides being unightly, take off part of the nourishment from the other trees and plants.

And where these stalks have been allowed a proper distance in the nursery where they have grown, the wood will be better ripened and more compact than those which have grown close, and have been drawn up to a greater height. The wood of these will be soft, and their vessels large; so that the scions grafted into them will shoot very strongly; but they will be less diffused to produce fruit than the others; and when these acquire a hard habit at first, it is difficult to reclaim them afterwards. The stalks must, in this case, be fixed to each other, and this will be explained under their particular genera, and in considering the nature of stalks. See Stocks.

 Implements proper for the Work. — These are principally a neat small hand-faw, for cutting off the heads of stalks; a good strong knife, with a thick back, to make cleks in the stalks; with a sharp pen-knife, or budding-knife, to cut the scions with; and a grafting chisel and small mallet. Other sorts of implements are sometimes necessary in performing particular sorts of grafting.

But besides these tools, other sorts of materials are wanted in performing the business, such as balsam-wax, or wood seen, to tie the stalks with; and a quantity of good tough clay, which should be prepared a month before it is wanted, and kept turned and mixed, like mortar, every other day, in the following manner : A quantity of strong good clay, in proportion to the quantity of stalk intended to be grafted, should be provided, and some new well-led horse-dung broken in among it; and if a little straw or hay be mixed among it, it will hold together the better. The addition of a quantity of salt will also prevent the clay from dividing in dry weather, and should be filled and mixed together, putting water to them occasionally, in the manner of making mortar. The whole should be hollowed like a dish, filled with water, and kept every
every other day firmed. It should be carefully kept from being exposed to frost or drying winds; and the oftener it is wrought over the better it will become.

Some have lately made use of another sort of composition for grafting, which has been found to induce the intention of keeping out the air better than the clayey mixture. It is composed of turpentine, bees-wax, and rosin melted together; which, when of a proper consistence, is put on the fock round the graft, in the same manner as the clay is usually applied; and though it be not above a quarter of an inch thick, it keeps out the air more effectually than the clay; and, as cold hardens it, there is no danger of its being hurt by frost, which is very apt to cause the clay to crack, and fall off; and, when the heat of the sunmer comes on, it melts and falls off without any trouble. In the using it, a tin or copper pot is necessary, with a convenience under it to keep a very gentle fire with small coal; otherwise the cold foom condenfes the mixture. It is necessary not to apply it too hot, lest the graft be injured. A perfon a little accustomed to this composition, applies it very fadt; and it is much easier for him to work with than clay, especially when the weather is cold.

In the busines of grafting it is found, that in long-continued dry fasons the grafts are liable to fail in taking, which is sometimes probably owing to the improper choice of the grafts, as well as to the dry weather. Great care should of course always be taken not to graft with weak shoots, particularly those taken from near the top, but fuch as are taken from the lower end of the shoots, and in which the wood is plump and fresh; such as are trimmed feldom or ever take well. When any have mifled in the firing, it has been advised to cut off, about the middle or latter end of June, some fine, healthy grafts of the forts that are wished to graft with, and to open the bark in the fame manner as for budding, inferting the graft with a piece of the former year's wood on it, and after this has been done, to rub in with a brush some of the composition of Mr. Forfryth in a liquid flate; then to warp back around it, as is done for spring grafting, leaving about three eyes in the fhot, which should be tied on with the hafs as fhort as pofible; then covering the outside of the hafs, thus tied up, with the composition to the thickness of about one-eighth of an inch, as well as the end of the shoot, to exclude the air and wet. In about three weeks or a month, the grafts should be looked over, to fee if they have taken. When the graft begins to swell, it will throw off the composition; in which cafe always rememher to apply more to prevent the air from penetrating the incifion or wound that has been formed.

About the month of September it should be examined whether the wounds are all healed up, and the two barks perfectly united; which, if they are, facken the hafs; and when they are perfectly healed up, it may be wholly taken off; but if not, the bafs must be again tied on, and covered with a composition as before, letting it remain till the following spring. It may then be taken off; and if it be found that the two barks have separated during the winter, with the point of a sharp knife, all the brown part of the bark (which, if left, would infallibly bring on the canker) should be cut out, and the composition rubbed into the wound. When the grafts have produced strong leading shoots, the tops of them should be pinch'd off with the finger and thumb; but if they have not fhot strongly, they should not be cut till the spring, when they may be cut down to three or four eyes, according to their strength, to make them produce horizontal shoots, and form handsome heads. This sort of grafting should always be performed in moist or cloudy weather, if possible; as under fuch circumstances the operation mostly succeeds better.

It has been remarked by Mr. Forfryth, that rubbing a little of his composition into the incifion will effectually prevent the canker, and in applying it round the graft, a much lefs quantity is fufficient than of the clay; as it need not be more than three inches round in grafting small fights or shoots, and in proportion for thofe which are larger. It keeps the fcion moist. When used in grafting, it should be of fuch a consistence as to work easily with the hand, or a knifc, or small trowel, rather fober than grafting-clay generally is. This method, on a fair trial, will, he thinks, be found "a fure, neat, and expedient way of grafting."

In grafting, or budding, they should be performed as near to the upper fide of a bud as poflible, and the mud proper place for inferting the fclons or buds is at the joints, a little above the crofs fhot.

And in refpect to the forts of trees that will fucceed upon one another, it may be obferved that all fuch as are of the fame genus, that is, which agree in their flower and fruit, take upon each other; hence all the nut-bearing trees may be safely grafted on each other, as well as all the plain-bearing trees, as the several forts of pums, almonds, peach, nectarine, apricot, &c., but as many of them are subject to admit gum from the parts wounded, as the peach and nectarine kinds, it is found the fureft method to bud or inoculate them.

All fuch trees as bear cones also do well upon each other, though they may differ in one being evergreen, and the other shedding its leaves in winter; as in the cedar of Libanus, and the larch-tree, which are found to succeed upon each other; but they must be grafted by approach, as they abound with a great quantity of refin, which is apt to evaporate from the graft, when separared from the tree before it is joined with the fock; whereby they are often deftroyed. The laurel-likewise on the cherry, or the cherry on the laurel. All the nut-bearing trees are also found to take upon each other, and those which have a tender soft wood do well if grafted in the common way; but such as are of a firm conftant, and are slow growers, must be grafted by approach. It is likewise by this method that many kinds of exotifc trees are not only propagated, but also rendered hardy enough to endure the cold of our climate in the open air; as by being grafted upon focks of the fame kind which are hardy, the grafts are rendered more capable of enduring the cold, and the general effects of the atmosphere.

**GRAFING Wax.** See Wax.

**GRAFTING Tool.** In Engineering signifies a kind of fpade, made very frong and curving, used in digging canals, often called only a tool; see fig. 50. CANALS, Plate VII.

**GRAFTON,** in Geography, a town of America, in Windham county, Vermont, chartered by the name of Tomlinson, but affuming its new name in 1791. It contains 1,109 inhabitants, and lies W. of Rockingham, adjoining. **Grafton County,** a county of New Hampshire, bounded N. by Canada, S. by the counties of Strafford, Hillsborough, and Cheshire, W. by the state of Virginia, and E. by the district of Maine. It is divided into 52 townships, and 17 locations, and contains 25,692 inhabitants.

**Grafton,** a poll-town in the county above-mentioned, 13 miles S.E. of Dartmouth college, and 19 S.W. of Plymouth. It was incorporated in 1758, and contains 682 inhabitants. Lapis specularis, of the best quality, is found in this town; it lies in a mountain about 20 miles E. of Dartmouth college, adhering to the rocks of white or yellow quartz, and lying in lamines, like felts of paper.

**Grafton, the Hopiamahoes of the Indians,** a township in Worcester county, Massachusetts, containing 985 inhabitants; 40 miles S.W. of Boston.

**Grafton, Cape,** a cape on the coast of New Holland,
GRA

GRAFTON ISLAND, the most northerly of the Bahama islands, in the East Indian sea. N. lat. 21° 8'. E. long. 118° 14'.

GRANANO, a town of Naples, in Princepato Citera; 11 miles W.S.W. of Salerno.

GRAHAM'S ISLAND, one of the Aladim islands, in the Mergui Archipelago, about 6 miles in circumference. N. lat. 9° 19'.

GRAIG, or graignamanax, a poll-town of Ireland, in the county of Kilkenny. Here is a good bridge over the Barrow, and the tide flows up. It is 58 miles S. by W. from Dublin.

GRAIN, John Baptist lee, in Biografie, was born, in 1565, at Paris, where he was educated with great care, and in early youth he was introduced to court, and attached himself to the service of Henry IV. He was appointed by that prince to the office of counsellor, and master of requelts in ordinary to the queen, Mary de Medicis. His employment was in writing, and in attending on the education of his children. On their account he drew up Memoirs relative to the history of France, which were published in MS. till the chancellor de Sillery perused them and published a part of them. His first publication, which he printed in his own house, was entitled, "Decade contenant l'Histoire de Henri le Grand, Roi de France et Navare, IV. du Nom," fol. 1614, in ten books. It comprises the period from the peace in 1559, to the king's death in 1610. He published a second decade, including the history of that king's reign, in 1618. The former decade was presented to the young king Louis XIII., who was highly delighted with the freedom displayed by the author, and it was at his desire that the other was made public. Le Grain, though fortunate in pleasing his sovereign, made himself many enemies by the honesty and candour which he displayed in the narration. Attempts were made to procure a cenfare upon it from the Sorbonne, but they were unsuccessful, that body declaring that they found nothing in it deserving of cenfare. The real grounds of the objections to it were that the author had supported the liberties of the Gallican church; that he had cenfured attempts to introduce into France those articles of the council of Trent, which had been rejected; that he disapproved the establishment of new religious orders, and was not favourable to the perfection of heretics. For these sentiments, which ought to have endeared him to his countrymen, he was continually harassed by bigots, till at length an order was procured from the king for the suppression of all the copies of his work, which remained in his hands. The treatment which he experienced disfigured him with the court, and he went into retirement on his estate of Montgeron, where he died in 1642. He left in MS. a manifesto relating to all the proceedings respecting his book, which is said to display in glowing colours the discouragements attending honest historians under an absolute monarchy. He left likewise the third decade of his history, and some chronological pieces in MS. Moreni.

GRAIN, Grain, primarily denotes a fruit, or feed, growing in a spica, or ear.

In this sense, grain comprehends all sorts of corn; as wheat, rye, barley, oats, &c.

GRAIN, Structure of. There are three particulars observable in every grain, whether it be wheat, barley, oat, or whatever else of that kind. These are, 1. The outer coat or pellicle, which contains all the rest. This in the same species of grain is found to be very different in thickness in different ears, and as it has grown in different soils, Vol. XVI. 2. The germ or bud; this is always hid within the feed or grain, and is the plant in miniature that is to arise from it. (See: Bud and Germ.) And, 3. The meal, or that farinaceous matter which is included in the skin, and which turns the germ, and serves to give it nourishment when first put into the earth, before it is capable of drawing it from the earth itself. Dr. Grew, in his Anatomy of Plants, has treated of this at large. See FERMENTATION OF PLANTS, GERMINATION, VEGETATION, &c.

The whole structure of the plant which produces these feeds is equally admirable. The chaffy hull is admirably adapted to shield and defend the feed as long as that is necessary, and then to let it fall; and the stalk, formed hollow and round, is necessarily at once light and strong, capable of sustaining the ear, without absorbing too much of the juice, directed to its nourishment; and the seeds of many kinds are a defence against the birds; that would otherwise destroy the feed before its ripening. The covering of the feed is formed of two membranes, which meeting in a line on one part of the feed, form together that furrow we fee on it. This is the place at which the feed is to burst open on being moistened. Had not nature provided this means of the germ's coming out, the toughness necessary to the coat of the feed, as a defence from injuries, would have suffered the farinaceous matter and the grain to rot together, within it, before it would have given them way to come out, and for the germ to grow.

Nor is this the only use of this place of opening. The great Creator of all things has provided these feeds, not only for a supply of the same species of plant, but for our food, and for that of birds, &c. We have art enough to erect machines for the reducing of the farina to powder, and the freeing of it from its covering membrane; but the birds eat it as it is, and it would pass through them whole, and without doing them any good, were it not that the juices of the stomach swelling it up, it bursts open at this furrow, and all the nutritive matter pours itself out. De Landes, Traité Phys. p. 62. See FARINA, PECULIUM, FLOUR, BREAD, &c.

For the laws relating to the importation and exportation of several sorts of grain, as wheat, barley, oats, &c. See CORN.

The cleaning and preparing of grain in a proper sweet condition have long been objects of considerable importance, but it is probable that the latter cannot be effected for any great length of time.

Different methods of managing grain, after being threshed out, are practised by farmers; some keeping a large proportion of it in the chaff on the barn floors, while others, after having it cleaned, put it into facks, and place them in the same situation, or in some room appropriated to that purpose, until they can be sent to the market. But each of these methods is liable to much objection; as when it remains for any length of time on low damp floors, it will obviously soon become musty, however much precaution is taken to prevent it, whether it be in facks, or in a loft, flate without being cleaned.

There is another practice sometimes employed in the northern parts of Scotland, according to the author of "Modern Agriculture," which is, that of twining straw into large bands, or ropes, and coiling them up in the manner of the cables of ships, placing the grain, when threshed and cleaned, within the coils, in a sort of well, as it were. But as the grain in this way rests on the ground or floor, and, of course, is liable to imbibe damp, it is not less objectionable than the others, while it is much more troublesome, and more exposed to loss.
BOOK OF GRAIN

It has been advised, in order to preserve grain in a proper state after threshing it out, to have it as expeditiously as possibly cleaned from the chaff, when the air is in a dry state, and put into a room, shed, or bin, which is perfectly dry and free from any sort of moisture, until it can be properly placed in the granary, or be sent away for sale. This should always be effected as early as possible, as, by delaying the cleaning of the corn, the sample is very liable to be injured.

The cleaning of the grain is performed in several different ways; but where threshing-machines are in use, they are now mostly confined in such a way as to execute it at the same time the threshing is going on. The winnowing-machine is also frequently employed for the same purpose, and answers perfectly well. And in some situations the casing-hose and sifter, or flat broom, as well as the 'feetle,' are made use of, the broom serving to remove the chaffy parts and the more minute heavy particles which are separated from the grain by the wind. This method can, however, only be employed with advantage where there is plenty of barn-room; under other circumstances the winnowing-machine is far more beneficial and proper. The practice of cleaning grain on the barn-floor, by means of the wind, is not only tedious and troublesome, but an extremely imperfect method.

In whatever way the extraneous matters have been removed from grain, it should, as soon as the operation has been performed, especially in barley and wheat, be put through a sifting-machine, which, in most of the more improved threshing and winnowing-machines, is provided with this intention, and is thereby rendered free from all sorts of small seeds and other foreign matters. In this way the ova of different sorts of insects are also removed, and the production of the weevil, moth, beetle, &c., prevented, as well as the destruction which they commit while in their volumetric state, guarded against.

Screen machines may be had separately from the others; but the work of cleaning the grain is the most readily, cheaply, and conveniently performed, where they are connected with the other necessary machinery.

It has been suggested, that as the prevention of all sorts of corn from being affected by the different causes that have a tendency to injure it, when laid up for the purpose of keeping, depends upon its being put by in a perfectly dry condition, and on its being afterwards preserved in that situation; so it is of much consequence, in those cases, to keep it from the period of its being threshed out of the straw, as much as possible from coming in contact with the earth, stone, or any other sorts of floors that are placed near to, or upon the ground, as they have constantly a great disposition to communicate moisture, and in that way injure the grain that relays upon them.

It is likewise found to be a highly beneficial practice to prevent, as much as possible, the entrance of the atmospheric air, whenever it is much loaded with humidity; as from the vast extent of surface that is exposed to its action, it is easy to perceive that it must be highly prejudicial to the corn, by imparting its moisture to it, as a sort of mucor, or mould, is thereby brought on, that is attended with a mufly disagreeable smell, and that prevents its keeping in a proper manner. In regard to the means of prevention, they must be different in different cases; but much may be done in the first of the above situations, by cautiously avoiding the too general practice of permitting the corn to remain upon the threshing-floors in the barns, particularly where they are of the earthy or rocky kinds, too long after it is threshed out, before it is cleaned from the chaff, and other extraneous matters; or, after it has been cleaned, by preventing its being deposited upon them, either in the looie state, or in sacks. And farther, by having great regard to the dryness of the air when the binyards is performed.

In instances of the latter kind much is capable of being accomplished by having proper apparatus, such as slides, shutters, and other suitable contrivances, fixed in the pipes, funnels, and other openings, designed for the purpose of ventilation in the corn-chambers and granaries; which should be preferred, constantly shut in a close manner at all times when the air is much impregnated with watery particles, so as to prove hurtful to the grain. Damp and frosty weather are, of course, always improper for exposings grain to the air in, as it must, in such seasons, do great mischief. But, besides air, light is essential in the preservation of grain in these circumstances, as, where it is not admitted pretty freely, a kind of vegetable mucor, or mould, as already noticed, is liable to fix upon the grain, and injure it greatly. The ingenious author of the 'Philosophy of Gardening and Agriculture' has remarked, that this possesses the same property as that of other funguses, of growing where there is scarcely any change of air, and in places where there is little or no light, provided there be the necessary degree of warmth and moisture. On the same principle, with the intention of retaining the grain in a state as free as possible from dampness, it is suggested by the same writer, that it might be useful to have well constructed floves in the bottom parts of corn-chambers and granaries, for the purpose of occasionally communicating such moderate degrees of heat to the grain so as would be sufficient to dry up and expel any injurious moisture that it might have attracted in damp wet seasons. On this idea it has, indeed, long ago been recommended as supported by experience by Mr. Tull, to preserve wheat, by exposing it to the action of a sun-shine degree of heat upon a hair-cloth, in a malt-kiln, produced by the combustion of clean straw, for such a length of time as may be necessary to remove the dampness, as from four or five to ten or twelve hours, according to the proportion in which it may exist. But in this method the heat should be cautiously kept at moderate as not to destroy the vegetable property, or life of the grain, as, if that were the case, its preservation and decay would be promoted. The degree of heat that would be the most adapted to answer the purpose, in different cases, would be easily regulated by those instruments which are in general use for measuring the heat and moisture of the atmosphere. These principles affult us much in reconciling the differences of opinion that have to long prevailed in respect to the use of air in the preservation of corn in granaries, as they sufficiently show, that when admitted in its perfectly dry and elastic state, it must be particularly useful in carrying off any moisture or disagreeable smell that the grain may have contracted by remaining closely heaped together for some length of time; as, by the stirring that mostly accompanies the ventilation, it must necessarily operate in a very extensive manner; but that when applied in its moist heavy state, it must be detrimental in an equally proportionate degree, by imparting its humidity to the grain, and thereby causing a fort of mildewing.

It is probable that the ventilation of grain is the most completely effected by stirring it by means of proper slides, doors, or other similar contrivances made in the floors, windows, and other openings of the granaries or corn-chambers; but it is capable of being accomplished in a more flow and less economical manner by shovels, rakes, and other similar tools. And in order that the work may be more readily and more effectually performed, the grain should not be spread
spread out too thickly over the floors of the granaries and
corn-rooms. From one to two feet, or two feet and a half
in depth, is considered fully sufficient for the purpose, in
proportion as it becomes more dry and the moisture more
dissipated. When grain is heaped together to too great a
thickness at first, from the natural moisture which it con-
tains, it is frequently apt to heat, and thereby greatly
injure the sample. Frequent screening should likewise be
had recourse to immediately after its being deposited in the
corn-rooms, and occasionally at other times as circumstances
may demand.

Other points have been suggested by Doctor Darwin, as
necessary to be attended to in this business, in order to
perform it in the most effectual manner; such as those of
having the doors, windows, and other principal apertures
of the buildings placed in such a manner as to face the
south, and as close to the ceiling as possible, so that the
rays of the sun may enter with the greatest freedom. And
in addition, the linings of all such corn-rooms should con-
stantly be formed of such materials, as have no tendency
to their coldness to precipitate the moisture from the
atmosphere, which is frequently the case with particular
substances, when warm, damp, south-well winds take place
after cold or east airs, and in that way impart it to the
grain that comes in contact with them. It is also equally
necessary in all such cafes that the entrance of wet and
moisture should be prevented in an effectual manner, by
having recourse to proper sheltering boards, slides, and other
contrivances of the same kind.

There is likewise a particular sort of management neces-
fary in the turning over and stirring of grain in order to its
complete ventilation, as when the corn is first placed in the
rooms it hangs in need of much more frequent turning over
than afterwards, when it has parted with a considerable
proportion of its moisture and is become somewhat dry.
For the first month or six weeks, once or twice in every
week or ten days may be sufficient to answer the purpose;
but afterwards for four or five months longer, about once
in the fortnight may commonly be sufficient, and from that
period only once in the month, except when the season
proves very moist, warm, and of course improper for keep-
ing the grain well.

In order to accomplish this business different methods are
in use; it is the custom in some places to have empty spaces
left on the sides of the heaps of grain and other parts into
which they may be turned over when necessary; while in
others, square holes are formed in the ends of the floors,
and round ones in the middle, by which means the grain
is thrown from the upper to the lower chambers, and back
again, and of course becomes agitated and exposed to the
air in a more perfect manner. This is a method that is
practised with success in some parts of the county of Kent.
As, however, in these methods such frequent turnings are not
only extremely troublesome, but expensive, in consequence,
especially in the first cafe, of being performed by the
hovel, the plan of having filling flutters in the middle of
the different floors so contrived, as to have an inclination
towards the centre of the granaries, has been laid recor-
d to by the occasional removal of which, and the opening
of the windows and ventilators, the grain is turned and
exposed to the influence of the air at the same time with
great cafe, convenience, and dispatch.

This mode of preferring grain was long ago found by
Monseur du Hamel to answer perfectly well, even in cafes
where it had been laid up in a moit, damp, and improper
state.

There can be no doubt, however, but that grain may
be preferred without having recourse to the means of venti-
lution, by depitting it, when in a perfectly dry state, in
dep pits, pits, and caverns that are free from any sort of
damp and moisture, and so far below the surface of the
ground that it cannot be affected by the heat or the changes
that take place in the seasons. But though grain has been
known to have been preferred in this manner for a great
length of time in those countries where it is the practice
to have it stored up for times of scarcity, it is by no means
either a very safe or convenient method.

It must be observed, however, that in whatever manner
grain is secured, it is essentially necessary that care should
be taken that such portions as are in a hot damp state, or
which have been badly har vested, should not, on any account
be laid up with that which is in a dry condition and perfectly
found; as from the quantity of moisture that is contained
in it, and the tendency to germination that takes place in
consequence of it, a small bad smell is liable to be im-
parted to the whole, and the sample either totally or in a
great degree destroyed.

The practice of exposing grain to the free action of the
atmospheric air, has been followed by some, in consequence
of the ova or eggs of insects being liable in that way to be
depitted among the grain, but it would seem more pro-
bable, when the economy of such insects is well considered,
that their ova were either depitted originally among the
grain in such situations, or brought in with different parcels
of it from different places. On this account it is evident
that great caution should be used in furnishing fresh parcels
of grain for being laid up, and that the screen should be
constantly employed before putting it into the rooms.

It is, however, pretty certain that where grain is to be
preferred for much length of time, though it may without
doubt be safely kept in the ways that have already been
mentioned; yet it is most probably only a much better,
but more certain and economical method to let it remain
untouched from the ear in the stacks in which it has been
built, particularly where they rest upon sladles that are
properly constructed for the purpose.

It may be proper to observe, that where grain is to be
long preferred after being threshed out, there should always
be proper buildings of the granary kind provided for its
reception, the sizes of which should be proportioned to
the extent of the farm, being constantly adequate to con-
tain about one-half of the grain-produce after it has been
threshed out and cleaned.

In cafes where the grain is ground and preferred after-
wards in the state of meal, it is the usual and by far the
best mode to pack it very closely by means of trampling or
ramming it into dry, close, small rooms, or large cellars, or
in this way, when laid up in a proper condition, it will
keep for a very great length of time quite safe and free
from mischief.

But, notwithstanding the custom of preferring grain in
stacks and granaries, from the convenience of it, may, in
some instances, be beneficial, not only to the farmer, but
and, consequently, in some measure necessary, it is clear
from the trials that have been already made, that the
storing of grain in either way should be carried to as
small an extent as possible, as it has been ascertained
that there is a constant decrease taking place in its weight
from the period at which it has been har vested or laid up,
that this loss is far greater at first, than alter it has been
kept some time.

In the second volume of the new edition of Georgiads
GRAIN.
GRAIN.

Essays, published by Doctor Hunter, the lots is rated by Mr. Holt to be in the following proportions in different sorts of grain:

In Wheat.

On being rubbed out in the hot-furn, and weighed the 31st of August, 1789, soon after being cut, afforded... 6 3
On being weighed again on the 18th of October... 0 2 0

Lofs of weight, per bushel, of 70 lbs. nearly... 6 8 3
Or almost one-tenth of the whole in forty days.

Of this wheat, thirty-two grains weighed one penny-weight.

It is, however, remarked, that this is the greatest possible loss that the grain can sustain, as though it was in a full state of maturity or ripeness, it had neither had the benefit of being dried by exposure to the sun after being cut, nor undergone the process of fermentation after it was put together.

In Wheat.

Another quantity, weighed on the 1st of October, produced... 0 6 3
Weighed again 23 days afterwards, afforded... 0 6 0

Lofs in that time per bushel, at the rate of... 2 11 15
A further quantity, weighed on the 8th of January, 1790, produced...

Lofs per bushel, on being weighed again 32 days afterwards, at the rate of... 2 0 15

In Barley.

On being weighed on the 25th of September, under similar circumstances, produced... 0 2 2
On being weighed again on October the 18th, afforded...

Lofs of weight per bushel of 60 lbs. about one-fifth of the whole in 47 days.

Twenty-four grains of this barley were found to weigh one penny-weight two grains.

In Oats.

With this sort of grain no experiment appears to have been made by the writer, but there can be no doubt but that the loss must be equally great as in any of the other sorts.

The results of these trials render it sufficiently evident, that the more e. pedantically grain is brought to the market, the less is the loss which is sustained by the cultivator.

Of course it should never be laid up or kept in any other way longer than circumstances render it necessary. But in addition to the loss that has been seen to occur from the gradual diminution in the weight of the grain in consequence of the dilution of the grain and of the moisture which it contains, there are others that arise occasionally from the ravages of different kinds of vermin, and the effects of damp, mould, and various other causes.

In regard to the preservation of grain from the depredations of insects, and other similar animals, it may probably be the best accomplished by a timely and frequent use of the screen, with proper ventilation, as has been noticed above.

Where the injury is produced by the weevil, the moth, or the beetle, it has always ceased at the period when these vermin appear, as they are, when in this state of existence, merely propagators of their several respective kinds of vermin, which, while they continued in that state or form, produced the injury.

In their ultimate or infect state they eat or consume very little, their business being principally that of depositing their own eggs, which they do by a sort of unerring instinct, in situations where the large collections of grain are free to furnish food for their succors during the period in which they are in the vermicular state. It is consequently a matter of great moment to prevent the generation of them, by the destruction of the eggs before they are hatched, which is usually the best performed by having recourse to the screen, and exposure to a free air, as has been already shown.

The frequent flitting of the grain breaks the cohesion of their own eggs, by which the nidus of this minute vermin is destroyed, as on hatching they collect together, and spin or weave numerous webs of a cob-web-like substance for their own security and protection. And a great number of grains are attached together by these webs, by an infinity of small threads both for their safety and food. Consequently, when their habitations are broken and separated by the use of the screen, they fall through its small interstices, and are capable of being easily removed with the dust and other refuse matters; and such as escape the early screenings are destroyed by those that follow, and the grain of coarse little injured by the operation, being only rendered more clean and free from impurities. See HArvesting of Grain, REAting of Grain, and STACKING of Grain.

GRAIN is also applied to the fruits or seeds of divers plants, as a grain of mullet, of pepper, &c.

GRAIN is also extended to a minute body, or parcel of a body pulverized. In which sense we say, a grain of sand, a grain of salt, a grain of gunpowder, &c.

GRAIN denotes also a small weight, used in estimating divers substances.

The grain is the smallest of all weights known in England. It is taken from the weight of a grain of wheat, gathered out of the middle of the ear, and well dried. By Stat. 12 Henry VII. cap. 7, every flinking or penny-weight was to weigh thirty-two such grains; but now twenty-four grains make a penny-weight, and twenty penny-weights an ounce. See PENNY and WEIGHT.

The grain is troy weight, and used in the weighing of gold, silver, jewels, bread, and liquors.

Among the ancients, the grain was the fourth part of the stola, or twelfth of the obolus, and the twenty-fourth of the drachma. It coincided with a scr.

Fenelius, lib. iv. cap. 6. Method. Medic. affirms it as a thing known and certain, that the grain is of the same weight everywhere; but he is mistaken. Mr. Gravers, in his treatise of the Denarius, in his Miscell. Works, vol. i. p. 276. has shown, that 179 Dutch grains, which Smellicus had found to be the weight of a Philip of gold, only amount to 134 English grains. Add, that Mouf. Perrault has computed the French grain to be less than the English, and yet bigger than the Dutch; to the English, it is as 158 to 134; and to that of Holland, as 178 to 179. See WEIGHT.

The grain used by the apothecaries is the same with that of
of the goldsmiths; though they make a difference in the weights raised from it. Thus, 20 grains, with them, make a scruple, 9; 3 scruples, a drachm, 3; 8 drachms, an ounce, 5. &c.

The carat used in estimating the fineness of gold, as well as in weighing diamonds and precious stones, is also divided into four grains; and the carat is about the one hundredth and fifteenth part of an ounce troy, according to Mr. Jeffreys, in his treatise on Diamonds and Pearls.

Hence, the jewellers' grain is to the troy grain, inversely, as 600 is to 480, that is, directly as four to five.

GRAIN.—In English troy and apothecaries' weight, is the 48th part of a troy pound = 20 mites = 480 druits = 5600 periots = 252.400, blocks, of the assayists, = 820.856 French grains = .36475 grams of the new weights of France = .000142877 pounds avoirdupois.

GRAIN, a weight in France, = 1.21893 English troy grains = .00017413 English pounds avoirdupois = .0531217 grams of the new weights.

GRAIN is also used for the figure or representation of grains on stones, fluffs, leathers, &c. Thus we say, morocco, has a bold and richer, that is, a larger grain, than flan-green.

In some marbles, the grain is very fine; in others coarser. Steel is known by its grain, which is much finer than that of iron.

GRAIN, in Mining, is applied by quarry-men and masons to the minute figures in most blocks of stone, by which they are distinguished from most other materials that are distinguished in any direction, and the grain in this way is very evident, as being of the same kind, and in the same direction, by working the figures of the minute plates of mica, or silver, as they call it, which are frequently found arranged, in the stone, in the direction of the grain, or best of the stone; which, in grains, is not always that of the beds or stratification, many rocks having stratification which crosses their beds obliquely, often at an angle, of from 30° to 45° with the bed or plane of the stratum, and such stratification, not uncommonly, divide the stone from its sides or parts, or even tile-stones, or plates for houses, and into the most thin and perfect lamina. Sometimes the name of the stone they are distinguished into, and such stratification itself, as Mr. Kirwan observes of the argillites or flates, p. 293 of his "Geological Essays." See Stratula and Strata.

GRAIN, Casked. See COCHNEAL.

GRAIN, Scarlet. See SCARLET.

GRAIN, Oily, in Botany. See MyAGRAM.

GRAIN, Tin. See STREAMING and TN.

GRAINS, in the Materia Medica, or the seeds of vegetables, are distinguished into emollient, which yield a considerable quantity of mucilage and oil, which may be separately extracted from them; such are almonds, and the seeds of most all fruits; and farinaceous, which are entirely composed of a dry substance, easily reducible into a fine powder, called meal. Of this kind are the grains of all grasses, and of plants.

GRAINS, in Rural Economy, a term applied to the remains of different substances of the grain kind after they have been employed in the brewing of beer, or the distillation of spirituous liquors. They are in much use by the farmers and cow-keepers near large towns for the feeding of various descriptions of domestic animals, such as milch cows, hogs, fowls, geese, ducks, &c. as well as sometimes for the fattening of neat cattle. In this last intension, it is however necessary to mix other substances with them, such as good pul-lard, coarse ground oatmeal, &c. It must be observed, that these matters can only be made use of while they are in a fresh state with advantage. It is of course necessary, particularly during the more hot fummer months, to employ such means as are proper for preventing their running into a state of fermentation, which would render them wholly useless. This is usually effected by having them well prefried and trodden down into large vats and ciphers, formed deeply in the ground, and covered from the action of the air. In this way they may be kept perfectly sweet and fit for use for a considerable length of time. See COOKING and STALL FEEDING.

GRAINS of Paradise. See MEDIA.

GRAIN-Coal, Malagueta, or Pepper-Coal, in Geography, a country of Guinea, extending about 300 miles along the coast of the Atlantic from the vicinity of Cape Palmas to that of the river Mefaruda, but its limits are not precisely ascertained; and bounded by the country of the Foulahs, or the Sierra Leone country on the west, and the Ivory Coast on the south-east. It derives its name from the great quantity of Guinea pepper which it produces. The climate is infectious, and is found to be particularly noxious to Europeans. The productions of this country are perfumes, gums, grains, lemons, oranges, bananas, and a kind of nut with a thick shell, which is a most delicious fruit. The palm-wine and dates are in high perfection; cattle, hogs, sheep, and goats, are very plentiful; but this country derives its chief wealth from the abundance of Guinea pepper, or grains of Paradise, called Malagueta by the Portuguese, which it produces. It supplies also a considerable quantity of pimento. Its commerce has also very much benefited in ivory and slaves. The natives are reckoned temperate and abominous; but they are said to allow Europeans every kind of familiarity with their females, and to invite them to love-banquets with their own wives and daughters. They are actuated in common with other negroes, by an insensible propensity to steal, not only from strangers and foreigners, but from the nearest of their own kindred. Their language is peculiar to themselves, and difficult of attainment. Their trade is carried on by signs and tokens, some of which are not very decent. The natives are, in general, well-formed, and handier in their persons and features. Their common dress is a "pan," or unshaped piece of cloth round the waist. They are extremely subject to hernias and ruptures. They have among them some excellent mechanics, some of whom understand and practice the art of tempering steel, making arms, and all steel instruments, and constructing canoes; others have introduced improvements in husbandry, particularly with respect to the method of cultivating rice, millet, and Guinea pepper. Their king, called "tala," "taba sley," or "taba sell," exercises despotic authority over his subjects, and never appears abroad without the utmost pomp and magnificence; and he receives from the people a degree of veneration and awe, which belongs to superior beings. They are said to be believers in a future state, which appears by the ceremonies performed to the souls of the deceased and the prayers they offer for a happy meeting in another world. They welcome the new moon with songs, dancing, and every kind of diversion; and their superstitious regard for foresters is extreme. The sole employment of many of the negroes, especially about the river Sellos, is fishing, which they perform in their canoes by a hand-line and hook. The artificers of Sellos are...
GRA

are also peculiarly expert in their manufacture of iron and metals.

The Portuguese, possessed for many years an independent and uncontrolled connection with this country; but in the year 1654 the English and Dutch, perceiving the advantages which were derived from their commerce, interfered, and their rivals prevailed to such a degree as to drive the Portuguese settlers into the interior parts of the country, where they united themselves with the natives; and from this intercourse sprung that mixed progeny of Malattos, who are more numerous here than in any part of Guinea. The small remnant of trade now possessed by the Portuguese is entwined with these perfons, to whom they give the appellation of the ladigos or gentleman, having professedly to them their forms of Christian faith and practice, and initiated some of them into holy orders, whom they employ in propa gating their notions of Christianity.

The months most favourable to trade on this coast are February, March, and April; small vessels, which are capable of faling up the rivers into the country, are more convenient than large ships; and it should be recollected, that the S.S.E. winds begin to blow in the month of May, and they bring with them heavy rains and tornadoes, with terrible thunder and lightning, extremely dangerous to shipping.

GRAINE, an island in the mouth of the river Thames, about 35 miles long, and 25 broad, separated from the coast of Kent by a narrow channel, called the "Stray," or "Yenlade." It is low, flat, and marshy, and has upon it only a number of detached huts, with some salt works. N. lat. 57° 27'. E. long. 0 42'.

GRAINED MEDALS. See MEDAL.

Graft. GRAINED Staff. See CROSS GRAINED.

GRAINGER, James, in Biography, a physician and poet, was born at Danse, a small town in the south of Scotland, about the year 1723. After finishing his school education, he was sent to Edinburgh, where he commenced his medical studies under professors who were highly celebrated through the medical world, and in due time he received his degree of M. D. He commenced his professional career as surgeon in the army, and in that capacity he served in Germany, under the earl of Stair, till the peace of Aix-la-Chapelle, in 1748. He afterwards settled in London, and practised as a physician. He here obtained and cultivated the friendship of several distinguished literary men; particularly of Shenstone, and Dr. Percy, afterwards bishop of Dromore. While in London, he published his translation of the elegies of Tibullus; but this work did not receive the approbation to which he thought it entitled, especially from Dr. Smollet, whose criticisms were the occasion of a long paper-war between them, and produced an irreconcilable difference. Probably his success in practice in London was not great, as he embraced an offer of settling advantageously in the island of St. Christopher, in the West Indies; where, by marriage, he became connected with several of the principal families, and practised his profession with great success. He continued, however, to cultivate his attachment to the muses, and wrote, during his buc...
after the appellation of it to Gramineae. The Latin word *gramen* is supposed to be derived from *gradens*, going or proceeding along, in allusion to the great increase of many of these plants by their creeping roots.

Jussieu's second class consists of monocotyledonous plants with a superior germen. His definition of the present order is as follows:

Calyx, (which he terms *gluma*), single or many-flowered, enclosing, in the latter instance, two or more flowers, disposed in two ranks in a little spike or ear; it is mostly of two valves, rarely of one or of many, or altogether wanting. Each flower has a corolla, (called *edge* by Jussieu) resembling the before-mentioned calyx, mostly of two valves, rarely of only one, or altogether wanting; the outer valve either beadless or awned. Stamens below the germen, of a definite number, except in the *Paria* of Aulanth, generally three, rarely two, or six, or one; their anthers oblong, forked at each end. *Germen* one, superior, accompanied at the base by two little scales, not always evident. *Styles* often two, with two feathery stigmas; sometimes one, with a simple or divided stigma. *Seeds* in either instance solitary, naked, or often clothed with the permanent inner valve of the corolla. *Embryo* small, attached below to the side of the farinaeous and much larger *albumen*. The lobe of the embryo in germination is permanent and fertile along with the annexed albumen, attached on one side, at the bottom, to the primary leaf which surrounds the plumula, or bud of the future plant.

The roots are fibrous and capillary. *Stems* or *culms* cylindrical, either hollow or filled with pith, jointed or separated into distinct portions by knots, mostly simple and herbaceous. *Leaves* alternate, generally solitary at each knot of the stem, sheathing, their sheath splitting down to the knot. *Flowers* either in dense clusters, or spiked upon a common *rachis*, or panicked, concealed before they arrive at maturity in the sheath of the upper leaf. Some species are monocious, by an abortion of some of the organs.

Botanists have differed much about the principles on which the genera of Grasses should be founded. Linnaeus and Jussieu take into consideration the number of flowers, or rather florets, in each calyx; Haller in a great measure rejects this, paying regard chiefly to the figure of the parts, which indeed is of primary importance. He does not, however, sufficiently attend to other equally important marks, as the distinction, for instance, between *Poa* and *Brixa*, consisting in the incorporation of the seed of the latter with the large valve of the corolla, and its deprecating figures. It were to be wished that the names of Grasses were permanent and constant in the same genus, or at least species, but though constant in some, as *Avena*, in others, as *Agrostis* and *Triticum*, they are not sufficient to discriminate species.

In the sexual system Grasses chiefly belong to *Triandra Digyna*. Some few have proper monocious, some dioecious, flowers, and several are polyanthous, having a few male blossoms intermixed with perfect ones furnished with both stamens and stigmas, and were therefore referred by Linnaeus to *Polygama*. But this latter circumstance is so common and variable, and causes such unnatural separations of species or genera, that botanists have generally agreed to pay no regard to it in this family, but to class all such grasses by their perfect flowers.

Linnaeus remarks that "Grasses are the most general of plants, constituting almost a sixth part of all the vegetables on our globe, especially in open situations. There they multiply, and extend themselves by creeping roots, to a vast extent. In confined and woody places they scarcely creep, but grow erect. They are the most important of plants,

especially as affording the chief succulence of animals who feed on vegetables. They furnish the verdure of our summers, and spread a carpet over our meadows. Their leaves are not easily damaged, even by our walking over them; and though winter destroys their foliage, and the early spring finds them dry and withered, they revive in a wonderful manner from apparent death. How efficaciously has the Author of Nature protected these plants, by giving them such hardy items, while they are perfecting their feed, that cattle cannot readily attack them in that state! Then, on the other hand, they are so constituted, that the more their herbage is cropped, or hardly used, the better they thrive, and extend themselves the more under ground. That they may be able to exist in almost every situation, their narrow spiny leaves are purposely contrived to intimate themselves between other plants."
The grasy crown, corona graminea, was but rarely conferred, and for some signal exploit; when, through the courage or dexterity of a general, an army reduced to the last extremity had been saved, or delivered, and the enemy put to flight.

**GRAMINEOUS HERBS**, among Latiynij, are such as have a long, narrow leaf, with no footstalk.

**GRAMINIFOLIA**, a name given by Dillenius to a genus of plants, called by Micheli and Linneus zanichellia.

**GRAMMAR** teaches the right use of language, or to speak, to read, and to write a language with propriety. Particular grammar teaches the principles peculiar to any one language. Thus the English grammar ascertains and teaches the principles which exclusively belong to, and which distinguish the English tongue. The French grammar professes the same end with regard to French; and this is the case with the grammar of any other language.

When grammar is limited to any particular language, it is employed in its humblest province, and may be considered only as a mere mechanical art, the rules of which are little investigated, and have no other foundation than the practice of those who speak and write that language. When grammar, rising above the consideration of any one language, compares many languages together, and by this comparison traces the principles which are common to them, unfolding by that means the nature and origin of speech, the causes by which it is divided into distinct dialects, and the analogies which facilitated the growth and determined the idioms of each: grammar, in this extensive view, affumes the nature of a science, and is justly distinguished by the name of general or universal grammar.

That grammar claims the dignity of a science, in consequence of investigating the general principles of speech, is evident from the slightest consideration. All languages, however different, have many properties in common. They have in general the same parts of speech, the same ideas or things which the grammar of any other language.

Men also, in all ages and countries, have the same organs of speech, which are similar in structure, however modified by peculiarities of pronunciation. Finally, the same great law of association regulates the mind of every man; and the political, moral, and religious institutions, which direct the operations of this law, however remote in age and country, considerably resemble each other. To these causes it is owing, that the languages of all nations, ancient and modern, are marked by a similitude truly surprizing; and the more closely they are examined, the more numerous will appear the points in which they all resemble each other. Hence may be justified the conclusion, that as all the tribes of men originated in one family, so all the languages of men are but ramifications of one original tongue.

Grammar has usually been divided into four departments, namely, **orthography**, **etymology**, **syntax**, and **prosody**.

Orthography teaches to form and to found letters, to analyze or combine syllables, or to express words by their proper letters. Etymology explains the character, the properties, or, more properly speaking, the derivation and composition of words. Syntax prescribes the government or the right order of words in a sentence; while prosody directs the just pronunciation, the poetical construction of words, or supplies the laws of verification. But this distribution of the parts of grammar is neither useful nor accurate, as they are not independent of each other. Etymology is a principle necessary to account for phenomena in every department, and it is that upon which orthography is chiefly founded. We therefore discard these divisions of grammar, and distilute and confine our observations on this subject.
to the origin, nature, classification, and the properties of words.

The Origin, Nature, and Classification of Words.

Words have been defined articulate or significant sounds, formed by the organs of speech, and used by common consent as signs of ideas. The propriety of this definition will appear, if we attend to the mode in which words acquire their signification. The bell method to teach a language, with which a youth is yet entirely unacquainted, would, if attended to, clearly unfold the nature and origin of speech in general. Suppose a book is held out before him for the first time, an inaccurate, pleasurable, or idea of that object is thus conveyed to his mind by the organ of sight. While this impression continues, suppose farther that the sound book is distinctly uttered; he will then have an impression or idea of the sound conveyed through the sense of hearing, which will be rendered more distinct, if he himself betakes to enunciate it. The two ideas, namely, that of the object, and that of the sound will then, if long continued, or often repeated, coalesce in his mind, and become strongly connected, that the idea of the object shall suggest that of the sound, book: and, on the other hand, the sound shall recall the object. The principle on which this coalition is founded, is a law of the human mind, known under the name association of ideas; and the progress of the learner in connecting other ideas with other sounds, is only a repetition of the operation, till the whole language is acquired.

From this brief description, naturally follow a few inferences of importance, to be observed on this subject. First, sounds, though so closely connected by frequent use with the things signified, as not to be separated from them even in imagination, have no natural affinity with them. Any other sound than book, sound for instance, might have been associated with that object, in the mind of a learner, and this last sound would as naturally, if by use, he applied to books, as we now apply it to the object so known in the sky. And this is the reason why the same idea is expressed by different sounds in different countries, where each sound is rendered equally natural and familiar by repeated associations. Secondly, as language altogether depends on an arbitrary compact between sound and sense, there exist not, in any regular polished tongue, such words as natural articulate sounds. There are, indeed, in all languages, certain sounds indicating desire or aversion, pleasure or pain, but these are natural cries, and not articulate sounds; and they arise more from the structure of man as an animal, than from his rank as an intelligent being, capable of forming distinct ideas, and expressing them by articulate sounds. Hence such sounds are common to him with inferior animals, and abound most among men in the savage state, where language is least formed. The above explanation farther excludes what have been called fictitious words, or words whose sound bears some resemblance to the sense. Some words indeed, of this kind, are supposed to exist in all languages; but the supposition, we venture to affirm, is erroneous, the imagined similarity being altogether the effect of association. This principle, when a word is heard, instantly fuggeits its meaning, and while we overlook the suggestion, we ascribe the sense to a fancied similitude between it and the sound. Let an idea be in your mind, when you hear a cock crow, or a bell toll, and you will immediately ascribe, that the sound of the cock, or of the bell, conveyed the entertained idea. This is a delusion precisely similar to that into which we fall respecting the import of fictitious words. If there be any word in our language, or in any language naturally indicative of the sense, it is cuckoo; and yet ask a foreigner, altogether unacquainted with English, what the term means, and he will not by any means be able, from the sound, to ascertain the object signified. The word is a repetition of cōc cōc, which exists in Greek under the form of ἔκος, and which in Persian signifies the sound made by a strong emission of the breath. Hence the Persian expressed the cock-kind by cōc, which we have borrowed and confined to the female cōv, which originally meant a lowing animal. In Chaldee, cuckoo means a magpie, the sound of whose voice is very different from that of the cuckoo. We cannot help remarking, that if a similitude between sound and sense obtained in any part of language, it would appear more manifest and predominant in the most ancient languages, and especially in Hebrew, which we conceive by far the most ancient, even of the Asiatic tongues. But we venture to affirm, that not a single influence of the kind can be produced in that tongue. And this early specimen of human language is a fair presumption, that the principle of fictitious sounds did not in the least obtain in the first formation of speech.

From the above explanation we infer, in the third place, that the names of things, at first, were names of individual objects, and that man learnt in youth, to form general ideas, solely by means of language. Thus with respect to the above-mentioned youth, when he has connected the sound book with the thing so called, the word is only a sign of the individual book which was first presented to him. Presently, however, he perceives the same sound applied successively to other objects of the same kind; and this application leads, and in a manner compels him to note those peculiar circumstances which distinguish each book, and these, on the other hand, which belong to that whole class of objects. As the sound is not repeatedly associated with the form, be forgets, and consequently overlooks them; while he combines the ideas belonging to the class, and retains them in a closer and yet closer union, under the term which was his instrument in forming those ideas. In this manner are all our abstract ideas acquired; and language, as the mind rises by means of it, from the contemplation of one to many objects, from individuals to classes, is the sole instrument in acquiring them. Some indissoluble idea of this process was probably the circumstance which led our celebrated grammarian, Mr. H. T. Tocke, to say, (vol. i. p. 36.) "That the composition of ideas was merely a contrivance of language; that the only composition was in the terms, and that they are not ideas, but merely terms which are general and abstract." In another place, he denies the operations of the mind as influencing speech, and talks of the operation of language. These, and such other remarks are, however, so palpably erroneous, that we cannot ascribe to him precision or attention in so enlightened a critic, but suppose them to have proceeded chiefly from a desire which pervades his works, of rejecting the ideas of others as unprofitable, because they were learned, and conspicuously displaying his own as right, because they were new. The composition of terms in grammar, is merely the derivation or combination of terms, by such laws as custom or analogy have previously determined. Composition of this kind, with which a grammarian, as such, has any thing to do, is as distinct from the composition of ideas, as sound is from sense, or grammar is from logic.

Language has no power but what it has derived from association; and he who speaks of the operation of language, instead of the operation of the mind, acts the absurd part of a man who ascribes to the pen, the motion of the hand which directs it. "If we can judge from his works," Mr. Tocke appears not to have studied the true theory of the human mind: Vol. XVI.
mind; and from the want of just ideas on this subject, he has, as we shall show in the sequel, plunged himself and his readers in deep and manifold errors.

As general or abstract ideas, which are the chief materials of science, are formed solely by the instrumenality of language, we may hence see the reason why the study of language ought to form the basis in every system of education; and why science can flourish only among a people previously acquainted with the arts of eloquence and composition. The philosophy of grammar, moreover, as it retraces the track of the human mind, in the formation of its ideas, through the medium of speech, is the key to the knowledge of its powers and operations, and consequently to their proper direction. Hence the only fyllems of metaphysics and logic, worthy the attention of a philosophical enquirer, are those which are built on the foundation of grammatical analysis.

But further, as words in the very commencement of every man's education denote individual objects, and become signs of classes or kinds by the successive application of each word to many individuals of that class, we might conclude that in the original language of mankind, if solely the effect of human invention, each term at first was but a proper name of a thing or of a quality, and afterwards represented a greater number of individuals as the mind advanced in the principle of generalization. But this inference is contrary to the fact. The Hebrew tongue carries us back almost to the infancy of human society, and, whether it be the original language of mankind or not, it presents us with much fairer specimens of what language must have been, than we can gather from any modern dialect. The primitive words of that language are founded upon the most comprehensive analogies; and the learner, in acquiring that tongue, instead of being carried up from the individual to the species, and from the species to the genus, finds himself on the top of the most extensive class; and in the formation of words he is made to descend from general to specific terms, and from specific terms to proper names; so that all the proper names which we meet with in the Hebrew records are really derived from general appellations. This phenomenon appears to us completely to annihilate the supposition, that language is solely the fruit of human ingenuity. Moses, in his history, obliquely states, and, with his usual brevity, accounts for the fact: "And out of the ground the Lord God formed every beast of the field, and every fowl of the air, and brought them to be seen what he would call them: and whatsoever Adam called every living creature, that was the name thereof." The Arabic translation, we apprehend, alone places this verse in its proper light, by rendering it so as to come to fes, i.e. to fes. The author then intimates that God showed or directed Adam in the application of names to things. And what can be more probable, than that He, who formed the organs of man, should at first instruct him in the proper use of them.

Lastly, it follows from the above explanation, that words, as they are at first associated with ideas, are in strict propriety signs of ideas, and not signs of things. For unless the idea be previously in the mind, there can be no union by association of sense with sound. The association takes place in the mind, and where the idea of the thing, and that of the sound do not meet, there can be no formation of articulate sound. The learner, however, is not capable of any distinction between his ideas and the external objects which are their origin or prototypes; and he refers the sound immediately to its prototype, without being conscious that an impression or idea of it exists in his mind. As, however, we know nothing of things but through the medium of our ideas, and as ideas must depend for their properties and distinction upon the things they represent, the above oversight is not productive of any error or inconvenience; and we may say that words are signs of things, or of the ideas of things, without any prejudice to philosophical accuracy. This leads us to the classification of speech, or its division into parts.

The common distribution in our own tongue is into nouns, articles, adjectives, pronouns, verbs, participles, adverbs, prepositions, conjunctions, and interjections. This division has obtained with little variation in other modern languages, and has been derived, on the authority of ancient grammarians, from the languages of Greece and Rome. The above classification, however general and convenient in a popular view, is by no means to be admitted in a philosophical grammar. And the few writers of this kind in English, or other tongues, have been sensible of the inaccuracy of the popular division. The Oriental grammarians admit only three parts of speech, the verb, the noun, and particles derived from these. Plato, whose notion of language as a science must have been formed in Egypt, mentions only two, the noun and the verb; tom. i. p. 261. Edit. Ser. And Aristotle mentions no more, where he treats of propositions. (De Inter. c. 2.) But Mr. Harris, Herm. p. 38, thinks that those philosophers were not ignorant of the other parts of speech, but spoke with reference to logic or dialectics, considering the essence of speech as contained in these two, because they alone combined to make a perfect affirmative sentence, which none of the rest without them are able to effect. But Aristotle, in his treatise of Poetry, where he was to lay down the elements of a more variegated speech, adds the article and conjunction to the noun and verb. The latter Stoics, improving on the authority of Aristotle, instead of four parts, made five, by dividing the noun into the appositive and proper. Others increased the number, by detaching the pronoun from the noun: the participle and adverb from the verb; and the preposition from the conjunction. The Latin grammarians went farther, and detached the interjection from the adverb, within which by the Greeks it was always included as a species.

Mr. Harris, following Aristotle and the elder Stoics, divides speech into words that are significant as principals, and those which are significant as accessories, including under the former clafs substantives and attributives, and under the latter definitives and connectives. This distribution is set aside and ridiculed by Mr. Tooke, who says, vol. i. p. 47; "In English, and in all languages, there are only two sorts of words, which are necessary for the communication of our thoughts, and they are noun and verb. And as to the parts of speech, they may be either two or twenty, or more. In the strict sense of the term, both the necessary words and the abbreviations are all of them parts of speech; because they are all useful in language, and each has a different manner of signification. But I think it of great consequence, both to knowledge and to languages, to keep the words employed for the different purposes of speech as distinct as possible. And therefore I am inclined to allow that rank only to necessary words: and to include all the others, which are not necessary to speech, but merely substantives of the first sort, under the title of abbreviations." In this hoastened division, as we shall presently see, there is neither utility nor accuracy, and the author was betrayed to it by a secret with to place the novelty of his own system in the most conspicuous light, namely, that conjunctions and prepositions are but abbreviations of nouns and verbs.

Now it is singular, that the division which we think the most philosophical, and, therefore, the most simple and useful, is that which is thus preferred in a very labouring treatise
tgatifie on grammar, in the Encyclopedia Britannica, (article 11.) "The division of words into those which are significant of themselves, and those which are significant by relation, is absolute nonsense, and has been productive of much error and mystery in some of the most celebrated treatises on grammar. It is indeed probable, that any attempt to establish a different classification of the parts of speech, from that which is commonly received, will be found of little utility, either in practice or in speculation. As far as the former is concerned, the vulgar division seems sufficiently commodious; for every man who knows anything, knows when he utters a noun, and when a verb. With respect to the latter, not to mention that all the grammarians, from Aristotle to Horne Tooke, have differed on the subject; it should seem to be of more importance, after having ascertained, with precision, the nature of each species of words, to determine in what circumstances they differ than in what they agree."

If these remarks be just, any attempt at a philosophical arrangement of the parts of language must be frivolous and useless. But we regard the paragraph as a manifest acknowledgment that the writer knew of no such arrangement, and that, as is often the case, he endeavours to confound himself and his readers, under the absence of this knowledge, with the consideration that if attained it would not be useful. We shall, however, attempt briefly to do what he thinks unnecessary to be done: but what we think not only useful and necessary, but even essential, in a philosophical treatise. An accurate distribution of our words, is but an accurate distribution of our ideas; and as in logic we cannot think juxta, unless we know how to distinguish our thoughts; so we cannot with precision reason in grammar, unless we have previously distinguished the parts of speech. The source of this distinction must be sought in the nature of the ideas expressed by those parts, and the enquiry, how many sorts of words there exist in human language, is merely, when directed to its proper object, how many sorts of ideas there are in human knowledge.

We have then ideas of things: we have ideas of the properties or attributes of things: we have ideas of the connection of things, i. e. of the arrangement of things, or of their increase or diminution; finally, we have ideas of the relation of things. Nor have we an idea which may not rank with one of these classes. And as language consists of terms expressing ideas, it consists of terms which express either ideas of things or the attributes of things, or the connection of things, or the relation of things. The terms expressing things are nouns, including substantives and the personal pronouns, which are only attributes for nouns, and therefore, in their nature, names of things. A sweet is an attribute of sugar, and so is to think an attribute of a man; to fly of a bird; to be of a being that exists, and so, moreover, loving, hating, are attributes of some creatures susceptible of love and hatred; finally, the circumstances which define things or distinguish them from others, may be considered as attributes or properties of the things so defined. The terms expressing attributes may be called attributes; and include adjectives, verbs, adverbs, participles, and definitives. The terms expressing the relations of things are propositions; while those which express the connection of things are conjunctions. And thus the most comprehensive, and, as we conceive, the most philosophical division of speech is into four parts, nouns, attributes, propositions, and conjunctions or connectives; nor is there any language, however few or numerous its terms may be, which is not capable of being distributed into these four classes. As to the interjection, it must be regarded as a sound which is either inarticulate, or which, as far as it partakes of articulation, partakes of the nature of a noun or of a verb. Having noted this distribution, we, as not prefixedly attempting to write a grammar, shall, in our remarks, follow the popular division.

Nouns and attributives, to use Mr. Harris’s language, are significant of principals, and we do not depart from philosophical accuracy, when we say that prepositions and connectives are significant by relation. Our notions of the relations and connections of things are by the principle of abstraction from our notions of the things themselves so related or connected. If all ideas of things or actions were obliterated from our minds, the ideas of their associated relations would be entirely obliterated with them. And as our notions of relation spring from the objects so related, so language, following the rite and order of ideas, has derived those terms which express relations and connections, from the terms expressing the things and operations so related and connected. In other words, prepositions and conjunctions are words which, by association, flowed from nouns and verbs as their real sources. If this be so, we shall see what Mr. H. Tooke, who assigns prepositions, conjunctions, and other particles, to be substitutes for those necessary words, the noun and verb. If this affection be put in clear language, it means that the relations of things, or of the operations of things, are substitutes for the things so related; that is, the relation of cause and effect is a substitute for cause and effect; the relation of beginning is a substitute for things which begin; the relation of instrumental is a substitute for that which is instrumental; and the relation of end is a substitute for that which ends. Moreover, the separation or concatenation of two or more affections is a substitute for the operations so separated or connected. This is not philosophical reasoning, calculated to throw light on language, but a sophistry calculated to confound the most distinct ideas which the human mind is capable of forming, and a jargon not to be equalled by any error or contradiction, which Mr. Tooke has so feverely censured and ridiculed in Mr. Harris. Besides, terms to express the relations and connections of things are not less necessary than those which denote things and their operations. A language without conjunctions and prepositions is not merely a fledge, (to use his own words,) which cannot be drawn along as smoothly, and easily, and swiftly, as a carriage with wheels, but is a fledge which has nothing to connect it with the horse; nothing to direct it in the way along which it should be drawn. The noun and the verb indeed may express a complete proposition; but the inferences in which such simple propositions occur are very few, compared with those more complicated cases where the use of prepositions and connectives is absolutely necessary. The distribution of speech into necessary words and abbreviations, is therefore, in this point of view, also frivolous and erroneous.

The Origin and Properties of Nouns.

Nouns are the names of things, or signs of those ideas by which we come to the knowledge of things. The term is a corruption of nomon, which is from nomos, while name came probably from the Perisan nām, which seems to be of the same origin with the Greek word. Nouns may be divided into three classes: names of individuals, names of species or kinds, names of abstract ideas. To this may be added, as a fourth class, the pronoun, which is made the substitutive or representative of all other nouns. But we shall consider this in the place usually alligned to it by grammarians. On each of the above classes we beg to make a few brief remarks.
Names of individuals do not enter into the composition of language; because individual objects are too numerous to have each a distinct name; and because language would then be changing in endless succession, each term dying away with the object it signified, and another rising to occupy its place. This is the reason why proper names cannot be translated from one tongue to another, the individuals specified by them, being confined to one time and one place, are not capable of being the prototypes of words in other times and places. Individuals, however, among men, animals, and places, which the purposes of life render it necessary to specify, have appropriate names given to them to distinguish them from all other individuals. And it sometimes happens that when individuals among men become eminent for any attainment or profession, their names are used to designate others who are eminent in the same way. Thus proper names are sometimes converted into common names. The former are called proper, as being peculiar to individuals, in opposition to such names as are common to all the individuals of a class.

The perceptions of the human mind, as we have observed, commence with individual objects: but we were soon induced to compare those objects; and on comparing individuals together, we readily discern a resemblance between them in some things while they differ in others. The mind then separates the particulars in which objects differ, and collects into one idea their points of similarity. Thus it forms ideas of classes, or in logic called species, comprehending under them various individuals. After this the species themselves soon become subjects of comparison; and excluding from each its individual qualities, the human mind formed those more general aggregates termed kinds, comprehending under them different species, as the species comprehend different individuals. Thus mankind classified all the objects around them, and acquired specific and generic ideas in nature, in art, and in abstract qualities. Having, as it is supposed, first advanced in the classification of their ideas, men gave names to each class, and thus acquired those general terms which are called specific and generic terms. But we have already shown that the processes of the human mind, in the principle of abstraction, is the reverse of this: general terms do not arise, as will appear evident if we attend to the commencement of education in ourselves and others, from general ideas, but, on the contrary, general ideas arise from general terms. The former have no existence till they are generated in the mind solely by the instrumentality of language: the learner being involuntarily and per- fectly led by the successive application of the same word to different individuals of the same class, to compare them, to separate their component parts where they differ, and to combine them where they agree. In this point of view, grammar is the foundation of logic and language, instead of being the offspring of human invention, is the sole medium of awakening the first dawn of intelligence in the human mind, and points for its existence to some intelligence superior to man.

Specific and generic ideas being thus formed, the subject matter of language is reduced, so as to be commensurate with the limited faculties of man; because, though individual objects are infinite, the classes comprehending them are comparatively few. The subject matter of speech by this means, moreover, is rendered permanent and universal, or confined to points of space and time; because, though particular things are local and transient, the species and kinds of things are universal and eternal. This is the reason why words which are unintelligible in one age and country are understood in other ages and countries; and may be translated from one tongue into another, without ambiguity or error, where the prototypes exist in common.

Further, though general terms are often indefinite and uncertain, yet whenever they express species or kinds, they may be defined by ascertaining the several ideas which constitute those species or kinds. And as the properties which constitute each class are found complete in each individual of each class, the name of the kind is applied to each of the species; and the name of the species to each individual included under it: and thus generic and specific terms are employed by the affluence of certain adjuncts hereafter to be considered, to denote individuals.

General ideas may be considered as abstract ideas, as they are generated by the mind separating or abstracting from each object those particularities which constitute individuality. But they are to be distinguished, at least in a grammatical view, from that numerous and important class of ideas which we acquire by the more simple art of separating from a thing the quality which belongs to it. Thus, the idea of fly becomes thought; and good is converted into goods. Abstract nouns of this kind are all, without exception, derived from verbs and adjectives, and formed by the simple power of withdrawing a property from the subject which supports it, and giving it an independent existence in the imagination. Now, it is a fact worthy of attention, that as general, so abstracted, ideas are formed by the sole agency of language, and would not have existed in the slightest degree, if words had not previously been applied to express the qualities of things. For as soon as a property was marked by an appropriate word, the separate and independent existence of that word, recognized by the eye or by the ear, induced the mind, without an effort and, perhaps imperceptibly, to give the property so designated an independent existence also. Mr. Tooke rejects the principle of abstraction; and would introduce in the room of it what he calls subordination. Thus, according to him, goods is that which is good; flying is that which flies: and under this erroneous and circuitous mode of explaining abstract qualities which he has borrowed from the neuter particle in Latin, he has attempted to bury out of sight the operation of the mind in forming abstract ideas. The existence of this operation, however, is too obvious to be denied with effect, and too important, in philosophical grammar, to be abandoned on the authority of any person whose acuteness of intellect may enable him sometimes rather to perplex than to unravel truth. In conformity to his own theory, Mr. Tooke supposes such words as science, diligence, which are abstract nouns, derived from the Latin scientia, diligentia, to be neuter particles plural in enit, a supposition contrary to the analogy of the Latin tongue, which affords not a single instance of plural adjectives being converted into abstract nouns.

Grammar cannot help noticing in this place an observation in the Encyclopaedia Britannica, viz.: "All the objects which exist must be either in the same state in which they were produced by nature, or changed from their original state by art, or abstracted from substances by the powers of imagination, and conceived by the mind, as having at least the capacity of being characterized by qualities; this naturally suggests a division of nouns into natural, as man, vegetable, tree, &c.; artificial, as boat, ship, watch, &c.; and abstract, as knowledge, motion, temperature, &c. This division has been borrowed from Mr. Harris, in his Hermes, and borrowed without consideration. Abstract ideas are the chief materials of science, which, giving birth to art, extended to the productions of art, as its genuine offspring, the life of its own terms. Accordingly, all artificial terms are abstract.
G R A M M A R.

abstrat terms, or terms derived from adjectives and verbs. Thus, *fusible* denotes an artificial production, and is at the same time an abstract noun from *fusilit*; and *phlog* is taken from the Hebrew *phlog*, phlog, and means an instrument of separation. And even natural objects are often expressed by abstract nouns, as *creation* from the verb *create*. And if abstract nouns are extended by association to designate natural and artificial objects, they cannot with propriety be said to form a class of nouns distinct from nature and art.

Abstract nouns, expressing ideas properly so called, are very numerous in our language, and worthy of attention. They are chiefly taken from the Latin; as those in *ion* or *ion*, ment, cera, ty, or tude, as *faction*, collufion, commandment, confefion, piety, altitude, and all the nouns of this termination, with others in *nfe* and *t*, such as *expag* and *merit*, are also from this source. Many others are derived from the Anglo-Saxon or Gothic, such as all those in *nfe*, *foms*, and *hood*; as *goodness*, *wisdom*, *neighbourhood*. The far greater part of Mr. Tooke's second volume is occupied in tracing nouns of this description. His etymological researches are, in many respects, useful and important; but we cannot help hearing our testimony against his work, as tending to direct the labours of philological enquirers to wrong objects, and to withdraw their attention from those sources, whence English and all other European languages, ancient and modern, have sprung. But let us hear his own words: "The bulk and foundation of the Latin language is Greek; but great part of the Latin is the language of our northern ancestors granted upon the Greek. And to our northern language the etymologie must go, for that part of the Latin which the Greek will not furnish; and there, without any twitting or turning, or ridiculous forcing and torturing of words, he will easily and clearly find it. We want, therefore, the testimony of no historians to conclude that the founders of the Roman state and of the Latin tongue, came not from Asia, but from the north of Europe. For the language cannot be and from the language of every nation we may with certainty collect its origin. In the same manner, even though no history of the fact had remained; and though another Virgil, and another Dionysius, had again in verse and prose brought another *Æneas* from another Troy to settle modern Italy, after the destruction of the Roman government, yet, in spite of such false history, we should be able, from the modern language of the country, (which cannot possibly lie,) to conclude with certainty, that our northern ancestors had again made another successful irruption into Italy, and again granted their own language upon the Latin, as before upon the Greek. For all the Italian which cannot be easily thrown to be Latin, can be easily thrown to be our northern language. Mr. Wakefield had, shortly before his death, agreed with me to undertake, in conjunction, a division and separation of the Latin tongue into two parts; placing together in one division all that could be clearly thrown to be of northern extraction." (Vol. ii. p. 142.) In p. 299, he gives the following infusions, with many others, of Latin words derived from the northern language:

<table>

According to Mr. Tooke, the words in Roman letters are plainly of northern origin, while those corresponding to them in italics are Latin verbs derived from them. The reverse of this position we can prove to be true. The Anglo-Saxon, or Gothic words, which this author dignifies as northern primitives, are no other than Latin words borrowed and corrupted by the northern barbarians when they over-ran the Roman empire. This position, if proved, will render the far greater part of Mr. Tooke's labours perfectly nugatory; and nothing more is necessary to prove it than to shew that the origins of the Latin words exit in Greek, or in one of the Oriental tongues, and exit in such a form, as to evince that these are the primitives, and consequently that the northern words are only corruptions derived from thence. Thus the Hebrew מָלִךְ, מָלִיך, is a hand; hence *capo*, to take in hand, and by softening, *t* into an aspirate, as is often the case, *bales*, to hold in the hand, *i.e.* to have. The Greek αὐτόρ, *autó*, overthrow, is the parent of the Latin *neos*, corrupted into *neuran*; *sōs*, I ego, go, *higan*; *xērho*, bend, *hentan*, to beise; *līdis*, *volos*, *velleapion*, to roll; *ēlōn*, *flūan*, *fluere*, to flow; *μόνα*, *flōs*, and *μονα*, *fūt*, signify life; hence *fusoe*, *sifte*, the action of the lips in throwing out of the mouth, *i.e.* *sīt*, *fīs*, *φυνα*, *fυνα*, to soften, *μελος*, *melos*, *νυκτα*, *nukei*, *νυλος*, *nuilei*, *μελακα*, to milk; *νυλος*, *recompense*, *peruim*, *pīne*, *pinnam*, to punish; *πορν*, a tail, *pango*, *pygian*, to act as a tail. does, *i.e.* to prick; *πτερ*, *fīg*, *fageian*, to fix; *κολο*, *koł*, *deko*, to wash down, to oblate by washing, *diligin*; *μολος*, *molo*, *Goth. molan*, to mill; *Chald. γωνη, *goen*, *gōn*, *kōn*, *kian*, to blow; *τοκε*, *toko*, to rice, *blūan*, *ekel*, to spin, *twill*, *netis*, *gitan*, or *gnatan*; *εγος*, *ego*, *tego*, or *tango*, *tekion*, to touch; *δεκλε*, *dame*, *deman*, *δηκε*, *dīke*, to take food, *profian*; to prove; *αρετη*, *transposing r*, as is often the case, *rapio*, *rapian*, *πνων*, to defire, *pēs*, to seek in consequence of desiring, *bidaman*.  

Though this lift clearly shews that the Northern language in a great degree, a corruption of the Latin borrowed from the Greek, the Hebrew, and other Oriental tongues, yet Mr. Tooke gives it as exhibiting infusions of the Northern dialect grafted on the Latin. The primitive language of the North could have been no other than a branch of the primordial language of men, conveyed there by the first emigrants, diversified and enriched by communications with the Earl on the north of Asia, by early irruptions into Greece, as is mentioned by Herodotus, and, in far later days, by amalgating with the Latin, when in the dark ages the tribes of the North invaded and dismembered the Roman empire. In this state, the Northern language became the parent of the English; and though a multitude of its words, especially monosyllabic words, are, no doubt, immediately from the Anglo-Saxon and Gothic, yet few influences we believe, can be produced, which may not be traced, by a competent etymologist, through the medium of those corrupt changes, to their primordial purity in Italy, in Greece, and in the Earl, the sole origin of language and literature. But Mr. Tooke reverses this natural and necessary order; and, without the testimony of historians, without any documents of the language fulfilling in the North, antecedent to that, which was spoken in the middle ages, he fixes on corruptions borrowed from the Latin, and holds them up as the origin whence Latin, Greek, and English have been derived. His theory, thus far, is ridiculous and mischievous; ridiculous, because it is a palpable error, professed by important discoveries; and mischievous, because, while it pretends to trace words
words to their genuine roots, flops up all the true sources of information on the subject of language. As we have palled this cenure on his stylen, we feel ourselves called upon to justify it by more numerous instances. And we think this the more necessary, as subsequent grammarians, and the public in general, seem willing to acquiece in his positions as incontrovertibly just.

In doing this we shall adopt the words which present themselves, without much felection, referring our readers to the page where they occur in his lecond volume. It was impossible to err as to the derivation of right from rectum; but something ordered is not the leading idea of the term, though Mr. Tooke employs many quarto pages in explaining it on this principle. The primary sense of right is straight, a relative term, denoting the means to an end. Thus, virtus is right, because it is the straight or direct road to happiness. That hand is right, which does its work in the foremost way. Property is right, because it is the straight road to the welfare of society. In this sense we may say of God, if we say it with reverence, that it is right in him, because, when he has an end to answer, right means the straight way to accomplish it. "The left-hand is that which is loved, or that which we are taught to leave out of use on such occasion," p. 10. This appears to us nonsense. Left is the Greek λεφτος, and Latin levus, with r, the usual termination of northern words. Lex, Fr. lai, and our law, is from lege, and means something read or dictated, and not something placed, p. 8. The Anglo-Saxon, legan, puer, is but a corruption of locare, to place. Juvius, indeed, means something commanded, jujrum, from juvo. But this last is the Hebrew ו'ג, gab, and the Arabic jahb, to answer or assert. Hence, in Latin, jubere legem, to enact a law, i.e. to allow to pass, and promise to obey it.

"To enact is to do as the cuckow does," p. 21. Few people know how the cuckow does; but all know how a cock acts on such occasions. Kokora is an Eastern word, which, coming into Italy, gave birth to civus, to crow; and, changing r into the commate l, as is often the case, to kokola, which, in Celtic, is klok and kilgée, to act as a cock does with a hen. This, we presume, is the origin of cuckold. Hen-pecked is a figure of the same nature, and from the same source. "Alert is all-ecret," p. 24. No, we presume it is all-ert, or all-art, i.e. all active. The word art, signifying skill, came to signify that diligence by which skill is attained. The opposite, which functions this etymology, is inerti, not active. A knave, i.e. a man cunningly skilful, came, by the fame allocation, from gnawus, diligent.

"Left, (French lache) of a whip, i.e. that part of it which is hi tope," p. 32. Rather from lapes, an offer. The French laches, or the Italian lascie, is the Latin lascare, from lapes, to bend. To bend, or to burn, gave birth to branch, i.e. a mark by burning—brand, i.e. spirits which burn—bruxon, i.e. bread burnt—brunt, brunt of the battle, i.e. the heat of the battle, or the place where the battle burns. The origin is furunc, an even. Odd is not the particle oved, i.e. something owed to make up a pair, p. 88; but the Hebrew יאשע, abad, one, single, singular, i.e. one that has no other to make an even number, or pair, with him. Thus we say, an odd man, i.e. a singular man. loud, p. 39, is, we presume, from όλος, a voice heard. The Anglo-Saxon, derived from this word, has preferred the s aspirated, blawen. In Celtic it is cladd, that which is heard in pratie of a man. The Latin has rejected the gutturall altogether in laudo. The Greek poets have applied the epithet όλος to such animals as beet; hence lau: stred, or stred, four, four, (as plough share) p. 41, come from lapes, to clap, by prefixing s, a practice very frequent in Latin; and hence the Anglo-Saxon stredan, to flcer.

One of these broad analogies by which the Latin separated from the Greek, is to convert a gutturall into a labial, as in ολος, flat, όλος, flourish. Thus it may be, culs became, as it were, fuls, flat, field, i.e. a cultivated ground, and not a place filled, p. 41. Coward is the participle of corner, to bend; but the parent of this verb is корн, to shrink, p. 42. Bread is bearing, i.e. the produce of the earth, as bread, offspring, is born, something born, and not from the obsolete bray, to pound, which is taken from the Latin frico or frango; both of which originated in the Arabic jοł, jολ. Freed, free, is the participial termination of jολ, or jολ, violence, in which, as Socrates says, there is emity; while friend is the same form of fraye, a woman, (from φραγι, i.e. the bearine animal,) by which we mean a female hewe. The letter l, being of the fame organs with n, is often changed for it in all languages, as ονκος, lympha; ρος, pubu. On the fame principle, the Hebrew ו, to marry, became lαf, or love. The Hebrew ו, and the Persian knob, felf, passing to the North, gave birth to the pronoun, or, as it is farther corrupted, it, which, like id in Latin, directs the attention to something going before, and is a substitute for it. Gothic haitan, Anglo-Saxon hetan, or getan, to speak or command, is, perhaps, the Greek φανα, which, in Grecian, is seynd, in English quoth, and in Latin in the compound form of in-qui, p. 53.

Tight, i.e. tied, and the Gothic tjian, is from ολος, to fold up, 67. Twill is tortus or tufus, and not that which is twisted. Quilt is called, (ωλος) twisted. Draught, drag, is τρομος, trudo. Tilt is tilted, lifted, from τάλα, tale. "Barren, i.e. barren, cloed, shut," p. 72. The verbs φρευ, φρευ, bare, bare, bare, bare, bare, with the numerous tribes of words derived from these in all languages, owe their existence to the Arabic barren, the earth, or that which produces all things; and barren, we presume, meant primarily an animal having produced; and thence it denoted infertility, consequent on production, or, more generally, incapacity to produce. The Hebrew ו, sier, denotes any thing close, sibor, or hard. Hence the Greek φευ, firm, rigid; and our firm, p. 73. The same word in Arabic means a harh or acute found, and hence seemingly the English fir. The Arabic ו, seer, which we should pronounce sier, denotes to flow, or to move as water does. Hence the Anglo-Saxon sieran, which means to cause a ship to move, which is the meaning of the hence-derived sier. Stern is that part of a ship which is thus moved. The Hebrew יאש, gur, to turn, has given birth to turn, turning or stirring cream being the means of obtaining butter, which in Anglo-Saxon is grean, to yeare, which is a revolution of time; to surn, which means therefore something turned or twilled, and not prepared. Homer, pilus, means hair on the head; hence it signified to form hair, or to grow into a head. And this is the origin of our words pile, build. Bold or built originated in validus, bodily strength naturally infusing mental energy; 79; but bolus, p. 128, is βόλος or βόλος, the thing cast, 129. Bore is the Hebrew יאשע, bacer, a sturdy rapid animal; but bresau we think is not barren, but park, parken, proven, brawn, from porcine, and therefore it means the flesh of a pig, 87.

Chop, chip, is something cut off, from κοτ, κοτ, the Anglo-Saxon pibtan, to pledge, is from κοτ or κοτ, to strike, plight being a bargain struck. Shunt is the fame in sense and found with the Arabic ינש, find. The Anglo-Saxon fætan is nothing but the Hebrew ינש, flit, notes; and hence it came to signify the action of the nates in throwing away the excrements. We shall merely add the following list, and all the words...
words in the labourd chapter on **abstraction** are, with few exceptions, capable of being traced in the same manner; and we defer our readers to compare the derivations here given with those of Mr. Tooke in the above mentioned to.

*Grammar*.

*Oracles*, to divulge or expose; *trull*, a public woman, p. 153.

_Tuis_, to turn, drab, a woman that turns about, a vagabond woman, 154: hence the Gothic *frilian*, to drive about, or turn out, 155. The Arabic ُعُلِّ, *alb*, means food, support, and hence *baws*, the means of subsistence. The Anglo-Saxon has preferred the nasal aspirate *blaf*, 157. From *aws*, a bill, came the Anglo-Saxon *byfian*, to rise to a high place; hence *tysi*, life, 152. ُتُهُّ, *rham*, Anglo-Saxon krye, vircere, green. ُتُهُّ, *Anglo-Saxon gerygan*, to decay. Grey, 167, the colour of old age. ُتُهُّ, *blaf*, flower. ُتُهُّ, *bahr*, fluidity. *Suir*, fire, fr. *Koga*, a wrinkle. Rough, Anglo-Saxon *ryf*, 177. ُتُهُّ, *woos*, word. Anglo-Saxon *swan*, 176. *Tows*, to arrange, bind, command; hence *teo*, to weare; *hos*, tribute, *i.e.*, tags, the thing felled, 179. *Tows*, to rule; hence *teles*, tall, i.e., what is raised. ُتُهُّ, *figi*, also to command, and hence it came to denote voice, or found in general *toll*, *tale*, *tall*, the found of a bell. 184, a tribute, *tita*, to pay, *tall*. ُتُهُّ, to slay, to tall, or, as it was formerly speelt, *tall*, 185; *teo*, to slay, *tall*, to slay the medium of toll, an instrument. Hence, moreover, Anglo-Saxon *thiuluin*, till, i.e., to slay on the ground, cultivate the ground, 182. ُتُهُّ, *bur*, something added on the outside for the sake of defence, is the origin of bar: ُتُهُّ, ُتُهُّ, *burich*, is bargh, borough, a place barred, *i.e.*, secured, which in Greek is *teyos*, a tower, and in English *park*; moreover, the bark of a tree is ُتُهُّ, *birk*, or that which separates from the tree. The Arabic *barbain*, a nobleman, is the parent of baron, and to this sense of the word St. Paul alludes, in *Acts*, xvii. "*THEBAN* were more noble than those of Thessalonica." ُتُهُّ, *phlak*, in Arabic means a *flap*, and this, by changing *l* into *r*, gave birth to *bark* and *large*, 182. ُتُهُّ, *bur*, pit or grave, *bary*. ُتُهُّ, *flora*, flower, treasure, 185. ُتُهُّ, *flora*, to inundate, is the Anglo-Saxon *furmian*, to rage as a flood, and hence *flora*, 183. ُتُهُّ, *flora*, in Arabic means a body of people come together; hence *town*, 201. ُتُهُّ, *beet*, means a house, a place that holds or contains; hence, bed, abode, pot, in Greek *paxos*, in Celtic *bed*, the lit abode of man, and pit. *Cruft*, to plead, to deliberate, gave birth to choices, the effect of deliberation, and to savem, i.e., to deceive by pleading. The *Persian pdrab*, is vine, juice; and hence the Latin *virgo*, and the English *frap*, 209. ُتُهُّ, *baran*, morrow, Anglo-Saxon *merna*, man. *Traps*, to heat, to dry, to evaporate by heat; hence Anglo-Saxon *drygan*, drain, 224. *Tros*, a garment, rag, *rig*. *Tenes*, trall, Anglo-Saxon *draggen*, dragon, drone, an insect that drags itself. ُتُهُّ, *shod*, produced. *Zill*, Anglo-Saxon *flidan*, to separate, seems to have come from *xalos*, *ig*, i.e., to put the legs in action, to separate one from the other.

These specimens (and they are ample specimens) will be sufficient to enable us to form a full estimate of Mr. Tooke's merit as an etymologist. If the above are well founded, they show that his labours have been greatly over-rated. His great error is, that by forced analogies, or rather contrary to all analogy, he has yoked together words as of a common origin, which have flowed from very different sources; and this error has arisen from his studied inattention to the operations of the human mind, to a still greater want of acquaintance with the Oriental tongues, whence all the European dialects, ancient and modern, have been derived; and to his prepositional attempt to deduce English, Latin, and Greek, from the corruptions of Latin and Greek by a barbarous people in the dark ages. Before we quit this subject, we shall make one or two observations worthy the attention of those who trace the ramifications of modern languages from their ancient roots.

In the Oriental tongues gutturals abounded, which, like other consonants, contained in themselves the vowels necofos, to their pronunciation. But it is the tendency of every guttural, when become habitual, to soften down, in the rubbish of utterance, into a mere aspirate, till it at length vanishes. Thus *causa* has degenerated into *caos*, and *xalmaux* into *hams*, and into *homos*, a creature of earth; in the Greek, the Oriental *Homos*, a king, became *xanatos*, to reign, which Homer pronounced *xanatos*. This principle has obtained in the formation of many words, derived into English through the medium of the Anglo-Saxon and the Gothic. And the inflections are still more numerous where the aspirate, instead of vanishing, has been converted into the labials *v*, *f*, or *y*. Thus *wicked* is the Arabic ُتُهُّ, *begnud*, *sworn*, the *Perian gorn*, *all*, *sos*, *sapolis*, the Hebrew *wuy*, *kab*, work, *sos*, the Chaldean ُتُهُّ, *dark*, *cheil*, *strength*, hence *xwad*, *wealth*, the strength of a filet; *xwaol*, the strength of a town; *xuliel*, health, the strength of the human body. ُتُهُّ, *hart*, write.

An intimation to this principle has betrayed Mr. Tooke into many errors; thus he derives *feld* from *felded*, that is, a piece of ground in which the wood is felled; whereas we conceive it is a corruption of *culus*; as if *fulbus*, *fuli*, field, i.e., a cultivated piece of ground, precisely in the same way as *xalma*, became *xer*, and *xalmaux*, felt, fall. This substitution of the labials for aspirate or aspirate obtained in an early period of the Greek, and constitutes the original of what is called the *digamma*. This digamma prevailed in the age of Homer, when the language was chiefly oral. But his poems, as being written, preferred the guttural or aspirate, the true original character, which being studied, enabled the aspirate to prevail in time over the digamma; and thus it reflored the language to its primitive purity. But the Latin, having flowed from the Greek at an early age, when the caprice of oral sounds spread uncontrolled by written letters, and having no monument of genius like the *Hind* and *Odyssey* to correct that caprice, as was the case in Greece, adopted the digamma, and thus separated, by a broad line of distinction, from the parent tongue. We now return to the properties of nouns.

The properties of nouns are gender, number, and case. Gender, as meaning the distinction of sex, was by no means a necessary property of nouns, for the signification was sufficient to show the sex to which it belonged. Thus, as there
there were but two sexes, there should have been two genders, masculine and feminine, nouns meaning males being ranked under the former class, those meaning females under the latter; while the neuter or neither gender comprehended the names of inanimate things, or such animals as had their sex not discernible, or not necessary to be distinguished. But unfortunately the termination of nouns became a mark of gender independent of their signification; and thus nouns were considered as masculine, feminine, or neuter, as they happened to have the endings which custom usually affixed to either of the three classes. The Hebrew tongue, in its primitive purity, appears to have been exempt from this unhappy embarrassment, and the only languages known to us which have maintained the empire of common sense against the caprice of custom are the English, the Persian, and the Bengalic. In Greek and Latin the dictates of reason have so far prevailed as to cause all those nouns, whatever be their terminations, which mean males and females, to be deemed masculine and feminine; while the names of inanimate objects only are determined by the termination. In other languages, such as the Arabic, French, and Italian, this absurdity has been carried much farther, the names of inanimate objects being said to have gender: the neuter, which is only the negative of sex, is excluded; and the learner has his memory loaded with the gender of nouns which really meant things without sex, and this without any one advantage to counterbalance so much fruitless trouble, and such glaring facric of common sense.

The English language, as conforming to nature in regard to the distinctions of gender, has greatly the advantage over other tongues: when rising to the rhetorical and poetical style it addresses the fancy by periphrasis. This figure is essential to poetry. In order to interfile the imagination, the subject of discourse, when inanimate, must be invested with the forms and attributes of living beings. Now, when things are thus periphrased or spoken of as persons, they must be represented as male or female. May they be made either? Or is there any analogy to give one the preference over the other? Let us hear what Mr. Harris (Herm. p. 44.) says on this subject. Having observed that some nouns are of such a gender from having such a termination, he thus proceeds: "In others we may imagine a more subtle kind of reasoning, a reasoning which discerns even in things without sex a dildant analogy to that great natural distinction which, according to Milton, animates the world. In this view we may conceive those substantives to have been considered as masculine, which were conspicuous for the attributes of imparting or communicating, or which were by nature active, strong, and efficacious, and that indifferently whether to good or to ill, or which had claim to eminence either laudable or otherwise. The feminine, on the contrary, were such as were conspicuous for the attributes either of receiving, of containing, or of producing and bringing forth; or which had more of the passive in their nature than of the active; or which were peculiarly beautiful and amiable; or which had respect to such exceedingly as were rather feminine than masculine." On this principle the sun, as imparting light, is masculine; the moon, as receiving it, feminine. The sky, or ether, time, death, the ocean, the Supreme Being are all masculine; while the earth, sky, city, virtue, religion, are feminine. And yet Mr. Tooke roundly pronounces this reasoning fallacious. "As for Mr. Harris's poetical authorities, the Mufs are bitter bad judges in matters of philosophy. Besides, that Reason is an arrant depôt, who, in his own dominions, admits of no authority but his own. And he is particularly unfortunate in the very outset: for his very first instances, the sun and the moon, destroy the whole subtility of this kind of reasoning. For Mr. Harris ought to have known that in many Asiatic languages, and in all the northern languages of this part of the globe which we inhabit, and particularly in our mother language, the Anglo-Saxon, sun is feminine, and moon is masculine," vol. i. p. 54. The author of the learned treatise on grammar in the Encyclop. Britannica, 17, relining no doubt on the authority of Mr. Tooke, thus pronounces on the reasoning of Mr. Harris: "Such speculations are wholly fanciful: and the principle on which they proceed are overturned by an appeal to facts. Many of the substantives which in one language have masculine names, have in others names that are feminine, which could not be the case, were this matter regulated by reason or nature."

The languages from which the objection to Mr. Harris's theory is derived are not regulated in regard to the distinction of gender by reason or nature. And facts borrowed from them are not fully to be admitted as conclusive against a principle in a language which is regulated by reason and nature. Mr. Harris deduced his theory from the English, though he has applied it with perhaps more fancy than truth to some instances in the classical languages. Our own tongue, as making all things neuter which have no life, admits the operation of fancy in perceiving inanimate objects; and where periphrasis is admitted, the analogy to the natural distinction of the sexes must necessarily be admitted also.

But, Mr. Tooke and his abettor say, it is fanciful because it does not obtain in other tongues. Their argument is briefly this:—The sun, by periphrasis, is not made masculine in English, where the consideration of gender is founded on reason, because it is made feminine in some languages where the termination, and not reason, determines the gender. Reaoning of this kind is not only inconclusive, but frivolous; and the analogy stated by Mr. Harris invariably and necessarily operates on our own tongue, and would have operated in all tongues, if, like the English, they had conformed to the standard of nature; and we ought no more from their caprice to argue against the dictates of reason and analogy, than we ought to deny a regard to the distinction of sex in the nouns of one language, because the gender of the same nouns in others is regulated by considerations independent of sex.

When a noun represents its object as one, it is said to be in the singular, and plural when meaning more than one. This property also can hardly be said to be necessary to nouns, as its place might have been supplied with greater accuracy by numerical adjectives when extended to express numbers, as two men, three men, &c. "Bengal nouns," says Mr. Halhed, in his excellent grammar of that tongue, p. 68. "have neither dual nor plural numbers, I may add that neither is wanted. The dual is found in no modern language, and probably never existed but in the Arabic and its branches, in the Shanferi and in the Greek. That the idea of multitude is not confined to the plural number, is clear beyond a doubt, because singular nouns are used in all languages with a collective sense, almost as frequently as plurals, thus: man love to fludy, and man loves to fludy, are phrases perfectly equivalent. So also we join to a noun in the singular number an epithet of indefinite plurality to convey a plural meaning: many a man is written by the Bengalic authors manbooy. Perhaps it might be safely urged that the singular number has more occasion for an accurate specification than the plural; at least this is the only circumstance which can account for the extensive use of the article or representative of unity in most of the modern dialects of Europe."

The plural number in its origin was no other than a noun-
of multitude, annexed to that preceding it, in order to mark its extension from one to many. Thus in Hebrew, 'whence high antiquity unfolds to the philosophical enquirer the several steps which mankind took in the formation of speech: יִשָּׁר מֶלַךְ, an ephah, a man, multitude, became contracted, for the sake of brevity, into יִשָּׁר מַלֶּא, an- 
some, men. In the Chaldean and Syriac the final _n_ was 
changed into _n_. Hence the Hebrew _n_ in Chaldean bec- 
came _m_ in Arabic _m_ in Persian _man_, to denote the names of 
animals, and _n_ inanimate things. And from this source 
are derived the plural terminations _m_ or _m_ in the Anglo-
Saxon and German tongues. The letters _n_ and _a_ being 
of the same origin, the Chaldean _n_ became _a_ in the formation 
of the Greek, or _a_ in the third declension of Latin nouns. 
Hence, too, the plural termination _s_ in English and French, 
while the Italian exclusively follows the analogy of the second 
Latin declension in _s_. Thus the plural termination in all lan-
guages, ancient and modern, appears to have been derived 
from one source: and that consisted of the annexation of a 
_n_ of multitude to the singular form of a preceding noun.

And it is remarkable that in the Bengalese, which is but 
a branch of the Sanscrit, this mode of expressing plural nouns 
is preferred to this day; as, _pure_ch, a peafant, _pure_h, a 
peafant-people, _pure_bak, peafants; _bak_ signifying people annexed 
to the singular noun whatever it might be. We shall only 
observe, that the names of clafhes only admit the plural form; 
while _proper_ names in all languages are, by their _nification_
confined to the singular, unless many individuals by accident 
have the same name. The names of _families_ and _nations_ must 
likewise be excepted, which, from a regard to their _nification_
are necessarily _plural_.

We come next to the consideration of _cafe_, which are 
properties of nouns, perplexed and undefined, as is evident 
from the different, and we may add, erroneous accounts 
given of them by most grammarians. The belt and 
luret way to aecertain the nature and origin of _cafe_, is to 
attend to the manner in which they were at first considered 
in the Peripatetic school. We adopt the words of Mr. 
Harris, p. 277. "The Peripatetics held the nominative to be 
no _cafe_, and likened the _n_ of this, its primary and original 
form, to a perpendicular line, such for example as the line

[Diagram of a perpendicular line with points A, B, C, D, and a right angle at C.

A B. The variations from the nominative, they considered 
as if A B were to fall from its perpendicular, as for example 
to A C or A D. Hence, they only considered the variations

VOL XVI. 

We copy this account because it is very plausible, though 
we regard it as erroneous; the learned author and Ammonius 
(De Interpret. p. 335) from whom he derived it, being 
misled by the figurative language borrowed from geometry. 
We believe that the nominative is said to be in the right 
cafe, not because it is an erect or upright falling from the mind,
but because the nominative, the verb, and its object following 
each other in direct succession, form one simple proposition. 
The nominative is the leading noun or _agent_, and the accusive 
is the _effect_, in which the action straightforward terminates. 
And when other nouns are introduced, they are spoken of not 
directly as the agent or subject, but collaterally or obliquely,
as objects to which the direct noun someway belongs. Thus 
the accusive as well as the nominative are right cafes, or _di-
erent parts of a proposition_; whereas the _cafe_, _dative_, ablative,
and vocative are oblique cafes, or _indirect parts of a propo-

tion_.

From this simple statement, which we recommend to our 
readers as important, we infer, that a _cafe_ did not at first 
mean a _change_ in the termination of a noun, but the _position_ 
of a _cafe_ expressing its relation to some other word in 
the sentence. And our next object is to ascertain those _leading 
relations_ which the _position_ of a _cafe_ and _cafe_ other means 
more specific, expresses. _God made man_ is a sentence in 
which the _agent_, the _action_, and the _object_ follow each 
other in the _order of nature_: _God_, as occupying the place 
of the _agent_, is the nominative; and _man_, as _correspond-
ing_ to the _cause_, is the _accusative_. But in the _sentence_

"God is good," we cannot say _God_ is the _agent_, because 
the verb _is_ does not express an _action_, but serves only to 
connect the _epithet_ with _God_. The nominative, therefore, here 
expresses not the _agent_, but the _subject_ of the attribute 
connected to it. The nominative _cafe_, then, is that leading 
_thing_ or _position_ which expresses the _subject_ of a _connecting_ 
verb. And the _accusative_ is that _position_ which expresses the _effect_ of an _active_ _verb_, and thus _one simple 
position_ will carry us: and the nominative and _accusative_ have evidently to each other the _relationship_ which 
a _cafe_ has to its _effect_, and that for no other reason, but that 
their _order_ corresponds to the _order_ of _cause_ and _effect_.

But suppose that my _purpose_ was not only to express 
a _cafe_ or _agent_, but the _origin_ of that _cafe_, or the _infr-_ 
ment by which it acts, or the _end_ for which it acts. In such cafes 
one _position_ will be of no avail. I must have recourse 
to some other expedient, and no expedient so well can serve as 
_futile_ words to express _origin_, _inframentality_, and _end_. 
Thus, the _Son of God_ redeemed mankind—he redeemed them 
by _his death_; he redeemed them for _happiness_. In the 
first sentence, _of means_ beginning or _origin_; and _God_, 
successing _it_, is the _subject_ of _God_, is _said_ to be in the _na-
ative_ _cafe_. In the _second_, _is means_ _inframentality_, or _medi-
ium_; and _as death_ is _the medium_ or _medium_ by which 
_Christ_ redeemed _man_, _it_ is _said_ to be in the _ablative_ _cafe_, 
and might more properly be said to be in the _inframental_ or _med-
dal_ _cafe_. In the _third_ _infrant for_ expresses _the end_ for which 
_Christ_ redeemed _man_; the _nominative_ _successing_ it, is 
therefore in the _final_ _cafe_, or as it is commonly, though un-
meaningly, called the _dative_ _cafe_.

The _cafe_, then, or those _leading positions_ of a _nominative_ 
that an _n_ the _purpose_ of _speech_, are the _nominative_, _accus-
ative_, _genitive_, _ablative_, and _dative_. Let it be added, that 
the _nominative_, as it implies the _name_ of its _object_, is _often_ 
used merely to address a _peron_, and thus to fix his _attention_. 
In this state the _nominative_ is often considered as the _cafe_.
GRAMMAR.

sometimes preceded by the preposition or. But we have not yet done: the nominative and accusative are expressed by position; while the oblique cases, the genitive, ablative, and dative depend on words expressing beginning, medium, and end. Let us a little contemplate the consequence of these words, or words of the same import, when first introduced into discourse. As the relations of things are in the order of our ideas consequent upon the things so related, prepositions denoting those relations must at first have succeeded the nouns which they now precede and govern. Thus in the above instance, the order would have been *God of—death by—baffings for.* And it is remarkable, that in the Hindoo-fanatic the prepositions to this day generally succeed the dependent nouns, instead of going before them, as in other tongues. The consequence of this was, that the prepositions, abbreviated perhaps into single letters, coalesced with the preceding noun, forming thereby one word with it. Thus godf, godf, godf, &c. and the variety of terminations given by this means to the noun is the origin of cafes. Modern tongues, in rejecting this variety, and substituting prepositions, have only returned to the original purity of language.

Grammarians have generally concurred in defining cafes to be changes of termination. In this, if the above account be just, they are mistaken, not only because *position* is the primary and essential idea of a cafe; but because while they reject prepositions as marks of cafes, the cafes defined by them are no other than the prepositions which they reject. Conformably to this notion, they maintain that the English noun has no other than the possessive cafe; and Dr. Lowth and Mr. Lindley Murray, pursuing the same error to its consequences, comprehend nouns expressing the relation of effect, the relation of beginning, the relation of medium, and the relation of end, under one unmeaning phrase of *objective cafe,* thus confounding relations the most necessary to the purposes of speech, the most distinct in themselves, and most requisite to be kept distinct in the mind.

The idea of the most acute and learned grammarians have hitherto been confused and contradictory on the subject of cafes, especially the oblique cafes. The author of the treatise in the Encyclop. Britannica has just left the matter obscure and uncertain, as he found it. "The genitive," says he, "is the most general of all the cafes, and gives notice that some connection indeed subsists between two objects, but does not point out the particular kind of connection. Thus we must infer, not from the nature or termination of the genitive itself, but from our previous knowledge of the objects connected. That the genitive denotes merely relation in general, might be proved by adducing innumerable examples, in which the relations expressed by this cafe are different." These observations clearly shew that this writer did not himself understand the meaning of the genitive cafe, which, instead of expressing some connection between two objects, or mere relation in general, uniformly expresses one and the same relation, namely, that of beginning, medium, or origin; and of, the mark of it, has uniformly the same sense with from. Thus a table of wood, a table from wood; wood being the origin of the table. Rays of the sun, rays from the sun, the sun being the origin of the rays. And beginning will appear to be the primary idea implied in of, if we trace it to its origin; cf. ab, as, 2N, ab, parent, from root. Thus also in Latin *Dei gratia,* the grace of God, the grace from God, the grace of which God is the source. Of the phrase *injury regi* the writer says, no man can know whether the injury mentioned be an injury *suffered* or an injury *inflicted* by the king. We deny this: if the terms be used in strict propriety they must mean an injury from the king, an injury of which the king is the source and author; and, if they are intended to denote an injury received by him, the expression is incorrect and ambiguous, though the ambiguity would be removed by the context; and this leads me to remark, that as the beginning of a thing is the *author* of it; and as the author has a full right to the fruits of his labours, so that state of the noun which express begins coming to signify the *owner* or *possession.* And thus the genitive in Greek and Latin expresses the relation of possession, and answers to what is call in English the *possessive* cafe. Thus, *my father's* will may mean the will of which my father is owner; it means also the will which originated in my father. The possessive cafe, in our tongue, is an evident abbreviation of the genitive termination of the third declension in Latin, *father's house,* *father's house,* the apostrophe above supplying the place of the excluded vowel.

The same writer has not defined the meaning of the *dative,* though the relation denoted by it is the most obvious of any, contenting himself with saying, that it has nearly the same sense with the accusative, to. No two relations, however, can be more distinct; as the accusative expresses the effect of an action, and therefore stands immediately connected with that action; whereas the dative denotes the *end* to which a motion or action tends, and in which it terminates, or the point to which the attention is directed forward, as that to which something else is related. Thus, in the instance given by him, *compara Virgilium Hincia.* The immediate object of comparison is *Virgil,* and *Homer* is the point, or standard placed before me in making that comparison. The two first words express the action and its effect, the last holds to view the point to which they are directed. It is true that in this and similar instances, the mind brings under one view the person compared and the person to whom the comparison is made; and this proximity or juxtaposition constituted the affinity which the writer erroneously supposed to be between the two cafes. *Antonius fuit Cicero,* he further supposes to be explications of the same import; but in this he has been misled by the genius of our tongue, which would express each phrase by *Antony buit Cicero.* But this is the exact meaning of the first clause only. In the second clause *seu litter expresses not an action, but affirms a quality.* Antony was hurtful to Cicero. Antony was hurtful, and Cicero was a perfon to whom his hurtful behaviour was directed.

The dative cafe stands opposed to the genitive as *end* to *beginning.* The latter is the point where motion begins, the former where it terminates, and the ablative is the medium or instrument between both. In consequence of this connection between the ablative and the genitive, on one hand, it came in Latin, by the mere impulse of repeated associations, to mean in many instances the same relation with the genitive, and this is the reason why the same word often governs a genitive or an ablative, why in our own tongue of and from have precisely the same signification, and why the French and Italian express the genitive by those prepositions which in Latin govern the ablative. On the other hand, as the instrument or medium is connected with the end, the ablative holds a similar connection with the dative. Hence in Latin these two cafes are often used one for the other, which is certainly a great impromptustry in that language, and which occasioned much perplexity to the learner; while in Greek, which has not a distinct ablative, the relations of instrumentality and end are expressed by the same termination, which is certainly a great defect in that elegant and copious language. Instrumentality implies *concomitancy,* but this is not the primary sense of the ablative, as the author of the above treatise erroneously supposes.
GRAMMAR.

The Origin and Properties of Adjectives.

Things or substances are known and valuable on account of their qualities; the qualities of things therefore first engaged the attention of mankind. And as they perceived that the same quality existed in the same or in a different degree, in different things, men, however rude or uniformed, learned to form ideas of qualities independent of the substances to which they belonged. Hence they acquired that classes of words called adjectives, which are only the names of qualities. Now as qualities result from things, the names of qualities are derived from the names of things; and, as moreover qualities are constant concomitants of the things they characterize, the names of qualities are constant adjuncts of substantives expressed or implied. Hence they are sometimes called nouns; because they have been borrowed from nouns; and always called adjectives, because they are always added or added to nouns, and for this reason they have also the name of adnouns. From this account of adjectives we deduce the following inferences, which are worthy of attention.

First, adjectives expressing the simple qualities of natural objects, which do not imply motion or action, are derived from nouns, by the mind first abstracting the quality from the thing it qualifies, and then generalizing it so as to make it an epithet expressive of a similar quality in different things. Thus in πέτρα, a steep rock, the quality steep, contemplated first as a quality of that particular thing, the mind soon learned to consider as separate from the rock, and hence to make it a general term of the like quality in other objects. Thus was derived the adjective πέτρινον, πετρίνον, pron. And in the manner this single adjective is formed, are formed all the adjectives which exist in all languages.

When adjectives became numerous in any language, analogy or custom soon simplified them a particular terminus.

Hence, on every conversion of a noun into an adjective, that adjective immediately assumed the ending which analogy had appropriated to words of that class. Thus χοῖρος, food, relish, was changed into πρόσωδις, signifying agreeable food or wholesome relish. Thus also χοῖρος, wood, became χαυκόν, a word, in our own tongue. It is obvious from this to observe, that in the earlier periods of human language, adjectives approached nearer in meaning and termination to the nouns whence they were derived; that is, they were less abstracted and generalized. But the principles of abstraction and generalization were greatly facilitated, when a quality was once expressed by an independent word; the eyes and the ears being made by that means to aid the conceptions of the mind. This is the reason why a barbarous people have few or no adjectives; and why, in the more ancient dialects of the East, the use of adjectives is far less frequent than in the more recent languages of Europe.

In speaking of the qualities of things, similitude or resemblance is an idea of high importance and frequent recurrence. A person discomposing to another of something unknown, naturally says, that it is like to some other that is known. Thus in Greek ὡς, image; ὡς, form; ὡς, like; are combined with nouns in order to express likeness: ὡς ἡμέρα, man-like; ὡς θεός, having the form of a God, God-like, i.e. the form of a God, God-like; adjectives, man-like. This last terminus, by inferring ὡς, gave birth to the Latin adjectives in ofis, and to our adjectives in our; pecunia, pecunious; glor, glorious. The numerous adjectives and adverbs in English are formed on the same principle. Earthly, i.e. earth-like, which is the Greek ἑαυτόν. Gladness is gladness, the same with glad; same or some being, we conceive, corruptions of similis. The termination /s is originally the Persian /s, added to a noun to express likeness; as /s, the moon; /s, gladness, like the moon; /s, a woman. The termination en, derived, it is allowed, from the northern language, is borrowed by that language from the Greek participle en. In the same manner we form some adjectives after the analogy of the past participles in ed, as boned, wooded; while that of y is the Anglo-Saxon in; but this is only the Latin termination en; as voces, Anglo-Saxon or y.

But it must not be omitted that a very numerous class of adjectives is derived from verbs, and that independently of participles. Of this origin are all those adjectives which denote actions: as /s, and that denotes a substance. If then I say a gold-ring, a brazen tube, a filk-string, here are the substantives used adjectively, yet names of things, and denoting substantives. If again I say a golden ring, a brazen tube, a filk-string, do gold and brass and filk cease to be the names of things, and cease to denote substantives, because, instead of coupling them with ring, tube, and string by a hyphen thus (-), I couple them to the same words by adding the termination en to each of them? Do not the adjectives which I have made such by the added termination golden, brazen, a filke, convey to the reader his mind, and denote the same things as gold, brass, and filk? Surely the termination en takes nothing away from the substantives gold, brass, and filk, to which it is united as a termination; and as surely adds nothing to their signification, but this single circumstance, viz. that gold, brass, and filk are designated by this termination en to be joined to some other substantive? p. 430. Again he says, p. 442, "But if, indeed, it were true that adjectives were not the names of things, there could be no attribution by adjectives; for you cannot attribute nothing. How much more comprehensible could any term be by the attribution to it of nothing? Adjectives therefore, as well as substantives, must equally denote substantives; and substance is attributed to substance by the adjective contrivance." He concludes with what Dr. Jonathan Edwards says of the language of the Muhekanem Indians. "The Mohicans have no adjectives in all their language, although it may at first seem not only singular and curious, but impossible that a language should exist without adjectives, yet it is an indubitable fact." This account, instead of unfolding that simplicity and precision which mark the process of the human mind in the formation of language, tends to erode the very elements of knowledge, and to confound ideas the most palpable and distinct. Our ideas naturally and obviously divide into two classes, ideas of qualities and ideas of things. The distinction between these classes is universal; it is common to the philosopber and the bulk of mankind; and is most readily comprehended even by children. As we have then ideas of qualities, language must have words to express those qualities, i.e. it must have adjectives; and as our ideas of qualities are in their nature distinct from, though connected ideas of things, so adjectives must in their nature be distinct from, though adjectives of nouns.
The first step in the formation of adjectives is **abstraction**; the mind being led to conceive of the quality independent of the thing, in consequence of perceiving it in different things. The frequent recurrence of the quality, which is one and the same, and therefore remembered, while the instances which present it are numerous and successive, and therefore forgotten, greatly facilitates our abstract conception. A similar facility, as we have already observed, is afforded by the independent use of words to express qualities. The dependence of adjectives on the principle of abstraction is evident from one circumstance. **Like** is a very abstract quality; and the union of this word with nouns is one copious source of adjectives in most languages of which we have any knowledge.

The next step in the formation of adjectives is **afficiation.** This principle is so powerful and infalliable, that it changes the nature of a word, in consequence of its connection with other words, and of our previous experience. Thus, "the ladies fan themselves"—"The pluney people eye the falling verdure." Because we have experienced the middle term of a simple direct proposition to be always a verb, we instantly, in the above examples, conclude that fan and eye do not here denote the things usually meant by them, but the operations of those things; that is, association and experience convert the nouns fan and eye into verbs, without any thing to aid or indicate that conversion but association suggested by the collocation. This conversion of a noun into a verb by simple experience, illustrates the conversion of a noun into an adjective. We place a word signifying a quality before a word denoting a substance; and as we uniformly find that qualities belong to the things which they quality, and first act upon our perceptions, we instantly infer from the collocation that the first expresses an attribute of the second; and this attribution is not indicated by the termination of the attributive, but an inference of the mind founded on experience. The termination by signifying to be added is a conceit of this grammar, and has no foundation in truth: for it is the Greek participial termination on, borrowed by the Goths. The formation of language did not require such petty, circuitous contrivances; but points to the broad and simple principles of abstraction and affection as the copious sources of all its phenomena.

From this it appears, that a peculiarity of termination is not necessary to form an adjective, the collocation being sufficient to ascertain its character as such. An adjective may have the same ending with any other noun, or with the very same from which it was derived; and it has this identity of termination in Greek and Latin, and yet no ambiguity arises as to its nature and use. The inference, which we instantly, and we may say, imperceptibly, draw from the juxtaposition in our own tongue, and from the similarity of terminations in the classical tongues, is an unerring guide in these respects. And this is the reason why, in a barbarous language, it is possible that the name of a quality may be always the same name with the name of the thing to which that quality belongs, and yet abound with adjectives, i.e. abound with nouns converted into adjectives by juxtaposition. And this is all that can be meant by the testimony of Dr. Edwards, in regard to the language of the Mohicans. If there existed a language which had no verbs, but nouns converted (as in the above instance of fan and eye) into verbs without any variation of termination, a person who did not understand the nature of the human mind, and who had been accustomed to classify words only by their endings, might lay of that language, that it had no verbs.

The foundation of Mr. Tott's error, is the circumstance that most adjectives were originally nouns. As they were nouns in their origin, and as he rejected the operations of the mind in the construction of language, he inferred with confidence, that they were nouns full, thus confounding in one promiscuous mass our ideas of qualities, and our ideas of things; yet, notwithstanding this confusion, he writes thus: "If in what I have said of the adjective, I have expressed myself clearly and satisfactorily; you will easily observe that adjectives, though convenient abbreviations, are not necessary to language; and, therefore, are not ranked by me amongst the parts of speech; and, perhaps you will perceive, in the misapprehension of this useful and simple construction of language, one of the foundations of those heaps of folly philosophy and obscure (because mistaken) metaphysics with which we have been bewildered."

Adjectives, as expressing not things, but their qualities, cannot, in strict propriety, have any gender; but, as in Greek and Latin, they have the same terminations with nouns, they are said to be masculine, feminine, or neuter, merely as they have masculine, feminine, or neuter terminations.

In most languages, adjectives vary their endings to correspond with the plural form of nouns; in English they have no such variation, nor is it necessary, since qualities are not susceptible of numerical distinction, being the same, whether applied to one or to many.

There is, however, one variation which adjectives have in all languages, namely, the variation to express the three degrees of comparison. The qualities of things differ in different objects, and must be expressed with augmentation or diminution, as they are compared with others more or less intense.

When a quality is expressed without reference to any other, the adjective is then said to be in the **positive** degree. When expressed with reference to the same quality or to another more or less intense, it is said to be in the **comparative** degree; and when in the highest or lowest degree of all, it is in the **superlative**. Different languages have different ways of forming the comparative and superlative; but in almost all, both these degrees are derived by certain syllables added to the positive: the adjective itself, by being thus lengthened, is made to correspond with the augmentation in feme, which the quality acquires by comparison. The mode of expressing the degrees of qualities being only two, and therefore very general and imperfect, while the qualities themselves vary in endless gradations, a more adequate method is used, by having recourse to those attributes of an inferior order, called **adverbs**, as much good, tolerably good, exceedingly good, more good, most good.

As it is not our object to detail the minute rules of grammar in our own tongue, we shall conclude this part of the subject with one or two observations on the three degrees of comparison. The **positive** degree, though not implying an immediate comparison with the same quality in a higher or lower degree, often conveys a relative or comparative idea; and for this reason may, by the assistance of a preposition, be made to express the comparative or superlative degree, as "Blessed among women, i.e. the most blessed of women." And this relative or comparative idea, implied in the positive, is the reason why the positive has sometimes after it the word which is used after the comparative. On the other hand, the comparative and superlative are used in a positive sense, or used to express a high degree without any immediate object of comparison. Thus Virgil speaks of Venus: "Tristior et lucernis occuas suis nigritas,"—"Tristior, more sad than usual, i.e. very sad. This is more usual in the superlative degree, *vir dejectus, a very learned man*. The comparative is used with propriety only when two things are compared;
The Origin and Properties of Pronouns and Determinatives.

Pronouns have been defined substitutes for nouns, to prevent their too frequent recurrence. Mr. Harris accounts for pronouns, or, as he calls them, *nouns of the second order,* in a different way; and, as his explanation is curious, we shall here place it before our readers. *All conversacion passes between individuals, who will often happen to be till that instant unacquainted with each other. What then is to be done? How shall the speaker address the other, when he knows not his name? or how explain himself by his own name, of which the other is wholly ignorant? Nouns, as they have been described, cannot answer this purpose. The first expedient on this occasion, seems to have been pointing or indicating with the finger or hand; some traces of which are still to be observed, as a part of that action which naturally attends our speaking. But the authors of language were not content with this: they invented a race of words to supply this pointing, which words, as they always stood for substitutes or nouns, were characterized by the name of pronouns. These, also, they distinguished into three several sorts, calling them pronouns of the first, the second, and the third person, with a view to certain distinctions, which may be explained as follows.

"Suppose the parties conversing to be wholly unacquainted, neither name nor countenance on either side known, and the subject of conversation to be the speaker himself. Here, to supply the place of pointing, by a word of equal power, the inventors of language furnished the speaker with the pronoun *I.* It signifies, *I say, I desire," &c.; and as the speaker is always principal with respect to his own discourse, this they called, for that reason, the pronoun of the first person. Again, suppose the subject of the conversation to be the party addressed. Here, for similar reason, they invented the pronoun *thou; thou writest, thou walkest," &c.; and, as the party addressed is next in dignity to the speaker, or at least comes next with reference to the discourse, this pronoun they therefore called the pronoun of the second person.

"Lastly, suppose the subject of conversation neither the speaker nor the party addressed, but some third object different from both. Here they provided another pronoun, *he, she, it;" which, in distinction to the two former, was called the pronoun of the third person. And thus it was, that the pronouns came to be distinguished by their respective persons."
GR. AMMAS.

Thus previous I it never an Mr. And lliaig we, her, derived fee corruption the for as the Greek and Latin do not abound with the same analogy, and therefore frequently use the personal pronoun in the genitive as equivalent to the pronominal adjectives.

The reciprocal or reflex pronomn self is added to: pronominal adjectives as myself, thyself, &c. The third person singular and plural by analogy should be his self and theirselves but in order to humour the ear or the organs of speech, these are changed into himself and therefore. Self means an individual in opposition to another, and is derived from the Latin self, along the medium of the Anglo-Saxon selfe, soul, Anglo-Saxonselfe, selfe: hence also fest, which means that part of man in which confines the vital principle in opposition to the body: even, when used to precede self, is a corruption of the Anglo-Saxon ges, which by the infusion of the letter g, after the analogy of that language, is borrowed from the Latin genus. Genself, therefore, is myself.

Mr. Harris gives the following account of that species of adjectives called definitives or articles: “The visible and individual existences of nature are infinitely more numerous than for each to admit a particular name. To supply this defect, when any individual occurs, which either wants a particular name, or whose proper name is not known, we ascertain it as well as we can, by referring it to its species: or if the species be unknown, then at least to some genus. For example, a certain object occurs with a head and limbs, and appearing to possess the power of self-motion and sensation: if we know it not as an individual, we refer it to its proper species, and call it dog, or horse, or man, or the like. If none of these names fit, we go to the genus, and call it animal.”

“Thus it is not enough: the thing at which we are looking is neither a species nor a genus. What is it then? An individual. Of what kind? Known or unknown? Seen now for the first time, or seen before, and now remembered? It is here that we shall discover the use of the two articles a and the. A respects our primary perceptions, and defines individuals as unknown: the respects our secondary perception, and denotes individuals as known. To explain by an example: I see an object passes by, which I never saw till now. What do I say? There goes a beggar with a long beard. The man departs, and returns a week after. What do I say then? There goes the beggar with the long beard. The article only is changed, the rest remains unaltered. Yet mark the force of this apparently minute change. The individual, once vague, is now recognized as something known, and that merely by the efficacy of this latter article, which tacitly infinuates a kind of previous acquaintance, by referring the present perception to a like perception already past.

“The truth is, the articles a and the are both of them definitives, as they circumscribe the latitude of genera and species, by reducing them for the most part to denote individuals. The difference between them, however, is this: the article a leaves the individual itself uncertain, whereas the article the ascertains the individual alto, and is for that reason the more accurate definitive of the two.”

We give this statement as that of an eminent grammarian, without subfixing it to as it but in all respects. It is not, we conceive, true, to say that the individual defined by a is always uncertain; nor does the necessarily imply a previous acquaintance, by referring the present perception to a like perception already past. And we cannot help observing that, if Mr. Harris and other writers on the subject had traced those words to their sources, and thus ascertained their primary meaning, their readers would have been more informa-
ed in one paragraph, than they otherwise could by the most elaborate treatise.

The article a is in truth the numeral adjective in Greek, but in Latin, in Anglo-Saxon; and the import of it precisely corresponds with its original signification of one. A book is one book; a man is one man. Hence we may learn with certainty the following particulars. That it is enveloping the word in mystery to call it an article, instead of calling it by the more appropriate name of numeral adjective, or indefinite. That as it means one it cannot be prefixed to plural nouns, unless these nouns be taken in a collective sense. That the usual rule, as before a vowel, should be just reversed in order to be true. "As becomes a before a consonant." That the equivalent of the article a exists in Greek, and in Latin, but is rejected as useless in those languages; and that the frequent use of it in English and other modern languages is far from being necessary, that it is an incumbrance and inleagance. I see man would be as intelligible as when we say I see a man; and they read book, as definite, as they read a book; and this, from the nature of the cafe, just as in Latin, video hominem, legunt librum, where unum would be both unnecessary and inexpressive. The English I see man, and the Latin video hominem, are both equally indefinite in themselves; but they are sufficiently limited by the nature of our perception, and by previous experience. "The indefinite article," says the author of the treatise on Grammar in the Encyclopaedia Britannica, "is much less useful than the other; and therefore the Greek and Hebrew languages have it not, though they both have a definite article. In languages, of which the nouns, adjectives, and verbs have inflexion, no mistake can arise from the want of the indefinite article; because it can always be known by the terminations of the noun and the verb, and by the whole circumstances predicated of the noun, whether a whole species or one individual is intended. But this is not the case in English. In that language the adjectives having no variation with respect to gender and number, and the tenses of the verbs being for the most part the same in both numbers, it might be often doubtful, had we not the indefinite article, whether the specific name was intended to express the whole species or only one individual." All this reasoning, however, appears to us fallacious, and only shews that even a wise and able man, such as the writer of this article certainly is, will readily think that necessary and useful to which he has been accustomed, and therefore will demand he be at a loss for some plausible reasons to justify it. In truth, the inflexions of adjectives and verbs in the learned languages alluded to, have no influence whatever in defining the extent of the general term, but serve merely to shew that they qualify that term, and depend upon it. The very example adduced by this writer shews the fallacy of his reasoning: *EYmenos apoxiomevos* pev Biajepxaln beetos. Here *apoxiomevos* as clearly denotes not the whole species, but an individual, as it was written *apoxiomevos* and that not because of the singular correspondence of *apoxiomevos* nor from the termination of *apoxiomevos*. Of this there is an evident proof; *apoxiomevos* and *apoxiomevos* would be full the same, though *apoxiomevos* had a specific or collective sense. But the individual sense of the noun appears from the nature of the case, from the context, and especially from the clause, *apoxiomevos* name *apoxiomevos* John: and these circumstances, which sufficiently define it in Greek, would be sufficient to define it in English, were it written "Man was sent from God whose name was John." It is impossible to feel in this as y ambiguity; and the exprefdon seems uncoutly only because we have been accustomed to the use of a man was sent from God, &c.

Mr. Tooke derives the and that from the Anglo-Saxon verb

then or thereon, to take. But these definitives exist in that language, and why should he attempt to derive them from any word, when they are already formed and employed in the same sense? He seems to have been aware of this objection. And he adds, vol. ii. p. 60, "The (our article, as it is called) is the imperative of the base verb given us, which may very well supply the place of the correspondent Anglo-Saxon article fe, which is the imperative of feon, videre. For it answers the same purpose in discourse to say—see man, or take man." The English take, and the Anglo-Saxon than, which this writer would lead us to regard as a primitive northern word, is only the Greek *tau*, to accept. Take this, therefore, means, receive this.

Light is the medium of light, and, hence, in the most ancient languages, the word signifying light gave birth to verbs signifying to see. Thus the Hebrew *kvef* *tau*, pronounced in Arabic *thaw*, but in Persian *fe*, light, is the parent of the Anglo-Saxon *seon* and our *see*, which accords with the Persian pronunciation, and also of the Anglo-Saxon article *fe* or *for*, or as we found it, conformably to the Arabic, the. It is remarkable the article in Greek is founded entirely on the same principle, though derived from a different word. For its original appears to have been the Hebrew article *ma*, which probably was *mou* or *bo* short, and which is but an abbreviation of *ma* *thaw*. Now the use of this last confills in directing the attention to an object, and answers to en or ree in Latin, and behold in our own tongue. And as the necessary congequence of looking upon a thing is to see it, as distinguished from other things, hence *ma* in Hebrew, and in English, from signifying to perceive, through the medium of light, came to signify an effect of perception, namely, the distinction or opposition which the thing to be seen has to other things which may be related to it.

From this account we may gather the following particulars respecting the nature and use of the definite article. Its primary force consists merely in directing the eye to the attention to an object; and the indefinite power assigned to it is rather an effect of the light where the object is present, or of the mind in drawing the necessary inference, where the object is previously described or specified. If this account be just, the assertion of Mr. Tooke, that the article, in combination with a general term, is a mere substitute for a particular term, (see vol. i. p. 69,) is erroneous. The article is only an index; having indicated the thing intended it does no more: the eye or the mind does the rest, and the general term is defined or made particular, by being brought under immediate inspection. It is necessary to subjoin the general term to the article, because it is necessary to specify the object intended; but the restriction of the specific or general noun to that individual object is a consequence of the article, rather than a power belonging to it. The article therefore cannot be a mere substitute, to do that which is done by another principle, namely, the eye or the mind.

The article serves as an index to specify an object hitherto unknown, as well as one previously known; and thus Mr. Harris's distinction, that a respects our primary perception, and denotes individuals as unknown; the respects our secondary perception, and denotes individuals as known, is confined. The index indeed may be directed to a past event or object, thus to make it the subject of inspection a second time. In this view Mr. Harris's position is true, but the use of the article is far more general, and by no means confined to such cases.

The article the is the name in origin, and often in use the same with that, and indeed in the Anglo-Saxon that is only the neuter gender of the; and Mr. Tooke ought to have made this remark instead of representing each as independent of the other. This
This definitive is in our tongue variously applied; and the objects of its application are to distinct and different, that it has been thought to change its nature, and to belong to different parts of speech. And Mr. Tooke has the merit of being the first to show that in all circumstances, that retains one and the same character. Let us briefly consider its various applications. And first, it is used to bring under the eye of the mind, i.e. to define individual objects or things, as in this: In this sense, it is equivalent to this, answering to as opposed to his in Latin. I.e., that, denotes the remoter of two objects, as, this, the nearer. "Alexander and Julius Caesar were great commanders, that (fill-) conquered Asia; that (hie) subdued the Gauls—that, meaning Alexander as the farthest off; this, Julius Caesar, as the nearest." In such a sentence it would be more usual to say the former and the latter. Second, that is frequently used to characterize a subject clause, which is the object of a transitive verb, thus serving to fix the attention on what is going to be said, and by that means to render it emphatic and prominent. Thus, "I with you to believe that, that thing which I am going to say, namely, I will not hurt a fly," which Mr. Tooke thus resolves, "I would not willingly hurt a fly; I wish to believe that affection." In this sentence it answers to quod in Latin. Third, that is an index to point out the end or purpose which a person has in view, and as such precedes a verb in the subjunctive mood without a preceding that end: Thus, "They never rise in the night that they may steal." Thieves rise in the night, that being their purpose, namely, they might steal. In this sense it corresponds to the Latin conjunction ut, which, perhaps, led to the error of considering that as a conjunction in the second and third persons. Fourth, that is an index pointing to a noun in the preceding clause, and is a substitute for that noun, or rather it agrees with that noun implied, though never expressed. "The man, that hath not music in himself, is fit for treason." Here the first clause, the man, is represented as definite, while the reader as yet is not able to recognize it as such. What man is fit for treason? To preclude the necessity of this question, a clause is introduced, that man, namely, he who hath not music in himself. In this sentence that is thought to be a relative equivalent to who, which may be substituted for it. But in reality it is still a definite, used to ascertain the preceding specified noun, which has the form of being definite without being really so, and the preceding noun is to be repeated, or, as that is descriptive, a generic or specific noun of the same import is understood to be introduced. Thus the man, namely, that fit of man, who hath not music in himself, is fit for treason. The subject of discourse may be plural, and yet the singular form of that, may, on this supposition, be used. "The men that have not music in themselves, are fit for treason," i.e. the men, that fit of men, namely, who have not music in themselves, are fit for treason: and this is the solution of the apparent anomaly of that being used in both numbers, without variation, when taken relatively.

We come next to speak of the relative pronoun, which Mr. Harris thus explains, p. 77. "But besides thehe there is another pronoun (in Greek ὃς, ἃ, in Latin qui, in English who, which), a pronoun having a characteristic peculiar to itself, the nature of which may be explained as follows. Suppose I was to say light is a body, that light moves with great celerity; the sentence would apparently be two distinct sentences. Suppose, instead of the second light, I were to place the prepositive pronoun it: Light is a body; it moves with great celerity; the sentence would be still distinct and two. But if I add a connective (as for example and) saying light is a body, and it moves with great celerity; I then by connexion make the two into one, as, by cementing many stones I make one wall.

"Now it is in the united powers of a connective and another pronoun, that we may see the force and character of the pronoun here treated. Thus, therefore, if in the place of and we substitute that or which, saying light is a body, that body moves with great celerity; the sentence still retains its unity and perfection, and becomes, if possible, more compact than before. We may with just reason, therefore, call this pronoun the subjunctive, because it cannot, like the prepositive, introduce an original sentence; but only serves to subjoin one to some other which is previous." This account, though elegant and precise, we nevertheless deem erroneous, because the relative pronouns in all languages are the same in their origin and use with the articled or definite pronouns. In Greek ὃς is only the article ὃ with an annexed after the analogy of that termination in Greek nouns. Hence: the reason why ὃ and ἢ are, by the more ancient writers, such as Homer and Herodotus, used for one another, either as demonstrative or relative pronouns. The Latin eus is also the article ὃ with a guttural annexed—bac; while qui, which Scaglier, and after him Mr. Tooke, derive from eus, is no other than the Persian ke or chs, who, which. Moreover, qui is the Oriental κο, who or w̃ho, and it is remarkable that in Hindostan eus is re-established as is, and this has been imported into Latin quippe. Finally, our who is the Greek ὃs, having the labial w̃ substified for the aspirate, which is a broad and general analogy, by which words in Latin and the Anglo-Saxon are formed from Greek or from the Oriental tongues. Which is the neuter termination of ὃ, formed on the same principle as bac in Latin, that is, a guttural is annexed to who, whose, which. And this is the reason that, while who is applied to persons, which is made to stand for inanimate things.

As the relative and definite pronouns have the same origin, they are also the same in use. For in Latin the relative always supposes the antecedent to be repeated, and is repeated when obscure or doubtful. In our own tongue, indeed, who never coalesces with the antecedent noun, and is therefore a substitute for it, and this peculiarity in our own tongue has caused who, with its other cases whom, whose, to drop its nature as a definite, and to become really a pronoun, i.e. a substitute for a noun. This peculiarity has also obtained in regard to kis, which was the Hebrew and Greek article π, πο, or Ἰσα. And this is the reason why the article in Homer may be often rendered by ke in our own tongue. Dr. Middleton, not perceiving this circumstance, was led, in a voluminous work published on the Greek article, to suppose that the Greek article is in its nature a personal pronoun, and may he always resolved into a pronoun. The foundation being thus fallacious, the whole superstructure, however learned and elaborate, is frivolous and useless.

We observe farther that his, its, and its, which are really definite, often refer, like qui, to a preceding noun, and for this reason have a claim equally just to be called relative pronouns. Thus, "Deus nobis hic est fact; neque enim ille militem Deum; illius asinum facere tener nelris in ovilibus imbnat agnus." Here the first ille is ille bone, or ille juvenis, meaning Augustus, elegantly kept out of sight, the reader being left to conceive of him only as a god; while illius is illius de, of that god. "Tres litteræ serva proscript concinnarent, hoc tota armata sequantur, i.e. hos corros." "Cognoscimus Deus ex operibus ejus," we know God from the works of the same—ejus de.

Because the relative qui is thus a definite, the defined noun, when not antecedent, is made to succeed in Latin and
and in Greek, as "Maximus laborbus sequuntur eam, quam ex difeudo capittis, voluptatem;"—literally, with the greatest toll they pursue that, which pleasure, (for that pleasure, which) they derive from flady. "Quas condulit arcem, ipfa colat,"—let her inhabit which citadels the built, for, let her inhabit the citadels which the built. In our own tongue such an arrangement is not allowed, or even illegible, because here the relative really is a substitute for the noun preceding it, and refuses to confide with it as an adjective. And it is obvious to remark in this place, that with the exception of who in English, the articles or definitives are not pronouns, but adjectives, numeral or restrictive, agreeing with a noun expressed or understood, and to be supplied from the context or the preceding clause. We remark, finally, that as articles are definitives, the Latin tongue has not only one but several articles, which is erroneously supposed to want. Thus, hic homo, this man, ille homo, that same man, ipse homo, that every man, are phrases, either of which is equally definite and emphatic with one the man, and on many occasions precisely the same with it.

Before we quit this subject we shall advert to a question proposed and solved by Mr. Tooke, vol. i. p. 273. "What is as?—The truth is that as is also an article; and however, and whenever, used in English, means the fame thing as is, or that, or which. In the German, where it still evidently retains its original significations and use, (as so also does, it) is written es."

Now, if Mr. Tooke had properly understood the nature of the article, he would not have made this assertion. As indeed, like the article, is an index, but it is an index directing the mind from one object to another, and the consequence of its being so directed is the perception of some resemblance between them. Accordingly as is is, an adjectival in Latin, in Greek, being inverted (as is often the case with monoaffixable words), has become ἄσ. On the other hand, the consequence of the indication conveyed by the article is not to the observance of some likeness between the objects specified, but the limitation of the general term to the individual object, circumvibled by the eye or the mind by being so indicated.

In a note this writer adds: "Dr. Lowth, amongst some falfe English which he has recommended, and much good English which he has reproved, says, "fors, was used by the writers of the last century to express a consequence instead of fo that. Swift, I believe, is the last of our good writers who has frequently used this manner of expression."

If that denote end or consequence, the third feminine we have affined to it in the preceding page, and if as, on the other hand, signify similitude between two objects, ἄσ is, as Dr. Lowth states, very improper; while ἄσ that alone is good English and good sense; and Mr. Tooke is himself guilty of the charge he brings against Lowth, namely, of recommending some falles, and reproving much good English. We cannot help observing that the object of comparison marked by ἄσ is often implied, and is to be gathered from the context; as in the following stanza:

Save that from yonder ivy-mantled tower,
The moping owl does to the moon complain
Of ‥‥ as, wandering near her secret bower,
Moleft her ancient solitary reign.

today, of such preterit, as those who wandering, &c.

The Origin and Properties of Verbs.

We shall begin this part of our subject also with an extract from Mr. Harris, because his opinion, though plausible, is erroneous, and has been the means of leading other grammarians, who followed his authority, into error. "We are now," says he, "to defend to the common herd of attributes, such as black and white, to stand, to speak, &c. among which, when compared and opposed to each other, one of the most eminent distinctions appears to be this. Some, by being joined to a proper substantive, make, without farther help, a perfect affirmative sentence; while the rest, though otherwise perfect, are in this respect deficient. To explain by an example, when we say Cicero eloquent, Cicero is the subject, there are imperfect sentences, though they denote a substantive and an attribute. The reason is, that they want an afiernion to shew that such attribute appertains to such substantive. We must therefore call in the help of an affermion elsewhere, an is or est, to complete the sentence. Cicero is wife, Cicero was eloquent. On the contrary, when we say Cicero convicted, Cicero is convicted, in instances like this there is no such occasion, because the words convicted and convicted imply, in their own form, not an attribute only, but assertion likewise. Hence it is they may be resolved the one into is and writing, the other is and writing.

"Now all these attributes, which have this complex power of denoting both an attribute and an assertion, make that species of words which grammarians call verbs. If we resolve this complex power into its distinct parts, and take the attribute alone, without the assertion, then have we participles. All other attributes, besides the two species before, are included together in the general name of adjectives; and thus it is that all attributes are either verbs, participles, or adjectives. Besides the distinctions above-mentioned, there are others which deserve notice. Some attributes have their essence in motion; such are to walk, to fly, to strike, to live. Others have it in the privation of motion; such are to stop, to rest, to conceal, to live. And lastly, others have it in subjects which have nothing to do with either motion or its privation; such are the attributes of great and little, noble and base, and equal and unequal, and in a word the several quantities and qualities of all things. Now these last are adjectives; those which denote nations or their privation are either verbs or participles.

"Of all the constituent parts of speech," says the writer in the Encyclopaedia, Britannica, 58, "none has given the grammarians greater trouble than the verb. The vast variety of circumstances which it blends together in one word, throws very considerable difficulties in the way of him who attempts to analyse it and ascertain its nature; at the same time that by its eminent use in language, it is entitled to all the attention which can be bestowed upon it. It should seem that the first object of our investigation ought to be the characteristic of the verb, or that which all these words have in common, and which constitutes them verbs, distinguishing them from every other species of words. Now it is obvious to the slightest attention, that every verb, whether active, passive, or neuter, may be resolved into the subjunctive verb is, and another attribution: for Hebe is of the same import as is he aged; and aged with aman is.

"But loving and aman are not verbs; whence it follows that the characteristic of the verb, which constitutes it what it is, and cannot be expressed by other words, must be that which is signified by the word is; and to us that appears to be neither more nor less than affection.

"Affection therefore, or predication, is certainly the very essence of the verb, as being that part of its office, and that part only, which cannot be discharged by other kinds of words. Every other circumstance which the verb includes, such as attribute, mode, time, &c. it may be possible to express by adjectives, participles, and adverbs; but without a verb it is impossible to predicate, to offer or deny."
any one thing of any other thing. The office of the verb, when stripped of all accidental circumstances, forms to be merely this: to join together the subject and predicate of a proposition; its powers are analogous to those of the sign + in algebra, which does not affect the separate value of the quantities between which it is placed, but only indicates their union or conjunction. The writer then, in illustration of this theory, takes the examples used by Mr. Harris, and then adds, "in resolving every verb, whether active, passive, or neuter, into the subjunctive verb is, and another attributive, we have the honour to agree with all the grammarians."

We respect the opinion of other grammarians, and that of this writer in particular, but we cannot think it an honour to agree with him and his predecessors on this subject; but we rather think it an honour to differ with them, because we conceive them to be in an error. Now the most sure way to ascertain the characteristic of a verb, or that which constitutes its essence, is to attend to that operation of the human mind by which verbs have been formed. But as the affirmative is thought essential to all others, we shall begin with it. And Mr. Harris thus explains it, p. 88, "Previous to every possible attribute, whatever a thing may be, whether black or white, square or round, wise or eloquent, writing or thinking, it must feel of necessity exist, before it can possibly be any thing else." For existence may be considered as an universal genus, to which all things, of all kinds, are at all times to be referred. The verbs, therefore, which denote it, claim precedence of all others, as being essential to the very being of every proposition, in which they may still be found either expressed or by implication; expressed, as when we say, "the sun is bright," by implication, as when we say, "the sun rises;" which means, when resolved, "the sun is rising."

According to this explanation existence is the primary idea of is; and Mr. Harris is little consistent with himself when, in resolving active verbs into this and another attributive, he supposes it to mean affect. But let us deduce a more adequate idea of it from examples—God is good; His food shall be honey, and wild honey; if we are virtuous we shall be happy. In the first of these, is connects good with God; in the second one connects honey and wild honey with God, and affects, that with regard to John they were the same. In the third instance, happy is, by shall be, represented a quality of be. For this reason the following terms would be more appropriate to any other. The leading noun the subject, the thing connected the predicate, and the verb connecting them the connecting verb. Thus, God is the subject, is the connecting verb, and good the predicate; and so in all other instances.

If then is be the characteristic or essential idea of every verb, and if farther, as appears from fact, the primary idea of is denotes a mention, it follows that not affectation, as the grammarians have hitherto supposed, but connection, is that which constitutes verbs, or that which distinguishes them from other species of words. But the connecting verb itself will not appear necessary, if we judge of its use in the ancient languages, the juxtaposition of the subject and predicate being sufficient to supply its place. Thus we say, to write, hēlêd the mur-derer; there verses, being placed by the side of a sôd, suggests that it belongs to it, and by virtue of this suggestion conveys to the mind as full and complete a proposition as though the connecting verb had been inserted. Thus too in Latin, Hanc precipitam opus Dei, man the principal work of God, meaning man is the principal work of God. Thus also in Hebrew, And Moses said unto God, who I, that I should go unto Pharaoh; and God said, certainly I will be with thee, and this taken unto thee, i.e. this shall be a token unto thee, ii. 11, 12. In this tongue, indeed, the subjunctive verb is comparatively of rare occurrence, and its place is supplied by the collocation of the terms to be connected, a principle in itself extremely simple, and suggested by the great law of the human mind. In Greek and in Latin its use indeed is more frequent; and it is remarkable that where it does occur, it generally occurs either in the beginning or the end of the clause, and not in the middle, a circumstance which arose from a desire of keeping together words that are related as subject and predicate. Now Mr. Harris and other grammarians, overlooking the force of juxtaposition, and judging of the importance of the subjunctive verb from its frequent use in modern speech, have hence supposed that it is absolutely necessary to the existence of language, and that no proposition can be communicated without it. And what is more remarkable still, "they have represented a word as essential to a verb, which, far from being necessary to a verb, is not necessary even to language."

Verbs express the operations or the active qualities of things; and as the growth of words corresponds to the growth of our ideas, it follows that verbs originally were the names of things; but by combining them with the personal pronouns, they became, in consequence of the allocation of ideas, to express not things, but their operations. The conversion of nouns into verbs we will illustrate by an example in the Greek tongue. Mr. Jones, in his Grammar of that language, has shown that the personal terminations of the Greek verbs are but corruptions of the personal pronouns, and all the variations of mood, tense, number, and persons have originated in these five elementary principles, thus:

\[
\begin{align*}
\text{εγώ} & \varepsilon\gamma, \\
\text{nó} & \nu, \text{θοῦ}, \\
\text{δο} & \delta, \text{κεῖ}, \text{σύ}, \text{αὐτός}.
\end{align*}
\]

Now let these in their corrupted state be annexed to any noun, for instance to ἄνθρωπον, man; and we shall have ἄνθρωπον, man; ἄνθρωπον ἱππό, horse; ἄνθρωπον ἡμέρα, day; ἄνθρωπον ἄρχω, I govern; ἄνθρωπον ἄφημι, I leave; ἄνθρωπον ἔρχομαι, I come; ἄνθρωπον ἐλθώ, I go. When the attention of the speaker or hearer was fixed on the first of these combinations, the union of the two words which signified being and was, and wine could not fail of bringing to his mind the circumstances which he had previously experienced or observed in regard to that liquid; and hence he necessarily recalled the idea of making or taking wine, or drinking wine. Consequently, the two terms thus combined he naturally employed to express one of those notions. A similar process took place with regard to the remaining five combinations. And thus have we in Greek, and other languages, verbs diversified by the personal pronouns. This extension of the names of things to signify the actions which these things have been observed to perform, is, it is obvious, founded on the law of association, and may be illustrated by many instances in all languages. But the principle is not so clear in any tongue as it is in Hebrew, where the personal pronouns annexed to the verb are preferred with little variation from what they are in their independent state.

In the above, and similar other examples, the agent, and that which is the effect or object of the action, combine to express that action; but in other combinations, the name of the agent alone is sufficient to express its operation. Thus, "the ladies him themselves," "the plumy people the falling verdure." Now having previously observed the use or action of the him, and learnt in ourselves the effect of the eye, being also previously aware that in a simple direct proposition,
position, the second usually denotes operation, we should immediately infer that *fan* and *eye* here express not the things meant by them but their active qualities; in other words, our previous associations would instantly convert those nouns into verbs, though we had never seen them so used before.

From this account of the deduction of verbs from nouns and *predicaments*, we may ascertain their nature and properties. A verb is a word borrowed from a thing to express the action of that thing. It implies connection, the connection of an agent and its object, or more generally the connection of cause and its effect. But this connection is not expressed by an independent word but by the juxtaposition, or the combination into one word of the agent and its object. On the other hand, it does not imply *affirmation* or *assertion*, as grammarians have hitherto supposed, because no word expressible of this enters into its composition. The operation of a verb is indeed positive; and therefore that implication which writers on this subject call *affirmation* may be considered to belong to it, but this is rather an inference formed by the mind than a property inherent in the verb; and is confined to a certain mood or form of it. We understand the indicative to affect, but this affirmation is lost in the imperative, subjunctive, and infinitive. So that if *affirmation* be essential to a verb, a verb ceases to be a verb in these moods.

A verb implying an abstract idea, and therefore often indefinite and obscure, may be ascertained in regard to its meaning by recurring to the noun from whence it has been derived. This noun, which probably is the name of some sensible object, fugis its primary sense; a circumstance of great importance in the construction of a *philosophical dictionary*, a work existing in no language, and much wanted in every language. "The most necessary verbs," says Dr. Crombie in his English grammar, p. 81. in every language, are those, the significance of which is the most extensive, and which would originally be of most general use, such as verbs denoting existence, possession, acting and being acted upon. Of this kind in our language, are the verbs to be, to do, to have."

We will take these, which this grammarians has cited, as examples to illustrate our theory. In the Great Indian language, *bhat*, is air, and *air* is the medium of existence; it gave birth to the verbs of being in most languages. Hence *bodhi* in Persian; *be* in Anglo-Saxon and English; *bha* in Greek, and the digaminated *vivo* in Latin, and *bheu* in Celtic. On the same principle the Hebrew *y* comes, *esir*, *light*, *air*, is the parent of our words *are*, *war*, and of the Latin *areus*, *corpus*. *To be* is to put with power to, and this, with other verbs of the same kind, are borrowed from abstract objects, as put forth their fruits, such as herbs, trees, the earth. Thus, *saw*, the graft, gave birth to *saw*, to produce. Hence such phrases as *saw* *saw*, to produce fruit; *saw*, is the oak; and hence *saw*, to bring forth as the oak; *seu*, the beech, hence *saw*, to yield fruit as the beech; *saw*, *saw*, means a flower; hence *saw* or *seu* to effloresce or flourish. In Chaldean *saw*, earth; hence in Greek *saw*, *saw*, and our verb *work*. In the same way *saw*, *saw*, to give, yield, is the real fource of the English *to do*.

Now, it is very evident that the principle which converted one of these nouns into a verb, is that which converts all other nouns into verbs. If this be the case, Dr. Crombie and other followers of Mr. Horne Tooke are mistaken, when they supposed that the junction of one of these verbs to a noun, caused that noun in courses of time to assume the character of a verb. And here we may observe that an infinitive verb, as separated from its agent or subject, is in reality an *abstractive noun*. In this state the preposition *to* is prefixed to it, and its use is to be ascertained from its etymology. In Arabic *saw* is a verb which signifies motion to a place or object. Hence in Celtic (a*te*, it) became a preposition denoting an *end*, or the point to which motion tended. In passing to Perian it dropped the initial vowel, and in the form of *ta* it denotes, in Perian, the interval in which motion reaches its object, or that object itself, and thus became the parent of our *to*, which it perfectly resembles in sound and sense. To then denotes that point of time or place to which motion or action tends, and in which it terminates; and prefixed to an infinitive verb, thus converted by abduction into a species of final nouns, holds it forth as the object to which the preceding verb is directed; thus, *I desire to learn*, I desire, and the object or end of that desire is learned, and the command which that command respects, is that I should tell you. This explanation appears valid, from the circumstance that when the infinitive verb is the immediate subject of action rather than a more remote object to which an action tends, the preposition *to* is dropped; as *I do plow*, *I* do the plough, or act the plough.

Let us not see what Mr. Tooke says on this subject.

"The preposition *to*," says he, vol. i. p. 350, "is the Gothic subjunctive *tanu*, or *tandu*, i.e. *ate*, *ate*, effect, result, conformation. Which Gothic subjunctive is, indeed, itself no other than the first participle *tandu*, or *tandu*, of the verb *tana*, *xere*. And what is done is terminated, ended, finished. After this derivation, it will not appear in the least miraculous or wonderful that we should, in a peculiar manner in English, prefix this same word *to* to the infinitive of our verbs. For the verbs in English not being dissingued, as in other languages, by a peculiar termination, and it being sometimes impossible to distinguish them by their place, when the old termination of the Anglo-Saxon verbs was dropped, this word *to*, i.e. *ate*, became necessary to be prefixed, in order to distinguish them from nouns, and to invest them with the verbal character. For there is no difference between the noun *love*, and the verb *to love*, but what must be comprised in the prefix *to*.

And he goes on, p. 355, "*Do*, the auxiliary verb, as it has been called, is derived from the same root, and is, indeed, the same word as *to*. The difference between a *be* and a *do* is so very small, that an etymologist knows by the practice of languages, and an anatomist by reason of that practice, that, in the derivation of words, it is scarce worth regarding. And, for the same reason that *be* is put before the infinitive, *do* used formerly to be put before such other parts of the verb which likewise were not dissingued from the noun by termination. As we still say—I do love, instead of I love. And I did, or did love, instead of I loved. But it is worth our while to observe, that if a dissinguing termination is used, then the dissinguing *do* or *did* must be omitted, the termination fulfilling its office. And, therefore, we never find—I did loved, or he did love. But I did love, be did love."

It is necessary briefly to expose what we conceive to be the fallacy and absurdity of this reasoning. *To*, in found and fence, is the farthest possible from the Gothic *tana*, which is only the Greek *saw*, to fabricate, the true origin of to being the Persian *tan*, which has precisely the same meaning with it. It is altogether unnecessary to prefix the *to*, in order to dissingue the verb from its corresponding noun, because this is done by the context, or the collocation of the verb; and what is most remarkable, when *to* is prefixed, the verb loses its verbal character, and becomes a noun by abstraction. That an infinitive verb has the nature of an abstract noun, is manifest from this. In all languages we may be made the subject or object of discourse; and, in Greek, it is admitted in the article before it, as nouns do; and in all instances where
ever, an abstract noun, where such exists, may be signified for it. I dof, to learn, 1 to, to be learning. To excel in learning is honourable. So then, according to Mr. Tooke, it is put before a verb to distinguish it as a verb when it has ceased to be a verb—when, from a verb, it becomes a noun. And the reason why we say he doth love, instead of he doth loves, is not that the termination supplies the place of to, but because loves and love are one a verb, the other a noun, which last does not admit such a termination.
