acquaintance with the rights of mankind, and his courage in afflicting them. His "Essay on the Intercourse of Men of Letters, with Persons high in rank and office," expounded the mean servility of the former, and the insulent tyranny of the latter. A lady of the court, who heard the author blamed for exaggerating the defects of the great, and the submission with which they required, exclaimed: "If he had told me, I could have told him still more of the matter." Thrice, with other essays on subjects of polite literature, "Elogies" on Bernoulli, Terraillon, Montequieu, Mallet, and Dumarais, and "Elements of Philosophy," were collected into 5 vols. 12mo, about the year 1752, and published under the title of "Mélanges de Littérature, d'Histoire, et de Philosophie." In 1753, M. d'Alembert published his "Dissertation on the Dejection of the Jettuits," (De la Délivrance des Jetuits.) 12mo, Paris; a work which not only ridicules, with the keenest satire, the divines of Ignatius Loyola, but treats with just severity their adorations, and which expounded the writer to many opprobrious and unmerited reflections. In the year 1772, he was chosen secretary to the Academy of Sciences; and soon after this honour, he founded the design of writing the lives of all the deceased academicians from 1700 to 1771, as a continuation of the "History of the Academy," published by M. de Pélisson and d'Olivet. This design he executed in three years, by composing 70 éloges or panegyrics, comprised in 6 vols. 12mo, and published at Paris in 1757, under the title of "Histoire des Mémobres de l'Académie Française, morts depuis 1700, jusqu'en 1772." This collection, notwithstanding some inequalities of style, is justly admired: it abounds with lively portraits, amusing anecdotes, ingenious parallels, and just reflections.

As soon as M. d'Alembert engaged in the design of publishing the Encyclopædia, he emerged from obscurity, and became an object of attention, not only in the circle of his friends, to which he had hitherto been confined, but to the public at large. Whilst many approved and commended both the design and execution of it, the freedom with which several articles were written, was condemned by others, and subjected M. d'Alembert, as well as others of his colleagues, to considerable obloquy. However, his literary merit was now thought sufficient to entitle him to royal patronage. In 1776 the interest of the minister, Count D'Arquenon, obtained for him a pension of 1200 livres. In 1762, he was invited by the empress of Russia to undertake the education of her son, the Grand Duke, with the offer of a salary of 100,000 livres, and other privileges; but this liberal and honourable office, though enforced a second time by a letter under the empress's own hand, his attachment to his country and friends, and his preference of literary leisure, induced him to decline. The next year he was invited to an interview with the king of Prussia at Weil: when they met, the king affectionately embraced him; and inquiring of the philosopher, whether the mathematics furnished any method of calculating the political probabilities? M. d'Alembert replied, "That if such a method existed, it could be of no use to a hero, who could conquer against all probability." The king offered him the presidency of the Academy of Berlin, vacant by the death of Maupertuis. But though the ferment, occasioned in France by some articles in the Encyclopædia, and especially that of Geneva, and the odium he had personally incurred, might have led him to seek an asylum in the court of a philosophical prince, he declined accepting the flattering proposal; nevertheless a correspondence fulfilled between the king and him as long as he lived. The letters are published in the "Polihomous works of the king of Prussia." This correspondence, and that with Voltaire and other eminent persons, his constant intercourse with learned foreigners, as well as distinguished characters at home, and his influence in the academy, concurred to give importance to M. d'Alembert; and though he was called the Masarim of literature, candour leads us to believe that his influence was only what his talents, his virtues, than to artful management, and fopple address. His abhorrence of superclition and pietersaf, it must be allowed, drove him into the extreme of infidelity; and he was not only lax in his religious principles, but on some occasions indecorous in his mode of attacking doctrines that have been generally received even amongst those who have been accustomed to think freely on the subject of religion. He seems to have adopted that system of deified nature, which bequeaves the world of a deigning cause, and providing his character, strict probity, a noble disinterestedness, and an habitual desire of obliging, were its distinguishing features. Many young people, who discovered talents for science and learning, found, in him a patron and guide. To worthy men, even in adversity and persecution, he was a firm and courageous friend. To those who had shewn him kindness, he never ceased to be grateful. Gratitude induced him to dedicate two of his works to two ministers, when they were in disgrace, the Count d'Argenon, to whom he owed his pension, and the Marquis d'Argenon, who had given him many proofs of respect and esteem. When in early life, Mad. de Tencin, informed of his singular talents, came to him, and fondly caressing him, discovered to him the secret of his birth: What do you tell me" he cried out: "Ah! you are but a stepmother; it is the glazier's wife who is my mother." Through life he retained for his nurse the affectionate sensibility of a grateful son. He remained in her house near 30 years; and did not leave it till in 1775, after a long illness, his physician represented to him the necessity of removing to a more airy lodging. His health being recruited, he continued to occupy his honourable situation among philosophers, till the 29th of October, 1783, when in the 67th year of his age, he expired; leaving behind him the reputation of amiable virtues and eminent talents. Perbap no character has ever appeared, which has more completely exemplified the union of strong mathematical genius with an elegant taste for polite literature. His eulogy by Condorcet is published in the "Hill. de l'Acad. Royale des Sciences," 1783. Monthly Rev. vol. xxxv. 239. Nouv. Dict. Hist. Hutton's Math. Dict. Gen. Biog.

ALEMBIC, Limbe, latin. Fr. An alembic is one of the numerous articles of distillatory apparatus. In the English laboratories and manufactories its use is almost imperfected by the retort and still; but on the continent, especially in France, it continues to be the favourite vessel for distillations in the large way. The French indeed appear to have no word in their language synonymous with the English one still, and hence the difference between these two vessels is but very imperfectly noticed even in their belt authors. As distillation depends on the separation of the volatile from the more fixed parts of a compound by the action of fire, it is obviously essential to every
every apparatus for this purpose that it should consist of at least two parts; the one for the reception and heating of the matter to be distilled, and the other for the collection and condensation of the more volatile part when in a state of vapour. Of all the vessels designed to this use the alembic is the simplest and the most ancient.

Both Dioscorides and Pliny mention the ἀλεμβρὸς (ambix) which is described by the latter of these writers, as a hemispherical iron cover, luted upon the earthen pots in which mercury was procured by the distillation of cinnaear; it is probable, however, that the ambix was in the time of Pliny a mere plain still, without any beak or gutter, since he mentions the mercury being wiped off in small drops from the inside of the vessel, the necessity of which manipulation would be superceded by the invention of a beak. The alembics having adopted this instrument, prefixed the Arabian article а to its name, and made considerable alterations in its form. Their object in all distillations and digestions being to separate, as much as possible, the most volatile products from those that are less so, they imagined that the greater distance which the vapour had to pass through, in its passage from the boiler to the condenser, the more perfectly would the spirit or quintessence be depolyglomated; for this purpose the body of the alembic was made of a globular form, terminating above in a long narrow neck, to the end of which was fitted the capital; (Chemistry, plate iii. fig. 10. A the body, B the neck, C the capital) sometimes for the purpose, of more effectually keeping down the impure particles, the neck was bent in a zig-zag or spiral direction. The characteristic difference between an alembic and a still seems to be in the construction of the head or capital, which in the alembic is contrived not merely to collect, but to condense the vapour: whereas, the corresponding part of a still serves merely to collect the vapour, which is transmitted in an elastic flat through the beak, and condensed in the worm. In the figure already referred to, the distance between the body and the capital is so great, that much of the heat must be given off from the vapour before it arrives in this part; the mere refrigerating power; therefore, of the atmosphere is amply sufficient to condense the vapour into drops on the inner surface of the capital, which, trickling down into the channel or gutter at the bottom, are delivered by the beak into any vessel placed to receive them. The length and narrowness, and convolution of the neck were, however, found to condense so much of the vapour before it reached the capital, as to render all processes, in which it was employed, unprofitably tedious; besides requiring to heat a heat as to alter and injure the products very considerably; the neck was therefore shortened and made wider, and as in consequence of this the vapour came into the capital more heated than before, it was necessary to substitute a more powerful refrigerating cause to the casual and varying action of the external air; with this intention, the capital of the metallic alembics was inflected into a vessel of water, (fig. 11.) called a refrigeratory, and thus the alembic, as far as concerned the number and general disposition of its parts, was completed.

The glass and earthenware alembics soon received all the perfection of form which their materials would allow; the body, instead of being a globe with a long neck, was altered into a cucurbit; and the capital assumed a more conoidal shape, being two parts or detached portions, well fitted closely into each other, by grinding with emery. The irregular expansion and contraction of glass by heat, rendered the use of a refrigeratory improbable, so that when distilling briskly, it is necessary to cover the capital with cloth soaked in cold water and frequently renewed: thus requiring a constant attention, besides running the risk of cracking the cucurbit by a drop of cold water falling upon it from the head. On this account, the glass alembics are but little employed, although capable, when skilfully managed, of distilling a much larger quantity in a given time, than a retort of equal capacity. (Fig. 12. A the body of the cucurbit, B the capital, C the channel, D the beak.)

The metallic alembics being formed of more manageable substances, and being appropriated to large processes, in which economy of time and fuel was of great importance, invited and obtained a number of valuable improvements. The most considerable of these are due to Beaumé, a representation of whose alembic, as further improved by Chaptal, is given in fig. 15. This vessel is composed of three parts; the one marked A is the boiler, being a hollow cylinder of tinned copper, of equal diameter at top and bottom, but bulging out into a shoulder at g, by which it is suspended over the furnace; in this part are fixed two handles, а а, and a short pipe j, fitted with a cork, for the purpose of supplying water or any other fluid, without the necessity of taking the apparatus to pieces. B is a cucurbit or balneum made of tin, of a cylindrical figure, with two handles, and a collar on the outside, which fitting into the inner groove b, of the boiler, supports it when suspended within this last. The third part of the apparatus is the capital, a section of which is represented at C: r is the collar by which it is fixed on the inner groove b, of the cucurbit B; ë is the proper capital, in shape a short cone, made of tin, terminating at its base in a circular channel r, slightly inclined towards the beak m. Surrounding the capital, and closely folded to it is the refrigeratory а, made of copper, and accommodated in flame to the capital; at the bottom is a large stop-cock p. For the distillation of water, or of spirits from the wash, where a brisk boiling heat is required, the liquor is put into the boiler, and the cucurbit is omitted; but for the rectification of alcohol and other similar processes, the substance to be distilled is to be put into the cucurbit, and the boiler being filled with water, the heat is conveyed through the medium of this fluid, and of course is more moderate and equal.

Most of the French brandies are prepared in alembics, whereas all British spirits are manufactured in stills; the advantage of the alembic is that less fuel is required, and the spirit is but little exposed to the risk of becoming empyreumatic. Its disadvantage consists in being less expeditious, and in requiring greater accuracy in the temperature of the refrigeratory; if too cold, the vapour is in part condensed before it touches the inside of the capital, and falls back into the boiler; if too hot, a portion of vapour escapes into the air; a greater proportion also of water is required for the condensation of a given quantity of vapour, than where a worm and still is made use of. Encyclopedia. Method. Art. Alembic.—Beaumé El-Mens de Pharmacie.—Macquer's Dict.—Boerhaave's Chemistry.

ALEMBROTH, SALT OF. This term, the use of which is derived from the alembics, has been successively applied to a variety of preparations and native salt. The general idea which the word seems to convey, is that of a flux or solvent, either to dilut in the fusion of metallic ores and earths, or to dissolve obstructions, and attenuate vital humours in the human body, when employed medicinally. A peculiar earth, found at Mount Olympus in the island of Cyprus, was called alembroth, which was said to be of a nitrous and aluminous nature, and was actually employed in metallurgy as a flux. Probably, however,
ALENQUER, in Geography, a town of Portugal in Estremadura, situate on an eminence near a small river, which falls into the Tagus. It is said to have been built by the Alans, being anciently called Aleker rana, i.e. the temple of the Alars. It contains about 2,500 inhabitants, is a marquisie, and has 14 parishes belonging to its diocese.

ALENSTEIG, a town of Germany, in the archduchy of Austria; 4 miles from Baden.

ALENTAKIE, or ALENTAK, a province of Ethiopia, upon the gulf of Finland; the capital of which is Narva.

ALENTEJO, or ALMTEJO, one of the largest and least populous provinces in Portugal, situate between the rivers Tagus and Guadiana, and extending from the mountains of Algarve on the south, to the frontiers of Estremadura on the north, and from the sea and Tagus on the west, to the borders of Spanish Estremadura and Andalusia on the east. Its length from north to south is computed at 36 leagues, and its breadth from east to west is nearly the same. It is called Alentejo, i.e. alem do rio Tejo, y d. beyond the river Tagus, because it lies in that direction with regard to Estremadura and the countries further south. It contains four cities, the chief of which is Évora, 10 towns, 35 parishes, and about 33,935 inhabitants. The towns are very populous; but there is a scarcity of villages, which contribute most to cultivation; and another cause of its scanty population is its always having been the theatre of war between Spain and Portugal. It contains a great number of fortresses, and maintains ten regiments of infantry and four of cavalry, which are constantly recruited here, and form a fourth part of the military establishment of the whole country. The lands in this province are far from being well cultivated, being only once in three years; though some of our geographers represent it as a fertile province, and call it the granary of Portugal. Its principal products are wheat and barley, and in many places it also affords grapes, olives, and other fruits, as well as game and fish. Some parts yield marble and gems. In this province there are three kinds of soil, viz., fertile black soil, fertile earth, which is found in the red clay of Elvas, Campomayor, Oliveira, Fronteira, Almecos, Beja and Serpa; and lighter earth mixed with a little sand, which forms the soil round Évora and Arrayolos, where the bad kinds of wheat, barley and rye, succeed very well, and cork trees and evergreen oaks also grow; and a sandy barren soil, which forms the heaths of Cantarinho, Ponte de Sor, Monte Argil, Tabacos and Vendas Novas, a tract of country about 30 leagues in circumference. At present these heaths, which afford beautiful varieties of heath plants and evergreen shrubs, serve only as pasture for goats; though the clayey soil is very capable of cultivation; as are also marshy tracts which might be drained. The rivers in Alentejo, particularly in winter, are very rapid, and do much damage. There is a small chain of mountains in this province, about seven leagues long, and two and one-half broad, which runs between the city of Évora and the town of Almécos, and which in reality belongs to the chain of Toledo. The commons are generally covered with cistus, which is used in some parts for heating ovens, and in other parts as pasture for cattle. The whole province is full of vagabond beggars, who beg or steal by day, and at night sleep in the huts of the hucksters. The nobility keep large herds of sheep and goats, and thus prevent the heaths from being cultivated. The prosperity of this province is impeded also by the luxury of the peasantry, by the number of fall-days, and by religious houses, and by the badness of the roads. The Upper Alentejo

ALENCON, a city of France, and capital of the department of Orne, situate on the river Sarthe, in an extensive and fruitful plain, which abounds with all sorts of corn and fruit, hemp and pasture. It has a well fortified caftle, and several public buildings. The number of inhabitants was some years ago computed at 19,000. M. de Tineau reckons them at 12,407; those of the canton at 11,044, and of the whole canton at 13,213; the territory comprehends 2332 square kilometres and 25 communes. Its commerce consists of linen, lace called point d'Alençon, lerges, ruffs, leather, &c.; and it has three markets every week. In its vicinity are mines for building, and others called flints of Alençon. It is 8 leagues north of Mons, 25 S. W. of Rouen, and 25 S. W. of Paris. N. lat. 48° 27', Long. 0°.

ALENCON is also a small town of Dauphiné, in the generally of Grenoble.

ALENDA, a town of Africa, in the empire of Morocco.

ALENIO, Julius, in Biography, was born at Brescia, in Venice, travelled into the Eastern countries, and arrived at Maca, in 1610, where he taught mathematics. Thence he went to China, where he was employed for 36 years in the propagation of Christianity. He is said to have been the first that planted the Christian faith in Xanfi, and to have built several churches in the province of Fokien. He died in 1649, and left several works in the Chinese language. Biog. Dict.
ALEPPO.

Aleutjó would export, and consequently grow, much more corn, if there were but roads for its conveyance. See Link's Journey through Portugal, p. 172—174.

ALEPPO, in Ancient Geography, a river of Asia, to the west of Smyrna, according to Ptolemy. To the waters of it was attributed the virtue of making the hair and skin to grow on different parts of the body.

ALEPPO, in Geography, the metropolis of Syria, is deemed in importance the third city in the Ottoman dominions. Although it is much inferior to Constantinople and Cairo, with regard to situation, magnitude, population, opulence, and courtly splendour, it may be reckoned superior to both those cities in the falsity of its air, the fertility and elegance of its private buildings, and also the convenience and neatness of its streets. With respect to commercial advantages, it has much declined, but still continues to maintain a trade that is far from being considerable. In Arabic, Aleppo is called Ḥalēb, to which is usually added the epithet Al Shubba. According to the fabulous history of the Arabian writers, who trace the origin of this city to the migration of the patriarch Abraham into the land of Canaan, who reigned for some time on the hill, where the castle of Aleppo is now situated, the appellation Ḥalēb is derived from the circumstance of his distributing milk to the poor of a neighbouring village. Their frequent repetition of the words "Ibrahim halēb," or "Abraham halēb," gave occasion, as it is said, to the name Ḥalēb, which was conferred on the town that was afterwards built on this spot. The same history refers the epithet Al Shubba to a pied cow, which the populace distinguished by its lowing in the herd of the patriarch. Goats and others, with much greater probability, deduce this term, which denotes a variegated grey and white colour, from the colour of the soil, and of the buildings. Some have supposed that Aleppo was the Zobah of Scripture; but it was, more probably, the Beraea of the Greeks. Aleppo is situated, according to ecclesiastical observations (see Conn. des Temps, 1792,) in N. lat. 36° 11' 25", and E. long. 37° 6', at a considerable height above the level of the sea, near the river Kebkab, which runs in a small stream to the west of the city. Its distance from Scanderbon or Alexandretta, the nearest sea-port, is in a straight line, between 65 and 70 miles; but in the caravan road, between 90 and 100 miles. It is encompassed, at the distance of a few miles, by a circle of hills, which are in general rocky, scantily provided with springs, and totally destitute of trees, but affording good pasture for sheep and goats. Within this circle, there are hills and hillys, which are intersected by plains and little valleys; the soil of which is in some parts of a reddish or black colour, rich and fertile, but in general whitish, shallow, and mixed with many small stones. This city, including its extensive suburbs, occupies eight small hills, the intermediate valleys, and a considerable extent of flat ground, comprehending in the whole a circuit of about seven miles; though the city itself is not above three and one-half miles in circumference. The wall that surrounds it, which was built, or at least repaired by the Mameluke princes, is neglected and mouldering into ruin. Besides this wall, the city was formerly defended by a wide and deep ditch, which is now filled with rubbish, or converted into garden grounds. It has, at this time, nine gates; two to the east, two to the south, two to the north, and three to the west. One of the northern gates, formerly called the Jew's gate, which the son of Saladin changed into Bab al Nafer, or Gate of Victory, was once, according to the Muslimaries, the residence of the prophet Elisha, and it has lamps which are kept constantly burning in commemoration of that fact. The cattle, which stands on a hill near the north-east corner of the city, and which is encompassed by a broad deep ditch, about half a mile in circumference, may be distinguished at a considerable distance; but a traveller, approaching from the west, can see scarcely any other part of the city, till he gains the brow of one of the hills within two or three miles of the gates; and thus it becomes an extensive and striking object. The mosques, the minarets, and numerous cupolas, form a splendid spectacle, and the flat roofs of the houses which are situated on the hills, rising one behind another, present a felicitation of hanging terraces, interspersed with cypresses and poplar trees. Aleppo is, in general, a well-built city, and the houses within are grand and handsomc. The streets are better disposed, and broader than those of eastern cities; they are well paved, and remarkably clean, and they have a commodious foot-way on each side, raised half a foot above the other part. The mosques in Aleppo are numerous; of which seven or eight are reckoned magnificent, though none have more than a single minaret, or steeple, whence the people are summoned to prayer. These minarets were first annexed to the mosques, as it is said, by Al Walced, who succeeded to the Caliphate, in the 85th year of the Hegira. Into these mosques none but Mohammeds are permitted to enter; and at Aleppo, it is only one of them to the court-yard of which Jews and Christians are allowed admission. The public edifices, next in importance to the mosques, are the Khanes, or Casaransaries, intended principally for the accommodation of strangers, and partly as warehouses for goods. The Bazaars, or Markets, are lofty stone edifices, arranged in the form of a long gallery, arched above, or roofed with wood. Of these the principal are situated close to one another, in that part of the city that is contiguous to the great khan; and others are distributed through several parts of the town, and the suburb called Bankūfa, where the corn-market is kept. The streets, in which are shops, for the necessaries of life, are also called bazaars, and they are defended from the sun by mats spread on wooden rafters, projecting from each side. The bazaar gates are regularly shut at fun-fest, and watchmen, provided with a pole and a lamp, are stationed for the night within them. These gates are secured merely by wooden locks and keys. There are also gates and watchmen in the principal streets, and by these the town is secured from nocturnal brawls and depredations. The natives, who are habitually sober and regular, retire to their habitations at an early hour, and the dread of being carried by the patrol to the foragio, restrains the most riotous from drunken frolics. The public baths, or humums, do not contribute much to the embellishment of the city, as their fronts to the street are very simple; but the coffee-houses, which are spacious and handsome, and dispersed through all quarters of the town, attract the notice of strangers. They are gaudily painted, and furnished with matted platforms and benches; and those of the better sort have a fountain in the middle, with a gallery for musicians. At certain hours of the day the coffee-houses are full of company, though they are not frequented by persons of the first rank. The dwelling-houses of Aleppo comprehend the foragio, or palaces, the houses of the opulent merchants, and the habitations of the middle and ordinary people. The foragio, in which the Bashi of Aleppo usually resides, is situated near the castle, and is a very extensive and lofty building, surrounded by a strong and lofty wall. The gates of this edifice lead to several interior courts, which are enclosed for barracks, stables, a hippodrome, and various other offices. The principal building.
TYING contains apartments for the baishaw, his harem, household, officers, and pages. It consists of three courts, one of which is the divan, where the baishaw gives public audience. The whole of this building is much neglected, and if it had not been originally a very substantial edifice, it would long ago have been in ruins. There are five or six other feraglios of more modern date, that are much smaller, well built, and gaudily decorated; they were erected at different periods by former baishaws, and belong to their heirs. They are now occasionally let to such governors as do not chuse to reside in the old feraglio, and to other officers of the Porte, who visit Aleppo on public business. Other buildings, constructed on the same plan with these, though not denominated feraglios, are occupied by the principal agas and effendees.

The roofs of all the houses, those that have domes excepted, are flat, and plastered with a composition of mortar, tar, ashes, and sand, which in time becomes very hard. These flat roofs, or terraces, are separated by party walls, and most of the natives sleep on them in the summer. The Franks, who live near one another, have doors of communication, and by means of their own and the bazar terraces can make a large circuit without descending into the street. The natives have no intercourse by the terrace, and guard by high walls against being overlooked.

To the lower classes of strangers, as Arabs, Kurds, and other Turks of foreign extraction, and Armenian Christians, there is appropriated a kind of accommodation, called Keifaria, which is a large area, surrounded by a number of mean, low houses, each consisting of two or three rooms. Other buildings, in the form of a clost or court, allotted to weaving and other manufactures, are called by the same name.

The castle of Aleppo is deemed, by the natives, absolutely impregnable; but its walls and turrets are in so bad a state, that a few cannon would soon demolish them. It is, however, of importance as a magazine for military stores; in times of war with Persia, for the awe of the city, and an asylum to the magnates in case of insurrection; as a prison for malefactors, and a place of execution for the Janizaries, when condemned to die. The Aga of the castle is immediately dependent upon the Porte, and subject, only in certain cafes, to the baishaw. He commands a numerous garrison; and the private men, with their families, lodge in the castle.

The fuel used at Aleppo is wood and charcoal; and that which is employed in heating the baths renders them a public nuisance. This consists chiefly of dung of animals, the filth of flables, and the parings of fruit, which, both in drying and burning, are very offensive. Cow dung is seldom used in the city; but by the Arabs and peafants it is used not only as fuel, but for forming a kind of flat pan in which they fry their eggs. Camel and sheep's dung with brushwood, or the stalks of such plants as grow in the desert, are the common fuel. At Aleppo, in one of the suburbs called Mahirka, they have a glass manufactory, and a tannery to the south-west of the town near the river. Their slaughter-houses are situated in an airy field, in the skirts of the suburbs, towards Bankufa, and their principal flesh market is in the suburb called Siedceida. They have several lime-kilns near the walls, on the south-west of the city, and a manufactory of catgut half a mile to the south, which occasionally emits a very offensive stench. Within the walls, they have only one public burial ground, besides several private cemeteries; but without the walls the burial grounds are of wide extent round the town, and the white tombs and grave stones, viewed at a distance, add to the rocky sterile appearance of the country.

The city is supplied with water by means of an aqueduct from two springs, at the distance of about eight miles to the north. This aqueduct, which is said to be coeval with the city, was repaired by the empress Helen, the mother of Constance, and again repaired and enlarged by the son of Saladin, in 1218. It supplies with water a range of gardens, formed on its banks, and called the gardens of Babulah, which is the name of an adjoining village, and the water is distributed through the grounds by means of small interfering channels dug in the earth; and regulations are established for its communication in due proportion to different persons. This tract of gardens extends about 12 miles, and generally belongs to some effendee or aga, possessing sufficient authority for the protection of his tenants, or forms a part of some religious estate. The whole extent of these gardens is subdivided into square or oblong fields, bordered with dwarf trees, flowering shrubs, and taller trees, such as the plane, weeping willow, ash, and white poplar. Within these enclosures are cultivated melons, melons, and cucumbers, with a variety of succulent roots, cabbages, and greens for the kitchen; in others, cotton, tobacco, sefaim, palma chiri, and lacerca; and some are fown with barley, which is used in the spring as green fodder for the horses. Among these enclosures are large plantations of pomegranate, plum and cherry trees, and sometimes groves, composed of the various fruit trees which the country produces. The gardens, those of Babulah excepted, are supplied from the river by means of Persian wheels. In most of the gardens there are summer-houses, furnished with fountains, and with kiloes, or a kind of balconies, projecting over the river. The Aleppo gardens are spoken of with rapture by the natives. They supply the city with greens and fruits, and contribute both to the health and amelioration of the inhabitants, by affording scope for exercise and a pure air.

In the vicinity of the city are many extensive quarries, which afford a gritty stone, from which dug easily cut and indurated by exposure to the air; and the more ancient of these quarries have subterraneous excavations of great length, which serve the Bedouin Arabs for winter habitations, as stables for the camels, and as dens of debauchery to the Janizaries. The marble of Aleppo is of a yellowish colour, but by rubbing it with oil, and exposing it to the moderate heat of an oven, it is made to resemble the red marble of Damascus. Aleppo is supplied with salt from an extensive plain, at the distance of about 15 miles, called the valley of salt, or salt lake.

Aleppo, though encompass'd by hills, is well ventilated, and enjoys a pure penetrating air, which is reckoned fruitful, that from the end of May to the middle of September, the inhabitants are accustomed to sleep exposed in their terraces, without receiving any injury. The spring begins to be yellow; and a few weeks bring on the harvest, and when the grain has been plucked up by the roots, the whole country bears a parched and barren aspect. Some flowers commonly fail in the beginning of June; but from the middle of this month to the middle of September, it is extraordinary to see any rain. The heat of July and August is mitigated by the westerly breezes; but when these fail, the weather becomes extremely hot. When the wind blows from the north,
ALEPPO.

north-west, call, north-east, or south-east, the heat is extremely oppressive, and the air is dry and scorching, as if it proceeded from an oven. The eyes, lips, and nostrils are parched, and it produces a latitude, attended with an oppression at the breath, of which the natives are not less sensible than the Europeans. It is usual to exclude these hot winds by fastening up the shutters from dusk till dawn. They do not, however, occur every year, nor do they produce such fatal effects as the desert winds, named Simoom. At the end of August the Nile clouds, as they are called, make their appearance, and are often attended with dew. About the autumnal equinox the air is refreshed by flowers, which are termed the first rains, and are usually preceded by irregular gusts of wind that raise the dust in vortices. These are succeeded in 20 or 30 days by the second rains, which are more plentiful than the first, and after them the weather becomes variable and much cooler. The transition from the Autumn to the Winter is slower than that from Spring to Summer. The trees retain their leaves till the beginning of December, and the most delicate perfumes have no fires till the middle of this month. The rigour of winter commences about the middle of December, and lasts forty days; but though there is almost always some frost in winter, many years pass without snow. The narcissus is in flower during the greatest part of the winter, and violets and hyacinths are plentiful in January. Although violent storms of wind are rare at Aleppo, squalls accompanied with heavy showers, and sometimes with thunder, are frequent in the Spring and Autumn. Lightning, unaccompanied with thunder, is frequently seen in the night during the months of September and October; and it is sometimes seen in Summer; but the nocturnal sky, in the hot months, is almost always serene, exhibiting a glorious scene to the astronomer, who may indulge his study, and at the same time enjoy the cool air on the terrace. There are few years in which earthquakes do not occur at Aleppo; but they are generally slight and do no injury.

The nature of the soil near Aleppo has been already mentioned; in the more dilatant plains, it consists of a redish, sometimes of a blackish, light mould, and produces the fruits of the earth in great abundance. The fields near the city yield, in consequence of much manual labour, two crops of grain every year, although of different kinds every year; but without manure, they are fown only once a year with different sorts of grain alternately, but are seldom sowed to remain fallow. They begin to plough in September; and the plough is drawn by one or two small cows, or by a single ass, in furrows so straight, that one would imagine a line must have been used in tracing them. They sow wheat, barley, lentils, chickes, beans, chiching, small vetch, a small green kidney bean, and Indian millet. The earliest wheat is sown about the middle of October, and barley so late as the end of February. They seldom use the harrow; the grain being covered by repaling the plough along the edge of the furrow; in sandy soil, they sow first, and then plough. The barley harvest commences in May, about 10 or 14 days before that of the wheat, and early in June corn of every kind is taken off the ground. Amongst the reapers in Syria, a custom prevails of accosting a palling traveller and presenting him a handful of corn, with a general shout; and a small present is expected in return. The corn, when reaped, is carried on asses to the summit of the nearest hill, and being laid on hard even ground, it is separated from the chaff, not by threshing, but by means of a sledge fixed on two or three rollers, and armed with several iron rings, with ferrated edges, so sharp as to cut the straw. This machine is drawn by oxen, mules, or asses, and driven by a man seated on the sledge, and as it palles circularly over the corn spread beneath, the grain, by repeated operation, is trodden out, while the flarw is chopped by the iron rings. The chaff and bruised spikes are then separated from the grain, by throwing up the whole into the air with wooden shovels, when the wind blows moderately. The spikes that have been imperfectly trodden are again submitted to the sledge. When the grain has been afterwards more perfectly winnowed and separated from the flarw, it is thrown together in a large heap, and is then divided in a stipulated proportion between the husbandman and the landlord. The cattle employed in the harvest are left unmuzzled at the heap, as the Scripture mentions. See Lowth's Com. on Isaiah, ch. xxviii. v. 27, 28. Notes, p. 130. The grain is then removed to granaries, which are subterraneous grottoes, with one round opening at top, which, when the magazine is full, is shut close and covered with earth, and thus completely concealed from the enemy. The corn is chiefly ground in mills wrought by mules, though there are some water-mills upon the river Kowick, and among the lower people by hand-mills. Wind-mills are unknown.

The olives produced at Aleppo resemble the Spanish olives, but are not so large, and the annual produce of them is inconsiderable. The city is supplied with oil from other parts, and particularly from Edlib and adjacent villages, where the olive plantations are more extensive. Large quantities are employed in making soap, and the ashes employed in this manufacture are brought from the Defert by the Arabs. The gardens afford several varieties of grapes; those that are ripe appear in the market in September, but the vintage is not at its height till the middle of November. The dried fruit of the vine affords part of the food of the inhabitants; it is eaten with bread and used in thebets; a large quantity of raisins is also confumed in the distillery, carried on both by Turks and Christians. Aniseed is added in the distillation, and the spirit, which is very strong, is called araki. The infusitated juice of the grape is much used by the natives; it is called elleb, and much resembles coarse honey in appearance. It is brought to town in goats skins, and serves for the common people instead of honey. The pitachioe tree is diligently cultivated, and the nuts reckoned layer to those of any other part of the world. Pliny (ib. xii. c. 5. lib. xv. c. 24.) says, that pitachios were first brought from Syria into Italy, by Lucius Vitellius, in the reign of Tiberus; and Galen (De Alim. Facult. lib. ii. c. 30.) mentions Berea as famous for that fruit in his time. Large quantities are exported from hence to Europe. The nuts of the wild pitachio are brought to town from the mountains; the tree not growing near Aleppo. The white mulberry is common in the gardens, and brought to market in May, and the fruit of the red mulberry, which is not ripe till two months later, is delicious. Very little fig is made at Aleppo; that which is exported from hence to Europe, by way of Scandreoon, is chiefly the produce of Antioch and the adjacent mountains, or it is brought to Aleppo from places more distant. The pomegranate is common in all the gardens, and is ripe towards the end of August. The markets are plentifully supplied with several varieties of figs; but the middle sized yellow fig is the most esteemed. The gardens also produce other fruits, as cherries, apricots, peaches, plums, apples, pears, quinces, cornelian cherry, almonds, walnuts, hazelnuts, jujubes and sumach; the former of these two last being valued much as a medicine, and the latter as an ingredient in cookery. Oranges, lemons, and citrons, were formerly produced in the orchards of Aleppo; but as they are not now cultivated,
cultivated, it has been inferred from this circumstance, that the
winters in Syria are now more rigorous than they were in for-
ter times, and this is the opinion entertained by the natives.
Among the vegetables which form part of the diet of the
inhabitants, the mad-apple (Solanum Melongena of Lin-
neus), of which there are three varieties, claims a principal
place. Their other edible vegetables, we shall not recite.
Of the vegetables produced in the fields without culture
there are capers, borago, common mallow, forrel, dandel-
ion, water cress and truffles. Savory is much used to give
a relish to their bread.
The number of inhabitants at Aleppo has been computed
at 300,000; but Dr. Ruffell conjectures, that they do not
now exceed 235,000, of whom 200,000 are Turks, 30,000
Christians, and 5000 Jews. M. d’Arvieux (Memoires, tom.
vi. p. 434, Paris, 1735) makes the whole number of houses
and public buildings in 1683 to amount to somewhat more
than 14,100, and the number of dwelling-houses 13,360.
From an account preferred by Dr. Ruffell, and supposing
the number of houses in 1752, amounted only to 10,742; so that, if thes
accounts be right, there had been a decrease from 1683 to 1752
of 2,628 houses. M. Volney observes, that as this city is
not larger than Nantes or Marflouks, and the houses confi-
only of one storey, it is not probable that the number of in-
habitants should exceed 100,000. The language universally
spoken by the natives is the vulgar Arabic; and the Turkifh,
which is spoken by people of condition, and which is the
court language ufed in the seraglio, is said to be corrupted
by the concourse of strangers from the northern provinces.
The people are generally of a middle stature, rather meagre
than corpulent, and neither vigorous nor active. Their
complexion is naturally fair, their hair black, or of a dark
cheesefruit colour, and their eyes for the most part black.
The females affect to appear full and plump; they ufe no flays,
and wear their girdles very loose. The men gird themselves
tightly with a broad belt, and a longshawl figure. The people
that are exposed to the sun become swarthy.
The men dress in the long caftian habit, and during the six
months in the year wear furs. Under the furs their garments
confift of a silk or linen shirt, and drawers, wide trousers
of red cloth, to which are fewn focks of yellow leather,
serving for breeches, stockings, and within drawers, for shoes;
but in walking, they ufe flippers without heels. They also
wear a waistcoat, called a funbaz, that comes lower than the
knee, and a long belt reaching down to the heels, which
covers all, and is named a dalaman. Above the dalaman,
they have a long Persian haif, and a belt under the waist-
coat, and to this clufure they affh a small dagger or knife,
and with men of buflines it ferves to support a silver
inliver. For an account of the turban, see Turfan.
The Abai is a silk, or cambric gown, with large sleeves,
laced down the fems with a narrow gold lace, which is worn
in summer instead of the kuyk, or loose gown trimmed with
furs. Abai is the name of the ordinary vesture of the
Arabs. The defis of the ladies in many respects refembles
that of the men. But their dalaman and funbaz fit clover
to the shape, and not folding over the breadth, leave the neck
uncovered. Instead of the collo, long-haired furs of the
men, they ufe fable or ermine, and they are formed in a dif-
fert fashion. The ladies are fond of thick long hair; and their
head-dres, confifting of a warm cloth cap, under cotton and
muffs, which compole the rind of the attire, is much the same as that of the men. They wear ear-rings,
a necklace, or collar, of gold, large clumsy gold bracelets,
on the wrist and ankles, a string of zecchins close to the hair,
on the forehead, and another, very long, across the body in
the manner of a sash. Both sexes wear rings on the fingers,
and some women wear them on the toes. The ufe of rouge
is very little known; but the women tinge their fingers,
hands, feet, and toes, of a dusky red or yellow colour, by
means of a paste formed of the powdered leaves of henna
and water. See Alcanna. The hands and feet are afterwards
covered with another paste, composed of flour and
water, with crude sal ammoniac and quicklime, which
changes the colour into a fort of black or very dark green.
They also tinge the inside of the eye lids with a powder,
called kobol. See Alcohol. The women apply another
composition called khatat, to the ey-brows, which tinges
them of a fine black colour, and makes the hair smooth and
glossy. It is the custom with the men to let the beard grow,
after a certain age, or after performing the pilgrimage to
Mecca, and much pains are bestowed upon dressing it; but
many of the Turks wear whifters only. Some conceal the
appearance of grey hair by tinging the beard with a black
or red dye; the practice, however, is not deemed reputable,
and is not common. Persuins of both sexes ufe a variety of
perfumes, composed of musk, sandal wood, and spikenard,
which they few in out small bags and carry in the breast
pockets. Women of every clafs, when they go abroad, wear
thin yellow boots, reaching up half the leg, and over these
yellow babooge or flippers, or in wet weather wooden clogs,
called kabak. They never appear in the streets without
their veils. The ordinary Aleppo veil is a lien net, cov-
ering the whole habit from head to foot, and concealing the
whole face, except one eye. The veils of the Christian and
Jewish women, are made of plain white calico, which the
Turkish women checker with blue and red, and the Jewish
women have one arm free, somewhat in the manner of the
Scots plaids.
As to the ordinary diet at Aleppo, it consists of a con-
siderable proportion of animal food, which is cut in small
pieces and blended with rice, herbs, and strong fauces.
The lower people live mostly on rice, butter, milk, new cheefe,
greens and summer fruits, with a very small proportion of
mutton. Their ordinary bread is formed into flat cakes,
and made of wheaten flour, not well fermented and ill baked.
Leaves of a superior quality are dried over with the feeds
of fefamum, or fennel flower. The Pilaw and Durble are
common dishes. M. d’Arvieux remarks, that a greater
quantity of fruit is consumed at Aleppo, than in any three
cities in Europe of equal fize. The butter brought to
Aleppo is made of the milk of cows, bulls, sheep, and
goats; and is churned in goat-flins, and thus brought to
market. Coffee, without sugar or milk, is in use among
people of all ranks; this is drank constantly after meals, and
in all familiar vifts prefented with the pipe. It was intro-
duced into Syria about the middle of the 16th century.
See Coffee. Tobacco is smoked immediately by all
the men, and by many of the women. Their tobacco is
brought from different parts of Syria, particularly from
Latakia, and is much milder than the American. See
Tobacco. The tobacco pipes are made of the twigs of
cherry-tree, almond, rofe or jasmine, dexterously bright-
cened and boreed, in length from three to fix feet, and
decorated with silver or gilt ornaments, with mouth-pieces
of amber or ivory; the bowl is made of reddish clay and often
changed. See Rakian and Nagafel. The practice of
taking fmuak through the Porte, about the year 1760, granted
a monopoly for making and vending Rappce ruffit at Aleppo,
which was much lefs common than that of fmoaking.
The custom of taking opium is held at Aleppo almost equally scandalous
with
ALEPPO.

with that of drinking wine, and is practised by few openly, except by persons regarded of their reputation. The bagnio, or hammam, is much resorted to by persons of both sexes. The people of Aleppo in general lead a sedentary life. Dancing is not reckoned a genteel accomplishment for people of condition, and even among the vulgar it is seldom practiced, unless by such as make it their trade. Chefs, and all kind of back-gammon, which they are fond to have learned from the Peri downs, are played by both sexes. They have two other games unknown in England, called makkafa and tab-waduk. The former is played by two persons, and the success depends chiefly on memory, and a reading in counting. The latter is a mixed game, the movement of the pins on the board being determined by casting four small flat slacks, on one side white, and black on the other. They are particularly described by M. d'Arvieux and Nieuhoff. The Turks play merely for amusement; gaming being prohibited by the Koran. The natives of every denomination observe very regular hours. They rise with the sun, and are in bed between nine and ten at night. The women never appear in the street after it is dark. The coffee-houses, as we have before observed, are not frequented by persons of the first rank, but by all others indiscriminately. They are entertained by a band of music, a puppet-show, and a story-teller. The Alppcans have, in general, a correct ear, and are fond of music. The instrumental music is of two kinds; martial and loud, intended for the field, and the other softer, more sonorous, adapted to the chamber. A band of music, belonging to the castle, smaller than that of the baihaw, performs regularly twice a day from the battlements; and the baihaw's band performs also twice a day in the court of the seraglio. The feasts of the natives, who are frugal in their domestic economy, have every appearance of plenty and hospitality; and all great entertainments are commonly attended by a host of buffoons, who are partly musicians, and others, who for hire assume the character of professed jellors.

The first chiefs of the inhabitants of Aleppo consists of Turks, comprehending all Mahometans, and they amount, according to Raffel, to about 20,000. These are a mixed race, partly descended from those who inhabited the city before it was subdued by the emperor Selim in 1516; partly from such as came to settle in the new conquest, and from others drawn thither by commerce from most of the Ottoman provinces. They are united under the same government, and belong to the sect of Sujites. The merchants at Aleppo are numerous, and some of them are esteemed opulent. The traders are divided into different companies, under their respective masters, feikhs, or feiliks. The mechanics are, in general, industrious and frugal; and the Alppcans possess the art of tent-making unrivaled; the tents for the sultan and great emperors of the Porte being usually made in this city; and many bands are employed in the silk and cotton manufactures. The kafiras, or small mean houses, in the city and suburbs, are inhabited by a considerable number of Arabs. These are called Bidowees or Bedouins, and the men are employed in various kinds of manual labour.

In the suburbs of Aleppo there are many families of Turkmen, who are a stout hardy people, chiefly employed in agriculture, or as camel-drivers in the caravans; and there are also a great number of Kurdeens, who are similarly employed.

With regard to nuptial contracts and ceremonies at Aleppo, they are similar to those generally observed among the Turks. When a matrimonial engagement is projected, the proposal is intimated to the mother of the intended bride, and the relations on both sides proceed to make the necessary inquiries. If the refuit prove satisfactory, the young woman is formally demanded of her parents by the father of the young man. Substitutes are then appointed to duplicate the necessary conditions; and these proxies adjudge the fun to be paid to the bride's father, with other articles of the marriage contract. When the money is paid, the contract is regularly signed and sealed, and then the Cadi grants his licence for the marriage. About ten days before the wedding, the bride is invited by her female relations to the bagnio, and there she is entertained till the day preceding the marriage, when they proceed to apply the henna. At Aleppo it is customary for the father of the bride to make some addition to what is paid by the bridegroom, and to lay it out for the benefit of his daughter; but among the Bidoween inhabitants, and in the villages, the father usually retains a part of what he received for his daughter; and in this respect they may be said to feel their daughters. This custom of purchasing wives is practised by all the oriental Christians, as well as the Turks, and appears from the sacred writings, to have been the ancient practice. Accordingly, among the Arabs, daughters contribute the riches of a family. On the nuptial day, the women go in procession from the bridegroom's house to fetch the bride, who is brought home amidst the acclamations of the women, accompanied by her mother, and several other female relations. The procession is in the daytime, and at Aleppo, they do not carry tapers, as some travellers have reported. On their arrival in the house, the remainder of the day is spent in feasting and music. When the bride, covered with a veil of red gauze, and drest in her wedding garment, has been introduced to her husband, the relations withdraw, and continue feasting till morning; and the nuptial rejoicings last several days. The mother for the most part fuckles her child, unless prevented by incapacity, and the child is seldom kept at the breast less than two years, sometimes three or four; and the mother often fuckles during the whole time of pregnancy. During the first week the child is swaddled, and then drest in clothes which are more loose and easy; and as soon as they are able, they are left at liberty to crawl about on the carpet. When children can support themselves, they are usually carried abroad on the shoulders; and the expression used by Isaiah, ch. ix. v. 4. upon which bishop Lowth comments (Notes on Isaiah, p. 258.), is literally that which is now used by the Arab women. The difference of carrying a child in the bosom or on the shoulder, referred to II. xlix. 22, and noticed by Harmer (Obse. on Scripture, vol. ii. p. 366.), may be owing to their different ages, without regard to sex.

In the funeral ceremonies practised at Aleppo, the women perform a conspicuous part. When a person is dangerously ill, one or two sheiks are employed to read portions of the Koran, and to pray by the bedside. At the approach of death, the attendants turn the face of the dying person towards the keblah, that is, towards Mecca. When he expires, the women in the chamber give the alarm, by shrieking as if they were distracted, and are soon joined by all the other females in the harem. This conlusion is termed the Wulwaly, and is so shrill as to be heard, especially in the night, at a prodigious distance. Schultens in his commentary on Job xl. 15, (tom. i. p. 278), considers the Arabic Wulwaly as corresponding to the Hebrew יִּבַּֽלוּיַד, and to the Greek ζωολάθ, and, he supposes that the former Greek word was applied in a joyful sense. However, the Arabic walwaly is applicable only to distress and affliction, and seems to have a greater affinity to the latter term than to the former, which was commonly used by the Greeks on sacred or joyful occasions. See Mark, v. 38. Plutarch refers to this practice in his account of Portia's fainting
A L E P P O.

The funeral ceremony of the deceased is performed by the imam in some neighbouring mosque, and the corpse is then deposited in the grave, in a reclining posture, with the head to the west, and the face turned towards Mecca. If a handful of earth is then thrown by the imam, or friar, after a funeral service, into the grave, which is also done by others who stand near, and who at the same time pronounce a short benediction; after which the grave is filled up. The funeral service in use among the Kurdes is very laconic, and is as follows: “If thou hast taken away, thou shalt restore; if thou hast given, it shall be restored to thee; and if thou dost not this, thou shalt now be convinced.”

The funeral service, recited by the imam at the grave, is as follows: “O man! from earth thou wilt at first created, and to the earth thou dost now return: this tranitory abode being the first step of thy progress to the mansions of eternity. If, in thy actions in life, thou hast been beneficent, God will pardon thy transgressions; and if thou hast not, fill the mercy of God has no bounds. But remember what thou didst profess in this world, that God is thy Lord, and Mahomed thy prophet—and thy belief in all the prophets and apostles, and that God’s forgiveness is amply extended. The sepulchre is visited by the near relations on the third, seventh, and fourteenth day after the interment: they also celebrate the anniversary: volurne prayers are offered at the tomb for the repose of the deceased; and victuals and money are distributed to the poor. The tomb is bewailed by the women, in their visitst, with flowrs and aromatic herds; and the wail is repeated. The men make no alteration in their dress as a mode of mourning; but the women lay aside their jewels, drefs in their plainest garments, and wear on the head an embroidered handkerchief of a dusky brick-dust colour. They commonly mourn 12 months for a husband, and six for a father.

The governor of Aleppo is usually a vizir bashaw, or a bashaw with three tails; though sometimes the province is conferred on an inferior bashaw of two tails. He seldom remains in office for more than 12 months at a time, though the office may be renewed in the same person; and infallies occur, in which he has been continued for several successive years. The regular revenue of the bashaw is barely sufficient to defray two-thirds of his annual expenses, including the fums which he is obliged to remit to Constan tinople, in order to secure the interest of friends at the Porte. To this circumstance is owing the nefarious practice of making avaniss upon the people, or raising money by false pretences, in order to supply the deficiency. According to M. d’Arvieux, the bashaw’s regular salary was 80,000 ducats, or above 8,300 £, of which 35,000 are allowed for the maintenance of his troops, confluting of 4 or 5000 men. But by extortions, presents, and other means, they raise their revenue to 200,000 ducats, or about 25,000 £. In 1760, the revenue of the bashaw fell short of 200,000 ducats, though avaniss were as common as ever. In 1783, Volney gives nearly the same account with d’Arvieux; but he mentions an instance of one bashaw, who, within 12 or 13 years, raised, by extraordinary extortions, in 15 months, 160,000 ducats.

A cadi, or judge, appointed by the Porte for one year, is sent annually from Constantinople, who brings with him his principal officer. A deputy, called Nabi, sits in the outer court, to hear inferior causes, while affairs of moment are decided by the cadi in person. There are three or four subordinate tribunals in different parts of the town, which are formed of the cadi by certain judges, who, under his authority determine petty suits; but from these an appeal lies to the superior court of the cadi, or the great Mahkamy, which is the name of the old palace, where he resides. The cadi has no established salary; but he finds means to raise a handsome revenue, though not merely from the legal pecuniaries of office, which, however, are very considerable. He has the appointment of all religious dignitaries; and he gives a fitwa, or an opinion, on all such cases that are laid before him; for which his fee is little more than a shilling. The nakub, or chief of the fereefs or greenheads, is nominated at Constantinople, and either annually confirmed, or changed. He judges in particular cases, and to his tribunal the fereefs are amenable. The mohaflil, formerly called ditter-dar, is reckoned the second person of the city in the civil line, and is usually appointed by the Divan, a temporary governor on the demise of the bashaw, till orders are received from the Porte. He is farmer-general of the land-tax, the customs, and the capitation-tax; his influence is extensive; he is much courted by the agas or land-renters, as well as by the merchants; and he lives splendidly. Volney states the mohaflil’s annual farm at 40,000/; besides 4 or 5000/. which he is obliged to pay to the officers at the Porte. The bashaw, mohaflil, cadi, muttia, nakub, and fardar or aga of the Janizaries are the officers, members of the Divan, or council. The Janizaries of Aleppo are mostly perfons who live in a domestic manner, in the exercise of their respective trades. They have no pay, but being enrolled in one of the odas or chambers at Constantinople, they enjoy in time of peace several privileges and exemptions. In war-time they are liable to be called out, and are obliged to provide themselves with arms, and to march to the camp at their own expense, as they receive no regular pay till they arrive there. Out of these is formed a city guard, under the command of the fardar, who holds his appointment from the Janizary aga of Constantinople. They have a peculiar dres, and the attendants of the fardar, when he appears abroad, as well as himself, are distinguished by particular turbans.

These Janizaries were formerly subject to regular exercise and discipline; but within the last 60 or 80 years, says Volney, there no longer remains the slightest trace of their ancient good order. When the bashaw or pasha abusés his authority, they are always the first to erect the standard of sedition. The Turkish government revenges itself, it is true, by ordering the most active mutineers to be strangled; but, on the first opportunity, the Janizaries create other chiefs, and affairs return to their usual course. The pachas, thus thwarted, have taken foreign soldiers into their service, who have neither friends nor families in the country. These are
of two forts, cavalry and infantry. The cavalry, who alone
merit the name of soldiers, allude for this reason the ap-
pellation of Doma and Delect, and likewise that of Delibahes
and Lawend, from whence we have formed Levanti. Their
arms are short fabres, pilots, millets, and lances. They
wear a kind of felt cap, nine or ten inches high, without
any projecting rifs; and their faces are made up in the Eng-
lish manner. In the rest of their clothing and accoutre-
ments, they resemble the MaMakers. Indeed, they are
more like banditti than soldiers, and frequently act as such.
Almost all the cavalry in Syria are Turkmans, Curds or Ca-
ranganians, who, after exercising the occupation of robbers
in their own country, seek employment and an asylum near
the perfon of the pacha; and they often lay waite the country
and pilage the peasants by open force. The infantry are
a corps in every respect inferior to the former. Within
the last 50 or 60 years, the peasants of Tunis, Algiers, and
Morocco, have, under the name of Mograbinians, or Men of
the Weft, fought employment in Syria and Egypt; and
theycompose the infantry of the pacha. Their whole
acoutrements and baggage are confined to a rufy firelock,
a large knife, a leathern bag, a cotton skirt, a pair of drawers,
a red cap, and fometimes flippers. Their pay is about 10s.
and 10d. per month, out of which they furnish themselves
with arms and clothing; but they are maintained at the
expenfe of the pacha. The pay of the cavalry is double,
besides which each horseman has his horse and ration, which
is a meafure of chopped straw, and 15 pounds of barley a
day. Thefe troops are divided by bairaks or colours, con-
ftifing of about 10 men each, under the command of an aga,
who reduces their number in order to purloin their pay.
The superior agas tolerate this abuse, and the pacha over-
looks it for the fake of the emolument derived from this
species of fraud.

On the demife of a baflhow, the mahaffil takes poftellion
of his effects till a capugi-baflhow, from Confiitantinopie, comes
to receive them in the name of the sultan. The ciftars of
merchants, and of other private perons, defend to the
heirs, agreeably to established laws, which allow a certain
portion only to be devifed by will, and the cadi is fuppoled
to fee frict jullice done to the heirs. The property of mer-
chants, strangers, who die in the public khanes, is fubject
to the infpefion and care of the mahaffi, who detains it
till it is claimed by the legal heir.

Crimes of a capital kind are very rare at Aleppo. The
ufual capital punifhments are hanging, beheading, ftrang-
ling, and impailing. Janizaries are ftrangled, not with a
bow-string, but by a cord put round the neck, and then
twifted with a ftick in the manner of a tourniquet. The
bodies of all who are executed remain for fome days ex-
pofed to public view. Theft is uncommon; when it oc-
curs, it is fometimes punifhed by amputation of the hand,
but more commonly with the baflmado, which is performed
with rods about the fize of a small walking-flick; and this is
the ufual punifhment for offences of an inferior kind.
Banifhment to the island of Cyprus, and the maritime towns
of Syria, is chiefly employed for removing turbulent mem-
bers from the city or the divan.

The agas are thofe who chiefly farm the lands; and the
peafants are entitled to one-third of the produce, from
which are annually deducted a part of what may have been
advanced by the aga to flock the farm, and also a certain
proportion of the avanias, that are from time to time im-
pofed on the villages. Thefe peasants are fimply clothed,
differently lodged, and live chiefiy on coarse bread, leban,
or a preparation of milk, pufle, barley, and melons; but
feldom take animal food. However, habit and ignorance
mitigate the rigour of their condition, which they bear with
patience, exerting out of the fnappy pittance of the fruits
of their labour, a spirit of hospitality.

The Europeans, or Franks, as they are called, refiding
at Aleppo, are Englifh, French, Venetian, Dutch, and
Teufcan, or Imperial fubjects. The language in common
among the Italian. The Englifh factory confis of a con-
furl and 10 merchants, a chaplain, chancellor, phyfician,
and an officer named a chaplain, who walks before the conf-
ful, carrying a staff tipped with silver, and takes care of
all letters and dispatches. The number of English houfes
in 1773 was reduced to four, and in 1783 to two. There
are two druggarmans or interpreters, Greek natives of
Aleppo, who fpeak the Italian, but can seldom read or
write any other language, besides the Arabic and Turkish.
They have salaries from the Levant company. Two ja-
nizaries are alfo kept in confinant pay, who attend at
the houfe of the conful, and walk before him when he goes
abroad. The French factory is more numerous than the
Englifh, each merchant having a clerk or writer, or a per-
fon under that title, who afterwards becomes a partner in
the houfe. The reidence of the French in the Levans
is limited to a certain number of years, after they take
the name of factors or merchants, and they are therefore
fent early in life from Marfelles, under the denomination of
Scrvains, and they evade taking the name of factor after
they have a fhare in the bufinefs, that they may pro-
long their fay in the country. The number of French
houfes of trade was reduced in 1772 to fix, or feven, the
number in 1783. The conful has his chancellor, chapaf,
and janizaries, and maintains the fame flate with the Eng-
lish conful; but he has precedence on all public audiences,
on account of the prior eftablfhment of the French factory
at Aleppo. Under the protection of the conful are two or
three French furgeons, who praftife phyfìc; the drug-
garmans are French fubjects of the Levant, or native
Frenchmen. Besides the merchants, a number of French
fubjects find their way here, and by intermarriage with the
native Chriftians, produce a half French race, called mezza
ræa. There are four convents, under the protection of the
French conful. The Dutch conful, being the fole perfon of that nation at Aleppo, exercised the fame
poffefion of a merchant; but the Englifh and French con-
fuls are prohibited engaging, directly or indirectly, in com-
merce. However, since the year 1772, the Dutch conful
has regular appointments, without benefit of trade. The
Venetians were eftablfhed at Aleppo before any other
European nations. For several years preceding 1751, the
Venetians had no conful, but they, as well as the Tuufcans,
were under the protection of the French or the Englifh;
but foon after 1754, a conful of their own nation came to
refide at Aleppo. The emperor appointed a conful there
in 1784, who was a rich Jew merchant, and who faved
his beard to affine the uniform and the sword: Ruffia
has also very lately fent one. The houfes of the Franks are
as commodious as their situation in the khanes will admit;
and their tables are well fupplied. Although they have
little or no focial intercoufe with the Turks, they live
together in harmony. The English gentlemen keep ex-
cellent houfes, and ufually take an airing every day; in
the month of April they retire to the gardens, in the vi-
cinity of Babullah, where they refide till towards the end
of May, coming to town for buifinefs in the morning, and
returning at night. The French natives at Aleppo are
equally protected by government, and they enjoy confider-
able privileges. The confular houfes are refpeoted as san-
cuaries: the officers of jullice cannot enter the houfes of
private
private merchants without permission; the custom on goods is very favourably rated; and in all suits at the malkanya court, above the amount of an inconsiderable sum, they have a right to decline the competency of the court, and to remove the cause to Constantinople. In consequence of the regard publicly paid by the government to the repairs, they are commonly treated with civility by people of all ranks.

The Christian inhabitants at Aleppo are said by Ruffell to amount to 35,000; of which number the Greeks compose 15,000; the Armenians 7,500; the Syrians 37,500; and the Maronites 3,030; and the remainder consists of strangers, occasionally resident in the city. Each of the four Christian nations has a church, and enjoys perfect toleration under the Mahomedan government. The Greek nation was once opulent and flourishing; but it has long declined, and is now reduced to a very low condition. This decline is ascribed partly to the decay of commerce, and principally to the contests that have fulfilled between those who adhere to the patriarch of the Greek church, and those who acknowledge the supremacy of the pope. The Greek language is almost obsolete at Aleppo. The ARMEANs are divided into two parties, the orthodox and the schismatic; besides their own language, they speak the Arabic and Turkish; but their church service is performed in the learned Armenian, which is different from the language vulgarly spoken. The Syrians of Aleppo are mostly reconciled to the Roman church. The MARONITES are more connected with the Franks than the other sects. They acknowledge the supremacy of the pope, and have added many rites borrowed from the church of Rome to their own. Divine service is performed in Arabic. The native Christians have no monasteries at Aleppo, but contribute towards the support of several in ancient Lebanon and its vicinity. For the regulation of expenses, and the transact of business at the seraglio, each of the Christian nations has a public agent or wakal; who, being elected in an assembly of the principal persons of the respective nations, is confirmed in his office by the baiwak, and invested by him with a police as a mark of honour. The turban usually worn by the Christians, differs somewhat in form from that of the Turks, and the feilk is blue and white striped; their flipper are red, and their drees is upon the whole, more plain. In the mode of eating, they generally imitate the Turks. Their women, when they appear abroad, wear a veil of white linen, and keep more at home than the Turkish ladies. They are extravagant in the article of drees, which varies in some circumstances from the Turkish fashion. They are more formal in their address, and their counterfeit borders too much on servility. The men are generally rather fawning than affable; but those in civil circumstances are hospitably social. Thofe of them who have obtained protection, under the appellation of honorary interpreters, are distinguished by a peculiar furred cap and yellow flipper.

The computed number of Jews at Aleppo, says Ruffell, is about 5,000. They have one synagogue, which possesse a MS. of the Old Testament, which, as they pretend, is of high antiquity. For its antiquity, they urge the concurrent tradition of their rabbis, and their submission to its authority in disputed passages, and also a prayer at the end of it for the preservation of the temple; from which they conclude, that it must have been written before the expedition of Titus; their prayers afterwards having been offered up for the restoration, and not the preservation of the temple of Jerusalem. A specimen of this MS was examined by Dr. Kenyon, who did not find sufficient reason for attributing such high antiquity to it as the Jews do. The Jews are distinguished by their violet-coloured babouche, and their turban, which is lower than that of the Christians. Few of them apply either to manufactures, or to worldly trades; most of them are bankers or merchants; the others are brokers, grocers, or peddlers. The established banker of the seraglio is a Jew, and the private bankers of most of the grandees are likewise Jews. The Jews are generally more sober than the Christians. The lower people live chiefly on bread, pulses, herbs, and roots, dressed with the expressed oil of fesmum; and they are of all people the most cleanly and dirty. Some of them are handsome, but the proportion of such is small. Their head drees differs considerably from that of the Turkish and Christian ladies; and is commonly richly decked with pearls. Their boots and flippers are of a violent colour. Their veil is white, and in the presence of strangers they always wear it.

The chief priest of the Jews is, by way of eminence, called the Khakan; and the priests are distinguished from the other Jews, by the size and colour of their turban, and by the inferior plucks of their outer garments. The khakan exercises temporal as well as spiritual authority, and his decisions are generally more respected than those of the bishop are by the Chirilians, but his civil jurisdiction is very limited.

The rate of literature at Aleppo is much degenerated from that of ancient times, when it was more respectable. There are indeed public day-schools adjoining to some of the principal mosques, but their colleges for students in advanced life are few in number, and poorly encouraged. They are more properly seminaries of pedantry and superstition than of science; and they are chiefly frequented by the children of the poorer classes, who dedicate themselves to the service of the mosque. Grammar and school-divinity are the subjects chiefly taught at college. The offenders, who assume an appearance of respect for learning, have no liberal notion of science. Astronomy, which was once a favourite study among the Arabs, is at present wholly neglected. Although they have books on the subject in their libraries, and some instruments, yet few is little is known of the science at Aleppo, that a person who is found capable of calculating eclipses, has, on this account, the reputation of a most profound astronomer. Almanacks are seldom constructed at Aleppo, but are brought thither from Constantinople or Cairo. As to mathematical studies, they are little attended by the modern Arabs; nor have natural history and the experimental part of philosophy made any progress amongst them for several centuries. History is little regarded by the literati at Aleppo. Their knowledge of distant states, and of the revolutions of empire in the western world is very partial and imperfect; and even their own history, before the appearance of their prophet, remains in great obscurity. Their geographical knowledge also lies within very narrow bounds; nor have they any good maps, except such as have been imported from Europe. Superstition has banished painting from Syria; and music, degraded by fashion to a mercenary profession, is rather tolerated than encouraged; poetry, which was formerly much cultivated among the Arabs, has very perceptibly declined and languished; and that the modern Aleppo bards never attempt any performance beyond a dirge, a ballad, or an epigram. Although the medical practitioners at Aleppo are numerous, their knowledge of medicine is superficial, perverted by prejudice, and accompanied with pedantic affectation, arrogance, and obstinacy. A very competent judge affirms their general practice to consist in specious trifling. Their knowledge of anatomy
ALEPPO.

is acquired by reeling, and not from digestion; and both anatomy and physiology remain precisely in the state in which they were transmitted by Galen. Their ignorance of the circulation of the blood leaves them quietly in possession of the ancient doctrines, which were held sacred before that important discovery. With a copious Materia Medica, and a large collection of compound remedies, their practice is confined to a few official preparations. The precious stones, pearls, bezant, and leaf gold, are in high esteem. The principal cords are the confessions of Alkinemes and Hyacinth. The few chemical preparations that are in use are brought from Constantinople, and the Aleppo pharmacy is chiefly confined to the distillation of simple waters, and the preparations of syrups, confections, and decoctions; for spirituous waters, tinctures, and elixirs are proscribed by the law of Mohammed. Some few individuals, however, are to be found, who are not only more learned, but in their practice sagacious, active, and rational; and who, allowing for the disadvantages under which they labour, are entitled to merit in their profession. Surgery is less cultivated than physic.

Of the quadrupeds found in Aleppo and its vicinity, we may mention two varieties of the cow, buffaloes, two varieties of sheep, as many of the goat; wild hogs, gazelles or antelopes; two farts of hare, the hudge-hog, the jerboa; four varieties of the camel; three varieties of the ass; various breeds of mules, horses, dogs, cats, varieties of mice, the mole, two varieties of bats, foxes, and wolves; an animal called the fheeb, the hyena, the lynx, and the panther. The markets of Aleppo are plentifully supplied with poultry; the cock and hen, turkeys, geese, ducks and pigeons. They have also abundance of game in the different seasons, &c. Dr. Ruffell has given an ample catalogue of the ornithology of Aleppo. The confpicious situation of Aleppo brings thither a great number of sea-birds, and affords the curious a singular amutcment. If, from the terraces after dinner, a motion be made of throwing bread, numerous flocks of birds which were floating in the air, at a height which rendered them invisible, will descend and fly about the place: having been accustomed to receive morsels of bread which have been flattered for amusement. For an account of the carrier-pigeons of Aleppo, see Carrier-pigeon.

The river Kowick supplies several species and varieties of fish; but it does not afford a sufficient quantity for the Aleppo market: so that the Christians, in their great lents, are supplied from the rivers Orontes and Euphrates, from the lake of Antioch, and also from another lake near Marath. Amongst the reptiles, we might enumerate the frogs, which abound on the banks of the Kowick, and from the croaking of which it is said to have derived its name. These are of a large size, and so delicious, that some European epicures have declared it was almost worth while to make a journey to Syria, for the sole purpose of regaling on them. The Kowick also furnishes a particular kind of crab (cancer fluviatilis) which is much esteemed. This river likewise affords tortoises in abundance. The silk-worm is a molt material object to Syria, being the chief source of its commerce with Europe. The bee is also of great importance, on account of the consumption of honey and wax. Among the noxious animals, the scorpion is the principal. The scolopendra, snakes, and serpents, are found in Aleppo and its vicinity. Few hares are exempt from bugs, fleas, and m Mpilipes. The common fly and horne fly are troublesome; but of the insect tribes, the locust is the most dreadful in its depredation; this lets all the defensive arts of man at defiance; and destroys, in a few days, the beautiful verdure of extensive tracts of cultivated country. Dr. Ruffell has given a catalogue of the reptiles, serpents, insects, and worms that are found in this country, and also a catalogue of Aleppo plants, with apposite remarks.

The epidemical diseases most prevalent in Aleppo are continual fevers, intermittent and remittent fevers, regular and anomalous, eratic fevers, commonly attended with diarrhoea the gangrene, quinsy, pleurisy, peripneumony, rheumatism, and ophthalmia. The sporadic and chronic diseases are, with few exceptions, nearly the same as in Britain. Tho' which are most common at Aleppo, are pulmonary complaints, spitting of blood, and consumptions, obstructions of the abdominal visera, cachexy, jaundice, dropsy, inguinal ruptures, the hemorrhoids, and worms. The inca is common, and various other cutaneous eruptions; but the true or confirmed leprosy is now become obfolute in Syria. The venereal disease is also very common in this country. The Europeans soon after their arrival at Aleppo are subject to a fever, which has been distinguished by the name of loca or gofe. The disease attacks but once; and the English are rather more liable to it than the Provençals and Italians. The natives of Aleppo and European strangers, after some residence here, are subject to a singular kind of eruption; which from the supposed time of its duration, is denominated the botch of a year, or the ring-worm or pimple of Aleppo; but by the Europeans and Turks, it mal d'Allephe, the Aleppo evil, and the Aleppo ulcer. No part of the body or limbs is exempt from this eruption, but it most commonly fixes on the face, and leaves a scar, with which almost all the inhabitants are disfigured. Volney suspects that it proceeds from the quality of the water. Dr. Ruffell has particularly described it; and he observes, that the mercurial plaster was the most efficacious remedy. The most calamitous and destructive disease to which Aleppo and its vicinity have been subject is the Plague. The means which are practised by the Europeans for their preservation, confine either in a retreat from the city, or in fluctuating themselves up in their town-houses, in such a manner as effectually to prevent all intercourse or communication, by which the infection might be received from without. Besides the common regulations adopted by the Europeans at Aleppo, and which have the sanction of long experience, Dr. Ruffell recommended some further precautions, which we shall here transcribe for the information of those who have no access to his comprehensive and valuable work. The spirit of these precautions, as in the general regimen of life, to guard against excels of all kinds, violent passions of the mind, and immoderate evacuations. 2. In respect to diet, not to live more sparingly than at other times, nor to lessen the quantity of wine; perhaps one or two glasses extraordinary might rather be beneficial; and the free use of acid liquors (such as very weak four punch) was in the summer, found not only grateful to the palate, but laudatory. 3. Never to venture abroad in the morning fasting. 4. When in the chamber of the sick, or in passing near a corpse, or any thing suspected of infection, carefully to avoid swallowing the saliva; and, at the same time, to breathe through the double folds of a handkerchief moistened with plain vinegar, or vinegar impregnated with rue. 5. To refrain inspiration as much as possible, while employed in examining the pulse, or such other circumstances of the sick as require drawing close to the bed; and upon coming out of the chamber, to wash the mouth, face, and hands with vinegar. 6. On the return home, after visiting the infected, or passing through the Bazaars, to undress and expose the clothes in the open air; and before dressing in fresh clothes,
to wash once more with vinegar. 7. The only preservation used internally was a large dose, twice a day, of extract of bark; drinking after it a draught of wine and water, acidulated with elixir of vitriol. These precautions, observed by the doctor himself, were attended with success.

Aleppo, slightly defended by the ruined walls and towers of its castle, and exposed to the approaches of assailants by the rising grounds that environ it, is a place of no importance in time of war, though it be the key of Syria to the north; but, considered as a commercial city, it is the emporium of Armenia, and the Diarbekir; sends caravans to Baghdad and into Persia: and communicates with the Persian Gulf, and India by Basra, with Egypt and Mecca by Damascus, and with Europe by Scanderoon or Alexandretta and Latakia. Commerce is here principally carried on by barter. The chief commodities are raw or spun cotton, coarse linens, manufactured in the villages, silk stuffs, manufactured in the city, copper, coarse cloths like those of Rousen, goat's hair, brought from Natolia, the gull-nuts of the Currclitan, the merchandize of India, such as shawls and muslins, and pilchard nuts of the growth of the neighbouring foundation. The articles supplied by Europe are the Languedoc cloths, cochineal, indigo, fagari, and some other groceries. The coffee of America, though prohibited, is introduced, and serves to mix with that of Mocha. Ruffell's Natural History of Aleppo, 2 vols. 4to. 1794, p. 159, &c. For the coins, weights, and measures of Aleppo, see Syria.

Aleppo, old, now Kinsasleen, the ruined remains of the ancient Chalced, of which there are vestiges of the foundation of walls without a single house standing. This ancient city surrendered on capitulation to the Saracens, in the 17th year of the Hegira, A.D. 678, soon after their invasion of Syria.

Aleppo, Bashawlick or Pachalic of, one of the five pachalics of Syria, is a province of great extent, reaching eastward from the bay of Scanderoon to the banks of the Euphrates, and from 40 miles north of the city, extending about 50 miles to the south-east. But it is not now nearly so extensive as it was in former times. Klillis, which was formerly dependent on Aleppo, is erected into a distinct province, on account of the frequent depredations of the Kurdeens, who inhabit the neighbouring mountains; and since the year 1752 an alteration has taken place with respect to Bylan, which, together with Caramoot, Scanderoon, Byas, and the adjacent mountains, has been put under the government of a native of Bylan, who for that purpose was created a baflaw of two tails. At present the pachalic on the north is bounded by the village Bawlil, situated in the road to Aintab, eastward, by the Defert, Bab at the distance of ten hours east-north-east, and Haglah, about the same distance to the south-eastward, being among the last inhabited villages: on the south it is bounded by the Great Defert, between the skirts of which and the west, or west north-west, are situated the most fertile and populous parts of the forel. Sirmecn is the latt town southward; and Antioch, with its dependencies, may be reckoned the western boundary, which, till a late period, reached to the sea; Scanderoon and Byas being then the two frontier maritime towns. About one half of the villages which flood formerly on the books of the province, are said to be totally deserted. Many of the inhabitants of this mountainous tract acknowledge fearlessly any authority but that of their own chieftains; and the champaign, in many places, is either desert, or only occupied tranfiently by the wandering tribes of Turkmans, Begdeelees, and Ruffians, from the north, or by the Bidowenees and Chingana; who, though they pay an annual tribute, can hardly; in other respects, be reckoned subjects of the province. The oppression of the agas, the destructive marches of the grandees through the province, and the roving of the ruffian troops of Lev- vends out of pay, oblige the peasant tenants to remove; so that vast tracts of the beautiful plains in the bahawlick are shamefully overrun with thieves, whilst the mountainous parts, better secured from oppression, are finely cultivated, full of people, and present on every side thriving hamlets.

Such is the account given of this pachalic by Dr. Ruffell. Volney describes it, as extending from the Euphrates to the Mediterranean, between two lines, one drawn from Scanderoon to Beer, along the mountains, the other from Beles to the sea by Mare and the bridge of Shogar, and as confining two plains, that of Antioch to the sea, and that of Aleppo to the sea: the north and sea coast being occupied by considerably high mountains, known to the ancients by the names of Amnum and Rhusos. The soil of this pachalic is generally fat and loamy; the greatest part of the lands lies walle, and the traces of cultivation are scarcely discernible in the environs of the towns and villages.

Those European merchants, who have resided at Aleppo 20 years, have witnessed the depopulation of the greater part of the environs of the city. The traveller sees nothing in this and other pachalics of Syria, but houses in ruins, cisterns rendered useless, and fields abandoned. Those who cultivated them are fled into the towns where the population is absorbed, and where the individual conceals himself among the crowd from the rapacious hand of despotism. Its principal produce consists of wheat, barley, and cotton, which are found in the flat country: in the mountains they cultivate the vine, mulberry, olive, and fig-trees. The sides of the hills, towards the sea-coast, are appropriated to tobacco, and the territory of Aleppo to pilchards. The pasturage is abandoned to the wandering Turkmen and Curds. For other particulars, see the article of ALEPP. Ruffell's Hist. vol. i. p. 314. 339. Volney's Travels, vol. ii. p. 130, &c.

ALER, a river of Siberia, which joins the Atiga at Alex- urka.

ALERE, Arvantes, in Ancient Geography, a city of Gaul, belonging to the Bituriges Cubi, and placed by M. d'Anville between Ernordum and Argentomagus.

ALERIA, a town of Corfica, situated on an eminence on the east side of the island, near the mouth of the river Rotanus, according to Ptolomy. Herodotus (lib. i. c. 165. p. 78.) mentions it under the name of Alalia, and says it was founded by the Phocæans. Diodorus Siculus (lib. v. c. 13. tom. i. p. 340.) calls it Kapia, Calaris, and says it was built by the Phocæans. Sylla established a colony in it, and, on this account, has been represented as its founder. It is now in ruins, and altogether abandoned on account of its unhealthy situation, though in former times it has been a con- siderable city, and the fee of a bishop.

ALERION, in Herod. See ALLERION.

ALES, Alexander, in Biography, a divine of Augsburg, was born at Edinburgh, April 23rd, 1500, and having made a considerable progress in the school of divinity, engaged in the controversy of the day against Luther. He also took part in the dispute with Patrick Hamilton, and endeavoured to prostrate him to the catholic religion; but in the progress of the conference, he himself began to entertain doubts, which were increased by the confinacy of this Scotts martyr at the stake. The persecution he suffered drove him into Germany, where he was at length converted to the protestant faith. Encouraged by the national change of religion, which took place on the marriage of Henry VIII. with Anna Bullen, he removed to London in 1535; and here he was highly esteemed by Cranmer, Latimer, and Thomas Crom- well,
ALESA, Aleso, or Alesa, in Ancient Geography, a very ancient city of Sicily, built, according to Diodorus Siculus (lib. xiv. c. 16. tom. i. p. 651.), by Archonides of Herbs, about the 2d year of the 94th Olympiad, or 403 years before Christ. It flood, he says, upon an eminence, about eight stadia from the sea; near the place, as Fazelles conjectures, where the city of Caronia now stands, on the river Aleus, or Fundi di Catania. The inhabitants were called Alefini and Helefini; and, as Diodorus and Cicero inform us, were exempted by the Romans from taxes. Near Alcusa a fountain, which, as Solinus pretends, used to bubble up at the foot of a fluted, so that it could not be kept within the basin.

ALESANI, in Geography, a town of Corsica, in the department of Golo, and district of Corte; the canton contains 2560 inhabitants.

ALESBURY. See AYLESBURY.

ALESENI, in Ancient Geography, a people of Arabia, whom Strabo places in Babylonia towards the Persian gulf.

ALESHAM, or AYLSHAM, in Geography, a town of England, in Norfolk, near the river Yare; 12 miles north from Norwich, and 121 north-north-east from London.

ALESA, or, as it is sometimes written, ALEXIA, in Ancient Geography, a considerable town of Celtic Gaul, belonging to the Mandubii, situated, according to Caesar (Bell. Gall. lib. vii. c. 68.), on a high hill, washed on two sides by two rivers, and of such antiquity, that Diodorus Siculus (lib. v. c. 24. tom. i. p. 349.) ascribes the building of it to Hercules in his war against Geryon. It was so strongly fortified, that when Caesar besieged and took it, Velleius Paterculus represents the undertaking as more the work of a god than a man. After Caesar destroyed this city, it was rebuilt, and maintained a considerable rank under the Roman empire. Pliny (H. N. tom. ii. p. 660.) says, that the art of filering the ornaments of hofe was invented in this city. It is supposed to be the present Alpe. The mountain on which it flood is said to be Mount Auxois, which is 100 toises high, and the foot of it is washed by two rivers, viz. the Oze and the Ozeain.

ALESIAS, a village of Laconia, in the road from Therapae to Taygetas, where, as Paunianus informs us (lib. iii. Lacon. c. xx. p. 260.), Myles, the son of Lelx, first taught the art of grinding corn by a mill; and where an heroic monument was erected to Lacedemon, the son of Taygetas.

ALESIUM, a town of Greece, in the interior of the country, at some distance south-west from Elis.

ALESONE, in Geography, a town of European Turkey, 20 miles north-west of Larissa.

ALESONNE, a town of France, in Languedoc, in the county of Toulouze, and diocese of Lavaur.

ALESSANDRI, Felice, in Biography, a young Italian composer, the husband of signora Guadagni, the original buone Figlina. He felt two comic operas of considerable merit for our stage; but Piccini's reputation flood too high, that the public unwillingly listened to any other. He went very young from Naples, where he had his musical education, to Turin, where he remained two years in the service of that theatre; and after continuing four years at Paris, he removed to London. His natural and easy style afterwards established his reputation all over Italy; and we find him composing for the greatest singers in the principal capitals of that country.

ALESSANDRIA. See ALEXANDRIA.

ALESSANO, a small town and bishop's see of Naples, in Italy, in the district of Otranto; 13 miles south-south-west of Otranto. N. lat. 40° 12' E. long. 18° 14'.

ALESSI, Galleazzo, in Biography, a famous architect, was born at Perugia, in 1530, and arrived at such eminence, that he was applied to from France, Spain, and Germany, for plans of public buildings. His plan for the monastery and church of the Eccoli was preferred to those of the ablest architects in Europe. Genoa has acquired the denomination of superf, partly from the buildings which he has erected in it. He died in 1572. Nouv. Dict. Hist.

ALESSIO, Alessio, or LISSUS, in Geography, a town of European Turkey, in Albania, on the Adriatic gulf, near the mouth of the Dain, and 16 leagues south-west of Albanopolis. This is the seat of a bishop, suffragan of Durazzo; and it is famous for having the tomb of Scanderbeg, king of Albania, who died in 1467. N. lat. 41° 45'. E. long. 29° 29'.

ALESUS, in Ancient Geography. See Alessio.

ALESUS, Sanginaria, a river of Italy, in Emilia.

ALEX, Lat. Alcena, in Electri, in Geography, a city of France, in the department of the Aude, and district of Limous, situate at the foot of the Pyrenees, on the river Aude. Before the revolution it was the seat of a bishop, suffragan of Narbonne, and the diocese contained 80 parishes. It is 14 leagues south-west of Narbonne, and 175 south of Paris. N. lat. 42° 57'. E. long. 2° 6'.

ALETA, in Ancient Geography, a town of Dalmatia.

ALETON, signifies meal, as Eroten and Hephchus explain it. It seems derived from ale, to grind, and to import the meal of any fort of corn. The word is frequently used by Hippocrates.

ALETRIS, formed from Aletris, or ale, to grind, in Botany, a genus of the section monogynia, chiefly of the natural order of ilicif or iliacae, the coronaria of Linn. and aphellis of Jull. Its characters are, that it has no calyx; that the corolla is one petalled, ovate-elongate, hexangular, or ovoid-shaped, semilong, much wrinkled, the divisions lanceolate, acuminate, spreading, erect, and permanent; the stamens have the awl-shaped filaments of the length of the corolla, inserted into the base of the divisions, the anthers ob-long and erect; the pistillum is an ovate germ, the style fructulate, the length of the flaments, and stigma triloculare; the pericarp is an ovate, three-cornered, acuminate, three-celled capsule; and the seeds are very many. Professor Mar- tyn enumerates eight, and Gimelinn nine species, viz. 1. A. fritrina, American A, fritenka, leaves lanceolate, membranous, flowers alternate, which grows in North America, and was cultivated here in 1768, by Mr. Miller. The natives frequently use it as a beech and incisive in coughs and in the pleurisy. 2. A. capen, waved-leaved A, with imia of Gleditchens, fritenka, leaves lanceolate waved, spike ovate, flowers nodding; a native of the Cape of Good Hope, flowering with us from November to April, and brought here in 1768, by Mr. W. Maclellan. 3. A. aevu, aloe uvaria of others, great orange-flowered A, fritenka, scape longer than the sword-shaped keeled leaves; a native of the Cape of Good Hope, cultivated at Chelsea in 1757, and flowering in August and September in large spikes.
of a fine appearance. There is a variety with narrower leaves, and longer spikes of flowers. 5. A. punicea, small orange-flowered, A. itemels, scape shorter than the linear sharply-keeled leaves; a native of the Cape, introduced in 1774, and flowering from September to November. 6. A. heinrichii, items, leaves lanceolate, linear, fleely, flowers germinate; having two varieties, reckoned by La Mare as distinct species, viz. A. zebrina. Ceylon A. or, alone, with one of the leaves subulate and compressed: and A. guineensis, Guinea A. or, alone, with all the leaves lanceolate, of which the cut katap of Rheed is considered by La Mare as a variety. The first of these is common in gardens, where exotic plants are preserved; the second was cultivated here in 1690; its flowers, which ascend its whole length, are of a clear white, but full do not continue in beauty more than two or three days; and it never produces seeds in England. 7. A. fragrans, sweet-scented A., cauliflous, leaves lanceolate, bode; found in Africa, and cultivated in 1763 by Mr. Miller. 8. A. cochinchenfos, cauliflous, leaves lanceolate-linear, reflex, flowers pendent; cultivated in the gardens of Cochinchina, in which it is a native; the juice of the leaves are used to dye green, and the flowers are eaten. The eighth species is A. japoica. A. itemels, with leaves petiolate, ovate lanceolate, seven-nerved, and spined flowers. The ninth species is A. aurea. The second, third, fourth, and fifth species are referred by Wildenow to the genus Feltheimia.

Culture. The first species may be preferred through the winter under a hot-bed frame. The roots of the second kind must be planted in pots filled with light earth, and sheltered in winter in a dry airy glass case. In May they may be placed abroad in a sheltered situation, and often refeshed with water in wet weather. The fourth is sufficiently hardy to live abroad in mild winters, when planted in a warm border and dry soil. It is propagated by seeds, sown in pots, and transplanted under a hot-bed frame; the plants, when they come up in spring, should be gradually exposed to the open air; and when they are large enough, some may be planted in pots, and others in a warm border, where they should be sheltered during the ensuing winter. The Ceylon, Guinea, and sweet-scented species are too tender to live through the winter in England, unless they are placed in a warm house: and they will not produce flowers, if the plants are not plunged into a tan bed. The creeping roots of the Ceylon and Guinea sorts send up many heads, which should be cut off in June, and, after having been laid in the stove for a fortnight, that the wounded part may heal, they should be planted in small pots of light sandy earth, and plunged into a moderate hot-bed of tanner’s bark, giving them but little water till they have put out good roots; they should then be treated like other tender succulent plants, and be never set abroad in summer. The seventh species is easily propagated from the seed heads, which it puts out after flowering.

ALEF, Guich-Alet, in Antiquity Geography, a town of the Gauls, mentioned in the Notitia Imperii, and placed by M. d’Arville upon the sea-coast, north-west of the territory of the Rhedannes. It was formerly a bishop’s see, which, in the 12th century, was transferred to St. Malo, about a mile from it.

ALEVISA, in Geography, a river of Siberia, which runs into the Penzincsof sea. N. lat. 63°. E. long. 157° 14'.

ALEURITES, Alwagi, farinaceus, of Alwagi, meal, parts of the tree having a meal scattered over them, in Botany, a genus of the monocica monandrophila class and order, of the natural order of trinices, and euphorbe of Jussieu: the characters of which are, that the flowers are male and female: the calyx of the male is a perianthium, three-clawed, very short, the clefts ovate and obtuse; the corolla has five petals, oblong, spreading, obtuse, much longer than the calyx; the nectary has five leaves from what corned, very short, at the bases of the petals; the stamens are numerous filaments, connate into a columnar receptacle, the anthers round, the female flowers are few, in the same column; the calyx, corolla, and pistilium, 22 in the male, but larger; the pistilium has a gern conic superior, the style none, the stigmas two, very short; the pericarpium a large, globoid, two-seeded berry; the seeds are two, globoid, coated with a double bark. There is one species, viz. A. triplata, which is a tree of the islands of the South Sea.

ALEMOROMANCY, Aleruromancy, derived from Aleruon, meal, and uro, divination, in Antiquity, is the same practice as that was otherwise called Alphitomancy and Cthomantia, and means an ancient kind of divination by means of meal or flour.

ALEURSA, in Geography, a town of Siberia, on the confluence of the Aygila and Aler, 64 miles north-east of Nertchina.

ALEUTIAN, or Alleutsk Islands, a group of chains of islands, on the north-east of Kamtschatka, and near the continent of America, belonging to Asiatic Russia. These islands were partly discovered by Behring in 1741, and the rest at several periods since his time. The most considerable of them amount to 40 in number, and they may be justly considered as a branch of the Kamtschatka mountains continued in the sea. Some have erroneously included Behring’s island and the Copper island in this group; but they are usually distinguished from them. South east of the Copper island, within 150 or 200 versts between the 5th and 55th degrees of north latitude, lie three small islands, known by the names of Attak, Strenya, and Semitsk; and these, with a few others, were denominated by the Russians Aleutskis Otoya, because a bold rock, in the language of these parts, is calledAleut. In the sequel this name was extended to the whole chain; though a part of it, namely, as far as the island Yamburg, is named the Andreansksot, and the rest lying further towards America, the Fox island. The Russian charts divide the long Archipelago, known under the name of the Aleutian and Fox-islands into serveal Archipelagos under different names. On the Aleutian islands, and on upwards of 300 leagues of coast, which extend beyond the polar circle, the indefatigable Russians have formed those numerous settlements or factories that support the fur-trade, from which the empire of Russia derives such great advantages in its commercial concerns and exchanges with the empire of China. This Archipelago, known, in the most extensive sense, by the collective name of the Aleutian-islands, forms with the north-west coast of America, and the north-east coast of Asia, a large basin of about 1,200 leagues in circuit, which communicates towards the north with the great Boreal ocean, by as many islands as the islands form channels between them; and towards the south, under the 60th parallel, with the Arctic Frozen Ocean, by Behring’s island alone. The survey of these islands, more accurately discovered by the Russians, and of the adjacent parts of the two continents, was made by captain Cook in his third voyage in 1778. If the Russians, then, can deftively claim the priority of the discovery, no one can withhold from the adventurous and persevering captain Cook, the glory and the merit of having fixed the distance of the two continents, and their respective extent, to the east for Asia, and to the west for North America; and, by his researches and observations, of having opened a career to the navigators of the European nations, who should be deftulous of avoiding themselves the benefits which the discovery of these coasts presents to the speculations and enterprizes of commerce. We shall add, that in ascending towards the north-west, Cook made Behring’s
ring's Mount St. Elias towards the latitude of 60° 30'. He anchored in a large bay, which he named Prince William's Sound; and thence steering again to the south-west, he discovered and ascended a river, on which, after his death, the gratitude of his nation implanted the name of Cook's River. He then coasted the east shore of the peninsula of Alaska, and touched at the island of Oonalashka, which is separated from the south-west point of the peninsula only by the island of Onosemak: these two islands are the nearest to the continent, and the most eastern of that Archipelago, or long chain of islands of various sizes, which extends from east to west, on a line bending towards the south, to within 350 leagues of the main land. If we consider Behring's island as the extremity of the chain, Capt. Cook extended his course into the north of Behring's bay, and made alternately the coasts of America and Asia; in the former he perceived the outline of a large bay, which he called Bristol Bay; and standing toward the middle of the bay, he saw the Matwia island of the Russians, which he named Gore's island, and further to the northward he distantly perceived the island called Clerk's Island. To the east-north-east of these, on the continent of America, he discovered Norton Sound; he then passed Behring's Strait, and advanced into the Arctic Frozen Ocean, as far as the parallel of 70° 44'. A plain of ice obstructed his progress nearer towards the pole. Here he might stay with the best Regard, when he reached the northern rocks of Lepland:—

"His tandem flatus nosis ubi definit orbis."

From comparing Cook's progres with those of Captain Phipps it appears, that the ocean is navigable much further towards the north, between Europe and America, than between America and Asia; for Captain Phipps, in his "Voyage to the North Pole," reached very near the Sirt parallel, whereas Captain Cook could not penetrate beyond the latitude of 71° 10'. See M‘Chand’s Voyage round the World in 1795, 1796, and 1797, by Fiercur. vol. i. Introduct. p. 46. A Russian expedition for making discoveries in the north-east sea was proposed by Catherine II. in 1784, and the co-shd of it entrusted with Capt. Belling, an Englishman, Capt. Behring: the grant of the Behring already mentioned, and some others. After wintering at Kamtschatka, these navigators explored, in the summer of 1796, the whole chain of the Aleutian islands, which seem to be of volcanic origin; and they proceeded to explore the large eastern islands explored by Capt. Cook, Oonalashka, and Kekichak, the bay of Cape St. Elias, &c. and returned to winter at Kamtschatka. In the summer of 1797 they renewed their search for a northern passage through the Frozen Ocean, and purposed their route from Gore’s and Clerk’s islands to the continent of America. From the account of their expedition, published at Gottingen by Blumenbach, we learn, that a principal ornament of the ladies of the Aleutian islands consists of a pair of the long tubks of a wild boar, cut down to a smaller size, which are stuck into two holes, one on each side of the under lip, from which they project, and give the wearer an appearance similar to that of the Walrus; and this is considered as a beauty almost irresistible. In these islands, when they were first discovered, more than 60 families were found, whose language had no relation either to that of Kamtschatka, or to any of the oriental languages of Asia; it is a dialect of the language spoken in the other islands adjacent to America, which seems to indicate that they have been peopled by the Americans, and not by the Aftatics. They have no wood in these islands beside that which is floated to them by the sea, and this wood seems to come from the south; for the camphor-tree of Japan has been found on the coasts of these islands. The inhabitants of these islands are, in proportion to their dimensions, tolerably numerous, and they are at present tributary to the Russian empire. See Fox islands.

ALEXANDER the Great, in Biography and Ancient History, was the son of Philip, king of Macedon, by Olympias, daughter of Neoptolemus, who was son of Aalectus, king of Epirus. He was born at Pella, the capital of Macedonia, in the first year of the 106th Olympiad, B. C. 356. His natural disposition, which is said to have been excellent, was betimes corrupted by the mercenary adulation of his first preceptor, Lyssamos, the Acalmanian; and neither the constel and example of Leonidas, his mother’s relation, nor the instructions of Aristo, were sufficient to counteract its pernicious effects. It was, however, a singular advantage to Alexander that he was placed under the tuition of this great philosopher. Soon after his birth Philip wrote to Aristo, informing him, that he designed to place this son that was just born under his instruction. "I return thanks to the gods," says he, "not so much for having given him to me, as for his having been given during the life of Aristo; and I may justly promise myself, that you will make him a successor worthy of a both, and a king of Macedonia." Accordingly, at the proper feast, he invited his attention to the offer of a considerable stipend, and he afterwards recommitted it to his beloved Strangus, the native place of Aristo, which he had destroyed a little earlier. The inhabitants who had fled from it, or who had been made slaves, and all during them a fine park in its vicinity for their studies and amusements. The pupil seems to have conceived an early and affectionate attachment to his master, whom he thought himself bound to love as much as if he had been his father; and to this purpose he declared, THAT he was indebted to the one for living, and to the other for living well." His progress in every kind of science corresponded to the natural talents which he possessed, and to the diligent and indefatigable attention and abilities of his tutor. He devoted himself with singular affability to the study of metaphysics, mathematics, and morals; he was no less solicitous to be a master of rhetoric both in the theory and practice of it: and to his solicitude in this respect we owe Aristo’s treatise on rhetoric, which, with a jealousy and together unbecoming a great character, he requited the author not to communicate to any but himself. His taste for classical literature is like-wise manifested in the very ardent esteem which he professed for Homer, whose poem he denominated, as Philo (H. N. lib. vii. c. 29. tom. ii. p. 551.) informs us, "the most precious production of the human mind." He particularly admired the Iliad, which might probably contribute to give his mind a decided direction to military glory. The passage, we are told, which pleased him most, was that (II. vii. 172) which represents Agamemnon as "a good king and a brave warrior." He had also a taste for the arts in general; he knew their importance and utility; and music, painting, sculpture, and architecture flourished in his reign. because they found in him a competent judge, and, as some say, a munificent protector. In his exercises he distinguished the useful from the fainthearted; in his diversions he declined whatever was unnatural; and in his studies he despised whatever was trivial or pedantic. In early life he manifested a genius and disposition formed for great and splendid actions. Emulation and ambition were the predominant passions both of his youthful and riper years. When he confered with the Persian ambassadors at his father’s court, at the age of no more than seven years, the subjects of his enquiry were, not the palaces and retinue of their king, but the character and manners of their sovereign, the number and discipline of his army, the road that led into Upper Asia, and "the number of days’ march from Macedonia to Sufa." When
ALEXANDER.

When he was requested to enter his name among the Olympian competitors, he replied, "So I would, if I were to have kings for antagonists." On occasion of this naming the famous horse Bucephalus, which none of his father's grooms would venture to mount, Philip was so delighted, that he paid to him, "My son, seek a kingdom more worthy of thee, for Macedonia is below thy merit." Besides the qualities which we have recited, the youth of Alexander was distinguished by temperance, chastezy, and self-command.

His dutiful respect for his mother, whom Philip divorced, produced a disagreement between him and his father; and it was incensed by a suspicion which they entertained, that he would be disinherited, and one of Philip's children, by another wife, preferred to him. However, before this period, when he was 15 years of age, he was appointed regent of Macedonia during his father's absence; and his conduct manifested such prudence and bravery, that he was afterwards employed in several military enterprises, in which he behaved with great honour to himself, and singular satisfaction to Philip, whose life he had preferred by his resolute and reasonable intercession. In the battle of Chersonesus, at the age of 18, he signalized himself by his valour, and greatly contributed to the victory. Before Philip undertook his projected expedition into Asia, he recalled his son from Epirus, whither he and his mother had retired, and was apparently reconciled to him: but when his father was assassinated by Pausanias, whom he had grievously offended, Alexander and his mother were suspected of being privy to the conspiracy. The suspicion, however, seems to have been groundless; and the first act of his reign was the just punishment of the murderers. In the 20th year of his age, B.C. 335, he succeeded to the throne of Macedonia; and commenced his military career by marching into Thessaly to overawe the Greeks, who were disposed to emancipate themselves from the Macedonian yoke, and bycausing Attalus, who encouraged their revolt, to be put to death. Having succeeded in this enterprise, he marched into Thrace, defeated the Triballi, who inhabited the modern Bulgaria, and drove them beyond the Danube; he also made the Getæ to fly at his approach; subdued several barbarous nations, and established a treaty of peace, in which the Celts, a fierce and high-spirited people, and others, were comprehended. During his absence in these expeditions, the cities of Greece, inflamed by the eloquence and influence of Demosthenes, formed a powerful alliance against him. The report of his death had induced the Thebans to revolt; and, having murdered two officers of the Macedonian garrison, they were preparing to besiege the citadel. Alexander, receiving intelligence of this event, hurried to Greece, B.C. 335, passed the Straits of Thermopylae, and entered Boeotia before the Thebans were undeceived as to his death. To those who accompanied him he spoke in the following manner: "Demosthenes, in his orations, called me a child when I was in Illyricum among the Triballi; he called me a young man when I was in Thessaly; and I must now flour him, before the walls of Athens, that I am a man grown." The city of Thebes, which was bravely defended by the inhabitants, animated by a love of liberty, was at length taken by storm, with a dreadful slaughter: the buildings were razed, the house of Pindar, the poet, excepted, from a respect to its owner; the inhabitants were sold for slaves, and the lands distributed among the soldiers; this conduct struck the Greeks with terror. Athens sent a deputation to Alexander, imploring his clemency; but he demanded the surrender of ten orators, whom he supposed to have been the chief instruments in forming the league which Philip his father had defeated at Chersonesus. On this occasion Demosthenes recited to the people the fable of the Wolves and the Dog; in which it is supposed, "that the wolves told the sheep, that if they defied to be at peace with them, they must deliver up to them the dogs who were their guard." Alexander having relented, by the interference of Demades, whom he had honoured with his friendship, waved the enforcement of his demand. Having re-established the tranquillity of Greece he went to Corinth, where his office of generalissimo was recognized and fetted. At Aegae he held a grand council of state and war, in order to deliberate upon his expedition into Asia. Antipater and Parmenio recommended delay, but Alexander had formed his purpose; and having offered sacrifices, and entertained his friends with feasts, and distributed among them the crown-lands, Perdiccas asked him what he had reserved for himself? "Hope," replied Alexander. "The fame hope ought therefore to satisfy you," was the rejoinder of Perdiccas. Accordingly he assembléd his army, and prepared for his march into Asia. When one of his attendants asked him why he succeeded so well in quieting the dangerous mutinies in Asia? he answered, "It was by delaying nothing."

In the 22d year of his age, B.C. 334, Alexander crossed the Hellepont into Asia, with an army of about 30,000 foot, and 4 or 5000 horse. Parmenio, who commanded the infantry, passed over with the greatest part of the army from Sestos to Abydos; and Alexander crossed first the Strymon, afterwards the Hebrus, and after 20 days march arrived at Sestos. Having prepared for his expedition by a variety of superfluous ceremonies, to which he was attached, he proceeded to Ilium, where he sacrificed to the heroes buried in the neighbourhood, and particularly to Achilles, to Minerva, and to the ghost of Priam. In his march he preferred Lampacus, which he had determined to desroy on account of its adherence to the Persians; and this he did in consequence of the interpolation of Anaximenes. "I swear solemnly," says Alexander to Anaximenes, who met him on the road, and the object of whole interview he supplicated, "that I will not do what you desire me." "My request, then," said the old man, "is, that you would burn Lampacus." The Persians collected a large force to meet him on the banks of the river Graicus, May 22, B.C. 334; but, after an obstinate resistance, they were routed with great slaughter. The consequence of this victory was the surrender of Sardis, the chief town of Lydia, and the possession of the whole country as far as the river Hermus.

Alexander proceeded to Ephesus, and restored the democracy; and by an edict he established the popular government in all the Greek cities. At Miletus, which he besieged and took, he diffimated his fleet, and advanced to the siege of Halicarnassus, which was abandoned by the Persians, and then to Tralles, which he took and levelled with the ground. Having demolished Halicarnassus, he appointed Adas, who claimed the title of queen of Caria, and who delivered up to him Alinda, governor-general of all Caria; and this conduct induced many of the princes of the Lycian side to revolt from the Persians, and to put themselves under his protection. Alexander ingratiated himself with the army, by permitting the soldiers who were married to spend the winter with their wives in Macedonia; a practice conformeable to the law of Moses, (Deut. xxiv. 5.) and which Arilottlce probably learnt of some Jew, and recommended to his pupil. Whilst the king was busily preparing for the next campaign, an attempt was made upon his life by the corruption and treachery of an officer of his army; but it was discovered and prevented from taking effect.

The next campaign was opened early in the spring; and Alexander, taking possession in his march of the cities of Lycia and Pamphylia, proceeded to Phrygia; and at Gordium, the capital, he was devout of seeing the famous chariot on which the Gordian knot was tied. The oracle had foretold, according to an ancient tradition of the country, that the man
man who could unite it should possess the empire of Asia; Alexander, persuade that this prediction related to himself, after many fruitless trials, exclaimed, "It is no matter which way it be acted," and cest with his sword. Having subdued Paphlagonia and Cappadocia, he advanced by petty marches into Cilicia, and arrived in the country called Cyrus's Camp. Through a narrow strait, called the Pats of Cilicia, he marched with his army to Tarbus, where Parmenio arrived just in time to prevent its being set fire to by the Persians. Alexander, heated and fatigued by this rapid march, plunged into the river Cydnus, which ran through this city, and was instantly feized with a flowering, which his attendants thought would prove fatal to him. His danger alarmed the whole army, and they expressed their apprehensions with lamentation and tears. In these circumstances, and whilst the speedy arrival of Darius was expected, Alexander conferred his friends and physicians, and intimated to them that the condition of his affairs would not admit either of flight or timid physicians. "A speedy death," says he, "is more eligible than a slow cure." Philip, an Acarnanian, one of his physicians, who tenderly loved him, and had attended him from his youth, offered to give him a dote, which would be speedy in its effects, and desired three days to prepare it. In the mean while Alexander received a letter from Parmenio, who had been left in Cappadocia; the purport of which was to bid him beware of Philip, because Darius had bribed him by the promise of a thousand talents, and his filter in marriage. But his confidence in a physician, whose fidelity he had experienced from his infancy, prevailed over his fears, and removed all his doubts. The contents of the letter he did not divulge. When Philip came to administer his medicine, Alexander took it from under his bolster, and gave it Philip to read; at the same time, fixing his eyes on the physician, he swallowed the draught without hesitation, or without discovering the least suspicion. The effects of the medicine were very violent, but the skill of the physician prevailed, and his fidelity was proved. Alexander recovered, and in three days presented himself to the joyful congratulations of the army.

During this interval Darius was on his march, and Alexander advanced to meet him near Idas, in the month of October, B. C. 333. The army of Darius consisted of 600,000 men; but by infatuated counsels, and a vain confidence in the number of his forces, he had quitted an open and level country, and prepared to engage in a close and mountaneous situation, where his multitude could only embarrass him in action. Victory was for some time obstinately disputed; Alexander received a wound in his thigh; but at length the Persian emperor fled, and his immense army was thrown into confusion. A dreadful carnage succeeded, and the tent of Darius, with his mother, wife, and daughters, came into the possession of the conqueror. When Alexander had performed the offices of duty and compassion to the dead and wounded, he entered the tent where the queens were lodged, accompanied only by his favourite Hephaestion. The queens, mistaking Hephaestion for the king, paid their respects to him as such; but as soon as Syigramis, the mother of Darius, had discovered the mistake, she fell prostrate at the feet of Alexander, and begged his pardon. The king raised her from the ground, and said to her, "Dear mother, you are not mistaken; he also is an Alexander." Alexander, after this respectful visit, declined exposing him self to the danger of human frailty, and solemnly resolved never to see the queen of Darius any more. At this time, the fourth year of his reign, Alexander was young, victorious, and free, or engaged in marriage, as has been observed of Scipio on a like occasion—

"Et juvenis, et celibus, et victor."

After this victory, Alexander pursued his march to Syria, Parmenio went to Damaicus, and pitched himself of the treaures of Darius. The king proposed to visit Tyre, that he might have an opportunity of sacrificing to the Tyrian Hecates; but the Tyrians refused not to admit a Macedonian within their gates. Alexander was incensed, and determined to besiege the city; and this siege, one of the most famous which history records, lasted for seven months; at length the place was stormed and utterly destroyed. The king, on this occasion, incurred deferred reproach by his cruelty towards a people, who had only offended by bravely defending their country. Troops were put to the sword, two thousand were crucified, and the rest sold for slaves. After having depopulated the city, he colonized it anew, and boasted of being the founder of a city which he had ruined. This event took place, August 20th, B. C. 332.

From Tyre Alexander proceeded to Jerusalem, with the intention of punishing the Jews for affording relief to the Tyrians during the siege; but on his approach he met Jaddua, the high priest, in his pontifical habit, accompanied by the priests in their sacred vestments, and the people clothed in white. When the procession drew near, Alexander bowed before the priest, and paid him religious adoration; alleging to Parmenio as the reason of this conduct, that the figure of a person in such habit had appeared to him at Dium, in Macedonia, and assured him of the divine guidance, and of ultimate success in his expedition. After this interview, Alexander accompanied Jaddua to Jerusalem, sacrificed in the temple, and conferred great favours on the Jewish nation. Such is the account given by Josephus, but the whole is rejected as fabulous by many judicious writers. Considering, however, the superstitious temper of Alexander, and his friendly conduct to the Jews, it is not altogether improbable. From Jerusalem Alexander proceeded to Gaza, besieged it, and took it by storm: from Gaza he marched to Pelium, left a garrison in it, and failed up the Nile. He afterwards marched through the deserts to Heliopolis, and crossing the river, he arrived at Memphis, where he offered pompous sacrifices not only to the Grecian gods, but to the Egyptian Apis. From Memphis he sailed down the river to the sea, and fixed on the place where he proposed to build a new city, which has since become so famous under the name of Alexandria. Here he formed the design of visiting the temple of Jupiter Ammon, situated on an oasis in the midst of the Libyan deserts. The senior priest of this temple flattered him with the title of the son of Jupiter, which Alexander joyfully accepted; and he was farther assured that he should be the monarch of the world. From this journey, which had proved so successful, he returned as from a triumph; and from this time, in all his letters and decrees, used the following style: "Alexander, king, son of Jupiter Ammon."

During his abode at Memphis, he settled the affairs of Egypt; and in the spring marched towards the east against Darius. In his way to Tyre, which was the place appointed for the general rendezvous of his forces, he heard that Anacharsus, whom he had appointed governor of Syria and Palestine, had been massacred at Samaria; and, in order to avenge this audacious act, he put those that were concerned in it to death, banished the rest from Samaria, supplied their place with a colony of Macedonians, and divided part of their territories among the Jews.

From Tyre he directed his march to Phasis, and having passed the Euphrates, he advanced towards new conquests. On his march he was informed of the death of Statira,
Statera, the captive Queen of Darius; and this event detained him, till he had visited Sogdiana, administered suitable consolation, and performed the funeral obsequies of the deceased queen in the most splendid and magnificent manner. Darius, though his mind harbored the suspicion of a dishonourable kind, that were equally unjust, was much gratified by the tokens of respect which Alexander had rendered to his queen and family, and renewed propositions of peace. On a former occasion, during the siege of Tyre, he had made very advantageous proposals, which Parmenio wished him to accept; declaring, that he would agree to them if he were Alexander. "And so would I," replied Alexander, "were I Parmenio." Darius now offered him all the provinces between the Euphrates and the Hellespont; but Alexander had more extensive views in his career of glory and ambition. Darius prepared for battle, and pitched his camp near a village called Gugamela, in a plain at some distance from Arbela. Alexander, at the height of his formidable army, consulted his officers, offered up prayers to them, and joined in prayers addressed to Jupiter, Minerva, and Victory. These ceremonies being ended, he went to bed, and slept soundly through the whole night. Parmenio awoke him in the morning, and expressing his surprise that he should be able to sleep so calmly, Julia as he was going to fight a battle in which his whole fortune was at stake: Alexander addressed him—"How could it be possible for us not to be calm, since the enemy is coming to deliver himself into our hands?" The army of Darius consisted of 60,000 foot and 40,000 horse; some fay of upwards of a million of men: but that of Alexander was more than 40,000 foot and 7 or 8,000 horse. The Persians were totally routed: Parmenio, who was in great danger, was rescued by Alexander in person; and they both joined in the pursuit of Darius, and, passing the river Lycus, marched to Babylon, which was instantly delivered by Mazarus, the governor, into his hands. According to Arrian, the Persians, on this occasion lost 300,000 men, besides those who were taken prisoners; but the losses of Alexander did not amount to more than 13,000 men. Such was the issue of this battle of Arbela, fought in October, B. C. 331, which decided the fate of Asia.

From Babylon Alexander marched towards Sufa, where he found treasures of various kinds, and of great value. Here he took Darius' mother and children; and having reduced the Uxii, whof- country lay near Susa, and extended to the frontiers of Persia, he forced his way through the Persian straits, and arrived at Peripolis. Having destroyed the royal palace, to which he and his companions in the fever of debauch and phrenzy, and at the request of Thais the courtezain, and Ptolomy's mistrels, set fire, and plundered the city, he purfued Darius first to Ecbatana, the capital of Media, and then as far as Rhages, a city one day's journey from the Caspian straits. But his progress was interrupted by the news of the death of this ill-fated and unhappy monarch, who was murdered by a conspiracy of his own subjects. Having settled the government of Persia, he reduced Hyrcania, plundered the Mardi, took possession of Zadragarta, the capital of Hyrcania, where for 15 days he celebrated solemn games, and offered magnificent facilities to the gods of Greece, and then entered Asia, and reduced the whole province to submiffion.

The relaxed discipline and unrefined luxury which the manners of the Persians produced in an army flushed with successes, terminated in faction and discontent, and even in a conspiracy against the life of Alexander. Philotas, the son of Parmenio, was forced by torture to confess his guilt, and punished with death; and his condemnation was soon followed by the assassination of the father, at the age of 70 years, and after a life delightful and zealously devoted to the service of his prince. The death of both Parmenio and Philotas, upon a suspicion of guilt, and without any direct proof, alienated the affections of the army from Alexander, and produced such a degree of dissatisfaction and disgust, that he separated those who were disposed to sedition from others, and proceeded without further delay to action. Having passed through Drangania, Arachofia, and the country of the Arimanius, all which submitted to his arms, he arrived at a post of Mount Caucausus, called Epargamum, where his army endured much toil and hardship; and where Bessus, whom he was pursuaging, had laid waste the country, in order to deprive him of provisions and forage. This Bessus was a principal agent in procuring the death of Darius, and he had afforded the imperial purple, under the title of Artaxerxes. Alexander having found an opening that led into Media, directed a city to be built there, which he called Alexandrin; and he also founded several other towns in its vicinity. From hence he penetrated into Bactria, and took Araxes and Bactra, the two strongest cities of the country; he then passed the river Oxus in pursuit of Bessus, who, although defeated by 7 or 8,000 Bactrians, had withdrawn with a few adherents over this river to Nauticus, a city of Sogdiana. When Alexander arrived at this small city inhabited by the Sogdians, he was guilty of an act of savage cruelty, which fixed an indelible stain on his memory. The fact, though omitted by Arrian, is related by Curtius (lib. vii. c. 5. tom. ii. p. 520. Ed. Smakenb.) and referred to by Strabo (lib. xiv. tom. ii. p. 787.) Here Bessus, deplored all the enormities of royalty, and flipp'd even of his garments, which was brought in chains to Alexander; who, having ordered his nose and ears to be cut off, delivered him up to OXatres, the brother of Darius, by whom he was sent to Ecbatana; where he suffered a cruel death; some fay that he was crucified. Plutarch relates, that being fastened by his limbs to trees which were bent together, he was torn asunder by their elastic force, when they were allowed to return to their natural position.

Alexander purfued his march to Marandunda, the capital of Sogdiana, known by the modern name of Samarcand, and by long and dangerous igles advanced to the river Iaxartes, erroneously called by Arrian, Curtius, and others, Tenis. On the side of this river he was surprized by the barbarians, who, rushing suddenly from their lurking holes in the mountains, and fighting with bows and flings, killed many of the Macedonians, and took others prisoners. The king himself was wounded in the conflict; but the barbarians were at length overpowered, and defeated with great slaughter. Soon after this transfaction he formed a treaty with the Abian Scythians, who, from the time of Cyrus, had lived in freedom and independence, and who were distinguished by the equality and liberty that subsisted among them, and by their love of poverty and jujtee. While he was forming a plan for building a city on the river Iaxartes, in order to curb the nations he had already conquered, and those he intended to subdued, he was diverted from the execution of his design by the revolt of the Sogdians and Bactrians; and, directing his arms against their combined forces, he took and destroyed in a few days seven of their cities. The capture of Cyropolis, which was one of them, and which was the greatest and most populous of the whole country, was vigorously resisted by the inhabitants; but it was at length taken, and razed to the very foundations. In these different sieges the enemy are said to have lost above 120,000 men; and in one of them Alexander, as well as Craterus, and many of his principal officers, were wounded. He then returned to the Iaxartes, and
marked a space of about three leagues in circumference, and built a city, which was called Alexandria. In less than a day, the ramparts were raised, and the houses built; and, in order to please them, he ranomed all the prisoners he could find, settled in it several Macedonians, who were wont out in the service, and permitted many natives of the country, at their own request, to inhabit it. His next conflict was with the Scyths, whom he defeated with difficulty, and to whom, as he had other objects in view, he granted a peace on their own terms. The Satraps, who were a powerful nation, submitted to him, and, by an embassy, requested his friendship.

At this time Alexander received a reinforcement of upwards of 16,000 men from Macedonia and Greece, and was thus enabled to subdue all those who rebelled; and, to curb them for the future, he built several fortresses in Magrida. But he was gradually throwing off both the habit and manners of a Macedonian prince, and assuming those of an eastern despot. He was also surrounded by a number of eunuchs, who were, and ever will be, says one of his biographers, the bane of princes, and the curse of nations. Thence, by indulging his humour and soothing his passions, precipitated him into extravagances of conduct, and deprived him of that equanimity and moderation, which were necessary for preserving the acquisitions he had made. One faithful friend declined concuring in this general adulation. At a banquet which succeeded the sacrifices performed at the anniversary festival of Bacchus, the honour of which Alexander had transferred to the Dioecrites, i.e., to Callirrhous of Persia, some of the attendants extolled the actions of the Macedonian prince above those of Callirrhous and Pollopus, and even of Hercules. Clytus remonstrated, alleging, that he "could not bear to hear such indignities offered to the gods, or the credit of ancient heroes undervalued, to tickle the ears of a living prince." As to Alexander's actions, he allowed they were great and glorious, but he maintained that they were not supernatural; that the army had shared in them, and that they had a right to participate in the praise belonging to them. Alexander was insatiable; and, as Clytus proceeded in the same strain, and affirmed that he had preferred the life of the king at the battle of the Granicus, stretching out his arm and saying, "this hard, O Alexander, saved thee?" the king rushed upon him, and endeavoured to kill him, but was prevented by the interposition of friends. At length, however, when his friends retired, he feared a lancer, or large Macedonian pike, and laid Clytus dead on the spot. His passion soon subsided, and reflecting on the deed he had perpetrated, he indulged excessive grief, refused food for three days, neglected his apparel, and, as some say, would have lain himself with the pike that killed Clytus. Flattered, however, by the army, and perverted by the detestable doctrine of Anaxarchus of Abdera, the sophist, who taught him, "that a sovereign prince do what he will, all his actions are just and lawful," he soon became more composed and tranquil, and lectures of this kind were more acceptable to his mind, already corrupted, than the honest and moral discourses addressed to him, with a view of settling his mind, by Callithenes, the disciple and relation of Aristotle. His servile attendants renewed their adulation, attempted to persuade him that he was more than man, and that it was unjust and disloyal in his subjects not to own his divinity; and some of the most officious of them, amongst whom Anaxarchus was the chief, endeavoured to engage the Greeks as well as the Asians to pay him adoration. Alexander was pleased; and was highly provoked by a speech of Callithenes, who attempted to awaken in his mind more sober thoughts. His restoring was insufficient; and it was determined that when the king drank to any guest, he should immediately rise, adore him, and having received a kiss from the king, depart.

The several circumstances that have been now related, produced a new conspiracy against the king: and the conspirators, being discovered, were floned to death by the army. Callithenes was apprehended, and, as some say, carried about in chains, till he died a natural death. But, according to others, he was first racked and then executed. The death of Callithenes, says Seneca (Nat. Quaest. lib. vi. c. 23), is an external reproach to Alexander, and a crime of so horrid a nature, that no quality, however excellent, nor military exploit, however illustrious, can ever efface its infamy. In favour of Alexander it is said, that he killed many thousand Persians; that he dethroned and killed Darius, the most powerful king of the earth; that he conquered innumerable provinces and nations, penetrated as far as the ocean, and extended the bounds of his empire from the most remote part of Thrace to the extremities of the coa. In answer to each of these particulars, "Yes," says Seneca, "but he murdered Callithenes;" a crime of so heinous a nature, that it entirely obliterates the glory of all his other actions.

The only strong hold which the rebels still retained was the Soggidian rock, or the rock of Oxus, into which Oxartes, the Bactrian, had conveyed his wife and family. It was defended by Arimazes, with 30,000 soldiers under his command, and furnished with provisions for two years. It was deemed by its situation impregnable; and therefore, when Alexander, before he commenced the siege, summoned the garrison to submit, the commander insulted him, and asked what Alexander, who was able to do all things, could also fly; and whether nature, on a sudden, had given him wings? Alexander was highly exasperated, and selected from the mountaineers in his army 300 of the most active and dexterous, directing them to seek a path to the top of the rock, to which the greater number of them at last ascended by means of wedges and ropes. When Alexander perceived the appointed signal, he sent a message to the commander, summoning him to surrender, and informing him, "that he had now a corps of winged soldiers." The whole Macedonian camp refunded with the shout of "victory," and the Barbarians surrendered the place at discretion. Alexander's repentance was invincible, and, regardless of the dictates of humanity, he ordered Arimazes and the principal nobility of the country who fought shelter in his camp to be scourged with rods, and afterwards to be fixed to crosses at the foot of the rock. After the reduction of Sogdiana, he marched into the country of the Parataces, where was another fortres, called the rock of Chorianas, which was also deemed impregnable. After the siege was begun, Chorianas, the commander, was induced by Oxartes to surrender it; and having been enrolled in the number of Alexander's friends, he was entrusted with the charge of it, and in return for this honourable treatment, supplied the Macedonian army with provisions. On one of these occasions, Roxana, the daughter of Oxartes, who was esteemed the most beautiful woman in Asia, after the death of the wife of Darius, tell into the hands of the conqueror; and such was the influence of her charms, that he publickly espoused her.

India was the next object to which Alexander directed his attention. Accordingly he dispatched a herald to Taxila, and the other princes on this side the river Indus, enjoining their submission; and Herophilus, with part of the army,
was dispatched to join Taxiles and the rest of the Indian princes, who were come out to meet them, and to reduce the country as far as this river. This commission was rashly and facetiously executed. Alexander bent his march towards the river Choaspes, and reduced several places in his progress, among which Andaca was one of the most considerable. He proceeded against the Afpoi and Asfacen, whom he successively defeated, notwithstanding obstinate resistance; but having invested Mygaza, the capital of the latter people, he was wounded in the siege, and the army was repeatedly repulsed. At length, however, the Indians were compelled to submit; and, by an act of perfidy, which Diodorus Siculus severely condemns, they were all put to the sword. Platane also proffes the king for this barbarous action. Oro and Bozira, and the rock of Aornus, to which the inhabitants of the latter place retired, were next reduced; and Alexander proceeded to the river Indus, where Hephaestion and Perdiccas had already provided a bridge of boats for the passage of the army. Having refitted his troops in the territory of Andrena and aflay, Taxiles, Alexander passed the Indus, B. C. 327; and advanced forward to the Hydaphes, known in modern times by the name of the Betala or Chelum, or, according to the orthography of Major Rennell, Behut and Thyulum, where Porus with a large army lay encamped to dispute his passage. When he approached the banks of this river, he found that the people with whom he had to contend were not to be subdued so easily as the Persians, and other Aziatics. The Indians were not only a very tall and robust, but also a very hardy and well disciplined people; and their king Porus, a prince of high spirit, invincible courage, and good conduct. Alexander, however, after encountering great difficulties, on account of the inundations to which the Indian rivers are subject at the time of his march, which was Midsummer, or about the height of the rainy season, passed the Hydaphes; and, having vanquished a detachment under the command of the son of Porus, who was slain in the action, he encountered Porus himfelf at the head of 4000 horse, 30,000 foot, 3000 chariots, and 200, or as Q. Curtius says, (lib. vii. 13.) 85 elephants. The dispute, though short, was very bloody. Porus behaved with singular prudence and intrepidity; but the Indians were completely routed after a great slaughter. Porus, compelled to submit, was conducted to Alexander, who received him with respect, and treated him with kindness. When he was asked “how he wished to be treated?” Porus replied, “as a king.” “That, for my own sake,” said Alexander, “I shall do.” “And therein,” rejoined Porus, “is comprehended all that I can ask.” Alexander gave him his liberty, restored his kingdom with additional provinces; and Porus, in return, became his true friend and constant ally. For perpetuating the remembrance of this victory two cities were built: one called Nicea, and the other Bucephala. Paffing the river Acefines, he entered the territories of another Porus, and in pursuit of him crossed the Hydaphes; and having conquered the whole kingdom of this prince, he gave it to Porus his ally. In the midst of this success Alexander received advice, that the Caxic, Oxydace, and Malli, the most warlike nations in India, were confederated against him, and had assembled a great force. He determined immediately to attack them; and, though they made a vigorous defence, they were put to flight; and soon after, their city of Jungala was taken by storm and razed. He then prepared to pass the Hyphasis, having nothing in view, as Arrian says, but to seek new enemies. Here he was told that after passing this river, he must travel 11 days through defects, and that he would then arrive at the Ganges, the largest river in India; and that farther in the country were the Gangaridae and Pafhi, who were collecting a great force in order to oppose his entering into their dominions. Rumours of this kind were spread through the army, and produced no inconsiderable degree of discontent and murmurs. Unable to aYay the ferment that was prevailing among the troops, and to satisfy them, that they had any object in view which could warrant their being led on to new difficulties and toils, he was constrained to terminate his progress, and to prepare for his return. When his purpose was made known to the army, he was saluted with loud acclamations, and received the thanks of his followers; “because,” they said, “he was invincible had suffered himself to be overcome by their prayers.” On the banks of the Hyphasis, the modern Belay, which were the limits of his conquests, he caused to be erected 12 altars, on which sacrifices were offer’d. These altars, if we may believe the biographer of Apollonius Tyanaeus, were still remaining, with legible inscriptions, when that fantastic sophist visited India, 375 years after Alexander’s expedition. Plutarch, vita Apollon. lib. ii. c. 44. ed. Olearius.

Having exhibited public shows in the Grecian manner, he added all the conquered country to the dominions of Porus, and began his retrograde march towards the river Hydaphes. From thence he proceeded to the Acefines, and marched on to the Hydaphes, proposing to embark on the river Indus, and to pass this river by the ocean. Whilst he was marching near these rivers, he observed many crocodiles, and that the country produced beans like those of Egypt; and hence he inferred, that he had discovered the source of the Nile, and prepared a fleet to sail down the Hydaphes to Egypt. Strabo. Geog. lib. xv. p. 1020. This circumstance shows, that the knowledge of the Greeks, in his age, did not extend beyond the limits of the Mediterranean. The breadth of the Panjub, as it is now called, through which Alexander passed, from Ludhiana on the Setlege to Attock on the Indus, is computed to be 259 geographical miles, in a straight line; and his march, computed in the same manner, did not exceed above 200 miles. But in his advance and return, his troops were so spread over the country, and all his movements were so exactly measured and delimited by men of science, whom he kept in pay for the purpose, that he acquired a very extensive and accurate knowledge of that part of India.

Having prepared a fleet, consisting of 80 vessels of three banks of oars, and about 2000 lighter ships and transports, and having offered sacrifices to the gods, he embarked, and at the signal of the sound of a trumpet the fleet began to move. Having arrived at the confluence of the Acefines with the Hyphasis, where these united streams roll with great rapidity into the Indus, many of his vessels were lost; he himself was in danger, and Nearchus, the commander of the fleet, not a little perplexed. When the danger was past, and the fleet and army were joined, Alexander went on shore; and began his march through a desert country, in order to reduce the Malli and Oxydace, who were raising forces to oppose him. He surprised them, unprepared, and unexpected his arrival; many of them were slain in the field, and the rest fled into the city and shut the gates. In burning their principal city, Alexander, with a romantic valour, which approached to fool-hardiness, sealed the walls, and leaped down into the city, accompanied by only three of his guards. Whilst he personally encountered a severe attack, he was wounded, and fainted through loss of blood; two of his guards, who were themselves wounded, covered him with their shields; till the soldiers from without ascended the walls, threw themselves into the city, and by an act of
ALEXANDER.

the most undaunted resolution released their sovereign; though, when he was carried out upon his shield to the camp, his recovery was very doubtful. As soon as he was able, he rejoined his forces, and was received in the camp with great joy.

His first thoughts were now directed to the increase of his fleet; and having accomplished this object, having given order for erecting a city in the commodious situation afforded by the confluence of two great rivers, and having conferred upon Oxyartes, the father of his wife Roxana, the government of Paropamisus, with some additional territories, he embarked on board his fleet and continued his voyage. But as he proceeded, he was occasionally employed in reducing some Indian princes, who were either negligent in paying him the attention and respect to which he conceived himself entitled, or who actually took up arms against him. Of this number were Musianus, the sovereign of one of the richest and most populous kingdoms in India; Oxyartes, another Indian prince, who was taken prisoner; and Sambus, whose capital Shudomana opened its gates to receive him. Musianus afterwards revolted; and Alexander directed him to be carried back into his own dominions, to be there crucified, together with all the Brahman who were about him, and who had intrigued him to this revolt. The king next failed to Patala, the modern Satta, an island formed by two branches of the river Indus, where he ordered an haven and convenient docks to be constructed for his ships; and when he had careened his fleet, he sailed down the right-hand branch of the river towards the ocean. As they approached the sea, they were exposed to great danger for want of skilful pilots; and therefore, after having gratified his vanity by entering the ocean beyond the Indus, performing religious rites in honour of Neptune, and surveying two small islands, he returned to Patala. Having surveyed the other branch of the Indus, and found a place of safety for his fleet, he gave directions to Nearchus to conduct the fleet, by the ocean, at the proper season, through the Perisan gulf, up the river Tigris, to meet him and his army in Mesopotamia; and he departed with the army in order to march back by land to Babylon. From the researches of Major Renell, we learn, that the distance of that place on the Hydaspes, where Alexander fitted out his fleet, from the ocean, cannot be less than a thousand British miles. Considering the various operations by which he was retarded, and the slow navigation of such a fleet as he conducted, it is no wonder that he was above nine months before he reached the ocean. When we attend to the various movements of his troops, the number of cities which they took, and the different states which they subdued, he may be justly said to have explored the countries through which he passed.

Alexander, having left Patala, crossed the Arabis, and marched through the country of the Ortae, whose capital he seized and converted into a new, and noble city, which he committed to the government of Hephaestion. He then pursued his arduous march through Gedrosia; and in the whole of his progress suffered much from sickness, excessive heats and fatigue, and also from famine and thirst; so that he brought back from India scarcely the fourth part of his army, which had consisted of 120,000 foot, and 15,000 horse. In these circumstances, trying and distressing as they were, he maintained an invincible resolution and patience, and by his example encouraged the perseverance of his troops. Having rested and refreshed his army at the capital of Gedrosia, he prepared his march into Caramania, a very plentiful country, where his attendants were amply recompensed for the hardships and fatigue they had endured. Here he punished those governors who were charged with maladministration, some of whom were put to death; and redressed the various grievances which the people had suffered during his absence. He then continued his march through Caramania, and was joined by Nearchus, his admiral; and turning aside to Peria, he visited the tomb of Cyrus, at Paeonoe; and ordered Orines, the governor of Peria, who was charged with many atrocious crimes, to be crucified, and placed Peucellas, who had saved his life in a city of the Malli, in his room; and commanded Baryxates, a Mede, who had usurped the title and tiara of king, to be put to death. In these marches Calanus, an Indian Brahman, who had accompanied Alexander, finding his health declining, requested to have a funeral pile prepared; on the top of which he stretched himself at full length, and remained without voice or motion in the midst of the flames.

At Sufa, to which Alexander next marched, he put to death Abilites and his son Oxeathres, who were charged with enormous crimes in the administration of public affairs; and he attempted to unite the Macedonians and Perians, by forming alliances between the noblest families of Peria and the principal persons of his own court; and he himself let them an example by taking two wives of the royal blood of Peria, viz. Statira, the daughter of Darius, and Parystas, the daughter of Ochus. He also bestowed fortunes on those Perian ladies of high rank, who were married to his own principal officers. He likewise paid the debts of his army, and conferred rewards and promotions on those who had signalized themselves in his service, without distinction of country.

Alexander, having still a curiosity to see the ocean, and to explore the maritime parts of his empire, went down from Sufa upon the river Eulaus; and having crossed the Perian gulf to the mouth of the Tigris, went up that river to the army, which was previously encamped, under the command of Hephaestion, on its banks, near the city of Opis. Here he issued an edict that those Macedonians, who were either unable or unwilling to make any more campaigns, might have their discharges, and return home; and that those who chose to remain with him should be duly encouraged. This edict, which was intended to please the army, produced a contrary effect, and excited a mutiny, which was quelled by extraordinary resolution and prudence. While the soldiers surrounded the tribunal on which he was seated, all clamouring for their discharges, reproaching him with the favours which he had conferred on the Barbarians, and innsolently telling him, that his father Ammon and he might go and fulfill the world by themselves, he leaped into the midst of them, ordered his guards to seize 13 of the ringleaders, whom he pointed out, and commanded their immediate execution. This act terrified them into silence and submission; and then remounting his tribunal, he pointed out to them, in an eloquent speech, the justice of his own conduct and the folly of theirs. He afterwards promoted the Perian nobility to the principal commands in his army; and by thus seeming to transfer his confidence to them, he humbled the Macedonians, and induced them to deliver up the authors of the sedition, and earnestly to seek reconciliation and favour; which they obtained, and which were succeeded by a solemn festival at which 9000 perissi were present.

At Ecberana, whither he next went, he offered sacrifices, and exhibited sports and games; which were followed by a royal banquet; but his joy on this occasion was unexpectedly interrupted by the sudden illness and death of Hephaestion. From Ecberana he marched against the Cibereans, and subdued
dashed them; and he then pursu’d his course towards Babylon, where he formed a variety of projects, for improving the city and extending his dominions. He proposed invading and conquering Arabia, draining the Babylonian seas, and constructing in the city a lake, capable of containing a thousand galleys. But before he could execute any of these grand schemes, he was seized with a fever, which, as some say, was occasioned, or at least aggravated, by excess of drinking, and which in a few days terminated in his death. He died on the 21st of April, in the second year of the 114th Olympiad, B.C. 323, after he had lived 32 years and eight months, and reigned 12 years and eight months. When his principal counsels, perceiving his death to be inevitable, asked him to whom he left the empire, he answered, “to the most worthy;” and when Perdiccas enquired at what time they should pay him divine honours, he replied, “when you are happy,” and having pronounced these words, he expired. When Alexander’s corpse had been embalmed after the manner of the Egyptians and Chaldeans, Aristaeus, his bailiff brother, who had been declared king, was appointed to convey it to the temple of Jupiter Ammon. Two whole years (see Eth. Lib. Lii. c. 30. tom. ii. p. 68, 83) were employed in preparing for this magnificent funeral, which made Olympias bewail the fate of her son, who having had the ambition to rank himself among the gods, was so long deprived of burial, a privilege allowed to the mankind of mortals. The funeral procession, conducted by Aristaeus, was singularly splendid; and some of our readers may probably be amused by the following brief account of it. It was preceded by pioneers, who cleared the way; and it consisted first and principally of a superb chariot in which the remains of the king were conveyed. The naves and spokes of the axle-trees of this carriage were covered with gold, and their extremities, made of gold, represented the muscles of lions biting a dart. It was drawn by 64 horses, harnessed to four draught-beams or poles; and these mules were adorned with crowns of gold, and collars enriched with precious stones and golden bells. On the chariot was erected a pavilion of solid gold, 12 feet wide and 18 feet long, supported by Ionic columns; and the inlaid was ornamented with jewels, disposed in the form of shells. The circumstances the universe was beautified with a fringe of golden net-work, to the threads of which were suspended large bells, the sound of which might be heard at a great distance. The external decorations consisted of four relevos. The first represented Alexander seated in a military chariot, with a splendid sceptre in his hand, and surrounded on one side with a troop of Macedonians in arms, and on the other with an equal number of armed Persians; and there were preceded by the king’s squires. In the second were feen elephants harnessed, with a band of Indians seated before, and a band of Macedonians, fated behind, and armed for battle. The third exhibited several squadrons of horse in military array. The fourth represented ships prepared for battle. The entrance of the pavilion was guarded by golden lions. The four corners were adorned with statues of gold, representing victories, with trophies of arms in their hands. Under the pavilion there was a square throne of gold, adorned with the heads of animals, with golden circles round their necks, and to which were attached crowns; glittering with the most brilliant colours, and such as were carried about at the celebration of sacred solemnities. At the foot of the throne was placed the coffin of Alexander, formed of beaten gold, and half filled with aromatic spices and perfumes; and the coffin was covered by a pall of purple, wrought with gold. The arms of the Monarch were disposed in the manner in which he used to wear them, between the coffin and the throne. The outside of the pavilion was covered with purple flowered with gold; and the top terminated in a large golden crown, resembling a cluster of olive branches. The rays of the sun, which darted on this diadem, as the chariot moved, caused it to emit a kind of rays resembling those of lightning. The chariot was followed by the royal guards, armed and magnificently arrayed. Among the numerous attendants and spectators, who were assembled on this occasion, Ptolemy advanced, with a numerous guard of his half troops, as far as Syria, to meet the procession. He prevented their depositing the corpse in the temple of Jupiter Ammon, and caused it to be conveyed, first to the city of Memphis, and thence to Alexandria. Here he reared a magnificent temple to the memory of Alexander, and rendered him all the honours which were usually paid to demi-gods and heroes by Pagan antiquity. Frenehimius, in his supplement to Livy (lib. XXXIII. c. 65. tom. vi. p. 910. ed. Drakenst.), relates, after Leo Africanus, who lived in the 1st century, that the tomb of Alexander was to be seen in his time, and that it was reverenced by the Mahometans, as the monument not only of an illustrious king, but of a great prophet.

As to the blue of Alexander, we may observe in general, that by Barfinus, or Asinus, the daughter of Artabazus, and the widow of Memnon, a lady of great beauty and merit, he had a son named Hereules, who was afterwards murdered; by Roxana, the half beloved of his wives, he had a posthumous son, named Alexander, who for a time enjoyed the title of king; by Cleophas, queen of part of India, he had a son named Alexander, who succeeded his mother in her kingdom; by Statira, the daughter of Darius, he had no children, nor by Paryfatis, the daughter of Ochus.

As to the extent of the Macedonian empire, and the distribution of it after his death; see Empire.

As to his person, Alexander was of a middle size, with his neck somewhat awry, with full eyes, and a fierce majestic countenance. Either through taste or vanity he would never suffer any portraiture to be formed of him except by the greatest artists of his age; Praxiteles in sculpture, Lyippus in cast metal, and Apelles in painting.

As to his talents and character, they have been differently appreciated by his biographers. From his more ancient biographers, whose memoirs are in a great measure lost, five polished writers have compiled the history of his life, namely, Dionysius Siculus, Plutarch, Arrian, Q. Curtius, and Diodorus Siculus, who were the same as Curtius in his "Critical Inquiry into the Life of Alexander the Great by the ancient Historians," which first appeared in the memoirs of the French Academy of Inferences and Belles Lettres, and obtained the premium of that society in 1772, and of which Sir R. Clayton published an English translation, with notes and observations, in 1793; has appreciated the merit and veracity of these historians. Historians, says another writer, have considered him either as an enterprising and successful prince, the glory of whose great actions fearfully suffered the blunders in his personal conduct to be seen, which is the light in which Arrian has placed him; or they make his virtues and vices alike conspicuous, which seems to have been the view of Curtius. Philosopher and moral writers have dealt more fitly with him, and have therefore seldom run into high panegyrics. Plutarch only excepted, who, in his orations on the fortune and virtue of Alexander, speaks as a rhetorician. The satirical Lucian hath described him with great spirit and with consummate judgment; but

he
he seems to have kept his eye too closely on the latter scenes of his life, where his fortune, not his merit, was at its greatest height. It is justly observed by Livy (lib. ix. c. 18), that Alexander appears very different, according to the times or feasons in which we consider him. He discovers in him a kind of double Alexander; the one wise, temperate, judicious, brave, intrepid, but at the same time prudent and circumspect; the other immered in all the wantonnesses of a haughty prosperity: vain, proud, arrogant, fierce; softened by delights, and abandoned to intemperance and excuses; in a word, reminding Darius rather than Alexander, and having made the Macedonians degenerate into all the vices of the Persians, by the new turn of mind, and the new manners he assumed after his conquests. M. Rollin, guided by this clue, contemplates him in two different periods of his life, and corresponding aspects of his character: first, from his youth to the battle of Issus and the siege of Tyre; and secondly, from that victory to his death. In the frist period, we acknowledge and admire a happy disposition, cultivated and improved by education. He had a great, noble, and generous soul, which was delighted in beffowing favours and doing service. He was also actuated by a high degree of emulation and love of glory; he was betimes accustomed to exercises of body and mind, and to a sober and temperate mode of living. No prince in the world had a nobler education than Alexander; so that he was conversant in eloquence, poetry, polite learning, the whole circle of arts, and the most abstracted and sublime sciences; and in the progress of his years he was a favourer and promoter of literature and the arts, and attached to his train poets, orators, and philosophers. Under Aristotle he enjoyed singular advantages of instruction; nor was he insensible of their value; and he rendered essential service to science by the precepts which he conferred on his preceptor, for enabling him to pursue his enquiries in natural history. He also employed men of talents of every description, and liberally rewarded them. In the early life of Alexander we perceive and admire the judgment manifest in his conversation with the Persian ambassadors; the wisdom with which he acted as regent during his father's absence, and by which he pacified the feuds that had broken out in Macedonia; and the valor by which he distinguished himself in the battle of Chaonera. The first years of his reign were, perhaps, all circumstances considered, the most glorious of his life. At 20 years of age, he appeased intestine feuds, subjected foreign enemies, disarmed Greece, when most of its states were combined against him; and in three years accomplished the plan which his father had projected. For effecting these purposes, intrepidity and prudence, courage and preference of mind, those qualities which form the character of the true hero, were indispensably necessary. In the former part of his expedition against Darius, the same qualities are manifest. When he was scarcely 20 years old, with dangers domestic and foreign, threatening him, with a treasury not only exhausted but encumbered with debts, with an army much inferior to that of the Persians, Alexander turns his eye towards Babylon and Susa, and projects the conquest of a vast empire. The twofeates of the execution corresponded to the wisdom of the project. Having gained the affeotion of his officers by an unparalleled liberality, and the attachment of his soldiers by condescension and affability, he astonished his enemies by bold enterprises, terrified them by examples of severity, and won them by acts of humanity and clemency. The passage of the Granicus, followed by a famous victory; the two celebrated sieges of Miletus and Halicarnassus, exhibited to Asia a young conqueror, to whom no part of military fel

ence was unknown. When he allowed to those whom he conquered, and who readily submitted, the enjoyment of their liberties and ancient laws, observers were led to believe, that the conqueror had no other view than to make nations happy, and to procure them an easy and lasting peace. The two battles of Issus and Arbela, with the siege of Tyre, proved, that Alexander polished the qualities of a great soldier; fell in chusing the field of battle; presence of mind in influing proper orders even in the heat of action; courage animated by preffing dangers; impetuous activity, tempered and guided by caution and circumspection; and an invincible firmness and constancy, neither disconcerted by unforeseen obstacles nor discouraged by difficulties. The circumstance which raises Alexander above most conquerors, and, as it were, above himself, was his conduct toward the mother, wife, and daughters of Darius; all of them princes of the Persepolis. If this conduct towards the family of Darius had been accompanied with the grant of a peace, which he supplicated on terms so humiliating to himself, and so advantageous to Alexander, the conqueror would have risen still higher in our esteem. Alexander, it is said, had a soul capable of friendship: he endeared himself to his officers and soldiers, by his attention and familiarity; he grieved for them when they were sick, rejoiced in their recovery, and participated in whatever befell them.

If we follow Alexander to the second period of his history, after the battle of Issus, we shall fee the virtues and noble qualities of this prince degenerate on a sudden, and make way for the greatest vices and the most brutal passions. He was ever enterprising more wild and extravagant than that of crossing the defects of Lydia, and interrupting the course of his victories, in order to purchase a title, that of the son of Jupiter Ammon, which, in reality, only served to render him contemptible. The drunkenness and debauchery to which he addicted himself, and the follies and crimes of which he was guilty in his fancies of intoxication, degrade his character, and expose it to just abhorrence and contempt. What shall we lay of his markless footstaps with fire and blood, of his burning cities and slaugthering their inhabitants? of his burning Persepolis, murdering Clytus, putting Philotas to the torture, disgracing Parmeno, an old, tried, faithful friend, and putting both father and son to death, and of permitting Callisthenes, the philosopher, to die in a dungeon, or in a worse mode? what expiation can be made for his wanton cruelties? the devastation of whole countries, the slaughter of millions of inhabitants, the crucifixion of an Indian prince, and the punishment of many Brahmins, whose only crime had been that of encouraging their countrymen to defend their liberties against a lawless invader? well might the Cento amans call him "a most mighty robber and murderer." How justly does the author of the first book of Maccabees characterize him, by laying that "he butchered kings," 1 Macc. xvi. 65-67. His debaucheries, his abominable ravellings, his more than Athise luxury, his Sardanapalian effeminacy, were flagrant, that his warmest encomiums have not been bold enough to deny, nor even to palliate them.

As to his magnanimity and generosity, which have been wonderfully extolled, these, upon close examination, would probably appear to be the fruits of that same vain-glorious ambition, which was the main source of all his actions. His liberal presents to writers and artists were the price of the groftest adulation; the most pitiful scribblers, if he was lavish in his flattery, was as lavishly repaid for his grateful incence; and a Charillus, a Cho, and an Agis, (the very dreg
dreaded by their respective countries, as Q. Curtius calls them) were as sure of being repaid as an Annuity or a Xenopho- 
thon, and were preferred by this famous hero, even to his 
own relations and generals. He was not less liberal to 
 fingers, lapars, and pipers; on whom he bestowed at one 
caroufal, above 10,000 talents, as we may naturally sup-
pole, for chanting his bloody victories and confounding his 
praise.

If we examine his character as a warrior and a conque-
ror, and trace his military exploits to his moving spring; it is natural to direct our enquiry to the justice of the war 
in which he engages, without a regard to which he is not 
 a conqueror and a hero, but an usurper and a robber. If we 
allow that the Persecutions were the allowed enemies of the 
Great Conqueror Alexander over the great number of 
nations who did not even know the name of Greece, and 
 had never done or designed him the least injury? The 
Scythian ambassador spoke truly, when he said: "What 
have we to do with thee? we never once set foot in thy 
country. Are not those who live in woods allowed to be 
ignorant of thee, and the place from whence thou comest? 
Thou boastest, that the only design of thy marching is to 
extirpate robbers; and thou thyself art the greatest robber 
in the world!" To the same effect was the answer of the 
 pirate, when Alexander questioned him, what right he 
had to infest the seas? "The same that thou hast to infest 
the universe; but because I do this in a small ship, I am 
called a robber, and because thou artest the same part with 
a great fleet, thou art entitled a conqueror." Upon the 
principle now stated, what idea ought we to form of Alex-
ander's last conquests? Was ever ambition more extravagant, 
or rather more furious, than that of this prince? It is in-
lated Alexander, who, when he was told by Anaxarchus the 
philosopher, that there was an infinite number of worlds, 
which in thinking that it would be impossible for him to 
conquer them all, since he had not yet conquered one. 
Quelt. lib. iii. pref.) to compare those pretended heroes, 
who have gained renown no otherwise than by the ruin 
of nations, to a configuration and a flood, which lay walle 
and deflroy, or to wild beasts which subfift merely by 
slaughter? Alexander, continues this writer, (De Benef. 
lib. i. c. 13,) an unjult robber from his youth, a cruel ra-
vager of provinces, an infamous murder of his friends, 
makes his happiness and glory to confit in rendering himself 
formidable to all mortals; forgetting that, not only the 
fierece animals, but even the urchin, makes themselves feared 
by their poisons. If the conquests of Alexander are ex-
amed in themselves separately from their moving spring, 
we shall find that they are frequently effected by a kind of 
valour nearly allied to a boldness that is blind, rash, and 
impeccable; that has no other guide besides a fanciful ar-
dour for false glory and a wild desire of distinguishing itself 
by any methods, let them be ever so unlawful. To form 
an accomplished general, prudence must often and direct 
the too fiery temper of valor; as this latter must animate 
and warm the coldness and slowness of prudence. Do 
these characteristics belong to Alexander? When we follow 
his to sieges and battles, are we not perpetually alarmed 
for his own safety, and that of his army? and do we not 
conclude, that they are every moment upon the point of 
being destroyed? Plutarch, in pronouncing the eulogy of 
Alexander, as an accomplished hero, gives a long detail of 
the various wounds he received; and intimates, that his 
courage was thus rendered more conspicuous. But it has 
been observed in praise of Hannibal, that he was never 

wounded in all his battles. It ought also to be observed, in 
eliminating the character of Alexander, as a conqueror 
and warrior, what Livy has suggested (lib. ix. c. 17.), who 
were the enemies with whom he combated. "Had he 
marshalled," says this writer, "against the Romans, he would 
soon have found, that he was no longer combating against 
a Darins, who, encumbered with gold and purple, the vain 
equipage of his grandeur, and dragging after him a multitude 
of women and eunuchs, came as a prey rather than 
as an enemy; and whom Alexander conquered without much 
blood, and without wanting any other merit, than that of 
daring to defile what was really contemptible. He would 
have found it very different from India, through which he 
marched in a riotous manner, his army quite flupided 
with wine; particularly when he should have seen the fords 
of Apulia, the mountains of Lucania, and the full recent 
footsteps of the defeat of Alexander his uncle, king of 
Epirus, who there lost his life." Alexander, therefore, 
partly owed his conquest to the weaknesses of his enemies. 
After all it cannot be denied, that Alexander possessed very 
great qualities; but they were those which were fitted to 
inspire admiration rather than esteem; while the worst 
rendered him a pest of mankind, and refleemed him, as an 
excellen biographer observes, "to one of those baleful met-
tors, which dazzle as they fly, but ruin where they fall." 
He possessed talents, says Dr. Robertson, (Hist. America, 
vol. i. p. 20.) which, notwithstanding the violent passions 
that incited him, at some times, to the wildest actions and 
the most extravagant enterprizes, fitted him not only to 
conquer, but to govern the world. If we throw into the 
scale of his errors and vices, the presumptuous idea he 
entertained of his merit; the high contempt he had for other 
men, not excepting his own father; his ardent thirst of 
pride and flattery; his ridiculous notion of fancying himself 
the son of Jupiter; of attributing divinity to himself; of 
requiring a free, victorious people to pay him a servile 
homage, and to prostrate themselves ignominiously before 
him; his abandoning himself so shamefully to wine; his 
violent anger, which rifes to brutal ferocity; the injustice 
and barbarous execution of his brave friends and most faithful officers, 
and the murder of his most worthy friends in the midst of 
feats and carousals: Can any one, says Livy, (ib. c. 17.) 
believe, that all these imperfections do not fully the 
reputation of a conqueror? But Alexander's frantic ambition, 
which knew neither law nor limits; the rash intrepidity 
with which he braves dangers, without the least reason 
or necessity; the weaknesses and ignorance of the nations, 
totallyunkilled in war, against whom he fought; do not 
these enervate the reasons for which he is thought to have 
erected the surname of Great, and the title of Heroes? Rol-
lin, in closing the estimate of Alexander's character, ob-
erves, that we do not find that he possessed the first, 
the most effcutional and most excellent virtues of a great prince, 
sO as to be the father, the guardian, and shepherd of his 
people; to govern them by good laws; to make their trade, 
both by sea and land, to flourish; to encourage and protect 
arts and sciences; to establish peace and plenty, and not 
subject his subjects to be in any manner aggrieved or injured; 
to maintain an agreeable harmony between all orders of the 
state, and make them conspire, in due proportion, to the 
public welfare; to employ himself in doing justice to all his 
ofjects, to hear their disputes and reconcile them; to con-
side his own as the father of his people, consequently as 
oblige to provide for all their necessities, and to procure 
them the severer enjoyments of life. He adds, Alexander 
seems possessed of such qualities only as are of the second 
rank,
ALEXANDER.

rank, those of war, and these are all extravagant. They are carried to the most rash and odious excess; and to the extremes of folly and fury; whilst his kingdom is left a prey to the rapine and exactions of Antipater, and all the conquered provinces abandoned to the infatiable avarice of the governors, who carried their oppressions to far, that Alexander was forced to put them to death. And as for his own soldiers, when they had plundered the wealth of the state, they became so licentious, so debauched, and aban-
doned to vices of every kind, that he was under a necessity of paying their debts, amounting to fifteen hundred thousand pounds. Although the Romans held Alexander's memory in great revere-
tion, it is very doubtful whether, in the virtuous ages of the commonwealth, he would have been considered as so great a man.

Upon the whole, if an impartial person of good sense reads Pintarch's Lives of Illustrious Men with attention, they will leave such a kind of impression on his mind, as will make him consider Alexander one of the least valuable among them. But how strong would the contrivance be found had all the lives of Epaminondas, of Hannibal, and of Scipio? How little would Alexander appear, let off with all his titles, and surrounded by all his conquests, even if considered in a military light, when compared with those heroes, who are truly great, and worthy of their exalted reputation! Diodorus Siculus, lib. xviii. ii. p. 160.—253. Ed. Woffington. Plutarch. Oper. tom. i. p. 604.—707. Ed. Xyland. Q. Curtii de Rebus gellis Alex. Mag. Paff.-

ALEXANDER SEVERUS. The Roman emperor, was born at Acta, in Phoenicia, according to one account, in the year 208, but, according to another preferred by Gibbon, Dec. 12, 205. His father was a Syrian, and became a conful. His mother was Mama, daughter of Julia Meza, the sister of Julia, wife to the emperor Severus; and as another daughter of Meza was married to Helogabu-
lus, Alexander, or Alexianus, which was his family name, was first cousin to that emperor. His mother, who was a woman of excellent talents and character, and who is impo-
sed to have imbued Christian principles, paid particular attention to his education, and employed such perfections for this purpose as were eminent for their probity and learning. His application and improved corresponded to his ad-

vantages; and every day was devoted to literary acquire-
ments, and to martial exercises. With a robust and grace-
ful form and considerable mental accomplishments, he com-
bined a mild, humane, and generous temper, so that he not only abhorred every kind of cruelty, but made it his chief study to please and oblige his parents and relations, and even his domestics. When Meza, his grandmother, perceived the approaching termination of Helogabalus's career of profligacy, she embraced a favourable opportunity of per-

fuading him to adopt Alexander. Accordingly he assumed this name instead of that of Alexianus, with the addition of Severus, and was invested with the title of Cæsar, A.D. 221. The young prince soon gained the affections of the people to a degree which excited the jealousy of the em-
peror; and he therefore resolved to destroy the envied and dangerous competition, either by corrupting the manners, or by taking away the life of his rival. Mama and her mother defeated his design in both these respects; and by means of the Praetorian guards, whose attachment they had secured, Helogabalus's attempt against the honour and life of the young Cæsar terminated in his own premature and ignominious death. By these guards Alexander was ad-

vanced to the throne, A.D. 222. The senate concurred, and immediately invested him with the various titles and powers annexed to the imperial dignity. At the same time they offered him the name of Antoninus, and the surname of Great; but therein he modestly declined. Alexander was a diligent and dutiful youth, of only 17 years of age; the reins of government were in the hands of his mother and grandmother; and after the death of the latter, Mama remained the favourite regent of her son and of the empire. With her consent he married the daughter of a patrician, who afterwards became the object of her jealousy and cruelty, and was banished by her influence, which Alex-

ander durst not oppose, into Africa. It has been said, in-
deed, by Lampridius, that the father was detected in a con-
spiracy, and that the repudiation of the daughter was the cause of his crime. But Herodian represents him as innocent. Under her direction, and with the approba-
tion of the senate, a council of state was appointed, consist-
ing of 16 of the wisest and most virtuous senators. At the head of this number, as praetorian prefect, was Ulpius, dif-
tinguished by his knowledge and respect for the laws of Rome, and the propriety of firmness of this aristocracy, for order and authority to the government. This city, whose influence, was purged from the superstition and luxury, which Helogabalus had introduced; his worthless creatures were also removed from every department of public adminis-
tration; and their places were supplied with men of virtue and ability. Learning, and the love of justice, became the only recommendations for civil offices. Valour, and the love of discipline, were the only qualifications for military employments. But the most important object of Mama's solicitude was that of forming the character of the young emperor. His excellent understanding encouraged cultivation, and led him duly to value the advantages of virtue, the pleasures of knowledge, and the necessity of labour. The natural mildness and moderation of his temper preferred him from the assaults of passion and the allurements of vice. His imalterable affection for his mother, and his re-
spect for the wife Ulpius, guarded his unexperienced youth from the poison of flattery. As Mama had probably em-

braced the profession of Christiani, it is no wonder that Alexander was very indulgent to the Christians, and would not suffer them to be persecuted on account of their reli-

gious tenets. He himself seems to have been well acquainted with the Christian morals; for he frequently repeated the golden rule of the gospel, "Do as you would be done by;" caused it to be inscribed over the gates of his palace, and on several public edifices; and observed it in his own conduct, with the greatest exactness.

"The simple journal of his ordinary occupations," says a popular historian, "exhibits a pleasing picture of an accom-

plished emperor, and, with some allowance for the difference of manners, might well defer the imitation of modern princes. Alexander rose early: the first moments of the day were consecrated to private devotion, and his domestic chapel was filled with the images of those heroes, who, by improving or reforming human life, had deserved the grateful reverence of posterity. But, as he deemed the service of man-

kind the most acceptable worship of the gods, the greatest part of his morning hours was employed in his council, where he discussed public affairs, and determined private causes, with a patience and discretion above his years. The drysnefs of business was relieved by the charms of literature; and a portion of time was always set apart for his favourite studies of poetry, history, and philosophy. The works of Virgil and Horace, the republics of Plato and Cicero, formed
formed his task, enlarged his understanding, and gave him the noblest ideas of art and government. The exercises of the body succumbed to those of the mind; and Alexander, who was tall, active, and robust, surpassed most of his equals in the gymnastic arts. Refreshed by the use of the bath and a light dinner, he returned, with new vigour, the business of the day; and, till the hour of supper, the principal meal of the Romans, he was attended by his secretaries, with whom he read and answered the multitude of letters, memorials, and petitions, that must have been addressed to the master of the greatest part of the world. His table was served with the most frugal simplicity; and, whenever he was at liberty to confute his own inclination, the company consisted of a few select friends, men of learning and virtue, amongst whom Ulpius was constantly invited. Their conversation was familiar and instructive; and the pauses were occasionally enlivened by the recital of some pleasing composition, which supplied the place of the dancers, comedians, and even gladiators, to frequently farronadoed at tables of the rich and luxurious Romans. The dress of the dinner was plain and modest, the demeanour courteous and affable; at the proper hours his palace was open to all his subjects; but the voice of a crier was heard, as in the Eleusinian mysteries, pronouncing the same salutary admonition: "Let none enter these holy walls, unless he is conscious of a pure and innocent mind."

His mother, though a princess of found judgment and good disposition, and though she owed many of the excellencies he possessed to her wisdom and attention, was more fond of pomp than himself; and did not approve the plainness and popularity of his behaviour. "Take care," said she to him one day, "your weakness not your authority, and render it contemptible." "I render it," he answered, "more secure and more durable." Whilst he was strict, and sometimes severe in his administration of public justice, and in the punishment of those who opposed the public, he was naturally mild and gentle; and though he practised rigid economy, and exercised self-denial in every thing that pertained to his own gratification, he was liberal and beneficent. In the course of his reign he made three general distributions of provisions to the people, and three largesses in money to the soldiers. To the intelligent and distrest he gave lands, flocks, cattle, and all necessaries of habitation; rightly judging, that this mode of exercising his liberality was more beneficial and less humiliating than the giving of gold and silver. If he granted pecuniary assistance, it was by way of loan; and he established a bank, where all who wanted money found it at a moderate interest, and on some occasions he lent without interest. It was a saying of this emperor; "Imperium in virtute, non in decore;" i.e. "The majesty of the empire consists in virtue, and not in an ostentation of riches." Although he was very religious, his offerings in the temples were not magnificent. He often repeated the words of Periuss (Sat. ii. v. 69). "In fuseo quiqul facit aurum." "What has gold to do with faced things?" His respect for virtue extended to the dead, as well as to the living. Accordingly he collected in Trajan's square the statues of the deified emperors of Rome, and of the famous Roman commanders, and adorned them with inscriptions, setting forth their great exploits and eminent virtues. In his palace he had two chapels, in which the principal objects of his veneration were ranged in two classes, the one deified to virtue, and the other to talents. In the first were placed the good emperors, among whom he very erroneously ranked Alexander the Great; and next to them the wife men, by whom useful leissons mankind had been benefitted; and here were blended Abraham, Orpheus, Apolloimus Tyanaeus, and Jesus Christ. The second chapel was devoted to military heroes, and men conspicuous in the republic of letters, Achilles, Cicero, Virgil, whom he called the Plato of the poets, and some others. In order to encourage the progress of letters and of science in general, he allotted pensions to rhetoricians, grammarians, physicians, architects, men skilled in mechanics, and even to amusicians and astrologers. He established schools for all these arts, and provided for the instruction of the poor without expense to them. His life, however, has not been free from blemishes. His deference for his mother was considered as carried to a culpable excess, more especially as she, with all her good qualities, was addicted to vanity and avarice. He gave her name to several buildings, which, as we learn from Ammianus Marcellinus (lib. xxviii. p. 372.), they retained in the fourth century; and caused her to be honoured with the titles of Augusta, mother of her country, of the armies, and of the senate. He was also charged, and not altogether without foundation, with being of a foppish and inquisitive temper, and with being inclined to vanity; which latter weakness he indicated by his aversion of polite, and his affection of being regarded as a Roman and of the family of Marcelli, and not a Syrian. His timidity likewise betrayed him into imbecility of conduct; particularly with reference to the pretorian guards, who by their mutiny produced a civil war in Rome, that lasted three days, and that terminated in the massacre of Ulpius. Although this wife man, who was the friend of the laws and of the people, sheltered himself from the reiterated rage of this class of persons in the emperor's palace, and was murdered even in his presence, he had not resolution sufficient to avenge this atrocious crime in the manner he desired. Such indeed was the weakness of government, that the tyranny of the army threatened with instant death his most faithful Ministers, provided that they were only infected of an intention to correct their intolerable disorders. The historian Dion Cassius, who had commanded the Pannonian legions with a spirit of ancient discipline, and whom the emperor recompensed by appointing him his colleague in the confusihip, was compelled to retire, by his advice, from the city, and to spend the greatest part of his confinement at his villas in Campania, and the remainder of his days in Bithynia, his native country. Dion. Caff. Hist. lib. lxxx. p. 1371.

On another occasion, however, he manifested a becoming firmness and magnanimity. When some of the soldiers at Antioch had excited a sedition in the legion to which they belonged, and interrupted his mild expostulations by their clamours, he addressed them in the following dignified and spirited language: "Refer your threats, till you take the field against the Persians, the Germans, and the Sarmatians. Be silent in the presence of your sovereign and benefactor, who beflows upon you the corn, the clothing, and the money of the province. Be silent, or I shall no longer flay you soldiers, but citizens; if thoes indeed who disclaim the laws of Rome deserve to be ranked amongst the meanest of the people.

When their bratified arms threatened even his person; "Your courage," reframed the intrepid emperor; "would be more nobly displayed in the field of battle; we may destroy; you cannot intimidate; and the severe justice of the republic would punish your crime, and revenge my death." The clamour continuing, the emperor, with a loud voice, pronounced the decisive sentence: "Citizens, lay down your arms, and depart in peace to your respective habitations." Such was the effect of the sentence, that the clamour was instantly silenced; the soldiers confessed their crime, and supplicated remission; nor were they refor to their rank in the army, till he had punished with death those
those tribes, whose connivance had occasioned the mutiny. The grateful legion served the emperor, whilst living, and revered him when dead. The difference of his temper and conduct on the occasions above recited must be ascribed to the different vigour of mind, which he possessed in his youth and in his ripeness. When he became capable of taking the government into his own hands, and of exerting his genius and courage, no prince could more effectually command the awe, as no one ever more deserved the love, of his soldiers. It was a frequent declaration of Alexander, "the soldier does not fear his commanders, unless he be fed and clothed, and has some money in his purse." And whilst he furnished them with mules and camels to carry part of their baggage in their marches, he used to say, "that he took more care of his soldiers than of himself, because it was on them that the welfare of the republic depended; and he perfected the plan which other emperors had concurred for securing to the troops a decent and comfortable retreat in their old age.

Whilst Artaxerxes, the reformer of the Persian monarchy, was preparing to invade the Roman dominions, Alexander sent ambassadors in order to dissuade him from engaging the two empires in a long and dangerous war. The missive was received with contempt; nor did any of Alexander's remonstrances avail to prevent the Persian monarch from ravaging Mesopotamia and entering Cappadocia. The emperor, therefore, resolved to march against him in person. In the spring of the year 233, Alexander, with an army of the pratorian guards and part of the hardy legions of Europe, advanced towards the frontiers of the Roman dominions to meet the great king, which was the haughty style assumed by Artaxerxes in his embassies; whose force consisted, as history, facetiously reports, of 120,000 horse, clothed in complete armour of steel, of 700 elephants, with towers filled with archers on their backs, and 1800 chariots armed with spears. Of the event of the battle which ensued, historians have given very contradictory accounts. Herodian affirms, and Mr. Gibbon acquiesces in his account, that the plan of Alexander for the conduct of the war, however judiciously concerted, totally failed. The emperor himself, influenced by his mother's counsels, and perhaps by his own fears, deserted the bravest troops and the fairest prospect of victory; and after confounding in Mesopotamia an inactive and inglorious summer, led back to Antioch an army diminished by sicknes and provoked by disappointment. But the Persian monarch, in several obstinate engagements against the veteran legions of Rome, lost the flower of his troops; and instead of expelling the Romans from the continent of Asia, found himself unable to wrest from their hands the little province of Mesopotamia. Crever, and many other modern writers chide rather to follow Lampridius, whose account is entirely different from that of Herodian. The Periana, says this last author, were totally defeated, and Alexander approved himself an intrepid soldier and a skilful general. The great king fled before his valour; an immense body suffered and the conquest of Mesopotamia were the immediate fruits of this signal victory. Alexander, it is said, having taken care to guard Mesopotamia with several well garrisoned forts, returned to Rome, A. D. 234, to give the senate an account of his exploits, and was received by perorns of all ranks with the greatest demonstrations of joy; and obtained a signal triumph. His triumphal car was drawn by four elephants; the air recondomed with acclamations, and the shouting attendants unceasingly exclaimed, "Rome is happy, whilst the fees Alexander alive and victorious."

Soon after his triumph, Alexander, accompanied by his mother, marched against the Germans, who had passed the Rhine, and who were making inroads into every part of Gaul. Upon his arrival in Gaul, he sent ambassadors to the barbarians, in order to treat with them; and if Herodian may be credited, to purchase peace, which he preferred to the precarious issue of a war. Having passed the winter in the neighbourhood of the Rhine, he employed himself in introducing discipline among the levied legions of Gaul. His attempts for this purpose produced discontent in the army, which were aggravated by a person, originally a barbarian of mean origin, whose father was a Goth, and mother an Alan, and who had been raised from the lowest station to the rank of a general officer. This person was proclaimed emperor by the turbulent soldiers; and made his way to the throne by the massacre both of Alexander and his mother. This event happened on the 19th of March, A. D. 235, when Alexander was in his 27th year, and after he had reigned 13 years. The untimely death of Alexander was universally regretted. The soldiers, who were not concerned in the plot, manifested their resentment by a speedy vengeance, which in immediately killing the murderers of their prince. The factions pressed both to him and his mother divine honours; appointed for them strange, priests, and sacrifices; and instituted, in honour of the deceased emperor, an annual feast, which was celebrated on the first of October, the day of his nativity. Crever's R. M. Emp. vol. viii. Book xxiv. p. 279—350. Anc. Hist. vol. xiii. p. 422—449. Gibbon's Hist. vol. i. p. 238, 242, 337, vol. ii. p. 450.

Alexander Œdipus, a disciple of Sosigenes, and preceptor of Nero, by whom he is said to have been corrupted, is known as the author of a commentary on Arilottel's Meteorology; which has been attributed to Alexander Aphrodisius. Suidas, Fab. Bib. Græc. lib. iii. c. 11.

Alexander Ætolus, a grammarian of Pleuron, in Ætolia, was a contemporary of Aratus, and celebrated among the seven writers of tragedy, called the Æthiop in the time of Ptolemy Philadelphus. He also wrote elegies, cited by Athenaeus (lib. xiv. p. 699), and other poems, commended by Servius on the 12th Eniad of Virgil, and referred to by Athenaeus (vii. p. 283, 296). Suidas, Fabr. Bib. Græc. lib. ii. c. 19.

Alexander Aphrodisius, so called from a city of Caria, where he was born, was an eminent philosopher of the school of Arilottel, about the close of the second or beginning of the third century. He was appointed public professor of the Arilottelian philosophy, under the Roman emperors, Septimus Severus and Caracalla, either at Athens or Alexandria, and dedicated the first fruits of his labours, which is an excellent treatise, "On Fate," affording the doctrine of Divine Providence, to these emperors. He was supposd to have fo well understood the speculations of his master, and to have so far successfully explained them, that he was respected by his contemporaries as an excellent preceptor, and followed by succeeding Arilottelians among the Greeks, Latins, and Arabicans, as the best interpreter of Arilottel. He obtained the appellation of "The Commentator," on account of the number and value of his Commentaries. Hottinger and Herbelot affirm, that Arabic translations of his commentaries are still extant. In his book concerning the foul, he maintained, that it is not a distinct substance but a self, but the form of an organized body; he denied its immortality, and affirmed, that to maintain the possibility of its exiling separately from the body, was as absurd as to say that two and two make five. The works of this philosopher still extant are his book "De Fato," published from the press of Aldus, at Venice, in 1534, with a translation by Grotius, 4to. at Amster-
A L E X A N D E R.

dom, in 1648; and in London, with a new Latin translation, in 1688, 8vo.; his Commentaries on Aristotle's Topics, Analytics, Metaphysics, Physics, Rhetoric, &c. first published at Venice, in the 16th century, and many of them afterwards reprinted in different places; but since the study of Aristotle has been neglected, his best commentator is forgotten. The principal of his medical works is his "Treatise on Fevers," translated into Latin by Vallis, of which Haller has given an analysis; Bib. Med. Pract. vol. i. p. 227. Tabls. Bib. Gracc. vol. iv. c. 25. Bruckner's Philos. by Enfield, vol. ii. p. 104.

ALEXANDER, CORNELIUS, surnamed Polybius, on account of the numerous histories written by him, a celebrated historian and grammarian, was born, according to Suidas, at Miletus, but, according to others, at Cetyzum, a city of Phrygia, and having been a slave, was sold to Cornelius Lentulus, to whom he was preceptor; and from whom he obtained his freedom and the name of Cornelius. He flourished about 80 years before Christ. In Suidas we learn, that he was the disciple of Ctesias, and that he was at Rome in and before the time of Sulla. He perilled in the flames of his house at Laurentum; and his wife became distracted by the event, and hanged herself. Suidas further adds, that he wrote innumerable works; and particularly five books concerning Rome, in which he says, that a Hebrew female, called Mofo, was the author of the Hebrew law. His works in history and philosophy are cited by Plutarch, Laertius, and other ancient writers. Clemens Alexandrinus (Strom. lib. i. tom. i. p. 306, ed. Potteri) cites a book concerning the Jews, in which Alexander mentions letters of Solomon to Vaphres, king of Egypt, and to the king of the Phenicia of the Tyrians, and their respective answers. He refers also (tom. i. p. 538.) to remarks made by Alexander on the mode of living in use among the Indian Brahmans; he reports (tom. ii. p. 357) from a book of Alexander concerning the Pythagorean Symbols, that Pythagoras was a disciple of Naouraus, an Ilyrian, erroneously supposed by some to be the same with the prophet Ezekiel, and that he had also received instruction from the Galli and Brahmans. Eusebius (in his Prep. Evang. lib. ix. c. 175.) makes a long extract from Alexander's book concerning the Jews, and extols the author's well-known great ingenuity and various learning. This is probably the work referred to by Justin Martyr, in his "Exhortation to the Greeks," when he mentions those who represent Moses as the leader of the Jews. Plutarch (de Mufica, Op. tom. ii. p. 1152.) and Atheneus (lib. xi.) speak of him as a writer in music; and his acquaintance with natural history may be inferred from Pliny's frequent references to his works. Fab. Bib. Gracc. lib. v. c. 35. tom. ix. p. 430.

ALEXANDER PSEUDOMANTIS, an artful and profligate impostor, was born at Abonoticho, in Paphlogonia, and practised his delusions in the reign of the emperor Aurelian, towards the close of the second century. He professed by nature a variety of talents and accomplishments, by the misapplication of which he was qualified for impeding upon the credulity of the vulgar. Deftinct of principle, he engaged with a countryman and disciple of Apollonius Tyaneus, who, under the mask of a medical profession, exercised the trade of an impostor and magician, and deluded those who applied to him by pretending to reveal secrets in concerns of love, and of lost and hidden property. Alexander was an useful servant and an apt scholar; and when his master died, practised his lefions and followed his trade. Such was his success, that he infatuated a rich Macedonian woman, and induced her to follow him and his associate from Bithynia to Macedonia and to Pella, and to contribute by her fortune to their support. Having procured, in the neighbourhood of Pella, one of those large serpents which are perfectly harmless and very tractable, and with which that country abounds, they determined by means of this animal to establish an oracle, which should impede upon those persons who were eager to gain the knowledge of futurity, and who by their credulity were susceptible of delusion. In their way to Abonotichos, the proposed scene of their operations, they visited Chalcedon and formed a party, by whose affiance they had access to the temple of Apollo, where they hid tablets of brass on which it was written, that Asklepius, with his father Apollo, would soon make Abonotichos the place of their residence. The inhabitants of this place were secretly deluded, that they laid the foundation of a temple to Asklepius, with whose presence they expected soon to be honoured. Alexander, by a pretended oracle, caused himself to be declared a descendant of the hero Perseus, and the son of Podalirius, which his stupid countrymen believed, though they well knew that his father and mother were persons of the meanest condition. With a drefs and accompaniments, suited to this high original, he entered his native town. Having hidden a goffer's egg, in which he had put a young serpent, near the foundations of the temple, and having previously performed a variety of superstitious ceremonies, he went with a crowd of attendants in search of his egg; and when he had found it, he declared that Asklepius, who was worshiped under that form, was actually arrived, and the people received him with acclamation. Alexander proceeded with his imposture by exhibiting his serpent, prepared for the purpose, to the deluded multitude, who believing him possessed of the power of working miracles, and misled by his affected enthusiasm, were fuitably disposed for everything that followed. From Abonotichos the delusion spread through all the neighbouring nations, and the people hastened from Gabilia, Bithynia, and Thrace, to see the new god, whom the prophet called Glycon. Money was procured to finish the temple, and the god was to make it the place of his abode, and to give oracular answers to those who consulted him. The oracle was consulted by a billet, which Alexander contrived to open secretly; and he adapted the answer to the purport of its contents. By degrees he made the god pronounce oracles with his own voice, by the affiance of a perdon that was concealed behind him; and these oracles were delivered only to the rich and powerful. This practice became a gainful trade, and the impostor derived from it a yearly income, which amounted to 7 or 800 thousand drachmas, and which enabled him to live sumptuously, and to purify those debauchees to which he was inclined, and to which he had been habituated from his youth. It was not long before the reputation of this prodigy reached Rome; and Rutilianus, a superfluous senator of the first rank, was deceived by him, and thus the number of those who consulted him was prodigiously augmented. Rutilianus, who believed the doctrine of the transmigration of souls, decried of being informed under what form he had lived in former ages, and whose soul he now posssied, received an answer which served the impostor's purpose, and which gave him such influence over the credulous senator, that he consented to marry his daughter, and conceived himself to be exalted to the rank of the gods. Lucian, who blends fiction with his humorous account of Alexander's impostures, relates, among other instances of his delusion, the following incident. Rutilianus, having procured for him access to the emperor, he delivered an oracle, commanding that, in the war between Marcus Aurelius and the Quadi and Marcomanni, two lions should be thrown alive into the Iliger, with spices and a Sacrifice, and promising, that the confederation would be victory, glory, and peace. The order was executed, and
ALEXANDER.

and the lions, who leaped from thence into the enemies' country, were destroyed; but the Romans were soon afterwards totally defeated. Alexander, for preserving his reputation, calmly said, that the oracle had foretold a victory, but had not declared whether it would happen to the Romans or their enemies.

Amidst the successes of Alexander, he found himself attacked by two classes of adversaries, who determined to unmask his imposture. These were the Christians and the Epicureans. In order to counteract their influence, he began the ceremony of the pretended mysteries, which he instituted in imitation of the Eleusinian, with proclaiming, "Hence all Christians;" and the choir rejoined, "Hence all Epicureans." He also often repeated, that Pontus was full of Atheists and Christians, and that these enemies of the gods ought to be stoned; and what he advised, he endeavoured more than once to execute. Lucian, who once endeavoured to enframe him, had nearly lost his life in the attempt. The impostor, however, determined to destroy him; and with this view he received him politely, and, at his departure, made him presents, and furnished him with a velict and rovers. When he was at sea, he observed the pilot weeping, and disputing in a mysterious manner with the sailors. At length the honest pilot disclosed the secret, and with great concern informed Lucian, that he had received orders to throw him into the sea; but that he had lived with honour for 60 years, and that he could not prevail with himself to render his old age infamous, and to incur the displeasure of the gods by murder. Lucian was put on shore, and escaped the villainy of the impostor. This delusion lasted 20 years; but it is said, that Alexander terminated his life in a tragical manner; being destroyed by worms, which proceeded from a mortification in the foot, leg, and thigh. Lucian's Alexander fea Pseudomantis apud oper. tom. ii. p. 207. Crevier's Rom. Em. vol. vii. p. 346—357. See imposture and truth admirably contrasted in the character and conduct of St. Paul, and this Alexander, by lord Lyttelton in his "Converction, &c. of St. Paul," Works, vol. ii. p. 54, &c. 8vo.

ALEXANDER, the Sophist, was born in Scelicia, a city of Cilicia, and educated under Favorinus, Adrian's great favourite, who taught him the art of speaking, in which he excelled, and for which he is highly commended by Philodorus. The first office he fulfilled was that of ambassador from Scelicia to the emperor Antonine; and he was afterward interpreter for the Greek tongue to M. Aurelius. He spent the greatest part of his life in the schools of Antioch, Rome, and Tarfus; and he visited almost all the parts of Egypt. Whilft he was at Athens, he acquired great fame by the extemporaneous orations which he delivered, and received very distinguished tokens of favour from Herod. He died, as some say, in Gaul; but according to others in Italy, at the age of 62, or by some accounts, 68 years. Philodorus de Vitis Sophistarum, apud oper. p. 570. ed. Olearri.

ALEXANDER TRALLIAN, a learned and ingenious physician of Trales, a city of Lydia, flourished at Rome in the time of the emperor Julian, about the middle of the sixth century. Friend is very copious in his account, and profuse in his encomiums on the works of this great man, whom he considers as one of the best practical physi- cians among the ancients.

Like Hippocrates he travelled over various countries, over Italy, France, Spain, and Egypt, to improve himself in knowledge; and is said to have acquired a competent acquaintance with the languages of the different countries through which he passed. He invented several compositions, and improved many of those in common use. He was liberal in administering preparations of iron internally, which before his time was little, if at all, done. He followed the practice of Hippocrates and Galen, though not servilely, but as preferring it to that of Epictetus and Orphus, with whose works he appears to have been well acquainted. He was not, however, free from some of the errors of the age in which he lived, being credulous and superstitious, and having great faith in charms and amulets. He has given no account of the diseases peculiar to women, which Friend justly thinks, considering the general estimation he was in, and the extent of his practice, is very singular.

His works were first printed in Greek by Robert Stephens, at Paris, 1543, in folio; in Greek and Latin, at Basle, 1556. Johan. Guinthero Interprete. For an account of various other editions, see Haller's Bib. Med. Prat. vol. i. p. 305. — Haller's edition was printed at Lauffane, in 1772.

ALEXANDER JANNÆUS, king of the Jews, was the third son of Hyrcanus, and succeeded his brother Aritobulus in the year before Christ 166. Queen Salome, the widow of Aritobulus, took him and his two brothers out of prison, and placed Alexander on the throne. His fourth brother endeavoured to deprive him of the crown, and was put to death; but the youngest, whose name was Abfalom, was favoured with his protection, as long as he lived. Alexander, being a frugle and warlike prince, began his reign with leading an army against Ptolemais; but his own dominions being invaded during his absence by Ptolemay Lathyrus, he was obliged to raise the siege, and return to defend them. On the banks of the Jordan he was defeated, with the loss of 38,000 men, besides those that were taken prisoners; and if he had not been succoured by Cleopatra, Lathyrus would have forced his way into Judea. Alexander, after an interview with Cleopatra at Ptolemais, returned to Jerusalem; and having recruited his broken army, he marched against Galara, and took it. He next proceeded against Amathus, and reduced it after a very short siege; but he was soon obliged to relinquish it in consequence of a defeat by Theodotus, the son of Zeno, tyrant of Philadelphia, in which he lost many men, his baggage, and the whole of the treasure which he had taken possession of at Amathus. The next place against which he directed his arms was Gaza, which had afforded protection and assistance to Lathyrus; and on this account, as soon as the town was betrayed to him, he revenged himself on the inhabitants, after leading them to expect clemency and moderation, by abandoning them to the fury of his soldiers. However, this act of vengeance, executed with singular severity, provoked the citizens to inflict the utmost of their power; so that he lost of his own men as many as he destroyed of the enemy. He then reduced the city to a heap of ruins. On his return to Jerusalem, the people, exasperated by the Pharisees, who were constantly calabbing against him, insulted him with the most opprobrious language, exclaiming that such a slave as he was unworthy of either the pontifical or regal dignity, and proceeded even to violence against his person. Although he took effectual measures to secure himself from further insult and injury, he was wearied with their clamours, and marched out of Jerusalem, in order to gratify his inclination for war. Having taken and destroyed the city of Arathus, he proceeded against the Arabsians, whom he subdued, and then laid the Moabites and Mountaniers of Gilead under tribute. Near Gadara he fell into an ambush; and it was with great difficulty that he escaped and regained his own capital. During his absence, his inveterate enemies, the Pharisees, had
caused a rebellion, which brought on a civil war, that lasted six years. Demetrius, surnamed Eucranes, affilid the rebels with a considerable force; and after some previous skirmishes Alexander was defeated, and forced to retire for shelter to the mountains. This defeat, however, induced the Jews who had joined Demetrius to desert him, and join the army of Alexander; and Demetrius, alarmed by this defection, left Judea. This circumstance afforded Alexander an opportunity to march against the rebellious Jews; but though he defeated them in every engagement, the fury of their resentment continued till a decisive battle put an end to the war. In this last act he lost the greater part of his army, and drove the rest into Bethme, which he besieged and captured. Josephus, who being a zealous Pharisee, may possibly have exaggerated, informs us, that he caused 300 of the principal captives to be carried to Jerusalem, where they were all crucified at the same time and place; and that whilst they were hanging on the crosses, he ordered their wives and children to be butchered before their faces. It is added by the historian, that a banquet was prepared for himself and his companions, to feast on this horrid scene, that they might behold and enjoy the torture and sufferings of the sufferers. After this event, the rebels dispersed; nor were the Pharisees able to make any effort against him as long as he lived. The succeeding years of his life were employed in extending his conquests through Syria, Idumea, Arabia, and Phœnicia; and in establishing his character as a warlike and victorious prince. His return to Jerusalem, after an expedition of three years' continuance, was the occasion of loud acclamations on the part of his subjects. But from this time he devoted himself to drinking, and other debaucheries; which at length brought on a quartan ague, that prevailed till the day of his death, which happened about three years after his return. His ambition for making new conquests still continued; but his strength being exhausted both by fatigue and intemperance, he died in his camp before Regaba, a fortress in the Gerafena territory beyond Jordan, which he was besieging, in the 27th year of his reign, in the year before Christ 79. He left two sons, Hyrcanus and Aristobulus; but deferred by his will, that his wife Alexandra should govern the kingdom during her life, and appoint for her successor either of them, according to her own pleasure. Alexandra, by conciliating the Pharisees, according to the advice of her husband, secured their influence with the people; so that they celebrated the funeral of the deceased king with great pomp, and confirmed her as a sovereign administratrix of the nation. Her elder son Hyrcanus was appointed high priest, and the direction of all affairs of importance was committed to the Pharisees. Their resentment against those who had opposed them in the late reign still continued; and they contrived every method that was practicable for destroying them. This conduct, to which they saw no end, induced them to assemble, and, with Aristobulus at their head, to wait on the queen, and to implore her protection. The queen, having surrendered herself and the government to the Pharisees, could devise no means for their liberty that were likely to be effectual. At length they complied with their request, and consented that they should dispose themselves into places where she had garrisons. In the year before Christ 76, Alexandria was besieged by a disorder which threatened her life; and when Aristobulus perceived her danger, he repaired to his friends, in the garrisoned towns, and they arranged themselves in great numbers under his standard; hoping that he would exert himself for abolishing the odious and oppressive tyranny of the Pharisees, and well knowing that no service of this kind could be expected from his brother Hyrcanus, who had been educated by his mother in a blind submission to this sect. The Pharisees were alarmed, and accompanied Hyrcanus to the queen, in order to represent what had occurred, and to demand her assistance. The impaired state of her health would not admit of her interference, and having left the care of the government to them, she appointed Hyrcanus her heir general, and soon after expired. Accordingly he took possession of the throne, and raised an army to oppose his brother, who was supported by the people. A battle near Jericho decided the quarrel. Hyrcanus, abandoned by the greatest part of his troops, who went over to his brother, was obliged to fly to Jerusalem, and afterwards to seek an asylum in the castle of Bithynia, whilst his partisans, who were chiefly of the sect of the Pharisees, took refuge in the temple. In a little while after, as well as Hyrcanus, submitted to Aristobulus; and in the year before Christ 69, he obtained both the high-priesthood and the crown. Josephus Ant. lib. xii. c. 12—15. tom. i. p. 666—675. Bell. Jud. lib. i. c. 4. tom. ii. p. 59—65. Anc. Unc. Hist. vol. iii. p. 114—125. Rollin's Anc. Hist. vol. viii. p. 4—11.

Alexander, Padas, king of Syria, was, as some say, the natural son of Antiochus Epiphanes; but, according to others, a young man of mean extraction at Rhodes, named Bassas, born under the name of Heracleides, at the instigation of Ptolemy, Attalus, and Ariares, to pervert the son of Antiochus Epiphanes, and under that title, to lay claim to the crown of Syria, in opposition to Demetrius. After he had been acknowledged by the three kings above-mentioned, Heracleides, who conducted the imposture, took him to Rome, in the year before Christ 152, and together with him Labecia, the real daughter of Antiochus Epiphanes, and presented them to the senate, who received them graciously, and paid a decree in their favour; though, as Polybius afferts (Legat. exilii. p. 666), the whole city was convinced of the imposture. The senate not only acknowledged Bassas under the assumed name of Alexander, but decreed that their allies should assent to him in his endeavours for recovering the rights of his father. Thus comtemplated by the Roman senate, he landed in Syria, and found no difficulty in raising troops, which, together with the succours afforded him by Ptolemy, Attalus and Ariares, enabled him to make himself master of Ptolemais, the reduction of which induced a great number of persons who were disaffected to Demetrius to join him. Demetrius and Alexander were competitors for the favour and support of Jonathan, who had succeeded Judas Maccabæus in the command of the Jewish forces, and were on to outvie each other in their alluring offers. Alexander, however, prevailed; and with him Jonathan formed an alliance. These two competitors took the field at the head of their respective armies; and though Alexander was defeated, he maintained his ground; and, being supplied by his powerful allies with fresh succours, he fought in a second battle, in which Demetrius was killed, before Christ 150. Alexander, having gained possession of the whole Syrian empire, sent an embassy to Egypt, demanding Cleopatra, the daughter of Ptolemy, in marriage; and the king not only complied with his request, but attended her in person, and the nuptials were solemnized at Ptolemais in a very splendid and magnificent manner. Alexander could not bear his elevation and prosperity, but became insolent and debauched, and committed the management of his affairs to a profligate and tyrannical favourite, whose name was Ammonius, and who conducted himself with a degree of debauchery and cruelty, which exposed him and
ALEXANDER.

and his master to the hatred of the whole nation. Demetrius, the eldest of the deceased king’s sons, availed himself of this opportunity for recovering his right; and was acknowledged by Appolonius, governor of Cilicia and Phoenicia. When Alexander was routed out of his legaturry, and perceived the danger of his situation, he applied to his father-in-law, Ptolemy, for assistance; and he marched to his relief with an army, which the author of the second book of Maccabees compares to the sand of the sea-shore. Upon his arrival at Ptolemais he was informed, or, as others say, he pretended, that Alexander was plotting against his life, and that Ammonius had charged him with the execution of this detestable scheme of treachery. Ptolemy complained to the king of Syria of this plot, and demanded the criminal to be delivered up to him; but Alexander refusing to comply, Ptolemy concluded that he was privy to the design; and that Ammonius was only executing his master’s orders. Upon this real or feigned plea, Ptolemy determined to turn his arms against his fon-in-law, and sent ambassadors to young Demetrius, offering him his daughter Cleopatra, the wife of Alexander, and promising to settle him on the throne of his ancestors. Demetrius accepted the offer, and when the news of this event reached Antioch, Ammonius was put to death by the populace; but the inhabitants of this city refused to declare in favour of Demetrius. However, such was the hatred they had conceived against Alexander, that they entered into a confederacy against him, and opened their gates to Ptolemy, offering to put the crown on his head. This prince, says Josephus, knowing how to fet bounds to his ambition, rejected the proposal, and with singular self-denial and generosity, declared, that he could not, without the most flagrant injustice, place himself on the throne of Syria, by excluding the lawful heir. He proceeded to recommend Demetrius by an eloquent on his character, and by pledging himself as guarantee for his future conduct, at the same time undertaking to sift him and to teach him the art of governing. These disinterested representations of Ptolemy had the desired effect. Demetrius was proclaimed king of Syria, and placed on the throne of his ancestors. Alexander, who was then in Cilicia, assembled a numerous army and advanced to Antioch. Ptolemy met him, and a bloody engagement ensued, in which Alexander was defeated; and his adherents abandoning him, expelled the caufe of Demetrius. Upon this Alexander fled to Arabia, and seeking refuge in the house of Zabadil or Zabel, or as Dioscorus Sicelus (in Excerpta Photii cod. 244.) calls him, Dioecles, was murdered by his treacherous host. Ptolemy was wounded mortally by Alexander’s friends; and when the head of the murdered prince was brought to him as a present from the Arabian, the joy he felt on the occasion soon put an end to his life. Demetrius, without any further opposition, took possession of his father’s dominions, and by himself from this victory, Nicator, or the conqueror. Alexander Balas had reigned according to Josephus, five, but according to the history of the Maccabees, fix years, reckoning from the 16th year of the era of the Seleucids to the 16th, which was the first year of the reign of D. nicatus Nicator. This happened in the year before Christ 145. Such is the account which Josephus gives of the troubles of Syria, and the death of Alexander Balas. But the author of the history of the Maccabees varies much from him, especially in what relates to the character of Ptolemy Philometor, whom Josephus highly commends; whereas the author of the first book of the Maccabees represents him as an ambitious and perfidious prince, who trampled under foot the most sacred laws of nature and justice, to raise himself on the ruins of his for-in-law, Josephus Ant. lib. xiii. c. 24. tom. i. p. 634—643. Diodorus Sic. tom. ii. p. 592. 1 Maccabees xi. 4—12. Anc. Un. Hist. vol. viii. p. 224—233.

ALEXANDER, bishop of Jerusalem, was a disciple of Panteus and Clement of Alexandria, towards the close of the second century, and distinguished his matuer years by the firmness and zeal with which he maintained his Christian profession at a period of severe persecution. In the 12th year of the emperor Severus, A. D. 204, when he was bishop of the church in Cappadocia, he was imprisoned for his profession of the Christian faith; and his fidelity and constancy on this occasion induced the church at Jerusalem to elect him as colleague to Narcissus, whose advanced age of 116 years, rendered him incapable of performing the duties of his office. His imprisonment seems to have continued from the year 204 to the year 217, at which time it appears from a letter written by him to the church of Antioch he was not released from confinement. About this time, however, or soon after, he visited the church at Jerusalem, and was promoted to the bishopric of that church. Of the revelation and visions which are said to have passed, he either himself, it is not necessary to give any account in this place, as they are not likely to obtain much credit. His known character and tried integrity, obviously recommended him to this choice, and he approved himself worthy of it by a course of service and suffering that lasted 59 years. When the persecution of the Christians was renewed under the emperor Decius, Alexander, now venerable for his old age and grey hairs, as Eusebius expresses himself, was summoned to the governor’s tribunal at Cesarca, and about the year 250, avowing his profession, before the tribunal, he was cast into prison, where his confinement and sufferings terminated in his death, A. D. 251. From the fragments of his history that remain, and that are chiefly preserved by Eusebius in his “Ecclesiastical History,” (p. 212. 216. 222. ed. Valet.), we learn, that Alexander erected a library at Jerusalem, which contained in his time, and furnished materials for his history. It appears also from the testimony of Origen, with whom Alexander was intimate, that he was not only eminently pious and devout, but peculiarly distinguished by his humility, meekness and gentleness; that he was a frequent and agreeable preacher; that he was a person of competent knowledge and learning, having been educated by Panteus and Clement, and maintaining an intimate friendship with Origen and Clement, two of the most learned men that ever lived, and that he was also a patron of learning. We are also indebted to him for his glorious testimony to the truth of the Christian religion, and his own remarkable example of Headships in the faith of Christ, of which he made two confessions before heathen magistrates, at the distance of about 40 years from each other, for the sake of which he suffered an imprisonment, under which he made a happy end. And certainly the succession of bishops and churches in the land of Judea, where the preaching, paths, and sufferings of Christ and his first apacles, are placed by the evangelists under so many difficulties and troubles, affords a strong argument for the truth of those great and extraordinary facts, upon which the Christian religion is founded. Lardner’s Works, vol. ii. p. 391—397. Cave. Hill. Liter. Sec. iii. tom. i. p. 100. ed Oxon.

ALEXANDER, bishop of Alexandria, succeeded Achillas in this see, in the year 512 or 513. In his time commenced the Arian controversy, in which he appears to have engaged with an ardour that was blended with a very considerable degree of bitterness of spirit. He calls Arius and his followers
Alexander was the name of one of the martyrs of Lyons, A.D. 157. He was a Pirygian by nation, and by profession a physician; he had lived many years in Gaul, and was known almost to all men for his love of God and boldness in preaching the word. When he fled before the tribunal, to which he was cited, he boldly confessed that he was a Christian; upon which the enraged president condemned him to the wild beasts. When he had undergone all the instruments of torture in the amphitheatre, which were invented to torment him, and his associate Attalus, they were both run through with a sword. Alexander neither flighted, nor said any thing at all; but in his heart conversed with God. Such is the account given by Eusebius, Eccl. Hist. lib. v. c. i. p. 105; ed. Valesii.

**Alexander, Benedictus**, of Verona, physician to the emperor Maximilian, taught anatomy and medicine with great reputation, & maxima frequenter auditorum, Cathalamanus fays, at Padua, towards the end of the 15th century. Of him we have the following, "Alexandri Benedicti phisici Anatomiae, five Historia Corporis Humani, ejudem collectiones ex auctoribus, 1537." The dedication to the emperor is dated 1533; this work has been several times reprinted. See Biblog. Auct. Specimen Jacobi Douglas, p. 67; Also, Pet. Cathalani Vite illustr. Medicorum, p. 179.

**Alexander, Massarius**, of Vicenza in Italy, practiced medicine there for 25 years. In 1578, he was made principal of the college of medicine at Venice. Having held this office, with great reputation, nine years, he went to Padua, ubi fono confessus, Douglas fays, obit, 1598. This physician was used to say, "se male cum Galeno errare, quam cum recentioribus vera dicere." He left a treatise, "De Urinis et pulvis," published 1658, at Frankfort, and "Opera Medica," published at Lyons, 1634. Douglas Biblog. Spec. p. 197.

**Alexander, bishop of Lincoln, in the 12th century,** was by birth a Norman, educated under his uncle, bishop of Salisbury, and by his interest promoted to the episcopal see in 1123. Having been accustomed in early life to a splendid mode of living, he affected a degree of state, and indulged in expenses which were fuitable neither to his character nor fortune. Henry of Huntingdon, in the dedication of his history to him, which is penned in the language of fervile adulation, calls him "the flower and top of the kingdom and nation," and he informs us, that at the court of Rome he was fyled "the Magnificent." St. Bernard, in a letter addressed to him about a year before his death, acts the part of a more honest friend, and cautions him "not to be dazzled with the lucre of secular grandeur, nor to look upon any worldly advantage as permanent; nor value his fortune more than himself; to guard against the flattery of prosperity, for fear of a turn of misfortune, which will last longer; not to be charmed with the transient satisfactions of life; for that scene will quickly be shut up, and make way for another both lueling and uncomfortable." He also advises him "not to deceive himself with any distant prospect of death; for such delusive hopes lead directly to danger and surprize, and are the likeliest way to hurry a man into the other world without preparation." In the course of his life thefe prudent and sagacious lectors did not seem to have been dully regarded by the ostentatious prelate. In imitation of the barons and some of the bishops, he built three castles; one at Banbury, another at Staford, and a third at Newark. He likewise founded two monasteries. King Stephen was, not without reason, offended by these stately edifices and strong fortresses; and when he determined to take the castles from the barons, he fixed that at Newark; in consequence of which the bishop was imprisoned for seven months, and with difficulty obtained his liberty. From this time he employed his thoughts and time in ornamenting his church, which he had rebuilt with a fine roof the year after his confiscation; increasing the number of its prebends, and augmenting its revenue with several mansors and eftates; and at length he rendered it the most stately and florishing of any in the kingdom. He went twice to Rome, vij. in 1142 and
and after his first visit, he returned as the pope's legate, and called a synod, in which he published several useful canons. In 1117 he visited the pope in France; and there fell sick, to that he returned with difficulty to England, where he soon died, in the 24th year of his presacy. *Biog. Brit.*

Alexander I. pope, was a Roman by birth, and bishop of Rome during the reigns of Trajan and Adrian, from the year 106 to the year 115. He is said to have introduced the use of holy water and other ceremonies. He was enrolled as a martyr, and canonized as a saint. Bow. Hist. Popes, vol. i. p. 21.

Alexander II. pope, was a native of Milan, of the name of Anfelm, and removed from the fee of Lucca to that of Rome, in the year 1061. He was elected pope by the influence of Hildebrand, who was at the head of the ecclesiastical faction at Rome, in opposition to the empress Agnes, widow of Henry III., who was regent during the minority of her son Henry IV. and who supported the lay-faction, in the contest that baffled between the clergy and laity. By her influence Cadolus, bishop of Parma, was elected pope, under the name of Honorius II. The dispute was terminated by a council at Mantua in 1164, and Alexander, by a signal triumph of the church over the civil power, was declared lawful pope. The discipline and privileges of the clergy were the principal objects of this pontiff's attention; and the subordinate instrument of conducting his measures was Peter Damiani, a monk, and a zealous defender of the monastic orders. Having acquired a power thus paramount to every other, Alexander laid hold of every opportunity that occurred for interfering in the secular concerns of kingdoms and princes. With a view of extending the influence and increasing the emoluments of the papal see, he functioned the project of William, duke of Normandy, for the conquest of England; denounced excommunication against Harold as a perjured usurper; and sent William a consecrated banner, and a ring with one of St. Peter's hairs in it; thus, as Hume says (Hist. vol. i. p. 186.) "covering over lustily all the ambition and violence of that invasion with the broad mantle of religion." His views were accomplished; William succeeded; the authority of the pope was confirmed; and his legates, till this time unknown in England, exercised arbitrary power.

Alexander extended his authority to other countries as well as to England. He not only prohibited the young emperor from divorcing his wife Bertha, but, in 1073, summoned him to appear at Rome, and to account for his conduct in the difposal of church benefices for providing his army with supplies. Henry was indignant; but the dispute was closed by the death of the pope in 1073. The increase of papal tyranny, under the direction of Hildebrand, to whom this pope was subservient, and by whom he was succeeded, discriminates his pontificate. Many of his letters on public affairs are extant; and one of them, addressed to the bishops of Spain for the purpose of restraining the cruelties which they exercised towards the Jews, does honour to his humanity. For an account of these letters, amounting in number to 45, see Dupin's Eccles. Hist. vol. iv. p. 29; and also Bower's Hist. Popes, vol. v. p. 224.

Alexander III. pope, was born at Sienna, where he was bishop under the name of Roland, and succeeded Adrian IV. in 1159. At the time of his accession to the papal chair, Frederic I. was making vigorous attempts for reducing the power of the Roman see; and cardinal Octavian was elected pope under the name of Victor IV., in opposition to Alexander. After the death of Victor, in 1164, cardinal Guy was chosen by the influence of the emperor, and deponented Paschal III. But the whole interval of the Roman clergy was exerted in favour of Alexander, who, in the former pontificate, had been compelled to retire into France, and he now returned to Rome, and was reinstalled to his see. Councils were summoned to settle the dispute. The council of Wurtzburg, convened by the emperor in 1166, produced an union of the nobility and clergy in support of the rights of Paschal; and the council of Lateran, called by Alexander in 1167, deposed the emperor, and abrogated the oath of allegiance by which his subjects were bound to him as their lawful sovereign. At length an appeal was made to the sword; and though Frederic was at first successful, and upon the death of Paschal procured the election of John, Abbot of Strum, as his successor, under the name of Calixtus III., he was in the issue obliged to give up the contest, and in a treaty of peace, made with Alexander at Venice in 1177, to acknowledge him as lawful pontiff. The pride of Alexander knew no bounds on occasion of this triumph. When Frederic was prostrate at his feet, he addressed him with the words of the Psalmist, "Thou shalt tread upon the lion and adder; the young lion and the dragon thou shalt trample under thy feet." and when the emperor replied, "Not to you, but to Peter;" the pope answered, "To me, and to Peter." This story is discredited by some writers, but believed by others, and the truth of it is confirmed by concurring circumstances, for which we refer to Dupin. After the establishment of Alexander, he treated his rival Calixtus III. with condescension and kindness, and appointed him to the see of Benevento. The pope, securely seated in the papal chair, directed his attention towards securing the independency, and maintaining the prerogatives and privileges of the triple crown; and in order to prevent the disorders likely to arise in future from equal factions, he obtained a canon in the third council of Lateran, held at Rome in 1179, which enacted, that the right of election to the pontifical dignity should not only be vested in the cardinals alone, but that two-thirds of the votes of the electors should be necessary for rendering it legal. Thus the people, and even the Roman clergy, were entirely excluded from all participation in the honour of conferring this important dignity.

At this council, the right of recommending and nominating to the vacant see was taken away from councils and bishops, and canonization was ranked among the greater and more important causes, the cognizance of which belonged to the pontiff alone. In this year he exercised that tyranny over princes, which had been usurped by the popes from the time of Gregory VII. in conferring the title of king, with the ensigns of royalty, upon Alphonso I. duke of Portugal, by an arrogant bull, in which he treats him as a vassal. Whilst he was in France, he had supported the cause of Thomas Becket against his sovereign Henry II., and in 1164, when the constitutions of Clarendon, which affected the king's jurisdiction over the clergy, were sent to him for confirmation, he rejected and annulled them. When Becket was banished, he received him kindly; obtained for him a pension from the French king, abrogated the sentence that had been passed upon him; reinvolved him with his dignity, and appointed him his legate in England. After the murder of this arrogant prelate, Alexander, who had kept the king in awe during the whole of the contest, by the terror of excommunication, compelled him to undergo a very severe penance; and having forgiven him, stilled bulls at his desire, against his son, and canonized the archbishop. Alexander, as a rigorous defender of the catholic faith,
faith, exerted his power on a variety of occasions, and with a severity which no circumstances can justify. With a view of restoring order and tranquillity in the church, he convoked a solemn and numerous assembly in the clergy in 1164, in which the licentious rage of disputing about religious matters was condemned; and in the council of Lateran, of 1179, a spiritual war was declared against heretics, and more particularly against the Albigenses.

Alexander IV. pope, was Rinald or Roland, bishop of Ohia, and succeeded Innocent IV. in 1254, at the time of the contest between the Guelphs and Ghibellines. The right of the Roman see to the disposal of the crown of Sicily was supported by a war, in the pontificate of Innocent IV. against Mainfroy or Manfred, regent for Conradine, the son of the emperor Conrad; and this pope, in order to engage the affinities of a powerful ally, had conferred the crown on Edmund, the second son of Henry III. of England. Alexander IV. purposed the plan of his predecessor, and published a crusade against Sicily, and for defraying the expenses of it, inflicted Henry to levy a tenth on all ecclesiastical benefices in England for three years. Upon the demand of farther supplies, though it was enforced by a legate and a threat of excommunication, Henry refused; and the nominal possession of the crown reverted to Alexander; but Mainfroy having defeated the crusaders became the real possessor of it, A.D. 1258. The pontiff was equally unsuccessful in his attempts to oppose the progress of Ezzelin or Ecelin, who, at the head of the Ghibellines, and on the part of the heirs of Frederic II., had made himself master of Lombard. The pope’s army was defeated, and his legate imprisoned. In defiance of the banner of the croce, and anathemas solemnized by the apostolic see, Ezzelin purified his victories; and Mainfroy kept possession of the throne of the two Sicilies, which he had usurped.

Alexander, in the exercise of his ecclesiastical authority, maintained the cause of the mendicant dominican friars, against the members of the university of Paris, who refused to admit them to a participation of the rights and privileges of their society; and he condemned a book written by William de Saint Amour, one of the doctors of the Sorbonne, and entitled, “The Perils of the Laïc Times,” in which the character of the dominicans was defamed, and their pride, hypocrisy, and licentiousness, indirectly but cruelly cenured. In the council of Arles, held in 1260, he condemned another book, written by the abbot Ioachim, under the title of “The Everlasting Gospel,” and at the same time proscribed those who, under the denomination of Joachimites, had adopted the doctrine which this book promulgated. Differences of another kind having arisen between the states of Venice and Genoa, a council for settling them was summoned to meet at Viterbo; but in the mean time Alexander IV. oppressed by the divisions of the church, and by the vexation which his ineffectual attempts for combating them produced, closed his life in the year 1261. “He appears to have been a narrow-minded bigot, more concerned to prefer and enlarge the privileges of a monastic order, than to correct abuses and encourage improvements.” Dupin, Eccl. Hist. vol. v. p. 50, 118, 138, &c. Bower’s Popes, vol. vi. p. 225. Cave II. L. tom. ii. p. 323.

Alexander V. pope, was born in the isle of Candia, about the year 1259. His original name was Philargus, and his parents were so poor, that in his childhood he was under a necessity of beggimg his bread. An Italian monk took him under his protection and instruction, and procured his admission into his order of friars minoris. By his recommendation he became a student at Oxford, and afterwards took his degree of doctor in divinity at Paris. Having passed through several gradations of preferment, being first bishop of Vicenza, then of Novara, and at length archbishop of Milan, cardinal, and legate of pope Innocent VII. in Lombardy, he was unananimously elected pope by the cardinals, at a council in Pisa, in the year 1439. This pontiff was good-humoured and liberal; and having no needy relations and dependents, for whom he was under an obligation of providing, he had the means of extending his generosity to those that were connected with the church, particularly to the mendicant orders of monks, who were distinguished by his patronage and favour. Such was his munificence during his pontificate, that he used to say, “When I became a bishop, I was rich; when a cardinal, poor; and when pope, a beggar.” He seems, however, to have counteracted the mildness and liberality of his natural disposition by the orders transmitted to the archbishop of Prague, enjoining him to proceed with rigour against Hus and his followers. This zealous reformer, confiding in the known candour of the pontiff, instead of personally appearing at Rome, in compliance with the summons that had been sent him, commissioned two friends to plead his cause, saying, on his own part, “I appeal from Alexander ill-informed, to Alexander well-informed.” Whence Alexander proposed to visit Rome, where he was expected, he was persuaded by Balthasar Coфа to accompany him to Bologna. Whilft he was at this city he died, as some say, by the contrivance of Coфа, in the year 1440, havingpossessed the papal fee little more than ten months; and Coфа, by his influence with the cardinals, and a recommendation from Louis of Anjou, king of Sicily, was chosen to succeed him. Dupin, Eccl. Hist. vol. v. p. 8, &c. Bower’s Popes, vol. vii. p. 123.

Alexander VI. pope, was born in 1431, at Valencia in Spain, and by the interest of his uncle, pope Calixtus III. was appointed cardinal in 1455; and afterwards archbishop of Valencia, and vice-chancellor of Rome. The emoluments of this last office enabled him to maintain the state of a prince, and supplied him with the means of licentiousness and extravagance, to which he was addicted from his youth. Under pope Sixtus IV. he was legate in Spain; and at last by obtaining a quitue, which his conduct did not justify, and by bribing the cardinals, he was elected, at the age of 61, to succeed pope Innocent VIII. in 1492. He then changed his original name of Rodric Borghia for that of Alexander VI. By Vanozza, a Roman lady, with whom he had continued an illicit connexioll for many years, he had five children. His second son was Cesard Borghia, who was a monitor of debauchery and cruelty, and who is said to have quarrelled with his elder brother for the favour of his fitter Lucretia, and to have killed him, and thrown his body into the Tiber. Notwithstanding his infamous character he was the favourite of his father, who trampled with contempt on every obstacle which the demands of justice, the dictates of reason, and the remonstrances of religion laid in his way, in order to aggrandize his children, and enrich himself. In his political connections he was faithless and treacherous; and formed alliances with the purpose of violating them. Having engaged

Charles
Charles VIII. in an enterprise for the conquest of the kingdom of Naples, he entered into a league with the Venetians and with Maximilian, to rob him of the fruits of his victory; and, after having obtained a large remittance from the Sultan Bajazet, in order to enable him to carry on war against this king of France, he delivered up to him Zaram, the brother of Bajazet. His perfidy was only exceeded by his hypocrisy; for, notwithstanding his notorious vices, he proposed to the Christian princes to march at the head of an army against the Turks; and under this pretext he issued a bull for a jubilee in 1503, by which he contrived to enrich his treasury. Of his presumption, as well as of his hypocrisy, we have a curious instance in his division of America between the Spaniards and the Portuguese. For this purpose, he appointed that a line, supposed to be drawn from pole to pole, a hundred leagues to the westward of the Azores, should serve as a limit between them; and, in the plenitude of his power, he hallowed all to the eall of this imaginary line upon the Portuguese, and all to the west of it upon the Spaniards. At the same time he professed, that zeal for propagating the Christian faith, which was the consideration urged by Ferdinand in soliciting a bull for this purpose, was his chief motive for issuing it. In consequence of this bull, a great number of Franciscans and Dominicans were employed, with the avowed design of instructing and converting the Americans, both in the Isles and on the continent.

The profligate career of this execrable hypocrite and tyrant was continued till the year 1513, when the paupon which he and his son Carlo had prepared for others, and particularly for Adrian, a wealthy cardinal, who flourished in the way of their avarice and ambition, by a happy mishap, terminated his own days. Some writers, amongst whom is Voltaire, have disputed this account of Alexander's death; but Guicciardini and other reputable historians attest it. The life and actions of this pontiff shew, says Mosehaim, that there was a Nero among the popes as well as among the emperors. The crimes and enormities which history has imputed to this papal Nero, evidently prove him to have been not only deftine of all religious and virtuous principles, but even regardless of decency, and hardened against the very feelings of shame. Besides other influences of infamous licentiousness with which, he is chargeable, he is accused of incest with his own daughter. And though it may be possible that the malignity of his enemies may have forged false accusations against him, and in some instances exaggerated the horror of his real crimes, yet there is upon record an authentic list of undoubted facts, which, by both their number and atrocity, are sufficient to render the name of Alexander VI. odious and detestable in the esteem of such as have the smallest tincture of virtuous principles and feelings. His infatiable avarice is pointedly expressed, says one of his biographers, in the following lines:

"Vendit Alexander claves, altaria, Chirillum, Vendere jure potest; emerat ille prius."" 

"Christi altars, keys, and Christ himself, 
Were bartered by this pope for pelf: 
But who shall say he did not well? 
That which he bought, he sure might sell." 

A L E X A N D E R VII. pope, was born of the illustrious family of Chiggi at Sienna, in 1509, and recommended by the marquis Pallavicini to pope Urban VIII. Having been inquisitor at Malta, and legate at Ferrara, he was pensioned in Germany, and employed at Mansfeld in conducting the conferences that were intended to restore the peace of Europe. Some writers relate, that at this time he had formed the design of allying popery, and embracing the protestant religion, but that he was deterred from executing his purpose by the fate of a civilian, who had been poisoned on a similar account; and that he was confirmed in his religion by the elevation to the cardinalship. Upon his return from this embassy, he was appointed bishop of Imola, in Romagna, and afterwards cardinal and secretary to the pope. His next advancement was to the papal chair, to which he was introduced by the unanimous suffrage of the 64 cardinals, which he contrived to obtain by the aid of diffusion and address, of which he is said to have been complete master. After his election in 16.15, he ordered his coffin to be placed under his bed in his apartments in the Vatican, that it might serve to him as a momento of mortality; when he was robed in the pontifical habit, he appeared to have a haircloth under his shirt; and when a wealthy female, signorina Olympia, waited upon him with congratulation, he dismissed her with a cold repulse, saying, "It is not decent for a woman to enter the dwelling of the father of the church." That the whole of this appearance of humility and self-denial was a farce, was sufficiently verified by his future conduct. The distinguishing feature of his character, next to his craft and diffimulation, was an attachment to his relations, for whom he provided by all the offices and honours which he could command. His zeal for religion, and his concern for terminating the wars which distracted the Christian world, seem to have subsided after his elevation to the pontificate; nor did he take any pains to conciliate the crowns of France and Spain. The five propositions of Jansenius, which contained the chief of his doctrine, had been condemned by Innocent X.; but the Jansenists had contrived to evade this sentence by a subtle dilution, which allowed them to acknowledge that these propositions were jujly condemned by the pope; but at the same time to maintain, that they were not contained in the book of Jansenius in the sense in which they were condemned. The benefit of this artful dilution they were not permitted long to enjoy. At the instigation of their enemies, Alexander VII. the successor of Innocent, issued a bull in 1656, declaring, that the five propositions which had been condemned were the tenets of Jansenius, actually contained in his book. He proceeded, in 1665, to lend into France the form of a declaration of this bull, which was to be subscribed by all those who aspired to any preferment in the church. This declaration produced the most deplorable divisions and tumults. It was vigorously opposed by the Jansenists, who maintained, that in matters of fact the pope was fallible, especially when his decisions were personal, and not confirmed by a general council; and, consequently, that they were under no obligation to subscribe this papal declaration, which had merely for its object a matter of fact. Notwithstanding this unwife and intolerant bull, Alexander is said to have been liberal in his sentiments; to have disapproved the severities exercised towards the Vaudois in Piedmont, and to have treated the protestants who visited Rome with consideration. It is further related, that when some English gentlemen prefented themselves at his feet to pay him the customary homage, upon finding that they were protestants, he courteously said, "Rife, you shall not commit what you think an idolatry: I will not give you my blessing, but I pray God you may be worthy to receive it." To the Jefuits this pontiff manifested a peculiar partiality; for though Innocent X. had, in 1645, condemned the indulgence which these artful missionaries had
ALKSE.
ALEXANDER.

Alexander, Dom James, a Benedictine of the congregation of St. Maur, was a native of Orleans. He died in 1734, at the age of 83 years, and left a treatise on "Elementary Clocks," in 180. Biog. Dict.

Alexander, Nicholas, a Benedictine of the congregation of St. Maur, was born at Paris, and died at an advanced age, at St. Denis, in 1728. He is known by two useful works, viz. "Phylic and Surgery for the Poor," Paris, 12mo. 1738; containing a collection of sleek and cheap remedies for both internal and external ailments; and "A Botanical and Pharmaceutical Dictionary," in which are found the principal properties of such mineral, vegetable, and animal substances as are used in medicine. He was devout and charitable, and devoted his knowledge of medicine and his property to the relief of the poor. Biog. Dict.

Alexander de Saint Eligio, so called from a town in Umbria, general of the Auguistine hermits, and archbishop of Ravenna, lived at the beginning of the fourteenth century.

He was the author of a treatise "Of the Jurisdiction of the Empire and the Authority of the Pope," written at the court of Charles, and published in 1210, under the title of "Aurora." Having assumed himself for some time with amorous verity, he removed to the court of King James VI. where he fulfilled the character of a private, but learned and accomplished gentleman. In this public situation he found leisure for exercising his poetical talents; and he now directed them to grave and moral subjects, with a view to the direction of princes and rulers, in a series of tragedies, formed upon the Greek and Roman models, at least in their choruses between the acts. One of these, on the story of Darius, was published at Edinburgh in 1607. This tragedy, with three others, viz. Crecus, the Alexanderian, and Julius Caesar, were published in 1607, under the title of "The Monarchick Tragedies." Our author wrote some other poems of a political nature; particularly his "Parenesis" to prince Henry, communicating important and useful lessons to an heir of royalty. He also wrote a supplement to complete the third part of Sir Philip Sidney's Romance, which was published in 1613, when the author was sworn one of the gentlemen-ushers of the presence of Prince Charles. In 1614 he printed a poem, intitled, "Dooms-day!" and in this year he was knighted by King James, and made master of the requests. At this time he commenced his political career; and, having projected the settlement of a colony at Nova Scotia, in America, he obtained a grant of that country, by his Majesty's royal deed, in 1621. King Charles, on his accession, encouraged the scheme, and Sir W. Alexander published a pamphlet, reciting the advantages which would accrue from it to the nation. The author was made lieutenant of Nova Scotia; and an order of knights baronet was founded in Scotland in the first year of the king's reign, whose aid was appropriated to this settlement, on condition that each should have a portion of land assigned him in the new plantation. Sir William had also the privilege of coined small copper-money. The design, however, failed; Sir William sold the whole country to the French for 5 or 6000l, and in the conduct of the whole transaction he incurred some degree of reproach. King Charles, however, continued to favour him; and convinced of his talents and fidelity, made him secretary of State for Scotland in 1626; and in 1630, a
peer of that kingdom, by the title of Viscount Stirling. In 1611 he was raised to the dignity of Earl of Stirling, at his Majesty's coronation, in the palace of Holywood-house. He discharged the office of secretary of state with great reputation till his death, in 1642. About three years before his death was published a new edition of his poems, viz. "The Four Monarchick Tragedies," "Dooms-day," the "Paranalisis," and "Jonathan," an heroic poem, which was now first published. The style and verification, particularly of the plays, are polished, and the plus, as far as the subjects are concerned, improved. The author's tragedies and other poems were well received at the time of their first publication. King James called the author his "Philosophical Poet," and Michael Drayton commends them; calls the author, "My Alexander," and wishes to be known as the friend of a writer, "whose muse was like his mind;" and John Davies of Hereford, in a book of epigrams, published about the year 1641, prefixs the tragedies of the author; and says, "that Alexander the Great had not gained more glory with his sword than this Alexander had gained by his pen." Mr. Addition, after perusing the several works of the author, testified his approbation of them, by saying, "That he had read them over with the greatest satisfaction." "They compose," says a biographer of unquittuable judgment, "a very respectable portion of the literature of that age; though their gravity and proximity are not much suited to the taste of the present." It does not appear that his plays were ever acted. They are rather dramatic poems for perusal in the closet.

Alexander Nequam, or Nequam, an eminent English writer of the 17th and 18th centuries, was born at St. Alban's, in Hertfordshire, and pursued his studies, with successful affability, in the universities of Italy and France. At Paris he was called a prodigy of genius and learning; and applauded as an excellent philosopher, a profound divine, and a good rhetorician and poet, confederating the age in which he lived. His school at Paris, where he read lectures in 1685, was thronged with scholars. About the year 1686 he returned to England; and, having become a canonregular of the order of St. Augustin, he was made abbot of Exeter in 1715, and died in 1727. His epitaph, written after the old monkish manner, in Latin rhyme, is as follows:

"Eclipsin patitur sapientia, Sol cepuit;\nCui si manus, minus ciet flebile fumus;\nVir bene discretes, et in onmis more facetus,\nDicius erat Nequam, vitam duxit tamen aequam."

The sense is this:

"Learning's eclips'd, the Sun himself's obfusc'd;\nOur laws were slate, had he left one superior;\nAccomplished was his mind, his manners pleasing,\nAnd though his name was ill, his life was good."

He wrote several works, which are preferred in MS, in the libraries of England and other countries; such as "Commentaria super quarum Evangelia?" "Expositio super Ecclesiaeem;" "Expositio super Cantica;" "Elucidarium Bibliothecae," in which are some expressions in consistent with the doctrine of transubstantiation; "Landus divinae Sapientiae," which is the same with the work, "De Naturis rerum;" and contains, amongst a variety of other matter, a large account of the three cities most celebrated for learning, Athens, Rome, and Paris. Gen. D. C. Cave H. L. tom. ii. p. 286.

Alexander I. king of Scotland, was the son of Malcolm III. and succeeded his brother Edgar in 1107. His character was distinguished by a degree of vigour and impartiality, which gave him the appellation of "the fierce;" and which, though previously concealed by his piety and devotion, discovered themselves on his accession to the throne. His conduct both in the northern and southern parts of the kingdom was so severe, that he saved the insurgents into submission; but a conspiracy was at length formed against his life, and the traitor, who was engaged in the execution of it, obtained admission into his bed-chamber at night, whilst he lodged at a castle in the Calve of Gowrie. Alexander, after having killed four of them, made his escape. Having reduced his own kingdom to order, he visited his brother in law Henry I. of England, and ambitiously in terminating a difference between him and the Welsh. He closed his reign in enacting and enforcing civil and ecclesiastical regulations, died a bachelor in the 17th year of it, and was succeeded by his younger brother, David. Mod. Un. Hist. vol. xii. p. 47.

Alexander II. king of Scotland, succeeded his father William the Lion, in 1214, in his 16th year. His attempt to recover the possessions of Northumberland was retaliated by a destructive expedition into Scotland, conducted by John, king of England. Whilst John was thus employed, Alexander reduced Northumberland; and being forced to discontinue his pursuit of the English king, who was burning the towns, ravaging the country, and advancing toward the capital, he entered England by the way of Carlisle, which he took and fortified, and proceeded as far as Richmond, in Yorkshire, retaliating upon the adherents of John severities similar to those which his own subjects had suffered. But his progress was impeded, and he was compelled to return through Westmorland to his own kingdom.

In 1221, he married the princess Joan, eldest sister of Henry III. of England, who contributed to preserve peace between the two kingdoms. After her death in 1239, they were again embroiled; but by the mediation of the earl of Cornwall, Henry's brother, and the archbishop of York, they were again reconciled. Alexander, in his voyage to quell some commotions that were excited in Argyllshire, fell sick, and being put on shore on an island called Kenerny, on that coast, died, in the 51st year of his age, and 35th of his reign. His successor was his son by his second queen, the daughter of Egelrand de Coucy, one of the most powerful of the French nobility. Mod. Un. Hist. vol. xii. p. 77.

Alexander III. king of Scotland, was son of the preceding, and succeeded his father at the age of nine years, in 1210. His marriage with Margaret, the daughter of Henry III. of England, was soon after solemnized in the presence of the two courts at York. On this occasion Alexander paid homage to Henry for his English possessions; and, on being pressed to perform his homage for the crown of Scotland, he declined it. Alexander, upon his return to Scotland, found that the Cummins, a family of very great influence, had formed a strong party against his English connections, under the plea that Scotland was never any better than a province of England; and both the king and queen were committed to close custody in the castle of Edinburgh, where they were debarr'd from seeing any company, or associating with each other, and prohibited from all concern in the government. When Henry heard of their situation, he determined to relieve them, and for this purpose assembled his military tants at York, and marched to the borders; and by his envoys, whom he dispatched to the castle of Edinburgh, released the royal pair, and afterwards dispossessed the usurpers. The king then assumed the exerise of the regal power; and, as soon as he was of age, pardoned the Cummins and their adherents, upon their submitting to his authority.

authority. However, in 1253, Haquin, king of Norway, appeared on the coast with a fleet of 100 ships, to make good his pretensions to the Western Islands; and, disembarking his troops, made himself master of the castle of Ayr, and advanced into the country. Alexander, having assembled an army, met him at a place called Largs; and, after a long and doubtful contest, the Scotch army was victorious. Of the Norwegians, 15,000 are said to have perished in the field, and the Scots lost 5000. The ships of Haquin were so much wrecked the day after the battle, that he could scarcely procure a vessel to carry him and a few of his followers to the Orkneys, where he soon after died of grief. His son and successor, Magnus, concluded a treaty with Alexander; and, in consideration of his receiving 1000 marks of silver in two years, and an annual payment of 500 marks for ever after, renounced all claim to those islands. As a further cement of friendship, Margaret, Alexander's daughter, was betrothed to Eric, the son and heir of Magnus. In 1256, Alexander and his queen repaired to the English court, where they were sumptuously entertained; and when the queen was delivered, they both returned to their own kingdom. During the war between Henry and his barons, Alexander afforded them 5000 men, and preferred the northern fortresses against all their attempts. Upon the accession of Edward I. to the throne of England, Alexander, with his family, was present at his coronation, and soon after paid him homage for his English titles. In the parliament, held at Westminster in 1265, Alexander attended as the first peer of England. In 1263 he left his son Alexander, in the 21st year of his age, and his death was soon followed by that of his sister, the queen of Norway, who left an only daughter.

Alexander, having no surviving issue besides this infant prince, was urged by the nobility and the states of the kingdom to marry; and in compliance with this request, he was married to Isotta, daughter to the Count of Dreux in France. This excellent prince was soon after killed, whilst he was hunting, by his horse's rushing down a high precipice, A.D. 1285, in the 45th year of his age, and the 37th of his reign. He was succeeded by Margaret, his grand-daughter, and heir of his crown, who did not long survive him. Scotland was now in a very critical state. Edward I. was acquiring an influence in the kingdom, which no other English monarch ever possessed, and revived the claim of over-representation, to which his father Henry had never pretended. The death of Alexander was at first attended with much regret; but on the whole, the performance to the kingdom demanded a tribute of respect to his memory. He had introduced many excellent regulations of government; he had divided the kingdom into parts, in each of which he occasionally resided, with a view of preferring the public peace, and for the purpose of more easily administering justice to all ranks of people; and he had greatly contributed to diminish the burdens of the feudal system, and to restrain the licence and oppressions of the nobility. The death of Alexander III. forms a remarkable era in the Scottish history. Mod. Uni. Hist. vol. xii. p. 79. &c.

A L E X A N D E R, king of Poland, was a younger son of Cazimir, and as duke of Lithuania, elected from motives of policy to succeed Albert in 1501. The archbishop of Gnefna hesitated for a long time in assenting to his coronation; and absolutely refused to concur in the ceremony for his queen, the princess of Mucrowy, because she adhered to the doctrines of the Greek church. This indignity was resented by her father, who, in consequence of it, laid siege to Smolenfo, but, upon the arrival of Alexander, relinquished the enterprise, and concluded a truce for six years. The fatigue of this expedition so much affected Alexander, that he fell into a chronic disorder, which only terminated with his life. During his illness, the Moldavians and Tartars made an incursion into Lithuania; and Alexander was carried in a litter, at the head of his army, to oppose them. The two armies met near Wilna, and after a severe contest, in which 20,000 Tartars fell, the Poles were victorious. Alexander received the news of this victory whilst he was dying; and making signs to express his gratitude, he expired in 1526, at the age of 45, after a reign of five years in Poland, and 14 in Lithuania. In his lifetime he was stout and robust; his figure was long, his eyes sparkling, and his carriage majestic. His genius was heavy, his taciturnity very remarkable, but his sentiments were generous and humane. He was a great patron of the liberal arts, and profuse in his grants under this character, and particularly to musicians; so that his donations were revoked, and a law was passed, called Statutum Alexanderinum, which prohibited the king from dispensing the revenue without the consent of the Senate or diet. Mod. Uni. Hist. vol. xxx. p. 410.

ALEXANDER NEVSKOJ, or NESKRY, grand duke of Russia, both a faint and hero of that country, was born in 1218, and distinguished by his strength and courage, and by the vigour of his character. He was afterwards inspired with a passion for conquest by the incessant wars in which his father Yaroslav was engaged with the Tartars and Mongols. Upon the death of Foulon, his eldest brother, he became sole victor of Novgorod. He married a princess of the province of Pochatek; and for the purpose of defending his government against the attacks of the Tschudens and Lithuanians, he drew a line of forts along the river Shkola, which falls into the Ilmen lake. While Yaroslav was engaged with the Tartars in 1259, a combined army of Swedes, Danes, and knights of the Teutonic Order, formed an expedition against Novgorod, and landed from their ships on the banks of the Neva. Alexander, after receiving a haughty embassage, determined to risk the event of a battle. Having implored the assistance of heaven in the pence of his people, he prepared for an engagement. The attack was begun at six in the morning, and the two armies were closely engaged during the whole day. When night put an end to the contest, the field of battle was covered with the bodies of the slain. This battle, in which Alexander is said to have wounded with his own sword the king of the northern nations, is embellished with a variety of fantasies; but the event of it was highly honourable to the courage and success of the young prince. He was received with much regard and respect from the river Neva, near which the battle was fought, he obtained the surname of Nevski. The remainder of his life was employed in exertions of valour and activity against the invaders of his country. He defeated the Tartars in several contests. In 1245 he reeled the siege of Novgorod, and gained a victory over the Germans, Danes, and Tschudens, on the borders of the Pechipus lake. After his father's death he paid a visit to the Tartar khan, who acknowledged, that though he had heard much to his praise, he far exceeded every thing that had been reported concerning him. In 1252, upon his return from a second visit to the khan, he ascended the throne as grand prince of Vladimir. With a very confidur force he now undertook an expedition against Sweden, and coming off victorious, he so far conformed to the then subsisting practice of war, as to ravage all the countries which he had captured, and returned to Russia with a multitude of prisoners, and heaps of spoil. On occasion of a difference which happened between the Russians, and particularly the inhabitants of Novgorod, and the Tartars, with respect to the humbling and burde, some tribute which was exacted by the latter, Alexander, in 1258, attempted to pacify the discontented, and to induce them
them to submit, without resistance to a superior power. In order
to give effect to his conciliatory endeavours, he took
the national payment on himself, and thus acquired the com-
pliance of the Novgorodians as well as of the Tartars. But
dissentions continuing to prevail, and resistance having arisen
to a degree so alarming in several places, that the Tartarian
collectors were massacred; the Tartars were exceedingly ex-
asperated against the Russians, and the Russian princes were
commanded to appear before the khans. Alexander under-
took the hazardous business of attempting, by a personal
interview, to avert the khans' wrath on account of the mur-
der of his deputies. After a delay of twelve months he at
last succeeded, and obtained a promise that the khans would
forgive what had happened, and forego his purpose of
raising an army; and in his return home he died suddenly at
Gorodetz, in the year 1762, with circumstances that render
it extremely probable, that in the camp of the khans his
son had been administered to him shortly before his departure.
For his various and signal services, and acts of valour, which
in those days were deemed miraculous, the grateful admira-
tion of his countrymen raised him to the rank of one of the
national saints. Peter the Great, availing himself of the ve-
neration that was paid to the memory of this disinguished
hero, founded, in 1712, a monastery near his new city of
Peterburgh, on the spot which was reported to have been
the scene of Alexander's victory; and in 1723 he caused the
bones of the great duke to be brought thither. This
monastery has been gradually enlarged by several sovereigns
since the time of Peter; and the late empress has built a
magnificent church within its walls, and a sumptuous maus-
oleum for herself and her descendants. The shrine of the
saint, which was caused to be made by Elizabeth, is of mady
silver. The order of knighthood of St. Alexander Nevskoi was
instituted by Peter the Great in 1722; but as he died before
the knights were appointed, this was done by Catherine I. in
June 1725. The badge of this order is a golden eight-
pointed star, enamelled with red, with the figure of St.
Alexander in armour on horseback. At the four corners of
the cross are as many gold spread-eagles, crowned. A broad,
deep red, watered ribbon is worn over the left shoulder; the
motto is in Russian characters, signifying, "For labour and
patriotism." The feal is held on the 30th of August. The
monarch and the knights attend masts at Kazan church, and
go on a pilgrimage on foot to the monastery of the saint, at
the distance of three versts, and attend masts again before his
silver shrine, and then return to the winter palace, where they
partake of a sumptuous dinner, under a discharge of can-
on. In 1750 the number of knights amounted to 122.

ALEXANDRENS, in Ancient Geography, a moun-
tain of Mylia, on the sea-coast, forming a part of Mount
Ida, where Paris pronounced judgment on the three god-
defees. Strabo.

ALEXANDRETTA, now called Seendoun by the
Turks, in Geography, is the port of Aleppo in Syria, and
situated in the gulf of Aja'ezo, near the sea-coast. N. lat.
36° 35' 10". E. long. 36° 26'. Its nearest distance from
Aleppo, in a straight line, is between 60 and 70 miles; but
the usual road for caravans, through Seendoun, is computed
to be between 90 and 100 miles.

Ancient and modern travellers, from Moryfon and Teix-
eira to Volney, concur in representing the wretched condi-
tion of this village, which owes its existence, as the habita-
tion of human beings, to its being the port and road that
lead to Aleppo. In this road vessels anchor on a solid bot-
tom, so that their cables are not liable to cleave; and from
hence merchants convey their goods as speedily as possible,
by means of their factors, to Aleppo and other places. In
winter this harbour is incommoded by a wind, called by the
French sailors Le Ragnier, which rushes from the snowy
summits of the mountains, and forces the ships to drag their
anchors several leagues; and ships are prevented by tempe-
tuous winds from entering the harbour for three or four
months. The road to Aleppo by the plain is also infested
by cady robbers, who conceal themselves in the coves of
the adjacent rocks, and plunder the strongel caravans. Be-
fides, such is the situation of this port, that it is environed
on three of its sides with a fenny plain, and on the fourth side by
the sea. On the east side, beyond the bay, is a high moun-
tain, which intercepts the rays of the sun, and the remote
mountains on the north side have the fame effect, that the
flagrant waters and septic exhalations produce an epidem-
ic disorder, which prevails from May to September, and
which is fatal to the inhabitants and to the crews of the
ships during their stay in this place. This disorder is an
interrupting fever of the most malignant kind, accompanied
with obstructions of the liver, which terminate in a dropy;
and, at the time when this fever is most prevalent, ships have
frequently lost all their men in two months; and "the place,
"as Moryfon (Travels, p. 250.) long ago observed, "is infamous
"for the death of Christian." Some years ago, says Mr. Vol-
ney, the merchants of Aleppo, disgusted with the numerous
inconveniences of Alexandretta, wished to abandon that port
and remove the trade to Latakia. They proposed to the
pacha of Tripoli to repair the harbour at their own expence,
on condition of his indemnifying them from all duties for ten
years. Regardless of any future advantages that might ac-
crue to his country from this plan, and of which he was not
likely to participate, their proposal was rejected, and the Eu-
erpean factors were obliged to remain at Seendoun.

The only curiosity of the place, it is said, that is shown for the
amusement of strangers, consists of fix or seven marble monu-
ments, sent from England, on which is read the following inscrip-
tion: "Here lies ——, carried off in the flower of his age by the fatal effects of a contagious air." It is added,
that the languid and yellow aspect, hivid eyes, and drophical
symptoms of those who shew these monuments, plainly indi-
cate that they are not likely long to escape the same fate.
To a village, however, called Beylan, situated on a high hill, about
four leagues distant, and abounding with fresh water, and
excellent fruits, the inhabitants retire, and here they find no
inconceivable relief. The plain of Antioch, which lies at
some distance, is watered with a number of streams and can-
als, and abounds with most of the needfuls of life, parti-
cularly with cattle, which are driven there to fattens. This
port has a governor and some few foilds, and is defended
by an old castle; but as it is insufficient to refit any force,
it is somewhat surprising that the pirates, who swam on this
coast, never attempt it. The age has, for many years past,
employed the duties of the custom-house at Alexandretta to his
own use, and rendered himself almost independent of the
pacha of Aleppo. In former times the carrier pigeon, Col-
omba Tabellaris, of Linnaeus, was employed by the English
factory to convey intelligence from Seendoun of the arrival
of the company's ships in that port. The practice has been
diffused for many years; but Dr. Ruffell (Hist. Aleppo,
vol. ii. p. 204.) informs us, that when it fulfilled, the pigeon
performed the journey in two hours and a half.

ALEXANDRIA, now called Scendoun, the ancient
capital city of Lower Egypt, was built by Alexander the
Great, in the year 332 before Christ. It was situated on
the Mediterranean between the Lake Mareotis and the beau-

tiful harbour formed by the Isle of Pharos, about 12 miles west of the Canopic branch of the Nile, in N. lat. 31° 10', and E. long. 30° 19'. It is probable, says a popular historian, that the opposition and efforts of the republic of Tyre, which gave Alexander so long and so severe a check in the career of his victories, led him to perceive the vast resources of a maritime power, and suggested to him an idea of the immense wealth which the Tyrians derived from their commerce, especially that with the East Indies. As soon, therefore, as he had accomplished the destruction of Tyre, and reduced Egypt to subjection, he formed the plan of rendering the empire, which he designed to establish, the centre of commerce as well as the seat of dominion. With this view he founded a great city, which he honoured with his own name, near one of the mouths of the river Nile, that by the Mediterranean sea and the vicinity of the Arabian gulf, it might command the trade of both the east and west. He had no sooner conceived the design than he hastened to execute it. Accordingly he himself drew the plan of the intended city, and fixed upon several places where the temples and public squares were to be erected. It is said, that as there were no materials at hand proper for this purpose, a quantity of meal was scattered over the ground, and that thus the circuit of the walls was marked out: and it is added, that Arrianus, the king's footstayer, interpreted this new mode of determining the site of the walls as a preface of the abundance which would distil with the city. The situation of Alexandria, it must be allowed, was selected with such discernment, that it soon became the chief commercial city in the world; and in this respect the design of its founder was fully accomplished. During the sublimity of the Grecian empire in Egypt and in the east, and amidst all the successive revolutions in those countries, through a period of about 1500 years, from the time of the Ptolemies to the discovery of the navigation by the Cape of Good Hope, commerce, particularly that of the East Indies, continued to flow in the channel, which the facility and fertility of Alexander had prepared. Although some part of the Indian commerce was conducted by means of the river Oxus and the city of Samarkand into the Caspian sea, and thence by land to Trapesazon, and passing to the Euxine and other neighbouring seas, centered in the city of Corinth; yet a considerable part of it, especially such as was carried on at the coast of Malabar, and in the Persian gulf, came up the Red Sea; and goods, which were landed at Elam, now Suez, were conveyed over land to the Nile, and then by water to Alexandria.

This city, says a modern traveller, was a league and a half long by one-third in breadth, which made the circumference of its walls about four leagues. Quintus Curtius (lib. iv. c. 8. tom. i. p. 221.) makes them 80 stad. or a little more than nine miles. According to Pliny (H. N. lib. v. c. 1o. tom. i. p. 258.) they were 15 miles. Strabo (lib. xvii. tom. ii. p. 1142.) makes the length of the city 90 stad., and the breadth between seven and eight stad.; and Diodorus Siculus (lib. xviii. tom. ii. p. 595. Ed. Weigel) makes the circuit 560 stad., or somewhat more than 11 miles; and he says, that the city was peopled by 300,000 free inhabitants, besides at least an equal number of slaves. The Lake Mareotis bathed its walls on the fourth, and the Mediterranean on the north. It was intersected lengthwise by fright parallel streets. This direction left a free passage to the northerly wind, which alone conveys coolness and salubrity into Egypt. A street two thousand feet wide began at the gate of the sea, and terminated at the gate of Canopes. It was decorated by magnificent houses, by temples, and by public buildings. In this extensive range the eye was never tired with admiring the marble, the porphyry, and the obelisks, which were destined at some future day to embellish Rome and Constantinople. This direct, the handomest in the universe, was intersected by another of the same breadth, which formed a square, at their juncture, half a league in circumference. From the middle of this great place the two gates were to be seen at once, and vessels arriving under full sail from the north and from the south. A mole of a mile in length, called Hepsa Stadium, stretched from the continent to the Isle of Pharos, and divided the great harbour into two. That which is to the northward preferred the name of the founder, and was called the Great Port. A dyke, drawn from the island to the rock on which Pharos was built, secured it from the westerly winds. The other was called Eunostos, or the Safe Return. The former is called at present the New, and is the port to which the vessels of Europe resort; the latter is the Old Harbour, and is that to which those only from Turkey are admitted; a bridge that joins the mole to the city served for a communication between them. It was raised on lofty pillars sunk into the sea, and left a free passage for the ships. The palace, which advanced beyond the promontory of Lochias, extended southwest by dyke, and occupied more than a quarter (a third or fourth, says Strabo) of the city. Each of the Ptolemies added to its magnificence. It contained within its inclosure the museum, an asylum for learned men, groves and buildings worthy of royal majesty, and a temple where the body of Alexander was deposited in a golden coffin. Pericles, it is said, undertook to convey the body of Alexander to the temple of Jupiter Ammon, agreeably to the will of that prince; but Ptolemy, son of Lagus, carried it off, and placed it in the palace of Alexandria. The infamous Seleucus Cibyraeactus violated this monument, carried off the golden coffin, and put a glass one in its place. In the great harbour was the little island of Anti-Rhades, where stood a theatre and a royal place of residence. Within the harbour of Eunomus was a smaller one, called Kibotos, or Cibotos, q. d. the harbour of the arch, dug by the hand of man, which communicated with the Lake Mareotis by a canal. Between this canal and the palace was the admirable temple of Seraspis, and that of Neptune, near the great place where the market was held. Alexandria extended likewise along the southern banks of the lake. Its southern part presented to view the Gymnasion, with its porticoes more than 600 feet long, supported by several rows of marble pillars. Without the gate of Canopus was a spacious circus for the chariot races. Beyond that the suburb of Nicopolis ran along the sea shore, and seemed a second Alexandria. A superb amphitheatre was built there, with a race-ground, for the celebration of the Quinquennalia, or feasts that were celebrated every fifth year. Such is the description, says Savery (Letters on Egypt, vol. i. p. 275.), left us of Alexandria by the ancients, and above all by Strabo.

This famous city, second only to Rome itself, was built by Democrates, a celebrated architect, who acquired great reputation by rebuilding the temple of Diana at Ephesus, which Herostratus had burnt. Alexandria owed much of its celebrity as well as its population to the Ptolemies. Ptolemy Soter, one of Alexander's captains, who, after the death of this monarch, was first governor of Egypt, and afterwards assumed the title of king, made this city the place of his residence, about 304 years before Christ. This prince founded an academy, called the Museum, in which a society of learned men devoted themselves to philosophical studies, and the improvement of all the other sciences; and he also gave them a library, which was prodigiously increased by his successors. He likewise induced the merchants of Syria and Greece to reside in this city, and to make it a principal mart of their commerce.
commerce. His son and successor, Ptolemy Philadelphus, pursued the deLights of his father, and completed the tower of Pharos, brought the image of the god Serapis from Pontus, and erected the famous temple of Serapis, and improved the Alexandrian library. He also continued the canal, projected and begun by Necho, and carried on by Darius Hydaspis, which was intended for joining the Nile to the Red Sea, and had the glory of completing it. Ptolemy Euergetes imitated the example of his predecessors, encouraged trade, and contributed to the wealth of Alexandria, and the prosperity of the Kingdom. But the affluence that was thus produced occasioned luxury and licentiousness, so that the voluptuaries of Alexandria became proverbial: "Non Alexandrinus quidem pulcritudine delicius." Quintilian. For about 300 years, from the commencement of the reign of Ptolemy Soter to the death of Cleopatra, Alexandria continued in rebellion to the Ptolemies; but most of them devoted themselves to various kinds of indulgence and pleasure, became effeminate and dissolute, and by their example contributed to such corruption and relaxation which prevailed among their subjects, and ultimately terminated in the ruin of this famous city. Ptolemy Philoctenus, in particular, was a monster of vice and cruelty. About the year B.C. 156, he put to death or banished most of the persons who had been in favour with his brother Philometor, and who had been employed during his reign, and permitted his foreign troops to plunder and massacre at discretion. Many of the inhabitants of Alexandria, terrified by his savage conduct, and in order to avoid his cruelty, retired into foreign countries, and left the city almost a desert. Of these there were grammarians, philosophers, geometers, physicians, magicians, and other masters in the liberal sciences, who disseminated the polite arts and general science through Greece, Asia Minor, and the islands, and indeed to every place where they fled. In order to supply the places of these fugitives, Ptolemy cau ded proclaimations to be made in all the neighbouring countries, that persons of any nation, who were defirous of settling at Alexandria, should receive suitable encouragement. The proposal was accepted by many, and the houses and privileges which belonged to the former inhabitants were assigned to these new settlers, and thus the city was repopulated. About this time Scipio Africanus the younger, and other Romans, were desirous of an embassy to Alexandria; and Julius says of him, that whilst he visited and considered with curiosity the magnificence of Alexandria, he was himself a fighter to the whole city; "Dum infipici urbem, ipse spectaculii Alexandrinus fuit!" so different were his aspects and manners from those of the Alexandrians. The new inhabitants, whom Ptolemy had invited into the city, soon found reason to dislike their situation, and to hate their new sovereign. Cruel and timid as he was, he determined to massacre all the young men of the city; and for this purpose he cau ded the Gymnasium, or place of exercise in which they were assembled, to be invested by his foreign troops, and put them all to the sword.

When Julius Cæsar, B.C. 48, in his pursuit of Pompey, landed at Alexandria, he found the city in great commotion, without law and without government. Having arbitrated between Ptolemy XII. and Cleopatra, and decreed that they should reign jointly in Egypt, Ptolemy indignified the Alexandrians to reful the decree, and to concur in driving Cæsar out of the city. Accordingly he brought 20,000 troops to effect his purpose, but Cæsar supported the attack; and in order to prevent any injury to their fleet, to which they next had recourse, he cau ded it to be set on fire, and posted himself of the tower of Pharos, which he garrisoned. Some of the vessels that were on fire came so near, that the flames caught the houses adjoining to the quay, and spread through that quarter of the city, which was called Brachion, and consumed the library that was placed there, confining of 400,000 volumes. In a decisive battle with the whole army of Ptolemy, Cæsar, afllicted by a considerable body of Jews, obtained a complete victory. Ptolemy, in endeavouring to make his escape in a boat, was drowned in the Nile; and Cæsar returned to Alexandria, which, together with the whole of Egypt, submitted to the victor. Before he left this city, he confirmed all the privileges which the Jews enjoyed, and the decree that the Jews were to have for their assistance, and ordered a column to be erected, in which these privileges were engraved, with the decree that confirmed them. The emperor Caligula was inclined to favour the Alexandrians, because they manifested a readiness to confer divine honours on him; and conceived the horrid design of massacring the chief senators and knights of Rome, A.D. 40, and then of abandoning the city.
Nothing equals their ingratitude; I have granted them every thing they could desire; I have restored their ancient privileges; I have given them new ones; in consequence of this they were grateful to me when precent; but I had severely turned my back when they insultingly attacked my son Verus, and I believe you know what they have said of Antoninus, &c. &c. Therefore the Alexandrians built baths in the city, when they expected a visit from him to Egypt; and because Cecina Tuscus, the son of his nurse, whom he had made prefect of Egypt, professed to make use of them, he was condemned to banishment. To Alexandria belonged the honour of being the first place where Vespasian was acknowledged and proclaimed, A.D. 69, and the emperor remained there whilst his generals and armies were fighting against Vitellius; and though he came Lither for the purpose of harrying Italy, by preventing its supplies of foreign corn, yet as soon as he heard of the death of Vitellius, and that Rome had submitted, the belt ships of Alexandria were immediately laden with corn, and ordered to fail for their supply. Whilst Vespasian continued in this city, he received ambassadors from the Vologeses, who offered him 46,000 Parthian horses; but peace was then restored to the Roman empire. During his stay in this place he was no favourite with the Alexandrians. They were fond of pomp and magnificence, and Vespasian loved simplicity. They had flattered themselves with the hopes of receiving a gratification, because they had been the first who acknowledged him for emperor; but on the contrary they were harassed with imposts, either new, or raised with uncommon rigour. The Alexandrians revenged themselves with thefts and forgeries, calling him Cyrilis, a name which they had formerly given to one of their kings, who was forcibly avaricious; but heaven, if we credit some pagan writers, distinguished him by miracles. The emperor Severus, in his visit to Egypt, A.D. 202, granted the Alexandrians a council, the members of which had the title and privileges of senators, and affixed in the administration of public affairs, and thus mitigated the rigour of the despotic government of the prefect instituted by Augustus. He also changed several laws in their favour; and they erected a column as a monument of their gratitude, called by Abu edd the Pillar of Success. It has already appeared that the Alexandrians were inclined to be facetious, and that they defaced the character given to them by Herodotus, who says, that they loved to be merry at the expense even of their princes. In the case of Caracalla, whose vanity they ridiculed, because, though he was of small stature, deformity, and dulness of every kind of military merit, he had compared himself to Achilles and to Alexander, their raillery was of a very serious consequence. Whilst the Alexandrians were preparing to receive him with joy and magnificence, when he visited the temple of Serapis, and the tomb of Alexander, he was meditating cruel retaliation. In the midst of peace, and on the slightest provocation, he laden his commands for a general massacre, A.D. 215. From a secure part of the temple of Serapis, he viewed and directed the slaughter of many thousands of citizens, as well as strangers, without distinguishing either the number or the crime of the sufferers; since, as he easily informed the senate, all the Alexandrians, these who had perished and those who had escaped, were alike guilty. Dion. (lib. xxvii. p. 1527.) represents it as a cruel massacre; Herodian (lib. iv. p. 155.) says, that it was also pernicious. The massacre was accompanied with the plunder both of temples and houses, and all strangers, except merchants, were driven from the city. The societies of learned men, who were maintained in the Muftaem, were abolished; and the different quarters of the city were sepulchred from each other by walls and towers to prevent all communication between them. However, this devastation was but a temporary evil; for Caracalla being soon after killed, Alexandria recovered its splendour by its own resources, and soon became again the second city of the empire. Under the reign of Gallicanus, Amilian, who had been prefect of Egypt for some years, assumed the imperial purple, on occasion of a violent sedition, which terminated in a ruino us war. All communication between the different quarters of Alexandria was cut off, and it was easier, says St. Dionysius, to go from one end of the world to the other than from Alexandria to Alexandria. The streets were filled with blood, the dead bodies putrefied, and, by their infection, brought on the plague. Amilian, in vain, endeavoured to appease the people. They were exasperated against him, and attacked him with lances and darts; upon which, in order to assert the imminent danger that threatened him, he declared himself emperor. The soldiers and the people, happy in the prospect of being rescued from the yoke of Gallicanus, acknowledged his sovereign authority. At length he was attacked and defeated by Theodosius, the minister of Gallicanus's vengeance. Upon this he retired to the Bruchium, a quarter of Alexandria, and sustained a siege, in which Antokus and St. Eufebius, intimate friends, and afterwards bishops of Laodicea, were admired for their ingenuous charity in comforting and relieving the unhappy beleaguered, who perished with hunger. Amilian was saved by Eusebius, and Eufebius remained with the Romans. The emperor, moved with compassion to the wretched circumstances of the besieged, applied to the latter to evacuate the town for those who should leave the garrison and surrender themselves. Having foreseen the application he immediately proposed surrendering the place, and making peace with the besiegers. The answer was, that no peace should be made. Amilian then proposed, that all who were of no service should leave the place in peace, and they were kindly received and fea rably supplied by Eusebius. Amilian was afterwards taken by Theodosius and sent to Gallicanus, who ordered him to be bludgeoned in prison. The various misfortunes that befel Alexandria did not depopulate this great city, that, after the calamities, the number of its inhabitants, from four to five hundred thousand, was the same as it was before, in the age of Augustus, as well as of those who were between 40 and 70. This enumeration is known by the registers that were kept for the greatest distribution of corn. Eufebius, Eccl. Hist. viii. 21. Diocliarius, A.D. 296, marched against Alexandria, who had usurped the government of Egypt; and, having driven him to Alexandria, besieged the city, cut off the aqueducts which conveyed the waters of the Nile into every quarter of that immense city, and rendering his camp impregnable to the fel low of the beleaguered multitude, he pushed his reiterated attacks with caution and vigour. After a siege of eight months, Alexandria, Wafted by the sword and by fire, im ported the demence of the conqueror, but it experienced the full extent of his severity. Many thousands of the citizens perished in a promiscuous slaughter, and there were few obnoxious persons in Egypt, who escaped a sentence either of death, or at least of exile. Eutrop. ix. 24. Orosius (vii. 25.) says, that he gave up the city to be plundered. As an apology for the severity of this emperor, it has been alleged that the seditions of Alexandria had often affected the tranquility and sublimity of Rome itself, and that his severity was counterbalanced by salutary regulations. In 502 he established, for the benefit of this city, a perpetual distribution of corn. Constantine, with a view of establishing his new city of Constantinople, distributed every day 87,000 bushel-
of corn brought from Alexandria; and he employed the Alexandria fleet in victualling New Rome, as it was called, leaving to Old Rome only that of Africa. Socrat. ii. 13. Alexandria suffered in common with other places by the violent and destructive earthquake which shook the greatest part of the Roman empire, July 218; A.D. 365; and this city annually commemorated this fatal day when 50,000 persons had left their lives in the immediate inundation.

It was in Alexandria chiefly that the Grecian philosophy was engraven upon the block of ancient oriental wisdom. The Egyptian method of teaching by allegory was peculiarly favourable to such an union; and we may well suppose that when Alexander, in order to preserve by the arts of peace that extensive empire, which he had obtained by the force of arms, endeavoured to incorporate the customs of the Greeks with those of the Parthian, Indian, and other eastern nations, the opinions as well as the manners of this feeble and oblique race would, in a great measure, be accommodated to those of their conquerors. This influence of the Grecian upon the oriental philosophy continued long after the time of Alexander, and was one principal occasion of the confusion of opinions which occurs in the history of the Alexandrian and Christian schools. Alexander, when he built the city of Alexandria, with a determination to make it the seat of his empire, and populated it with emigrants from various countries, opened a new mart of philosophy, which emulated the fame of Athens itself. A general indulgence was granted to the promiscuous crowd assembled in this rising city, whether Egyptians, Grecians, Jews, or others, to profess their respective systems of philosophy without molestation. The consequence was, that Egypt was soon filled with religious and philosophical sectaries of every kind; and particularly, that almost every Grecian sect found an advocate and professor in Alexandria. The family of the Ptolemies, as we have seen, who after Alexander obtained the government of Egypt, from motives of policy, encouraged this new establishment. Ptolemy Lagus, who had obtained the crown of Egypt by usurpation, was particularly careful to secure the interest of the Greeks in his favour, and with this view invited people from every part of Greece to settle in Egypt, and removed the schools of Athens to Alexandria. Thus enlightened princes spared no pains to raise the literary, as well as the civil, military, and commercial credit of his country. Under the patronage first of the Egyptian princes, and afterwards of the Roman emperors, Alexandria long continued to enjoy great celebrity as the seat of learning, and to send forth eminent philosophers of every sect to distant countries. It remained a school of learning, as well as a commercial emporium, till it was taken, as we shall see in the sequel of this article, and plundered of its literary treasures by the Saracens. Philosophy, during this period, suffered a grievous corruption from the attempt which was made by philosophers of different sects and countries, Grecian, Egyptian, and Oriental, who were assembled in Alexandria, to frame, from their different tenets, one general system of opinions. The respect which had long been universally paid to the schools of Greece, and the honours with which they were now adored by the Egyptian princes, induced other wise men, and even the Egyptian priests and philosophers themselves, to submit to this innovation. Hence arose an heterogeneous mass of opinions, under the name of the Eclectic philosophy, and which has been the foundation of endless confusion, error and absurdity, not only in the Alexandrian school, but among Jews and Christians; producing among the former that seditious kind of philosophy, which they called their Cabala, and among the latter innumerable corruptions of the Christian faith. The Alexandrian school is celebrated by Strabo (lib. xvii.) and by Ammianus (xxiii. 6.) Brucke's History of Philosophy, by Enfield, vol. i. p. 520.

At Alexandria there was, in a very early period of the Christian era, a Christian school of considerable eminence. St. Jerome says, the school at Alexandria had been in being from the time of St. Mark. Pantaenus, placed by Lardner as the ear 195, succeeded in it St. Clement. St. Ignatius of Antioch succeeded Pantaenus in this school about the year 195; and he was succeeded by Origen. Lardner's Works, vol. ii. p. 202.

As the extensive commerce of Alexandria, and its proximity to Palestine, gave an easy entrance to the new religion, it was at the school of this city that the Christian theology appears to have assumed a regular and oriental form: and when Adrian visited Egypt, he found a church composed of Jews and Greeks, sufficiently important to attract the notice of that inquisitive prince. The theological system of Plato was introduced into both the philosophical and Christian schools of Alexandria; and of course many of his sentiments and expressions were blended with the opinions and language of the professors and teachers of Christianness. See Platonism.

The city of Alexandria, which had maintained its reputation for power and wealth, as well as for literature and science, was ruined by the Saracens, and which was captured by them, and which had been in sedition from the time of the Ptolemies, the Romans, and the Greek emperors, was at length captured by the Saracens, and in process of time totally ruined. In the year 688, Amrou, the general of Omar, invaded Egypt; and in the following year he commenced the siege of Alexandria. This siege is perhaps the most arduous and important enterprize in the annals of Saracen conquests. The first trading city in the world was abundantly replenished with the means of subsistence and defence. Her numerous inhabitants fought for the dearest of human rights, religion and property; and the enmity of the natives seemed to exclude them from the benefits of peace and toleration. The city was continually opened and held in subjection by the Ptolemies, the Romans, and the Greek emperors, and was plundered by the Saracens, and in process of time totally ruined. In the year 688, Amrou, the general of Omar, invaded Egypt; and in the following year he commenced the siege of Alexandria. This siege is perhaps the most arduous and important enterprize in the annals of Saracen conquests. The first trading city in the world was abundantly replenished with the means of subsistence and defence. Her numerous inhabitants fought for the dearest of human rights, religion and property; and the enmity of the natives seemed to exclude them from the benefits of peace and toleration. The city was continually opened and closed, and its narrow ends exposed a front of no more than 10 furlongs. The efforts of the Arabs, however, were not inadequate to the difficulty of the attempt and the value of the prize. The faithful natives devoted their labours to the service of Amrou; and in every attack his sword and banner glittered in the van of the Mollens. The general, having been relieved from a temporary captivity, into which his imprudent valour had betrayed him, advanced towards the city doomed to destruction. At length, after a siege of fourteen months, and the loss of 25,000 men, the Saracens prevailed; the Greeks embarked their dispirited and diminished numbers; and the standard of Mahomet was planted on the walls of the capital of Egypt. Dec. 22, A.D. 640. "I have taken," said Amrou to the caliph, "the great city of the world." It is impossible for me to enumerate the variety of its riches and beauty; I shall content myself with observing, that it contains 4000 palaces, 4000 baths, 400 theatres or places of amusement, 12,000 shops for the sale of vegetable foods, and 40,000 tributary Jews. The town has been subdued by force of arms, without treaty or capitulation, and the Mollens are impatient to seize the fruits of their victory." According to the Arabian historians, Alexandria, at this time, consisted of three cities, viz. Menna, or the port, which included Pharos and the adjacent parts; Alexandria, properly so called, where the modern Scanderia stands; and Nekita, or the
ALEXANDRIA.

The present state of Alexandria affords a scene of magnificent ruin and desolation. In the space of two leagues, enclosed by walls, nothing is to be seen but the remains of pilasters, of capitals, and of obelisks, and whole mountains of shattered columns and monuments of ancient art heaped upon one another, and accumulated to a greater height than that of the houses. The famous tower of Pharos has been long since demolished, and a square castle, without turrets, ornament, or strength, called Farillon, erected in its place. The mole which joined the continent to the isle of Pharos is neglected and is now but a part of the main land, the island of Anti-Rhodes is in the middle of the present town, and is discoverable only by an eminence covered with ruins. The harbour Kiberos is choked up. The canal which conveyed the water of lake Mareotis has disappeared. This lake itself, through the negligence of the Turks in preserving the canals which conveyed the waters of the Nile, is no longer in existence, but is entirely occupied by the sands of Lybia. The canal of Pompey, the only one which at present communicates with Alexandria, and without which that town could not subsist, since it has not a drop of fresh water, is half filled with mud and sand. Under the Roman empire, and even under the domination of the Arabs, it was navigable all the year, and served for the conveyance of merchandise. Its banks were shaded with date trees, covered with vineyards, and adorned with country houses. At present it has no water till about the end of August, and its supply is hardly sufficient to fill the cisterns of the town. The fields adjoining to it are deserted; the groves and gardens that surrounded the ancient city have disappeared, and without the walls there are only a few scattered trees, some fycamores and fig-trees, some date and carps trees, and halis, that hide the burning sands, which would be otherwise inapplicable to the fight. Nevertheless, every trace of ancient magnificence is not obliterated. Some parts of the old walls are yet standing; and they are flanked with large towers, at the distance of about 200 paces from each other, and with smaller intermediate ones. Below are magnificent cisterns, which may serve for galleries in which to walk. In the lower part of the towers is a large square hall, whose roof is supported by thick columns of Thebaic stone; and above this are several rooms, over which are platforms more than 20 paces square. The refervories, vaulted with much art, and extending under the whole town, are almost entire at the end of 2000 years. Of Cesar's palace there remain only a few porphyry pillars, and the front, which is almost entire, and appears very beautiful. The palace of Cleopatra was built upon the walls facing the port, having a gallery on the outside, supported by several fine columns. Towards the eastern part of the town are the two obelisks, vulgarly called Cleopatra's Needles. They are of Thebaic stone, and covered with hieroglyphicks; one is overturned, broken, and lying under the sand; the other is on its pedestal. These two obelisks, each of them of a single stone, are about 60 feet high, by seven feet square at the base. Towards the gate of Rosetta are five columns of marble, on the place formerly occupied by the porticoes of the Gymnasion. The reef of the colonnade, the design of which was discovered 100 years ago by Maillet, has been since destroyed by the barbarism of the Turks. Pompey's pillar, and the Catacombe, at half a league distant to the southward of the town, still engage the attention of travellers. The canal of the Nile, already mentioned, is about 200 paces from Pompey's pillar; and on the top of the hill is a tower, in which a sentinel is placed,
placed, who gives notice by a flag, of the ships that are coming into port. From this hill may be seen the sea, the whole extent of the city, and the parts in its vicinity. On the sea-coast there is a large basin, cut out of the rock that forms the floor, having on its sides two beautiful fountains that are hewn out by the chisel, with benches across them. A canal of a zig-zag form, for the purpose of stopping the progress of the wind by its different windings, conveys into them the water of the sea, purer and transparent as crystal. The water rises a little above the wall, when a person is seated on the stone bench, and the seat roll on a fine sand. The waves of the sea dash against the rock and foam in the canal. The salt water rises up, and leaves you; and thus alternately entering and retiring, furnishes a continual supply of fresh water, and a coolness, which is grateful and delicious under a burning sky. This place is vulgarly called the Bath of Cleopatra, and some ruins indicate its having been formerly adorned.

The modern Alexandria is built near the brink of the sea on a kind of peninsula, situated between the two ports above-mentioned. The new port alluded to Europeans, is clogged up with sand, which renders the entrance into it both difficult and dangerous, and in stormy weather endangers the bilging of the ships; and the bottom is rocky, so that the cables soon chafe and part; and thus vessels are driven against one another, and are sometimes lost. An instance of this kind happened in March 1775, when more than 40 vessels were dashed to pieces on the mole by a north-west gale. Similar accidents have also happened at different times; and under the Turkish government, which, as it is said, ruins the labours of past ages and destroys the hopes of future time, no provision is likely to be made for preventing their occurring again. The other port, or the Eunusotis of the ancients, to the westward of the Pharos, is called the port of Africa; it is much larger than the former, and lies immediately under part of the town of Alexandria. It has much deep water, though many ships are continually throwing their ballast into it; and without doubt it will be at length filled up and thus joined to the continent. Christian vessels are not suffered to enter this port; and the only reason is, lest the Moors should be seen taking the air in the evening at open windows, and this has been thought sufficient to induce Christian powers to submit to the restraint, and to overbalance the constant loss of ships, property and men. The houses at Alexandria, like those of the Lycus, have flat terrace roofs; they have no windows and the apertures which supply their place are almost entirely obstructed by a wooden lattice protecting, of various forms, and so close, that the light can hardly force a passage. In those countries, more than any where else, such inventions, which transform a manion into a prison, are real jealosies, as Somnini calls them, or window-blinds. Narrow and awkwardly disposed streets are without pavement, as the city is without police; no public edifice, no private building arrests the eye of the traveller; and on the supposition that the fragments of the old city had not attracted his attention, he would find no object in the present town that could supply matter for a moment’s thought. Turks, Arabians, Barbariques, Copts, Christians of Syria, and Jews, constitute a population which, according to Somnini, may be estimated at 5000, as far as an estimation can be made in a country where no regiter of any thing is kept. Commerce attracts thither besides, from all the countries of the east, strangers whose residence is very transient. This motley assemblage of persons of different nations, jealous of and almost always hostile to each other, would prevent to the eye of the observer a singular mixture of vulgarities, manners and depressions, if a refect of thieves and robbers could repay the trouble of observation. The present Alexandrians, like their predecessors in former times, chargeable with a pronounced fanaticism, which is avoided and repressed by the severity of their government. The British and French nations carry on a considerable commerce with Alexandria, and have each a consular residing there. Some Venetian ships also sail thither yearly, under the colours and protection of France. The subjects of those kingdoms who have no capital here are subjected to a tax by the Grand Seigneur; but the Jews make themselves for this disadvantage, by selling their commodities cheaper than other foreigners can afford to do; and they are also favoured by the farmers of the revenues, who know that the Jews have it in their power to lessen the quantity of merchandise that comes into their port, for the period of two years, which is the duration of their farm. The language spoken at Alexandria is the Arabic; but most of the Alexandrians, and those in particular whom commerce leads into an intercourse with the merchants of Europe, speak likewise the Italian. The morcello or lingua franca, which is a compound of bad Italian, Spanish, and Arabic, is likewise spoken in this place. The government of Alexandria is like that of other places in Egypt; and is conducted by an aga, who has under him a kadi and sub-basha, all nominated by the chief basha. It has a small garrison of soldiers, part of which are Janizaries and Alalites; who are haughty and insolent, not only to strangers, but to the mercantile and inoffensive part of the people. They are lodged in the fortresses or castles that guard the port, where the aga or governor that commands them also resides. But though the Pharos, according to established regulations, ought to be garrisoned by 500 Janizaries, it has never had half that number, and not more than four cannons for its defence. The whole of the fortifications might easily be beat down by a single frigate; but a foreign army would experience great difficulty in maintaining possession of Alexandria for want of water; as the city has not any besides that which is conducted by canals into their refectories at the time of the overflowing of the Nile; so that it would be necessary to conquer the whole country, or at least those parts that lie on the banks of the river. Alexandria was taken by assault on the fourth of July, 1798, by the French army under the command of Bonaparte, the present prime confid of France; after putting to flight the Arabs and Mamelukes who defended it, and killing about 300 of them. The troops, that were left in possession of the town, when the army began its march across the Desert, having been forbidden, under penalty of death, from entering the houses or mosques of the Turks, or committing any violence on their persons, or those of their families, built huts of palm-branches without the city, to shelter themselves from the sun. The men of science, who accompanied the army, were lodged in the houses of the few Europeans resident at Alexandria, but a dozen of them were crowded together in one chamber, under the heat of a torrid climate. Miserably supplied both with food and water, modelled with the flings of insects, and surrounded with filth and wretchedness, they at the same time contemplated in a city, once renowned for industry, commerce, and activity, nothing but ruins, barbarism, and poverty; rampaging looking citizens, with long pipes, indolently sitting in the public places, half starved and naked children, and the forms of bare-footed women, in blue serge gowns, and black fluff veils, flying the approach, or turning away with precipitation, whenever they met a Frenchman. The French beheld every where monuments of antiquity, but every where misplaced;
A L E X A N D R I A.

pillar of granite, inscribed with Egyptian hieroglyphics, showed the orbits, or divided by the bow, fixed for their bolts and bracelets; marble and porphyry hafts and capitals, baths and catacombs, were found in ruins, with nothing entire but a bath of black granite, designed for the museum of Paris; the pillar of Pompey, and the obelisk of Cleopatra, which were yet in good preservation. When the blockade of the port by the English fleet, after the famous battle of Actium, cut off the communication with Rosetta, and the supply of water was thus impeded, Bonaparte caused the canal which led from Khamania to Alexandria, across a defile of 30 miles, to be cleared; by which means not only this city received a larger supply of water and provisions, but the artillery was conveyed more expeditiously and conveniently by water to the general depot at Giza, than it could have been by land. Bonaparte also drew plans for the better defence of the port of Alexandria, and the city of Cairo; he also formed a grand establishment for the mechanical arts; and with the concurrence of the scientific men who attended him formed a national academy, called the Institute. In the year 1801, Alexandria was taken by the English army, under the command of General Huchinson, the news of which was announced soon after the preliminaries of peace between England and France were signed, by the respective agents of the two countries; by one article of which Egypt is to be delivered up to the Sublime Ottoman Porte. Alexandria is situated in N. lat. 31° 11' 20'. E. long. 30° 16' 39'. Nautical Almanac. According to Bruce (Travels, vol. i. p. 15.) N. lat. 31° 11' 42'. E. long. 30° 17' 20'. Anc. and Mod. Un. Hill. Rollin's Anc. Hill. Savary's Letters on Egypt, vol. i. letter 2. Sonnini's Travels through Upper and Lower Egypt. Gibbon's Decline, &c. of the Rom. Emp.

Alexandria was also a name given to several other cities; viz. a city of Arachosia, on the river Arachotus, the Alexandropol of Isidor of Stephanus, and by some thought to be the modern Cabul:—another of Gedrosia, both built by order of Alexander the Great; (Pliny, H. N. lib. vi. c. 23.)—A third of Aria, near the lake Arius, according to Ptolemy; but according to Pliny (lib. vi. c. 23.) on the river Arius, built by Alexander, who settled a colony of Macedonians there. (Strabo, lib. xx. Ammianus lib. 22.)—A fourth in Bactriana, so called, says Pliny, (lib. vi. c. 23.) from its builder.—A fifth, an inland town of Carmania, built also by Alexander, and mentioned by Pliny, Ptolemy, and Ammianus.—A sixth, in the country of the Dahre, in Sagdiana, (Isidorus Characenus.)—A seventh, in India, at the confluence of the Aconenes and Indus, (Arrian, lib. v. c. 15.)—An eighth, built by Alexander the Great, between Ifus and the Strates which lead from Cilicia into Syria, called also Alexandretta, and now Scanderoon.—A ninth, in Margiana, which was built by Alexander, and rebuilt, after it was demolished by the barbarians, by Antiochus, the son of Seleucus, and called Antiochiana by Syria, and also Seleucia, watered by the river Margus; 70 pedes in circuit, according to Pliny (lib. vi. c. 16.) who adds, that, after the defeat of Cratinus, Orodes conveyed the captives to this place.—A tenth of the Oxiana, in Sagdiana, built by Alexander on the Oxus, near the confluence of Bactria, (Pliny lib. vi. c. 16.)—An eleventh, built by Alexander, at the foot of Mount Paropamisus, which was called Cascaucus, (Pliny, lib. vi. c. 23.)—A twelfth, in Tross, called also Trosae and Antigonia, ordered to be erected by Alexander, in commemoration of Troy, which had long ceased to exist. Antigonus, one of his lieutenants, laid the foundations of it, and gave his name to the city; but the name of Alexander was restored by Lycurgus, who afterwards pacified, embellished, and extended it. Having passed under the dominion of the Romans, it became, under Augustus, one of the handomest cities of the part. Under Adrian, Herodes Atticus contrived a superb aqueduct, some few traces of which are still to be seen. The walls of the city, of the housetops, of the temples, and of other monuments, are built of a hard flinty stone. The marble of Paros, and that of Marmora, are common here, and also several sorts of granite. Near the rivulet to the south of the city are two springs of mineral waters, referred to by the Turks and Greeks, which are recommended for disorders of the skin, the leprosy, and syphilis. The harbour is narrow extent, and almost choked up with sand. History does not mention the epoch in which this city was destroyed. It had no existence when the Turks established themselves in this country. The environs present a fruitful soil, forming a plain, in which the solani oak grows in abundance, and without culture. The ruins of this city are six leagues to the south of Cape Siganum. Olivier's Travels, &c. vol. ii. p. 46.—A thirteenth Alexandria, built by Alexander on the Jaxartes, bounding his victories towards Scythia. A twentieth in Adabene, mentioned by Pliny, and as Hardouin liggida, designed to perpetuate the remembrance of the defeat of Darius. A sixteenth in the northern coast of the island of Cyprus, built of the promontory of Callinichos. A seventeenth in Palatine, on the river Scham, to the south of Tyre, near the sea.

Alexandria, or ALEXANDRIA, surnamed Della Paglia, became the habitations of a bubble for fuel instead of wood, or became the Germans contemptuously called it Palaris; or a fortress of Baw, a city of Italy, in the district of Alexandri, or Alexandrum, belonging to the duchy of Milan, has a castle, and is situated in a marly country, on the river Tenaro. It was built in honour of pope Alexander II in 770, and is said to have 10000 inhabitants. By this pope it was made a bishopric, suffragan of Milan, with several privileges annexed to it. The citadel is strong, but the fortifications are mean. It was ceded to the duke of Savoy in 1703, taken by prince Eugene, after three days' siege, in 1706, by the French in 1743, and retaken by the king of Sardinia, to whom it belongs by the treaty of Utrecht, in 1746. It is 38 miles east of Turin, and 37 four-fifths-west of Milan. N. lat. 44° 48'. E. long. 8° 39'.

Alexandria, a town of New Russia, in the government of Ekaterinodar, on the confines of Poland, 75 miles west of Ekaterinodar, and 150 four-fifths west of Kiow. N. lat. 48° 25'. E. long. 32° 54'.

Alexandria, or ALEXANDROV, a town of Poland, in the palatinate of Volhynia, upon the river Horin, 50 miles east-north-east of Lucko.

Alexandria, township in Grafton county, N. Hampshire, in America, containing 266 inhabitants, incorporated in 1782.

Alexandria, a township in Hunterdon county, New Jersey, containing 1503 inhabitants, including 40 slaves.

Alexandria, a small town in Huntingdon county, Pennsylvania, on the Frankstown branch of Juniata river, 192 miles north-west of Philadelphia.

Alexandria, formerly called Bellarvus, a city of Virginia, situate on the southern bank of the Patowmac river, in Fairfax county, about five miles south-west from the federal city, and 210 from the sea; N. lat. 38° 45'; W. long. 72° 17'. Its situation is lofty and pleasant, and the farms are laid out upon the plan of Philadelphia. It contains 400 houses, well built, and 2748 inhabitants. It bids fair, from the advantages of its situation, to be one of the most thriving commercial places on the continent.

Alexandria,
ALEXANDRIAN COPY.

ALEXANDRIA, Patriarch of, in Ecclesiastical History. See Patriarch.

ALEXANDRIAN, in a particular sense, is applied to all those who professed or taught the sciences in the school of Alexandria.

Thus, Clemens is called Alexandrinus, or the Alexandrian, though some say he was born at Athens: the same epithet is applied to Apion, born at Oasis; and to Arifarchus, by birth a Samothracian. The chief Alexandrian philosophers were Euclid, the famous geometer, the two ancient astronomers, Arillus and Timocharis, Eratotheneus, Apollonius Pergaeus, Conon, Hipparchus, Cleobulus, Heron, Ptolemeus, Pappus, Thecon, Hypathia the daughter of Theon, Ipotemy; and Philopopous and Didymus, the last mathematicians of this school. To these we may add Ammonius, Plotinus, Origens, Porphyry, Jamblichus, Sopater, Maximus, and Diciptius.

Alexandrian is more particularly understood of a college of priests, consecrated to the service of Alexander Severus, after his dedication.

Alexandrian Copy, is a manuscript, consisting of four volumes, in a large quarto, or rather a folio size; which contains the whole Bible in Greek, including the Old and New Testament, with the Apocalypse, and some smaller pieces, but not quite complete. This manuscript is now preserved in the British Museum, where it was deposited in 1755.

It was sent as a present to Charles I. from CyriUus Lucaris, a native of Crete, and patriarch of Constantinople, by Sir Thomas Rowe, ambassador from England to the Grand Seignior, in the year 1628. CyriUus brought it with him from Alexandria, where, probably, it was written. In a schedule annexed to it, he gives this account: that it was written, as tradition informed them, by Thecla, a noble Egyptian lady, about thirteen hundred years ago, a little after the council of Nice. He adds, that the name of Thecla, at the end of the book, was erased; but that this was the case with other books of the Christians, after Christianity was extinguished in Egypt by the Mahometans: and that recent tradition records the fact of the laceration and erasure of Thecla's name. The proprietor of this manuscript, before it came into the hands of CyriUus Lucaris, had written an Arabic superscription, expressing that this book was said to have been written with the pen of Thecla the martyr. Various disputes have arisen with regard to the place whence it was brought, and where it was written, to its antiquity, and of course to its real value. Some critics have believed upon it the highest commendation, while it has been equally depreciated by others. Of its most illustrious adherents, Wetstein seems to have been the principal. The place from which it was sent to England was, without doubt, Alexandria, and hence it has been called Codex Alexandrinus.

As to the place where it was written, there is a considerable difference of opinion. Matthaus Mutzis, who was a contemporary, friend, and deacon of CyriUus, and who afterwards instructed in the Greek language John Rudolph Wetstein, uncle of the celebrated editor of the Greek Testament, bears testimony, in a letter written to Martin Bogdan, a physician in Bern, dated January 14, 1604, that it had been brought from one of the 22 monasteries in Mount Athos, which the Turks never destroyed, but allowed to continue upon the payment of tribute. Woide endeavours to weaken the evidence of Mutzis, and to render the testimony of the elder Wetstein dubious: but Spohn, in his edition of the "Notitia Codicis Alexandrinii," p. 10-13, shews that the objections of Woide are ungrounded. Allowing their reality, we cannot infer that CyriUus found this manuscript in Alexandria. Before he went to Alexandria, he spent some time on Mount Athos, the repository and manufactory of manuscripts of the New Testament, whence a great number have been brought into the West of Europe, and a still greater number has been sent to Moscow. It is therefore probable, independently of the evidence of Mutzis, that CyriUus procured it either by purchase or by pretext, took it with him to Alexandria, and brought it thence on his return to Constantinople. But the question recurs, where was this copy written? The Arabic superscription above cited clearly proves that it had been in Egypt, at some period or other, before it fell into the hands of CyriUus. This superscription shews that it once belonged to an Egyptian, or that during some time it was preferred in Egypt, where Arabic has been spoken since the seventh century. Besides, it is well known that a great number of manuscripts of the Greek Bible have been written in Egypt. Woide has also pointed out a remarkable coincidence between the Cod. Alex. and the writings of the Copts. Michaelis alleges another circumstance as a probable argument of its having been written in Egypt. In Ezekiel xxvii. 18, both in the Hebrew and Greek text, the Tyrians are said to have fetched their wine from Chelbon, or, according to Bochart, Chalybon. But as Chalybon, though celebrated for its wine, was unknown to the writer of this manuscript; he has altered it by a fanciful conjecture to εχ, δια xι. wine from Hebron. This alteration was probably made by an Egyptian copyist, because Egypt was formerly supplied with wine from Hebron. The superscription, before mentioned, ascribes the writing of it to Thecla, an Egyptian lady of high rank, who could not have been, as Michaelis supposes, the martyr Thecla, placed in the time of St. Paul; but Woide replies, that a confusion must be made between Thecla martyr, and Thecla proto-martyr. With regard to these superscriptions we may observe, with a learned writer (Marth), that the true state of the case appears to be as follows: "Some centuries after the Codex Alexandrinus had been written, and the Greek superscriptions, and perhaps those other parts where it is more defective already lost, it fell into the hands of a Christian inhabitant of Egypt, who, not finding the usual Greek superscription of the copyist, added in Arabic, his native language, the tradition either true or false, which had been preserved in the family or families to which the manuscript had belonged, 'Memorant hunc codicem scriptum effe calamo Theclae martyris.' In the 17th century, when oral tradition respecting this manuscript had probably ceased, it became the property of CyriUus Lucaris; but whether in Alexandria, or Mount Athos, is of no importance to the present inquiry. On examining the manuscript, he finds that the Greek superscription is lost, but that there is a tradition recorded in Arabic by a former proprietor, which firmly related that it was written by one Thecla a martyr, which is what he means by "memoria et traditio recens." Taking therefore upon trust, that one Thecla the martyr was really the copyist, he consults the annals of the church to discover in what age and country a person of this name and character existed, finds that an Egyptian lady of rank, called Thecla, suffered martyrdom between the time of holding the council of Nicea, and the close of the fourth century; and concludes, without further ceremony, that she was the very identical copyist. Not satisfied with this discovery, he attempts to account for the loss of the Greek superscription, and ascribes it to the malice of the Saracens; being weak enough to believe that the enemies of Christianity would exert their vengeance on the name of a poor transcriber, and leave the four folio volumes themselves unburnt." The learned Woide, who has himself transcribed and published this manuscript, and must be better acquainted with it than any other person, affirms, that it was written by two different copyists; for
for he has observed a difference in the ink, and which is of greater moment, even in the strokes of the letters. The conjecture of Oudin, adopted by Wetstein, that the manuscript was written by an Aegyptian is, in the judgment of Michaelis, worthy of attention. (See Acodmer) and he adds, that this conjecture does not contradict the account that Thecla was the copyist, since there were not only marks but names of this order.

The antiquity of this manuscript has also been the subject of controversy. Grabbe and Schulze think that it might have been written before the end of the fourth century, which, says Michaelis, is the very utmost period that can be allowed, because it contains the epistles of ATHANASIUS. Oudin places it in the tenth century. Wetstein refers it to the fifth, and supposes that it was one of the manuscripts collected at Alexandria in 615, for the Syriac version. Dr. Semler refers it to the seventh century. Montfaucon (Pala
gro. Græc. i. p. 187.) is of opinion, that neither the Cod. Alex. nor any Greek manuscript, can be laid with great probability to be much prior to the fifth century. Michaelis apprehends, that this manuscript was written after Arabic was become the native language of the Egyptians, that is, one, or rather two centuries after Alexandria was taken by the Saracens, which happened in the year 640, because the transcript frequently confounds M and B, which is often done in the Arabic: and he concludes, that it is not more ancient than the eighth century. Woide, after a great display of learning, with which he examines the evidence for the antiquity of the Cod. Alex, concludes, that it was written between the middle and the end of the fourth century. It cannot be allowed a greater antiquity, because it has not only the αγγελα or αναγελα majora, but also the αγγελα minora, or Ammonian sections, accompanied with the references to the canons of Ephesus. Woide's arguments have been objected to by Ephon, in p. 42—119, of his edition of the "Norititia Codicis Alexandrinii." Some of the principal arguments advanced by those who refer this manuscript to the fourth or fifth centuries are the following: the epistles of St. Paul are not divided into chapters like the Gospels, though this division took place fo early as 396, when each chapter was prefixed a supercription. The Cod. Alex. has the epistles of Clement of Rome; but these were forbidden to be read in the churches, by the council of Laodicea, in 362, and that of Carthage, in 419. Hence Schulze has inferred, that it was written before the year 364: and he produces a new argument for its antiquity, deduced from the fact of the 14 hymns found in it after the psalms, which is supercribed τετράγωνον, and is called the grand doxology; for this hymn has not the clause αυτος ο θεος, αυτος ο κυριος, αυτος ο πατερ, αυτος ο ευαγγελιστης, αυτος ο ιησους, which was used between the years 434 and 444: and therefore the manuscript must have been written before this time. Wetstein thinks that it must have been written before the time of Jerome, because the Greek text of this manuscript was altered from the old Italic. He adds, that the transcript was ignorant that the Arabs were called ἠγαρανεας, because he has written, τα Χρον., v, 29, αγγελιαν for αγγελιαν. Others allege that αγγελιαν is a mere erratum: because αγγελιαν occurs in the preceding verse, as γηαλιαν in τα Χρον. xxvii, 51, and Αγγελια in Pf. Lxxvii. 7. These arguments, says Michaelis, afford no certainty, because the Cod. Alex. must have been copied from a still more ancient manuscript; and if this were faithfully copied, the arguments apply rather to this than to the Alexandrian manuscript itself. It is the hand-writing alone, or the formation of the letters, with the want of accents, which can lead to any probable decision. The arguments alleged to prove that it is not so ancient as the fourth century; are such as these. Dr. Semler thinks, the epistle of Athanasius, on the value and excellency of the Psalms, would hardly have been prefixed to them during his life. But it ought to be recollected, that Athanasius had many warm and ardent advocates. From this epistle Oudin has attempted to deduce an argument, that the manuscript was written in the tenth century. This epistle, he says, is spurious, and could not have been forged during the life of Athanasius, and the tenth century was fertile in spurious productions. Again, the Virgin Mary, in the supercription of the Song of the Blessed Virgin, is listed φασιν, a name which Wetstein says was the fifth century. Further, from the probable conjecture, that this manuscript was written by one of the order of the Aegyptians, Oudin concludes against its antiquity; but Wetstein contends himself with affixing, that it could not have been written before the fifth century, because Alexander, who founded this order, lived about the year 420. From this statement, pursued more at large, Michaelis deduces a reason for paying his adoption to the Cod. Alex. than very eminent critics have done, and for the preference that is due, in many respects to ancient versions, before any single manuscript, because the antiquity of the former, which is in general greater than that of the latter, can be determined with more precision.

As to the value of this manuscript, it has been differently appreciated by different writers. Wetstein, though he de-notes it by A, the first letter of the alphabet, is so great admirer of it, nor does Michaelis estimate it highly, either on account of its internal excellence or the value of its readings. The principal charge which has been produced against the Alexandrian manuscript, and which has been strongly urged by Wetstein, is its having been altered from the Latin version. It is incredible, says Michaelis, who once agreed in opinion with Wetstein, but found occasion to alter his sentiments, that a transcript who lived in Egypt, should have altered the Greek text from a Latin version, because Egypt belonged to the Greek diocese, and Latin was not understood there. On this subject Weide has eminently displayed his critical abilities, and ably defended the Greek manuscripts in general, and the Codex Alexandrinus in particular, from the charge of having been corrupted from the Latin. Griesbach concurs with Weide, in his "Symbolae Criticae," vol. i. p. 119—17; and both have contributed to confirm Michaelis in his new opinion. If this manuscript has been corrupted from a version, it is more reasonable to suppose the Coptic, the version of the country, in which it was written. Between this manuscript, and both the Coptic and Syriac versions, there is a remarkable coincidence: Griesbach has observed, that this manuscript follows three different editions: the Byzantine in the Gospels, where its readings are of the least value; the Western edition in the Acts of the Apostles, and the Catholic Epistles, which form the middle division of this manuscript; and the Alexandrine in the Epistles of St. Paul. The transcript, if this assertion be true, must have copied the three parts of the Greek Testament from three different manuscripts, of three different editions. It is observable, that the readings of the Cod. Alex. coincide very frequently, not only with the Coptic and the old Syriac, but with the new Syriac and the Ethiopic; and this circumstance favours the hypothesis, that this manuscript was written in Egypt, because the new Syriac version having been collated with Egyptian manuscripts of the Greek Testament, and the Ethiopic version being taken immediately from them, have necessarily the readings of the Alexandrine edition.

This manuscript, as we have already observed, consists of four volumes: the third fifth of which contain the Old Testament, the fourth the New Testament, together with the first
A. L. F. A L E

first Epistle of Clement to the Corinthians, and a fragment of the second. In the New Testament there is wanting the beginning as far as Matt. xxv. 6. 9. 13, 14, 15; 15, 1. 2 (in the Vulgate from Joh. vii. 50, to viii. 52, and from 2 Cor. iv. 1. to xii. 7). The Psalms are preceded by the epistle of Athanasius to Marcellinus, and followed by a catalogue, containing those which are to be used in prayer for each day, both of the day and of the night; also by 14 hymns, partly apocryphal, partly biblical, the eleventh of which is an hymn in praise of the Virgin Mary, entitled ΠΡΩΤΟΝ ΜΑΡΤΥΡΙΟΝ ΣΩΤΗΡΟΝ: the hypotheses of Eusebi are annexed to the Psalms, and his ex.-

cesses to the Gospels. This manuscript has neither accounts nor marks of acription; it is written with capital, or as they are called, uncial letters; and there are no intervals between the words, but the face of a passage is sometimes terminated by a point, and sometimes by a vacant space. Although abbreviations are not very numerous, yet this manuscript abbreviates ἀπαθήραημα, ἀπαθήραημα, ἀπαθήραημα, ἀπαθήραημα, ἀπαθήραημα, ἀπαθήραημα; and it has also other marks of abbreviation. Dr. Sandel supposes, that the more ancient manuscripts from which this Cod. Alex. was copied, had a much greater number; from a false method of deciphering which marks, he explains many errors committed by the copyist of the latter. See his Note 53 to Wetstein's Prolegomena. Of these abbreviations, and the points annexed to certain letters, which before appeared unintelligible; and of the large initial letters, which are sometimes placed in a very extraordinary manner; and of other particulars, a full account may be seen in Woide's Preface, who has given a very accurate description of the manuscript in general. No manuscript has been more frequently and more accurately collated; and it was supposed, that the last extracts, made by Wetstein, would have rendered future labours of this kind superfluous; but Woide informs us, that Wetstein is chargeable with several omissions and errors, and has admitted into his collection of readings the mistakes of Mill. We are now in possession of a perfect impression of this manuscript, accompanied with so complete and so critical a collection of various readings, as is hardly to be expected from the edition of any other manuscript. Dr. Woide published it in 1786, with types cast for the purpose, line for line, without intervals between the words, as in the manuscript itself; the copy is so perfect a refurnance of the original, that it may supply its place; its title is "Novum Testamentum Graecum Codex MS. Alexandrinus qui Londini in Bibliotheca Musei Britannae effervatur descripturn." It is a very splendid folio, and the produce of the learned editor contains an accurate description of the manuscript, with an exact list of all its various readings, that takes up not less than 80 pages, and each reading is accompanied with a remark, in which is given an account of what his predecessors, Judins, Walton, Full, Mill, Grabbe, and Wetstein, had performed or neglected. Those who are dubious of further information concerning this manuscript, may consult the Prolegomena of Mill, Grabbe, Wetstein, and Woide. See also Michaelis's Introduction to the New Testament, by Marth, vol. ii. part i. p. 186—202. part ii. p. 648—660.

Alexandrian Library, called by Livingston "Elegantiae regum curnque egregium opus," was first founded by Pottery Soter, for the use of the Academy, or Society of learned men, which he had founded at Alexandria. Befide the books which he procured, his son Pottery Philadæus added many more, and left in this library at his death a hundred thousand volumes; and the succeeding princes of this race enlarged it still more, till at length the books lodged in it amounted to the number of seven hundred thousand volumes. The method by which they are said to have collected these books was this: they hired all the books that were brought by the Greeks, or other foreigners, into Egypt, and sent them to the Academy, or Museum, where they were transferred by persons employed for that purpose. The transcripts were then delivered to the proprietors, and the originals laid up in the library. Pottery Euergetes, for instance, borrowed of the Athenians the works of Sophocles, Euripides, and Aëschylus, and only returned them the copies, which he caused to be transferred in so beautiful a manner as possible; the originals he retained for his own library, presenting the Athenians with 15 talents for the exchange, that is, with three thousand pounds sterling and upwards. As the Museum was at first in the quarter of the city called Bruchion, the library was placed there; but when the number of books amounted to four hundred thousand volumes, another library, within the Scrapeum, was erected by way of supplementation to it, and on that account called the daughter of the former. The books lodged in this increase to the number of three hundred thousand volumes; and these two made up the number of seven hundred thousand volumes, of which the royal libraries of the Ptolemies were said to consist. In the war which Julius Cæsar waged with the inhabitants of Alexandria, the library of Bruchion was accidentally, but unfortunately, burnt. But the library in Scapeum still remained, and there Cæsar deposited the two hundred thousand volumes of the Pergamene library, with which he was presented by Marc Antony. These, and others added to them from time to time, rendered the new library of Alexandria more numerous and considerable than the former; and though it was plundered more than once during the revolutions which happened in the Roman empire, yet it was as frequently supplied with the fame number of books, and continued for many ages to be of great fame and use, till it was burnt by the Saracens in the 642d year of the Christian era. Abulpharagius, in his history of the 16th dynasty, gives the following account of this catastrophe. John Philoponus, furred the Grammarm, a famous Papyrus, who being at Alexandria when the city was taken by the Saracens, was admitted to familiar intercourse with Ammon, the Arabian general, and permitted to solicit a gut, inquillable in his opinion, but contemptible in that of the barbarians; and this was the royal library. Ammon was inclined to gratify his wish, but his rigid integrity seemed to align the lead object without the content of the Caliph. He accordingly wrote to Omar, whose well known answer was dictated by the ignorance of a fanatic. If the writings of the Greeks agree with the Koran, or book of God, they are useless, and need not be preserved; if they disagree, they are pernicious, and ought to be destroyed." The sentence of destruction was executed with blind obedience: the volumes of paper or parchment were distributed to the four thousand baths of the city; and such was their number, that six months were barely sufficient for the consumption of this precious fuel. Since the dynasties of Abulpharagius have been given to the world in a Latin version, this tale, as Mr. Gibbon (Hist. vol. ix. p. 440) calls it, has been repeatedly transferred; and every scholar, with pious indignation, has deplored the irreparable waste of the learning, the arts, and the genius of antiquity. "For my own part," says this historian, adopting the scepticism of Renaudot (Hist. Alex. Patriarch, p. 176), "I am strongly tempted to deny both the fact and the consequences; the fact is indeed marvellous." "Read and wonder!" says the Historian himself; and the solitary report of a stranger who wrote at the end of six hundred years in the confines of Medina, is overbalanced by the silence of two annals of a more early date, both Christians, both natives of Egypt, and the most
Alexandrian, or Alexandrian, in Poetry, the name of a kind of verse, which consists of twelve, or of twelve and thirteen syllables, alternately; the rel. or pauoe, being always on the fifth syllable.

It is said to have taken its name from a poem on the life of Alexander, entitled, the Alexandriad; written, or at least translated into this kind of verse by some French poets; though others will have it to be divided from one of the translators, Alexander Paris.

This verse is thought by some very proper in the epopea, and the more sublime kinds of poetry; for which reason it is also called Heroic Verse.

It answers in our language to the hexameters in the Greek and Latin; though, according to some, it rather answers to the pæroni of the ancient tragic poets. — Chapman's translation of Homer consists wholly of Alexandrians.

The advantages of the Alexandrian verse, are its keeping the rhymes from coming too near, and consequently hindering them from being too much perceived. To this may be added, that coming nearer to the nature of prose, it is fitter for the dialogical, and supplies the office of the ancient spondees, or the end of any rhyme.

ALEXANDRINUS, Julius, in Biography, born at Trent, in the early part of the 16th century, was physician to the emperor Charles V., and afterwards to Maximilian II. by whom he was highly esteemed. He also acquired reputation as a poet, particularly for his Psedotrphia, a poem published at Zurich, 1524, 8vo.

His medical works, which are numerous, and principally compiled from the ancients, or written in defence of the doctrine of Galen, are of little value. For their titles see Eloy's Dictionnaire Historique de la Medicine. He died at Trent, in the year 1593, aged 84 years, and was honoured with the following epitaph:

Cæsaribus & quis multos inferi vivos
Accepit magnis principibus suis
Te, Julii, vatem postum medicumque, & fater
Doctrina in cujus gratia tanta fuit.

ALEXANDROV, in Geography, a town of Kuban Tatarry, in the Russian government of Causcasus, 16 leagues west-north-west of Ekaterinograd.

ALEXANDROVSKAIA, a fortress of Russia in the government of Kazanofl, 16 leagues north-east of Chernon. N. lat. 55° 35'. E. long. 38° 44'. This is also the name of another fortress in the same government, 28 leagues north-west of Chernon.

ALEXICACUS, compound, of aLEX, I drive away, and éx, evil, is something that preserves the body from harm or mischief, and alexicacus amounts to much the same with alexiterial.

ALEXICACUS, in Antiquity, was an attribute of Neptune, whom the tunny fishers used to invoke under this appellation, that their nets might be preserved from the Ægis, or sword-fish, which used to tear them, and prevent the abundance which it was pretended the dolphins used to give the tunnies on this occasion. It was also an epithet of Hercules, as the defender of men.

ALEXINTA, in Geography, a town of European Turkey in Servia, six leagues north north-east of Nîfîa.

ALEXIPHARMIC, in Medicine, expresses that property which a remedy, either simple or compound, hath to refit or destroy every thing of a poisonous or malignant nature. The word is derived from aLEX, driver, ÆXOL, and ÆXON, poison.

The ancients had a notion, that there was poison in all malignant diseases, and in the generality of those whose cause was unknown. Whence alexipharmic became a denomination for all remedies and antidotes against malignant diseases, and for amulets.

The study of poisons and antidotes appeared at an early period among the physicians of Greece and Rome, and continued as long as the Greek physis lasted; and hence has arisen the number of antidotes and theriacs so frequently mentioned by those ancient writers. But their compositions for the correction of poisons were equally injurious and unfruitful. Modern physicians, and particularly the Galenists, adopting the ideas of the ancients, have transferred them from the cafe of poisons taken into the body, to that of noxious powers arising from contagion, or in any other way. The cure of the diseases proceeding from thief, they have, therefore, attempted by the correction or expulsion of the morbid matter, and they have administered medicines for this purpose, under the titles of alexipharmics and alexiterials.

Alexiterial, cardiac, antidote, alexipharmic, and counter-
ALEXIS, Michaelowitz, or Mikhailovitch, in Biography, and History, czar of Russia, succeeded his father Michael Theodorovitch in 1649, at the age of 15 years. He was immediately crowned by the direction of Morosoff, who became his prime minister, and engrossed to himself the whole power of government. In order the more effectually to secure his influence with the czar, he married him to one of the daughters of a nobleman of small fortune, attached to his interest, and took the filler for his own wife. Although Morosoff was in some respects an useful minister, by his attention to the army, by strengthening the frontiers against Poland and Sweden, and by erecting manufacturies for arms, none of these services were sufficient to compensate the oppression which the people suffered under his administration. These grievances at length, viz. in 1648, produced an insurrection at Moscow, and the people demanded justice against Morosoff and his confederates.

Two of their principal oppressors were put to death, and the minder escaped merely by the intercession of the czar himself. About this time appeared an impostor, the son of a linen draper of Wologda, who under various pretences laid claim to the throne. Neither the Swedes nor the Poles, whom he endeavoured to interest in his cause, afforded him any support; and after a short course of extravagance and profligacy, he fell into the hands of the Russians, who, after in vain attempting to obtain from him a confession by torture, put him to a cruel death. When these tumults were appeased, Alexis assumed the government, and exhibited promising tokens of capacity and vigour. Having settled a dispute between Russia and Sweden by an embassy to queen Christina, he directed his attention to Poland, and offered to employ his army in subduing the Cossacks, on condition of their conferring upon him the vacant crown. But the interest of France prevailing in favour of Catharina, the brother of Ulitchan their late king, Alexis declared war against the Poles, and assisted by the Cossacks, succeeded in recovering Smolenskow, Wilna, Kiow, and the province of Czernichow, which had been ceded to the Russians by the late peace. Poland being at this time, viz. in 1656, invaded by Gustavus king of Sweden, with a formidable army, Alexis made a truce with that kingdom; and as the Swedes had appropriated to themselves the duchy of Lithuania, which the czar looked upon as his conquest, he marched his army into Carelia, Ingrid, and Livonia. At length, however, he thought it advisable, in 1658, to conclude a three years truce with Sweden; which, in 1661, was confirmed into a peace by the treaty of Cardis. By this treaty it was agreed, that, disregarding all that had passed between the two powers, every thing should remain as it had been settled by the treaty of peace made at Stolbova in 1617. The war of Alexis with Poland terminated more honourably for Russia. An armilice for 13 years, agreed upon at Andruftow in Lithuania, was the forerunner of a complete pacification, which was effected in 1686, and which restored to the empire Smolentko, Sevria, Czernichow, and Kiow. The king of Poland likewise relinquished the supremacy he had hitherto affected over the Cossacks to the czar; and these people became now a protected relative of the Russian empire. Notwithstanding this favourable issue of the czar’s contest with the Poles, a formidable domestic rebellion obstructed the operations of the plans which he was pursuing for the good of his country. This was occasioned, in 1669, by Steenko (Stephen) Radzin, whose brother had been hanged by order of Dolgorouchi, the Russian commander; and as he had thus infringed upon the liberty of the Cossacks, they made this a pretence for arming against their sovereign, though there is reason to believe that ambition was the ruling principle of Radzin. Whatever was the motive, a civil war was the consequence, which was carried on with various successes, and equal cruelty on both sides. Radzin gained possession of Altcharach, and being joined by a multitude of peasants, who murdered their lords, his army at one time amounted to 200,000 men. This rebellion was not suppressed till the year 1671, when Radzin was betrayed into the hands of the czar, and executed. The affairs of Poland, and the measures which Alexis had taken for making himself protector of the Cossacks, produced a misunderstanding between the Grand Scignior and the czar, which terminated in actual hostilities. Alexis endeavoured to engage all the Christian potentates in his dispute, and to form a league against the Turks; and with this view he sent ambassadors to several of them, and one to Rome, who refused
refused to degrade himself by killing the pope's toe. He returned with fair promises, and no other succour. Alexis joined with the Poles, and the Turkish conquests were stopped by the great commander Sobiecki. At the vacancy of the crown of Poland, he proposed his son for king, and to unite that kingdom with his own; but the electors preferred Sobiecki. Jealousies arose in the progress of the war with the Turks between Russia and Poland, and they terminated in the conquest of the whole Ukraine by the Poles. Alexis did not live to see the end of this war; for his death happened in 1676, at the early age of 46; and it is supposed that he fell a victim to the empirical remedies of an old Polish woman, in whom he repose greater confidence than in his physicians. Alexis had claims of various kinds on the esteem and gratitude of his country. He not only restored, by his successful wars with Poland, the provinces that had been wrested from the empire, and laid a foundation for a sovereignty over the Cossacks, but he was equally attentive to the internal improvement of the country. He caned an epitome of several sciences he translated into the Russian language, and took pleasure in perusing it; he collected the laws of the various provinces of his empire into one body, and by the advice of the nobility, clergy, and burghers, made laudable attempts in legislation; he introduced several new manufactures, particularly those of silk and linen, and encouraged the trade of the country; he added two suburbs to Moscow, and built several market towns, which he peopled with Poles and Lithuanians: he brought several large deferts into a state of culture and population, by letting in the prisoners taken in war: he formed a design, executed by his son Peter, of maintaining fleets in the Caspian and Euxine seas, and of making the Russians acquainted with the art of constructing ships, and with maritime commerce: he received ambassadors from Persia, China, and Asia; and was the first emperor who maintained a close correspondence with the principal European powers. The mildness of his government allured Germans, Dutch, Italians, and about 3000 Scotchmen into Russia. By augmenting the power of the crown he prepared for the general improvement of a country, like Russia, polled by a powerful and barbarous Inquisition. He instituted a private chamber for the trial of offences against himself, and though he proceeded cautiously in his examination, he executed justice with rigour on the guilty, and generally in a private manner. With small revenues, he nevertheless contrived, by economy and prudence, to maintain a large army and a magnificent court, and left his treasury rich. Alexis had formed many useful projects; but death prematurely carried him off in the 47th year of his age. Under him the Russian empire made some progress in civilization; and he traced out a variety of important plans which his son Peter the Great improved and executed.

Alexis loved his people, and was a father to them; he studied their happiness, and made his government as easy to them as possible. He loved justice and peace; and, though valiant, never made war but when he could not avoid it. He endeavoured, in the progress of his reign, to repair theills which his favourites and ministers had occasioned in his youth, and at the commencement of it, by abating his confidence. Upon the whole, he was one of the greatest princes of his time. By his first wife he had two sons and four daughters; and by his second wife Natalia, the daughter of Narishkin, a captain of hussars, one son, 4½. Peter, who succeeded him, and one daughter. Mod. Un. Hist. vol. xxii. p. 434—492. Tooke's History of Russia, vol. ii. p. 14—38.

ALEXIS, a famous satirist, mentioned by Pliny, N. H. tom. ii. p. 649.

ALEXIS, a Greek comic poet, uncle to Menander, who flourished in the time of Alexander the Great, about 363 years before the Christian Era. Fragments of this poet may be found in "Vetustissimorum Graecorum Bucolica Gymnica," &c. Crispin, 1570, 160.

ALEXIS, William, a benedictine monk, in the abbey of Lyra, was living in 1500, and has left several pieces of poetry, which were esteemed in their time. The principal are "Four Chants-Royaux," 4to. "Le Paffé-temps des d'etout hommes et de fOUSE femmes," Paris, 4to. and 8vo, translated from a work of Innocent III. and describing the miseries of man, from the cradle to the grave. "Le grand blason des feauxj' amour," 16to. and 4to.; a Dialogue on the evils occasioned by love. Brg. Dict.

ALEXIS, a Piedmontese, was born of a noble family, and by his early application acquired the knowledge of the Latin, Greek, Hebrew, Chaldee, Arabic, and other languages. Alexis is supposed to be a feigned name; and the real name of this author, who wrote in the beginning of the 16th century, is apprehended to be Hieronymus Ruffelius; and he is said to have died in 1565. It has been generally asserted, though it be not strictly true, that he was the first person who mentioned Ultramarine. His receipt, however, has been followed since that time as the best and most certain. His work "De Secretis," furnishes materials for the technological history of inventions. It was printed for the first time at Milan, in 1557; though Beckman apprehends that the first edition must have been of an older date. A French translation was printed at Antwerp in 1557. "The Secrets of Alexis," London, 1558, is mentioned by Ames in his "Typographical Antiquities," p. 26. Wecker, a physician at Colmar, translated this book into Latin, and enlarged it with additions, under the title of "De Secretis Libri xvii." The first edition, according to Haller, was printed at Basle, in 1550. 8vo. Many editions of it have since appeared. The last, by Zwingier, was published at Basle in 1573. Alexis, it is said, urged by a curiosity to be acquainted with the secrets of nature, collected as much as he could during his travels for 57 years, and valued himself on concealing them; but when he was 87 years of age, he saw a poor man, whose disorder proved fatal, because he had not discovered an eff. that remedy, of which he was possessed; upon which his confidence was troubled him, that he became a hermit; and in his solitary retirement, arranged his secrets in an order fit for publication. Gen. Dict. Beckman's Hist. Inventions, vol. ii. p. 351.

ALEXIS, in Entomology, a species of Papilio Plebejas, with eucrated brown wings, and a carniolick band under the posterior; found in India.

ALETERTERIAL in Medicine, a term of the same import with alexipharmic; but chiefly applied to the milk-water of that name, and remedies against the poisonous bites of animals.

But it is said by some authors that alexiterialls differ from alexipharmics; thus, alexipharmics signify medicines against poisons taken internally; whereas alexiterialls are remedies against the poisons of venomous animals inflicted externally.

ALEXIUS I. Comnenus, in Biograph and History, emperor of the East, was the son of John Comnenus, the brother of the emperor Isaac, and born at Constantinople, A. D. 1048. He was endowed by nature with the choicest gifts both of mind and body; these were cultivated by a liberal education, and exercised in the school of obedience and
and adversity. Alexius, and Isaac, his elder brother, distin-
guished themselves in the war against the Turks, and adhered
to the emperor Michael Ducas, till he exchanged the empire
for a monastic habit and the title of archbishop of Ephesus.
On this occasion Alexius offered his services to Nicephorus
Botaniates, the successor of Michael, and with a noble
frankness addressed him: “Prince, my duty rendered me
your enemy; the decrees of God and the people have made
me your subject. Judge of my future loyalty by my past
opposition.” His fidelity and valor, as well as his humanity,
were sufficiently evinced by his victorious exploits against
the three rebels, Urol, Brysiunius, and Basilicus, who dis-
turbed the peace of the empire. But his refusal to march
against the fourth rebel, the husband of his sister, cancelled
the merit and the memory of his past services; and the two
brothers, driven into rebellion, and supported by the army,
succeeded in deposing Botaniates. Isaac, though the elder
brother, was the first to invest Alexius with the name and
enigma of royalty; and being placed emperor by the army,
he marched immediately against Constatinople, which he
took and plundered; and the fleet was induced by the in-
fluence of George Paleologus, to declare in his favour.
Botaniates resigned the empire, and Alexius, without further
contest, ascended the throne, A.D. 1081. Having com-
plimented for the plunder of the churches and monasteries at
Constatinople, by every penance compatible with the pur-
fession of the empire, he prepared for reconquering the con-
quists of the Turks, who had fixed on several provinces,
and threatened to subvert the empire. The Turks, however,
made overtures of peace, which were accepted by Alexius,
in consequence of the promises that were meditated against
him in the west by Robert Guiscard, duke of Puglia and
Calabria. Robert, having landed at Bathurum, in Epirus,
and having advanced to Dyrachium or Durazzo, which was
defended by a garrison under the command of George Pa-
leonogus, was there met by Alexius with a large army. In
a general action, which he commenced against the advice of
his wife, Matilda, Oct. 18, A.D. 1081, he sustained a
defeat, which was attended with great loss, and followed by
the surrender of Durazzo, Feb. 8, A.D. 1082. Alexius
was affllicted in raising new levies, and in order to obtain
necessary supplies, he professed, in a manner very offensive
to the ecclesiastics, to borrow the superfluous ornaments of
the churches. He also formed an alliance with Henry, em-
peror of Germany, who invaded Calabria, and whose pro-
gress demanded the hasty return of Robert. Bohemond,
the son of Robert, was appointed his lieutenant in the east;
but after several places in Illyria, he was con-
strained by a mutiny in the army, to repair to his father in
Italy. In October, A.D. 1084, Robert resumed the design
of his earlier conquests, and made a second expedition into
Greece. Alexius, apprehending an attack, had obtained
a very considerable succour to his naval forces from the re-
cpublic of Venice. By the union of the Greeks and Venet-
ians, the Adriatic was covered with an hostile fleet; but
by the vigilance of Robert and the concurrence of favourable
circumstances, the Norman troops were safely disembarked
on the coast of Epirus. The dominion of the sea was dis-
puted in three engagements in flight of the island of Corfu;
in the two former, the skill and numbers of the allies were
superior; but in the third, the Normans obtained a final and
complete victory. On this occasion, Anna Comnenus, the
daughter of Alexius, and the mother of his life, deplores
the loss of 13,000 of his subjects or allies. But in the isle of
Cephalonia, the projects of Robert were fatally blased by
an epidemic disease; and he himself, in the 70th year of
his age, expired in his tent; not without the suspicion of
poison, which public rumour imputed to his wife, or to the
Greek emperor Alexius, who had trembled for his empire,
and now rejoiced in his deliverance. The Normans withdrew
their forces from Greece, and tranquillity was restored. This
war was succeeded by another with the Slavonians, who
passing the Danube, laid waste a great part of Thrace, and
were guilty of many horrid outrages. The generals of
Alexius, of whom several were first employed in opposing them,
sustained several defeats; but they were at length completely
subdued, with a very general slaughter, by the emperor
himself. His next attention was engaged by the Turks, and
again by the Serbians; but Alexius having terminated his
contests with both these enemies by a peace, returned to
Constatinople; where he was informed, that the Western
Christians were making great preparations for the recovery
of the Holy Land, at that time possessed by the Turks and
Saracens. At the council of Placentia, held March A.D.
1095, the ambassadors of Alexius appeared to plead the
diftresses of their sovereign, and the danger of Constatinople,
which was divided only by a narrow sea from the victorious
Turks, the common enemies of the Christian name; and
the relief of Constatinople, was included in the larger and
more dilatant project of the deliverance of Jerusalem. The
emperor's ambassadors had solicited a moderate succour, per-
haps of 30,000 foot and 5000 horse, whereas the Crusaders arrived,
A.D. 1096, he was astonished by their number, and fluctu-
bated between hope and fear, between timidity and courage.
His conduct was irresolute and ambiguous, and he has been
charged by the Latin writers, with the base treachery.
His gifts and promises, however, infamously fothred the fire
of the Western crusaders; and as a Christian warrior,
he rekindled their zeal for the protection of their holy
temple, which he engaged to second with his troops and
treasures. By his skill and diligence, Alexius prevented the
union of any two confederate armies, at the same moment;
under the walls of Constatinople; and he contented himself,
either from pride or prudence, with extorting from the
French princes an oath of honour and fidelity, and a solemn
promise, that they would either reforre, or hold, their Asiatie
conquests, as the humble and loyal vassals of the Roman
empire. Nice was the first object of attack on the part of
Alexius, after which the means of conquest were supplied by
the prudence and industry of Alexius; he guarded with
jealous vigilance this important conquest, and the city was
delivered up to his lieutenant. When the crusaders after-
wards took possession of Antioch, they elected Bohemond
prince of that metropolis, alleging that Alexius had viol-
ated his agreement, and under various pretences, declined
affording them the least assistance. The consequence of this
appointment was a war between Bohemond and Alexius,
who fitted out a powerful fleet, which obtained a complete
victory over that of the Crusaders, near Rhodes. He also
retook Laodicea, which Bohemond had appropriated to him-
self as prince of Antioch. Alexius, by his endeavours to drop
the progrcss of the Christian princes in the East, incensed
the pope and the people to such a degree, that they con-
sidered him as an enemy to the Christian name, and supplied
Bohemond with large succours to oppose him. Bohemond,
thus aided, laid siege to Durazzo; but the place held out
till the war was concluded by a negotiation. Alexius, dif-
engaged from this contest, marched in person against the
Turks, who renewed their incursions as far as Nice, and
defeated them with great slaughter. They returned, however,
the next year, and being dispirited by successive defeats, they
sued for peace and obtained it. The remaining part of the
life of Alexius was devoted to the purpose of healing the
divisions, which at that time rent the Greek church. After
a long
A long reign of 37 years. Alexius died, A.D. 1118, and was succeeded in the empire by his son John Comnenus.

Of the character of this emperor the Greek and Latin writers have given a very different account. In the biography of his daughter, the celebrated Anna Comnena, it is lost in a vague constellation of virtues, and the perpetual strain of panegyric and apology awakens our jealousy to question the veracity of the historian and the merit of the hero. On the other hand, the Latin writers, who have written the history of the holy war, represent him as a monster of perfidy. The circumstances of the times in which he lived, whilst they afford a display of his political wisdom and military valour, furnish some apology for the diffamation and artifice to which he occasionally resorted. To his relations and friends he was grateful and liberal; and to his enemies tolerant and forgiving. At the head of his armies he was bold in action, skilful in stratagem, patient of fatigue, ready to improve his advantages, and capable of rising from his defeats with in-exhaustible vigour. The discipline of the army was revived, and a new generation of men and folders was created by the example and precepts of their leader. In his intercourse with the Latins, he was patient and artful; and he contrived with superior policy to balance the interests and passions of the champions of the first Crusade. In a long reign of 37 years, he subdued and parceled the envy of his equals; the laws of public and private order were reformed; the arts of wealth and science were cultivated; the limits of the empire in Europe and Asia were enlarged; and the Comnenian sceptre was transmitted to his children of the third and fourth generation. Yet the difficulties of the times betrayed some defects in his character; and have exposed his memory to some just or ungenerous reproach. His happiness was interrupted, and his health was impaired by public cares; the patience of Constan-tinople was fatigued by the length and severity of his reign; and before he expired, he had lost the love and reverence of his subjects. Although he had applied the riches of the church to the service of the state, and thus incurred the displeasure of the clergy; yet they applauded his theological learning and ardent zeal for the orthodox faith, which he defended with his tongue, his pen, and his sword. His character was degraded by the super-fition of the Greeks; and whilst he founded a hospital for the poor and infirm, he ordered the execution of an heretic, who was burnt alive in the square of St. Sophia. The incivility of his moral and religious virtues was suspected by his intimate associates. In his later hours, when he was befriended by his wife Irene to alter the succession, he rivalled his head, and breathed a pious ejaculation on the vanity of the world. The ignominious reply of the empress, says a popular historian, may be inscribed as an epitaph upon his tomb: "You die, as you have lived—an hypocrite." Anc. Un. Hist. vol. xvi. p. 136—141, Gibbon's Hist. vol. i. p. 83, &c. vol. x. p. 294, vol. xi. p. 45, &c.

Alexius II. succeeded his father Manuel, as emperor of the East, in 1180, at the age of 12 years. His mother Maria, a princess of Antioch, assumed the government during the minority of her son, and his education was neglected, that he might retain her absolute authority. During this period, Andronicus, who had long aspired to the empire, attempted to attain the object of his ambition. Having, notwithstanding the profligacy of his character, gained a considerable degree of popularity, he was declared protector of the empire during the minority of Alexius; and when he had caused the young prince to be solemnly crowned, he contrived to be elected his colleague in the empire. Notwithstanding a solemn oath, that he accepted the dignity merely for the purpose of protecting the young emperor and supporting his authority, he soon caused him to be murdered; and arranging him with a bow-string, terminated his life in the third year of his reign, and 15th of his age. Anc. Un. Hist. vol. x. p. 137—140.

Alexius III. Angelus, obtained the empire of the East, A.D. 1195, by the exclusion of his brother Isaac Angelus, whom he threw into prison and deprived of sight. Indolent and devoted to pleasure, he committed the conduct of public affairs to his wife Euphrosyne, who oppressed the people, and sold the chief offices of state to the highest bidder. In 1202 he released his brother Isaac, and called his son Alexius, who was then about 12 years of age, to the court, and treated him as his child. But the young prince, aided by his sister Irene, wife to Philip, emperor of Germany, elapsed from Constantinople, and landed safe in Sicily. Philip, by means of his ambassadors, engaged the French and Venetians in his support. A treaty for this purpose having been concluded between them and Alexius, the army of these united powers embarked for Corfu, which was the place of rendezvous; and proceeded to Constantinople. Upon their approach the usurper escaped; and in 1203 the young prince was associated with his father Isaac in the empire, and crowned with extraordinary pomp and solemnity. The usurper, who had fled to Zara, a city of Thrace, at the foot of mount Hæmus, after various adventures, fell into the hands of his son-in-law, Theodore Lascaris, against whom he had inflicted the Turks, who put out his eyes, and shut him up in a prison at Nice, in Aia, where he died some years after. Anc. Un. Hist. vol. xvi. p. 164—166—173. Gibbon's Hist. vol. i. p. 165, &c.

Alexius IV., the son of Isaac Angelus, was crowned associate with his father in the empire in 1205. The price of his rescue and advancement to the throne involved him in difficulties that were insuperable. This was no less than the submision of the Eaftero empire to the pope, the succour of the Holy Land, and a contribution, as soon as he was invested with the crown, of 200 thousand marks of silver. After his ascension to the throne, he prevailed on the Marquis of Montferrat, at the price of 1000 pounds of gold, to lead him with an army round the provinces of Europe; but upon his return, as his father was destitute of account on his infinites, he was hated as an apologist, who had renounced the manners and religion of his country. His secret covenant with the Latins was divulged or suspected. The people, and especially the clergy, were devoutly attached to their faith and superition; and every convent, and every chapel, refounded with the danger of the church, and the tyranny of the pope. Whilom complaints were muttered against the emperor and his government, and quarrels were fomented between the Greeks and Latins, Constantinople was visited with a calamity which might be justly imputed to the zeal and indiscipline of the Flemish pilgrims. A conflagration spread, during eight days and nights, above a league in front, from the harbour to the Propontis, over the most populous regions of the city. By this outrage the name of the Latins became still more unpopular. Upon the return of Alexius, his youthful mind hesitated between gratitude and patriotism, between the fear of his subjects and that of his allies. By his feeble and fluctuating conduct, he lost the esteem and confidence of both; and whilst he invited the Marquis of Montferrat to occupy the palace, he suffered the nobles to confiscate, and the people to arm, for the deliverance of their country. The Latins, regardless of his critical situation, repeated and enforced their demands, and reminded the emperor, with menace and intimation, of his own
own engagements and of their services. The threats of the Latins concurred with the dissatisfaction of the Greeks in exciting a tumult among the people; of which a prince of the house of Ducas, surnamed Mourtoule, perfidiously availed himself to cause a vacancy of the throne. Alexius, hurried by the arts of this false friend into a prison, was feized, stripped, and loaded with chains; and, after tasting some days the bitterness of death, he was poisoned, or strangled, or beaten with clubs. A. D. 1204. The emperor Theophilus soon followed him to the grave; if, indeed, he survived his death. Anc. Hist. vol. xv. p. 102. Gibbon's Hist. vol. xi. p. 225.

ALEXIS V. DUCAS, surnamed Mourtoule, on account of the close junction of his black and bugzy eyes-brows, was, according to Ducas, second cousin of young Alexius, whom he betrayed and detroned, and succeeded to the empire on his death. The people having advanced him to the throne, he found it necessary to prepare for the defence of the metropolis of the empire. The princes of the Crusade renewed their claims, and pitying the fate of Alexius, the late emperor, to which, indeed, they themselves had contributed, resolved to revenge his death. Accordingly they mulled all their forces in Aia, crossed the Straits, and closely besieged the Imperial city, both by sea and land. Mourtoule, who was a man of warlike valour and experience, made a vigorous defence; but in a nocturnal assault, he was overpowered; the city was taken and plundered, and the capture of it was attended with a dreadful slaughter. The emperor made his escape in the night with Euphrodyne, the wife of the late usurper Alexius Angelus, and his daughter Eudokia, for whose sake he had abandoned his lawful wife. This happened, A. D. 1204. Mourtoule fought an asylum in the camp of his father Alexius, in Thrace, and was at first received with smiles and honours; but as the wicked can never love, and should rarely trust, their fellow-criminals, he was seized in the bath, deprived of his eyes, stripped of his troops and treasures, and turned out to wander an object of horror and contempt to those who with more propriety could hate, and with more justice could punish, the affidavit of the emperor Isaac and his son. As he was privately passing over into Aia, he was seized by the Latinus of Constantinople, and condemned, after an open trial, for the murder of young Alexius, to an ignominious death. His judges, having debated the mode of his execution, resolved, that he should ascend the Theodorian column, a pillar of white marble, 117 feet high, and be cast down headlong from its summit, and dashed in pieces on the pavement, in the presence of a great multitude of spectators. Anc. Hist. vol. xv. p. 169. Gibbon's Hist. vol. xi. p. 225. 252, &c.

ALEYN, CHARLES, an elegant historical poet, in the reign of king Charles I., was educated at Sidney college, Cambridge, and afterwards settled as usher in a grammar school in London. In 1631 he published two poems, entitled, "The Battles of Crefy and Poictiers, under the fortunes and valour of king Edward, third of that name, and his sonne Edward, prince of Wales, named the Black." Having left the school in which he was usher, he was domestic tutor to the son of sir Edward Sherburn, afterwards clerk of the ordnancy and commissary general of the artillery to king Charles, at the battle of Edgcum. In this situation he wrote another elaborate poem, in honour of king Henry VII., and that important battle which gained him the crown of England. This poem was published in 1638, and entitled, "The Historie of that wise and fortunate prince Henrie, of that name the seventh, king of England; with that famed battle, fought between the said king Henrie and Richard III., named crook-back, upon Redmore, near B. worth." He died about the year 1642; before which time he published a translation, "The History of Eurialus and Lucietia," from a flavy found among the Latin epistles of Arnobius Sylvius. Biog. Brit.

ALEZONNE, in Geography. See Alesonne.

ALFABUCELIS, in Ancient Geography, a place of Italy, assigned by Ptolemy to the Marit.

ALFACAR, in Geography, a town of Spain, five miles north-west of Grenada.

ALFANDEGA DA FE, a small district of Portugal, in the province of Tras-oz Montes, containing 15 parishes.

ALFANDEGA, the name of the custom-house at Lisbon.

ALFAQUES, among the Spanish Moriscoes, were the clergy, or those who instructed them in the Mahometan faith. The alfaques differed from the Morabites, who answered to monks, or religious among Christians.

ALFAQUES, or ALFAQES, in Geography, a sea-port town of Spain, in the province of Catalonia, on the coast of the Mediterranean, sittuate on an island of the same name at the mouth of the Ebro, three leagues south of Tortosa.

ALFAQUES, a town of Africa, in the kingdom of Tunis.

AL-FARABI, or ABU NASR, in Biography, a native of Balkh Farab, a town of Afia Minor, called by the Turks Oterar, was a celebrated philosopher of the school of Bagdad, and flourished in the 10th century. His parents were opulent, but he preferred the study of philosophy to the acquisition or possession of affluence. He studied mathematics and medicine, but chiefly excelled in logic. Such were his talents and learning, that great men and princes were emulous to confer upon him honours and emoluments. But Al-Farabi declined every offer of this kind, and preferred, either through his love of philosophy or from a natural gloominess of temper, solitude, and an abstemious life. During winter, he constantly slept on straw, his countenance was always sorrowful, and he found consolation in nothing but philosophy. Lamenting the imperfection and vanity of human life, and deirding intercourse with the world as destructive of innocence, he employed his time in study, and devoted his whole attention to the perusal of the writings of Aristotle. He wrote 60 distinct treatises on the Aristotelian philosophy, which were popular and much read among the Arabs, and also among the Jews. Many of his books were translacated from Arabic into Hebrew. The subjects on which he principally treated were logic, metaphysics, and physics. Among his writings on the law of these subjects are mentioned treatises on optics and astronomy. Abulf. Dyn. x. p. 208. Pococke, p. 172. Fabric. Bib. Gr. vol. xiii. p. 265. Brucker's Hist. Philos. vol. ii. p. 239.

ALFARO, in Geography, a town of Spain, in the province of Old Castile, on the south side of the Ebro, and on the borders of Navarre, nine miles north-west of Tudela.

ALFAS, small islands of the Red Sea, over again the west side of Arabia Felix. They are only inhabited occasionally by the Moors, who come thither from other islands for the sake of the pearl fishery. N. lat. 17° 10'. E. long. 45° 44'.

ALFATERNA, in Ancient Geography. See Nocera.

ALFAYATES, in Geography, a town of Portugal, in the province of Beira, sittuate on an eminence, near the confines of Spain, is walled and guarded, but contains only one parish,
ALF

parish, and about 500 inhabitants; distant 150 miles north-

east from Lisbon. N. lat. 40° 45', W. long. 5° 44'.

ALDDOUCJ, a name given by the Moors to a fort of

vermicelli, which they make of flour and water, and which

they are very fond of in their entertainments.

ALFECIA, or ALFETA, in Sardinia, a name given to

the town commonly called ISOLA CORONA.

ALFIZERAO, in Geography, a town of Portugal, in

Sobremont, is a small place lying on the sea, and contains

about 700 inhabitants.

ALELD, a town of Germany, in the circle of Lower

Saxony, and bishops of Hildesheim, situated on the Leine,

30 miles south of Hanover, and 15 south of Hildesheim.

ALELD, a town of Germany, in the circle of the Lower

Rhine, four miles north of Niederau.

ALELDHA, a mountain of Periada, in the province of

Kirman, 12 leagues south of Sirjan.

ALFENUS, Varus, in Geography, a Roman Civilian,

was a native of Cremona, and a disciple of Servius Sulpicius.

He flourished about the year 754, or the first of the

Christian era. Horace mentions him as a person who

had been brought up in the mechanical occupation of a shoe-

maker, of such a nature that he had quitted his humble flation

for a profession in which he had acquired reputation.

"— Alfenus vafer, omnin

Albocto instrumento artis, claueaque taberna,

Sutor erat; fast. operis hic optimus omnin;

Elt epites, que rex fules." Sat. lib. i. lat. iii. v. 130.

"Shuffling Aften, though he lost his awl,

And threw away his left, and shut his flall,

And broke his threads, yet was a cobbler still;

Thus every tradesman, if he hath but skill,

Is wife, and therefore only king."— CREEK.

Ammianus Marcellinus refers to Alfenus, (lib. xxx. c. 4, p. 438, ed. Gronov.) as a person whose authority was held in

high estimation in matters of law. Anius Gallus also, cit-

ing his works, (lib. vi. c. 53) speaks of the author as a dis-

tinguished inquirer into antiquities; "Rerum Antiquarum non in-

curius." He wrote 42 books of Digests, which are mentioned

in the index of the Pandects, and several books of

Collectans. Paulus, the Civilian, made an abridgment of

his works. Some Fay that he was a confil, and an old

Scholastic on Horace says, that he was buried at the public

expense. If this be the case, Alfenus, without enriching

himself by his profession, had acquired an honest reputation,

and exhibits an encouraging example to those who poffes

talents, for rising from a lower sphere of life to eminence by

ALFRED, in Geography, a town of Arabia, 24 leagues

south of Medina.

ALFET, in Ancient Customs, signified a large caldron,

which contained boiling water, in which a person accursed

plunged his hand and arm as far as the elbow by way of trial

or purification.

ALFIDENA, in Geography, a town of Naples, in

the province of Abruzo Citera, 15 miles south-east of Sul-

mona; famous in the war of the Samntes.

ALFONSUS, in Biography. See ALPHONSOI.

ALFORD, Michael, an English Jesuit, was born in

London, in 1567, and entered into the society in 1607.

Having studied theology and philosophy in Spain, and at

Louvain, and having resided some years at Rome, he returned

to England, where he was arrested, but afterwards released.

From that time he remained in England for 30 years as a

missionary from the society. He died at St. Omer's, in 1572,

and left two treatises in ecclesiastical history, viz. "Britain-

nia Illustris," printed at Antwerp, 1641, in 4to.; and "Amma-

ales Ecclesiae Britannorum," printed also at Ant-

werp, by B. Gro. Alford, in Geography, a town of England, in the county of

Lincoln, about six miles from the sea, 23° north of

Bolton, and 142° north of London. It has a market on

Tuesday, and two fairs on Whitsunday and Nov. 8, for

cattle and sheep. It has a spring which contains a purging

falt, and has been recommended in the fevbr, jaundice, and

other glandular obstructions, and also in disorders of the

kidneys and bladder. N. lat. 53° 30'. E. long. 1° 57'.

ALFORD, a township of America, in Berkshire county, in

the Misnehalucts, containing 577 inhabitants, 145 miles west

from Bolton.

ALFORDTOWN, a small town in Moor county,

North Carolina.

ALFRAGAN, Ahmed Ebn Kothier Al Fargani,

or as others call him, Mohammed Ebn Ketir Al For-

gani, in Geography, a celebrated Arabian astronomer,

was born at Fargan, in Sygia, now Samarcand, and flourished

in the beginning of the ninth century, under the Caliphate

of Al-Mamun. "His work, in Arabic, entitled, "The Ele-

ments of Astronomy," consists of 30 chapters or sections,

and is formed upon the principles of T扑komy, whom the

author often cites. Of this work we have a Latin transla-

tion by Johannes Hifpalensis, in the 12th century, printed at

Ferrara, in 1496; and at Nuremberg, in 1557, with a pre-

face by Melanchlon; another by James Chilifman, from the

Hebrew version of James Antolfi, at Frankfort, in 1590, to

which the editor added an ample commentary, in which he

compares the calendars of the Romans, Egyptians, Peri-

ans, Syrians, and Hebrews, and shews the correspondence of

their years; and a third, which is the best, by Golius,

with the Arabic text and valuable notes on the first nine

chapters, printed in 1699, at Amsterdam, in 4to., after the

death of the editor, which he did not live to finish. Mod.

p. 607.

ALFRED, or ALFRED the Great, the glory of our

Saxon monarchs, was the youngest son of Ethelwulf,

king of the West Saxons, and was born at Waunnting,

supposed to be Wantage, in Berkshire, in the year 849.

Ethelwulf, being a man of great piety, sent Alfred to Rome,

when but five years of age, to receive confirmation, some

fay regal union, from the hand of pope Leo X. who, on

performing the sacred rite, fixed him his son, and foretold,

it is said, his future greatness.

His three elder brothers, Ethelbald, Ethelbert, and Ethel-

red, having regularly succeeded to the throne, and died

after short reigns, Alfred assumed the sovereignty, and was

crowned at Winchester, in 871. He had given early and

manifold proofs of courage and ability, though his inclina-

tions are known to have rather disposed him to the calm

pleasures of literature, than the tumult of war. But "he had

time to attend his brother to the grave, ere he found

occasion to fight for the crown to which he had succeeded;

for the Danes had poured innumerable multitudes into the

island; and in that very year eight battles were fought be-

tween them and the Saxons. The strength of the latter was

almost wasted, while that of the former was constantly

reduced, after every loss, by fresh tholes of their countrymen.

At length a bloody engagement took place at Wilton, in

Wiltshire; where, though the king was defeated with some

lofs,
lent, no so great was the dread in which the Danes flourished among the English, that they made a treaty with him, and retired from his dominions into those of the king of Mercia. Soon after, however, they broke their faith; for, meeting on the road to Mercia a body of English horse, advancing in an unprepared manner, as they relied on the late treaty of peace, they flew the greater number of them, and took possession of Exeter. The king presently marched against them with what forces he could collect, and besieged them there. At this juncture Alfred's fleet engaged a numerous enemy's force; and dispersed the raft, which, attempting to gain some of the English ports, were driven on the coasts and wholly lost. The Danes now again sued for peace, and gave hostages; but in 872, having obtained new reinforcements, they entered Wiltshire in such numbers, and so wearied out the Saxons, that the latter could no longer be persuaded to make head against them. Some retreated into Wales; others submitted to the invaders; and Alfred himself found it necessary to be governed by circumstances. He, therefore, assumed a disguise, the most likely to conceal him; not giving up either his hopes or his courage; but waiting for a proper opportunity to recover his throne, and restore to their liberties his sorely oppressed people.

Having properly disguised his family, and settled a mode of communication with his tried and faithful friends, he engaged himself in the service of his own chief, to take the care of his cows. After and other ancient writers relate, as a proof how completely Alfred was disguised, that one day the good woman of the house set a cake before the fire to bake, where the king was busy employed in trimming his bow and arrows; on coming back, and finding it burnt, through neglect of turning it in her absence, which she supposed he would have done, the child him very severely for his inattention; and told him, that though he could not turn the cake, he knew he was ready enough to eat it. We find, however, that Alfred soon left this station; and with his wife and some of his most valued friends, found a safe retreat in the Isle of Athelney (Athelney), in Somersetshire, which was secured by vast morasses around it, and accessible only by one very obscure passage. The following story, which we receive from William of Malmesbury, has been cited to shew the extremities to which this most illustrious monarch was now reduced. A pilgrim came to this castle and requested alms. The king answered him in such a manner that he had only some small loaf remaining, which was insufficient for themselves and their friends, who were gone abroad in quest of fish and other food, though with small hopes of success. 'Give the poor man one half of the loaf,' said the king: 'he that could feed 5000 men with five loaves and two fishes can certainly make that half of the loaf suffice for more than our necessities.' The man was relieved accordingly; and the king's benevolence was compensated by the early arrival of his people with an unexpectedly ample store of fresh provisions. [A beautiful painting from this subject, by Mr. Wells, was presented by the venerable alderman Boydell some years since to the stationers company; in the court room of whose hall it still remains an honourable specimen of the artist's talents, and a lasting memento, among many others, of the liberality of the donor.]

When the king had been about a year in this retreat, being informed that some of his subjects, under the brave OUCE, earl of Devonshire, had routed a great army of the Danes, killed their chiefs, and taken their magical standard, he sent letters, giving notice where he was, and inviting his friends to come and consult with him. Before they came to such determination, however, Alfred, disguised as an incipient harper, strolled into the enemy's camp; where, without suspicion, he was admitted not only to the tents of the common soldiers, but even into those of the chief Danish commanders. Having examined every thing with great accuracy, he prepared again to Athelney, and summoned with all privacy his faithful subjects to meet him in arms at Breston, in the forest of Swinstead, in Wiltshire. They obeyed the summons; and, fired with the hopes of liberty, fell upon the Danes with incredible acclivity, at a moment when the latter had not the leaf in question of a foe, and imagined Alfred to be a mere fugitive from them.

The attack was made at Athelney, now Eddington. Thrice of the enemy who escaped from this battle possessed themselves of a neighbouring castle, or fort, almost ruined, which they fortified inmediately, and in which they were quickly beleaguered by the victorious Saxons; but, after a long and close siege, the Danes were forced to surrender at discretion. Alfred, however, treated them like a merciful prince, giving up to each of them as should embrace the Christian religion, the whole kingdom of the East Angles, on condition that they should oblige the rest of their countrymen to quit the island, and prevent, as far as they were able, the landing of any more foreigners. For the performance of these articles he took hostages; and when, in pursuance of the treaty, Guthrum, the Danish chief, came, with thirty of his chief officers, to Alfred, to be baptized, the king answered for him at the font, gave him the name of Ethelstan, and adopted him for a son. His friends and himself were nobly entertained for twelve days, and then dismissed with royal presents.

One advantage the Saxons derived from these actions turning Christians; which was, that now they kept their oaths, and removed into the country which had been assigned to them, where they quietly settled themselves.

In 884 a new swarm of Danes landed in Kent, and laid siege to Rochester; but the inhabitants boldly defended the place till the king, reaching them with an army, compelled the enemy to raise the siege, and return once more to France. Alfred, having now some leisure, resolved to repair, reform, and repopulate the ancient city of London, which he had lately recovered from the Danes; and meant to keep as a frontier. Accordingly, he placed a garrison in it, and made Ethelred governor thereof, whom he had created earl of Essex, and to whom he gave his daughter Ethelfleda in marriage.

After some years of rest, however, Alfred was again called into the field; for the Danes, being sorely beaten in the west of France, in 891, came with a fleet of 500 sail on the east coast of Kent, and, landing, fixed themselves at Ashle. Shortly after came another fleet up the Thames, consisting of 80 vessels, and, having landed the soldiers, built a fort at Middleton, near Milton. Alfred drew together a considerate army; but, before he marched toward the enemy, compelled the Danes to setle in Essex and Northumberland, to give him hostages for their good behaviour. He then moved toward the invaders, and prudently pitched his camp on a spot between the enemy's two armies, thereby preventing their junction. A great body, however, moved into Essex, and thence, crossing the river, came into Surrey, at Farnham; in which country, the king's forces met and defeated them.

Amid these contests, the Danes of Northumberland, in breach of their oath, and notwithstanding the hostages which they had given, equipped two fleets, one of 100, the other of 40 vessels, and came to Exeter, which place they besieged. Alfred left not a moment in opposing this new enemy. Having left some forces at London to make head against
against Hallings (Hadden), and the other Danes, he marched suddenly to the West; and, falling on the rebels before they were aware, pursued them to their ships with great slaughter. The enemy, fleeing next to Suffolk, began to plunder the country near Chichester; but the order which Alfred had everywhere established sufficed here, without his presence, for the defence of the place and the rebels, meeting with a new repulse, in which many of them were killed, and some of their ships taken, were obliged again to put to sea. They now failed to join Hallings, the Danish chief, at Beamsley, in Essex, who, thus strengthened, and encouraged by the absence of the king, ravaged all the lands belonging to Alfred in Mercia. The troops which the king had left in London for the security of that place, now, in turn, took advantage of the absence of the Danish chief on his incursions in the Mercian districts, hastily attacked Beamsley, and carried the place by storm, in which they found Hallings's wife and her two sons, who had been lately baptized. Thence they made prisoners, and sent to Alfred; who, with a greatness of soul unparalleled in those times, returned them to Hallings, with this message, "I make no war upon women and children." Hallings, returning from his pil­laging expedition, gave up all for lost, and once more sued for peace; which Alfred, with his usual clemency, granted, on his giving fresh hostages for his fidelity in time to come.

Before Alfred had time to retrench himself, another Danish leader, whose name was Lafi, came with a great army out of Northumberland, and destroyed all before him. Having invaded North Wales, plundering or desiring every thing, this army divided itself; one body returning to Northumberland, the other marching into Essex, and taking possession of a small island called Merefaeg (Mersey). Here, however, they did not long remain; for, having parted, some fell up the river Thames, and others up the Lea Road; where, drawing up their ships, they built a fort not far from Lon­don, which proved a great restraint upon the citizens, who went in a body and attacked it, but were repulsed with great loss. This obliged the king, when harvest-time came, to encamp with a body of troops in the neighbourhood of the city, in order to cover the reapers from the incursions of the Danes. Riding one day by the side of the river Lea, a thought struck him, that by narrowing the channel and cutting some trenches, and thus turning the course of the stream, he might render the Danish ships useles, by leaving them on dry ground. This was promptly executed; the pigeons, stuck with astonishment and dismay, quitted their ships and camp, and fled to Quatford, where they were finally broken and subdued. Such of the Danish ships as could be got off, the Londoners carried into their own road; the rest they burnt and destroyed.

The Dnes, ever unquiet, in a short time began again to invade the territories of the West Saxons, both by land and sea; but their chief enterprises were in the way of piracy, under the command of Siegert, a Northumbrian, who, well acquainted with Alfred’s naval preparations, had framed vessels of a new construction, higher, larger, and swifter than the English; but the king, improving on his invention, caused a number of galleys to be built with all possible expedi­tion, of still greater bulk, swifter in sailing, and loftier than those of the Danes, some of them carrying 62 rowers. With thefe, falling upon the enemy while they were exercis­ing their ravages in the West, he took twenty of their ships; and, having tried all the prisoners at Winchelsea, he gave judgment that they should be hanged as piratical mur­derers and enemies of the human race. The well-timed fe­verity of this execution, together with the excellent policy of defence every where established, restored complete tranquillity in England for the three remaining years of Alfred’s reign, which he chiefly employed in establishing and regulat­ing his government for the security of himself and his succes­sors, and the safety and benefit of the people at large.

"His mighty genius (says Sir W. Blackstone) prompted him to undertake a most great and necessary work, which he is said to have executed in as masterly a manner. No kfs than to new-model the constitution; to rebuild it on a plan that should endure for ages; and out of its discordant materials, which were heaped upon each other in a vast and rude irregularity, to form one uniform and well-connected whole. This he effected, by reducing the whole kingdom under one regular and gra­dual subordination of government, wherein each man was answerable to his immediate superior for his own conduct and that of his nearest neighbours; for to him we owe that master-piece of judicious policy, the sub-division of Eng­land into shires and hundreds, if not into counties; all under the influence and administration of one supreme ma­gistrate, the king; in whom, as in a general referral, all the executive authority of the law was lodged, and from whom justice was dispensed to every part of the nation by direct, yet comprehensive, duets and channels; which wise institution has been preferred for near a thousand years unchanged, from Alfred’s to the present time. He also, like another Theodosius, collected the various customs that he found dispersed in the kingdom, and reduced and digested into one uniform system or code of laws, in his Som­bee, or litter judicatis. This he compiled for the use of the court baron, hundred and county-court, the court leet, and sheriffs’ tourn; tribunals which he established for the trial of all causes civil and criminal, in the very districts wherein the complaint arose; all of them subject, however, to be inspected, controlled, and kept within the bounds of the uni-veral or common law, by the king’s own courts; which were then itinerant, being kept in the king’s palace, and re­moving with his household in those royal progresses which he continually made from one end of the kingdom to the other. The Danish invasion and conquest, which introduced new foreign customs, was a fever blow to this noble fabric; but a plan, so excellently concerted, could never be long thrown aside. So that, upon the expulsion of these intruders, the English returned to their ancient law; retaining, however, some few of the customs of their late visitants; which went under the name of Dane-Lage: as the code compiled by Alfred was called the West-Saxon-Lage; and the local con­stitutions of the ancient kingdom of Mercia, which obtained in the counties nearest to Wales, and probably abounded with many Britih customs, were called the Mercian-Lage. And these three laws were, about the beginning of the eleventh century, in use in different counties of the realm: the pro­vincial policy of counties, and their sub-divisions, having never been altered or discontinued through all the shocks and muta­tions of government, from the time of its first institution; though the laws and customs therein used, have often suffer­ed considerable changes.”

Than Alfred, no man could be a more absolute monarch for, besides that he was the legal inheritor of the crown, he had won it by his sword, having fought 36 set battles by sea and land (eight of them in one year), and enlarged his dominions beyond what any of his ancestors possess’d. But, though thus absolute, he soon showed, that he desired not to establish

Historicus quondam fecit me Beda latinius, Alfred rex Saxo translatit ille patris.

20. "Ætiop fables. The fables, which he is said to have translated from the Greek both into Latin and Saxon. — 21. "Plitiatrum Davidicain, lib. i. David's Psalms, in one book." This was the last work that the king attempted, death surprising him before he had finished it; it was however completed by another hand, and published at London in 1640, in quarto, by Sir John Spelman.

The foregoing article has been chiefly compiled from Biog. Brit. Hume.—Blackstone.—Spelman.—And Wife's Annales Alfredi Magni.

Alfred, an English bishop, was a monk of Malmefbury, of the order of St. Benedict, and preferred to the see of Exeter. He flourished in the 10th century, and was one of the most learned men of his time. He wrote a treatise, "De Naturis Rerum." "The Life of Alfred.

Alfred, of Beverley, an ancient historian, wrote his "Annals," published by Hearne, between the years 1148 and 1150, and borrowed his account of the British kings from Geoffrey of Monmouth. Bong. Dict.

ALFREDON, in Geography, a small market town of England, in the county of Derby, is said to have been founded by king Alfred. It has a considerable corn market on Friday. It is 15 miles north of Derby, and 1413 north of London.

ALFTER, a borough, citadel, and leigarchy in the electorate of Cologne and prefecture of Bonn, belonging to the county of Salm-Ritterfield.

ALGA, in Natural History, a species of millepora, with thin semicircular lamina, forming horizontal leaves; the millepora lichenoides of Solander and Ellis, found of a red, purple, yellow, and whitish colour, on the shores of Cornwall.

ALGÆ, in Botany, an order or division of the cryptozoonia class of plants. — It is one of the seven families or natural tribes into which the vegetable kingdom is divided in the Flora Botanica of Linnaeus; the 57th order of his fragments of a natural method; and the second genus of the section marine aut fluviatiles, in the class affirmia vulgo Loddie of Tournéfort.

The plants belonging to this order are described as having their root, leaf, and stem entire, or all one. The whole of the sea weeds, and various other aquatic plants, are comprehended under this division.

From their admitting of little distinction of root, leaf, or stem, and the parts of their flowers being equally incapable of description, the genera are distinguished by the situation of what is supposed to be the flowers or seeds, or by the resemblance which the whole plant bears to some other substance.

The parts of fruitification are either found in succaera or tubercules, as in leichen; in hollow bladders, as in the fiscti; or dispersed through the whole substance of the plants, as in the ulce. The fibres of the plants have much variety; it is flesh-like or leather-like, membranaceous or fibrous, jelly-like or horn-like, or it has the resemblance of a calcareous earthy matter.

Mr. Valley has lately shown that some of the plants which belong to this order possess a high degree of irritability. Withering's Arrangement of British plants, vol. 1. p. 369.

Lamarck distributes the algae into three sections; the first comprehends all those plants, whose fruitification is not apparent or seems doubtful. These commonly live in water, or upon moist bodies, and are membranous, gelatinous, or filamentous. To this section he refers the byllii, conferva, ulna, tremella, and varce. The plants of the second section are distinguished by their apparent fruitification, although it be little known, and they are formed of parts which have no particular and sensible opening or explosion at any determined period; their fruitification is ordinarily crustaceous or coriaceous. They include the taffella, ceratoferma and lichen. The third section comprehends plants, which have their fruitification very apparent, and distinguished by constituent parts which open at a certain period of maturity for the escape of the fermenting fluid or seeds. These plants are more herbaceous, as to both their fruitification and their colour, than those of the other two sections, and are more nearly related to the mollusks from which they do not essentially differ. Their flowers are often contained in articulated and very elastic filaments. To this section are referred the ricia, blain, antocoros, turgia, hepatica, and jungermannia. In the Linnaean system the algae are divided into two classes, viz. the terriformes and aquatilia. The former include the antocoros, blain, ricia, lichen, and hisia; and the latter are the alva, fuci, and confervae. The fruitification of the algae, and particularly of those called aquaticæ, is denominated by a judicious botanist, the appressis botanicores. See observations on this order of plants by Dr. Goodenough and Mr. Woodward in the Linnean Trans. actions, vol. 3. p. 84, &c.

ALGE, in Ancient Geography, an inland city of the island of Euboea, called by Strabo, the Euboic Alge, and also Ages, to distinguish it from two other cities of that name, one in Asia, near the river Cetas, the other in Helles. He conceives, that from this place, in which was a temple of Neptune, the Algean sea derived its name. See XEUS.

ALGà, a port of Italy, which Antonine places three miles from Custumeta.

ALGAGLIA, a sea-port town of Corsica, defended by a castle, situated upon a rock, was almost destroyed by the naval-contests in 1731, but soon afterwards rebuilt. N. lat. 42° 20'. E. long. 9° 45'.

ALGAILA, or ALIARA, in Geography, a river of Spain, joins the Cabriel, before its conflux with the Xocar.

ALGALA, or ALGALIE, in Surgery, the Arabian name of a hollow curved instrument employed for drawing off the urine, or searching for a stone, by introducing it into the bladder. The more common appellation of this tube is Catheter of Sound, which see.

ALGARDI, ALESSANDRO, in Biography, an eminent artist, both as a sculptor and architect, was born at Bologna in 1558, and became a disciple of Julius Caesar Conventi, under whose instruction he acquired a reputation in sculpture little inferior to that of Michael Angelo Buonarroti. He also frequently the school of the Caracci, where he probably learned the art of engraving; his style, resembling that of Angolino Caracci, being slight and free, and his execution with the graver bold and open. Having studied at Mantua and Venice, he visited Rome in 1625, and became acquainted with Domenichino, by whom he was recommended to the flatory work of the chapel Bandini, which he was painting. For some years he was chiefly employed in repairing antiques and modelling for goldsmiths; but his talents and reputation procured him superior work. Among his performances may be reckoned a statue of St. Philip de Neri, in the sacristy of the oratory at Rome; his group of the decollation of St. Paul for the Barnabite church at Bologna, and the tomb of Leo XI. at St. Peter's. One of his capital performances was a bas-relief in this cathedral, representing the story of Attila, 72 feet by 18, which was the labour of four years, and which gained him universal applause, with the honour of knighthood and the golden crown. His bronze figure of Innocent XI. is reckoned the finest of the statues of the popes in Rome. A crucifix likewise, called, by way of distinction, Algard's crucifix, has been much celebrated, and often copied by many of the principal artists. He was affable and quick in execution, but becoming corpulent and infirm, he was under a necessity of recurring to the assistance of his pupils, of whom he formed an eminent school. He died in 1654, at the age of 53 years. His disposition was lively, his conversation pleasant, and his manners irreproachable. He lived in celibacy, and left his property to his father. His works, which are held in high estimation, though the air of his head,
is thought to be artificial and studied, and he is somewhat of a manurit in the fols of his draperies, are chiefly at Rome and the neighbouring villages. Two plates, supposed to be his, are "Christ upon the Cro:" a large upright plate, and "the Deliverance of the Souls from Purgatory," a small oval. Strutt. Gen. Biog.

ALGAROTTI, Powder of, in Chemistry, is a white oxd of antimony, procured by adding pure water to the butter or oxymuriate of antimony, whereby the metallic oxd is precipitated. This, when thoroughly colored and dried, forms the powder of algaroth, and is a very perfect oxd of antimony. It was first applied, as an internal medicine, by Algarotti, an Italian physician. It is now not to be found in the later pharmacopoeias of the London college, but if it were of any advantage to increase the number of antimonial medicines, it might deserve notice from the col with which it is prepared, and the apparent uniformity of its composition. It is retained by the Edinburgh pharmacopoeia, and in several parts of the continent as the basis of the cement tar, or tartarized antimony. See Antimony, nitrate and tartarite of.

ALGAROTTI, FRANCIS, in Biography, was born at Padua in 1712, and finished his studies in the university of Bologna. He commenced his travels at an early period, and in his visit to England acquired a predilection for the Newtonian philosophy, which led him to write his "Newtonianimo pour les Dames;" or, "Newtonianism for the Ladies," dated at Paris in 1736. This popular work is formed upon the model of Fontenelle's "Plurality of Worlds," and is equally instructive and amusing. At Berlin Algarotti was kindly received by Frederick, king of Prussia, who conferred upon him the knighthood of the order of Merit, the title of count, and the post of chamberlain. By Stanislaus, king of Poland, who admitted him into his court, he was appointed a privy-councillor. His character was that of a man of letters, a philosopher, and one of the first connoisseurs in Europe in the arts of music, painting, sculpture, and architecture. He contributed much to the improvement of the Italian opera, and wrote verses in his own language replete with sentiment and imagery. An associate at Berlin represents him, somehow in the style of fatire, "as full of wit, affection, and fell-love; a Frenchman in genius, an Italian in character, disregardeal in society, often exposed to royal witticisms, and receiving them as tokens of favour." After his return to Italy he died at Pisa, May 24, 1764. The manufacum which he erected for himself indicates both his taste and his vanity. The epitaph for his tomb was written by himself; "Hic jacet Algarottus, fed non omnis." A collection of his works, in Italian, was published at Leipsin in 1765, in four volumes, 8vo. They consist of his dialogues on the philosophy of Newton, on effays on the fine arts, and on commerce, of dissertations on subjects of language, of historical dilutions, and of miscellaneous literary and philosophical. An edition of them, in French, was published at Berlin in 1772, in eight vols. 8vo.; and they have been also translated into English and other languages. They display genius and profound reflection, but are thought by competent judges deficient with respect to nature and simplicity. He designed and engraved, for his amusement, several plates of heads in groups, one of which, containing 13, in the antique style, is dated Feb. 15, 1744. Nouv. Dict. Hill. Strutt.

ALGARVA, in Geography, the most southern province, anciently a kingdom of Portugal, is bounded on the south and west by the ocean, and hence formerly called Coasts or wedges, on the salt by Andalusia, from which it is separated by the Guadiana, and on the north by a ridge of hills, called Serra de Algarve and Serra de Monchique, which divides it from Alentejo. The greatest length of this province is about 90 miles, and its greatest breadth is about 28. The city of Lagos is properly the chief town of Algarve, though Tavira is now the residence of the governor, and Faro possesses the greatest part of its trade. According to the first enumeration in 1750, this small kingdom contained 93,472 inhabitants, of whom 6,521 were fishermen, and 5,575 labourers. It lies close to the sea, and is well cultivated; but this cultivation does not extend more than two leagues inland, beyond which are desert hills. Corn is not grown in sufficient quantity for the consumption; the oil that is produced here is reckoned the best in Portugal, and exported. The wine is white, and good. Figs constitute the principal produce of Algarve, and it also abounds with almonds, particularly about Tavira, which are exported. This is the only province of Portugal from which dried figs are exported. Oranges are also cultivated, especially in the vicinity of Monchique and Faro; and there, together with oranges and Spanish rods (aranjado danse), are exported from Faro to England. Algarve, it is said, is the only country, Greece excepted, where Caprification is practiced; for there are some varieties of figs, which are very excellent, that fall to the ground immature, unless they are parched by the grates. The common people live principally on fish, and are very poor, because the province, though capable of great cultivation, is shamefully neglected. A quantity of tunny-fish is taken on the coast, and particularly in the neighbourhood of Lagos and Cape St. Vincent, and salted in May and June; the colour of it resembles that of smoked Lec. and a forehouse for it is opened at Lisbon, where it is found to supply the place of cod. The inhabitants, in general, are less refined and polite than the other Portuguese, but they are celebrated through the country for their wit and shrewdness. They are also considered as the best mariners in Portugal; and on this account many of them emigrate, and most of the boatmen at Lisbon come from this province. The mountains that separate this province from Alentejo, rise in height as they approach the north, and consist of argilaceous slate and sandstone. They are arid and barren, and only bear the cactus ludaniferus, with two other kinds of cactus. The province is for the most part surrounded by lime-stone mountains, which exhibit few, if any, traces of cultivation. Olive-trees and fig-trees, and also the carob-tree (ceratonia silqua) grow abundantly in the corn-fields, and afford a pleasant shade. The fan palm (ehemerae glabra of Linnaeus) is very plentiful throughout the province; and its fan-shaped leaves are used for making the baskets in which figs are packed. Link's Travels through Portugal, p. 437, &c.

ALGAS, a river of Spain, which runs into the Mata-rana, near Nonafpe, in Aragon.

ALGATRANE, a fort of pitch found in the bay formed by the point of the Cape of St. Helena, on the north of the Isle of Plata.

ALGAT. See Algaw.

ALGAVAREIA, the language anciently spoken by the Morefoes of Spain, which was a fort of Arabic, and was contradistinguished from the Algarian.

ALGAZEL, in Biography, a learned Arabian, about the beginning of the 12th century, was a native of Tos, or Tus, in Asia, and celebrated among the Mahometan theologians for his numerous tracts in defence of the Mahometan religion, against the Jews and Christians; particularly for his "Demonstration of Islamism," and his "Treatise on the Unity
UNITY OF GOD." But he was suspected of heresy, and one of his pieces, entitled, "The Restoration of the Law of Science," was condemned after his decease, because it contained some of the precepts of the Islamic law; and if any copy of it was found within the sacred empire, it was ordered to be burned. He also wrote a treatise "On the Opinions of Philosophers," and another, entitled, "The Destruction of Philosophers." After living in great splendour as a public preceptor at Bagdad, he distributed his riches among the poor, and took the habit of a hermit, and retired to Meccca. From Meccca he travelled into Syria and Egypt, and staying some time at Cairo, and afterwards at Alexandria, he returned to Bagdad, where he died. Poem on Spec. Hist. Arab. p. 371. Herbelot, p. 62. Leo Alr. c. 12. Brucker's Hist. Phil. by Einfield, v. ii. P. 243.

ALGEBRA. See Antilope. ALGEBRA, a general method of resolving mathematical problems, by means of equations; or, it is a method of computation by symbols, which have been invented for expressing the quantities that are the objects of this science, and to express their mutual relation and dependence. These quantities might probably, in the infancy of the science, be denoted by their names at full length; these, being found inconvenient, were succeeded by abbreviations, or by their mere initials. And, at length, certain letters of the alphabet were adopted as general representations of all quantities; other symbols or signs were introduced to prevent circumlocution, and to facilitate the comparison of various quantities with one another; and, in consequence of the use of letters or species, and other general symbols, or indiscriminate quantities, algebra obtained the appellation of specious, literal, and universal arithmetic.

The term, algebra, is of Arabic origin; but its etymology has been variously assigned by different writers. Among the Arabsians, from whom it was immediately transmitted to us, this science was denominated al-gibbar almucabalah; and as giibbar signifies to reflect, and mukbalah to compare or to oppose, the nouns formed from these words, with the prefix al, denote the science of reduction and comparison or resolution and equation; and thus understood, they express its nature with sufficient precision. Accordingly, Lucas de Burgo, the first European author on algebra, calls it the rule of restoration and opposition. Others, however, have derived it from Giber, either the name of a celebrated mathematician, to whom they ascribe the invention of the science; or from the word giber, which forms, with the particle al, the appellation algebra. Signifying, according to Galus, in his Arabic lexicon, a reduction of broken numbers or fractions into integers. Herbelot says, that giber or giber is never used by the Arabs for algebra, without adding the word mukhbalah; but Dr. Russel (Hist. Alcpan, v. ii. 107) observes, that, at Alcpan, and also in books, al Giber is used sometimes alone, as well as in conjunction with mukhbalah. This science has been distinguished by other names, besides algebra. Lucas de Burgo calls it l'art magique, or the greater art, by way of contradictions to common arithmetic, which is denominated l'art minore, or the lesser art. The Italians call it regola de la coffa, or re; coffa with them signifying res or thing, and being used in the same sense with radix, or root, whence proceeded the term rule of cofa, and cofica numbers, denoting the root, square, cube, and other powers. Other Italian and Latin writers have called algebra regula rei et cozens, or the rule of the root and square; cozen being used for improvement, or the square. By a corruption of cozenus were formed xensus, for the square, and the term xenzic applied to the square root. Hence also the characters c, s, c, deduced from the letters r, s, c, became the symbols of res, xensus, and cubus; or, in our mode of expression, the root, square, and cube; xul as k and c, formed from R, r, are with us the signs of radicality. Wallis's Algebra, c. i. p. 3.

Some authors have defined algebra, as the art of resolving mathematical problems; but this is rather the idea of Analysis, or the analytic art in general, than of algebra, which is only a particular branch of it. Algebra, duly considered, consists of two parts, viz. the method of calculating magnitudes or quantities, represented by letters or other characters, and the mode of applying these calculations to the solution of problems. When algebra is applied to the solution of problems, all the quantities that are involved in the problem are expressed by letters, and all the conditions that serve to denote their mutual relation, and by which they are compared with one another, are signified by their appropriate characters, and they are thus thrown into one or more equations, as the cese requires; this is called synthesis, or composition. When this is done, the unknown quantity is disengaged by a variety of analytical operations from those that are known, and brought to stand alone on one side of the equation, whilst the known quantities are on the other side; and thus its value is investigated and obtained. This process is called analysis or resolution; and hence algebra is a species of the analytic art, and is called the modern analysis, in contradistinction to the ancient analysis, which chiefly regarded geometry and its application.

The origin of algebra, like that of other sciences of ancient date and gradual progress, is not easily ascertained. The most ancient treatise on that part of analytics, which is properly called algebra, now extant, is that of Diophantus, a Greek author of Alexandria, who flourished about the year of our Lord 350, and who wrote 13 books, though only fix "Arithmeticon" of them are preserved, which were printed together with a single imperfect book on multangular numbers, in a Latin translation by Xylander, in 1575, and afterwards in Greek and Latin, with a Comment, in 1621 and 1670, by Gaspar Bachet, and M. Fermat,首选. These books do not contain a treatise on the elementary parts of algebra, but merely collections of some difficult questions relating to square and cube numbers, and other curious properties of numbers, with their solutions. In his prefatory remarks, addressed to one Dionyrius, for whose use Diophantus probably wrote, he recites the names and generation of the powers, the square, cube, 4th, 5th, 6th, &c. which he calls dynamis, cubus, dynamonismis, dynamocubus, cubocubus, according to the form of the indices of the powers, and he marks those powers with the Greek initials; and he expresses the unknown quantity by agapoun, or the number, simply marking it in the solutions by the final s or, and denoting the monades, or indefinite unit, by w0. In his references on the multiplication and division of simple species, he shows what powers they produce, and observes that minus (wt+w) multiplied by minus, produces plus (w=+w), and that minus multiplied by plus produces minus; the mark which he uses for minus is c or the inverted and curved t, but he has no mark for plus, expressing it by a word or conjunctive copulative. Supposing his reader acquainted with the common operations, viz. addition, subtraction, multiplication, and division of compound species, he proceeds to remark on the preparation of the equations that are deduced from the questions, which we call reduction of equations, by collecting like quantities together, adding quantities that are minus, and subtracting those that are plus, called by the moderns transposition,
transformation, so as to bring the equation to simple terms, and then depressing it to a lower degree by equal division, when the powers of the unknown quantity are in every term: which preparation or reduction of the complex equation, being made, or reduced to what we call a final equation, this author proceeds no further, but merely says, what the root, or verum, is, without giving any rules for finding it, or for the resolution of equations: thus intimating, that rules for this purpose were to be found in some other work, either of his own, or of some other person. The chief excellence of Diophantus's collection of questions, which seems to be a series of exercises for rules which had been elsewhere given, is the neat mode of substitution or notation, which being once made, the reduction to the final equation is easy and obvious. This work indicates much accurate knowledge of the science of algebra, in none of its most abstruse parts. But as the author reduces all his notations to a simple equation, or a simple quadratic, it does not appear how far his knowledge extended to the resolution of compound or affected equations.

Algebra, however, seems not to have been wholly unknown to the ancient mathematicians, long before the age of Diophantus. We observe the traces and effects of it in many places, though it seems as if they had intentionally concealed it. Something of it appears in Euclid, or at least in Theon upon Euclid, who observes that Plato had begun to teach it. And there are other instances of it in Pappus, and more in Archimedes and Apollonius. But it should be observed, that the analysis used by these authors is rather geometrical than algebraical; this appears from the examples of it that occur in their works, and therefore, Diophantus is the first and only author among the Greeks, who has treated professedly of algebra. Our knowledge of the science was derived, not from Diophantus, but from the Moors or Arabs; but whether the Greeks or Arabs were the inventors of it has been a subject of dispute. It is probable, however, that it was much more ancient than Diophantus, because his treatise seems to refer to works similar and prior to his own. Abulfaragius, an Arabic historian, in one place afirms the invention, or rather the arrangement of the principles and rules of the science, to Diophantus; and from him we learn that the arithmetic of Diophantus was translated into Arabic by Mahomet Ben-Yahya Bazzini: but in another place he afirms to have afcribed it to Mahomet Ben Mufs, who is said to have lived about the year 850 or 900 and was the father of the Arabs by whom this science was cultivated. Cardan attributes the invention of it to this Arabian, and apprehends that he obtained the appellation of Geber from this art. See Bib. Arab. et Hisp. tom. i. p. 370. cited by Ruffi in his Hist. of Aleppo, vol. ii. p. 469. Stevinus is of opinion that this science, and other parts of mathematicks, were much more ancient among the Orientals, than any learning they derived from the Greeks. Dr. Wallis adopts the sentiments of those who think that the Arabs derived this science, as well as the knowledge of numeral figures, from the Persians, and originally by their means from the Indians; and he alleges, as a presumptive evidence of their not having derived it from the Greeks, that the name they give it, viz. al-giabr wa-al-muqabala, seems to have no affinity with any Greek name. We may here add, that some vestiges of algebraical calculation have been discovered among the Brahmins; particularly rules for the solution of certain arithmetical questions, with which it would seem that nothing but algebra could have furnished them. Aathic Researches, vol. ii. p. 468. note. 467. 475. But wherever algebra was invented or first cultivated, the science, and also the name of it were transmitted to Europe, and particularly to Spain, by the Arabs or Saracens, about the year 1100, or somewhat sooner. It seems to have taken the lead in the cultivation of this science, after its introduction into Europe: and Lucas Paciolius, or Lucas de Burgo, a minorite Franciscan friar, was the first author on the subject, who wrote several treatises in the years 1476, 1483, 1479, 1487, and 1509: but his principal work, entitled, "Summa Arithmetice et Geometrice, Proportionumque et Proportion singledum," was published in Italian at Venice, in 1494, and again in 1523. In this work he mentions several writers, and particularly Leonardus Piscator, placed by Vossius about the year 1500, or a little sooner, and laid to be the father of the moderns who wrote of algebra, from whom he derives his knowledge of those sciences; and from the treatise of Leonard, not now extant, the contents of that of Lucas were chiefly collected. The age of Leonard of Pisa has been usually fixed to the end of the 13th century. But it now appears by a manuscript of this algebraist, discovered in a library of Italy, by M' Targioni Tozzetti, and communicated to M. Cossali, a canon regular of Parma, that he lived two centuries before this period, or at the commencement of the 15th century: and of course that Italy is indebted to him for its first knowledge of algebra. The proper name was Bonacci, and he was a merchant, who traded in the sea ports of Africa, and the Levant. Being ambitious of obtaining an acquaintance with the sciences that flourished amongst the Arabs, and particularly that of algebra, he travelled into their country. Accordingly his arithmetic was published in 1202, and a new enlarged edition of it appeared in 1228. At this time, however, algebra was not a part of arithmetic, but was distinguished from it by the title of "Artem Magnae," or "Arte Maggiore." From the manuscript above-mentioned it appears, according to Cossali's account of it, that Leonard had penetrated deeply into the secrets of the algebraic analysis: that he was particularly acquainted with the analysis of problems similar in kind to those of Diophantus, and with the resolution of equations of the second degree; and that he had written a treatise, entitled "De Numeri Quadrati," which is not extant, but which Cossali has restored from some fragments of Lucas del Burgo. This Leonard, therefore, must not be confounded with another called Camillus Leonardus of Pefaro, author, as it is said, of a book entitled, "Liber deificatur canonum aequatorum motum celebrium fine calculo, &c." Fisaur. 1496, 416. Montucula Hist. Mat. tom. ii. p. 716. This Leonard of Pisa made long voyages into Arabia and other eastern countries, in order to gain the knowledge of the mathematicks. Montecula (tom. i. p. 550.) mentions two other personas who previously to this discovery were thought to have preceded Leonard in this department of science, viz. Paul d'Abaco, who lived towards the end of the 14th century, and who is supposed by Ximenes, to have been the first person in Italy, who used algebraic equations; and also Profodinico Balmandano, or Beldomando, of Padua, who was supposed to have shared with Leonard the honour of introducing into Italy the knowledge of algebra. His book, entitled, "Dell Algoritmo," was printed in 1483, but dated at the beginning of the 15th century. Lucas informs us, that algebra came originally from the Arabs, and never mention Diophantus; for which circumstance it has been inferred that this Greek author was not then known in Europe. From the book of Lucas de Burgo, we learn, that the knowledge of the Europeans in his time, or about the year 1500, extended no further than to quadratic equations, of which they used only the positive roots; that they admitted only one unknown quantity; that they had no marks or signs for either
either quantities or operations, excepting some few abbreviations of the words or names; and that the art was merely employed in resolving certain numerical problems. If the form had been carried farther in Africa than quadratic equations, which was probably the case, as we may infer from an Arabic manuscript, said to be on cubic equations, deposited in the library of the university of Leyden, by Werner, the Europeans had at this period obtained only an imperfect knowledge of it. The publication of the works of Lucas de Burgo, professor of mathematics at Bononia, in Italy, discovered the first rule for resolving one case of a compound cubic equation. The next Italian, who distinguished himself by the cultivation and improvement of algebra, was Hieronymus Cardan2, of Bononia, who published nine books of his arithmetical writings, in 1530, in Latin, at Milan, where he practiced physic, and read lectures on mathematics; and in 1545, a tenth book, containing the whole doctrine of cubic equations. Cardan denominates algebra, after Lucas de Burgo and others, "Ars Magna quam velbo Coftam vacant," or "Regula Algebraica," and ascribes the invention of it, on the authority of Leonard of Pisa, to Mahomet, the son of Moes, an Arabian. He adds, that this supposed inventor left four rules or cafes, which perhaps only included quadratic equations; that afterwards three derivatives were added by an unknown author, supposing by some to have been Lucas Pacioli, and afterwards three other derivatives for the cube and sixth power, by another unknown author; all which were resolved like quadratics; that then Scipio Ferreo, about 1505, found out the rule for the cube "cubum et rerum numero equalem," or, as it is now written, \( x^3 + bx = c \), which he represents as a thing admirable; that the same discovery was made in 1535, by Tartalca, who, after earnest treatises, disclofed it to him (Cardan); and that he and his former pupil, Lewis Ferrari, much augmented and extended the cafes; and that all the demonstrations of the rules are his own, except three of Mahomet for quadratics, and two of Ferrari for cubics.

To Cardan's treatise on cubic equations is annexed, "Libellus de Aliza Regula," or the Algebraic Logics, in which he treats of some of the more abstruse parts of arithmetic and algebra, especially cubic equations, with many additional attempts for the solution of the irreducible cafe, \( x^3 = bx + c \).

From a minute and accurate detail of the contents of Cardan's treatise, given by Dr. Hutton, it appears, that the improvements in algebra, communicated by this author, are as follow. To the rules furnished by Tartalca for resolving these three cases of cubic equations, \( x^3 + bx = c \), \( x^3 = bx + c \), and \( x^3 - c = bx \); he has added rules for all forms and varieties of cubic equations, demonstrating these rules geometrically, and fully discussing almost all sorts of transformations of equations in a manner before unknown. Cardan also appears to have been well acquainted with all the real roots of equations, both positive and negative; or, as he calls them, true and fictitious, both of which he occasionally used. He has also shewn that the even roots of positive quantities are either positive or negative; that the odd roots of negative quantities are real and negative; but that the even roots of them are impossible, or nothing as to common use. He also well knew the number and nature of the roots of an equation, partly from the signs of the terms, and partly from the magnitude and relation of the co-efficients. He also knew that the number of positive roots is equal to the number of changes of the signs of the terms; that the coefficient of the 2d term of the equation is the difference between the positive and negative roots; that when the second term is wanting, the sum of the negative roots is equal to the sum of the positive roots; how to compose equations that shall have given roots; that changing the signs of the even terms changes the signs of all the roots; that the number of roots failed in pairs, or that the impulsive roots, as they are now called, were always in pairs; to change the equation from one form to another, by taking away any term from it; and to increase or diminish the roots by a given quantity. It appears also, that Cardan had rules for extracting the cube root of such binomials as admit of extraction; that he often used the literal notation, \( a, b, c, d, &c. \); that he gave a rule for quadratic equations, setting all their cafes; and that, in the investigation of that rule, he made use of an affirmed indeterminate quantity, and afterwards found its value by the arbitrary assumption of a relation between the terms; that he applied algebra to the resolution of geometrical problems; and that he was well acquainted with the difficulty of the irreducible cafe, and that he devoted much time and attention to the solution of it; and that, though he did not completely succeed, he laid down rules for many particular forms of it, and shewed how to approximate very nearly to the root in all cafes whatever.

Tartalca, or Tartaglia, of Brescia, was a contemporary of Cardan, and published his book of algebra, entitled, "Qua-riti e Invenzioni diversi," in 1546, at Venice, where he resided as public lecturer in mathematics. This work was dedicated to Henry VIII. of England, and consists of nine books, the full of which contains all those questions that relate to arithmetic and algebra. These questions comprehend examples of simple and quadratic equations, with complex calculations of radical quantities, evincing the skill of the author in the science of algebra. He retained the notation or forms of expression used by Lucas de Burgo, calling the 1d root of the unknown quantity "cosa," the 2d power of the unknown quantity "cena," the third "cubo," &c.; and he expressed the names of all the operations in words, without any contractions, except the initial \( R \) for root, or radicality. What is most remarkable in this collection of questions is the discovery of the rules for cubic equations, together with the various circumstances that attended it. The first two of these were discovered by Tartalca in 1530, viz. those for \( x^3 + ax^2 = c \), and \( x^3 = ax^2 + c \); and the rules for the other two cafes, \( x^3 = bx + c \), were discovered, in 1535, at Venice. Under question 31, we have an account of the correspondence between Tartalca and Cardan on the subject of cubic equations, and on the manner in which Cardan drew from him his discoveries relating to them; for a more particular account of which, see the biographical articles Cardan. Tartalca published at Venice, in 1556, &c. a very large work, in folio, on arithmetic, geometry, and algebra; the latter of which is imperfect, and extended no further than quadratic equations, his death having prevented his completion of it.

The contemporaries of Tartalca and Cardan were Michael Stifelius and Scheuchelius. The "Arithmetica integra" of Stifelius was written at Norimberg in 1544, and is, says Dr. Hutton, an excellent treatise on arithmetic and algebra. The invention of the science is ascribed by this author to Geber, an Arabian alchemist. The improvements of Stifelius and other Germans beyond those of the Italians, recited in Cardan's book of 1539, were as follow. He introduced the characters \( +, - \), \( \sqrt{\cdot} \), for plus, minus, and root, or radix; and the initials \( 2, 3, 4, 5, 6, &c. \) for the powers \( 1, 2, 3, \)
5. 4. 5. &c. He treated all the higher orders of quadratics by the same general rule. He introduced the numerical exponents of the powers, \(-3, -2, -1, 0, 1, 2, 3, \&c.", both positive and negative, as far as integral numbers, but not fractional ones; called them by the name exponents, exponent; and taught the use of exponents in the operations of powers; and he used the literal notation A, B, C, D, \&c. for so many different unknown and general quantities.

John Scheubelius, professor of mathematics at Tubingen, in Germany, published several treatises on arithmetic and algebra. From one of them, entitled, "Algebra compendiosa faciliisque Dofcriptioni, qua demonstrantur magna Arithmeticae miracula," printed at Paris in 1552, which Dr. Hutton has analysed, it appears that he was the first modern algebraist who mentioned Diophantus, to whom writers, as he says, refer this art; that his characters and operations are much the same with those of Stifelius, but that he used \(x\) for 1 or the power; and prefixes the numeral coefficients. He treats merely of two orders of equations, viz., simple and quadratic equations, though, he says, they may be of infinite degrees; and he uses for the square root \(\sqrt{a}\) for the cube root \(\sqrt[3]{b}\), and \(\sqrt[4]{c}\) for the 4th root. He gives the four fundamental rules in the arithmetic of surds; in squaring the sum or difference of the surds he sets the root to the whole compound; and this root called by Cardan, "radix universalis," he denominates "radix collectiva;" but when they may be reduced to a common factor, he unites them into one number. He proceeds in a similar manner with cubic surds and 4th roots. He remarks the different kinds of binomial and residual surds corresponding to the several irrational lines in the 10th book of Euclid's Elements; and he follows the general rule for extracting the root of any binomial or residual \(a \pm b\), in which one or both parts are surds, and the greater quantity, \(a\), that the square root of it is \(\sqrt{\frac{a + \sqrt{a^2 - b^2}}{2}} \pm \sqrt{\frac{a - \sqrt{a^2 - b^2}}{2}},\) which he illustrates by examples. As he takes no notice of cubic equations, it is probable that though they were known in Italy he had not heard of them in Germany.

Robert Recorde, in England, published the first part of his arithmetic in 1552, and the second part in 1557, under the title of "The Whetstone of Witte, which is the second part of Arithmetique; containing the Extraction of Roots, the Cube extracted, with the Rule of Equation; and the Workes of Surde Numbers." What is principally new in this work comprises the extraction of the roots of compound algebraic quantities, the use of the terms binomial and residual, and the use of \(\sqrt{a}\), as the sign of equality.

The Algebra of Peletarius was printed at Paris in 1540, in 1538, under this title, "Jacobi Peletari Cenomanae, de Oscinata Parte Numerorum, quam Algebrae vacant. Lib. duo." This work, containing an account of rational and irrational or fund quantities, is an ingenious treatise on those parts of the science that were then known, cubic equations excepted; and the discoveries or improvements of the author are the following, \(\sqrt{a}\), that the root of an equation is one of the divisors of the absolute term; that binomials may be reduced to simple terms by multiplying them by compound factors; and that a series both of square and cube numbers may be constructed by addition only, that is, by adding successively their several orders of differences.

Peter Ramus wrote his Arithmetic and Algebra about the year 1570. He expresses the powers by \(l, q, r, s, t,\) the initials of latus, quadratus, cubus, and biquadratus, and he treats only of simple and quadratic equations. In 1567, Peter Nomius, or Nunez, a Portuguese, published his Algebra in Spanish, though he informs us in an epistle, dated 1564, that it had then been written 20 years before in Portuguese. He proceeds no farther than quadratic equations. The Algebra of Raphael Bombelli was published at Bologna, in 1559, in the Italian language, but was written some time before, as the dedication bears the date of 1572. Among other writers on this science he particularly mentions Diophantus, whose Greek work had been found in the Vatican library; and he adds that he and Antonio Maria Pazzi Reggianio, professor of mathematics at Rome, had translated five out of the six books, which were then extant; and that they had found in the said work frequent citations of the Indian authors. Hence, they inferred, that this science was known among the Indians before the Arabs became acquainted with it. Such references, if they actually existed, would serve to determine the controversy relating to the origin of this science; but they do not now remain in the work, nor are they mentioned by any other writer. In his work Bombelli has very well explained the rules and methods of former writers; but, except the subdivision of angles by means of a cubic equation, and his mode of notation, he has not introduced any new invention or improvement. In this notation he uses the initial \(R\) for root, with \(q\) or \(c\) after it for quadratic or cubic, \&c. root; \(p\) for plus, and \(m\) for minus. He calls the unknown quantity \(lato\), and marks it thus: \(\sqrt{2}\), the 2d power \(\sqrt{2},\) its cube \(\sqrt{2}\), and the highest powers \(\sqrt{2}, \sqrt{2}, \&c.\) denoting all the powers, which he denominates dignita, or dignity, by their exponents set over the common character \(\sqrt{2}\). Christoffe Clavius, who follows Stifelius and Scheubelius in his notation and method, without fearlessly any variation, wrote his Algebra about the year 1580, which was published at Orleans in 1608. Simon Stevinus, of Bruges, published his Algebra soon after his Arithmetic, which appeared in 1585; and both were printed in an edition of his works in 1614, with notes and additions by Albert Girard. The peculiar inventions contained in this ingenious and original work are as follow. The author invented a new character, \(\sqrt{2}\), a fundamental for the unknown quantity, and he also improved the notation of the powers by numerical indices, first applied to integral exponents by Stifelius, which Stevinus included within a circle, thus: \(\sqrt{2}\), \(\sqrt{2}\), \(\sqrt{2}\), \(\sqrt{2}\), \&c. or the \(o, f, b, 2d, 3d, \&c.\) powers of the quantity \(O\); and he further extended them to fractional and all other sorts of exponents; so that \(\sqrt{2}\), \(\sqrt{2}\), \(\sqrt{2}\), \&c. are the square, cube, 4th roots, \&c. and \(\sqrt{2}\) is the square root of the square, and \(\sqrt{2}\) is the square root of the cubic, \&c. Stevinus also extended the use and notation of co-efficients, making them to comprehend fractions, radicals, and all sorts of numbers. He distinguished a quantity of several terms by the general appellation of a multinomial; and denoted all nominals whatever by particular names, expressing the number of their terms, as binomial, trinomial, quadrinomial, \&c. He also proposed one general method for a numeral resolution of all equations whatever.

About the same time with Stevinus appeared Francis Vieta, who contributed more to the improvement of algebraic equations than any former author. His algebraical works were written about the year 1603: some of them were not published till after his death in 1622; and all his mathematical works were collected by Francis Schönemann, and printed in 1646, in folio. The two books, which contain his chief improvements in algebra, are intitled "De Equationum
ALGEBRA.

Recognition, et Emendatione;" and were not published till the year 1615, by Alexander Anderson, an ingenious Scotman, with various corrections and additions. Vieta's improvements comprehend the following particulars. He first introduced the general use of the letters of the alphabet to denote indeterminate quantities, and accordingly did enter unknown quantities by the vowels A, E, I, O, U, Y, and the known ones by the consonants B, C, D, &c. He also invented many terms and forms of expression which are in present use; as co-efficient, affirmative and negative, pure and affected or affected, unies, homogeneum adjectives, homogeneum comparations, and the line or vinculum over compound quantities, thus $A + B$. And his method of arrangement is to place the homogeneum comparations, or absolute known term on the right-hand side alone, and all the terms that contain the unknown quantity, with their proper signs, on the other side. He somewhat improved the rules and modes of reduction for cubic and other equations; he showed how to change the root of an equation in a given proportion; he deduced the cubic and biquadratic, &c. equations from quadratics, not in Harriot's way by composition, but by squaring and otherwise multiplying certain parts of the quadratic; and as some quadratic equations have two roots, the cubic and other equations raised from them will also have two roots and no more. In this way Vieta perceived the relation which the two roots bear to the co-efficient of the two lowest terms of cubic and other equations, when they have only two terms, namely, by comparing them with similar equations thus raised from quadratics; and, vice versâ, what the roots are in terms of such co-efficients. He also made some observations on the limits of the two roots of certain equations; he stated the general relation between the roots of certain equations and the co-efficients of the terms, when the terms are alternately plus and minus, and none of them are wanting, or the roots all positive. He extracted the roots of affected equations by a method of approximation similar to that for pure powers; and moreover, he gave the construction of certain equations, and exhibited their roots by means of angular sections. See Equations and Negative Signs, under which articles, the system of baron Maferes and Mr. Frenel, will be particularly noticed.

In the History of Algebra, Albert Girard, an ingenious Dutch or Flemish mathematician, already mentioned, as the editor of Stevinus's arithmetic, who died about the year 1633, deserves particular notice. Amongst his works, he published "Invention Nouvelle en l'Algebre, tant pour la Resolution des Equations, que pour reconnatre le nombre des Solutions qu'elles recoivent, avec plusieurs choises qui font necessaires a la perfection de cette divine Science;" printed at Amsterdam in 1629, 4°. From an analysis of this work, it appears that Girard was the first person who understood the general doctrine of the formation of the co-efficients of the powers from the sums of the roots, and their products, &c. He was also the first who understood the use of negative roots in the solution of geometrical problems; who spoke of the imaginary roots, and understood that every equation might have as many roots real and imaginary, and no more, as there are units in the index of the highest power, and who applied the denomination of quantities left than nothing to the negative; and he was the first person who discovered the rules for summing the powers of the roots of any equation.

The next person who claims particular notice in the history of this science is Thomas Harriot, who died at the age of 50 years in 1621, and whose Algebra was published by his friend Walter Warner, in 1631. The book is a folio volume, and entitled, "Artis Analyticae Praxis, ad Algebrae Vol. I."
geometrical conceptions adapted to it. He gives also a good tract on angular sections; and concludes the work with the

demological resolution of affected equations, in the manner of

Vieta, but more explicit.

In 1637, Des Cartes first published his geometry, which

can be considered as an application of algebra to geometry,

and not as a separate treatise on either of these sciences. As

Dr. Wallis has manifested too great a degree of partiality to

our countryman Harriot, and ascribed to him discoveries which

had been made by Vieta and others; and as Bombelli and

M. de Guin, in the Memoirs of the Academy of Sciences for

1741, cited in the last edition of the Encyclopaedia, have de-

voted far into the other extreme, in vainly extolling the dis-

coveries of Vieta, and the said of Des Cartes, to the prejudice

of Harriot, we shall avail ourselves of the analysis of Dr.

Hutton in giving a particular account of the improvements

and inventions of Des Cartes, that our readers may be able to

form their own judgment in this controversy. Montucla

indeed seems to have given an impartial account of the

discoveries both of Harriot and Des Cartes, in-

termined with reflections, which some may think

less candid than they ought to have been, on our illustrious coun-

tyman Dr. Wallis. Hist. des Math. tom. ii. p. 106—

186. This excellent historian of the mathematical sciences

acknowledges, that Des Cartes might possibly have been in-
debted to Harriot, though he thinks it very probable that the

principal discoveries of his geometry were anterior to the

date of the work of the English author. It ought however to be

recollected, that the work of Harriot was posthumous,

that he lived to the age of 60, and that his discoveries, at a

period when the spirit of enquiry was excited, might have

been communicated to men of science, between whom an in-

tercourse subsisted, long before he died. Montucla, by way

of balancing the account between Des Cartes and Harriot,

or rather between Wallis and the partial advocates of Des

Cartes, intimates, that if Des Cartes was indebted to Harriot,

the latter was under no less important obligations to Vieta,

whose works were published before the year 1600. To

strengthen the presumption that this might have been the case,

he alleges, on the authority of Sherburne, the translator

of Manilius, that Vieta had for some time employed an

English secretary, or amanuensis, whose name was Nathaniel

Torporey: and as this Torporey was frequently in familiar

intercourse with Harriot at the table of the Duke of Nor-

tumberland, he suggests the probability of his having com-

municated the ideas and manuscripts of Vieta, of which he

was the depository, to Harriot.

The geometry of Des Cartes (Apud Opera. tom. iii.

Franco. ad Moenum, 1695. &c.) consists of three books.
The first is entitled, "De Problematis, quae confrunt pot-

funt, adhibendo tantum rectas lineas et circulos." In this

book the author shews how to accommodate arithmetical

computation to geometrical operations. For this purpose

he assumes a line to represent unity, and then, by means of

proportions, teaches the method of multiplying, dividing,

and extracting of roots by lines. He proceeds to explain his

mode of notation, which is not different from that of other

authors. Alluming $a$ and $b$ for two quantities, their sum

is expressed by $a+b$, their difference by $a-b$, their product

by $ab$, their quotient by $\frac{a}{b}$, the square of $a$ by $aa$ or $a^2$, its

cube by $a^3$, &c. the square root of $a^2+bb$ by $\sqrt{a^2+bb}$,

and the cube root by $\sqrt[3]{a}$. The resolution of

equations as there are unknown lines or quantities, and that all

of them must be reduced to one final equation, by exter-

minating all the unknown letters except one; so that the final

equation will appear in the following forms, the character

will be substituted for $=, =$, and the highest term or

power being on one side of the equation, and the other terms

with their proper signs on the other side:

$$a \to b, or,$$

$$a^2 \to \pm ab \to b^2, or,$$

$$a^3 \to \pm a^2b \to b^3, or,$$

$$a^4 \to \pm a^3b \to b^4, &c.$$

Having defined plane problems, or such as can be re-

solved by right lines and circles, described on a plane su-

perficies, and having in the final equation only the $2d$ power

of the unknown quantity, he constructs such equations or

quadratics by means of the circle, and thus geometrically in-

vestigates the positive root or roots. But if the lines, by

which the roots are determined, neither cut nor touch, he

observes that the equation in this case has no possible root, or

that the problem is impossible. This book closes with the alge-

braical solution of the celebrated problem, considered by the

ancients, which is that of finding a point, or the locus of all

the points, from which if a line be drawn to meet any num-

ber of given lines in given angles, the product of the seg-

ments of some of them shall have a given ratio to that of the

rest.

The second book is entitled, "De Natura Liniarum Con-

vexarum." This is the first treatise of the kind on curve lines

produced by the moderns. The nature of the curve is here

expressed by an equation, containing two unknown or

variable lines, and others that are known or constant, as

$$y^3 \to c^2y \to - \frac{c^2y}{b} \to ay \to - ac.$$

See Curve. We have in this

book a discovery of importance, as it is the first step towards

the arithmetic of infinites; and that is the method of tan-

gents, or of drawing a line perpendicular to a curve at any

point, which is an ingenious application of the general form

of an equation, generated in the method of Harriot, that

has two equal roots, to the equation of the curve. See Tan-

gent.

The third book, entitled, "De Constrictione Problematum

Solidorum, et Solida affinedentum," commences with remarks

on the nature and roots of equations; and the author ob-

serves, that they have as many roots as dimensions; and he

shews, after Harriot, that they may be obtained by multi-

plying a certain number of simple binomial equations to-

gether, as $x^2 \to 20 x \to x-3 \to 0$, and $x-4 \to 0$, which pro-

duce $x^3 \to -6xx+26x=24 \to 0$, in which equation $x$ has

three dimensions, and also three values, viz. 2, 3, and 4. He

here remarks, that some equations have their roots false, as,

or as he expresses it, less than nothing, called by us negative,

and thee he contradistinguishes them to those that are true

or positive, which Cardan had before done. F. C. Let $x+5\to 0$

be multiplied by $x^2 \to -5xx+2 x \to 24 \to 0$, and we shall

have $x^3 \to 4x^2 \to 19xx+10x=24 \to 0$, in which equation

three roots, viz. 2, 3, and 4 are true, and one, viz. 5,

false. From the generation or composition of equations by

multiplication Des Cartes naturally deduces their redu-

tion, depression, or decomposition, by dividing them by the

binomial factors which compose them, and hence he ob-

serves, that this divisor is one of the binomial roots, and that

there can be no more roots than dimensions, or than such as

form with the unknown quantity $x$ binomials that will ex-

actly divide the equation, as Harriot had before shewn. Our

author adverts to other properties, most of which had been no-

ticed before; e. g. that equations may have as many true roots

as the terms have changes of the signs + and −, and as many

false
false ones as successions of the same signs; which had before
been partly shewn by Cardan and Vieta from the relation of
the co-efficients and their signs, and more fully by Harriot.
Hence Des Cartes was led to adopt Cardan's method of
changing the true roots to false, and the false to true, by
merely changing the signs of the even terms. He then di-
rects his attention to other reductions or transmutations
caused by Cardan, Vieta, and Harriot; such as increasing
or diminishing the roots by any quantity, taking away the se-
cond term, and altering the roots in any proportion, and thus
extracting the equation from fractions and radicals. Having
observed (p. 76.) that the roots of equations, both true and
false, may be either real or imaginary, which imaginary roots
were first noticed by Albert Girard, as in the equation
\[ x^3 - 5xx + 13x - 10 = 0, \]
that has only one real root, viz. 2: he proceeds to the depre-
ssion of a cubic equation to a quadratic or plane problem, &c. &c.
that it may be constructed by the circle, by dividing it by the other
of the binomial factors, which, in Harriot's method, compose the equation. As Pe-
laterius had shown that the simple root is one of the divisors
of the known term of the equation, and Harriot had ob-
served that this term is the continual product of all the roots:
Des Cartes tries all the simple divisors of that term, till he
finds one of them, which connected with the unknown quan-
tity \( x \) by \( + \) or \( - \), will exactly divide the equation: and the
same process serves for higher powers than the cube. But
when a divisor cannot be found in this way, in order to de-
press a biquadratic equation into a cubic one, he gives a new
rule for dividing it into two quadratics, by means of a biquad-
ric equation, in the following manner (p. 79, &c.): Let
the given biquadratic equation be \( x^2 + px + q \); &c. &c.
and suppose it composed of these two
\[ x^2 + px + q = 0, \]
\[ x^2 + px + q = 0, \]
in which two quadratic equations the sign of \( \frac{1}{2}p \) must be the
same with the sign of \( p \) in the given equation; and in the
first of them, having \( + px \), the sign of \( \frac{1}{2}p \) must be the
with that of \( q \) or \( -q \), and in the second quadratic, having \( -px \),
its sign must be \( -q \); and \( + px \) vice versa. Then find the root
\[ \frac{\sqrt{y^2 + 4y + 4q}}{2}, \]
of the following cubic equation, viz. \( y^3 + 2py^2 + 2pqy + q^2 = 0 \),
in which the sign of \( 2py^2 \) is the same with that
of \( p \) in the given biquadratic, but the sign of \( 4p \) contrary to
that of \( r \) in the same equation; and the value of \( y \), deduced
hence, and substituted for it in the two quadratic equations,
and their two pairs of roots being taken, there will be the
four roots of the proposed biquadratic. \( E. G. \)
Let the bi-
quadratic be \( x^4 + 4xx - 8x + 35 = 0 \), for which must be
substituted \( y^2 - 8y + 123y - 64 = 0 \), because the quan-
tity called \( y \) being in this case \( 4y - 8y \) must be substi-
tuted for \( 2py^2 \), and \( r + 35, + \frac{16}{140} \), or \( -124y \),
must be substituted for \( \frac{4py^2}{-4} \); and \( q \) being \( 8, -q \) will
be \( -64 \). And so on. In the same manner, says
Des Cartes, may equations of the 6th power be reduced to
those of the 5th, and those of the 8th power to those of the
7th, &c. The investigation of this rule is not given by Des
Cartes; but it has been evidently done by assuming indeter-
minate quantities after the manner of Ferrari and Cardan, as
co-efficients of the terms of the two quadratic equations, and
after multiplying the two together, determining their values
by comparing the resulting terms with those of the proposed
biquadratic. Des Cartes, after these reductions, in
order to simplify and depredate the equations as much as pos-
ible, proceeds to give the construction of cubic and other
higher problems, or of cubic and higher equations by means
of parabolas and circles; observing, that the false roots are
denoted by the ordinates to the parabola lying on the con-
trary side of the axis to the true roots: and he closes the book
with illustrating these constructions by various problems con-
cerning; the extraction of an angle, and the investigation of
two or four mean proportionals.

Of the improvements contained in this work, it is ob-
served by Dr. Hatton, that Des Cartes, with a view to the
more easy application of equations to the construction of
problems, mentions many particulars concerning the nature
and reduction of equations, and states them in his own lan-
guage and manner, which is usually more clear and explicit
than that of others, and frequently accompanied with his
own improvements. Here he chiefly followed Cardan, Vieta,
and Harriot, and especially the last, explaining some of their
rules and discoveries more distinctly, and with some little va-
ration in the notation, in which he puts the first letters of the
alphabet for known quantities, \( a, a, r, &c. \) and \( x, \) \( \alpha \) for \( x \). But Hugone
had two years before used the same numeral exponents. Des
Cartes explained or improved most parts of the reduction of
equations, in their various transmutations, the number and
nature of their roots, true and false; real and imaginary, as
he calls them, or as they are denominated by Girard, in-
volved; and also the depression of equations to lower de-
grees. His inventions and discoveries comprehend the applica-
tion of algebra to the geometry of curve, the construction
of equations of the higher orders, and a rule for resolving bi-
quadratic equations by means of a cubic and two quadratics.

Fermat, who published Diophantus's arithmetic with valu-
able notes, was a contemporary of Des Cartes, and also a
competitor for some of his most valuable discoveries. This
ingenious mathematician, before the publication of Des
Cartes's geometry, had applied algebra to curve lines, ex-
pressed them by an algebraic equation, and by them con-
strued equations of the third and fourth orders; and he
had also discovered a method of tangents, and a method de-
maxima et minimis, approaching very nearly to the method
of fluxions or increments, in the manner of treated the prob-
lems as well as in the algebraic notation and process. Fermat
was also distinguished by his knowledge of the Diophantine
problems.

At the period to which we have now referred, algebra had
acquired a regular and permanent form; and from this time,
the writers on the whole, or detached parts of this science,
became so numerous, that the limits of this article will
fearfully admit our reciting their names and publications, and
much less doing justice to the improvements which this
branch of mathematical science derived from their perform-
ances. In the course of our biographical articles, and on
other occasions, we shall endeavour to supply the defects of
the present cursory notice.

The geometry of Des Cartes engaged the attention of fe-
veral mathematicians in Holland, where it was published; and
also in France and England. Francis Schooten, professor of
mathematics at Leyden, was one of the first cultivators of
the new geometry; and in 1649, he published a translation
of Des Cartes's geometry, from the French into Latin, with his
own commentary and notes by M. de Beaune. In 1659,
appeared an enlarged edition in two volumes, with several
additional pieces by De Beaune, Hidde, Van Herret, De
Witt, with some tracts by Schooten, the editor. Rabbel,
a Jesuit, published an elaborate commentary on the fame
work;
work; which was enriched with notes by James Bernouilli, and printed at Basle. Huygens also directed his attention to the algebraic analysis, and his inventions are cited by Schooten, who was his pupil. Stifflus, canon of Liege, published in 1659, "Mefolabum, seu ducis proportionalita per Circulum et Ellipin, vel Hyperbolam, infinitis mediae exhibitor," a new edition of which appeared in 1668, containing much valuable matter relating both to algebra and geometry.

But before the time of Des Cartes, as well as after the publication of his geometry, algebra engaged the attention of mathematicians. In 1619 several papers by Lodge, Collen, or Cavelin, were translated from Dutch into Latin, and published at Leyden, by W. Snell; one of which is a particular treatise on Surds. In 1624, Bacher published an edition of Diophantus with notes, and Fermat's edition, with additions, appeared in 1670. The same author published, in 1624, a treatise of mathematical recreations under the title of "Problemes plaisans et delectables." Herigone, in 1634, published at Paris the first course of mathematics in 6 vols. 8vo.; containing a treatise on algebra, and bearing, says Hutton, evident marks of originality and ingenuity, in which he uses the notation by small letters, introduced three years before by Harriot; he also expresses plus by +, minus by -, and 1 for equality, with other abbreviations. In his notation of powers and roots, he annexes to the letter the numeral exponents. Cavalierius, in 1635, published his "Individibvs," and introduced a new sign in analytical science and new modes of computation. He was followed in 16,0 by Roberval, whose improvements in analytics were published in the early volumes of the memoirs of the Academy of Sciences, by De Billy, who published in 1643, "Novv Geometrlas Chalis Algebra," and in 1670, "Diophantus reduvis;" and by Renaldine, who, in 1655, published in 4to. "Opus Mathematicum," both ancient and modern, with mathematical resolution and composition, enlarged and republished in folio, in 1662, 1667, and 1682, under the title of "Ars analytica Mathematica, in tres partes distributa, etc." This author uses the parentheses \((a+b)\) as a vinculum. In 1675, Dr. Wallis published his "Arithmeticus Infinitorum," which greatly improved the Individibvs of Cavalierius, and led the way to infinite series, the binomial theorem, and the method of fluxions. The "Algebra Rhoni, (or Rahni) Germanici," was published in 1659, and translated into English in 1668, by Mr. Thomas Brancner, with alterations and additions, by Dr. John Pell, who used a peculiar method of registering the steps of an algebraic proof by means of marks and abbreviations in the margin, explaining each line or step, as Harriot had before done in words at length. Hemeling was also the author of a German work, resolui 600 questionis, published in 1682. Mr. Kinckluyfien, in 1661, published a treatise of algebra in Dutch, which Sir Isaac Newton, when professor of mathematics at Cambridge, used and improved, and which he designed to republish, with his method of fluxions and infinite series, but was prevented by the accidental burning of one of his papers. In 1667, Jacob Ferguson published his "Labyrinthus Algebrae," in 4to. Dutch; and in 1679, De Graaf gave a course of mathematics, in the same language and size. In 1665 or 1666, Sir Isaac Newton made several of his most valuable discoveries, though they were not published till a later period; such as the binomial theorem, the method of fluxions and infinite series, the quadrature, rectification, &c. of curves, the investigation of the roots of all sorts of equations, both numerical and literal, in infinite converging series, the reduction of series, &c. M. Francicle, in 1666, communicated several tracts concerning combinations, magic squares, triangular numbers, &c., which were printed in the early volumes of the Memoirs of the Academy of Sciences. In 1668, Mercator published his "Logarithmotechnia," in which he gives the quadrature of the hyperbola, by means of an infinite series of algebraic terms, found by dividing a simple algebraic quantity by a compound one; which operation was now first made public, though Newton had before expanded all sorts of compound algebraic quantities into infinite series. The demonstration of Mercator's quadrature of the hyperbola and other finite series, was published in this year, by James Gregory, in his "Exercitationes Geometricae," and in the same year Lord Bruncker published in the Philosophical Transactions, his quadrature of the hyperbola by another infinite series of simple rational terms, of which he had been in possession since the year 1657, when Dr. Wallis announced it to the public. His series for the quadrature of the circle had been published by Wallis in his "Arithmetica Infinitorum." In 1669, Dr. Barrow published his "Optical and Geometrical Lectures," abounding with profound researches on the dimensions and properties of curve lines, and containing his method of tangents, by a mode of calculation similar to that of fluxions or increments, and little differing from it, except in the notation. In the 13th lecture, (p. 277, Stow's Ed.) the subject of which is equations, he adopts a new method of explaining their nature, different from that of Vieta, who illustrates it by the analogy of the terms, or that of Harriot and Des Cartes, by multiplying them into one another. His method of explaining them depends upon the description of lines adapted to each, and thus he investigates the nature and number of their roots, and the limits of their magnitudes, considering the subject as a branch of the maxima and minima.

The "Elements of Algebra" were published by John Kersey in 1675, in 2 vols. folio, containing the illustration of the science and of the nature of equations, the explanation of Diophantus's problems, and many additions concerning mathematical composition and resolution, from Ghetaldus. This work, says Hutton, is very ample and complete. The first part appeared in 1673, and the second in 1674. In 1675, Prellet published his "Nouveaux Elements des Mathematiques," to which the author, with a preface hardly executable, has prefixed a dedication of the work to God Almighty. In 1677, Leibnitz discovered his "Methodus Differentialis," or made a variation in Newton's fluxions or extended Barrow's method, of which he gave the first influence in the Leipsic acts for 1684. See EQUATIONS. In the same acts for 1682, he communicated an improvement of infinite series, and a simple formula for the quadrature of the circle. An amplification of Wallis's arithmetic of infinites was published in folio, in 1682, by Isaac Bulliald, entitled, "Opus novum ad Arithmeticae Infinitorvm." Tschirnhaus, in 1687, communicated a memoir in the Leipsic acts, proposing the extraction of the roots of all equations in a general way; but his method did not succeed. Baker's "Clavis Geometica Catholica, Geometrica Key, or Gate of Equations unlocked," was published in Latin and English in 1684. This was an improvement of Des Cartes's construction of all equations under the 5th degree, by means of a circle and parabola for all equations, any diameter being used instead of the axis of the parabola. Dr. Wallis's "Treatise of Algebra," both Historical and Practical, having the original, progress, and advancement of it from time to time," was published in 1685, in folio. In 1687, Dr. Hall; communicated in the
the Philosophical Transactions the construction of cubic and biquadratic equations, by a parabola and circle, with improvements of the methods of Descartes, Baker, &c.; and also a memoir on the number of the roots of equations, with their limits and signs. M. Rolle, in 1690, published in 4to. "Traite d'Algebre," in 1699, "Une methode pour reduire les questions indeterminees;" and in 1704, "Memoires sur l'infereure des Tangentes," and some other pieces. Joseph Raphson, in 1690, published his "Analyse Equationum Universalis," which is a general method of approximating to the roots of equations in numbers. His "History of Fluxions" was published in English and Latin in 1715. Dechales published his "Curius quos Mundus Mathematicos," in 4 vols. folio, in 1690. About the year 1691, &c. De Lagny published many pieces on the resolution of equations in numbers; and in 1693 appeared a little volume, entitled, "Synopsis Algebrae, opus posthumum Johannis Alexandri," An ingenious tract on the numeral extraction of all roots, without any previous reduction, was communicated in the Philosophical Transactions, by Dr. Halliky in 1693. This tract is annexed to some editions of Newton's Universal Arithmetic. Craig published, in 1694, in 4to. his treatise, "De figur. curvill quadratis et locis geometricis," in which he proposed new formulae for the construction of equations: and this method was improved by Herman in 1737, in Mem. of Peterborough. Mr. John Ward of Chester, published in 1690, "A Compendium of Algebra;" and in 1706, the first edition of "The Young Mathematician's Guide," which has been much used. In 1696 the "Analyse des Infiniments Petits," of the Marquis de l'Hospital, was published, and a posthumous treatise by the same author, entitled, "Traite Analytique des Sections Coniques, et le Construit de Lieux Geometrique;" was published in 1707. Mr. Ab. Demoivre, in 1697, and succeeding years, furnished the Philosophical Transactions with various papers, containing improvements in algebra; in 1697, a method of raising an infinite monomial to any power, or extracting any root of the same; in 1698, the extraction of the root of an infinite equation; in 1705, an analytical solution of certain equations of the 3d, 5th, 7th, &c. degrees; in 1722, of algebraic fractions, and recurring series; in 1738, the reduction of radicals into more simple forms; and in 1739 he published "Miscellanea Analytica de Seriesbus et Quadraturis," containing great improvements in series, &c. Mr. Richard Sault published, in 4to. "A new Treatise of Algebra, applied to numeral questions, and geometry; with a converging series for all manner of affected equations," which series is Raphson's method of approximation, which had been lately published. In 1698 Hugo d'Omer published his "Analyse Geometrica, &c." in which, by combining the algebraic analysis of the moderns with that of the ancients, he resolved in an elegant and simple manner various problems. In 1695, Mr. Christopher published at Naples, in 4to. a tract, entitled, "De Construccionis Equationum." Ozarana's algebra, containing the Diophantine analysis, was published in 1702, his mathematical dictionary in 1691, and his course of mathe-

A GEOMETRY.

matics, in 5 vols. 8vo. in 1693. In 1705, Dr. Harris, the author of the "Lexicon Technicum," published a small piece on algebra and fluxions. M. Guinée published, in 1705, his "Application de l'Algebre a la Geometrie," in 4to. In 1706, Mr. Jones published his "Synopsis Palmariorum Matheseos," which is an useful compendium of the mathematical sciences; and in 1714, he published in 4to. a collection of Sir Isaac Newton's papers, entitled, "Analyse per quantitatum seres, fluxiones, &c. differentiae; cum enumeratione literarum tertii ordinis." The first edition of Newton's "Arithmetica Universalis, five de Composicion et Resolutione Arithmetica liber," was published by Whiston in 1737, and many editions have been published since. It is of course included in Horsey's edition of Newton's works. This treatise was the text book of the author at Cambridge; and though not designed for publication, it contains many very considerable improvements in analytics; particularly in the nature and transmutation of equations; the limits of their roots; the number of impossible roots; the invention of divisors, both tard and rational; the resolutions of problems, arithmetical and geometrical; the linear construction of equations; the approximation to the roots of all equations, &c. Commentaries have been published on this work for the amusement of beginners, by S. Gravereau, Cuthjon, Wilder, &c. The "Analyse Demontree" of Runcenn, was published in 4to. in 1708, and in 1714, "La Science du Calcul," and reprinted with additions in 1736, under the title of "Ufage de l'Analyse," &c. In 1709 an English translation of Alexander's algebra was published, with an appendix, by Humphry Ditton. In 1725, Dr. Brooke Taylor published his valuable work, entitled, "Methodus Incrementorum," and in the Philosophical Transactions for 1718 an improvement of the method of approximating to the roots of equations in numbers. M. Nicole, in 1717, communicated, in the Memoirs of the Academy of Sciences, a tract on the calculation of finite differences, and in following years various other tracts on the same subject, and also on the resolution of equations of the third degree, and on the irreducible case in cubic equations. Ronayne, in 1717, published a treatise on algebra; and in the same year Mr. James Stirling published a work of improvement on analytics, entitled, "Lineae tertii Ordinis," and in 1730, "Methodus Differentiatis; five tractatus de summatione et interpolatione serierum infinitarum," with great improvements on infinite series. Maclaurin, in 1726 and 1729, gave, in the Philosophical Transactions, tracts on the imaginary roots of equations, and afterwards his "Algebra" was published from his posthumous papers, with its application to curve lines. S. Gravereau's algebra, with a commentary on Newton's Un. Arithm. appeared in 1727; and in 1738 Mr. Campbell communicated, in the Philosophical Transactions, an ingenious paper on the number of impossible roots of equations, and the papers of Maclaurin and Campbell were annexed to Gravereau's edition of the "Arithm. Univ." at Leyden in 1732. Leceno, a Jesuit, published the "Arithm. Un." with an imperfect commentary, in 3 vols. 8vo. in 1752. Wallis's algebra was published in 1732, in his "Elementa Matheseos Universals," in 5 vols. 4to. Mr. John Kirkby's arithmetic and algebra were published in 1735, and in 1748 his doctrine of ultimates. Several improvements in series, and other parts of algebra, are contained in Mr. Thomas Simpson's "Elements," published in 1746, in his "Differationes," 1747; and in his Treats., 1753; and also in his "Algebra," first printed in 1745, and in his "Select Exercises," in 1752. In 1740, Saunderson's "Elements of Algebra," were published in 2 vols. 4to. M. de la Caille, published in 1734, "Lesons de Mathematique, ou Elements d'Algebre et Geometric," and in the same year M. de Gua, in the Memoirs of the Academy of Sciences, communicated two articles on the number of positive, negative, and imaginary roots of equations, with an historical account of the improvements in algebra, in which he severely cenures Wallis for his partiality, whilst he himself is, at least, equally faulty. M. Clairaut published his "Elements d'Algebre," in 1749, in which he has many improvements.
improvements, particularly with reference to the irreducible cale in cubic equations. A fifth edition of this valuable treatise, with notes and additions, was published at Paris in 1797, in 2 vols. 8vo. He has also several papers on analytics, in the Memoirs of the Academy of Sciences. In 1747, M. Fontaine gave, in the same memoir, a paper on the resolution of equations, and other papers in subsequent memoirs. In 1748, Madelemelle M. G. Agne, published at Milan in Italian, “Analytical Institutions, in 2 vols. 4to. M. Caffit- tion, in 1761, published in 2 vols. 4to. Newton’s Universal Arithmetic, with an ample commentary. In 1763, Mr. Emerson published his “Increments,” and in 1764 his “Algebra.” Mr. Landen published his “Refined Analysis,” in 1764, his “Mathematical Lucubrations,” in 1765, and his “Mathematical Memoirs, in 1768. M. Euler published his “Elements of Algebra,” in the German language in 1770; and in 1774, a French translation was published, by J. Bernoulli, with the analysis of indeterminate problems, by M. de la Grange. An English translation was published in 1797, in 2 vols. The memoirs of Berlin and Petersburg abound with various improvements on series and other branches of analysis by this celebrated mathematician. Dr. Waring, late of Cambridge, has communicated several valuable papers to the Philosophical Transactions, and many of his improvements, are contained in his separate publications, particularly the “Meditations Algebraicæ,” published in 1779; the “Proprietates Algebraicæ Curvarum,” in 1772; and the “Meditations Analyticas,” in 1776. The first of these publications deserves particular notice. The first chapter treats of the transformation of algebraical equations into others, of which the roots have given algebraical relations to the roots of the given equations. The limits and number of impossible and affirmative and negative roots of algebraical equations are the subjects of the second chapter. The third chapter comprehends the investigation of the roots of equations or irrational quantities, which have given relations to one another, the resolution of equations, &c. &c. The fourth chapter is principally conversant concerning more algebraical equations and their reduction to one; and the fifth chapter treats of rational and integral values of the unknown quantities of given equations. Francis Mañeres, cæ, claims honourable mention, not only as an original writer, who has contributed to the explication and improvement of some of the most abstruse and yet most interesting branches of algebra and analysis, but on account of the labour and expense which he has bestowed on the publication of the “Scriptorium Logarithmicæ,” in five vols. 4to. 1791, 1796, &c. containing many curious and useful tracts, which are thus preferred from being lost, and many valuable papers of his own on the binomial theorem, series, &c. After this detail, for which we are in a considerable degree indebted to the researches of Montucla and Dr. Hutton, many authors who have, in separate treatises or in occasional clays, contributed to the improvement of algebra in general, or some particular branches of it, or who have published treatises on the science, still remain unnoticed; and we must content ourselves with merely mentioning Franciscus Caligarius, Rudolphus, Adam Giga or Ricu, Butco, R. Westwood, Ant. Maria Floridus, Lazarus Schonerus, Bernard Salignac, Leonard Digges, and Robert Norman, in the 16th century, Christopher Clavius, in 1668, Georgius Henricus, in 1679, Schaffran Kurz, Cognet, Lalonde, Degrave, MeCher, the Bernoullis, Malbranche, Wells, D. 1on, Manfre, Regnault, Rowing, Hammond, Lorgna, Henns, de la Grange, de la Place, Bertrand, Kohnius, Hales, Maikelyne, Vince, Wood, Manning, Frend, Boneycaile, &c. &c. &c.}

**Algebra** is a peculiar kind of *Arithmetic*, which takes the quantity sought, whether it be a number, or a line, or any other quantity as if it were granted; and by means of one or more quantities given, proceeds by a train of deduction, till the quantity at first only supposed to be known, or at least some power of it, is found to be equal to some quantity or quantities which are known, and consequently itself is known.

**Algebra** is of two kinds, *numerical* and *literal*. **Algebra, numerical, or vulgar**, is that which is chiefly concerned in the resolution of arithmetical questions. In this, the quantity sought is represented by some letter or character; but all the given quantities are expressed by numbers. Such is the algebra of the more ancient authors, as Diophantus, Paucius, Stifelius, &c. This is thought by some to have been an introduction to the art of keeping merchants’ accounts by double entry.

**Algebra specious, or literal, or the new algebra**, is that in which all the quantities, known and unknown, are expressed or represented by their species, or letters of the alphabet. There are instances of this method from Cardan and others about his time; but it was more generally introduced and used by Vieta. Dr. Wallis (“Algebra, p. 66”) apprehends, that the name of specious arithmetic applied to algebra is given to it with a reference to the fence in which the Civilians use the word species. Thus, they use the names Titius, Sermunius, Cambus, and the like, to represent indefinitely any person in such circumstances; and cafes so propounded, they call species. Vieta, accustomed to the language of the civil law, gave, as Wallis supposes, the name of species to the letters A, B, C, &c. which he used to represent indefinitely any number or quantity, so circumstantial as the occasion required.

This mode of expression frees the mind and imagination from that struggle or effort, which is required to keep several matters, necessary for the discovery of the truth invested, present to the mind; for which reason this art may be properly denominated metaphysical geometry. Specious algebra is not, like the numeral, confined to certain kinds of problems; but serves universally for the investigation or invention of theories, as well as the solution and demonstration of all kinds of problems, both arithmetical and geometrical. The letters used in algebra do each of them separately represent either lines or numbers, as the problem is either arithmetical or geometrical; and together, they represent planes, solids, and powers more or less high, as the letters are in a greater or less number. For instance, if there be two letters, \(a, b\), they represent a rectangle, whose two sides are expessed, one by the letter \(a\), and the other by \(b\) so that by their mutual multiplication they produce the plane \(a \cdot b\). Where the same letter is repeated twice, as \(a^2\), they denote a square. Three letters \(a, b, c\), represent a solid or a rectangular parallelepiped, whose three dimensions are expressed by the three letters \(a, b, c\); the length by \(a\), the breadth by \(b\), and the depth by \(c\); so that by their mutual multiplication, they produce the solid \(a \cdot b \cdot c\).

As the multiplication of dimensions is expressed by the multiplication of letters, and as the number of these may be so great as to become incommensurable, the method is only to write down the root, and on the right hand to write the index of the power, that is, the number of letters of which the quantity to be expressed consists; as \(a, a^2, a^3, \text{ &c. the last of which signifies as much as a multiplied four times into itself; and so of the rest. But as it is necessary, before any progress can be made in the science of algebra, to understand the method of notation, we shall here give a general view of it. In
In algebra, as we have already stated, every quantity, whether it be known or given, or unknown or required, is usually represented by some letter of the alphabet; and the given quantities are commonly denoted by the initial letters, $a, b, c, d, \ldots$ and the unknown ones by the final letters, $u, v, w, x, y$. These quantities are connected together by certain signs or symbols, which serve to shew their mutual relation, and at the same time to simplify the science and to reduce its operations into a few compasses. Accordingly the sign $+$, plus or more, signifies that the quantity, to which it is prefixed, is to be added, and it is called a positive or affirmative quantity. Thus $a + b$ expresses the sum of the two quantities $a$ and $b$, so that if $a$ were 5, and $b, 3, a + b$ would be 5 or 3, or 8. If a quantity have no sign, $+$ plus is understood, and the quantity is affirmative or positive. The sign $-$, minus or left, denotes that the quantity which it precedes is to be subtracted, and it is called a negative quantity. Thus $a - b$ expresses the difference of $a$ and $b$; so that if $a$ being 5, and $b, 3, a - b$ or $5 - 3$ would be equal to 2. If more quantities than two were connected by these signs, the sum of those with the sign $+$ must be subtracted from the sum of those with the sign $-$. Thus, $a + b - c - d$ represents the quantity which would remain, when $c$ and $d$ are taken from $a$ and $b$. So that if $a$ were 7, $b, 6, c, 5,$ and $d, 3, a + b - c$ or $d$ or $7 + 6 - 5 - 3$ or $13 - 8$ would be equal to 5. If two quantities are connected by the sign $\times$, as $a \times b$, this mode of expression represents the connection of $a$ and $b$ when it is not known which of them is the greatest.

The sign $\times$ signifies that the quantities between which it stands are to be multiplied together, or it represents their product. Thus, $a \times b$ expresses the product of $a$ and $b$; $a \times b \times c$ denotes the product of $a, b,$ and $c$; $a + b + c$ expresses the product of the compound quantity $a + b$ by the simple quantity $c$; and $a + b + c \times a - b + c + a + c$ represents the product of the three compound quantities, multiplied continually into one another; so that if $a$ were 5, $b, 4,$ and $c, 3,$ then would $a + b + c \times a - b + c + a + c$ be $12 \times 4 \times 8$, or $864$. The line connecting the simple quantities and forming a compound one, placed over them, is called a vinculum. Quantities that are joined together without any intermediate sign form a product; thus $a b$ is the name with $a \times b$, and $a b e$ the name with $a \times b \times c$. When a quantity is multiplied into itself, or raised to any power, the usual mode of expression is to draw a line over the quantity and to place the number denoting the power at the end of it, which number is called the index or exponent. Thus, $a + b$ is the name as $a + b + a + b$ or second power, or square, of $a + b$ considered as one quantity; and $a + b^2$ denotes the name as $a + b \times a + b$ or $a + b$, the third power, or cube, of $a + b$. In expressing the powers of quantities represented by single letters, the line over the top is usually omitted; thus, $a^2$ is the name as $a \times a$ or $a \times a$, and $a^3$ the name as $b \times b \times b$ or $a \times b \times b$ and $a^4 b^3$, the name as $a \times b \times b \times b \times b \times b \times b \times b$. The full point and the word into are sometimes used instead of $\times$, as the sign of multiplication. Thus, $a + b$. $a + c$, and $a + b$ into $a + c$, signify the same thing as $a + b \times a + c$, or the product of $a + b$ by $a + c$. The sign $\div$ is the sign of division, as it denotes that the quantity preceding it is to be divided by the succeeding quantity. Thus $\frac{c}{b}$ signifies that $c$ is to be divided by $b$; and $a + b \div a + c$, that $a + b$ is to be divided by $a + c$. The mark $\frac{1}{2}$ is sometimes used as a note of division; thus, $\frac{a + b}{a + c}$, denotes that $a + b$ is to be divided by $a + c$. But the division of algebraic quantities is most commonly expressed by placing the divisor under the dividend with a line between them, like a vulgar fraction. Thus $\frac{b}{a}$ represents the quantity arising by dividing $b$ by $a$, or the quotient; and $\frac{a + b}{a + c}$ represents the quotient of $a + b$ divided by $a + c$. Quantities thus expressed are called algebraic fractions. See Fraction.

The sign $\sqrt{\text{ }}$ expresses the square root of any quantity to which it is prefixed; thus $\sqrt[2]{25}$ signifies the square root of 25 or 5, because $5 \times 5$ is 25; and $\sqrt{a b}$ denotes the square root of $a b$; and $\sqrt{\frac{a b + b c}{d}}$, or of the quantity arising from the division of $a b + b c$ by $d$; but $\sqrt{\frac{a b + b c}{d}}$, which has the separating line drawn under it, signifies that the square root of $a b + b c$ is to be first taken, and afterwards divided by $d$; so that if $a$ were 2, $b, 6, c, 4$, and $d, 9, \sqrt{\frac{a b + b c}{d}}$ would be $\sqrt{\frac{36}{9}}$ or $2$; but $\sqrt{\frac{a b + b c}{d}}$ would be $\sqrt{\frac{36}{9}}$ or $\sqrt{4}$. $\sqrt{\frac{36}{9}}$ or $\sqrt{4}$ which is 2.

The sign $\sqrt{\text{ }}$ with a figure over it is used to express the cubic or biquadratic root, &c. of any quantity; thus $\sqrt[3]{64}$ represents the cube root of 64; or 4, because $4 \times 4 \times 4$ is 64; and $\sqrt[4]{b a + c d}$ the cube root of $a b + c d$. In like manner $\sqrt[16]{16}$ denotes the biquadratic root of 16, or 2, because $2 \times 2 \times 2 \times 2$ is 16; and $\sqrt[3]{a b + c d}$ denotes the biquadratic root of $a b + c d$; and so of others. Quantities thus expressed are called radical quantities, or Surds; of which those, consisting of one term only, as $\sqrt{a}$ and $\sqrt{a} \sqrt{b}$ are called simple surds; and those consisting of several terms, or numbers, as $\sqrt{a - b}$ and $\sqrt{a - b \sqrt{b} + b}$, are termed compounded surds. Another commodious method of expressing radical quantities is that which denotes the root by a vulgar fraction, placed at the end of a line drawn over the quantity given. In this notation, the square root is expressed by $\frac{1}{2}$, the cube root by $\frac{1}{3}$, the biquadratic root by $\frac{1}{4}$, &c. Thus $\sqrt[3]{3}$ expresses the cube quantity with $\sqrt[3]{3} a$, and $a^3 + b \frac{1}{2}$ the square of the cube root of $a$, and $a^3 + b \frac{1}{2}$ the cube of the cube root of $a$; and $a + \sqrt[3]{2}$ the seventh power of the biquadratic root of $a + z$; and so of others; $a^3 \frac{1}{2}$, is $a$, $a^3 \frac{1}{2}$ is $a$, &c. When the root of a quantity represented by a simple letter is to be expressed, the line over it may be omitted; so that $a$ signifies the same as $a^{\frac{1}{2}}$, and $b^3$ the same as $3^\frac{3}{1}$ or $\sqrt[3]{b}$. Quantities that have no radical sign $(\sqrt{\text{ }}$ or index annexed to them are called rational quantities.

The sign $=$ called the sign of equality, signifies that
the quantities between which it occurs are equal. Thus
\[ 2 + 3 = 5, \] shows that 2 more 3 is equal to 5; and \( x = a - b \) shows that \( x \) is equal to the difference of \( a \) and \( b \).

The mark \( : \) signifies that the quantities between which it stands are proportional. As \( a : b :: c : d \) denotes that \( a \) is in the same proportion to \( b \) as \( c \) is to \( d \); or that if \( a \) be twice, thrice, or four times, &c. as great as \( b \), \( c \) will be twice, thrice, or four times, &c. as great as \( d \).

When any quantity is to be taken more than once, the number which shows how many times it is to be taken must be prefixed; thus \( 5 \) a denotes that the quantity is to be taken 5 times, and \( 3 b c \) represents three times \( b \) and \( c \), and \( 7 \sqrt[2]{a^2 + b^2} \) is to be taken 7 times, &c. The numbers thus prefixed are called co-efficients; and if a quantity have no co-efficient, it is understood, and it is to be taken only once.

Similar or like quantities are those that are expressed by the same letters under the same powers, or which differ only in their co-efficients; thus, \( 3b \), \( 5b \), and \( 8b \), are like quantities, and so are the radicals \( 2 \sqrt{b + c} \) and \( 7 \sqrt{b + c} \).

But unlike quantities are those which are expressed by different letters, or by the same letters with different powers, as \( 2a \), \( 5a^2 \), and \( 3a^3 \).

When a quantity is expressed by a single letter, or by several single letters multiplied together, without any intervening sign, as \( a \), or \( 2ab \), it is called a simple quantity. But the quantity which consists of two or more such simple quantities, connected by the signs + or -, is called a compound quantity; thus, \( a - 2ab + 5a^2c \) is a compound quantity; and the simple quantities, \( a \), \( 2ab \), and \( 5a^2c \), are called its terms or members.

If a compound quantity consists of two terms, it is called a binomial of 3 terms, a trinomial of 4 terms, a quadrinomial, &c. of many terms, a multinomial.

If one of the terms of a binomial be negative, the quantity is called a residual quantity. The reciprocal of any quantity is that quantity inverted, or unity divided by it; thus \( \frac{1}{b} \) is the reciprocal of \( b \), and \( \frac{1}{a} \) is the reciprocal of \( a \). The letters by which any simple quantity is expressed may be ranged at pleasure, and yet remain the same figure; thus \( a \) and \( b \) are the same quantity, the product of \( a \) and \( b \) being the same with that of \( b \) by \( a \). The several terms of which any compound quantity consists may be disposed of in any order at pleasure, provided they retain their proper signs. Thus, \( a - 2ab + 5a^2b \) may be written \( a + 5a^2b - 2ab \), or \( -2ab + a + 5a^2b \), for all these represent the same thing or the quantity which remains, when from the sum of \( a \) and \( 5a^2b \) the quantity \( 2ab \) is deducted.

For the method of performing the several operations in algebra, see Addition, Subtraction, Multiplication, Division, Fraction, Involution, Evolution, Equation, Series and Surd. See also Application of Algebra to Geometry, Binomial Theorem, Construction of Equations, and Reduction of Equations.

Algebra has been also applied to the consideration and calculus of infinites; and from this application of it a new and extensive branch of science has arisen, called the doctrine of Fluxions, or Analysis of Infinites, or the Calculus Differentialis. For an account of the rise and progress of Algebra, as well as other branches of mathematics, see the last and most improved edition of Montucla's Hist. des Mathém. by De La Lande, 4 vols. 4to. Paris, 1794, 1802.

ALGEBRICAL, something that relates to algebra. Thus we say, algebraical characters, or symbols, curves, solutions, &c. An algebraical curve, is a curve, wherein the relation of the abscissae to the ordinates may be defined by an algebraical equation. These are also called geometrical lines, or curves, in contradistinction to mechanical or transcendent ones. See Curve.

ALGEBRAIST, a person skilled in algebra.

ALGEDO, in Surgery, a suppurated gonorrhea, attended with pain in the genital and urinary organs. This name seldom occurs except in old authors. See Gonorrhea.

ALGEDYM ZANO, in Geography, is the name of a considerable chain of mountains in Independent Tartary, which extends from the river Kaik or Ural, towards the Altai range.

ALGEMISI, or Algemesin, a small town of Valencia, in Spain, not far from the river Zueur, near which grow quantities of Pita, as it is called, or American aloe, AGAVE, of which the people make cordage, and the Calatans spin it of sufficient fineness for making lace; it is six leagues south of Valencia, and five north-north-west of Gandia.

ALGONED, or Algobis, in Astronomy, a fixed star of the second magnitude, on the right side of Perseus.

ALGEO, or CARSON, in Geography, a river of Europe.

TURKEY, which runs into the sea, eight miles west-south-west of Olimpia, a town in the Morea.

ALGERANCA, island, one of the Canaries, in the North Atlantic Ocean. N. lat. 20° 23'. W. long. 15° 58'.

ALGERI, or Algiers, a small peopled city of Sardinia, situated near a bay on the Western coast. It is a bishop's see, and has a coral-fishery. It is 79 miles north-west of Cagliari. The bay of Algiers is spacious and affords good anchorage; it is formed by the fourth point of Cape della Caccia on the north, and by a point of land on the south. N. lat. 40° 31'. E. long. 8° 50'.

ALGEZIRA, or Algeriza, a sea-port town of Spain, in the province of Andalusia, on the Straits of Gibraltar, and 5 miles west of it. The Moors entered Spain by this town in 713, and were dispossessed of it in 1344. It is said to have been the first town in which cannon were used. The word Algezira in Arabic signifies an island, and as the harbour is formed by two islands, it has been called in the plural number Algeziras. It was also called Old Gibraltar. The harbour is now decayed, and the town lies in ruins. N. lat. 36° 5'. W. long. 5° 20'.

ALGEZIRA, or Alzora, is also a town of Spain, in the province of Valencia, situated on a small island on the river Xucar, 20 miles south of Valencia. Though the town is small, its silk trade has been extensive.

ALGEZUR, a small town of Portugal, in the province of Algarve, at the mouth of a small river near the Atlantic Ocean, 17 miles north-west of Lagos. It contains about 800 inhabitants.

ALGHEMI, a country of Africa, on the Slave coast.

ALGHISI, Thomas, in Biography. The father of this writer, who was a surgeon of eminence, at Florence, took care to imbue his mind early with the principles of his art. His instructor in anatomy was the celebrated Laurentius Bellinus. At a proper age he was made surgeon to the hospital at Florence, where applying himself particularly to the operation of lithotomy, which he performed with singular facility and success, he acquired considerable reputation. In 1705, he was made doctor in medicine at Padua. In 1707, he published a treatise on lithotomy, in 4to., written in Italian, which contains, Haller says, Bib. Chir. vol. i. p. 580, several original observations, the fruits of his own experience. Exstant etiam, he adds, hujus Authoris, De Mumin Aegyptia involuta peripherei epistola ad Valentinum. He died September 713, being only 44 years of age, in consequence of the amputation of his left hand, which had been wounded by the bursting of a field.

ALGIABARII
ALGIARII, a Mahometan sect of predestinarians, who attribute all the actions of men, good or evil, to the agency or influence of God.

The Algerian people are scattered over a large extent of territory, including two provinces and 1600 inhabitants. King John I. obtained in this way a victory over the Caliphates in 1385.

ALGIDUM, in Ancient Geography, a town of Latium or Italy, between Pompeii and, Alba to the south-west near the town. It belonged to the Equi, according to Dionysius Hal. (lib. xi. tom. i. p. 573.) ed. Oxon. and Livy, (lib. iii. c. 38. tom. i. p. 693. ed. Burman.) and had a temple of Diana on the top of a height called by the same name. This temple was in Greek denominations Artemis, and hence the mountain was called by the same name. It has been supposed that Algida or Algids was deriv ed from gelidus, cold or freezing. on account of the quality of its air. Harcoras refers to this mountain, (lib. i. ed. 21.) "Qua evenque ant gelidum proximitat Algido," said (lib. iii. ed. 23.) "Qua nivalis pacitut Algido," &c.

ALGIES, in Geography, a kingdom of Africa, comprehends part of the ancient Mauritania, particularly that which was called Mauritania Cæsariensis, and the ancient Numidia, and forms one of the most considerable districts of that part of Africa which lies on the northern coast, and which in latter ages has been denominated Barbary. The country derives its name from its metropolis, called by the Turks Algezair, Al Jezair, or Al Jezireh, in Arabic, signifying the island, because there was an island before the city, to which it hath been since joined by a mole. The extent of this kingdom has been variously given by different writers. Sanlon, who marks its boundaries by the rivers Mullosiah or Malva, and the Zaine, gives it a length from east to west of 900 miles. De La Croix, 726. Luysts reckoning 48° for one degree of longitude, 63°; but if with Dr. Shaw, we take the boundary of Algiers to the west the Trara mountains, which separate it from the dominions of the emperor of Morocco, or Twant, which lies 40 miles to the ealward of the Mullosiah, and that to the east the river Zaine, formerly called Tafca, it will be found to extend 460 miles, or from 9° 16'. W. long. to 9° 16'. E. longitude. The breadth of Algiers is very unequal in different parts: for near Tlemman it is not more than 40 miles, from the Sahara to the sea-coast; near the sources of the rivers Sigg and Sheflif, it is about 60 miles, and this in the western part, may be taken at a medium for the extent of what the Arabs call Tell, or land proper for tillage. But to the east of Algiers, its breadth is much more considerable; particularly in the meridians of Boujijjah or Bugia, and Dona, where it extends above 100 miles, especially under that of Jigeri or Gigeri, in lat. 36° 55' to Lulajah, situate among the mountains of Atlas, in lat. 44° 50'. The Algers dominions beyond the Tell, or more advanced parts of Atlas, are very precariously and not easily defined, so that the northern limits of the Sahara, or Defert, seem to be the proper boundaries on that side. Accordingly, Algiers may be considered in general, as bounded on the north by the Mediterranean, on the east by the river Zaine, which divides it from Tunisia, on the west by the Mullosiah, or by Twant, and the mountains of Trara, which separate it from Morocco, and on the south by the Sahara, or Numidian desert. If we take the mean difference of latitude to be 2° 30', and the difference of longitude to be 5° 30', the superficial extent of the whole kingdom would amount to about 4218.

or according to a more accurate astronomic calculation of M. von Zach, 4262 geographical square miles.

This kingdom has been divided by geographers into many provinces, according to the several provinces into which it was ceded, at different periods, before and after the time of the Turkish conquests. At present it contains, according to Shaw, three principal divisions, viz., the province of Temisan, to the west, called by others Tremecen, and Mascara; that of Titeri or Tittera to the south; and that of Constantina to the east, to which some have added, as a distinct province, the territory of the city of Algiers. The western province comprehends the towns of Oran, Mustygannin, Temesan or Tremecen, Mascara, Shersheff, Tennis, besides several other inconsiderable places. In this province, coasting from the Tarara mountains, we meet with Mount Cape Horn, Tackumbreet, at the mouth of the river Tafna, the island of Agra or Harthogho, &c. The principal rivers are the Malva, Salt-river, Tafna, Sigg, Hebra, Mafrafan, and Shelif. The mountains are Atlas and Trara. See Mascara.

The southern province has no towns along the coast, but in the interior of the country the two chief towns are Belida and Mebeda; the mountains are branches of the Atlas, the Boujeraah, the Anwall mountains on the river Yiffer, and those of Jurupa and Felizia; and the rivers are the Haratch, Hamacfe, Regya, Budawowe, Corefe, Merdas, and the Yiffer, of which the last is most considerable. See Titeri.

The eastern province, called the Levantine government, is the largell and richest. See Constantina.

The territory of Algiers is principally distinguished by its capital, the metropolis of the kingdom. Within about half a mile to the north-east of the city commences the plain of Mattijah, called by Abulfeda Bledeah Kibera, i.e., a good country, which stretches 50 English miles in length and 20 in breadth, as far as the branch of mount Atlas, at the foot of which lies the town of Belida. This plain is better cultivated than the other districts of the kingdom. It is watered by several springs and rivulets; particularly by the Mafrafan, which at its entrance into the sea is a very considerable river, and little inferior to the Shelfifi, the Shiffa, and the Haratch. The country fronts and Mafrafan, as they call the farms of the principal inhabitants of Algiers, are found in these plains; and it is chiefly from them that the metropolis is supplied with provisions. Flax, alhenna, roots, potherbs, rice, fruit, and grain of all kinds, are produced here to such perfection, that the Mattijah may be justly reckoned the garden of the whole kingdom. For the nature of the soil, productions, inhabitants, population, government, commerce, &c. of the kingdom in general, we refer to the sequel of this article.

After the expulsion of the Greeks from Africa by the Saracens, towards the close of the seventh century, (see Africa), the country was divided into a number of small kingdoms and states, under chiefs of their own nation and choice. This government continued till the year 1051, when they were expelled by Abubecker ben Omar, or as the Spaniards call him, Abul Tesefen, an Arab of the Zinghian tribe, with the assistance of some powerful Marabouts; the conqueror assumed the title of Amir al Miminin, or chief of the faithful, and his subjects were denominated Morabites, and corruptly Almoravides. Tesefen, having succeeded in driving the Arab tyrants out of Numidia and Lybia, and all the western parts, reduced under his dominion the whole province of Tingitania. He was succeeded by his son Joseph, who laid the foundation of the city of Morocco, which he intended for the capital of his empire; but whilk he was.
building this city, he deputed an embassy to the Zeneiti who inhabited Tremecen, under a pretence of reclaiming them to the true faith; but the Zeneiti assembled in hostile array at Amafi or Amin, their capital, and invaded the dominions of Joseph with an army of 50,000 men. The Zeneiti, retiiled by the inhabitants of Fez, whose succour they expected, were overpowered by Joseph, so that about a million of persons are reckoned to have left their lives in this contest, and their country was depopulated; but afterwards repopulated by a colony from Fez, who settled there under the protection of their reigning kings. Joseph directed his next attack against the inhabitants of Fez, whom he subdued and made tributaries, and extended his conquests along the Mediterranean. He also pursued some Arabian sheiks, who had not submitted to him, into their retreats, in the deserts of Lybia, and totally subdued them. The empire of the Morabitins, which was thus established, and which promised permanence, was nevertheless of no long duration. This race was again expelled in the 12th century by Mohavedins, or Al Mohab, a Marabout, who dethroned Brah Ali, the last emperor of the Zindigian dynasty. This usurper and his successor, denominated themselves Mohavedins, and they were afterwards called Mohavades, Mohades, and Almeneses. However, they were extirpated by Abdulac, governor of Fez; and he was again stripped of his new conquests by the followers of Hacen, the descendants of the Arabian princes of the 10th century. With a view of securing his new dominions, he divided Barbary into several small kingdoms or provinces, affixing to each a separate chief. On this occasion Algiers was divided between four of their native princes; one of whom had Tremecen, and the other three had Tenez, Algiers proper, and Bujeyah, and thus these four cities became the capitals of four distinct kingdoms. For some centuries these monarchs continued in mutual peace and amity; but disputes arose among them; and Abdul-Fariz, prince of Tenez, declared war against the king of Tremecen. In a little while he became master of both Tremecen and Bujeyah. At his death he divided his kingdom between his three sons; one of whom had Tenez, another Jigeri, and the third, whose name was Abdalanan, had Bujeyah. This last attacked the king of Tremecen, and having succeeded against him, the Algerines, who had been his tributaries, transferred their subjection and tribute to the conqueror, by which means he became so powerful, that if the Spaniards had not interfered, he would have made himself master of the whole of Barbary. Their interposition, however, checked his progress, and produced a signal change in the aspect of his affairs. In 1505 cardinal Ximenes, prime minister of Ferdinand V., king of Aragon, sent thither the count of Navarre with a powerful army and fleet, principally with a view of restraining the depredations of the Moors, who had been banished from Spain about 32 years before; and thither was his succour that he soon became master of Oran, Bujeyah, and other considerable places. The Algerines were alarmed; and fought the succour of Solim Eutiemi, a warlike Arabian prince, who possessed the fertile territory of Mettitiah. He marched to their assistance; but his co-operation was ineffec- tual; and the Spaniards, having landed a considerable number of forces near Algiers, reduced this capital to subjection, and compelled it to become tributary to Spain. They also erected a strong fort on the small island opposite to the city, and thus prevented the Algerine Corsairs from sailing into or out of that harbour. On the death of Ferdinand in 1516, the Algerines made an effort for recovering their liberty; and they invited Barbarossa, who was then on a cruise with a squadron of gallies, to assist them in throwing off the Spanish yoke, promising him a gratuity corresponding to a service of importance. The bold and adventurous Cor- far gladly accepted the invitation; and leaving his brother Hayraddin with the fleet, and having dispatched 18 gallies and 13 backs to the assistance of the Algerines, he hastened his march to them by land. At the head of 800 Turks, 3000 jeniticals, and 2000 Moorish volunteers, he directed his course, not to Algiers, which needed his immediate protection and assistance, but to Shafiel, where Hassan, another Corfar, had settled. Having obliged him to surrender under a pernicious promise of friendship, he caused his head to be cut off, seated on his shoulders, and compelled the Turks, who had been his adherents, to follow him in his new expedition. Thus reinforced, he approached Algiers; and was conducted into the city by prince Eutiemi, and the people, with acclamation and triumph. Lodged in one of the noblest apartments of the prince's palace, and treated with every possible token of respect by the deluded inhabitants, Bar- barossa conceived the design of assuming the sovereignty; but dreading opposition on the part of the people, who were irritated by the unceasing licentiousness and insolence of his troops, he determined to facilitate his advancement to the throne by the murder of the prince, and then to be proclaimed king of Algiers by his own soldiers. The measure was no sooner projected than it was accomplished. As he was a guest in the palace of Eutiemi, he easily found an opportunity of strangling him, and of thus removing the chief obstacle to his attainment of the sovereignty. The people suspected him, but they dared not punish him, nor even to complain of his conduct. Many of them, apprehending measures of further violence and slaughter, abandoned the city and country; and those who remained, endeavoured to secure themselves in their houses, so that the pirate and his followers were left complete masters. At their request he ascended the throne, and was proclaimed with great pomp. The Turks and Moors, who attended the procession, exclaimed, as he paraded the streets on horseback, "Long live Aruch Barbarossa, the invincible king of Algiers, the chosen of God to deliver the people from the oppression of the Christians, and pour destruction on all that shall oppose or refuse to obey him as their lawful sovereign." The Algerines soon experienced the evils they had apprehended. Barbarossa exercised his sovereignty in the most despotic and cruel manner; and his Turkish soldiers conducted themselves with a degree of insolence and licentiousness, which rendered it dangerous for women and children of either sex to appear in the streets. The people were speciously drained and impoverished by the taxes that were levied upon them, and yet none could venture to remonstrate, or even to complain of the wretched condition to which they were reduced.

The Algerine chiefs, perceiving the exasperated temper of the people, and observing that Barbarossa had alienated the affections of the warlike Arabs by his rapacious exactions, and that he had disbursed the greatest part of his Moorish troops, availed themselves of these circumstances to make a bold attempt for regaining their liberty. A plot was formed; and a day was appointed for assassinating Barbarossa and his Turks. But the fopacious and watchful tyrant discovered the whole design, and caused the heads of 20 of the principal leaders of the conspiracy to be cut off at the door of the mosque into which they had entered at the hour of prayer, and their bodies to be thrown out on the dung-hills. He also confiscated their eftates, and laid a heavy fine on others of their accomplices. This dreadful execu- tion terrified the Algerines, that they never en-
gaged in any similar attempt against him or his succes-

The young Arabian prince, the son of Eutemi, was at this time under the protection of the marquis de Gomarce at Oran. Eager to revenge the wrongs which his family had suffered, he proposed to the marquis a very practicable plan for putting the city of Algiers into the possession of the Spanish monarch, and this scheme was laid before cardinal Ximenes. The cardinal approved it, and sent a fleet, with 10,000 men, to drive Barbarossa and the Turks out of Algiers, and to restore young Selim Eutemi. But the fleet was dispersed by a storm; many of the Spaniards were drowned; and those who escaped to shore, were either killed by the Turks or made slaves. The Algerines, in consequence with the Arabsians and Moors, made their next application to Hamid the Bey of Tunis, and requested his aid against Barbarossa and his adherents. This prince consented, on condition that the kingdom of Algiers should be settled upon him and his descendants. When he entered the Algerine dominions at the head of 13,000 Moors, he was joined by the Arabsians of the whole country. Barbarossa, however, with 7000 Turkish musketeers and 500 Granada Moors, defeated this numerous army; pursued Hamid to the gates of his capital, took the place, and obliged the inhabitants to acknowledge him for their sovereign. Barbarossa having taken possession of Tunis, received an embassy from the inhabitants of Tremecen; who, diffatisfied with the reigning prince, because he had beheaded his own nephew, requested his assistance to depose the usurper, and offered him the sovereignty. The invitation was readily accepted. Barbarossa obliged the king of Tremecen, after a severe engagement, to retire to his capital, where he was instantly beheaded by his subjects, and the conqueror received a fresh invitation to take possession of the kingdom. When Barbarossa, thus invested with new power, began to tyrannize over his subjects, the Tremecencians were exasperated; and repenting of their having invited such a tyrant to their affiance, they deliberated on the best means for expelling him, and restoring their lawful prince. Their design, however, was discovered, and many of the conspirators were cruelly miscarried. The prince had fortunately made his escape to Oran, and put himself under the protection of the marquis of Gomarce, who sent immediate advice of his flight to Charles V., lately arrived in Spain with a powerful fleet and army. This politic monarch, foreseeing the advantage that was likely to redound to him from placing the prince of Tremecen on the throne, ordered for him a succour of 10,000 men, under the command of Gomarce or Comares, the governor of Oran. This army, in its march, was joined by prince Selim, and a great number of Arabs and Moors from the adjacent countries. Their first enterprise was the attack of Calau, an important fortres situated between Tremecen and Algiers. This place, after a vigorous defence, was compelled to surrender; and, after a severe plunder, delivered into the hands of the king of Tremecen. Barbarossa, fearing a revolt on the part of his own subjects, and disappointed in his expectations of affiance from the king of Per, kept close to his capital. But upon the approach of the enemy he marched out of Tremecen, and determined to force his way through the hostile army which was preparing to lay siege to the city, to the field. He was advised, however, by his council to return and to fortify himself in the city; but the inhabitants refused him entrance, and he was therefore under a necessity of retiring into the citadel, and of there waiting for an opportunity to escape. Here he defended himself valiantly, and made several successful sallies during a long siege; but apprehensive of famine from the failure of his provisions, he took the advantage of a subterranean passage, through which he privately conveyed himself and his treasure. His flight was discovered and he was pursued; but ordering a considerable quantity of his money, jewels, and plate, to be scattered in the way, he hoped by this stratagem to divert the attention of his pursuers. The artifice failed; for the Spanish general obliged the army to march on, till at length they overtook the fugitive on the banks of the river Haçda, about eight leagues from Tremecen. A bloody engagement ensued; but the Turks were overpowered by numbers; they were all massacred by the Spaniards, and Barbarossa, among the rest, in the 44th year of his age. This defeat occasioned great consternation at Algiers. The Turks, to whom the defence of the city was committed, were much alarmed; and they soon agreed, as the best measure for preventing a revolt, to cauce Hayradin, the brother of Barbarossa, to be proclaimed king of Algiers, and high admiral of the sea. In order to secure himself from an insurrection, which his tyrannical and oppressive conduct had given reason to apprehend, he dispatched an ambassador with magnificent presents to Selim I., then emperor of Con-

Accordingly Charles, with a fleet of 120 ships and 20 gallions, and 7,000 chosen troops, accompanied by a great number of noblemen and gentlemen, who served at their own expense as volunteers, from motives of religion and glory, set sail towards the end of summer in 1541, and after a tedious and perilous voyage from Majorca to Africa, appeared on the coast of Algiers. The fleet anchored at
cape Metafuz; about two small leagues to the east of Algiers, and the army landed without opposition. Haffan's force, which garrisoned the city, amounted only to about 800 Turks and five or 6000 Moors, without fire arms, poorly disciplined and accounted. As Charles's army drew near the city, the inhabitants were much alarmed; but when Haffan was rumoured to forrander, he returned, as some say, an ambiguous, and according to others, a fierce and haughty answer.

On the second day, however, after the emperor's landing, the clouds began to gather, and the heavens presented a very threatening aspect. In the evening the rain fell, and the stormragged with violence through the whole night, so that the soldiers who had neither tents nor shelter, were much incomforted. The ground also became too wet, and the camp was so much overflowed with water, that they could neither lie down, nor stand without sinking to the ankles in the mud. Their matches also were extinguished, and their powder so moistened, that their muskets were useles.

Haffan perceived their diftrusts, and availing himself of it, falled out with his soldiers to attack them. In this situation the whole army, with the emperor himself in person, was obliged to advance to support the dispirited and retreating troops, who were first engaged, before the enemy could be repulsed; and they at length, after spreading general conflagration, and killing a great number of men, retired in good order. The hurricane, however, which still continued, produced a more dreadful disaster. The emperor's ships, on which depended the safety and sublimity of his whole army, were driven from their anchors; some of them dashed against each other, some were beat to pieces upon the rocks; many were forced on shore, and not a few were sunk in the waves. In less than an hour, 15 ships of war and 14 transports with 8000 men perished; and such of the unhappy crews as escaped the fury of the sea, were murdered without mercy by the Arabs, as soon as they reached the land. The emperor fled in silent anguish and afflangement, beholding this fatal event, which at once blotted all his hopes of success, and buried in the deep the valiant forces which he had provided, both for annoying the enemy and for subduing his own troops. At last the storm abated, and afforded some hopes that the ships, which had escaped, might save the army from perishing by famine, and transport them back to Europe.

The approach of evening, however, disappointed these expectations; the sea was covered with darkens; and it was impossible for the officers aboard the ships that had outlived the storm to send any intelligence to their companions who were aho: thus they remained during the night in all the anguish of suspense and uncertainty.

Next day, a boat dispatched by Doria, the admiral, against whom advice this expedition had been undertaken, reached land, with information, that having weathered out the storm, to which, during 50 years' knowledge of the sea, he had never seen any equal in fiereness and horror, he had found it necessary to bear away with his shattered ships to cape Metafuz. He advised the emperor as the face of the sky was still lowering and tempestuous, to march with all speed to that place, where the troops could reembark with greater ease. Metafuz was three days' march from the emperor's camp; his provisions were consumed; and his followers, exhausted with fatigue, and dispirited with a succession of hardships, were in no condition to encounter new toils. But no alternative remained; they were ordered instantly to march; some of them could scarcely furnish the weight of their arms; others, spent with the toil of forcing their way through deep and almost impassable roads, sunk down and died; many perished by famine, as the whole army subsisted chiefly on roots and berries, or the flesh of horses, killed by the emperor's order and distributed among the several battalions; many were drowned in brooks, twilh by the excessive rain, which, in palling them, they were obliged to wade up to the chin; and not a few were killed by the enemy, who, during the greatest part of their retreat, alarmed, harassed and annoyed them night and day. At last they arrived at Metafuz; and here they were supplied with plenty of provifion, and cheered with the prospect of safety. When the forces were embarked, a new storm arose, which by its fury scattered the fleet, and obliged them, separately, to make towards such ports in Spain or Italy as they could first reach. The emperor himself, after escaping great danger, and being forced into the port of Bugia, in Africa, where he was obliged by contrary winds to remain several weeks, arrived at last in Spain in a very disafflicted condition.

Haffan, the bashaw of Algiers, after this signal deliverance, undertook an expedition against Muley Hammed, king of Tremecen, who had submitted to Charles V., in order to be restored to his kingdom; but this prince purchased peace for a large sum of money, and became his tributary. Soon after this expedition Haffan died in the 66th year of his age, and was succeeded by Haji, who was compelled to surrender his dignity, much respectful as he was by the Algerines, to Haffan, the son of Hayradin, the brother of Barbarossa, whom Sultan Solymam had been prevailed upon to appoint bashaw of Algiers. Haffan was engaged in various enterprises against Tremecen, which was at length taken and plundered by the Algerines; and the head of Abdallah, the youngest son of the Sheriff, who had been killed in a previous engagement, was put into an iron cage, and placed on the principal gate of the city, called Bab Azoun, where it continued till the year 1573. During an interval of peace, Haffan erected some public edifices at Algiers, and performed other useful acts both at Algiers and in his alcaydship of Tenez, which rendered his government popular, and his death an occasion of regret. His succesor was Salha Rais, the fifth bashaw of Algiers, and the first of Arabian extract, that ever governed the Algerines. Of this bashaw, who was much respected, and who died in the 70th year of his age, it is said, that he was leant in all his resolutions and successful in all his enterprises. From Metafuz, where he died, his body was removed to Algiers and buried among the bashawas, his predecessors, in the sepulchre near the sea-side, over which his unfortunate successor, Haffan Corfo, caufed a handtom dome to be erected. Corfo, who was advanced to the dignity of bashaw by the interell of the Janizaries, was displaced in four months by Tekelii, a principal Turk of the grand Signor's court. He was at first oppossed by the Algerines, but at last they were under a necessity of submitting to him. One of the first acts of his government was to condemn Corfo, who welcomed him on his arrival, and peaceably surrendered his dignity, to the chimnun, or hook; a dreadful punishment, on which he hung by the ribs three whole days, and expired in the most exquisite torture. Aliardo, governor of Bugia, who was reckoned immensely rich, also fell a sacrifice to the inexorable Tekelii, who, after infticting the cruel tortures of baldinaing, burning and scaringifying him, in order to obtain a discovery of his wealth, ordered him to be impaled alive. This act of cruelty, and the ignominious punishment of Corfo, raised a great revelment among the Janizaries. Yufef, governor of Tremecen, determined likewise to revenge his death; and at a time when the plague raged furiously at Algiers, and Tekelii had removed to an old demolished town near the sea, about five miles wellward, he secretly and speedily
facedly marched to the place of his retirement, before Tekelli had any apprehension of his design. Tekelli fled, and was closely pursued by Yufet, who at length overtook him and pierced him several times with his javelin, till he expired. This action was highly applauded by all the Janizaries; and upon Yufet's entering into Algiers, he was received with universal acclamation, as their deliverer from the tyranny of Tekelli, who fell a just sacrifice to his avarice and cruelty, in the 50th year of his age and third month of his viceroyship. Yufet was unanimously chosen baizhaw of Algiers, but soon died, to the great grief of the Algierines, by whom he was buried in the same grave with the unfortunate Hassian Corfo. The new viceroy appointed by the Porte was Hassian, the son of Hayradin, who had been displaced by Selha Rais, at the instigation of Raisan, and who had now the good fortune to be restored to his Algerine government. His first enterprise was directed against Tremecen, in which he was defeated with great loss. The next year proved more glorious to the Algierines, who encountered the Spaniards in their expedition against Morefco, under the command of the brave count d'Alcandela. The cause of this defeat was the count's excess of valor, or rather his precipitancy, in engaging the enemy before he received the supply of troops that were destined to this service; and the consequence was the loss of his own life, the total rout of his army, and the captivity of above 15,000 Spaniards, among whom were the sons of the count, and many other noblemen and gentlemen.

Hassian, after this victory, returned to Algiers, laden with laurels and spoils. His next expedition was directed against Abdalazis, prince of the Beni Abbas, who inhabited the mountains, and who had discontinued to pay the usual tribute to the Algerine state. Having for this purpose collected a large army, he commenced the war, which was soon terminated by the death of Abdalazis, in consequence of a musket ball, which penetrated his breast. About this time the Christian merchants began, with the permission of Haffan, to build a fort on the coast, at a small distance from Carie, where the French have since settled; but the fort was in a few years demolished by the Algerine forces, under pretense that the French had bought all the corn, and craved a famine in their kingdom.

Hassian, having married the king of Cuco's daughter, permitted the subjects of this prince to purchase ammunition at Algiers; and this traffic gave such offense, that the Janizaries made an insurrection, feized on the baizhaw and some other officers, and sent them in irons to Constantinople, accusing Hassian to the Porte of having a design to make himself king of Algiers. Upon their arrival, they vindicated their conduct to the satisfaction of the Porte, and were set at liberty; but a new viceroy was sent to Algiers. The name of this baizhaw was Ahamed, or Achmet; he was a favourite of the Sultan, and inestimably avaricious; and had bought his dignity with a view to the emolument that were likely to accrue from it. He enjoyed it, however, only four months; and Hassian was restored. Such was the joy of the Algerines on his return, that even the women appeared on the terraces and balconies to welcome him. Having collected a very numerous and powerful army and fleet, he set out on his expedition against Marsa al Quibbir; intending, after the reduction of this place, to attempt that of Auran or Oran. This city was commanded by the count d'Alcandela, who succeeded his father, and the former by his brother Don Martin de Cordova, who had obtained his liberty at an immense sum, and now made a most gallant defence against the Turks. Hassian, after having made several vigorous attacks both by sea and land, and suffering several repulses, very fatal to his troops, was obliged to retire precipitately from the siege by the approach of the Genoese admiral Dorcia, who was advancing with a powerful succour from Genoa, Naples, and Sicily. This Genoese armada having miffed its aim of intercepting the Algerine galleys, bore away for Penon de Velez, hoping to drive them out of that harbour, but it was shamefully repulsed by a few Turks that were then in garrison and compelled to fall away with no small loss and ignominy. The loss of this place in the course of the next year was much regretted by the Algerines and their baizhaw, and also by Sultan Solymann. Hassian was displaced by Mahomed baizhaw, the son of Selha Rais; and departed for Constantinople, where, three years after, viz. in 1570, he died in the 50th year of his age.

Mahomed, upon his first arrival, performed several public-spirited acts, which attached to him the love of all the Algerines. Whilst he was consulting how to advance the Algerine power and wealth, a Spanish adventurer, named Gafcon, was meditating a design against him. This was nothing less than to purloin the whole prati cal navy in the bay, and to set all the ships on fire in the dead of the night. For this purpose he obtained the permission of King Philip II. and a supply of all necessary vessels and materials. Having advanced to the Mole-gate, and dispered his men with their fire-works, the garrison, during the delay of the execution of his plot, was alarmed, and Gafcon was under a necessity of securing himself by flight; but being pursued and overtaken, he was brought back to Algiers; and the baizhaw ordered a gibbet of considerable height to be erected on the spot where he landed, on which he was hoisted, and hung by the feet, that he might die in the most exquisite torture; and as an infult on his master, the king's commision was fastened to his toes. Soon after he was suspended, a strong representation was made in his favour, and in a little while the baizhaw ordered him to be taken down. This lenity of the baizhaw occasioned great murmurs among the people; and the unhappy Gafcon was ordered to be hoisted up by a pully to the top of the execution wall and let down again upon the chinkin or hook, which occasioned his instant death; and his body was hung up in perpetuity. This unsuccessful project of Gafcon has procured for him a place among the Spanish martyrs. Mahomed, after enjoying his government for about 14 months, was removed in order to make way for the accession of the Corfair Hali Fartaz, or Scalid-head, commonly known by the name of Ochali, who was appointed his succesfor by the Ottoman court. Ochali arrived at Algiers in 1586, when the war against the revolted Moretcoes in Granada was at its height. Being solicited to affliit them against the Spaniards, he conferred that some Fews should go to this service as volunteers, but he declined taking any oneflible and active part in it. In the first year of his government, he laid the foundation of the fortres called Bébal-weyd Castle. Next year he totally reduced the kingdom of Tunis, which was then under the protection of Spain, to the obedience of the Ottoman empire. Having continued a whole year at Tunis, he left the place, and assigned the office of his viceroy to a Sardinian renegade, named Ramadon Sardo, who became afterwards baizhaw of Algiers. This person raised himself from the condition of a slave to this dignity, by his superior understanding and good conduct. He became master of the Arabic and Turkish language; read and wrote well; and having followed traffic for some time, he was adopted, on account of his good qualities, by Hali baizhaw, who appointed him his deputy governor in the city of Fez; and in conformance of the application.
plication of the Algerines in his favour to the Sultan, he was appointed babaw of Algiers. In 1577, after governing Algiers little more than three years, he was forced to resign his office to Haflan Venetian babaw, a Venetian renegade. During the whole government of Ramadan, it was conducted with so much justice and equity, that a single complaint was not uttered against it. The conduct of his successor was very different; his administration was so oppressive, that complaints being preferred against him to the Porte, he was recalled, after being in office three years and a quarter; and a new babaw, Jaffer Aga, an Hungarian renegade, appointed in his room, A. D. 1580. At the commencement of the government, Algiers was reduced to the greatest misery by famine, so that 9000 Arabsians and Moors are said to have died in the streets for want in six weeks, chiefly through the avarice of Jaffer's predecessor, who quitted his administration with immense wealth amidst the executions of the people. Jaffer was of a generous disposition, and did every thing in his power to relieve and mitigate the distress of the country; he also exercised strict justice against those who abused the power with which they were entrusted. A plot, however, was formed against him; but the execution of it was prevented by some of the principal officers of the Janizaries to whom it was proposed; who declared, that they would prefer being cut in pieces to the ignominy of proving traitors to the Sultan, and his worthy Jaffer Aga. By the inconsequence of the Ottoman court Jaffer was displaced, and the infamous Haflan restored to the dignity of babaw. He closed his life at Constantinople by poison, administered to him by the renegade Cigala, who succeeded him in the post of captain babaw. The new babaw of Algiers was Memni Arnaud, an Albanian. This officer exhibited signal proofs of his great capacity and strict justice; and gave much satisfaction, not only to the Algerines, but to the Christian merchants who traded with them. During his administration, A. D. 1585, Morat Rais ventured to fail through the Straits of Gibraltar into the Atlantic, and thence to the Canaries, and he was the first of the Barbary Corsairs who engaged in an expedition of this kind. After a government of two years, Memni succeeded in 1586 by the rapacious Ahmed, who purchased the viceroyship of Algiers for a large sum, and exercised his government by violent exactions. His successor Hadir gained the office by the same means, and conducted it in a manner so haughty and tyrannical, that the Algerines were made very happy by his recall in 1592; but such was his interregnum, that after a short interval he was nominated babaw a second time, to the great concern and mortification of the Algerines. Mullahla succeeded in displacing this arbitrary and rapacious tyrant, and secured the affectionate attachment of the people by his courteouness and generosity; though nothing remarkable happened, during his administration, excepting that he repaired the mole, fortifications, and other public buildings.

At the beginning of the 17th century the Algerines complained to the Porte in very strong terms of remonstrance of the oppressive conduct of the Turkish viceroy, and in consequence of this remonstrance obtained leave to chuse their own Dey. They engaged, that the usual tribute should be faithfully transmitted to the Porte; to acknowledge the Grand Signor for their sovereign; to be ready on all occasions to affix him with their forces and shipping; to pay a due respect to his babaws, and to maintain them in a manner suitable to their dignity; provided that the government of Algiers should be wholly committed to the direction of the Dey and his jouwar. The great jouwar proceeded to the election of a Dey from their own body, and to enact a variety of laws and regulations for the better maintenance of this new form of government. This century, however, opened with a fresh attempt of the Spaniards on the capital of this kingdom, under the conduct of the famous John Andrew Doria, but the event of it, in consequence of adverse winds, was unsuccessful. The Algerines, in order to counteract these renewed attempts, determined to direct their attention to the improvement of their navy; and in 1616 they had so far succeeded, that it consisted of 40 sail of ships, of between 200 and 400 tons, divided into two squadrons; one of 18 sail lay before the port of Malaga, and the other, without the Straits, at the cape of Santa Maria, between Lisbon and Seville, where they attacked all Christian ships, without distinction, that came in their way, and rendered themselves formidable to all the maritime states of Christendom. The French were the first who dared to reflect this contemptuous breach of treaty; and M. Benouk was sent with a fleet of 50 sail of men of war and galleys against the Algerines; but upon his departure, they returned to their accustomed depredations on the Spanish coasts, which, being belt known by the expelled Moors, were exposed to all the barbarity and relentment of those exasperated infidels. In 1626, in consequence of the earnest solicitations of the Spanish court, by means of Conde Mar, an English squadron was sent into the Mediterranean, under the conduct of admiral Sir Robert Manfel. He directed his course to the bay of Algiers, and attempted to set fire to the shipping in the harbour, but returned without doing much damage. As soon as he retired, the Algerian Corsairs put to sea, and made prize of about 40 good ships belonging to the subjects of the English sovereign. With all the European power, except the Dutch, the Algerines were at open defiance; but to them they sent a proposal, A. D. 1635, addressed to the prince of Orange, that if they would let 20 sail of ships to be employed in the next year against the Spaniards, they would join them with 60 sail; but the proposal was not accepted. In the next year the Collogues, or Coniolies, i.e. the children of such Turks as had been permitted to marry at Algiers, formed a conspiracy, and feized on the citadel of Algiers, and had very nearly made themselves masters of that place. The plot was discovered, and the insurgents were defeated with great slaughter. About two years after this conspiracy, the Algerine state underwent a memorable change, by which they became soon after able to shake off the Ottoman yoke, and to become an independent state under their own Dey.

The occasion of this revolution was a truce for 23 years, which Amurath IV. had concluded with the emperor Ferdinand II. This truce was universally disapproved by the Barbary Corsairs; and by none more than the Algerines, who were become haughty and opulent in consequence of their gainful depredations on the Christians for the last three years. They and their neighbours unanimously resolved, to set up for three independent states, and to consider themselves as wholly unconcerned in any treaties which were made by the Porte with any Christian power. Having adopted this resolution, the Algerines began to make prizes of several ships belonging to powers at peace with the Ottoman Porte, and even pursed some of them to the port of Rhodes and carried them off. They did the same at Salamis, in the ile of Cyprus; and at Alexandretta, they not only feized a Dutch ship and a polacre, but ventured on shore, plundered the magazines and warehouses, and then set them on fire. They also drove the French away from a new fort, called the balion of France, which Louis XIII. depending on his league with the Turks, had erected on their coast, instead of that which had been formerly constructed by the Marilhans. The Porte considered their depredations as open
A L G I E R S.

instances of defiance to his authority; but as he was much occupied by the Persian war, and other disturbances in the East, his grand vizir and courtiers were allowed to compound with these pirates, by sharing their spoil. Having, for form sake, reprimanded and threatened them, they returned an inflexible reply, declaring that they were the only bulwark against the Spaniards, who were the sworn enemies of the Muslim name, and that if they paid a pittance regard to every circumstance that could procure peace, or liberty, to trade with the Ottoman empire, they must set fire to all their shipping, and become mere camel-drivers in order to obtain a subsistence. Accordingly the Algerines pursued their piratical excursions at sea for many years with impunity. Amongst other enterprises in which they engaged, they surprised the baton of France upon their own coast, containing about 600 inhabitants, whom, with all their effects and ships, they carried off to Algiers. In the course of the following year they fitted out a fleet, with which they ranged the seas and feized all the Christian shipping that fell in their way; and they even meditated an attack upon Loretto, which would have proved a great prize. But in this object they were prevented from succeeding by contrary winds; however they made a defent on Paglia, in the kingdom of Naples, where they made captives of both sexes, and fleeing towards Dalmatia, they figured the Adriatic, and loading themselves with immense plunder, left those coasts in the utmost consternation. The Venetians, alarmed at their depredations, equipped a powerful fleet of 28 sail, under the command of admiral Capello, who had orders to burn, sink, and take all the Barbary corsairs, wherever he found them. The Algerine admiral was overtaken by this fleet; and an obstinate conflict ensued, which terminated in the defeat of the Algerines; but Capello was recalled, and the republic were under a necessity of purchasing peace with the Porte, at the expense of 500,000 ducats. The news of this defeat and loss, which were owing to the avarice of the Algerine admirals, filled Algiers with inexorable grief and confusion, and the whole city was preparing for a general insurrection; but it was prevented by a proclamation of the bakhaw and douwan, who expressly prohibited all complaints under the severest penalties. The application was made to the Porte for an order, that the Venetians, settled in the Levant, should indemnify them for the loss they had sustained. Their requist was rejected, and they were under a necessity of repairing their losses at their own charge. One of their corsairs soon landed with a freth supply of 600 slaves of both sexes, which he had brought from the coast of Iceland. In two years after this disaster, the Algerines appeared at sea with a stronger and more numerous fleet than they had ever equipped before. This fleet, consisting of 65 sail, besides other galleys and inferior vessels, performed many exploits in different parts of the Mediterranean, which our limits will not allow us to recount. It is sufficient to observe, that the Algerines became quickly more powerful and more formidable than ever to the European powers, and plundered the subjects of England, France, and Holland. As for Spain, Portugal, and Italy, they determined never to make any peace with them, as they were sworn enemies to the Mahometan religion. In this height of power and grandeur, which the Algerine state had attained, the English, French, and Dutch, were glad to secure peace with it at any rate. About the latter end of the reign of Charles II. the British nation obtained from the Algerines that lifting alliance, which, with some renewals, additions, and alterations, hath subsisted to this day. The outrages committed by them on the coasts of Provence and Languedoc, induced Louis XIV. to equip a considerable fleet, and the command of it was assigned to the marquis Du Queine, vice-admiral of France. Sailing to their capital, he bombarded and cannonaded it with such fury, that in a little time the whole town was in flames, and the terrified inhabitants were preparing to leave the place; but the wind suddenly changing, he was obliged to return for Toulon. When the form was lifted, the dog-fish assembled, and ordered a fleet of gallies and galleons to fail immediately for the coasts of Provence, where they committed dreadful ravages. The French, apprised of this outrage, fitted out a new armament at Toulon and Marseilles; and the Algerines repaired their walls and fortified the town, in order to be ready for their expected attack. In May 1683, the French squadron cast anchor before Algiers, as it was determined to bombad the town, and the execution of their purpose was attended with dreadful havoc. Upon this the whole government of the town sued for peace; but some delay having taken place with regard to the surrender of captives, hoithits were renewed; and the greatest part of the city was reduced to ashes, and the fire burnt with such vehemence, that the sea was enlightened by it to the distance of above two leagues. The Algerine commander, in the midst of this scene, caused all the French who were in the town to be cruelly butchered, and ordered their consuls to be fastened alive to the masts of a mortar, and shot against their navy instead of a bomb. The French admiral, exasperated by this unheard-of inference of inhumanity, did not leave Algiers till he had utterly destroyed all their shipping, fortifications, buildings, and, indeed, almost all the lower part, and above two-thirds of the upper part of the city. After his departure the Algerines seriously thought of procuring a peace with France; and for this purpose they deputed an ambassador to supplicate pardon for the murder of the consuls, which they attributed to the populace, and to fire for peace. The speech of their envoy on this occasion was a matterly address. The result of their submission was a ratification of the peace at Paris in the course of the following year: upon which the Dey and douwan proceeded to repair the dreadful dilapidations which the metropolis had suffered. In 1686, the Algerines concluded a treaty of peace with England, which was renewed in the second year of James II. and in the second year of king William's reign, and again in the reign of George II. when all former treaties with the Algerine Republic were ratified. The only remedy to which recourse has been had for the occasional violations of this treaty has been that of making reprisals, instances of which have frequently occurred. But it was not till after the capture of Gibraltar and Port Mahon, by Sir George Rooke, that Great Britain could have a sufficient check upon them to oblige them to the observance of treaty; and since this period they have been accustomed to pay a greater deference to the English than to any other European power. In the year 1703, the Algerines retook from the Spaniards the city of Oran, and were at great pains to strengthen it with new fortifications; but, notwithstanding their precautions, it was recaptured in 1737. The year 1710 was signal propitiates to Algiers, upon several accounts; as, first, the annihilation of their worthless Dey Ibrahim, crowned the Madman; 2dly, the election of the brave Hali to the throne; and, 3dly, the expulsion of the Turkish bashaw, the abasement of that dignity by the courage and address of the new Dey, and the union of that office with that of the Dey. This introduced that form of government which still subsists in Algiers. Mod. Un. Hist., vol. xv. p. 93. Robertson's Hist. of Ch. V. p. 98—100. p. 239—248.
A L G I E R S.

The government of the Algerines consists of the Dey, who may be compared to the former Dutch Stadholders, and of a douwan, or Common Council. The Dey is chosen out of the army; each order, even the most inferior, having an equal right and title to that dignity with the highest. Every bold and aspiring soldier, however obscure his origin, may be considered as the heir apparent to the throne; nor does he wait for his accession till sickness or old age shall have removed the present ruler, provided that he can protect himself by the name feymetar which he plungs into the breach of his predecessor. Accordingly the succession at Algiers has been usually very rapid; and Dr. Shaw observes, that scarcely one in ten has had the good fortune to die in his bed; and those who have enjoyed their power for a longer period, have incurred it, not so much by the attachment and good will of the people, as by their own sagacity in perceiving the first tendency of an infurrection; and by their ability to check it by the death of the conspirators before they have had an opportunity for accomplishing their designs. This faction and discontented humour has, however, in some degree, subsided, and the power of the Dey is more permanent than it used to be, though he is still liable to be deprived of it by unforeseen rebellion, arising from trivial circumstances, and unavoidable affimation. The whole body of the militia is concerned in the election of a new Dey, and every person, however low his rank, claims a right of voting. Every election is of course generally attended with tumult, and sometimes with serious contests and bloodshed. When the choice is determined, the perdon elected is inspired with words which signify, "God blest, or prosper you;" and he is then invested with the kaitan, or insignia of sovereignty, whilst the Cadi, or Chief Judge, addresses him with a congratulatory speech, and an exhortation to govern with equity, and to maintain the liberty, and promote the welfare of his subjects. The douwan, or divan, at first consisted of about 800 military officers, without whose counsel and consent the Dey could not act; and on extraordinary occasions, all the officers that resided at Algiers, amounting to above 1,000, were summoned to assist. But since the Dey's have become more powerful and independent, the douwan is principally composed of thirty yah-bahaws, with the muti and cadi, upon some emergencies; and upon the election of a new Dey, the whole body, as we have observed, are allowed to give their votes. Of late the douwan is little regarded; it is, indeed, formally convened, for the purpose of sanctioning measures previously concerted between the Dey and his favourites; so that, in effect, the whole power is lodged in one perdon. The next officer in dignity and power to the Dey is the Aga, a general of the Janizaries, who is one of the oldest officers of the army, and enjoys his post for two months, and is succeeded by the chia, or next senior officer, or eldred yah-bahaw. During these two months, the keys of the metropolis are in his custody; all military orders are issued in his name, and the sentence of the Dey upon any soldier that has offended, is executed in the court of his palace. When he is displaced, he is considered as reemul, or superseded, and receives his pay, and is occasionally summoned to assist with his advice, but not with his vote, at the grand council. The next officer to the aga is the secretary of state, who registers all public acts; and next to him are 24 or 30 chia-bahaws, or chief colonels, from whom are commonly chosen ambassadors to foreign courts, or messengers, to conduct the orders of the Dey through the realm. Next to these are the bolluk-bahaws, or eldest captains; after them the old-bahaws, or lieutenants, 400 in number; and other military officers are vakelards, or purveyors of the army, peys, and foulaaks. The officers now enumerated, compose the douwan. The strength of this kingdom consists of its land and sea forces. Its strong cities are few, and it has fewer garrisons, which are weakly fortified and guarded. Dr. Shaw, in 1732, computed the whole force of Algiers to be 6,500 military Turks and Coloumbes, 2,000 of whom were excused from duty, 1,000 employed in relieving garrisons, and the rest assigned to their cruizing vessels, or forming the three flying camps which, every summer, attend the provincial viceries. To the Turkish troops may be added about 2,000 zowiwaans, as the Moorish horse and foot are called. The deficiency of their army is supplied by recruits, collected by their cruizing vessels once in five or six years, in the Levant; and these are commonly shepherds, outlawes, and persons of the lowest condition. Besides these, the Dey, on occasions of emergency, enrolls the coloumbes, or colonels, who are the sons of Turkish soldiers as have been permitted to marry at Algiers; but there are dangerous persons, and are not much encouraged, and when they are admitted into the army, they are exlcuded from the honour of being Dey, aga of the Janizaries, and other considerable offices and employments. The officers of the Algerine army are the agas or general, 30 chia-bahaws or colonels, 800 bolluk-bahaws or captains, and about 400 oldah-bahaws or lieutenants; and these several posts are attained, not by money or intered, but by seniority. The pay of the army is very small, the youngest soldier receiving only 456 alpers every two months, and the oldest, or thofe in full pay, no more than 5,200, of which 666 make a dollar. The whole army, therefore, with regard to its demands upon the governmect, may be reduced to about 3,500, so that a sum, less than 200,000 dollars, or about 30 and 40,000l. of our money, will defray its expense. Besides the pay, thofe chia and bolluk-bahaws, that are unmarried, have each eight loaves of bread a day, and the old-bahaws and private soldiers, of the same condition, have four; each loaf being about five ounces in weight, and three alpers in value. In their battles or engagements, the fables or cavalry, are of little service; their principal dependance is on the infantry. Their fighting is always at distance; small parties, or platoons, continually advancing in full career from the main body; and after they have discharged their fire-arms, or their javelins, they as speedily retreat, and make way for others; and hence it happens, that if a few persons are killed, the battle is called bloody.

The naval force of Algiers is more formidable than its army. It commonly consists of 20 ships, one of which belongs to the government, and is assigned to the admiral; but all the rest belong to private persons. The Corsairs, though they are not allowed any concern in the affairs of state, nor in the election of the Dey, are held in great esteem, on account of the prizes they continually bring in, which are one main source of the public revenue, and the means of procuring them respect from the Christian powers for the security of their trade. The government claims an eighth part of all the prizes, slaves, cargo, and vessel; the rest being divided amongst the proprietors and ship's company. Passengers are entitled to a share in their prizes. All the officers of the ships must be either Turks or Coloumbes; the Moors not being allowed to come upon the quarter deck, or into the gun-room, unless they are in port; but Christian slaves are permitted to act as seamen or inferior officers, and allowed a share according to their abilities and behaviour. The Dey of Algiers pays no other revenue to the Porte than a certain number of fine boys, or youths, and some other annual presents. His own income is variously computed; some estimating it at 40,000 ducats, whilst others raise it to 400,000, and others to 600,000. Dr. Shaw computes the yearly taxes of the whole kingdom at 300,000 dollars.
dollars; but he supposes that the eighth part of the prizes, the effects of persons who die without children, contributions from the districts, together with presents from foreigner, fines and oppressions, may produce as much more.

The commerce of Algiers is principally carried on by their corsairs or pirates, and with this view it is certainly the interest of the Algerines to be at war with those nations that trade in the Mediterranean; because they have always found that the balance of the captures made by them was greatly on their side, both with regard to number and value; and without such a constant supply, their state could not support itself, or prevent the most dangerous insurrections. On the other hand, all the maritime powers in Europe wish to be at peace with the Algerines. Nevertheless, free Christians, Jews, native or foreign, Arabsians, and Moors, are permitted to exercise a free commerce both by sea and land, together with other trades and manufactures in silk, cotton, wool, leather, and other commodities. These, however, are mostly carried on by the Spaniards, that are settled in this kingdom, and especially near the metropolis. Carpets also constitute a manufacture of this country, though inferior to those of Turkey. There are also at Algiers, for velvet, taffetais, and other wrought silks, and a coarse kind of linen is also made in most parts of the kingdom. Few of their commodities or products are sent into foreign markets; their oil, wax, hides, pulp, and corn, being barely sufficient to supply the country: although whilst grain was in possession of the Algerines, the English merchants shipped from thence seven or eight thousand tons of wheat and barley every year. Their other exports consist chiefly of olive feathers, wax, hides, wool, copper, rugs, silk fabrics, embroidered handkerchiefs, dates, and Christian slaves. Their imports consist chiefly of gold and silver flutes, damasks, cloths, spices, tin, iron, plated brass, lead, quicksilver, cordage, calico-cloths, bullets, linen, cochinila, tartar, alum, rice, sugar, soap, cotton raw or spun, copperas, aloes, brazil and logwood, vermilion, arsenic, gum, tar, sulphur, opium, mace and cummin feed, mastic, larcharzolli, apice, frankincense, gall, honey, paper, combs, cards, dried fruits, and a variety of woolen flutes. But of these a small quantity is imported by the merchants, though there is a constant demand for them, on account of heavy duties, frequent exactions, precarious payments, and uncertain returns. They are also furnished by the English confid with powder, balls, bombs, fire-arms, cordage, and other naval stores; as the country furnishes no materials for ship-building.

The coin of Algiers is molly foreign; their own being only of three kinds, viz. the barba of copper, bearing the arms of the country on both sides, fix of which were formerly worth an asper, but now only half that value; the asper or square piece of silver, with Arabic characters on each side, 15 of which make a Spanish real, and 24 a dupla, worth about a crown; and gold coin of three forts, coined only at Tramceans, viz. the rupee, worth 35 aspers, the median, 50, and the zian or dian, 100. Besides these, the Turkish fulkams of gold, worth about a ducat, the motocules of Fez, worth about 22 pence, the Spanish rials, French crowns, Hungarian ducats, and other European money, are current among them; but without any fixed standard. The established species here is the patachicka, or pataca of aspers, an ideal sum like the English pound, worth always 32 aspers, the third part of a pataca gorda, commonly of the weight of two and a-half pistoles, which weight is raised or lowered at the pleasure of the Dey, or according to the exigence of the government. The silver mint at Algiers is under the superintendence of the Jews, for which they pay a yearly sum to the Dey.

**Vol. I.**

The religion of the Algerines differs from that of the Turks only in their adopting a greater variety of superstitions. They acknowledge the Koran as the rule of their faith and practice, but are remiss in the observance of it. They have three principal officers, who preside in religious matters, viz. the Muifi, or High Priest; the Cali, or Chief Judge in ecclesiastical, and the other concerning civil and military, that are referred to him, and the grand Marabout. These three officers have their seats in the great duwan next under the Dey, and on his right hand. The cali is obliged to attend at the court of justice once or twice a day, to hear and determine complaints. But affairs of moment are submitted to the Dey, or, in his absence, to the treasurers, master of the horse, or other principal officers of the regency, who sit in the gate of the palace, according to a custom recognized in scripture (Deut. xxi. 15. xxv. 7. II. xxix. 3. Amos v. 10. Dan. ii. 49.) for that purpose. The caife is thus quickly decided, and sentence executed in less than an hour. In cases of debt, the debtor is usually detained in prison till the bailiff seizes his effects and sells them; after sale, if there be an overplus, it is returned to the prisoner; but if it falls short, he is released; and no further demands are made upon him. The baftid, which is filled with small flicks about the size of the figure, which are brought in bundles to the place of punishment, is the punishment of small offenders, and it is applied to the belly, back, or soles of the feet, according to the nature of the crime, or the pleasure of the judge, who likewise appoints the number of strokes to be given. For clipping or debasing the public coin, the old Egyptian punishment of cutting off the hands of the transgressor is inflicted. When a Jew or Christian slave, or subject, is guilty of murder, or any other capital crime, he is carried without the gates of the city, and burnt alive; but the Moors and Arabs are either impaled for the same crime, or else they are hung up by the neck over the battlements of the city walls, or else thrown upon the ching-ban, or hooks, that are fixed over the walls below, where sometimes they break from one hook to another, and hang in the most exquisite torments, 3 or 40 hours. The Turks are not publicly punished, but sent to the house of the Agra, where, according to the quality of the crime, they are batinadoed or strangled. When the women offend, they are sent to some private house of correction; and if the crime be capital, as when they are taken in adultery, &c. they are tied up in a sack, carried out to sea, and drowned. The western Moors use the barbarous punishment of sawing the body of the criminal in two. See Math. xxiv. 51. Luke xii. 45. Heb. xi. 37. For this purpose they prepare two boards, of a proper length and breadth, and having tied the criminal between them, they proceed to the execution by beginning at the head. A portion of the first rank in that country, who had been ambassador at the British Court, was put to death in this manner.

As to the population of Algiers, it is not easily ascertained; but we may observe in general, that it is much less than in other countries of the same extent, where arts, sciences, and industry are not so much restrained. Tracts of country are here uninhabited and uncultivated; not to add, that despotism, want of commercial intercourse in the inland provinces, and the frequent ravages of the plague, contribute to the diminution of the inhabitants. The soil of this country is generally fertile, and more especially towards the seacoast and in the valleys. There are few forests, but tracts of thicket and bruswood are more common. The most woody part of the country, and that which supplies the greatest quantity of timber, is the district about Bugia. Upon the whole, the face of the country is mountainous, and in the
chains of its mountains there are various minerals, particularly lead and copper. The fertility of the soil decreases in approaching Sahara or the Desert, although in its borders, and even in the Desert itself, there are some districts which are capable of cultivation, and which produce corn, figs, and dates. These regions are inhabited by Nomadic tribes, who, valuing themselves on their independence, endure with fortitude and resignation the inconveniences attending their condition, and scarce regret the want of those advantages and comforts that pertain to a civilized state of society. The cultivated parts of this country enjoy a wholesome and temperate air; and the climate is distinguished by the equality of its temperature; the barometer indicating all the changes of the weather from 29, 1 to 30, 4, or within the space of 1, 3 inch. The winds generally blow from the sea, or from the west by the north to the east; those from the east are common at Algiers from May to September, and then the winterly winds become the most frequent. The southerly winds, which blow from the Sahara, are usually hot and violent, but not frequent. When they blow for five or six days together in July and August, they are very frequent, and the inhabitants sprinkle the floors of their rooms with water or vinegar. The quantity of rain that annually falls in Algiers is, at a medium, 27 or 28 inches; but in this climate little or no rain falls in the summer season, and in most parts of the Sahara they have no rain at all. The first rains fall in September, and sometimes a month later; after which, or about the middle of October, wheat is sown and beans are planted. Barley is sown about the end of November. If the latter rains fall, as usual, in the middle of April, the crop is deemed secure; and the harvest comes on in the end of May or beginning of June. The inhabitants cultivate, not only wheat and barley, but rice, Indian corn, and a kind of millet, called drad, which they prefer to barley in fattening their cattle, and which they are obliged to guard from the depredations of birds, by a screaming noise continued through the whole day. Here they dare out their corn after the primitive customs of the East, by spreading the sheaves open, and driving mules or horses round about the neddles or threshing-floors. When the grain is trodden out, they winnow it by throwing it up against the wind with a shovel; they then lodge it in the mattamores, or hibbertaneous magazines. Of the pulse kind, beans, lentils, kidney beans, and the chick pea, are the most abundant; and of the roots, herbs, and fruits of the kitchen garden, they have a very considerable variety. For the zoology, ornithology, &c. of Algiers, see Barbery.

The inhabitants of the Algerine state are partly Turks, partly Moors, and partly Christians and Jews. The Turks have been established since the middle of the sixteenth century; they form the highest rank in the country, and possess all the offices and employments. According to the constitution of Algiers, no native can be a Turk; he alone is regarded as a genuine Turk, and entitled to the privileges of this class, who is descended from Mahometan parents, or born of a Mahometan mother, in the dominions of the Grand Seignior. The number of Turks at Algiers was formerly computed to be from 14 to 16,000; but they are now reduced to 9 or 10,000; and they are reckoned, with regard to their disposition and character, ignorant, proud, indolent, voluptuous, jealous, and revengeful; but at the same time faithful, sincere, courageous, and tolerant. With ideas of superiority, brought with them from their own country, and enlarged by the privileges which are granted to them at Algiers, the meanest Turk considers himself far superior to the Moors, Christians, and Jews. Their principal enjoyment consists in ease and inactivity. Besides the qualities we have already mentioned, the Turks are noted for their avarice. It is therefore proverbial, "Give a Turk money with one hand, and he will permit his eyes to be pickled out by the other." Nevertheless, he is faithful to his engagements, and a stranger to dissimulation. With regard to those who do not profess their religion, they are generally compassionate and tolerant; and infinaces have occurred, in which Turks have exhorted the Christian to the observance of the external rites of Christian worship: but they despise and abhor apocryphal and renegadoes. As to their privileges, they pay no poll-tax, and they have an exclusive title to all the chief offices of the State; they cannot be punished except by the express order of the Dey; when condemned to die, they are strangled; they purchase the necessaries of life at a lower price than others; and from gardens and vineyards that are not enclosed by high walls, they may take as much fruit as they can eat; and their testimony, other circumstances being equal, is always held in higher estimation than that of the Moors, Jews, and Christians.

The chiefs of perfons next in rank and dignity to the Turks, consist of the Colophes or Colories, who are the children of Turks by women that are natives of Algiers. The number of these, in the vicinity of the capital, is considerable, and they compose some of the richest and most respectable families in the country. They form a middle class between the Turks and Moors, and resemble the former in courage, pride, jealousy, and voluptuosity; but are more laborious and diligent; and they partake of the perjury and dissimulation of the Moors, and also of their propensity to superstition. In corporeal strength and form they are not inferior to the Turks; and they belong to the most intelligent and cultivated part of the inhabitants of Algiers, so that the most expert artisans and artificers are of this class.

Under the general name of Moors, who constitute another division of Algerines, are comprimended the Moors, properly so called, the Cabyles or Kabyles, mixed with Berbers or Brebers, and several Arabian tribes. The Moors are very distinct from the Negroes, as their natural colour, unchanged by the burning rays of the sun, is as white and beautiful as that of the natives of the South of France, and Italy. With respect to their moral character, they are inferior to the Turks. They are malicious, false, cowardly, revengeful, fanatical, ignorant, superstitious, fraudulent, avaricious, and, among the lower classes, thievish and rapacious. But they are more active than the Turks, and they have an inclination for commerce and the mechanic arts. Those of them who live in cities and engage in commerce, are more polished, and less odious in their disposition and manners; some of them are rich, and look down with contempt on the Turks, though they sow the earth and secure their patronage by dissimulation and flattery. Of these some are addicted to study, but their knowledge extends little beyond the Koran and History. The less wealthy Moors are artificers, and some of them moderns. In the lowest class of Moors, inhabiting the cities, are found the most abandoned and profligate persons, who cannot be restrained from crimes of every kind, except by a degree of severity approaching to cruelty. The Biscaris, however, form a small exception. Of the Moors, who inhabit the country, few are wealthy; they are ignorant and rude, and strangers to the benefits and pleasures of social life. They retain the ancient custom of distinguishing themselves by families and tribes, which is lost among those who live in towns. Some of them lead a wandering life, and others gain a subsistence by cultivating the land for the richer among themselves, or for the Turks, or for the Colories. Among the Moors tribes in the country polygamy prevails, but this practice does not prevail in towns.
ALGIERS.

The Moors are not admitted into the infantry of the Algerine state, which is the most honourable and useful corps, but they compose the cavalry of the Dey, which is not much esteemed. The Mournih mountaineers are denominated Cabyls. The Arabian tribes, who inhabit the Algerine dominions, are those who, without blending with the Moors, or with the ancient proprietors of the country, have uniformly maintained their separation from others, partly in a state of independency, and partly as tributaries to the Dey. They are distinguished from the rest by their language, their rude manners, and a peculiar mode of living; and also by a degree of pride which leads them to look upon themselves as better and more noble than others. They are also distinguished by their love of liberty. They live either in the desert, or in inaccessible ridges of mountains, divided into families and clans, under the patriarchal government of a lik, who may be considered as the judge, instructor, and leader of his tribe. Their wealth consists in their flocks and herds. Whenever they think themselves secure, they defend from the mountaineers into the plain country. The number of these marauders decreases every year. The Arab tribes that are the subjects of the Algerine state, pay a final tribute, and are treated with great severity, that they may not be provoked to unite with the Cabyles and the independent Arabs. The number of Jews in Algiers is not considerable; they are despised and oppressed, distinguished by a dress of dark colour, restrained from acquiring landed property, and forbidden to ride through the gates or in the city. If a Jew be attacked, he would incur danger by defending himself against the abufe of the Turks and Moors, and therefore they purchase the protection either of powerful Turks, or European consuls. The Algerine Jews are, in general, very superstitious and fanatical, and also cowardly, perfidious, avaricious, and addicted to cheating and fraud. In their own concerns they are amenable to their own tribunal, and have an elder amongst them, known by the appellation of "King of the Jew." The number of negroes annually imported as slaves into Algiers, amounts to from 150 to 180; and their price varies from 50 to 130 francs. The females are often kept as concubines by the wealthy Turks and Moors. Most of these blacks obtain their freedom, either gratuitously or by purchase; and during their slavery, they are treated with cruelty, and severe usage is noticed and even punished by the government. Both negro and Christian slaves are employed at Algiers in the same offices with our domiciliary servants. But Jews and Christians are forbidden to keep negro slaves who profess the Mahometan religion. An emancipated slave becomes entitled to the same privileges with the Moors.

The Christians of Algiers are transient residents, and can hardly be reckoned in any class of inhabitants. They are seldom found in the open country. On the westem coast the Spaniards occupy Oran and Mafalquyvr; but the greater part of the citizens who reside there consist of fugitives from their native land, and derive a scanty subsistence from the garrisons and depredators, agriculture and manufactures, pafs their time in indolence and wretchedness. The Christians in other cities are, generally speaking, all slaves. Some of them are such as have been captured by the Algerine corsairs; of whom some are selled by the Dey, and the rest are sold in the market-place to the highest bidder. The other Christian slaves are such as enter on their own accord into a state of slavery; and these are for the most part defectors from the Spanish garrisons at Oran and Mafalquyvr; so that Oran is the nursery of this class of slaves, amounting annually to about 100. As to the treatment of these Christian slaves, those that are defectors from Oran, and those that are captured by the cruisers, are treated without discrimination; they are generally well kept, but overawed with labour or cruel usage. Those who attend upon the Dey live sumptuously, and are richly clad, but they must include themselves from society, and are seldom allowed to leave the palace. The young men and women are exposed to the seduction of licentious courtiers. Others, who are the principales of the state, are employed in docks-yards and magazines, and are under the command of Turkifh tale-masters. They labour from sun-rise to sun-set, and their fare is coarse, and their accommodations at night, amidst the filth and vermin and corrupt air of the bagnios, are more intolerable than the fatigues of the day. The condition of slaves, purchased by private persons, is, upon the whole, preferable to that of those who belong to the state. In the cities, they are employed as menial servants: in the country, they cultivate the vineyards and gardens. Those who have an opportunity to acquire property, take taverns in the city, and gradually become rich. Those slaves who have been captured by the corsairs, often regain their liberty by being ransomed; but the Oranite slaves have seldom any hopes of deliverance. Sometimes the government of a country ransoms all its slaves without exception, which was the case with the French in 1784. Their number, however, is not commonly very great. In 1785, they for all the French ransoms, it amounted to about 200. In 1786 and 1787, 500 Spaniards and Neapolitans were liberated, and about 700 died of the plague; so that there remained about 800, all of whom were defectors from Oran.

As to those called renegades, there are few of them in this country. They are either Jews or Chrlsrians. The former, of whom there are commonly more men than men, renounce the faith of their ancestors, and embrace the predominant religion of the country, for the purpose of being re-engaged in their relations, or with a view to escape from merited and apprehended punishment, or from motives of ambition or interest. If such persons possess talents and render service to the government, they are esteemed equal to the Cubolies, and have a chance of being advanced to honourable and lucrative employments. The admirals of the Algerine fleet was a renegade, and formerly a Jew. Of Christian renegades the number is not so great. The zeal to gain prof. Its from Christian is unabated: such conversions are not now encouraged, and in many instances, are forbidden, as the proprietors of the slaves would lose, and be deprived of the expected ransom. Renegades are despised and distrusted, and not without reason, for most of them are in judgment and afflicted, attached neither to one religion nor to the other. Shaw's Travels. Paffin. Pitt’s Account of the Religion and Manners of the Mahomctans, ed. iv. 1784. Paffin. Mod. Un. Hifl. vol. xiv. p. 435—456. 8vo.

ALGIERS, the capital of the country above described, was formerly called Meggan, from an African family of that name, and derives its present name Algiers, or Al-Jezeir, the island, from its being in the vicinity of the eastern mound of the harbour, which, before the time of the Turkish conquest, was severed from the continent. Some have supposed that this was the ancient Jeyfour; but Dr. Shaw is of opinion that the ruins of a Roman city on the banks of the river Harat, the ancient Savus, four miles to the south-east of Algiers, bids fairer than Algiers to be the ancient Jeyfour. The city is situated on the declivity of a hill, and is built in the form of an amphitheatre. The houses are gradually above one another, and their roofs or terraces are flat and white, so that at sea it appears, says Pitts, like the top-fall of a ship, or like a whiter’s ground covered with linen. It is, says Dr. Shaw, about a mile and a half in circuit, and is computed to contain about 2000 Christian slaves.
ﬂaves, 15,000 Jews, and 100,000 Mahometans. But since his time the number has been much reduced; and the number of inhabitants is now estimated at about 8,000, in which number are included several thousand Jewish families. It is surrounded by high walls, 12 feet thick, ﬂanked with square towers, but so decayed as to afford very little defence. A ditch 20 feet wide and seven deep, formerly encompassed the whole city, but is now almost ﬁlled with mud. It has ﬁve gates, which are open from sun-rise to sun-set; and without the walls seven towers or forts, of which the greatest is that on the mole, all which are supplied with cannon. Its best defence is towards the sea. The mole, the work of Hayradin, the son of Barbarossa, is built on the small island that faces the town, in form of a large semicircle, with a handlome opening into the haven, which is 130 fathoms long, and 80 broad, and where the largest vessels may ride so as to be secure from the violence of the waves. The mole is defended by a wall, which stands upon the solid rock, and which also serves as a light-house. It has three batteries of cannon. At the south end of the island is another fort, conﬁning three batteries, to defend the entrance of the harbour. There are also other forts along the coast. In the town there is but one handlome street, which reaches from the entrance to the well end, and in which are the built houses, the houses of the principal merchants, and the market for corn and all provisions. All the other streets are so narrow that two persons cannot walk abreast, and the middle being much lower than the sides for the reception of water and ﬁlth, the passage of camels, horses, mules, and asses, renders it still more inconvenient and difagreeable for foot passengers. It is still more dangerous to meet with a Turkish soldier, to whom the westward Christian must give way, or be likely to feel the effects of his brutal resentiment. The houses are supposed to be placed thus near to each other, either to shelter them from the fun, or for the convenience of mutual support, by means of props, when earthquakes occur. They are built of brick or stone, mostly square, with a paved court in the middle, somewhat like our old inns; round this court there are galleries supported by columns, and over these a second range, and upon this upper gallery are the terraces, which serve for walking on drying days. Their chimneys rife in the form of a cupola on the four corners of the terrace, and their roofs are whitewashed every year. As the houses are contiguous, a person may walk from one end of the town to the other along the terraces, and in this way they keep up an intercourse with each other. The houses of private people are within meanly built up and furnished, but those of the rich are interlaced with marble, supported on columns, and have their ceilings ﬁnely carved, painted, and girt. The most magnificent building is the palace of the Dev, in the midst of the city, which has two spacious halls, in one of which the dawn meets thrice a week. The barracks for the Turkish soldiery are likewise grand edifices, and each of them contains about 600; their mosques are numerous, of which the larger are seven, and the baths are many and spacious, but they are of different kinds, for the accommodation of persons of every rank and condition. Besides the public baths and those appropriated to women, there are others called bafios, which are hothome prisons, and in which their slaves sleep every night. There are some mammone edifices without the walls of the town, and a great number of tombs, some of which are adorned with chapels and oratories, to which the men and women resort every Friday. The city of Algiers, which had formerly neither wells nor fountains, is now supplied with excellent water by two aqueducts, which convey it from the adjacent mountains to a number of fountains at convenient distances from one another. The territory about Algiers is very fertile; the hills and valleys are every where ornamented with gardens, groves, and country seats, whither the richer sorts retire during the summer season. Their villas are little white houses, ﬂanked with a variety of fruit-trees and evergreens, which, besides the shade and retirement, afford a beautiful prospect towards the sea. The gardens are ﬂocked with plenty of fruit-trees, melons, and pomegranates, and well watered by a multitude of fountains and rivulets. Algiers, although it has many forts, and though in former times it has counteracted the assaults of some of the greatest powers of Christendom, is but weakly defended, and incapable of maintaining a regular siege. The Spaniards, however, attacked it in 1775, both by land and sea, with a force consisting of about 20,000 foot, and 2000 horses, 47 king's ships of different rates, and 546 transports, and were repulsed with great loss. In 1783 and 1794 their attacks were renewed, but without success. N. lat. 36° 49' 30". E. long. 2° 12' 43". The bay of Algiers lies to the east of the city, and the mole that forms the harbour is 500 paces long, and here is anchorage in 18 to 23 fathoms water. Cape Matignon lies to the north-west extremity of the bay, and Cape Biskine to the north-west of the city, and the westerly limit of the bay.

ALGOA BAY, or Zwaartkops, a bay of South Africa, situate in S. lat. 37° 50'. E. long. 26° 53', and distant from the Cape of Good Hope 500 miles. Mr. Barrow, a late traveller, luggered, that from the vicinity of this place to the falt-pans, from the cave of procuring bullocks in good condition, and from the abundance of excellent ﬁsh on the coast, great beneﬁts would accrue to the East India company, if an establishment was formed for the preparation of salted beef and ﬁsh. The river Zwaartkops ﬂows through a valley, in which our traveller found a species of antelope, called the riet-bok, or red-goat, hitherto undescribed by naturalists. By Barrow's Chart, Cape Reieef in this bay is in S. lat. 4° 10'. E. long. 27° 40'; the variation 26° 40' W.

ALGODONALES ISLANDS lie on the coast of Peru, in S. lat. 21° 53', and W. long. 72° 53', eight leagues north from the harbour of Cobija, and afford fresh water.

ALGODRES, a district of Beira, in Portugal, containing eight parishes and 450 inhabitants.

ALGONIDES, in Botany, a name given by Vaillant for genera of plants, called by Micheli and Linnaeus ZANNICHELLIA.

ALGOL, or Medusa's Head, in Astronomy, a star of the second magnitude, in the constellation Perseus. This star has been subject to singular variations, appearing at different times of different magnitudes, from the fourth to the second, which is its usual apparence. These variations were noticed at the close of the 18th century by Montanari and Maraldi; also by Flamsteed, 1666 and 1717; but they have been more accurately observed by Mr. Goodricke, at York, in 1783, who has, by comparing a great variety of observations, determined the period of their return to be 2°, 20', 48', 56'. As to the cause of this variation, Mr. Goodricke conjectures, that it may be owing either to the interposition of a large body revolving round Algol, or to some motion of its own, in consequence of which, part of its body, covered with spots or fuch like matter, is periodically turned towards the earth. M. de la Lande, comparing his own observations with those of Mr. Goodricke, and M. Wurms, of Nortingen, determines the period of variation to be 2°, 20', 48', 56'. Mem. Acad. Sc. Paris, 1788. See Phil. Trans. vol. lxxiii. p. 474. Vol. lxxiv. p. 287.

ALGOMEIZA, a name given to the ﬂar Procyon.

ALGONQUINS, in Geography, an Indian nation of North America, which formerly possessed considerable tracts of land along the north-west shores of the river St. Lawrence, in Canada. As hunters and warriors they had no rivals, and were
were long in alliance with the Iroquois; whom they agreed to protect from all invaders, whilst the Iroquois stipulated to pay them a tribute out of the produce of the earth, and to perform for them all the menial duties, such as faying the game, curing the flesh, and dresling the skins. At length the Iroquois associated with the Algonquins in their hunting matches and military expeditions; but by degrees the Algonquins became jealous of their associates and allies, and murdered several of their number. The Iroquois for some time filled their retreatmen, but determining upon revenge, they applied to the body of the art of war, as it was practiced among the savage nations; and having acquired a competent knowledge, which they improved by experience, they attacked the Algonquins with such fury, that, unless they had been prevented by the interposition of the French, their whole race would have been exterminated. They are daily decreasing in number, submits principally on fishing and hunting, and have scarcely any notion of agriculture. The Algonquins are now dispersed along the river Atawar, and occupy different parts of Upper Canada, above the lakes Huron, Ontario, and Superior. The lake of the Two Mountains, which may be deemed the commencement of the Usawas river, and which is about 20 miles long, and three miles wide, and surrounded by cultivated fields, is nominally in possession of the two tribes of Iroquois and Algonquins, whose whole village is situated in a delightful point of land under the hills, which, under the denomination of mountains, give a name to the lake. Near the extremity of the point their church is built, which divides the village into two parts, forming a regular angle along the water-side. On the east is the habitation of the Algonquins, and on the west one of the Iroquois, consisting in all of about 500 warriors. Each party has its missionary, and divine worship is performed, according to the rites of the Roman church, in their respective languages, in the same church: and so zealous, is it said, have their pastors been, that these people have been instructed in reading and writing in their own language, and are better taught than the Canadians of the country of the lower ranks: but, notwithstanding these advantages, and though the establishment is nearly coeval with the colonization of the country, they do not advance towards a state of civilization, but retain their ancient habits, language, and customs, and are becoming every day more depraved, indigent, and insignificant. The country round them, though capable of cultivation, presents few signs of culture; and houses are few, and formed of wood, covered with wattle and reed, and supplied with maize and vegetables. During the winter season they leave their habitations and their plantations to follow the chase, according to the custom of their forefathers. A tribe of the Algonquin nation occupies the parts adjacent to the lake Nesipiug. Some few families inhabit the island of St. Joseph, near the lake Huron: also a village, near the fall of St. Mary, about 50 miles farther towards the north-west, who are ravaging for one-half of the year, and in a state of intoxication for the other half, and the coasts of lake Superior, where they live chiefly on fish. The residence of the first chief, or Sachem, of all the Algonquin tribes inhabiting different parts of the country, is at the trading establishment, situated on a high bank on the north side of the river Le Plue, in N. lat. 48° 37'. This chief is by way of distinction called Necsam, implying personal pre-eminence. In this place the elders meet in council to treat of peace or war. Of this tribe some few are found near the river Assiniboine, who are in almost constant hostility with the Nadowasis. Those of them who occupy the country near lake Winipic and its sources, are employed in fur-hunting, so that they thus acquire the additional articles of cloth, blankets, &c. but their passion for rum puts it out of their power to supply themselves with real necessaries. The Algonquins and Knisenteaux are supposed by an intelligent traveller to have been originally the same people, and to have inhabited the Atlantic coast, the banks of the river St. Lawrence, and adjacent countries. Their progress has been westerly, and they are even found west and north as Athabasca. The language of the Algonquins is one of the principal languages, or of those which have been called radical, or mother tongues, amongst the Indians of Canada. The other two are the Sioux and the Huron. By means of an acquaintance with the Algonquin and Huron languages, a person may travel 1500 leagues in this country without an interpreter. The Algonquin language is said to excel that of the Hurons in smoothness and elegance. See Knisenteaux. The Baron la Hontan has given a small dictionary on the Algonquin language: Reland has also given a gloss on several words of the same. The first is entitled, Mem. de l'Amerique, Septentr. Hist. 1703: the last is in his Diff. Mijc. p. 3. Diff. 2. Mod. Un. Hist. vol. xxxv. p. 379. Mackenzie's Voyages, &c. through the Continent of North America, &c. p. 25, 53. &c.

ALGOR is used by some Medicinal Writers, to denote a preternatural coldness or chills in a part. Muys speaks in this sense, of an agony of the arm, attended with an atrophy. ALGORAB, in Astronomy, a fixed star of the third magnitude, in the right wing of the constellation Corvus. ALGORITH, or ALGEBRA, an Arabic term, which some authors, and especially the Spaniards, make use of to signify the practical operation of several parts of algebraic arithmetic or algebra. Sometimes it is also used for the practice of common arithmetic in ten numeral figures. 

Algorithm is properly the art of numbering truly and readily, and comprehends the six common rules of arithmetic. It is sometimes called logistica numeros. We lay the algorithm of integers, the algorithm of fractions, the algorithm of finite, &c.

ALGOZAREL, in Botany, a name used by Avicenna, and some other authors, for the common wild carrot, or Daucus fivemestris.

ALGOW, or ALGAE, in Geography, a canton of Germany, in the circle of Swabis, bounded on the north by the Danube, on the east by the Leck, on the west by the Hegow and the lake of Constance, and on the south by the county of Tyrol. It includes the marquisate of Burgau, the counties of Bregent and Montfort, the territory of the bishop of Augsburg, the abbey of Kempen, the courts of Fuggers, Walburg, Konigseck, and Mindelheim, with the cities of Augsburg, Kempen, Memmingen, Igny, Landau, Eberbach, and Wangen.

ALGOZ, a small place of Trazou-Montes, in Portugal, situated on the river Maeus, containing 20 parishes, and about 400 inhabitants.

ALGUAZIL, in the Spanish Policy, a sergeant or official of a judge, or magistrate, appointed to see his decrees executed.

ALGUEL, in Geography, a town of Africa, in the empire of Morocco and province of Hec.

ALHABOR, among the Arabian Astraronomy, is that star commonly called Stabius.

ALHAO I. in Botany, a species of Hedysarum. The inhabitants of Maspotamia and the eastern countries gather from this shrub a kind of manna, by means of the juice which transudes from its leaves, in the form of drops of various colors, which is indurated by the heat of the sun. Tournefort has particularly described this tree, and made a distinct genus of it, under the name of Alhagi. The shrub grows plentifully about Taurus; it has been also found in Tinos, and in many plains of Armenia and Georgia; and the manna is known in the Levant by the name of Terejvan. bin.
The leaves are said to be of a hot drying nature, and the natives use the flowers as a purgative, one handful of which, boiled in water, suffices for a dose. 

ALHAMA, in Geography, a pleasant town of Spain, in the province of Granada, situated in a narrow valley between high and very steep mountains; and having warm baths and medicinal waters that are much frequented. It was taken from the Moors, after a gallant defence, in 1481, and surrendered to the pillage of the Christian folders, who, besides pillaging an immense quantity of gold and jewels, made slaves of 5000 of the inhabitants. It is about 25 miles south-west of Granada, and 28 north-call of Malaga. N. lat. 36° 55', W. long. 3° 16'.

ALHAMA is also a town of Spain, in Cordova, near the Sierra Morena, nine leagues west of Cordova.

ALHAMA is also a small town or village of Spain, in Aragon, celebrated for its medicinal waters.

ALHAMA, a river of Spain, which runs into the Ebro, near Allaro.

ALHAMA la Seca, a town of Spain, in Granada, situated on the river Almeria, ten miles north-west of Almeria.

ALHAMBRA, a town of Spain, in Aragon, seven miles north of Teruel.

ALHAMBRA is also a river of Spain, which joins the Guadalquivir at Teruel.

ALHAMBRA, one of the four wards of the ancient city of Granada, so called by the Moors from the red colour of its materials, Alhambra signifying a red house; and by the Spaniards la Sierra del Sol, because, by its elevation on a high mountain, it is exposed to the rising sun. The inhabitants confit of the descendants of the ancient Moors. In this district are two palaces, one built by the Moors, the other by Charles V. and Philip II. The first, which is very large, is covered with walls, towers, and balconies; and both command, by their eminence, an extensive and delightful prospect. Above the old Moorish palace is the magnificent and beautiful house of Xeneralife, which was also built by a Moorish prince; and on the top of the mountain stands a church dedicated to St. Helena. The Moorish palace, according to the description given of it by Svinburne in his Travels, appears to have been a most magnificent and magnificent edifice. The court to which you are first admitted, called the Commun, or del Mefazar, i.e. the common baths, is an oblong square, with a deep basin of clear water in the middle, into which is a descent by two flights of marble steps, and having on each side a parterre of flowers and a row of orange trees. A peristy, paved with marble, runs round the court, and the arches are supported by pillars, in a style different from all the regular orders of architecture; and the ceiling and walls are inlaid with inlaid with marble. In every division are Arabian sentences of different lengths, denoting "there is no conqueror but God," and "obedience and homage to our Lord Abouabdallah." The ceilings are gilt or painted, and the colours still retain their freshness; the lower part of the walls is Mosaic, disposed in fantastic knots and foliages. The porches resemble grotesque work; and that on the right-hand opens into an octagon vault under the emperor's palace, which forms a whispering-gallery, communicating between the offices of both houses. Opposite to the door by which you enter into the Commun, is another leading into the quarto de las lomas, or apartment of the lions; which is an oblong court, 100 feet long, and 50 broad, encompassed by a colonnade, seven feet broad on the sides, and ten at the end. Two porches or cabinets, about 15 feet square, project into the court at the two extremities. The square is paved with coloured tiles, and the colonnade with white marble. The walls are covered to the height of five feet from the ground with blue and yellow tiles, placed chequerwise. Above and below is a border of small elutscheomis, enamelled blue and gold, with an Arabian motto on a bend, signifying, "No Conqueror but God." The columns that support the roof and gallery are of white marble, very slender, fantastically adorned, and irregularly disposed. The ceiling of the portico is much more highly finessed than that of the Commun. The capitals are of various designs. Amidst the various of foliages, grotesques, and irland ornaments, there does not occur the slightest representation of animal life. About each arch is a large square of arabesques, surrounded with a rim of characters that are generally quotations from the Koran. Over the pillar is another square of beautiful filigree work; and higher up is a kind of wooden cornice, enriched with carving as much as the flanco below. Over this project a roof of red tiles, which disfigure this beautiful square, and which has been lately added when the Alhambra was repaired. In Moorish times the buildings were covered with large painted and glazed tiles, some of which still remain. In the centre of the court are twelve ill-formed lions muzzle, bearing upon their backs an enormous basin, out of which rises another of smaller size. When the pipes were kept in order, a volume of water was thrown up, which, falling into the basin, passed through these lions, and was discharged out of their mouths into a larger vessel, communicating by channels with the jets d'eau in the apartments. This fountain is of white marble, adorned with fountains and Arabic ditiches, to this purpose: "Seek thou not how the water flows copiously like the Nile?" "This resembles a sea flowing out its shores, threatening shipwreck to the mariner." "This water runs abundantly to give drink to the lions." "Terrible as the lion is working in the day of battle." "The Nile gives glory to the King, and the lofty mountains proclaim." "This garden is fertile in delight; God takes care that no noxious animal shall approach it." "The fair princely that walks in this garden, covered with pearls, ornaments its beauty so much, that thou mayest doubt whether it be a fountain that flows, or the tears of her admirers." Beyond the colonnade, and on its south side, is a circular room used by the men as a place for drinking coffee, &c. And it was refurnished in summer by a fountain. The form of this hall, the elegance of its cupola, the cheerful distribution of light from above, and the exquisite manner in which the flanco is designed, painted, and finished, exceed all powers of description. In this delightful scene, it is said, Aboubaloubi assembled the Absureghars, and caused their heads to be struck off into the fountain. At the head of a court are two rooms, which are supposed to have been tribunals, or audience chambers. Opposite to the Sala de los Absureghars is the entrance into the Torre de los dos Hermanos, or the tower of the two filters, so denominated from two very beautiful pieces of marble laid as flags in the pavement. This gate exceeds all the rest in profusion of ornaments, and in beauty of prospect, which it affords through a range of apartments, where a multitude of arches terminate in a large window open into the country. In a gleam of sunshine, the variety of tints and lights thrown upon this enfilade are uncommonly rich. The first hall is the concert-room where the women sat; the musicians played above in four balconies. In the middle is a jet d'eau. The marble pavement is much admired for both the size of the flags and evenness of the colour. The two filters, which give name to the room, are flasks measuring 15 feet by 7½, without flaw or flaw. The walls, to a certain height, are mofolic, and above, are divided into neat compartments of flanco. The ceiling is a fretted cove. For preferring this vaulted roof, and
ALHAUR, a river of Alizia, which runs into the Sakkaria, eight miles south of Amuris.

ALHAUS, a town of Prussia, four miles south of Coln.

ALHAZEN, in Biography, a learned Arabian, lived in Spain about the close of the 11th, or beginning of the 12th century; though Montucla says, that it is not known what was the precise period in which he lived. He wrote a treatise on astrology; and another on optics, which was printed in Latin in the Thesaurus Opticus of Risner, in 1572. In this optical treatise he gives a tolerable description of the eye, and discusses largely concerning the nature of vision; maintaining that the crystalline humour is the most important organ for this purpose, without confusing it as a lens, and inferring that vision is not completed till the ideas of external objects are conveyed by the optic nerves to the brain. He accounts for simple vision with two eyes, by supposing, that when any corresponding parts of the retina are affected, the mind perceives but one image; and he treats very diffusely of optical deceptions, both in direct vision, and also in vision by reflected and refracted light. Alhazen pursued his enquiries into the nature of refraction much further, and with greater success, than the more ancient writers. He deduces from experimental and general reasoning several properties of atmospheric refraction, observing, that it increases the altitudes of all celestial objects; and he was the first who advanced the notion, that the flars are sometimes seen above the horizon by means of refraction, when they are really below it. He also observed, that refraction contracts the diameters and distances of the heavenly bodies, and that it is the cause of the twinkling of the stars.

The word is formed of the Arabic handal, or bandhal, a name for colocynth. They are esteemed good purgatives, and are used on divers occasions.

ALHANDA, in Geography, a town of Portugal, in Estremadura, containing two parishes, and about 1,350 inhabitants.

ALHANEA, a small town of Spain, in Estremadura, belonging to the order of St. Jago, seated on an eminence, and defended by a strong castle standing on a rock.
moreable on the centre of the instrument, and carrying two figures, which are erected perpendicularly at the two extremities of it.

ALHIRTO, in Astronomia, a fixed star of the third magnitude, in the constellation Capricorn. This is otherwise called roifum galline. Near this star, in the year 1600, appeared a new star, which lasted twenty-one years, and then disappeared again.

ALHUSWYs point, in Geography, is situated upon a river falling into the Baltic, in a bay which bears nearly N.N.W. a little westerly from the island of Bornholm. If a ship is a league east of this point, the course will be due north to the bottom of the bay, having the land all the way on the larboard, but the depth of the water is uncertain. It is in N. lat. 55° 35’, E. long. 14° 30’. Malham’s Naval Gaz.

ALI, in Biography, the son of Abu Talib, who was uncle of Mahomet, and was eminently distinguished among the Mahometans, both during the life and after the death of their prophet. Ali was an early convert to the divine mission of his cousin, and contributed, in no small degree, by his zeal and activity, to the success of his cause. Having been taken in his infancy under the protection of Abubeker, the father-in-law of Mahomet, and the ardent promoter of his interest, he was directed by his patron to summon the kingdom of the prophet, to receive from him a solemn declaration of his prophetic office. Mahomet, after announcing his compliance to his assembled relatives, asked them who would become his vizir or vicegerent? Whate’er they were hesitating, Ali started up and exclaimed, with the enthusiasm that marked his character, “I, O prophet of God, will be thy vizir; I myself will beat out the teeth, pull out the eyes, rip open the bellies, and cut off the legs of all who shall dare to oppose thee.” Upon this Mahomet embraced Ali with great affection, and enjoined all who were present to regard him as his deputy. To him he afterwards committed the promulgation of the ninth chapter of the Koran; which commission he executed at Mecca, by reading 20 or 30 verses of this chapter to those who were assembled, and then announcing to them four particulars which were strictly to be observed, viz.: “that no idolater is to come near the temple of Mecca after this year;” “that no man is to profane or compasst the Caaba naked for the future;” “that none but true believers shall enter paradise;” and “that public faith is to be kept.” Ali was equally celebrated for his eloquence and his valour; his surname of “the Lion of God, always victorious,” sufficiently evinces his military renown; and as he succeeded his father in being chief of the illustrious family of Hashim, and hereditary guardian of the city and temple of Mecca, and had married Fatimah, the daughter of Mahomet, his talents and his rank, as well as his near relation to the prophet, and the personal favour by which he had been distinguished, established claims of pre-eminence, which naturally directed his views to the honour of succeeding Mahomet in the regal office. To this honour he also aspired; but he wisely declined contending for it during the three caliphates of Abubeker, Omar, and Othman. Upon the affimation of the bulk of those, Ali was unanimously elected caliph. When he was urged by some of the chief Moslems to accept the office, he said to them, “If you intend to recognize my authority as the successor of Mahomet, swear to be faithful to me, or else permit me to take the oath of allegiance to one of you.” As soon as he was deposed, he hastened to the mosque at Medina, at the time of prayer, in a thin cotton gown, tied about him with a girdle, with a coarse turban upon his head, carrying his slippers in one hand, and in the other a bow, which he used as a walking stick, and was there publicly inaugurated, in the third year of the Hujira, A.D. 655.

As soon as Ayefha, the daughter of Abubeker, and the widow of Mahomet, heard of Ali’s election, she expressed her disapprobation; having conceived an invincible prejudice against him, because, as it is said, he had discovered her infidelity to the prophet; and Teha and Zobeir, two persons of great influence, who had concurred in the choice, fled to Balfarah, and there raised the standard of rebellion. Ali had also routed the remnants of a strong party, by displacing those governors of the provinces, who had been appointed by his predecessor Othman. Ayefha appeared at the head of the mail-contents at Balfarah, and there Ali met them with an inferior force with regard to number, but formed of veteran troops. Ayefha was mounted on a great camel, in a pavilion resembling a fort of cane, from which circumstance the day of battle was called the day of the camel. Ali gained a complete victory. Teha was slain in the engagement; Zobeir was afterwards assassinated; and Ayefha was taken prisoner; and, after some submission, treated courteously, and sent back to Medina. The next enterprise of Ali was directed against Moawiyah, a former governor of Syria, who had been proclaimed caliph, and was supported by the house of Omnimjah, and by Amra, the conqueror of Egypt. The armies met at the plain of Seliein, on the western banks of the Euphrates. After several skirmishes, and an ineffectual challenge of Moawiyah to single combat, the hostile forces engaged, and the contest was continued all night, to the great disadvantage of the Syrians; and this night was denounced by the Arab historians, “the valiant night.” As victory was likely to be decided in favour of Ali, Moawiyah, in concert with Amra, contrived an artifice that might induce the caliph’s men to desert. With this view they ordered some of their men to carry lances, bearing upon their points copies of the Koran, at the head of the troops, and to cry out as they advanced, “This is the book that ought to decide all differences between us; this is the book of God between us and you, which absolutely prohibits the effusion of human blood.” Ali was thus compelled by some of his troops, who threw down their arms, to found a retreat, and thus to give up the contest in the moment of victory, and after having lost, as it is said, 2,500,000 men, and killed 45,000 of the enemy. The dispute was submitted to arbitration, and by the award it was to be determined, in deposing Ali. Sentence was pronounced on a tribunal erected between the two armies. Abu Mafa, one of the arbitrators, first pronounced his award: “I depose from the caliphate both Ali and Moawiyah, in the same manner as I take this ring off my finger.” Amra, the other arbitrator, immediately acceded the tribunal, and said, “I concur with Abu Mafa in deposing Ali, and confer the caliphate upon Moawiyah; I therefore inveil that prince with the supreme authority in the same manner as I put this ring on my finger. And this I am the more disposed to do, as he has justice on his side; having been declared by Othman his successor, and being the most worthy of the Moslems to occupy the high station to which I now advance him.” Thus commenced that schism among the Mahometans, which has produced animosity and mutual excommunication, and which is visible to this day in the rooted antipathy which subsists between the Turks and Persians. Ali and his adherents were disgraced and irritated; but they were under the necessity of acquiescing and retiring to Cufa, where Ali was soon defeated by the Kharejites, i. e. as the name imports, rebels or revolters. These were called Moskkimites, or Judæans, because the reason they gave for their revolt was, that Ali had referred a matter concerning the religion of God to the judgment of men; whereas, in such case, the judgment belonged solely to God.
Ali

Khurajites, not convinced by Ali's reasoning, associated in arms, and fixed upon Naharwan, about four miles to the east of the Tigris, for their place of rendezvous. Ali Marched out against them, and having reclaimed most of them to their former attachment by persuasion, he destroyed the rest in battle, and gained again the possession of Arabia. But his rival Moawiyah established himself in Syria and Persia, and Annu fixed upon Egypt in his name. The Syrians also made an incursion into Ali's territories, exercised great cruelty, and committed various depredations. At this time three of the Khurajites happened to be present at Medina, who, occurred in lamenting the miseries of the civil war which the people were enduring, and resolved to terminate them by assassinating the principal authors of them, viz. Ali, Moawiyah, and Annu. One of them hallowed to Damasius, and wounded Moawiyah, but the wound, though dangerous, was not mortal. Another went to Egypt, and entering a mosque, where he expected to find Annu, mistook another person for him, and dispatched him, whilst Annu survived unhurt. The third conspirator, whose name was Abdallah, was more successful than either of his two profligate companions. Having arrived at Cufa, he engaged two associates, who joined in assailing Ali at the door of the mosque, when Abdallah gave him the fatal blow. The expiring caliph left in charge with his son Hassan, in care of his death, to execute the assassin at one stroke, thus humanely guarding against the lingering torments which usually accompanied the death of offenders. Ali, pierced as it is said, by a poisoned sword, expired on the fifth day after his wound, in the 63rd, 57th, or 58th year of his age, for each are the different accounts that are given of his age, in the 40th year of the Hegira, A.D. 666. His sepulchre at Cufa was concealed till the expiration of the caliphate of the Ommiades; but in the year of the Hegira 367, A.D. 977, Addad ed Dowlat erected a superb monument over it, which has been decorated by the Perian kings, called, "the dome of the distributor of lights and graces," and regarded as a great object of the devotion of his votaries. A city, called Mehael Ali, has also been built to his honour, not far from the ruins of Cufa. Some of his most zealous devotees supplicate that he is still alive, and expect his advent in the clouds of heaven to fill the earth with justice. Ali, after the death of Fatima, by whom he had three sons, Hassan, Houiffian, and Mohaffian, the first of whom succeeded him, had eight other wives. The Mollem writers, particularly those of his sect, speak highly of his corporeal, mental, and moral endowments. They extol his valour, munificence, and benignity of temper. Among them he also ranks high as to his learning. There are still extant his "Centialoquium," or collection of a hundred maxims or sentences, which has been translated from the Arabic into the Persian and Turkish, part of which has been published in English by Mr. Ockley; and also his "Divan," or collection of verses. But his most celebrated relic is a parchment, written in mysterious characters, intermixed with figures, prophetic of all the events that are to happen in the world. This was a deposit in the hands of his family. Many of Ali's sayings and apophthegms are recorded by authors; one of the most instructive is the following: "He who would be rich without wealth, powerful without subjects, and a subject without master, has only to forfake sin and serve God."

The appellations by which Ali was honoured by the Arabs are very distinguishing and honourable. On account of his superior bravery, they called him "Ali Haidar," the lion, and "the victorious Lion of God." They also denominated him "Wahi," i.e. legatee or heir of Mahomet, and "Mortad," q. d. beloved by, and acceptable to God.

He was also called by his followers, "the distributor of lights and graces"; and "the king of men." Ali has given denomination to a sect or party among the Mahometans, who adhere to the right of succession of Ali, the fourth caliph, or successor of Mahomet, and the reform of Mufullimnain introduced by him. The sectaries of Ali are more particularly called Shiites, and stand opposed to the Sunnites, or sect of Omar, who adhere to the law as left by Mahomet, Ababeker and Omar. The followers of Ali are divided into two distinct parties, the one being professedly Mahometans, and the other sectaries of Ali, who professed the Shiites; and at present the Persians, part of the Ubeir Tartars, and some Mahometan sovereigns of India are of the sect of Ali; whilst the Turks are of the sect of Omar, and hold Ali in execration. The distinguishing badge of Ali's followers is a red turban, which is worn by the Persians, who are hence called, in derision by the Turks, "Kifilbachit," i.e. red heads. Mod. Un. Hist. c. ii. vol. i. Gen. Dict. Sale's Prel. Dict. to the Koran.

Ali BEY, an eastern adventurer, whose history and exploits have interested much attention, was probably born among the Abazians, a people inhabiting Mount Caucasus, and brought by the slave-merchants to one of the annual fairs at Cairo, where he was purchased by the brothers, Isaac and Yousef, Jews, employed in the custom-house, and by them presented to Ibrahim, a kiaia, or veteran colonel of janizaries, who was then one of the most confederate men in Egypt. At this time he is supposed to have been 12 or 14 years of age. By the favour of his patron, to whom he rendered the useful services of the Mamlook, he was taught Arabic and wrote, in the customary exercises of a military kind, in which he displayed a fire and activity that obtained for him the appellation of djendab, or madman. At the age of 18 or 20 his heart was allowed to grow, or he was made free; and his patron gave him a wife and revenues; promoted him to the rank of kacheb, or governor of a district; and at length procured him to be elected one of the 24 beys. Thus favoured and advanced, his ambition was excited; and the death of Ibrahim, in 1757, opened a free course for the execution of his projects. After an absence of a few years, during which he had been engaged in a variety of intrigues, for raising and displacing several chiefs, and two years of which he had passed in a state of exile in Said, or Upper Egypt, deviating and maturing his plans of future dominion, he returned to Cairo in 1768; and, in one night killed four beys, who were his enemies, banished four others, and thus became from that time the chief of the most numerous party. Not contented with the trivial title and dependent office of bey, he aspired to the title and honour of Sultan of Egypt; and with these views he determined to throw off the supremacy of the Porte; and accordingly he expelled the pacha, refused the customary tribute, and in 1768, he proceeded to coin money in his own name. The attention of the Porte was so much occupied by other concerns that he was under a necessity of temporizing; and Ali, well apprised of his situation, pushed forward his enterprises with success. He began with dispossessing Hammam, an Arab theik, of a part of the Said, which he had occupied, and where he had formed a power capable of giving disturbance; and towards the end of this year, 1769, he fitted out some vessels at Suez, which were ordered to seize on Djedda, the port of Mecca, whilst a body of cavalry marched by land to take possession of Mecca itself, which was given up to plunder. The project which he had formed, in consequence of the pillage to the East Indies by the Cape of Good Hope, by submarine route of the Mel-
ALI

Terranean and the Red Sea. Failed with success in the petty enterprises he had already accomplished, and flattered by his servile courtiers, his ambition suggested to him more extensive conquests. Syria was the first object of his contemplation; and the war with the Russians, which broke out in 1769, and which occupied all the Turkish forces in the north, favoured his design. Besides, the Daher, in actual rebellion against the Porte, would be a powerful and faithful ally; and the extortions of the pachas of Damascus and Hama disposed those he had oppressed for revolt, and made way for his obtaining the title of dervish of nations. Ali having laid his plans, detached in 1770 a corps of Mamlouks to take possession of Gaza, and thus to secure an entrance into Palestine; and soon after he sent a larger army, to form a junction with Daher at Acre; and to proceed from thence to Damascus. Ofman, pacha of Damascus, was diligent in his preparations, and collected an army quite as numerous and ill regulated. On the 6th of June 1771, the two armies met, and a decisive action took place, in which Mohammed, the friend of Ali, and Daher his ally, proved victorious. They immediately took possession of Damascus; but the battle rekindled. At the moment when the signal of surrender was expected, Mohammed suddenly commanded a retreat, and all his cavalry turned towards Egypt. This singular revolution was at first attributed to a pretended report of the death of Ali Bey; but it was really owing to a conference which had preceded the preceding night between a crafty agent of Ofman and Mohammed Bey, Ali's commander. Ali, though disappointed and chagrined, did not renounce his projects; he prepared, in conjunction with Daher, a second army for the campaign of 1772; but the event was unpropitious. The ecape of Mohammed routed his jealousy and his fears; he beheld in him a dangerous rival, and resolved on his ruin. Having ordered the gates of Cairo to be shut, and no Mamlouk to be allowed to pass, he sentenced Mohammed into immediate exile in the Said. Mohammed, however, contrived to make his escape; and from this moment all was lost. The Mamlouks, wearied with the insulences of Ali Bey, repaired in crowds to his rival, and in about six weeks he left the Said, with a strong force, and marched towards Cairo. Ali prepared to meet him; and in the month of April 1772, the two armies had a rencontre in the plains of El-Mafateh, at the gates of Cairo; the issue of which was, that Mohammed and his party entered the city, fabre in hand; and Ali Bey had barely time to escape with 800 of his Mamlouks. With this inconceivable force he repaired to Gaza, and attempted to join his ally, Daher, at Acre, who, after some danger from which he was rescued, conducted him to Acre. Both Ali and Daher marched to the succours of Said, (Sidon) which was then besieged by the troops of Ofman, in conjunction with the Druzes. At their approach the Turks raised the siege, and retired to a place about a league north of the city, on the river Aouba. There, in July 1772, an engagement took place; and the Turkish army, three times more numerous than that of the two allies, was entirely defeated. The seven pachas, who commanded it, fled; and Said remained in the possession of Daher. Ali Bey and Daher, on their return to Acre, proceeded to chastise the inhabitants of Yafa or Jaffa, who had revolted; and after a siege of eight months the town capitulated in February 1773. Ali now determined to return to Cairo; and he was encouraged in his purpose by the promised succours of Daher, and of the Russians. This affiance was delayed, and Ali became impatient. In April 1773, quickened in the execution of his purpose, by fabricated letters, which he received from Cairo, he began his march at the head of his Mamlouks, and some troops furnished by Daher; but when he advanced into the Dafar, which separates Gaza from Egypt, he fell into an ambush of 1000 Mamlouks, who were waiting his arrival. This corps was commanded by Mourad, a young bey, who, being enamoured of the wife of Ali Bey, had obtained a promise of her from Mohammed, in case he should bring him the head of Ali. The attack was impetuous; Mourad met with Ali in the crowd, wounded him in the forehead, made him prisoner, and conducted him to Mohammed. By his former matter, Ali was received with perjuries respect; but on the third day, this parade of civility and politeness terminated by the death of Ali Bey, who, according to some, died of his wounds; or, as others report, by poison.

Ali Bey was certainly a character of original vigour and capacity; and was superior in his views to what could have been expected from one who was bred in a school of barbarism and ignorance. He governed Egypt with a steady hand, and was particularly favourable to the Franks; but he undertook more than he had power or talents to perform, and exhausted his revenues in fruitless enterprises. He is also blamed for too soon refraining active labours to his lieutenants, and for placing unlimited confidence in his favourites, and winking at the exaggerations of his officers. His morals were those of his chiefs and country, where perfidy and murder are allowable means in pursuing the objects of ambition; yet he was not devoid of generosity and a sense of justice. During his administration, several neifs of Cairo in Egypt were annihilated, villages which had been inhabited by the pirates of the Nile were razed; the communication between different parts of the country was free; the roads were no longer infested with robbers, nor was navigation interrupted by that spirit of pillage, which, since his death, has resumed its fatal activity. It was his wish, "that every man might be able to carry his purse in his hand, and leave his door open, even during the night, without running any risk."

ALI, in Geography, a town of Afia, in the country of Georgia, 50 miles west of Teliss.

Ali, a town of Asia, in the country of Georgia, in the province of Satabago, 22 miles south-west of Akalzika.

ALIA, Asis, in Greek Antiquity, solemn games celebrated at Rhodes on the 24th day of the month Gorpiae, corresponding to the Athenian Bedromion, in honour of the sun, Hec, or Aisos, who is said to have been born there; the inhabitants of which were hence called iEnadoi, Heliod. The victors were crowned with poplar. Strabo, tom. ii. p. 966.

ALIABAD, in Geography, a town of Persia, in the province of Tabirian, 10 leagues south-fourth-east of Ferabat.

ALIACMON, or HALLACMON, in Ancient Geography, a river of Macedonia, separating it from Thessaly, rises in the Penetra mountains, and running south-east, enters the bay of Thessalonica, between the cities of Thysus, and Dium.

ALJAKI, in Geography, a town of Poland in the province of Xov, 20 miles south-east of Crakofy.

ALJAMEA is a name which the Morefoes in Spain give to the language of the Spaniards.

Among other articles agreed on by the Junto, which was appointed
appointed by the emperor Charles V. in 1536, in favour of
the Moriscoes, this was one, that the Moriscoes should no
longer speak Algavaire, i. e. Moorish, or Arabic, but
should all speak Aljamia, i. e. Spanish, as it was called by
the Moors, and all their writings and contracts should be in

ALIANA, in Geography, a bishopric of Phrygia, sub-
ject to the metropolis of Laodicea.

ALIANELEO, a town of Italy in the kingdom of
Naples, and province of Bafilicata, 27 miles east of Po-
tenza.

ALIANO, a town of Naples, in the province of Basilici-
cata, 23 miles south-east of Potenza.

ALIANO, also a town of Naples, in the country of La-
vora, two miles west of Gaeta.

ALIANSKOI, a fort of Russian Siberia, in the govern-
ment of Kolovan, 120 miles south-west of Kolovan.

N. lat. 52° 52'. E. long. 79° 34'.

ALIARBUCHA, in Natural History, the Arabian
name for a large kind of rat, the Jerboa of other writers,
common in that country, and good to eat, according to Bo-
chart, who thinks it the same as the fapan, mentioned in
Leviticus, and there declared unclean. Lev. xi. 5.

Dr. Shaw thinks the fapan to be the daman Isracl, or a
species of rabbit.

ALIARDII, in Ancient Geography, a people of Africa,
according to Ptolemy.

ALIARIA, a town of Comagene, placed by Antonin,
in the route from Nicopolis to Edelea.

ALIARTUS. See Aliartus.

ALIAS, in Law, a second or farther writ issued from
the courts of Westminster, after capias, &c. issued without
effect.

ALIBACA, in Ancient Geography, a town placed by
Ptolemy, in the Pentapolis.

ALIBANI, or Alibini, in Geography, a town of
Arabia, 140 miles south-east of Amamiridin.

ALIBAG Ree', a town of European Turkey in Bulga-
ria, eight leagues east of Silifirdin.

ALIBI, in Law, denotes the absence of the accused
from the place where he is charged with having committed
a crime; or his being elsewhere, as the word imports, at
the time specified.

ALICA, in the Ancient Physic and Diet, a kind of food;
but the various accounts given of it by authors, make it
uncertain what it was; some representing it as a sort of grain,
and others as an aliment made of grain.

The Greek word for alica was χελώνας, which term, and
chelone, seem to have been general names for all ψηλήνας,
as the genus from the species.

ALICA, in Geography, a town of Italy in the duchy of
Tuscany, 20 miles west south-west of Florence.

ALICANDRA, or Alidracca, in Ancient Geography,
a town placed by Ptolemy in Media.

ALICANE, in Geography, a river towards the south-
west part of the island of Ceylon, nearly east from Barberine
island, and south from Calitire.

ALICANT, a small, but well-built, rich, populous, and
fortified sea-port town of Spain, in the kingdom of Valen-
cia. It is situated on the Mediterranean, between a moun-
tain, on which the castle stands, and the sea; and it is well
defended by strong fortifications. This mountain is white, and
being visible at a great distance, seems as a guide to pilots.
The bay in which it stands is sheltered on the east by Cape
de la Huerta, and to the west by Cape St. Paul, and the
island of Taborca. Vessels anchor about a mile from the
mole, which is large and commodious, in water from six to
10 fathoms, and may enter and go out without any wind.
This bay is said to have been the famous gulf of Ilici, so
called from a Roman colony, now Elche; but the declin-
ing state of that port, and the improvements of Alicante,
gave it the name which it now bears: it begins at Cape St.
Martin, and terminates at Cape Palos. The coast is
guarded by watch-towers against the incursions of the Cor-
fairs. Alicante was taken from the Moors in 1244. The
castle was taken by the English in 1706, and retaken
1707, by the Spaniards. The adjacent territory is fertile,
and produces white and red wines that are much valued.
The export trade, which is considerable, consists of barilla,
antimony, alum, aniseed, cummin-feed, dried fruit, wool,
and wine. As the duties of entry are lower than those at
Valencia and Cartagena, this circumstance has contributed to
the increase of its commerce and riches. Linen, from
France, Switzerland, and Silefia, and camlets and woollens
from France, are the chief imports. The English, French,
Dutch, and some Italian States have usually had a consul at
Alicant. N. lat. 38° 34'. W. long. 8° 7'.

ALICARIAE, in Ancient History, a term synonymous
with profiteers.

ALICANUM, or Halicanum, in Ancient Geography,
a town of Pannonia.

ALICASTRUM, in Botany. See Brosimum.

ALICATA, in Geography, a small town of Sicily in
the valley of Noto, built partly upon a slope, and partly
on the beach, at the end of a long chain of hills; 15 miles
cal. south-east of Giontoni, and 60 south-west of Catania.
This is a place of little strength, the castle of St. Angelo
on the brow of the hill being ruinous, the town walls much
decayed, and the fortresses on the peninsula wanting repairs.
It forms two small bays for the barges that carry out the
corn to ships that lie in the harbour.

It has great connections with Malta in the corn trade.
This town contains 10,000 inhabitants. The populace pay a
great respect to the bard of the district; the women and children
carrying on their knees in the streets before a clergyman, touching his
garments with a finger and then kissing their hands with great
generation. Alicata is said to possess some ancient Greek
manuscripts relating to the ancient city of Calvella: the most
remarkable is a pithograph, or decrec of the senate, for
crowning Heracles director of the public academy. This
town was plundered by the Turks in 1543. N. lat. 37°
1'. E. long. 13° 51'. Swinburne's Travels into Sicily,

Alicata is also a mountain of Sicily not far from this
town, in which, as it is thought, was situated Daldalian,
where Phalaris kept his brazen bull.

ALICORDA, or Alidora, a town, placed by
Ptolemy in Baetiana.

ALICE, a river of Sicily, was the ancient boundary of
the Lucanian state. Immense quantities of anchovies fre-
quent the mouth of this stream and the adjacent coast: it
is therefore probable that either the fish derived its Latin
name Halic from the river, or the river was called after the
fish.

ALICONDA, in Botany, an African tree, growing na-
turally in the kingdom of Congo, of such bulk that 10
men cannot fathom it round. The natives call it bonda,
and as the wood easily roots, they do not build their huts
near it, lest its fall should crush them to death, or its fruit,
which is of the size of a large gourd, and easily broken from the
the tree, should knock them down. The bark of this tree, well beaten and macerated, yields a coarse thread, of which they make their ropes, and which macerated and dried, and beaten with bars of iron or wood, becomes like a large piece of cloth, with which the natives cover their middle from the girdle to the knees. The shell or rind of the fruit, which is hard like that of a gourd or calabash, being freed from its pulp, which in time of scarcity may be made into a nourishing pap, serves for vessels of various kinds, and gives to water, preferred in it, a pefiant aromatic taste. The small leaves are eaten in time of scarcity, and the large ones serve to cover houfes, or being burned, to make good foap. Mod. Un. Hill, vol. xiii. p. 23. 8vo.

ALICONEA, in Entomology, the name given by Cra- merr to the PAPILIO JULIA.

ALICUDA, or ALICUS, one of the Lipari islands, near the coast of Sicily. N. lat. 38° 31'. E. long. 14° 32'. This island is about six miles in circuit; its popula- tion is not so great as that of Felicuca, which contains about 650 inhabitants, and the houfes are built at the fouth and fouth-call end of the island, on the declivities of the mountains about half-way up their acfent, in order to be guarded againft the nightly furpizze and attack of the Tunisian Corsairs. Besides Indian figs, and fome olive- trees, these two islands contain many vines, from the grape of which a good wine is made, though it be not malmey, nor the grape the paffhoa or paffohlain. The corn grown here is barley and wheat, which, together with the grapes, amount in value of produce to about 3000 Neapolitan crowns. The industry and patience of the people of Alieuda are incredible; they do not lofe an inch of the ground they cultivate. Their foil is almofl wholly interrupted by points of rocks, maffes of lava, clefts and craggs; and yet they render tracts of this kind productive, by turning and breaking them with pointed foedes: fo that the Liparife humorously fay of them, that the people of Alieuda till their lands with the point of a knife. In all the Zolan ifles there is not better bread than that of Alieuda. Three or four flowering boats belong to this island, which are mostly the property of the parish prieff, and are employed for the augmentation of their ecclefaical revenues, amounting to little more than 12 fequins. There is not a fingle fpring of fresh wa- ter either in Alieuda or Felicuca; and therefore when it does not rain for feveral months, the diftreffes of the inhabitants is extreme. They have no ferpents in thefe islands, as they furnifh no food neceflary for their fubfiftence. The people are exempted, on account of their poverty, from every kind of taxation, the tythes which they pay to the bifhop excepted. These iflanders, notwithstanding their extreme pof- tivity, and inhabiting huts, formed of pieces of lava, fearely admitting a ray of light, and appearing like the nets of birds hung to the cliffs, are finguHarly contented and happy. Their fare consists of black barley bread, and wild fruits, and fometines, by way of dairy, falt fih, and their drink of pure water; and yet fuch is the temperature of the climate, and the fublimes quality of the air, that they enjoy, with little interruption, health of body and cheerfulness of mind. The veifiges of fire are difcoverable in every part of this ifland, but the actual exiftence of volcanic eruptions and conflagration precedes the records of history. The vol- canic materials, now found in it, and particularly examined by the accurate and infuftrious Spallanzani in his visits to this ifland, are pumice, tufts, and glaffes, and great quan- tities of lava, in detached globules and continued currents, which have pefiofex for their bafe. Dolomieu was of opinion, that Felicuca and Alieuda had once formed a fingle conical mountain, which had been opened and feparated on one fide; but Spallanzani alleges feveral cirnumstances that evince the improbability of this opinion. Although these two iflands exhibit numerous and induftrious characters of fire, no figns of it in a flate of acitivity are now to be feen. The ancient name of Alieuda was Eriqua; and the author of the epitome of Stephanus fays, that it was fo named from the erica or heat which grows there plentifully. Strabo likewise (lib. vi.) informs us, that these two iflands derived their names from plants. But in the time of Ariobote and Strabo, and other ancient writers, the conflagrations in these two iflands, as they are un- noticed by them, must have been entirely extinguifhed. Spallanzani's Travels in the two Sicilies, vol. iii. c. 18— vol. iv. c. 24.

ALICULA, in AnPiiity, a kind of puerile habit worn by the Roman children. This was a sort of chlamys; fome explained it by tunica manifata.

ALICYRNA, in Ancient Geography, a place of Greece, fituate, according to Steph. Byz., in Acamania, and ac- cording to the periplus of Scylax in Etolia. It is probably the hecrna of other authors, to the south of Calydon on the borders of the sea.

ALIDES, in the Mabometan History, the defendants of Al, otherwise called Fatimites. See ALI.

ALIES, in Ancient Geography, a sea-port town of Pe- loponnesus, in Laconia, inhabited by fishermens, whence its Greek name.

ALIE-KRUIYK, in Natural History, a Dutch name given to a kind of sea-fiall, the history of which is given by Swanmerdam. Bib. Nat. tom. i. p. 180.

ALJEMBUT, or, as fome write it, gembut, in Botany, a name given by the Arabians, Avicenna, and others, to a species of acacia, which they also call the Nabatanian pod, and ceration, or siliqua, and which fome have supposed to be the fame with the common carob; but they expressly diftinguith it, by faying that it is an alriment, whereas the other is gently purgative; and that the fruit of it was given in haemorrhages. Nay, ifidore goes fo far as to fay, that the acacia juice of the fhips was made of its fruit, while unripe.

ALIEN, in Law, a foreigner or perfon born out of the king's allegiance; or under the juftification of some other Sovereign; and not naturalized, or made a denizen.

Of these there are two kinds; viz. alien friends, who are of those countries which are at peace and league with us; and alien enemies, who are of countries at war with us; to which fome add a third, viz. alien infidels.

A man born out of the land, but within the limits of the king's obedience beyond the seas; or of English parents out of the king's obedience, provided the parents at the time of the birth be of such obedience, is no alien, but a fubjeft of the king, lat. 2. 25 Edw. III. commonly called the statute De natis ulra mare.

By several more modern statutes, (7 Ann. c. 5; 10 Ann. c. 5. 4 Geo. II. c. 21, and 13 Geo. III. c. 2.1.) these re- frictions are further taken off; fo that all children born out of the king's allegiance whofe fathers, or grandfathers by the father's fide, were natural born fubjefts, though their mo-thers were aliens, are now deemed to be natural born fubjefts themselves to all intents and purpofes, unlefe their fald an- celer were attainted, or banifhed beyond seas for high treafon; or were at the birth of fuch children in the fervice of a prince at enmity with Great Britain. But the grandchil- dren of fuch ancefors shall not be priviledged in refpeft of the aliens duty, except they beperfomans, and actually reside within
within the realm; nor shall be enabled to claim any estate or interest, unless the claim be made within five years after the same shall accrue. The children of aliens born in England are, generally speaking, natural born subjects, and entitled to all the privileges of such. 1 Comm. 373.

By the 11th and 12th W. III. cap. 6. all persons being the king’s natural born subjects, may inherit as heirs to their ancestors, though their ancestors were aliens. Children of an ambassador in a foreign country by a wife who is an English woman, are natural born subjects by the common law. 7 Rep. 11. And if an English merchant living beyond sea, have a child by a foreign wife, and hath a child by her and dies, this child is born a denizen, and shall be heir to him, notwithstanding the wife be an alien. Cro. Car. 607. Persons born in English plantations are natural born subjects.

An alien can hold no land by descent or purchase, or be tenant by courtesy, or in dower; and if he purchase, the king shall have it; but he may purchase a house for years for habitation, during his residence, as necessary for trade. If an alien merchant leaves the kingdom, the king shall have the lease; if he be no merchant, the king shall have his lease for years, though it were for his habitation; and by the 32 Hen. VIII. there is a penalty for letting houses to aliens. 5 Rep. 502.—7 Rep. 18.—1 Inst. 2129. —2 Inst. 741.

By 13 Geo. III. c. 14. aliens are enabled to lend money on the security of mortgages of estates in the West India colonies, and may have every remedy to recover the money lent, except foreclosing the mortgage and obtaining possession of the land.

A devise of lands to an alien is void; and if a man be bound to an alien in a bond, it is void to him, but the king shall have it.

Aliens, however, may obtain goods and personal estate by trade, &c., and may bring actions for the same; and make a will and dispose of their personal estate; but an alien enemy cannot maintain any action whatever, nor obtain any thing lawfully within the realm. 1 Build. 124. Term de Ley. 36.

Aliens are not to be returned on any jury; but where an alien is party in a causa, the jury are to be half denizens and half aliens, except in cases of high treason. 2 Inst. 17. By the 27 Ed. III. c. 8, if both parties are aliens, the inquest shall be all aliens. By the 12 W. III. cap. 2, aliens are incapable of being members of parliament, or of enjoying offices; neither have they any vote for the election of members. Hob. 271. Aliens likewise are by several acts of parliament put under several other restrictions, with regard to exercising trades, taking apprentices, and are likewise disabled from being factors in the plantations, &c. See 

Denizen and Naturalization.

A very great influx of Frenchmen into England having been occasioned in the years 1892 and 1793, by the troubles in France, and there being cause to suspect that fame of them were bent here for dangerous and injurious purposes, an act was passed, flat. 33 Geo. III. c. 4, commonly called the Alien Bill, compelling the masters of ships arriving from foreign parts, under certain penalties, to give an account at every port of the number and names of every foreigner on board to the custom-house officers; appointing justices and others to grant passports to such aliens; and giving the king power to restrain and to confine them out of the kingdom on pain of transportation, and on their return, of death. The same act also directs an account to be delivered of the arms of aliens, which, if required, are to be delivered up, and aliens were not to go from one place to another in the kingdom without passports. This act was continued by several subsequent acts; by 38 Geo. III. c. 50, to Aug. 1, 1800, and from thence to the end of the then next session of parliament, and by 41 Geo. III. c. 24, till six months after the conclusion of a general peace.

Aliens duty, an impost laid on all goods imported into England, by aliens, or denizens, and even on certain goods imported by natural subjects, if they be brought on foreign bottoms, over and above what is paid for the same goods imported by British, and in British shipping. 12 Stat. 271.

Aliens duty is otherwise called petty customs, and navigation duty. This was first granted in 31 Ed. I. Fish, dried or salted, and cod-fish, or herring, not caught in British vessels, and cured by British, pay a double alien duty.

Aliens duty outwards, is taken off by the following acts. 12 Car. II. cap. 4.—25 Car. II. cap. 6—5 Ann. cap. 27.—6 Ann, cap. 10.—7 Ann. cap. 7.—9 Ann, cap. 6.—8 Geo. I. cap. 15.—11 Geo. I. cap. 59.

Severance, packages, and ballasting, payable to the city of London, are properly alien duties. On what footing aliens are permitted to import foreign commodities into Great Britain. See Duty.

Alien is sometimes used, in Middle Age Writers, for exempt. Du-Cange. Alien-amv, or alien friend. See Alien.

Alien prioria, a subordinate kind of monasteries in England, belonging to, and independent on, other monasteries in foreign countries. In the reign of Henry V. the alien prioria, or abbies for foreign monks were suppressed, and their lands given to the crown. Vide Dudg. Monast. Abr. p. 44.

Alienation, Alienatio, in Law, the act of making a thing another man’s; or the altering or transferring the property, and possession of lands, tenements, or other things from one man to another.

To alienate, or alien in Mortmain, is to make over lands or tenements to a religious community, or other body politic. To alienate in Fee, is to sell the fee-simple of any land, or other incorporeal right.

All persons who have a right to lands may generally alien them to others; but some alienations are prohibited: such as alienations by tenant for life, &c., whereby they incur a forfeiture of their estate. 1 Inst. 118.

By the statute of Edward I. a bar was put to alienations by what we call entails, which is an expedient for procuring perpetualities in families; but counter-expedients were devised to defeat this intent, and a practice was introduced of cutting off entails by fines, and of barring remainders and reversion by recoveries.

Estates in tail, for life or years, where the whole interest is not parted with, may be made with condition not to alien to others, for the preservation of the lands granted in the hands of the first grantor.

The statute for alienations in Henry the Seventh’s time, had a great effect on the constitution of this kingdom: as among other regulations of that reign, it tended to throw the balance of power more into the hands of the people. By the 12 Car. II. cap. 24, fines for alienations are taken away; except fines due by particular customs of nanors.

Crown lands are only alienable under a faculty of perpetual redemption.

The council of Lateran, held in 1123, forbids any clerk to alienate his benefice, prebend, or the like. By the laws of the ancient Jews, lands could only be alienated
Alienated for the space of fifty years. At each return of the jubilee, all returned again to the primitive owners, or their descendants, to whom the lands were originally allotted, at the first distribution of Canaan.

**Alienatio a familiar.** See ABDICATION.

Alienation aforesaid, is an office to which all writs of covertant and entry, upon which fines are levied, and recoveries suffered, are carried, to have fines for alienation flats and paid thereon.

**ALIEU,** or **ALIEY,** in *Ancient Geography,* islands placed by Pliny in the Adulic gulf, near Ethiopia.

**ALIPI,** in *Geography,* a town of Italy, in the kingdom of Naples, and country of Lavora; five miles north of Capua. This town, placed by M. d'Anville to the south-west of Boeotia and north-west of Beneventum, was formerly a Roman colony, and possessed by the Samnites.

**ALIFORMES nufculi,* in *Anatomy,* are thus called from *ala,* being and *forma,* shape, as resembling wings. See Pterygoidus externus et internus.

**ALIFORMES procissi,** are processes of the *splanchnic* bone, under which article they will be described.

**ALI multa,** *Ali de regno,* are phrases which often occur in our ancient records and historians. Their meaning has occasioned much dispute. Dr. Brady will have them to signify only tenants in *capite,* which Mr. Tyrrell endeavoured to refute, and shew that they denote the whole commons of the kingdom. Hist. of Eng., vol. i. appen.

**ALILEI,** in *Ancient Geography,* a people who inhabited the western part of Arabia Felix; among whose gold, it is said, was so abundant, that it was held in lower estimation than copper and iron, which were probably very scarce.

**ALIMA,** among *Mineralia,* a kind of sand found in gold mines, out of which lead is extracted.

**ALIMEA,** or *Alimisus,* a district of *Attica,* belonging to the Leontid tribe, situated near the Phalerum, and in the vicinity of Athens. In this district was a temple consecrated to *Ceres Thesmophoria,* or the *legistatrix,* and to *Proserpine,* according to *Pausanias,* in Attic. lib. i. c. 31. p. 76.

**ALIMENA,** in *Entomology,* a species of *Papilio Nymphid,* with dentated black wings, an interrupted carunclear fascia, and seven white marginal points, found in South America and India.

**ALIMENT,** *Alimentum,* formed of alece, to nourish, in a physical sense, is whatever may be dissolved and turned into chyle, so as to be afterwards converted into blood, for augmenting the body, or repairing its continual waste. The subject of aliments has been very diffusely and comprehensively divulged by Dr. Cullen, in his *Mat. Med.* vol. i. p. 217–408. See CHLORIZATION, DIGESTION, DRINK, FOOD, and NUTRITION.

**ALIMENT OF PLANTS.** See PLANTS.

**ALIMENTARY,** *Alimentarium,* something that relates to aliment, or food.

**ALIMENTARY duct,** or canal, is a denomination that has been given to the whole of those passages which the food permeates from the mouth to the anus. It is divided into the gula, which is subdivided into the pharynx and oesophagus, the stomach, and the intestines. For an account of its structure and functions, the reader is referred to these divisions.

This duct is said to be the true characteristical of an animal, or *proprium quarto modo,* there being no animal without it, and whatever has it, being properly enough ranged under the class of animals. Plants receive their nourishment by the numerous fibres of their roots, but have no common receptacle for digesting the food received, or for carrying off the recrements. But in all, even the lowest degree of animal life, we may observe a homach and intestines, even where we cannot perceive the leaf formation of any organs of the fishes, unless that common one of feeling, as in oysters. Phil. Trans. No. 269. p. 776, &c.

Dr. Wallis deduces an argument from the structure of the alimentary tube in man, to prove that he is not naturally carnivorous. To the cogency of which, Dr. Tyson makes some objections. Phil. Trans. No. 269. p. 777.

**ALIMENTARY duct,** is sometimes also understood of the thoracic duct.

**ALIMENTARY leg, leg alimentaris,** was an old law among the Romans, whereby children were obliged to find subsistence for their parents.

**ALIMENTARY boys, Alimentarii puiri,** &c., were certain children maintained and educated by the munificence of the emperors, in a fort of public places, not unlike our hospitals.

Trajan was the first that brought up any of these alimentary boys. He was imitated by Adrian. Antoninus Pius did the same for a number of maids, at the solicitation of Patilla; and hence, in some medals of that emperor, we find *PELLAE PAVSTINAE.*—Alexander Severus did the like, at the request of Maunus: and the maids thus educated are called Manunia.

**ALIMENTATION** is used by some naturalists, for what we more ordinarily call NUTRITION.

**ALIMENTUS, Cincius,** in *Biography,* a Roman historian, was a preceptor in the confufulship of Claudius Marcellus and Marcus Valerius, in the year 152, B.C. Livy represents him as a diligent collector of historical facts; and as an eminent writer, giving him the appellation of "maximus auctor." Livy, lib. vii. lib. xxx. He wrote the history of Hannibal, in whose hands he was a prisoner; and the history of Gorgias of Leontium, probably from materials which he collected during his preceptorship in Sicily. He was also the author of a tractise on the military art, mentioned by Aulus Gellius, (lib. xxvi. c. 4.) and Arnobius, (lib. iii.) mentions him in his account of the foreign divinities, called *Novemus.*

**ALIMINE,** in *Ancient Geography,* a town of *Alia,* in Phrygia, supposed to be the fame with that called also Alimonium.

**ALIMONY,** *Alimonia,* properly signifies nourishment, or maintenance; but in a modern sense, for such it denotes that portion, or allowance, which a married woman fues for, upon any occasional separation from her husband, wherein the is not charged with elopement or adultery.

This was anciently called *rationabile* *exhorverium,* reasonable maintenance, and was recoverable only in the spiritual court; but now it is recoverable also in chancery.

Where a woman is divorced *mena & thora,* the may sue her husband in her own name for alimony, or maintenance, out of her husband's estate, during the separation, either in the chancery, or in the spiritual court; and it will be allowed, except in the cases of elopement and adultery, as aforesaid. 1 Hilt. 255.

**ALIMOS,** in *Botany,* the name given by some of the Greek writers to the common liquorice. It has been thus called, from its quality of palling the appetite, and making it insensible either of hunger or thirst.

**ALINA,** in *Ancient Geography,* one of the three small islands
ALIPLERA, in Ancient Geography, a town of Arcadia, situated in the western part of it, and south of Heraea, by which the river Alpheus passed, on the top of a high and steep hill, which was defended by a strong fort. Some say that it took its name from Alpheus, the son of Lycaon. It was abandoned by the greatest number of its inhabitants, when Megalopolis was founded, and at the time of the Achaean league it was joined to Triphylia. This city was reduced by Philip of Macedon, when he brought the whole country of the Triphylians under subjection. We learn from Polybius, (lib. ii. p. 343.) that there was to be seen in this fort a bronze statue of Minerva, famous for its size and workmanship. But he adds, that the inhabitants could give no satisfactory account why it was placed there, and the motive was not that it was thought to house the god: workmanship. It was the work of Heculados and Solon the poet, and generally esteemed the most beautiful and finished piece which they ever executed. Minerva and Hercules had both temples in this place; and the tradition of the country reports, that Minerva was born and educated here.

ALIPILARIUS, or ALIPILUS, in Antiquity, an officer belonging to the baths, who, by means of wax, and waxen plasters, took off the hairs from the ale or arm pits. The women who performed this office were called pleiatries, and parthuriis.

The Alpilus answered to what the Greeks called ἀριστερος. The ancient Romans made it a point of cleanliness to keep the arm-pits clear and smooth. In after-times, they went farther, and took off the hair from their arms, legs, and other parts, with pitch and rosin, and by the vellum, an ingredient for that purpose.

ALIPOW MONTIS CETI, in the Materia Medica, a kind of white turbah, which is a strong purgative. It is to be found in several places of Languedoc, particularly near Ceres, whence the modern botanists have given it its name. It is sometimes used instead of safest; which, however, may be dangerous, since it is a much stronger purgative.

ALIPTA, from αλιπτα, I anoint, in the Ancient Gymnastics, an officer appointed to anoint the athlete.

In which sense the alipta amount to the fame with what are otherwise called unctores, and jatraphta.

ALIPTA is sometimes also used, in a less proper sense, for the director, or superintendant of the exercises of the athlete.

In which sense alipta is synonymous with gymnastes, and pedotribas.

ALIPTERIUM, αλιπτεριον, in Antiquity, a place in the ancient polis of Tarentum, where the alipthe were anointed before their exercises.

The alipteria, or aliptermes, was otherwise called ελεοθεσις, and undecarium; sometimes also ceroma.

ALIPTES, the name of a fountain near Ephesus.

ALIQUANT part, in Arithmetic, is that which will not measure or divide any number exactly. Or an aliquant part is that which being taken any number of times, is always greater or less than the whole.

Thus five is an aliquant part of 12; for being taken two times, it falls short; and when taken three times, it exceeds 12.

The aliquant parts of a pound, or 20s. are,

3. an aliquant part composed of a tenth and 20th.
6. of a 5th and a 10th.
7. of a 4th and a tenth.
8. of two 5ths.
9. of a 4th and a 5th.
10. of a half and 20th.
12. of a half and a 10th.
13. of a half and a 20th.
14. of a half and a 4th.
15. of a half and a 4th.
16. of a half and a 5th.
17. of a half and 20th.
18. of a half and two 20ths.
19. of a half and 20th.
20. of a 4th, and 5th. See Multiplication.

ALIQUOT part, is such part of any number or quantity, as will exactly measure it, without any remainder.

Or, it is a part which being taken a certain number of times, becomes equal to the whole, or integer.

The word is formed of aliquoties, any number of times. Thus 3 is an aliquot part of 12; because, being taken four times, it will just measure it.

All the aliquot parts of any number may be thus found. Divide the given number by its least divisors, and divide the quotient also by its least divisor, and so on always dividing the least quotient by its least divisor, till the quotient 1 is obtained; and all the divisors thus taken, are the prime aliquot parts of the given number. Then multiply continually together these prime divisors, viz. every two, every three, every four of them, &c.; and the products will be the other or compound aliquot parts of the given number. E.G. Let the aliquot parts of 60 be required; first divide it by 2, and
and the quotient is 50; then 50 divided by 2 gives the quotient 25; and 15 divided by 3 gives 5, and 5 divided by 5 gives 1; and therefore, all the prime divisors or aliquot parts are 1, 5, 15. Then the compound ones obtained by multiplying every two, are 2, 4, 6, 10, 15; and by multiplying every three, 6, 15, 30; and all the aliquot parts of 60 are 1, 2, 3, 4, 5, 6, 10, 15, 20, 30.

The aliquot parts of 297 are, 1st, half of 297; 2nd, a third; 3rd, a sixth; 4th, a tenth; 5th, a twentieth; 6th, an eighth; 7th, a twentieth; 8th, a sixteenth; 9th, a twenty-fourth; 10th, a twenty-fourth; 11th, a sixteenth; 12th, an eighth.

To multiply by the help of aliquot parts, see Multiplication.

We must not confound an aliquot part with that of a commensurable; for every aliquot part is a commensurable, but not vice versa. Thus four is commensurable with six, but is not an aliquot part of it. Phil. Trav. No. 41.

Alisæ, in Ancient Geography, a name given by Josephus to the inhabitants of Eolis.

Alisander, in Botany. See Smyrnium.

Alisana, or Halisana, in Ancient Geography, a city of the Troas, in Asia Minor.

Alisca, a town of Lower Pannonia. In the Notitia Imp. it is called Alisca, and placed in Valeria, near the Danube.

Alisaca, a town of Media, according to Ptolemy.

Alise, or Alisea Ste. Reine, in Geography, a town of France, in the department of the Cote d’Or, eight miles north-east of Semur-en-Auxois. This town was the ancient Alisea. The celebrity of this place in the time of the Romans is discernible in the vestiges of the Roman ways, which lead to and from it. After the fall of the Western empire, Alise was ruined, the name continued to be appropriated to some dwellings that remained on the declivity of the adjoining mountain. The site of the ancient city is now cultivated ground; “a Non eges ubi Troja fuit.” The commerce of this place consisted of chaplets, shrines, flowers, &c. for the accommodation of the pilgrims, who reforted hither from all parts of France, to celebrate the feast of Ste. Reine, which was kept twice a year. The fountain of Ste. Reine is a reser voir of clear and fresh water, about two feet square; and its water was formerly held in high estimation. But the place has long since lost its reputation.

Alisincum, Anizzi, a town of Gaul, belonging to the Edui, between Angullodunum to the call, and Deccitia to the south-west.

Alisio, in Geography, a town of Corfia, in the district of Capo Corio.

Alisium, a town of Elia, situate on a high mountain, between Elia and Olympia; the Aligion of Steph. Byz. It had a river of the same name, according to Strabo.

Alisium or Alisius, a mountain of Arcadia, separating it from the Argolid.

Alisma, from ἀλησία anxiety, or rather from ἀλης, the sea, Water Plantain, in Botany, a genus of the

beandria polygynia class and order, of the natural order of tripetaloides and junct of Jullien: its characters are, that the perianthium is three-leaved, leaflets ovate, concave and permanent; the corolla three-petalled, petals roundish, large, flat and very spreading; the stamens have awl-shaped filaments, shorter than the corolla, anthers roundish; the pistil has germen more than five, styles simple, stigma oblong, the capsules of the carpellium are compressed, (many and aggregate, Smith,) and the seeds solitary and small.

There are nine species, viz. 1. A. plantaginea, great or broad water plantain, or greater threemore, with leaves ovate, acute, capsules obtusely triangular. This species is easily known by its smooth entire leaves on very long petioles; and by its purplish flowers growing in a kind of umbel, at the end of a long scape. The flowers are fully expanded about four in the afternoon. It grows in watery places, on the banks of pools, lakes and rivers, is perennial, and flowers in July. This plant possesses the poisonous quality of the ranunculi, to which order it is naturally allied. Dr. Smith mentions two varieties, viz. A. lanceolata of Withering, or narrow water plantain, and plantago aquatica leptocyclus of Dill. in Ray Synop., or greater water plantain. 2. A. flavum, damasonium flavum of Miller, with leaves ovate, acute, peduncles umbellate, capsules globose. This grows in Jamaica, Barbadoes, and several other places in the warm parts of America, in flagrant waters and swampy places; but being of no great beauty, and not easily preserved in England, it is not worth cultivating. 3. A. damasonium, damasonium A. of Miller, flaccid water plantain, with leaves cordate-oblong, flowers fix-equal, capsules awl-shaped, the flowers are white; styles fix, and capsules fix, divaricated, with a flaccid appearance, of a hard texture, and so closely united at the base, as to appear like a single fruit. Stokes. This is a native of France, Siberia and England; there is found, more rarely than the former, in ditches and flagrant waters, about London in several places, on Hounslow Heath, Winkfield plain, near Windsor; &c.; is perennial, and flowers in June and July. 4. A. cordifolium, with leaves heart-shaped, obtuse, flowers twelve-flaminened, capsules hook-pointed. This species connects the genus alisma with that of fagittaria; and is found in North and South America. 5. A. natans, creeping or floating water plantain, with leaves ovate or elliptic, obtuse, peduncles foliary, and capsules fricated. The leaves which float on the surface are ovate, and those under water linear. It is found in ditches, in France, Sweden, Germany, and Siberia; in the lakes of Bala and Lakewith, in North Wales; is perennial, and flowers in July and August. 6. A. ranunculoides, small water plantain, with leaves linear-lanceolate, capsules pinnate, in curved, globose-aggregate. The corolla is bluish-white, and opens about noon. It is a native of Sweden, Holland, France, Germany, Italy, and England, in marshes and moors; is perennial, and flowers in August. 7. A. sublacta, with leaves awl-shaped; a Virginian plant, the dwarf sagitta of Clayton, with a very tender white corolla, and fimbulate leaves. 8. A. parnassifolium, with leaves heart-shaped, acute, petioles jointed; a native of Italy, in the marshes under the Apennines. 9. A. reptans, with stems creeping, leaves lanceolate, petiolar, acute, a native of Spain, on the sandy banks of the river Manzanares; flowering in August; and seeming to be the same, though much smaller, with the alisma, which Abbé Poiret found on the Northern coast of Africa, described by Lamark. Willdenow adds a roth species, A. sagittifolia, with leaves sagittate, and capsule obvolute, obtuse; found in Guinea. Martyn Miller, Smith’s Flor. Brit. vol. 1. p. 400.

Alisma. See Ainsia, Primula and Senecio.
ALK

ALISO, ALIS, in Ancient Geography, a small river of Germany, mentioned by Dion Cuthus. This was also the name of a castle built by Drusus in Germany for the confinement of the Sicambri.

ALISONTIA, Alsetz, a rise of Germany, which passing by Luxembourg, discharges itself into the Moselle.

ALISTA, a town placed by Ptolemy, in the southern part of the island of Corica.

ALISTRES, a fort of Epirus, rebuilt by Justinian.

ALISUS, a town, placed by Ptolemy in the northern part of Germany.

ALITAMB, a people of Africa, placed by Ptolemy between Libya and mount Thala.

ALITES, formed from ala, a wing, in Antiquity, a name given to those birds which afforded auguries by their wings and flight. In this sense alites stands opposed to oisines, or birds, which gave auguries by their mouths, by singing, or croaking, &c. To the class of alites belong the buzzard, ciprey, &c. To that of oisines, the crane, raven, owl, &c.

ALITROPS, in Ancient Geography, a town placed by Sclavas in a part of Greece, assigned by him to the Acheans, which was the district of Pithiota, usually comprised in Thessaly.

ALJUBARROTA, in Geography. See ALIGARROTA.

ALJUCEN, a small river of Spain, which runs into the Guadiana, not far from Montachet in Leon.

ALJUSTREL, a town of Portugal, in Alentejo, 16 miles W. S. W. of Beja, containing one parish, and about 100 inhabitants.

ALIXEN, a town of France, in the department of the Ardeche, two leagues E. E. N. of Valence.

ALKADARI, formed from the Arabic, alkadar, which signifies decrees, a fact among the Mahometans, who deny any eternal, fixed, divine decrees; and are affirors of free will. The Alkadari are a branch of the Moatazalites.

They stand opposite to the Algibarari.

ALKENDA, in Botany, see MYRTUS.

ALKAHEST, or ALKAHEST, in Chemistry. This word, so famous in the last ages of alchemy, occurs, for the first time in the treatise of Paracelsus, De Fisibus Membrorum, where it is mentioned as a sovereign remedy against dropsy and all diseases of the liver. Notwithstanding that its particular use is here expressly stated, without any hint of its other qualities, or the method of preparation; notwithstanding also that the term is not to be met with in any other of his writings, yet Van Helmont, giving his master credit for the knowledge of more mysteries than ever he himself has pretended to; has raised the alkalhef from a mere medicine in the disorders of a particular organ to the lofty character of an universal solvent, and the most active of all the alchemical medicines.

The origin of the word is variously derived from fulis-qišš, spirit of salt; a-qišš, all spirit, i.e. a perfectly pure spirit; or alk-qiš, i.e. alkali elf, according to a custom common with Paracelsus and other alchemists, of concealing the name of a substance by abbreviation or transposition, of which a similar example occurs in the name author of the word araph, for aroma-philosophorum.

The properties of the alkhef, according to Van Helmont, are the following. It is a fluid of perfect simplicity and purity, is never found native, but always prepared by art; is capable of dissolving all substances into a liquor, which remains wholly in distillation, leaving no fixed behind; at the same time that the alkhef itself spontaneously separates from the body on which it has produced such a remarkable change. The substances thus acted upon retain, however, their essential properties, but by further digestion with the alkhef, are all resolved to the same indolent, insipid, infirkeless, and elementary water. A menbruim of such surprising powers was immediately supposed to be of the utmost consequence in the higher alchemical processes; and the solemn declaration of Helmont, that he was yearly in possession of such an agent, gained easy credit even among many from whom a fuller explanation of such enigmatic and unheard of qualities might have been expected. As Helmont never divulged the secret method of preparing the alkhef, most of the later alchemists did not any chance to had such particular theory or the subject; Becker imagined it to be contained in sea salt and Glauber, in his very ingenious tract, "De Mercurio Philosophorum," endeavours to prove it to be nitre; and indeed by taking the liberty, as this author does, of applying the nitre in solution or fusion, or separated into its acid and alkaline elements, there are few substances that are not capable of being thus brought into a fluid state.

In modern chemistry nothing is acknowledged as true till it has stood the test of repeated and accurate experiment; and we now hear no more of the alkhef than of the ehirr of metals, and the universal medicine. Boerhaave's Chemistry, Glauberi Opera, vol. 1.

ALKALINE is also used in a more extensive sense, so as to comprehend all fixed salts volatilized, and reduced into a quintessence.

ALKHELSTIC is used by some to denote the quality of bodies which are powerfully soluble.

In which sense, alkalihef amounts to much the same with the menbruim; except that the former imports a greater degree of the solutive power than the latter. See MEMBRURUM.

ALKALISAR, in Geography, a sort of Asia, in the Arabian Irak, 106 miles west of Bagdad.

ALKALECENT, denotes a substance filthy alkali, or in which an alkali is beginning to be formed and to predominate. As the volatile alkali, or ammonia, is the only one which is usually observed to be produced by spontaneous change, the term alkalihef generally refers to the generation of this alkali, in certain vegetable and animal substances by the process of putrefaction or any similar decomposition. Some species of vegetables, especially the tetradynamious plants, have received the name of alkalihef, because, when placed in circumstances favourable to fermentation, they have a peculiar tendency to form ammonia, which may be separated in a very sensible quantity, by the process of distillation.

ALKALI is the generic term for an order of salts of the highest importance, and the most familiar use in chemistry.

Alkali is a word of Arabian origin, and it was employed by the Arabian chemists and physicians, to express the salt which was procured from the ashes left after the combustion of several vegetables, particularly the salt kali of the defart, and several plants growing on the sea shore. The same salt is also found native in immense quantities, mixed with sea salt, in the waters and on the shores of several lakes of Lower Egypt, and has been known, from time immemorial, by the name of natron, or the niter of the ancients. The Greeks and Romans were equally familiar with the alkali salt contained in vegetable ashes, which was termed lixivium ashes (lurbium cinis, Plin.), whence the name of alkalihef, lixivium, or lixivious salt, which is still retains. The use of the word alkali was at first confined to the salt which was yielded by the fus. or incombustible ashes of vegetables; but the volatile salt, which rises in distillation of vegetable, and especially of animal matter, having been found to possess similar chemical properties with the fixed lixivium salt, in the most essential
Full particulars, the respective apppellations of fixed and volatile alkali have long been adopted by chemists. For the account of the procress of procuring these salts as an article of commerce, for their natural history, and other particulars, we shall refer the reader to the words Potash, Soda, and Ammonia.

The properties common to all alkalis are the following: they have a highly acid tate, which acts with so much energy upon the tongue as to produce the sensation of burning, and unless they are much diluted, they very soon corrode the thin skin which covers it, and produce a small eczema or dead part, which, for a time, leaves a slight sore on that sensible organ. They have an acrid taste like the fumes of leafy plants from any oily nature in the alkalis, but because they directly diffuse the surface of the skin, and produce a kind of foam. They effect a remarkable change on vegetable colours. The red of roses, and the blue of violets, are turned by them to a dull green; the red of archil or litmus, to a blue; the yellow of turmeric, the light brown of jalap root, liquorice root, and of many other roots and woods, are all rendered much deeper in colour, approaching to a brick-red. They unite with sulphur, forming compounds which have the property of absorbing the oxygen from atmospheric air, and, when moistened, of giving out a peculiar fetid gas. These compounds have therefore been deominated alkaline before, or forever, and in the modern nomenclature, sulphuroi. They have a very powerful action on almost vegetable and animal matters, producing speedy disorganization, and disfusing them into a thick pulp. With oils they form the well-known compound, sop. They are largely soluble in water, giving out heat on union with this liquid. They unite with every acid, and produce neutral salts of various degrees of solubility; in which the contents are naturally saturated, the distinguishing properties of both acid and alkali are neutralized, and no longer to be perceived. Owing to the very strong affinity which they bear for acids, they decompose the acid solutions of all metals and molt earths. These are the most characteristic properties common to all alkalis; but there are others which are confined to one or other of the two species. These we shall enumerate, referring the reader for more particular information, to the individual articles.

The Volatile Alkali (Ammonia) is distinguished, (as its name implies) by its volatility. The pure form in which it is known to us is that of a gas, which is permanent at any degree of cold that has ever been applied to it, and unites readily with water in large quantity, from which, however, it may be again expelled by a heat much below boiling. It has never been procured in a solid form, unless combined with some other substance; nor as a liquid, except by its union with water. It differs remarkably from the fixed alkalis in having a very perceptible smell, which highly stimulates the organs, and excites coughing and tearing. Owing to the ease with which it affines a gaseous form, it is incapable of uniting with many substances which the fixed alkalis will diffuse, when suffused by fusion in a strong heat. The volatile alkali is weaker in all its affinities than the fixed. It is also the only one which is decidedly proved to be a compound substance; the nature of its constituent parts (which are hydrogen and azote) having been ascertained by numerous experiments both of synthesis and analysis. See Ammonia.

The Fixed Alkalis, (Alkali fierbestandiges, Loningensole, Germ-Alkali fillo Ital.) are the proper lative alkalis, or those that are procured by lixiviation of the ashes of burnt vegetables. They may be obtained in a very pure solid form, either crystallized, or as a simple concrete. Besides the properties which have been mentioned as common to all alkalis, these possess considerable fixity in air, and at a red heat they run into thin fusian. A higher heat, however, volatilizes them, and they fly off in sensible vapour. The fixed alkalis, when in fusion, will readily diffuse silicious earth into the perfectly homogeneous transparent compound, glass. They also will diffuse by heat all the metallic oxides, and thereby receive various tints. They afford in the fusion of all earthy and metallic admixtures, and their degree of fixity in the fire enables them to combine more intimately than the volatile alkali, with sulphur, phosphorus and charcoal. When pure and solid, they are remarkably deliquescent, absorbing water from every surrounding medium; and hence they have been used by chemists to render the air of any vessel in which they are confined perfectly dry. The fixed alkalis are two in number, potash and soda, the former being procured from the ashes of all vegetables except marine plants, and a few that grow near the sea shore, which yield the latter alkali. The former is also termed the vegetable alkali, and the latter, (owing to its being sometimes found native in the earth), is called the mineral alkali. The general properties of these two alkalis were long known, and they were long employed in various arts, before the circumstances by which they are distinguished were well ascertained, and their separate existence established. The close resemblance which they bear to each other when pure, and the similarity in all their most remarkable chemical properties, prevented a proper distinction between them; and it was chiefly by the researches of Pott, Duhamel and Margraff, that the nature of the two alkalis was fully explained. The two neutral salts with which the older chemists were the most familiar, nitre and sea-salt, have for their bases, the former the vegetable, and the latter the mineral alkali; and it was principally by enquiries into the properties and decomposition of these neutral salts that the distinct nature of their alkaline bases was ascertained.

Potash and soda differ from each other in the strength of their affinity with acids, which is greater in the former; in some slight variation in their action on oils and animal fats; but chiefly in the neutral salts which they form with the acids, which in all cases differ in form of crystallization, in solubility, often in taste, and in several other particulars.

The intimate nature of the fixed alkalis is still unknown to us. From the very strong analogy with the volatile alkali, the component parts of which are fully established, it must be considered as highly probable that the fixed alkalis are compounds, though their decomposition has not yet been effected by any experiments which can be allowed to be unexceptionable. Fixed alkalis have been supposed to be generated by the process of combustion of vegetables; since no plants, even those whose ashes yield the most of this salt, contain before combustion any sensible quantity of uncombined alkali. The accurate analyses of several of the modern chemists have however detected, in the native juices of plants, several neutral salts, whose alkaline bases are united to an acid which is easily destructible by fire. But for this, and other speculations on the nature of the fixed alkalis, we shall refer the reader to the article Potash.

Alkali (Caustic or Pure). The alkaline salt procured from vegetable ashes, besides being mixed with other salts, and with earth, is always saturated more or less completely with fixed air, or carboonic acid; so that the fixed alkali which was the subject of the experiments of all the chemists, till within a few years, was a salt compounded of carboonic acid and the alkali basis. The beautiful experiments of Dr. Black fully illustrated this point, and showed that the reason of the greatly increased causticity of alkalis, when mixed with quick-lime, was the loss of the carboonic acid, which had passed from the alkali to the earth. Caustic alkalis, therefore,
ALKALI

are alkalies deprived of carabolic acid by quick-lime or any other method; and this is the only state in which, properly speaking, alkalies can be considered as pure; though even when they contain much of this volatile acid, the peculiar qualities of the alkaline part predominate so considerably as to enable them to exhibit (though in a weaker degree) all the chemical properties by which alkalies are characterized.

ALKALI (Effervescent or Mild), is opposed to the state of causticity, and expresses that degree of saturation with carabolic acid, which, as has just been mentioned, diminishes, but does not suppress, the characteristic properties of the alkalies. Owing to the alkali obtained from vegetable alkalies being always left after combustion in union with carabolic acid, effervescence with acids was considered by the older chemists as an essential character of alkalies in general, who thus ascribed to a property inherent in this genus of salts, an appearance which is now known to depend upon the expulsion of the gaseous acid. The terms caustic or pure, and effervescence or mild, are applied to the volatile as well as to the fixed alkalies.

ALKALI (Extemporaneous), is a mild vegetable alkali, prepared by deflagrating nitre with tartar. See Carbonat of Potash.

ALKALI (Flour), is a solution of pure Ammonia in water.

ALKALI (Phlogistic), is prepared by calcining carbonated potash with bullocks' blood or other animal matter, in which process it unites with the PRUSSIC acid, formed during the calculation.

ALKALI (of Tartar), or Salt of Tartar, is properly a mild vegetable fixed alkali, prepared by the combustion of tartar, which yields it in great purity. The name is used more extensively for any pure carbonated potash, and it is the term by which this salt is more generally known in common language and in medicine.

ALKALINE EARTHS. It is by no means easy to draw the line accurately between alkalies and earths. The original idea of an earth, entertained by the ancient chemists, was that of a substance of considerable density, insoluble in water, without taste, smell, or any perceptible action on the organs of sense, entirely unoffending, and fixed in the most intense fire; and, in short, with properties as opposite as possible to those of a salt. This opinion principally attached to earth, considered as one of the four elements of which the material world was supposed to be constituted. The progress of chemical investigation having, however, discovered several species of earths, which could not by any means be proved to be compounds, in which the simple or universal earth was so disguised as to lose some of its essential characters, it became necessary to alter and modify the original definition of an earth, and to allow to it more of a saline nature.

Some of the modern chemists, therefore, have adopted the term falsifiable, and others alkaline earths, in order to allow of more accuracy in systematical arrangement. By alkaline earth has been meant an earth which agrees with alkali in the property of solubility in water to a certain extent, and thereby rendering it rapid, of changing to green certain blue and red vegetable colours; of absorbing carbonic acid with eagerness, and of posseffing, when pure, those caustic or acid qualities that so much distinguish the alkalies. Magnesia, lime, barytes and frontan, or the earths which may be termed alkaline, but the former is very imperfectly so, being scarcely more soluble in water than flesh; and though its habits with carbonic acid are partly similar to those of the alkalies, it does not acquire any taste, or any degree of causticity, by the loss of this gaseous acid. Barytes and frontan, on the other hand, approach nearer to an alkaline nature than lime, in being very largely solubile in water, and readily crystallizable from its solution in a determinate form. They have therefore been actually enumerated as alkalies by Fourcroy, who reckons the following; potash, soda, ammonia, barytes, and frontan. The two latter even stand before the three ancient alkalies in their order of affinity with most acids, but, till the intimate nature of the fixed alkalies be fully cleared up, it will perhaps be proper to relinquish the term alkali to the three above-mentioned, and to retain in the class of Alkaline Earths magnetia, lime, barytes, and frontan, all of which, however they may be alkalies in many respects, differ from them in being unfusible for so in very intense fire, and being entirely incapable of being volatilized by the utmost heat that has ever been applied to them.

ALKALI, in Botany. See Salicoria.

ALKALINE, in a general sense, something that has the properties of an ALKALI.

In this sense we lay, alkaline salts, alkaline spirits, alkaline substanaces, &c.

Alkaline salts, considered in their reference to the Materials Medica, are known to possess antipathetic powers. Experiments upon them, out of the body, sufficiently indicate and attest these powers; but Dr. Cullen observes, that it is at the same time equally well known, that they are constantly imbued with such an acrimony, that they cannot by themselves be introduced into the body without acting more by their stimulating than by their antipathetic powers. The volatile alkali may sometimes be an useful remedy in putrid fevers; but it cannot, as some have imagined, be given more freely on account of its antipathetic powers, as it can never be given copiously enough to have any effect by these qualities. The volatile alkaline salts flue their stimulating power in every dose, wherever the energy of the brain is weakened, and consequently the action of the heart is languid, or requires to be accelerated. In such cases this stimulus is among the safest, as it is always transitory; and when their acrimony can be covered, so as to pass the mouth and fauces without irritation there, they may be given in large doses from 10 to 20 grains. These are prepared in two different ways; one of which is from sal ammoniac, which gives the ammonia of the London Dispensatory, or the sal ammoniacus volatilis, and spiritus fals ammoniaci of the Edinburgh. These are the purest forms of the volatile alkali, the most free from any adhering animal substanaces; but whilst the procex of preparing a volatile alkali from the bones or other solid parts of animals continues, there will come into the shops a salt and spirit that hardly ever be so pure, from some empyreumatic animal substance adhering to it; and such adherance may probably give some peculiar quality to the salt and spirit, and render it more antipsamodic. It cannot be very considerable in any ofes of the salt or spirits given to adults, but it may produce more sensible effect in the spasmodic affections of infants. The liquid volatile alkali is commonly employed in its mild state; but by a distillation of the sal ammoniac with quick-lime, the alkali may be obtained in its caustic state. In this state it may be readily joined with spirit of wine, and gives the spiritus fals ammoniaci of the Edinburgh Dispensatory, or the spiritus fals ammoniaci vinculos of that of London. The combination affords an excellent menstruum for dissolving the several fetid substanaces employed as antipsamodes, and renders them more suddenly digestible, and perhaps gives them a greater effect in all spasmodic affections. The caustic volatile alkali is seldom administered alone; but if its acrimony be covered while it palls the mouth and fauces, it may be very safely employed. Its chief use is external, and when smelted at the nose, it gives a more powerful stimulus than the mild alkali can do. Its acrimony is so considerable, that when applied to the skin, it reads...
readily irritates, and even inflames it, and may be so managed, as to produce an useful stimulant and rubeficient in many cases. 

But this requires its being blended with a mild, expressed oil, so as to prevent its inflaming too much. See Fossil Oil. 
The fixed alkaline fats have been commonly administered as diuretics. Dr. Cullen has chiefly employed the vegetable fixed alkali, and has sometimes obtained its effects in a remarkable degree; but he has been often disappointed, which he ascribes to the neutralization of the alkali in the stomach, and to this fact they could have no other effect than other neutral, which is commonly inconsiderable, either as laxatives or diuretics. Alkalines of this nature, however, occasionally manifest their diuretic power; and upon the supposition of their neutral state in the stomach, their considerable operation as diuretics cannot be easily accounted for. Of this fact Dr. Cullen offers two explanations. One is, that the quantity of alkali thrown into the stomach may be more than the acid can there neutralize, and therefore some portion of it may reach the kidneys in its alkaline state, and prove a more powerful stimulant than any neutral salt would be; and on this ground a large quantity of alkali is always necessary to produce diuretic effects. Another explanation of the fact is as follows. As the acid of the stomach may be presumed to be of the nature of the fermented acid of vegetables, so an alkali joined with it must form a regenerated tartar, a salt diuretic, or alkali acetate; and if this be left perservative, and more diuretic than other neutrals, while it is also conveyed to the blood-vessels in larger quantity, we can understand why, from these circumstances, the fixed alkali may often produce a diuretic. With respect to its operation as a diuretic, another conjecture may be offered. When it is given with bitters, after the manner of Sir John Pringle, it commonly proves diuretic; and Dr. Cullen imagined, that as the bitters are absorbents of acid, they might absorb so much of that present in the stomach, as to prevent its being so fully applied to the alkali. As alkalines may be often prevented, by purging, from reaching the kidneys, so their diuretic effect may be often more certainly secured by giving an opiate at the same time; and for the utility of this practice, see Dr. Mead on the subject of Dropy. Besides the laxative and diuretic powers of the fixed alkali, another is ascribed to it, which is that of dissolving the fluids, or the concretions which may happen to be formed in them, expressed by French writers under the denomination of foudant. Dr. Cullen does not allow it to possess this power to any great degree, or to produce the effects in this way that have been ascribed to it. Cullen’s Med. Med. vol. ii. p. 568. Vol. ii. p. 582, 512.

Alkaline armony, in Medicine, signifies a morbid quality in the blood, which is indicated by a desire of and thirst after four things, loss of appetite, and alteration to alkaline food, bluish eruptions on the skin, tumours, and other parts in the mouth, thickens in the stomach, a frequent diarrhoea, a sense of heat, lassitude, and general uneasiness, a dilution of the texture of the blood, the urine high coloured and red. It produces a putrefaction in the blood, &c. and is to be remedied by the same means as the febrifery and other putrid disorders.

Alkalization, Alkalization, in Chemistry, the act of impregnating a liquor with an alkaline salt. 

This is done either to make it a better diffusent, for some particular purposes; or to load the phlegm, so as it may not rise in distillation, whereby the spurious parts may go over more pure.

Alkalization, is a name applied to operations, by which alkaline properties are communicated to bodies; or to those by which alkali is extracted from bodies which contain it, or in which it may be formed; e. g. spirit of wine is said to be alkalized, when it has been digested upon alkali; a part of which it dissolves, and thence acquires alkaline properties. On the other hand, when a neutral salt is decomposed, in order to obtain its alkaline basis, this salt is to be alkali.

Vegetable substances when reduced to ashes, may also be said to be alkalized, because the ashes contain fixed alkali.

Alkamare, in Geography, a town of Persia, in the province of Isk-Agund, 28 leagues east of Bagdad.

Alkamet, in Botany. See Auckhia.

Alkansas, or Auckhia, an Indian nation of Louisiana, on the west side of the Mississippi river, near the river of the same name, in N. lat. 34°. See Auckhia river.

Alkena. See Auckhia and Lawsonia.

Alkekeni, in Botany. See Atropa and Phyalis.

Alkekeni, a medicinal fruit or berry, produced by the Phyalis Alkekeni, popularly also called winter-cherries; formerly used and much commended as an astringent, diuretic, and diuretic.

These berries were well known to the ancients, and are characteristically described by Dioscorides, under the denomination gypri acuminatae. They have an acidulous and not unpleasant taste, followed by a slight bitterness, which they are said to derive in a considerable degree from the inverting enyzmes, if not gathered with great care. Although these berries are esteemed to be astringent and aperient, they have been chiefly recommended as a diuretic, operating without heat or irritation, in suppressions of urine, and for removing obstructions occasioned by gravel or mucus. With this intention the number of 6 to 12 cherries in subfus, or an ounce of the expressed juice has been the usual dose; but there seems to be no danger from a much larger quantity; for, we are told, that in some parts of Germany the country people eat them by handfuls with much benefit; and in Spain and Switzerland they often supply the place of other cestable fruits. Ray informs us, that a gouty person prevented the returns of the disorder by taking eight of these cherries at each change of the moon; and infirmities are recorded of their good effects in dropical and calculous complaints, but at present they are wholly disregarded.

The cherries may be dried so as to be pulverizable, or the depurated juice infusipated with a gentle heat to the consistence of a rob or extract, which Dioscorides commends, and in this state preferred for use. They have been sometimes mixed with opium. Dr. Cullen (Mat. Med. vol. ii. p. 553.) observes, that as it is allowed the berries take a taint from the leaves, it will always require some caution in employing any part of a plant which is taken from an order of a very poifious kind. Lewis, Mat. Med. Woodville, Med. Bot. vol. iv. p. 144. Murray’s Mat. Med. vol. i. p. 679.

Alkendi, or Alkendi, Jacob Ern Isaac, in Geography, a celebrated Arabian philopher and writer, was the son of the prefect of Cuda, under Muhammad Medi and Rabinon, and flourished in the caliphate of Al-Mamon, or at the beginning of the ninth century. He acquired such eminence in literature and philosophy in the school of Baffora, that he was called, by way of distinction, “The Philosopher.” Although he yielded implicit obedience, in common with his contemporaries, to the authority of Arilotte, and principally devoted himself to the office of interpreting and illustrating his writings, he directed his attention to other more important and useful studies. His name is mentioned among the mathematicians and astronomers of his age; and his medical writings, that are still extant, prove that he furnished a very honourable rank among the Arabian physicians. Heriblet represents Alkendi as a Jew, who was perfecuted on account of his religion; but the account of
his genealogy in the manuscript "History of Philosophers," referred to by Dr. Rush, contradicts this statement; for his father's great-grandfather is said to have been one of the companions of the prophet. This manuscript contains a catalogue of his writings; but the medical tract usually ascribed to him, and translated into Latin, under the title of "De Medicinam Compositurum Gradibus Investigandis," is not included. Abulpharagius mentions an anecdote concerning him, which furnishes a very amiable trait of the moderation and liberality of his temper towards a malicious adversary. Whilst he was visiting the schools of Bagdad, to which the learned and studious usually resorted in his days, he gave great offence, by promoting the study of philosophy, and endeavouring to reconcile the doctrines of Islamism with the principles of reason, to one Albumasar, one of the interpreters of the Koran, who was alarmed lest increasing knowledge should undermine vulgar superstitions. Accordingly this zealot accused him of heresy and impiety. Alkendi, instead of resenting this conduct, and countering, by his interest with the caliph, the design which Albumasar had formed against his life, endeavoured to subdue his adversary by lessons and admonitions of philosophy. Fully apprized of the influence of wildness as a means of mellowing the disposition, he engaged a preceptor to instruct his adversary in mathematics and philosophy. Albumasar was thus led to perceive the folly and bafeness of his part conduct, and to offer himself as a pupil to the philosopher whom he had perverted. Alkendi received him with condescension and kindness, and Albumasar became an or-sidebar to his school. Brucker's Hist. Phil. Enfield, vol. ii. p. 257. Ruffell's Alkendi, vol. ii. Appendix, p. 9.

ALKERNE, in Medicine, &c. a term borrowed from the Arabs, denoting a celebrated remedy, of the form and confidence of a conformation, whereof the kermess are the knots. The other ingredients are rose-water, sugar, ambergris, musk, cinnamon, aloes wood, pearls, and leaf gold, &c. but the sweet are usually omitted.

The confitio alkerne was chiefly made at Montpelier, which place supplies most of Europe with it. It is said to be better made there than it can be elsewhere; the reason of which doublets is, that the drug, which gives it the denomination, is no where found so plentifully as there. The manner of preparing the grain for making the confection is described in the Phil. Trans. No. 20.

It has been much used as a cordial; especially, says Dr. Quincy, among female preachers, and in composition of tonics; but that author decries its value in that intention, and thinks it ought only to be regarded as a sweetener.

Count Marigli, in an inquiry into the composition of this medicine, shows, that many of the ingredients with which the ancient so plentifully loaded it, and which are still retained in it by the moderns, are not only useless, but hurtful; more particularly the Uspis tenuis, by many mistakenly held cordial, on account of the appearance of veins of gold in it; whereas, in reality, it is only a marcella of sulphur and vitriol, and contains a great quantity of acid, directly repugnant to the alkaline nature of the kermess, and highly prejudicial in diseases where the blood tends to coagulation.

ALKES, in Astronomy, a star in the constellation Crater.

ALKEITH, in Geography, one of the Fidew islands, in the North Pacific Ocean.

ALKMAAR. See Alcmaar.

ALKMAAR, Henry of, in Biography, a native of Alkmaar in Holland, and the reputed author of the celebrated fable of "Keayward the Fox," a poem written in Low Dutch in the 17th century, which, under the allegory of a Society of Animals, satirizes the different vices of mankind. This poem has been very popular, and translated into all the languages of Europe. A German edition of it, by Gottfried, is adorned with figures, and enriched with learned disquisitions. It now appears that this poem was actually written by Nicholas Baumann, an Ensk-Frieslander, and that he assumed the name of Henry Von Alkmaar, in order to procure himself from the inquiries of the decal court of Juliers. Baumann was a member of the council of deke Magnus of Juliers, who died in 1593; but being driven from court by means of a cabal, he composed this allegorical poem, for the purpose of satirizing his enemies, and painting the intrigues carried on there. Nov. Dict. Hist.

ALKMAR, in Geography, a small island near that of Java, within sight of Batavia.

ALKOHOL. See Alcohol.

ALKORAN, See Alcoran.

ALKUSA, in Ichthyology, a name given by the Swedes to a fish, which they also called lake. It is a species of the silurus, and is distinguished by Arbedi by the name of the silurus, with only one cirrus, or beard, under the chin. The common silurus, which is the suburus of the ancients, has four cirri.

ALKY of lead, among Alchemists, denotes a sweet substance procured from lead.

ALL, in the Wind, a sea-phase, which expresses the state of a ship's sails when they are parallel to the direction of the wind, so as to shake or shiver.

All Hands away! the call by which the ship's company are summoned upon deck.

All Saints, in the Calendar, denotes a festival celebrated on the first of November, in commemoration of all the saints in general, which is otherwise called All-hallows.

The number of saints being so excessively multiplied, it was found too burdensome to dedicate a feast-day to each. In reality there were not days enough, scarce hours enough, in the year for this purpose. Hence an expedient was had recourse to, by commemorating such in combination who had no peculiar days of their own. Boniface IV. in the ninth century, introduced the feast of All Saints into Italy, which was soon after adopted into the other churches.

All Saints, in Geography, islands near Guadaloupe island, in the West Indies.

All Saints, a parish in the district of George-town, South Carolina, containing 2225 inhabitants, of whom 429 are whites, and 1705 slaves. It sends a member to each house of the State legislature.

All Saints Bay, a spacious harbour near St. Salvador in Brazil, in South America, on the Atlantic Ocean.

All Saints, in Geography, a star in the constellation Crater.

All Saints Day, a name given by the Swedes to a fish, which they also called lake. It is a species of the silurus, with only one cirrus, or beard, under the chin. The common silurus, which is the suburus of the ancients, has four cirri.

Almost all kinds of discord, which we call pulling notes, that appear in the melody, but are unnoticed in the harmony. These discords, Alla Sinfonia, require no preparation or resolution like notes in ligature.

All Souls, in the Calendar, denotes a feast-day held on
AL

the second of November, in commemoration of all the faithful departed.

The tablet of All Souls was first introduced in the 15th century, by Oddil, abbot of Cluny, who enjoined it on his own order; but it was not long before it became adopted by the neighbouring churches. Others say it was established A.D. 998. See Justin's Rem. on Eccl. Hist. vol. v. p. 11. p. 54.

ALLA, in Geography, a small town of Italy, in the valley of Trent, upon a small river which falls into the Adige. N. lat. 45° 40'. E. long. 13° 44'.

ALLA, a river of Poland, in Ducal Prussia, which runs into the Pregel, about five leagues above Königsberg.

ALLA, Ital. joined to, or rather following, a fullbarb, has the force of the word like in English; as alla Francôfo, like the French, or in the French style or manner; alla Tencurina, in the Venetian manner. Thus in music, alla breve implies a quick time, though the notes look slow, as when breves are played or sung like or as quick as semibreves, semibreves like minims, and minims like crotchets. This measure is seldom found in secular music composed by authors subsequent to Corelli, Geminiani, and Handel. A bar in alla breve time contains two semibreves, performed as quick as minims; and as few black notes appear in such movements, which are generally fugato, or in fugue; mudecians, in sport, term them corde fuguo. Alla Scalafo, in the Scott style; alla Polusca, Polonius; alla zoppa, limping, as in movements full of binding or driving notes or figures; all' uccio, in the octave, all' uccio più aia, an octave higher; più la fessa, lower. In passages for the additional keys to piano-forte, all' inno implies that all the notes from this indication, included under the line drawn over them, till the words in loco (the usual pitch) occur, are to be played an octave higher. This precludes the trouble and fatigue to the eye of longer lines, as ascending to C in altissimo would require five additional lines and spaces to be paled on the usual staff of five lines. Choral music is said to be alla Palestrina, when the style of composition resembles that of this venerable father of ecclesiastical harmony.

ALLABA, or ALLAY, in Ancient Geography, a town of Sicily, on the southern side of it, near the mouth of a river of the same name, and not far from Heraclea Minora.

ALLAH, or ALL, an Arabic word, and the name which all who profess Mahometanism give to God, and make frequent repetitions of in their prayers.

ALLAHABAD, in Geography, a souk or province of Hindostan, about 160 miles in length and 120 in breadth, bounded on the east by the province of Babar, on the north by Oude, on the south by Berrar, and on the west by Malwa and Agra. It contains, according to the distribution of Akbar, recorded in the Ayen-Akbery, 10 circums or counties, divided into 177 pargunnahs, or hundreds. Its revenue, according to the statement of Maurice, in his Indian Antiquities, is 3,310,695 rixas rupees. It furnishes 11,375 cavalry, 237,870 infantry, and 323 elephants. The greater part of it is in the possession of Azepul Dowlah, a tributary ally of the British power. The principal cities are Allahabad, Benares, and Icpeonpur.

ALLAHABAD, a city of Hindostan, situate at the confluence of the two great rivers Jumna and Ganges. It is composed of two towns—the old, which is near the Ganges, and the new, about a mile long and a mile wide, near the Jumna. It was called Allahabad by the emperor Akbar, who erected a strong fortress of stone in it, which occupies a large space of ground, and of which we have an elegant delineation by Mr. Hodges, in No. IV. of his Select Views in India. The tomb of Sultan Khurin is also an excellent specimen of Mahometan architecture; and a pillar 40 feet high, of one stone, covered with illegible inscriptions, is ascribed by tradition to Bima, one of the heroes of the Mahabarat. Allahabad is a seat of devotion so noted that it is denominated “the king of worshipped places.” We also learn from the Ayen-Akbery, that the territory round it, to the extent of 40 miles, is deemed holy ground. The Hindoos believe, that when a man dies in this place, whatever he wishes for he will obtain in his next regeneration. Although they teach that suicide in general will be punished with torments hereafter, yet they consider it meritorious for a man to kill himself at Allahabad. There are various objects of veneration in and about this city, which are still visited with great devotion by an immense number of pilgrims. Dr. Robertson is of opinion, that the ancient Palibothra is the modern city of Allahbad; but major Rennell has placed Palibothra on the same site with Patna. Robertson’s India, p. 39. p. 356. N. lat. 25° 27'. E. long. 82° 5'.

ALLAKNANDARA, a river of Thibet, which runs into the Ganges, about 20 miles south of Srinagar.

ALLAMANDA, fo called from Mr. F. Allamand, a Dutch surgeon, who visited Guiana about 1769, and Ruffia about 1775, and sent descriptions, figures, and specimens of plants to Linnaeus, in Botany, a genus of the pentandria monogynia class and order, of the natural order of costisos, and apocrine of Jullien; the characters of which are, that the calyx is a perianthium one-leaved, five-parted, parts ovate and acute; the corolla one-petalled, funicle-shaped, tube cylindrical, tube semiquincuncial, five-rowed, divided spreading, obtuse; the stamina, with scarcely any filaments, anthers five, flagitate, converging in the throat of the tube; the pistillum has a geml ovum, surrounded with a ring, fylite fiform, of the length of the tube, stigma headed, contracted in the middle; pericarpium, an orbicular, lens-shaped, echnate, one-celled, two-valved capsule; the seeds very many, imbricate, orbiculate, flat, edged with a membranous wing. There is one species, viz. A. carthacea, galaripa of Allamand, orda grandiflora of Aublet, a milky thorn, with flum twining and climbing on trees, which grows wild at Cayenne, in Guiana, &c. by the sea-side. The leaves are cathartic, and an infusion of them is used at Surinam, in the colic; introduced in 1785 by Baron Hake. Martyn.

ALLAMP, in Geography, a town of France, in the department of the Meurte, and district of Toul, three leagues south of Toul.

ALLAN, a river of Scotland, which runs into the Frith of Forth near Stirling. Allan Water is also a river of the same country, which runs into the Tweed, about a mile north-west of Melrose.

ALLANCHE, a town of France, in the department of Cantal,
Cantál, and district of Murat, situate in a valley, and having a considerable commerce of cattle; four leagues and a half north-west of St. Flour. N. lat. 45° 12'. L. long. 2° 54'.

ALLANTOS, or ALLANTUM, a town of Macedonia, supposed to be inhabited by the Allantofes of Play.

ALLANTOIDES, called also Farcimiialis, in Comparative Anatomy, is a thin transparent fac or bag, found amongst the membranes, invading the fetus of quadrupeds; it is connected with the urinary bladder of the young animal, by means of the urachus, and is supposed to serve the purpose of a reservoir for the urine.

Malpighi, Haller, and others have attributed this membrane to the chick during the period of incubation.

The word is derived from adnax, farcimen, a gut: and obs, formae, fæce; because, in many brutes, it has somewhat the appearance of an inflated intestine.—For a further account, see Mammalia, in Comparative Anatomy.

ALLARD, Guy, in Biography, was born at Dauphiné, about the middle of the 17th century, and acquired reputation by several works relating to the history of that province. His "Nomibulaire du Dauphiné avec les Armories," (12mo). Grenoble, 1714, and "Histoire des Maîons Dauphinoises," are his principal and most esteemed works.

ALLAT, in Mythology, derived from Alla, God, is the name of an idol among the Arabian and idolatrous Jews.

ALLATIA, in Ancient Geography, a town of Arabia Deferta, according to Ptolemy.

ALLATA, a town of Dalmatia, in the itinerary of Antoninus.

ALLATIUS, or ALLACI, Leo, in Biography, a voluminous writer of the 17th century, was born in the island of Chios, and at the age of nine years, after having been educated in the Greek church, removed to Calabria, where he enjoyed the patronage of the noble family of Spinelli, and embraced the Catholic religion. At Rome he was admitted into the Greek college, where he acquired reputation by the study of polite learning, philosophy, and divinity. From Rome he went to Naples, and was made great vicar to the bishop of Angliena; and having settled for some time in his native country, he returned again to Rome, studied phylical, and took his degree of doctor in that science. But the belles lettres best suited his taste and engaged his principal attention; and, instead of pursuing the practice of phylic, he taught the Greek language in the college of his own nation. About the year 1622 he was employed by Gregory XV. in removing to Rome the library of Heidelberg, which the elector of Bavaria had presented to that pontiff; he was afterwards librarian to Cardinal Barberini; and at length pope Alexander VII. appointed him librarian of the Vatican. His publications, which consisted of editions of old MSS, translations from Greek authors, and original compositions, are very numerous. Some of the principal of the latter class are the following: "De Ecclesiae Occidentalis et Orientalis perpetuo confensione," 4to. Cologne 1648; "On purgatory," 8vo. Rome, 1655; "De patria Homer," 8vo. Lyons, 1640; "De Septem orbibus Spectaculis," 8vo. Rome, 1640; "Confutatio Fabule de Joanna papilla," "De Piellis," "De Georgius," "De Simonibus." His retentive memory and application qualified him for compiling catalogues; accordingly he published a work of this kind under the title, "Apex Urbanus," in allusion to the bees borne in the arms of pope Urban VIII. which contained a history of the learned men of Rome for the years 1630, 1631, and 1632, with a catalogue of their works: and another tract of a similar kind, entitled, "Dramaturgii," giving an account of dramatic authors and their works, printed at Rome in 1636, and reprinted at Venice in 1655. Allatius also wrote several Greek poems, one upon the birth of Lewis XIV., in which he introduced Greece speaking. Allatius was a diligent and rapid writer; and he is said to have written Greek 40 years with the same pen, the loss of which he lamented with tears. His erudition and industry are more commended than his judgment; and he is generally reproached for want of liberality and candour. His criticisms were harsh and ill-natured: his reflections on those who differed from him were coarse and vulgar, as well as severe; and his animosity and intolerance, in his conduct towards those who were not comprehended within the pale of the Romish church, to which he was a profite, and for which he was an ardent advocate, were such as led him to denounce against them the most cruel penalties. The Roman pontiff, as he maintained, was independent; judged the world without being accountable to any; his unjust commands were to be obeyed; and he had an absolute authority as legislator and judge, and was incapable of illusion and error. As for heretics and schismatics Allatus was of opinion, that they ought to be proscribed and exterminated, and if they perished in their heresy, to put to death and consumed in the flames. In his zeal for uniting the Greek church to the Latin, and with this view for inculcating himself into the favour and confidence of pope Urban VIII., he is charged by F. Simon with insincerity and misrepresentation. The gentlemen of Port Royal have attempted a vindication of Allatus, particularly against the attacks of Mr. Claude.

Allatius was neither married nor took orders; and in accounting for this part of his indecisive conduct, when he was asked by pope Alexander VII. "why do you not enter into orders?" he replied, "Because I would be free to marry." "Why then," said the pope, "do you not marry?" "Because," replied Allatus again, "I would be at liberty to take orders." He died at Rome in the year 1666, at the age of 83 years.

ALLAY. See ALLOV.

ALLAZONIUM, in Ancient Geography, a town of Aia in Mylica, north coast of Scyphus.

ALLBURG, in Geography, a township of America, in Franklin county, Vermont, situate on Millisique Bay, and containing 446 inhabitants.

ALLCHURCH, a village of Warwickshire, said to have been formerly seven miles in circumference, and having the Roman Icknald street passing through it. It was once a borough, with a market and several streets. The bishop of Worchester had a palace in it, and the church, parts of which are of Saxon architecture, contains many ancient monuments. It is situated five miles from Bromfringe, in the road to Leicesters.

ALLECTUS, in Ancient Biography and History, the confidential friend and prime minister of Carausius, emperor of Britain, apprehending punishment for several crimes with which he was chargeable, murdered his master, A.D. 294, and usurped the imperial dignity, which he maintained for three years. During this period Constadius was preparing for the recovery of Britain; and at length the principal squadron, destined for this enterprise, and assembled in the mouth of the Seine, was intrusted to the command of the praefect Acelpheidotus. The weather proved favourable, and under the cover of a thick fog, the invaders crossed the
the fleet of Allectus, which had been floated off the Isle of Wight to receive them, landed in safety on the western coast; and convinced the Britons, says Gibbon, "that a superiority of naval strength will not always protect their country from a foreign invasion." As soon as the troops were landed, the intrepid commander set fire to the ships, and marched forward to meet the enemy. The usurper had posted himself near London in expectation of an attack from Conlantius, who commanded the fleet of Boulogne; but upon hearing of the defeat of Aplepodotus, he made forced marches opposite him. With his small body of harried and disheartened followers, Allectus encountered the Imperial troops, and the engagement soon terminated in his total defeat and death: so that a single battle decided the fate of this great island. When Conlantius landed on the shores of Kent, he was welcomed by the loud and unanimous acclamations of obedient subjects; and Britain, after a separation of 10 years, was thus restored, A.D. 257, to the body of the Roman empire. Crevier's Rom. Emp. vol. ix. p. 311. Gibbon's Hist. vol. ii. p. 127.

ALLEGHANY, or Alleghany County, in Geography, a district of Pennsylvania in America, extends from the junction of the river of that name with the Ohio, where its chief town Pittsburg is situated, to the New York line. It contains 103,599 inhabitants, including 159 slaves. Morfe.

Alleghany is also the most western county in Maryland, and has Pennsylvania on the north. The windings of the Patowmac river separate it from Virginia on the fourth, and Sideling-hill Creek divides it from Washington county on the east. It contains 480,995 inhabitants, including 255 slaves. Its chief town is Cumberland.

Alleghany Mountains of America, situate between the Atlantic Ocean, the Mississippi river, and the lakes, are a long and broad range of mountains, formed of a great number of ridges, extending to the north-east and south-west, and nearly parallel to the sea-coast, about 900 miles in length, and 60 to 150 and 250 miles in breadth. The different ridges, which compose this immense range of mountains, bear appropriate names in the several states; viz. the Blue Ridge, the North Mountain or North Ridge, or Devil's Back-bone, Laurel Ridge, Jackson's Mountains, and Kittatinny Mountains. All these ridges, except the Alleghany, are broken through by rivers, which appear to have forced their way through solid rocks; and between the several ridges numerous tracts of fine arable and grazing land intervene. In those districts, however, which lie in the back parts of Pennsylvania, Mr. Evans, who travelled over them, observes, that scarcely one acre in 10 is capable of culture. The principal ridge is more appropriately called Alleghany, and distinguished by the appellation of the Back-bone of the United States. From the several ridges proceed innumerable branches or spurs. The general name of the whole range, taken collectively, seems not yet to have been determined. Mr. Evans calls them "the endles mountains," others have called them "the Appalachian mountains," from a tribe of Indians, who live on a river which proceeds from this mountain, called the Appalachian; but the most common name is the "Alleghany mountains" to call, probably from the principal ridge of the range. These mountains are not confusedly scattered, rising here and there into high peaks, overtopping each other; but they run along in uniform ridges, scarcely half a mile high. They spread towards the south, and some of them terminate in high perpendicular cliffs; others gradually subside into a level country, giving rise to the rivers which run to the southward into the Gulf of Mexico. Morfe.

Alleghany River, an American river of Pennsylvania, rises on the western side of the Allegheny mountains, and after running about 200 miles in a south-west direction, unites with Monongahela at Pittsburg; and both together form the Ohio. The lands on each side of this river, for 150 miles above Pittsburg, consist of white oak and chesnut ridges, and in many places of poor pitch pines, interfened with tracts of good land and low meadows. This river, and the Ohio likewise, from its head waters until it enters Mississippi, are known and called by the name of Alleghany river, by the Seneca and other tribes of the five nations, who once inhabited it. Morfe.

ALLEGATION, in Antiquity, a word formerly subscribed at the bottom of recripts and constitutions of the emperors, as signata, or testata, was under other instruments. In this sense allegata imports as much as verified, verificata. Allegata was a kind of subscription, somewhat less usual than data, proposition, accepta, jubepit, supposita, or subscripsita.

ALLEGATION, is used for the producing of acts, or instruments, to authorize a thing. In the ecclesiastical courts, articles are drawn out in a formal allegation, or by libel, to set forth the complainant's ground of complaint against the injuring party, brought before the court by citation. To this succeeds the defendant's answer upon oath, when, if he denies or extenuates the charge, they proceed to proofs by witnesses examined, and their depositions taken down in writing, by an officer of the court. If the defendant has any circumstances to offer in his defence, he must also propound them in what is called his defensive allegation, to which he is entitled, in his turn, to the plaintiff's answer upon oath, and may from thence proceed to proofs as well as his antagonist.

'Allegation, in a literal sense, denotes the act of citing or quoting an author, or passage of some book.

ALLEGEAS, or Allegas, in Commerce, a stuff manufactured in the East Indies. There are two sorts of them; some are of cotton, and others of several kinds of herbs, which are spun like flax and hemp. Their length and breadth are of eight ells, by five, six, or seven-eighths; and of twelve ells by three fourths, or five-eighths.

ALLEGANCE, in Law, the legal faith and obedience, which every subject owes to his prince: or, it is the tie or ligament, which binds the subject to the king, in return for that protection which the king affords the subject.

This was anciently called ligamentia, or ligament; from the Latin ligare, and allegare, to bind; q. d. ligament. This was anciently called ligamentia, or ligament; from the Latin ligare, and allegare, to bind; q. d. ligament. This thing itself, in the substance of it, is founded in reason and the nature of government; the name and the form are derived to us from our Catholic ancestors. Under the feudal system, every owner of lands held them in subjection to some superior or lord, from whom or from whose ancestors the tenant or vassal had received them; and there was a mutual trust or confidence subsisting between the lord and vassal, that the lord should protect the vassal in the enjoyment of the territory he had granted him; and, on the other hand, that the vassal should be faithful to the lord, and defend him against all his enemies. This obligation on the part of the vassal was called his feudalitas, or fealty; and an oath of fealty was required, by the feudal law, to be taken by all tenants to their lord; which is couched in almost the same terms with our ancient oath of allegiance, except that in the usual oath of fealty there was frequently a faving or exception of the faith due to a superior lord by name, under whom the landlord himself was perhaps only a tenant.
tenant or vassal. But when the acknowledgment was made to the superior lord himself, who was vassal to no man, it was no longer called the oath of fealty, but the oath of allegiance; and therein the tenant swore to bear faith to his sovereign lord, in opposition to all men, without any saving or exception; *contra omnes homines sedehabitatem fecit.* Land held by this exalted species of fealty was called "Feudum lignum," a liege fee, the vassals "homines ligni," liege men, and the sovereign their "dominus ligni," or liege lord. And when foreign princes did homage to each other for lands held under their respective sovereignties, a distinction was always made between *simple* homage, which was only an acknowledgment of tenure, and *liege* homage, which included the fealty before mentioned, and the services consequent upon it. Thus, when our Edward III. in 1329, did homage to Philip VI. of France, for his ducal dominions on that continent, it was warmly disputed of what species the homage was to be, whether *liege* or *simple* homage. But with us in England, it becoming a settled principle of tenure, that all lands in the kingdom are holden of the king as their sovereign or lord paramount, no oath but that of fealty could be taken to inferior lords, and the oath of allegiance was necessarily confined to the persons of the king alone. By an easy analogy the term of allegiance was soon brought to signify all other engagements, which are due from subjects to their prince, as well as those duties which were simply and merely territorial. And the oath of allegiance, as administered for upwards of 600 years, contained a promise "to be true and faithful to the king and his heirs, and truth and faith to bear of life and limb, and to render them *therefor* without end or day." Thus intended him, without defending him therewith. At the revolution, the terms of this oath being thought to favour too much the notion of non-refinunce, the present form was introduced by the convention parliament, which is more general and indeterminate than the former; the subject only promising "that he will be faithful and bear "true allegiance to the king," without mentioning "his "heirs," or specifying in the least wherein that allegiance "conflits. Accordingly, the convention of eflates having offered the crown to the prince and princes of Orange, who accepted it, the old oaths of allegiance imposed by the *flat. 1 Eliz.* and *3 James I.* were abrogated; and a new oath was drawn up to be taken by all the subjects of Eng- land, on penalty of being deprived of all employments, civil, military, and ecclefaical. The form of the oath of allegiance by *I Geo. flat. ii. e. 13.* is "I, A. B. do sincerely "promise and swear, that I will be faithful, and bear "true allegiance to his majesty King George. So help me "God." This oath may be tendered to all persons above the age of 12 years, whether natives, denizens, or aliens, either in the court-leet of the manor, or in the sheriff's tour, which is the court-leet of the county. See PREMIS- NIRE. The quakers are exempted from taking the oath of allegiance; and, in lieu thereof, are only enjoined a declaration of fidelity, 8 Geo. c. vi. The oath of allegiance, taken by the people to the king, is only the counterpart to the coronation oath, taken by the king to the people; and, as fuch, partake of the nature of a covenant; that is, is conditional, and ceases on a violation of the contract by the prince; at least this is the doctrine of some of the chief advocates for the revolution. The anti-revolutionists, on the contrary, hold the oath of allegiance to be absolute and unconditional. Archdeacon Paley, in his illustration of this oath, observes, that it excludes all intention to support the claims or pretentions of any other person or persons to the crown and government, than the reigning sovereign; and also all design, at the time, of attempting to dethrone the reigning prince, for any reason whatever; and that it forbids the taking up of arms against the reigning prince, with views of private advancement, or from motives of personal resentment or dislike. On the other hand, this oath permits refusal to the king, when his conduct or behaviour is such, as to make refusal beneficial to the community; nor does it require obedience to such commands of the king as are unauthorized by the law, or that we should continue our allegiance to the king, after he is actually and absolutely deposed, driven into exile, carried away captive, or otherwise rendered incapable of exercising the regal office, whether by his fault or without it. Besides this exprs engagement, the law also holds, that there is an implied, original and virtual allegiance, owing from every subject to his sovereign, antecedently to any express promise; and although the subject never avere any faith or allegiance in form. For as the king, by the very defeat of the crown, is fully invested with all the rights, and bound to all the duties of sovereignty, before his corona- tion; so the subject is bound to his prince by an intrinsic allegiance, before the superinduction of those outward bonds of oath, homage and fealty, which were only instituted to remind the subject of his previous duty, and for the better securing its performance. The formal profession, therefore, or oath of sujection, is nothing more than a declaration in words of what was before implied in law. Allegiance, both express and implied, is however distin- guished by the law into natural and local; the first being also perpetual, and the latter temporary. Natural allegiance is such as is due from all men born within the king's dominions immediately upon their birth; for immediately upon their birth, they are under the king's protection; at a time too, when (during their infancy) they are incapable of protecting them- selves. Natural allegiance, therefore, is a debt of gratitude, which cannot be forfeited, cancelled or altered, by any change of time, place or circumstance, nor by any thing but the united concurrence of the legislature. An Englishman who removes to France, or to China, owes the same allegiance to the king of England there as at home; and 20 years hence as well as now. For it is a principle of universal law, that the natural born subject of one prince cannot by any act of his own, not by swearing allegiance to another, put off or discharge his natural allegiance to the former: for this natural allegiance was intrinsic and primitive, and antecedent to the other, and cannot be divested without the concurrent act of that prince to whom it was first due. Local allegiance is such as is due from an alien, or stranger born, for so long time as he continues within the king's dominion and protection; and it ceases the instant such foreigner transfers himself from this kingdom to another. Natu- ral allegiance is, therefore, perpetual, and local, temporary only; and that for this reason, evidently founded upon the nature of government, that allegiance is a debt due from the subject, upon an implied contract with the prince, that so long as the one affords protection, so long the other will demean himself faithfully. As therefore the prince is always under a constant tie to protect his natural born subjects at all times, and in all countries, for this reason their allegiance, due to him is equally universal and permanent. But, on the other hand, as the prince affords his protection to an alien, only during his residence in this realm, the allegiance of an alien is confined, in point of time, to the duration of his residence; and, in point of locality, to the dominions of the Britis empire. Blackstone's Com. book i. ch. 10. vol. i. p. 376—371. 8vo. Paley's Principles of Moral and Political Philosophy, book iii. ch. 18. vol. i. p. 263—207. 8vo.
ALLEGORICAL, something containing an allegory.

The divines divide divers fenes in scripture; as a literal, a mystical, and an allegorical sense. See Prophecy, and Type.

ALLEGORY, Allegoria, a figure in Rhetoric, whereby we make use of terms which, in their proper significations, mean something else than what they are brought to denote; or it is a figure whereby we say one thing, expecting it shall be understood of another, to which it alludes; or which, under the literal sense of the words, conceals a foreign or distant meaning.

An allegory is, properly, a continued metaphor, or a series of several metaphors in one or more sentences. Such is that beautiful allegory, in Horace, lib. i. Od. 14.

"O navis, referunt in mare te novi
Fluctus, &c."

Where the ship is usually held to stand for the republic; waves, for civil war; port, for peace and concord; ears, for folders; and mariners for magistrates. Thus also, in Prior's Henry and Emma, Emma describes her.continy to Henry in the following allegorical manner:

"Did I but purpose to embark with thee
On the smooth surface of a summer's sea,
While gentle zephyrs play with prosperous gales,
And fortune's favour fills the swelling sails;
But would forsake the ship, and make the shore,
When the winds whistle, and the tempests roar?"

Cicero likewise speaking of himself (in Pison. c. 9. tom. vi. p. 187.) ues this allegorical language: "Nor was I fo timorous, that after I had ferred the ship of the state through the greatest storms and waves, and brought her safe into port, I should fear the cloud of your forehead, or your colleague's pelilent breath. I faw other winds, I perceived other storms, I did not withdraw from other impending tempests; but I exposed myself singly to them for the common safety." Here the state is compared to a ship, and all the things that are said of it under that image, are expressed in metaphors made use of to denote the dangers with which it had been threatened. We have also a very fine example of an allegory in the 80th Psalm; in which the people of Israel are represented under the image of a vine, and the figure is supported throughout with great correctness and beauty. Whereas, if instead of describing the vine as wailed by the boar from the wood, and devoured by the wild beasts of the field, the Psalmist had said, it was afflicted by heathens or overcome by enemies, which is the real meaning, the figurative and the literal meaning would have been blended, and the allegory ruined. The learned Bishop Lowth (De Sacra Pochi Hebræorum. Pat. 10. ii. p. 129-140.) has specified three forms of allegory that occur in sacred poetry. The 1st is that which rhetoricians call a continued metaphor. When several metaphors succeed one another, says Cicero (Orator. c. 27. tom. i. p. 520.) they alter the form of the composition; and this succession has very properly, in reference to the etymology of the word, been denominated by the Greeks ἀλληγορίας, an allegory; although Aritotle, instead of considering it as a new species of figure, has referred it to the class of metaphors. The principle of allegory in this sense of the term, and of the simple metaphor, is the same;

- nor is it an easy matter to restrict each to its proper limit, and to mark the precise termination of the one, and the commencement of the other. For examples of this kind, we refer to Metaphor. This eminently judicious critic observes, that when the Hebrew poets use the congeneric figures of metaphor, allegory, and comparison, particularly in the prophetic poetry, they adopt a peculiar mode of doing it, and seldom regulate the imagery which they introduce by any fixed principle or standard. Not satisfied with a simple metaphor, they often run it into an allegory, or blend it with a direct comparison. The allegory sometimes follows, and sometimes precedes the simile; and in this case is added a frequent change of imagery, as well as of persons and tenets; and thus are displayed an energy and boldness, both of expression and meaning, which are unconfined by any flated rules, and which mark the discriminating genius of the Hebrew poetry. Thus, in Gen. xlix. 9. "Judah is a lion's whelp," this metaphor is immediately drawn out into an allegory, with a change of person: "From the prey, my son, thou art gone up," that is, to the mountains, which is understood; and in the succeeding sentences the person is again changed, the image is gradually advanced, and the metaphor is joined with a comparison that is repeated.

"He flepeth down, he coucheth as a lion;
And as a lion's; whom shall heoufe him?"

A similar instance occurs in the prophecy, recorded in Psalm cx. 3. which explicitly foretells the abundant increase of the gospel on its first promulgation. This kind of allegory, however, sometimes assumes a more regular and perfect form, and then occupies the whole subject and compass of the discourse. An example of this kind occurs in Solomon's well-known allegory, Eccles. xii. 2-6. in which old age is so admirably depicted. There is also in Isaiah, xxxviii. 24-29, an allegory, which, with no less elegance of imagery, is more simple and regular, as well as more just and complete, both in the form and the method of treating it. Another kind of allegory is that, which in the proper and more restricted sense, may be called a parable; and consists of a continued narration of some fictitious event, accommodated by way of similitude to the illustration of some important truth. The Greeks call these allegories ανασ, or apologies, and the Latinus fabulae, or fables. See Parable. The third species of allegory, which often occurs in the prophetic poetry, is that in which a double meaning is couched under the same words, or when the same discourse, differently interpreted, designates different events, dissemblar in their nature and remote as to time. These different relations are denominated the literal and mystical sense. This kind of allegory, which the learned prelate calls mystical, seems to derive its origin from the principles of the Jewish religion; and it differs from the two former species in a variety of respects. In these allegories the writer may adopt any imagery that is most suitable to his fancy or inclination; but the only proper materials for this allegory must be supplied from the sacred rites of the Hebrews themselves, and it can only be introduced in relation to such things as are immediately connected with the Jewish religion, or their immediate opposites.

The former kinds partake of the common privileges of poetry; but the mystical allegory has its foundation in the nature of the Jewish economy, and is adapted solely to the poetry of the Hebrews. Besides, in the other forms of allegory, the exterior or visible image is mere fiction, and the truth lies altogether in the interior or remote sense; but in this allegory each idea is equally agreeable to truth. The exterior or visible image is itself a reality; and although it sustains another character, it does not wholly lay aside its own. There is also a great variety in the use and conduct of the mystical allegory; in the modes in which the corresponding images are arranged, and in which they are ob-
feared or eclipsed by one another. Sometimes the obvious or literal sense is so prominent and conspicuous, both in the words and sentiments, that the remote or figurative sense is fearfully perverted to it through the mind. On the other hand, the figurative sense is more frequently found to be a shade, or becomes insoluble. Sometimes the principal or figurative idea is exhibited by an evident light, and sometimes it un-expectedly glares upon us, and breaks forth with sudden and astonishing corruptions, like a flash of lightning bursting from the clouds. But the mode or form of this figure, which poises the chief beauty and elegance, is, when the two images, equally conspicuous, run, as it were, parallel through the whole poem, mutually illustrating and correspondent to each other. The learned author has illustrated these observations by instances selected from the 2d and 72d Psalms. He adds, that the mythical allegory is, on account of the obscurity resulting from the nature of the figure, and the fyle of the composition, so agreeable to the nature of the prophecy, that it is the form which it generally, and indeed lawfully affinns, as being adapted to the prediction of future events. It describes events in a manner exactly conformable to the intention of prophecy; that is, in a dark, disguised and intricate manner, sketching out in a general way their form and outline; and seldom defending to a minuteness of description and exactness of detail. On this subject in its immediate connection with the double sense of prophecy, which some eminent critics and commentators have not only disputed, but absolutely rejected as groundless and fanciful, and leading to great uncertainty of interpretation; see Prophecy.

Allegories were a favourite method of delivering instructions in ancient times; for what we call fables or parables, are no other than allegories, where, by words and actions attributed to beasts or inanimate objects, the dispositions of men are figured; and what we call the moral, is the un-figured sense or meaning of the allegory. An enigma or riddle is also a species of allegory; one thing represented or imaged by another; but purposely wrapped up under so many circumstances as to be rendered obscure. Where a riddle is not intended, it is always a fault in allegory to be too dark. The meaning should be easily seen through the figure employed to shadow it. However, the proper mixture of light or shade, in such compositions, the exact adjustment of all the figurative circumstances with the literal sense, so as neither to lay the meaning too bare and open, nor to cover and wrap it up too much, has ever been found an affair of great nicety; and there are few species of composition in which it is more difficult to write, fo as to please and command attention than in allegories. In some of the visions of the Spectator, we have examples of allegories very happily executed. In the right management of allegories, care should be taken that the fame kind of trope be carried through the whole, so as to compose one uniform and consistent set of ideas: otherwise they dres up a chimera, a thing that has no existence, and of which the mind can form no conception. Quinctilian very justly observes (Init. Orat. I. viii. c. 6.) that "to begin with a tempel and end with a fire, would be very ridiculous and unnatural." It is likewise very necessary that the allusions be all plain and evident, especially where the name of the thing alluded to is not expressed. These are called pure allegories. But where the reference is not evident, it becomes a riddle, which is nothing else but an ob- serve allegory. To avoid this the best writers use what are generally called mixed allegories, or such as express the proper name of the thing which the whole similitude respects. Of this kind is that in the speech of Philip, king of Macedon, given by Justin (I. xxix. c. 3.), where he says, "I perceive that cloud of a dreadful and bloody war arising in Italy, and a thunder-storm from the west, which will fill all places with a large shower of blood, wherever the temple of victory shall carry it." The proper words "war," "blood," and "victory," being joined to the tropes "cloud," "snower," and "tempet," in this sentence, render the several parts of the similitude plain and evident. Quinctilian thinks those allegories most beautiful, where the whole similitude is expressed, and those words, which in their proper sense relate to one of the two things, between which the comparison is made, are allegorically applied to the other: as when Cor- nelius Nepos says of Atticus (cap. x.), "If that pilot gains the greatest reputation, who prefers his ship in a boisterous and rocky sea; ought not he to be thought a man of singular prudence, who arrived in safety through so many and so great civil tempests?" These are the allegories which orators are chiefly concerned. See Ward's Oratory, vol. ii. p. 27-31. Blair's Lectures, vol. i. p. 395-399.

The Old Testament is suppos'd, by many, to be a per- petual allegory, or typical representation of the mysteries of the New. Mr. Collins, in his "Grounds and Reaons of the Christian Religion," pretends, that the Old Testament, literally understood, no where serves the purposes of Chris- tianity; but if it be of any use, it must be understood al- legorically. He first recommends allegory, as the only mode of rendering proper for bringing men to the faith of Christ; and then ridicules this allegorical interpretation as ab- surd. p. 87, 90, 94, 160. In effect, allegories have entered into most religions.—The Jews, we know, abound with them. Philo Judaeus has three books, of the allegories in the history of the six days. Nor are the heathens without allegories in their religion: it may be even said, that the use of them is of a much earlier standing in the Gentile than in the Jewish world.—Some of their philosophers, un- derstanding to give a rational of their faith, and to shew the reason and scope of their fables, and the ancient histories of their gods, found it necessary to put another construction on them; and maintain, that they signified something very different from what they seemed to express. And hence came the word allegory, or a discourse that, in its natural sense, aλλoς aλεγομεν signifies something other than what seems in- tended by it. This shift they had recourse to, in order to prevent people from being shocked with those absurdities which the poets had introduced into their religion; and to convince the world, that the gods of Greece had not been those vile persons which their histories represented them to be. By this means the history, as well as religion, of Greece, was at once converted into allegory; and the world left to seek for them both in a heap of fables, few of which have been satisfactorily solved, either by ancient or modern writers. The Jews, finding the advantages of this way of explaining religion, made use of it to interpret the sacred writings, so as to render them more palatable to the Pagans. The same method was adopted by the primitive writers of Christianity. The practice of allegorical interpretation, which the Jews had learned from the Egyptians, and which, before the time of Christ, was common among them, the early converts to Christianity brought out of the Jewish into the Christian church. Some traces of this method we find in the New Testament, particularly in St. Paul's argument against the Jewish advocates for the perpetual and universal obligation of the Mosaic ritual, drawn from the history of Abraham, in the epistle to the Galatians, ch. iv. 22; and in the typical applications
application of the ceremonial appointments of Moses to the Christian institution, in the epistle to the Hebrews. But a
let's sober and judicious use was made of this kind of lan-
guage by the Christian fathers. This was more especially
the case with those Gentile converts who had been educated
in the Alexandrian school, where, by the help of allegory,
the several figures of philosophy were mixed and confounded;
and with those Jewish Christians, who, by the same
means, had been instructed in the Cabalistic doctrines,
which, before this time, had sprung up in Egypt, and passed
thence into Judea. Several of those facts of Christians,
who were called heretics, particularly the Valentinian
Gnostics, made use of allegorical language to disguise the unna-
tural alliance which they had introduced between the fanciful
dogmas of the oriental philosophy and the simple doctrine
of Christ. The orthodox fathers of the church, too, de-
defended themselves with the same armour, both against heretics
and infidels, applying, with more ingenuity than judgment, the
symbolical method of interpretation to the sacred scriptures.
In the same manner in which Philo and other Alexandrian
Jews had corrupted the Jewish church, Clemens Alex-
drinus, Origen, and other disciples of the Alexandrian
school, in the second century, introduced error and corrup-
tion into the church of Christ. Whitby on the interpretation
of Scripture, Lond. 1744. Brucker's Hist. Philos. by

Allegories are distinguished into diverse kinds: as verbal,
real, simple, allusive, physical, moral, political, theological, &c.

Allegory, simple, according to some writers, is that
which is taken from any kind of natural things.

Allegory, allusive, is that which relates to other words,
or things.

Allegory, verbal, is a thread, or series of metaphors;
or a continuation of the same trope, chiefly metaphor,
through many words. Such is that in Virgil:

"Claudie jam rivos pueri, fat prata bibebant."

Where the metaphor of watering the ground is carried on
to the futting of the fishes, &c.

Allegory, perpetual, or continual, is that where the al-
egorical thread is pursu'd through all the parts of a con-
siderable discourse. Such are the books of Jonah, of Can-
ticles, of Job, not to say the whole Old Testament, accord-
ing to the hypothesis of some divine.

Allegories, physical, those wherein some point of na-
tural philosophy is represented: such in Homer, are Juno,
who represents the air; Jupiter, the other, &c.

Allegories, medical, those wherein some secret of physic
is revealed: such is Solomon's description of old age, Eccle-
xii. 1, &c. wherein, according to certain authors, the cir-
culation of the blood is indicated: such also, according to
a modern writer, is the story of the labours of Hercules.
For an illustration of Solomon's allegorical description of
old age, see Meda's Medica Sacra, chap. vi.

Allegories, chemical, those relating to chemistry: such,
according to Suidas, and many moderns, is the story of the
Aragonite expedition, wherein the process of making gold
is exactly described: such also, according to Tolius, is the
name and title of Bafli, Valentine, Beneficent, Monk, under
which are concealed the secrets of the philosophical mercury.

Allegories, moral, those where by some useful moral
inference is held forth: such, in Homer, is the victory
of Diomed against Venus, or fleshly lust: such also are the Py-
thagorean metempsychosis, and the story of the judgment
of Hercules, related by Proclus. To which may be added,
the fables of avarice and luxury; of the grotto of grief, and
and others in the Spectators and Tatlers. Spectat. N° 55.

Allegories, poetical, those wherein some maxim of good
government is artfully wrapped up; such is that celebrated
one of Memmius Agrrippa, whereby he prevailed on the Roman
people, who had withdrawn in discontent at the magistrates,
to return into the city: to which purpose he related to them
the parable of a war raised by the several parts of the human
body against the Romans.

Allegories, theological, those wherein some truth relat-
ing to the nature and attributes of God is couched.

Allegory is also used for the drawing of some words,
plainly and literally intended at first, from their natural and
proper meaning, to a foreign sense; for the better instructing
of our minds in some point of faith or manners. This coin-
cides with what is otherwise called accommodation.

Allegory, in Painting, is used as in poetry, and
sometimes too licently, by painters, who, while they
enrich their pictures by allegories, offend the spectator,
especially in representations of modern history. Rubens,
whose works are full of great and noble ideas, cannot be
justified in the licentious treatment of allegory in his famous
pictures representing the history of Mary of Medicis, and
in several others of that great master's works which could
be mentioned. In the Luxembourg gallery Rubens has so
united the Christian ceremonies with heathen mythology as
greatly to offend the eye of the intelligent spectator, not-
withstanding the grandeur of the composition and richness
of the colouring, which are produced by this very means.
A great general has been represented crossing a river with
his troops by an armed warrior dashing over a stream of wa-
ter flowing from an urn held by a river god; which would,
it is apprehended, have been expressed with greater propriety
by the general holding his truncheon, while the troops, at
a distance, were represented as fording a river. Allegory
seems better employed in poetical subjects than in historical
representations. See more upon this subject under the
article Painting.

ALLEGRI, Gregorio, in Biography, an eminent musi-
cal composer of the 17th century, was a native of Rome,
and by profession an ecclesiastic. He was a disciple of
Nannini, who was contemporary with Palestrina, and his in-
mate friend. His abilities as a singer were inconsiderable,
and yet he was accounted an admirable master of harmony :
and so much was he esteemed by all the musical professeurs
of his time, that the pope, in order to appropriate him to his
service, appointed him to be one of the fingers of his chap-
el in 1629. To his extraordinary merit as a composer of
church music he joined a devout and benevolent disposition,
and an excellent moral character; for he not only affil-
ted the poor, by whom his door was usually crowded, to the
utmost of his power, but daily visited the prisons of Rome,
in order to bellow his alms on the most deserving and dis-
tressed objects he could find in them. He fet many parts of
the church service with such divine simplicity and purity of
harmony, that the los of him was much felt and sincerely
lamented by the whole college of singers in the papal ser-
dice. He died Feb. 18th, 1652, and was buried in the
Chiefa Nuova, before the chapel of S. Filippo Neri, near
the altar of annunciation, where is a vault for the reception
of deceased fingers belonging to the pope's chapel.

Among his works preferred, that are still in use, is the
famous Miserere, which, for upwards of 270 years, has
been annually performed at the pope's chapel in Rome on
Wednesday and Good Friday in Passion week, and which in
appearance is so simple as to make those who have only seen it
on
on paper wonder whence its beauty and effect could arise, and which owes its reputation more to the manner in which it is performed than to the composition: the same music is in many instances repeated to different words, and the fingers have, by tradition, certain munitions, expressions, and graces of convention (certe effigizioni e gruppi), which produce great effects, such as swelling and diminishing the sounds altogether, accelerating or retarding the measure at some particular words, and singling some entire verses quicker than others. This information was communicated to the author by Signor Santarelli, the pope's maestro di capella. And Andrea Adami affirms, in his Osservazioni per la reg. il coro delle Cap. Pont. 1711, p. 36, "That after several vain attempts by preceding composers, for more than a hundred years, to let the fame words to the satisfaction of the heads of the church, Gregorio Allegri succeeded so well as to merit eternal praise; for with few notes, well modulated and well understood, he composed such a Misere, as will continue to be sung on the same days, every year, for ages yet to come; and one that is conceived in such just proportions as will attend future times, and ravish, as at present, the soul of every hearer. However, some of the great effects produced by this piece may, perhaps, be justly attributed to the time, place, and solemnity of the ceremonial us'd during the performance: the pope and conclave are all prostrated on the ground; the candles of the church and the torches of the balustrade are extinguished one by one; and the last verse of this psalm is terminated by two choirs; the maestro di capella beating time flower and flower, and the fingers diminishing or rather extinguishing the harmony, by little and little, to a perfect point:

It is likewise performed by select voices, who frequent rehearsals, particularly on the Monday in Passion week, which is wholly spent in repeating and polishing the performance.

This composition us'd to be held so sacred, that it was imagined excommunication would be the consequence of an attempt to transcribe it.

Padri Martini said that there were never more than three copies of it made by authority, "one of which was for the emperor Leopold, one for the late king of Portugal, and the other for himself." Of this last he favoured the author with a transcript at Bologna, and Signor Santarelli indulged him with another from the archives of the pope's chapel. Upon collating these two copies, they were found to differ very little from each other. - Present state of Music in France and Italy.

Before we quit the subject so interesting to the lovers of church music, we shall add the following anecdote, with which we were likewise favoured by Signor Santarelli.

"The emperor Leopold the first, not only a lover and patron of music, but a good composer himself, ordered his ambassador at Rome to entreat the pope to permit him to have a copy of the celebrated Misere of Allegri, for the use of the imperial chapel at Vienna; which being granted, a copy was made by the Signor maestro of the pope's chapel, and sent to the emperor, who had then in his service some of the first fingers of the age; but, notwithstanding the abilities of the performers, this composition was so far from answering the expectations of the emperor and his court in the execution, that he concluded the pope's maestro di capella, in order to keep it a mystery, had put a trick upon him, and sent him another composition. Upon which, in great wrath, he sent an express to his lieutenants, with a complaint against the maestro di capella, which occasioned his immediate disgrace, and dismissal from the service of the papal chapel; and in so great a degree was the pope offended, at the supposed imposture of his composer, that, for a long time, he would neither see him nor hear his defence. However, at length, the poor man got one of the cardinals to plead his cause, and to acquaint his holiness that the style of singing in his chapel, particularly in performing the Misere, was such as could not be expressed by notes, nor taught nor transmitted to any other place, but by example, for which reason the piece in question, though faithfully transmitted, nullifies in its effect when performed elsewhere. His holiness did not understand music, and could hardly comprehend how the fame notes should sound so differently in different places; however, he ordered his maestro di capella to write down his defence, in order to be sent to Vienna, which was done; and the emperor, seeing no other way of gratifying his wishes with respect to this composition, begged of the pope that some of the musicians in the service of his holiness might be sent to Vienna, to instruct those in the service of his chapel how to perform the Misere of Allegri, in the same expressive manner as in the Sistine chapel at Rome, which was granted. But, before they arrived, a war broke out with the Turks, which called the emperor from Vienna; and the Misere has never y.t. perhaps, been truly performed but in the pope's chapel.

With respect to the intrinsic worth of this renowned Misere, as a musical phenomenon, we know that more sublime compositions have been produced, since Allegri's time, by musicians of superior genius; but the words were thought by the heads of the Roman church to be set to too much propriety, reverence, and effect, than by any former ecclesiastical composer whose productions had been allowed admission into the service of the papal chapel during the holy week, that, besides the manner in which it was performed, its merit was perhaps somewhat exaggerated in imagination by the mystery with which it was sedulously preserved from profane examination.

ALLEGRI, ANTONIO. See CORREGIO.

ALLEGRI, FRANCESCO, an engraver, who lived at Florence, and flourished in 1760. By him we have many portraits, from different masters. The image of St. Francis d'Assisi is held in high estimation at Sienna, in the church of St. Alberino. - Strutt.

ALEGRO. Ital. Miste, denotes gay, cheerful, quick. The force of this term is augmented by the words più, affai, and the superlative degree of comparison, as più allegro, more quick; allegro affai, and allegroissimo, very quick. It has likewise its diminutives, as poco allegro, and allegretto, a little gay, cheerful, or quick. Allegro is the degree of time between Andante and Presto, which fee.

ALLEIN, RICHARD, in Biography, a nonconformist divine, was born at Dichter, in Somersetshire, in 1612, educated by his father, who was rector of the parish, and entered a commoner at St. Alban's Hall, Oxford, in 1627. Having taken the degrees of bachelor and master of arts in the University, he became first, adulator preacher to his father, and afterwards, viz. in 1641, rector of Bathurst, in the county of Bath, where he faithfully discharged his duty. Having received from his father a bias towards the sentiments of the Puritans, he attached himself to that party, and zealously supported the solemn league and covenant, though he disapproved the enthusiastic spirit of some of its adherents; as appears by a paper printed in 1648, and entailed, "The testimony of the ministry of Somersetshire to the truth of Jesus Christ, and to the solemn league and covenant." In 1653, he was employed as adulator to the commissioners appointed by parliament for ejecting scandalous ministers; at the restoration he manifested an inclination to yield submission to the government; but unable conscientiously to comply with.
with the terms of conformity, he preferred the alternative, imposed by the act of uniformity, of quitting his living after having retained it for 20 years, and of running with about 2000 other sufferers, who were distinguished by the denomination of ejected ministers. Under the restraints and penalties of this act, he exercised his ministry in the house of Mr. More, who had been formerly a member of parliament, and who lived in his neighbourhood; and though he was reprimanded by the magistrates and imprisoned, his reputation for piety, learning, and exemplary conduct, procured a mitigation of the rigorous treatment with which he encountered. In consequence of the "Lavenda Act," he was under a necessity of removing from Batcombe to Frome-Selwood, where he continued in the discharge of his professional duties, notwithstanding the dangers to which he was exposed. In this situation he remained, till death terminated his trials and labours in 1681. He was distinguished by his plain, practical and pathetic manner of preaching, and by his fidelity in the duties of his pastoral office, such as catechising, visiting the sick and instructing the ignorant. Although he was as avowed non-conformist, and strictly attached to his principles, the moderation of his temper, as well as his general character, recommended him to the clergy and laity of sentiments different from his own, and he lived amongst them on terms of friendship and intercourse. Mr. Jenkins, vicar of Frome-Selwood, preached his funeral sermon, and bore testimony to his piety, meekness, and moderation. His works, which were all of the devotional kind, were much esteemed, and frequently reprinted. The principal of these was his "Vindiciae Pictatis," or, "A Vindication of Godliness, in the greatest trifling and spirituality of it, from the imputations of folly and fancy," which was published in 1665, without a printer's name, because it was not licensed; but the copies of it were seized and sent to the king's kitchen for waste-paper. They were afterwards bought by the king's bookkeeper, who had caused them to be seized, at a cheap rate, and sold; for which artifice he was brought on his knees to the council table, and the books were again sent to the king's kitchen and burnt, i.e. struck over with ink, so as to be illegible. The other works of Allein were "Heaven opened, or a brief and plain discovery of the riches of God's covenant of grace," printed in 1665; "The World Conquered," 1668, 8vo.; "Godly Fear," 1671, 8vo.; "A Returne to Backfielders, and a Spur for Loiterters," 1677, and 1684, 8vo.; "A Companion for Prayer," 1680, 12mo.; "Instructions about Heart-work, &c." 1681, 8vo. Calamy's Life of Baxter, vol. ii. Wood's Athen. Oxon. vol. ii. Biog. Brit. 

Allein, Joseph, a nonconformist divine, was born at Devizes, in Wiltsire, in 1633. Having manifested at a very early age an eminently pious disposition and an inclination for the ministry, he was educated with this view and sent to Oxford at the age of 16 years. At college he was distinguished by diligence in his studies and gravity in his deportment. In 1653 he became a tutor in the college of Corpus Christi, to which he belonged, and where, for the exercise of his gifts in prayer, he had performed the office of chaplain, which he preferred to a fellowship; and in this situation he was so affable and so successful, that many of his pupils occupied respectable stations both in the established church and among the nonconformists. In 1655 he left college, and was assistant minister at Taunton Magdalen, in Somersetshire, until the year 1662, when he was deprived for nonconformity. During this connection he was indefatigable in his ministerial services, and his conduct was so amiable and exemplary, as to secure the affectionate esteem and attachment of his parishioners. After his exclusion from the church, he persevered in his labours, and preached commonly six or seven, and sometimes 14 or 15 times a week; till in 1663 he was committed to Tivedenker jail, where seven ministers and 50 quakers were closely confined and enduring similar hardships. At the ill-fame Allein was convicted of having preached in the preceding May, and sentenced to pay 100 marks, and to remain in prison till the fine was paid. "I am glad," said he on receiving his sentence, "that it has appeared before my country, whatever I am charged with. I have been guilty of nothing but doing my duty; and that all which appeared from the evidence was, that I sung a psalm, and instructed my family, others being there, and both in my own house." By an imprisonment of 12 months, Allein's constitution was impaired and the duration of his life shortened. After his release he renewed his labours, and his sufferings were also renewed; his health gradually declined; and in 1668 he finished his course, at the age of 35 years. His biographers, Anthony Wood excepted, bear testimony to his learning and charity. Zealous in his own mode of worshipping God, he was not, as ministers of the established church have testified, in the least bitter towards any Christians who worshipped in another manner. He preferred a great respect for the church, notwithstanding all his sufferings, and was eminently loyal to his prince, notwithstanding the severities of the times. His writings breathe a true spirit of piety, for which they have been always and deferred esteemed. His works are, "An Explanation of the Assembly's Shorter Catechism," 1658, 8vo.; "A Call to Archippus," exhorting the ejected ministers to continue in their ministry, 1663, 4to.; "An Alarm to the Unconverted," 1672, 8vo. and 12mo. of which 20,000 were sold, and after it was printed in 1675 under the title of "A Sure Guide to Heaven," 50,000; "Christian Letters, full of Spiritual Instruction," 1672, 8vo.; "Cales of Confidence," 1672, 8vo.; "Remarks, &c." 1672, 2vo. and several other small practical pieces; besides an imperfect body of natural theology in Latin, which has not been printed. An account of his life and death is often annexed to his writings. Calamy's Baxter, vol. ii. p. 577, &c. Neal's Hist. of the Puritans, vol. ii. p. 670, 4to. Biog. Brit. 

Alien, John, in Antiquity, a kind of tax, or tribute, which the rich paid to the poor, when absent in the armies. 

Allegophagi, from αληγόφαγος, one another, and ἄγω, to eat, in Natural History, a term used by Mouffet, and other writers on insects, to express a peculiar genus of flies, which feed on one another. They are thus called in distinction from another class, called the biteropophagi, from their feeding on different substances, not on one another. 

Alleluia. See Salleluia. 

Alemaengel, in Geography, a small Moravian settlement on Swetara river, in Pennsylvania. 

Allemand, a river of America, which falls into the Mississippi from the south-east, about 43 miles south of the Natchez. 

Allemanda, in Map, an ancient movement in common time, moderately quick; supposed, from its title, to be of German invention. In almost every election or onata for the harpichord in Handel's time, there was a prelude, an allemand, a farandab, a courant, and a jig, which see. Rouffeau says, the allemand is a dance very common in Switzerland and Germany, as it became in England a few years ago. But the allemand for dancing is very different from those in the works of Corelli, Handel and Mattheson. 

Alleman, in
ALLEMMANNIC, in a general sense, something relating to the ancient Germans. The word is also written Allmanic, Allemanic, and Almaneic. It is formed from Allmann, Alman, or Almen; the name whereby the German nation was anciently known. See Allemannic.

In this sense we meet with Allemannic history, Allemannic language, Allemannic laws, &c. Goldaftus, and others, have published collections of writers on Allemannic affairs. *Allmannicarum rerum scriptores.*

Allemannic language was spoken throughout the southern parts of Germany. It is divided into several dialects; the principal of which are the Suevic, and Helvetic. The Allemannic differed from the Frisian, which was the language in use through the northern parts of Germany; the chief dialects of this are the Palatine, Franconian, and Saxon.

Allemannic laws, i.e. Allemannisc, is the same with what is otherwise called the Suevic law, being that which obtained in the more southern parts of the country, as the Saxon law did throughout the northern.

Scheffler has published the provincial Allemannic law, and also the code of the feudal Allemannic law.

**Allen, John**, in Biography, archbishop of Dublin, in the reign of Henry VIII., was educated at Oxford, and took his degree of bachelor of laws at Cambridge. Having been sent to the pope by Warham, archbishop of Canterbury, on some ecclesiastical affairs, he continued at Rome nine years; and after his return, was chaplain to cardinal Woffley, and commissary or judge of his court as legate in Ireland in the execution of which office he was suspected of dishonesty and even of perjury. In return for his services, the cardinal procured for him the living of Dalby, in Leicestershire. In 1525 he was incorporated at Oxford, doctor of laws, which degree he had taken either at Rome or some Italian university; and in 1528 he was consecrated archbishop of Dublin, and made chancellor of Ireland. He was cruelly murdered by command of the eldest son of the earl of Kildare, in a time of rebellion, A.D. 1534, in the 58th year of his age. His works are, "Epitola de Pallii significationes activa et passiva," and "De confunditibus ac statutis in tuto risi causis observandis," and several other pieces relating to the church. Biog. Brit.

**Allen, or Allen, Thomas,** an eminent mathematician, was born at Uttoxeter, in Staffordshire, in 1542, and admitted scholar of Trinity college, in Oxford, in 1551, fellow in 1565, and in 1567, master of arts. Averse from taking orders, and inclined to retirement, he withdrew from college and took up his residence in 1570 at Gloucester-hall, where he sedulously purfued his studies and became an eminent antiquary, mathematician and philosopher. His talents and learning attracted the notice of several persons of distinction; he was offered a bishopric by Robert, earl of Leicester, and strongly solicited by Albertus L'Aisle, count or prince of Sisrde, in Poland, to reside with him in his own country; but he declined every proposal of this kind, and preferred the pleasure of retirement and study to secular advantages that were likely to accrue to him from the patronage of the great. He associated, however, with persons most distinguished for literature and science at the period in which he lived, to whom he had access in the house of Henry, earl of Northumberland, the great friend and patron of the mathematicians. By the ignorant and vulgar he was regarded, on account of his great skill in the mathematics, as a magician and conjurer. Mr. Selden informs us, "that he was a person of the most extensive learning and comummate judgment, the brightest ornament of the university of Oxford;" and Camden extols him as "highly accomplished in an extensive acquaintance with the most valuable arts and sciences." He was curious and diligent in collecting MSS. relating to various branches of learning. These collections have been cited by several authors; but they are now dispersed and lost. His works are, "The second and third books of Ptolemy, concerning the judgment of the stars, with a commentary," published in Latin; notes on many of Lilly's books, and on Bale's book "De Scriptoris Mai. Britanniae." It is justly to be regretted, that the world has derived so little advantage from the erudition and literary labours of a person, who in his funeral eulogy by Burton, was denominated "not only the Coryphaeus, but the very soul and fun of all the mathematicians of his time. He died Sept. 3th, 1632. Wood's Athen. Oxon. vol. i. Biog. Brit.

**Allen, Thomas,** a learned divine, was born in 1573, educated in the king's school at Worcescr, and removed to Oxford in 1589, where he made a great progress in philosophy, and became a noted disputant. He took orders, but applied to the abstruse and critical parts of learning more than to preaching. He wrote in Latin "Observations on St. Chryfoftom's book upon I fabulous," published in Sir H. Savile's edition of Chryfoftom's work; and affiliated him in his annotations on this father's homilies on the Evangelists. Savile represents him as "a very learned man, and no less skilled in the Greek learning than in divinity." He died in 1646, and was buried in the chapel of Eton-college, of which he was a fellow. Biog. Brit.

**Allen, Benjamin,** M. D. published in the year 1700, at London, "The natural history of the chalybeat and purging waters in England," 8vo. This was republished in the year 1711. He gives the analysis of the several waters, which he classifies under the heads of chalybeat, saline, fulphurous, or mixed, and attributes their virtues to a subtle gas or spirit with which they suppostes they are imbued. There are no memorials extant of the life of this writer.

**Allen, John,** M. D. F. R. S. published in the year 1719, "Synopsis universi Medicina Practica," 8vo. The work is dedicated to the president and fellows of the Royal College of Physicians, London; and comprises brief descriptions, and accounts of all the diseases incident to the human body, with the most approved modes of treating them; taken, as the author every where acknowledges, from the most eminent writers, ancient and modern. Of this work the author speaks very modestly, and particularly admonishes the reader not to content himself with the abstracts he has given, "fed potius addentes ipso ubicunque consultat: nam in 'transferendis,'" he adds, "eorum lamentationibus, veritate et dilectis," et, "frequentier errasse, ut Allen semper obtusiusse, ut imperitus," "fece tradidisse. Dulcius ex ipso fonte bibitur aqua." The work was, however, received with such avidity, not only in England but in all parts of Europe, that in the space of a very few years, it passed through numerous editions, to which, from time to time, the author made such additions, as increased it to nearly double its original bulk. In the year 1734 he gave an English translation, which was published in two volumes, 8vo.: it had been before translated into French. The author appears to have practiced medicine in London, but no particulars of his life have been published.

**Allen, Flopert Van,** an engraver, who flourished in 1686. He drew the town of Vienna, in 1686, and engraved the town of Prague, a large, flight print, with many figures. Strutt.

**Allen, Francis,** an obscure engraver of Lubeck, who flourished in 1652.
Allen, in Geography, a small river of Flintshire, in North Wales, which sinks under ground near Mold, and is lost for a short interval.

Allenbach, or Ellenbach, in Geography, a prefecture of the principality of Hersfeld, in Germany, lying between the rivers Nahe and Glans.

Allenburg, a small town of Prussia, in the government of Tapien, well situated on the river Albe, eight leagues east-south-east of Konigstberg.

Allendorf, a bailiwick of Lower Hesse, in Germany, situate amidst high and rocky mountains, of which those of Geburg and Holbeberg, on the frontiers of Etchfield, are the most remarkable, and producing some wine. The town of Allendorff is situated on the river Werra, or Witer, about fifteen miles east of Caflid, N. lat. 51° 18'. E. long. 9° 44'. This town was destroyed by fire in 1637. Near it are the great salt-works in the Solod, which are more ancient than the town itself, as they are mentioned in an instrument of the emperor Otho II. bearing date in 973.

Allendorf is also a prefecture of Upper Hesse. The town, surnamed An der Lunde, was erected in 1370. It is six miles north-east of Gießen, and eight south of Marburg.

Allenstown, a town of America, in New Jersey, in Monmouth county, 15 miles north-east of Burlington, and 12 south by east from Princeton.

Allenstown is also a township in Rockingham county, New Hampshire, containing 354 inhabitants, situate on the east side of Merrimack river, 25 miles north-west of Exeter, and 40 from Portsmouth.

Allen-town, in Pennsylvania, Northampton county, on the point of land formed by Jordan's creek, and the little Lehigh, contains about 90 houses and an academy.

Alletrop, a town of Germany, in the circle of the Lower Rhine and duchy of Weilphalia, situate on the river Sorbeck, three leagues south of Avenberg.

Aller, a river of Germany, rises in the duchy of Magdeburg, passes by Luneburg, Gifhorn, Zell, &c. and joins the Wefer, a little below Verden.

Aller good, in our Ancient Writers. The word aller serves to make the expression of superlative signification. So aller good, is the greatest good. Sometimes it is written alder.

Alleria. See Aleria.

Alleron, or Aleron, in Heraldry, a sort of eaglet, represented without either beak or feet.

The name is French; and is said to have been introduced for the word eaglet: it is added, that the practice of calling eaglets, allertons, and of representing them spread, without feet and beaks, is not above a hundred years old, and is of French invention; introduced to represent the Imperialist as subdued. Hence, Menage derives the word from aquilario, a diminutive of aquila. In Latin they are called aquila nutica.

The alleron, represented Tab. Heraldry, fig. 1. appears much the same with the martlet, except that the wings of the latter are close, and it is represented, as it were, pillion; whereas the alleron is spread, and is represented in pale. Add, that among our heralds, the martlet has a beak, which the alleron wants.

Allersheim, in Geography, a town of Germany, in the circle of Swabia, and capital of a bailiwick, in the principality of Ortingen, five miles south of Ortingen.

Allersheim is also the name of a bailiwick, in the principality of Wolfenbuttel, containing four villages, and anciently called Eilleden.

Allersberg, a town of Germany, in the circle of Franconia, six leagues south of Nuremberg.

Allerstein, called in the Polish language Olstein, is a small town with a castle in the province of Posenland, situate on the river Alle, and built in 1367.

Allertsberg, a town of Germany, in the archduchy of Austria, seven miles north of Bavarian Wald-Auven.

Allesani, a town of Corfica, 13 miles east-northeast of Corte.

Allers]+=Richard, in Biography, an English episcopal divine, was born at Uppingham, near the Wreken, in Shropshire, in the year 1619, and after receiving part of his education at Coventry, under Philemon Holland, the translator, was entered a commoner in Christ-church, Oxford, under the tuition of Richard Bubly, afterwards Dr. Bubly, the famous master of Westminster school. From a course of study and improvement, in which after he had taken the degree of bachelor of arts, he was chosen moderator in philosophy, the distraction of the times suddenly called him forth to military service. In this new occupation, he and the other Oxford scholars, manifested their loyalty; but having been protected and supported by Sir John Biron, with a party of horse, Allestry and his associates returned to their studies. It was not long before their safety was again endangered by a republican party, who entered Oxford for the purpose of plundering the colleges. Allestry contrived secretly to remove the booty which they had collected; and as soon as it was known that he was the cause of their disappointment, they seized him, and would probably have treated him with severity, if they had not been suddenly called away by the earl of Essex. On a sublequent occasion he was taken prisoner by a party of horse, but when the parliament garrison at Broughton-houfe, whither he was conveyed, surrendered to the king's forces, he was released. Allestry returning his studies, took his degree of master of arts. As soon, however, as he recovered from a disorder which threatened his life, and which had prevailed in the garrison at Oxford, he entered again into the king's service, and encountered the fatigues and hazards of a military life, in the humble station of a common soldier. In this service, blending the watchings of a soldier with the labours of a scholar, he continued till the end of the war; and when the republican party became triumphant, he retired to his college. Here he was employed in the office of censor, and as private tutor to several students; and though he had no prospect of ecclesiastical preferment, he entered into holy orders. Still zealously attached to the royal party, he signed the decree passed in the university of Oxford, against the solemn league and covenant. In consequence of this act, he and other members of the university, with whom he concurred, were proscribed and banished from Oxford by the parliamentary visitors. To him, however, a short epistle was granted for settling his affairs, "because," as one of their number asserted, "he was an eminent man." During the depredation of the royalists he found an asylum, first in the house of Francis Newport, Esq. in Shropshire, where he officiated as chaplain, and afterwards in that of Sir Anthony Cope, in Oxfordshire. His talents and fidelity rendered him an useful and active instrument in preparing the way for the restoration of Charles II. In one of his expeditions for this purpose he was seized at Dover by a party of soldiers, and committed to the jail of the king's friends at Lambeth house. Upon his release from confinement, he proposed to visit his friend Dr. Hammond, at Weftwood, near Worcester; but when he approached his house, he met
his funeral procession. Of his esteem, however, he received a valuable testimony in the legacy of his library, which was bequeathed to him for this reason; because the teller 4 well knew that the books in his hands would be useful weapons for the defence of the cause which he led during life to vigorously supported.

Soon after the Restoration, Allely returned to Oxford, and took the degree of doctor in divinity. In recompence of his past services he was soon made a canon of Christ church, one of the king's chaplains in ordinary, and regius-professor of divinity. In 1665 the king conferred upon Dr. Allely the provostship of Eton college, which he held till his death. To this college he was a munificent benefactor, by retributing his own dues in order to pay off its debts, and by erecting at his own expense the west side of the outward court of the college; nor was he less liberal in other respects, as he settled penions on indigent persons and families, and distributed his income in occasional charities. At the instance of Dr. Allely, and in compliance with the petition of the provost and fellows of King's college, Cambridge, the king placed a grammar school under the head of St. John's, which was formerly the fellowships of Eton were generally disposed of to pensions of foreign education, for the future five of the seven fellows should be such as had been educated at Eton school, and were fellows of King's college. In 1679, Dr. Allely, finding his health, and particularly his sight, much impaired, resigned his professorship of divinity; and in 1681 a dropy terminated his life, and he was buried in Eton chapel, under a monument of white marble, on which is inscribed a Latin epitaph, distinguish'd by its tercentenary and elegance. A biographer in an account of his life prefixed to his sermons represents Dr. Allely as a man of uncommon talents and singular merit. " Memory, fancy, judgment, eloquence, great modesty, and no less affluence; a comprehension of things, and a fluency of words; an aptness for the pleasant, and sufficiency for the rugged parts of knowledge; a courage to encounter, and an industry to make all matters, make up the character of his happy genius. There was not in the whole a man holier and more humble; no temptation could bribe him to do a base thing, or terror affright him from the doing a good one. This made his friendships as lasting and inviolable as his life, without the dirty considerations of profit, or fly reserves of craft; not the pagentry of ceremonious address, or cold civility, much less the sordid self-seeking of obsequious flattery." Whatever may be thought of his political principles, no doubt can be entertained of his sanctity; and of the benevolence of his disposition, his numerous acts of liberality afford sufficient evidence. Of his literary talents poecility can only judge by a volume of 40 sermons, printed in folio at Oxford, in 1654; and excepting one singular instance of credulity which they furnish, they do no discredit to the memory of the author. His lectures, which gave satisfaction to those who heard them, he would never be prevailed upon to publish. His valuable library be left to his college. Biog. Brit.

Alley, Jacob, a poet of the 17th century, was the son of a bookseller, in London, and entered Chirch church, in Oxford, in 1671, at the age of 18 years. He took the degrees of bachelor of arts and of arts, and was master in 1679, and tenant in 1682, both which offices he executed with great applause, as he was esteemed a good philologist and poet. He died in 1686, in consequence, as it is said, of the vices of his youth, and was buried in the church of St. Thomas, at Oxford. The pieces of poetry, written by him, were printed in a book, entitled, "Examen Poeticum." Biog. Brit.

Alleu, or Alode, in Antiquity. See Allodium.

Alleward, in Geography, a town of France, in the department of Here, and district of Grenoble, six leagues north-west of Grenoble.

Allervare, the smallest copper coin that is struck in Sweden, it is not worth quite two deniers Tournois of France, or about 4d of English money.

Allievare, in Old Records, to levy or pay an ac- culuted fine or composition.

Allievation, denotes the art of making a thing lighter, and easier to bear or endure.

The word is originally Latin, compounded of ad, to; and levare, to lift.

In which sense, alleviation is synonymous with lightening, and hands opposed to aggravation.

Allew, in Geography, a town of France, in the department of the Drome, and district of Crest, on the north side of the Drome, 10 miles south of Valence.

Alley, William, in Biography, bishop of Exeter, in the reign of Queen Elizabeth, was born at Great Wycomb, in Buckinghamshire, educated at Exon School, and removed to King's college, in Cambridge, in 1529. Here he took the degree of bachelor of arts, and afterwards pursued his studies at Oxford. He was a zealous reformer; and upon Queen Mary's accession he quitted his benefice, and travelled in the northern parts of England, where he was not known, gaining a decent subsistence by the practice of physic and the instruction of youth. When Queen Elizabeth ascended the throne, he came to London, and acquired such reputation in preaching the divinity lecture at St. Paul's, that he was consecrated to the see of Exeter in 1560; and in 1561 he was created doctor of divinity at Oxford. He died in 1570, as some say, according to others in 1571, and, as Fuller says, in 1576, and was buried at Exeter, in the middle of the choir. Over his tomb is a Latin inscription, representing him as "A zealous advocate for the truths of the Gospel, eminent for his virtues, and remarkably skilled in all the useful parts of learning." He wrote "The Poor Man's Library," a miscellany, in two volumes, containing lectures upon the Epistle of St. Peter, and "An Hebrew Grammar." When the version of the Bible was undertaken by command of Queen Elizabeth, this bishop translated the Pentateuch. "His Judgment concerning the Doctrine and Discipline of the Church," has been published by Strype in his Annals of Queen Elizabeth. Biog. Brit.

Alley, derived from alle, to go, in Gardening, signifies a narrow or confined path between beds, borders, or other compartments of a garden, and is chiefly formed for the convenience of going between them, in order to perform the necessary business, such as hoeing and weeding the plants, and also to cut, pick, and collect the plants or fruits. Alleys are made of different breadths, according to the sizes of the beds or compartments; but in general a breadth from one to two feet is sufficient. In extensive kitchen-gardens, where borders are carried round next the walks, and immediately adjoining the main quarters of the ground, they should be divided from them by two-feet alleys, for the convenience of carrying in dung, water, &c. and the large compartments should likewise be divided by one or two cross alleys, with the same intention. Alleys between asparagus beds should constantly be two feet wide; those between strawberries, a foot and a half; but between beds of aromatic herbs, fifteen inches may be fully sufficient; and between beds of onions, leeks, carrots, parsnips, lettuce, endive, and all other small crops, the width of ten or twelve inches is as much as is requisite in general; and the same distance between beds of feeding and prick-ed cabbage, savoys, celerly, &c. for the convenience of going in to weed, water, and draw the young plants for transplantation, will be the most convenient. Alleys are frequently intended both for
ufe and ornament in flower-gardens; therefore, between beds of tulips, hyacinths, ramnicales, anemones, and other similar garden-flowers that are bedded, they should in general be eighteen inches or two feet wide; and in order to have them ornamental, the beds should be edged with box, and the alleys filled with the bolt colored fine gravel; or where that cannot be readily procured, with sand, shells, or other porous substanccs. See Gravel Walks.

Alley, in Drill Husbandry, implies the vacant space between the outermost row of corn on one bed, and the nearest row to it on the next parallel bed. In the practice of drilling it was at first suppos'd that narrow alleys would not answer the end for which they were intended; while, on the other hand, the making them very wide would be a loss of ground; about four feet, exclusive of the spaces or partitions, between the rows of corn in the beds, was therefore considered as the most suitable and convenient distance. But as it is obvious, that it is not necessary to make the alleys so wide in good soils as in those of inferior quality, and that some sorts of crops require much larger spaces than others; the intelligent husbandman should always decide what breadth is the most proper in different cafes, and for different purposes; one circumstance must, however, be duly attended to, which is, that wide alleys are more easily and much better thr'd between than those that are narrower; for, when an alley is wide, the large furrow in the middle of it may be cut deep, there being then sufficient room to turn the earth over towards the rows, while, on the contrary, the earth where alleys are narrow cannot be thr'd deep enough, nor can room be found for what is turned over out of the furrows, without danger of burying some part of the rows of corn or other crops that may be cultivated. In hoing these spaces the whole of them is not to be thr'd, either with the plough or cultivator, when the crop appears; neither of these instruments should go too near the rows of corn or other crop, for fear of rooting up the rows of corn or young plants; but a dip of earth, about six inches wide, is directed to be left untouched on the outside of each bed, by which means the part of the alley that is to be thr'd will be reduced to the breadth of three feet; and even that space is lessened in the first ploughing before winter by a deep furrow, which is then cut close to, and all along those fire-inch slips, and the earth taken out of each furrow is thrown into the great furrow in the middle of the alley, which it fills and arches up. These two side-furrows make together a breadth of about eighteen inches, and consequently leave, in the middle of the alley, a space of about eighteen inches more, on which is heaped up the earth thrown out of the two furrows; and thus the alleys are to remain during winter. By the first hoing in the spring, the earth heaped up in the middle of the alleys is to be turned back towards the rows of corn. The two furrows that were opened before winter are then filled up, and a new one is cut in the middle of the alley. This business may be very easily performed with the common plough; two turns of that instrument being frequently sufficient for the purpose, one on each side of the alley, as near as possible to the beds. But when these two turns are not sufficient to form the furrows perfectly, or where too much earth remains between it and the bed, a third turn becomes necessary, and sometimes a fourth, in order to hollow the middle furrow as it ought to be. —

When this work is performed with the cultivator with two mould-boards, the instrument must be placed in the middle of the alley, and the horces in one of the two furrows; the share readily entering a great depth into the earth, which was laid there by the left hoing before winter, the horces advancing, the ridge of the earth is divided into two parts, and fills up the furrows that were made before winter, on each side of the alley, close to the beds. Thus, the high furrow in the middle of the alley may be opened, and the whole operation performed by a single turn of the cultivator; by which so much time and labour is saved, that the farmer may afford one or two firings more in the summer, which will be of great utility in many cafes. See Cultivator, Horse-hoing, and Drill-husbandry.

Alley, in Perspective, is that which is larger at the entrance than at the exit; to give it the greater appearance of length. ALLEYN, Edward, in Biography, a celebrated comedian, was born in London in 1565, and trained at an early period to the stage, for which he was naturally qualified by a lately port and aspect, corporal agility, flexible gait, lively temper, retentive memory, and fluent eloquence. Before the year 1592 he seems to have acquired a very considerable degree of popularity in his profession; he was one of the original actors in the plays of Shakspeare, and a principal performer in some of those of Jonson; but it does not now appear what were the characters which he impersonated. They were probably the most dignified and majestic, for to thefe the portly and graceful figure of his person was well adapted. At length he became master of a company of players, and the proprietor of a play-houfe, called the Fortune, which he erected, at his own expense, near White-cross-street; and he was also joint proprietor and master of the Royal Bear-Garden, on the Bank-side, in Southwark. By the profits accruing from these occupations, added to his paternal inheritance, and to the dowries of his two wives, by whom he had no children, he amass'd a considerable property, which he bestowed in a manner that has rebounded more to his honour than his professional merit. The wealth thus acquired enabled him to lay the foundation of a college, for the maintenance of aged people, and the education of children, at Dulwich, in Surry, which institution, called, "The College of God's Gift," subsisted at this time in an improved and prosperous state. The liberal founder, before he was 48 years of age, began this building after the design, and under the direction, of Inigo Jones: and it is presumed that he expended eight or ten thousand pounds upon the college, chapel, &c. before the buildings and gardens were finished, which was about the year 1617. It is hardly necessary to mention a fabulous tradition concerning the origin of this college, recorded by Mr. Aubrey. The idle tradition, which deferves no credit, and needs no confutation, reports, that Mr. Alleyn, "playing a daemon, with six others, in one of Shakspeare's plays, was in the middle of the play surprized by the apparition of the devil, which so worked on his fancy, that he made a vow, which he performed at this place." After the founder had built this college, he met with difficulties in obtaining a charter for settling his lands in mortmain, that he might endow it, as he proposed, with 80l. per annum, for the support and maintenance of one master, one warden, and four fellows, three of whom were to be ecclesiastics, and the other a skilful organist; also five poor men, as many women, and twelve poor boys, who were to be maintained and educated till the age of 14 or 16 years, and then put out to honest trades and callings. The master and warden were to be unmarried, and always to be of the name of Allen or Alleyn. At length the opposition of the Lord Chancellor Bacon was overcome, and Alleyn's benefaction obtained the royal licence, and he had full power granted him to establish his foundation, by his Majesty's letters patent, under the great seal, bearing date June 21, 1619. When the college was finished, the founder and his wife retired in it, and conformed in every respect to the regulations established for the government of his almshouses. Having, by his will, liberally provided for his widow, and for founding 20 alms-houses, 10 in the parish of St. Botolph, with-
All Good, in Botany. See Chenopodium.

All-Heal. See Heracleum and Stachys.

All, or Semirus, in Ancient Geography, a river of Bruttium, in Italy.

Allia, a small river of Italy, in the territory of the Sabines, to which Virgil (lib. vii. v. 717.) annexes the epithet of "infans nomen," in allusion to the defeat of the Roman army by the Gauls on the banks of this river, when, in the year of Rome 363, 45,000 Romans were either killed or put to flight. Hence, "Alliens dies," is in their almanacks marked as an unlucky day, i.e. the 15th of July, which was the anniversary of this battle. Livy (lib. vi. c. 37. tom. ii. p. 165.) represents this river as running down a very steep channel from the mountains of Cumaeum, at the 11th mile-stone, and mixing with the Tiber. Our ancestors, says Cicero (ad Attic. lib. ix. 5. tom. viii. p. 355.) deemed the day of the battle of Allia, more fatal than that of the capture of the city.

Alliance, in the Civil and Canon Laws, the union or connection of two persons, or two families, by means of marriage; otherwise called affinity.

The word seems formed of the Latin adligatio, q. d. a tying together.

The law of the Twelve Tables forbids all alliance between persons of unequal rank and condition. And in Portugal, we are told, the daughters of the nobility are prohibited to ally with such as have never been in the wars.

Alliances are also extended to the leagues or treaties concluded between sovereign princes and states, for their mutual safety and defence; in which sense they are the same with what we elsewhere call confederacy, league, &c. Alliances make a species of treaties, which are usually divided into treaties of peace, of commerce, and of alliance, properly so called. These are sometimes particularly denominated foreign alliances.

Alliances are variously distinguished, according to their object, the parties in them, &c. Hence we read of equal, unequal, triple, quadruple, grand, offensive, defensive, &c. alliances. Unequal alliances, i.e. an inferior to one of the contracting powers promises patronage or protection, and the other fidelity and observance; by which they stand contradistinguished from alliances, wherein the several powers treat on a par. Offensive alliance is, that whereby the parties oblige themselves jointly to attack some other power. This stands contradistinguished from defensive alliances.

Alliances, offensive and defensive, are those in which the contracting parties agree to regard as a common enemy any power that attacks either of them, as well as mutually to defend each other. Such was that between the Emperor and the States-General against France, concluded at Vienna the 12th of May, 1689, and which was the commencement of that which was called the general or grand alliance. To this treaty Spain was to be invited by the emperor, and

England by the States, and it was stipulated that all the allies of either party were to be admitted, if they thought proper to accede. The triple alliance between England, Holland, and Sweden, in 1668, concluded by the negociation of De Wit and Temple, was an event of importance in the history of Europe. England thus recovered her influence and credit in Europe. Temple was appointed for it. The French monarch and the court of Spain were greatly displeased; but they were obliged to acquiesce, as the whole of Europe seemed to repose with security under the wings of that powerful confederacy, which had been so happily formed for her protection. Another alliance of this kind was formed in 1701 between the kings of Great Britain and Denmark, and the States-General; and another between the Emperor, England, and Holland was concluded in the same year. A triple alliance was formed in 1716 between Great Britain, France, and the States-General. The intrigues of Cardinal Alberoni, prime-minister to Philip V. of Spain, produced various negociations in 1718, from which at length sprung the treaty, called at first the triple alliance between Great Britain, France, and Holland; and, after the accession of the emperor, filled the quadruple alliance. The object of this alliance was to settle all disputed pretensions between Spain, Germany, and some of the Italian princes. The king of Sicily was admitted into this treaty; and at length the king of Spain himself was forced to accede to it; and Alberoni was banished by Philip V. But as some points were still controverted between the emperor and king of Spain, these were referred to be amicably determined in the congress opened at Cambrai in 1721, under the mediation of his Britannic Majesty and the most Christian king. Puffendorf, Grotius, and other writers upon the laws of nature and nations, have distinguished alliances into personal and real. The former are those which are made with a king considered personally, so that they terminate with his life, and real are such as exist between states and nations, and which subsist and retain their obligation after the death of the king or ruling magistrates. It has been argued by others, that the admission of personal alliances is inconsistent with the foundation of political society, and that they tend to separate the sovereign from his subjects.

Through the title of allies, focti, of the Romans, was a sort of favouritism, it was much coveted. Ariarathes, we are told by Polybius, offered a sacrifice to the gods by way of thanksgiving for having obtained this alliance. The reason was, that thenceforth peoples were sure not to receive any injuries except from them. Cesar informs us that a great number of kings had this honour. There were divers forts of allies: some only united to them, by a participation of the privileges of the Romans, as the Latini and Hernici; others by their very foundation, as the colonies; others by the benefactions they received from them as Maffinifi, Eumenes, and Attalus, who owed their kingdoms to Rome; others by free treaties, which lib., by a long alliance, became subjects, as the kings of Bithynia, Cappadocia, Egypt, and most of the cities of Greece; lastly, others by compellative treaties, and the law of infraction, as Philip and Antiochus. For they never granted peace to an enemy, without making an alliance with him; that is, they never subdued any people without using it as a means of subduing others.

The allies of Italy, Socii latini, were distinguished from other foreign allies. Of these there were two kinds: those distinguished by the name of prefectures, who were governed by Roman magistrates and laws, and those who retained the privilege of being governed by their own ancient laws, and were denominated autonomi. The Latin allies, Socii latini, were those who enjoyed the jus Latii, and who held the rank

4 X 2
rank in the order of allies; of these there were three distinctive, viz. those who inhabited Latium, the Latin colonies, and those on whom were conferred the privileges of the Latin colonies, on account of some service which had been rendered by them to the Roman state, or by the peculiar favour of the Roman people and the emperors. There was a great difference between the allies and the auxiliaries, when they were admitted into the armies of the Roman empire. The allied troops were always taken from the allies of Italy, which had never been reduced into Roman provinces. The auxiliaries were furnished by the foreign allies. The allied troops maintained themselves at their own charge, and were supplied only with corn by the Romans; the latter were kept in pay by them. When the allies joined the Roman army, the consuls chose 12 out of their number to command them, under the name of prefects. They were of the same number, and possessed similar powers with the tribunes of legions. The places which they occupied in the army and camp were assigned to them by particular regulations. The allies of the provinces, *foedri provinciales*, held the first rank among the foreign allies. The honour of this appellation was conferred on provinces, which submitted to the dominion of the Romans, and were governed by their own magistrates, according to the customs and laws of Rome, and paid an annual tribute to the senate. The *foedri immunes* were those who had never been enemies to the Romans, and who were exempt from every kind of imposition. Such were Ptolemy, king of Egypt, and the Jews, who were the first of the eastern nations which solicited the friendship of Rome. Others, after having been enemies of the Romans, laid down their arms and contracted alliances with them.

The forms or ceremonies of alliances have been various in different ages and countries. The Romans conferred it on sovereigns by a deputation of senators, who accompanied it with a sceptre of ivory, the toga picta, and the titles of ally and friend of the Roman people. Among us, signing and swearing, sometimes at the altar, are the chief; anciently eating and drinking together, chiefly offering sacrifices together, were the customary rites of ratifying an alliance. Among the Jews and Chaldeans, heifers or calves; among the Greeks, bulls or goats; and among the Romans, hogs were sacrificed on this occasion. Among the ancient Arabs, alliances were confirmed by drawing blood out of the palms of the hands of the two contracting princes with a sharp stone, dipping herein a piece of their garments, and thereon, accompanied by seven flocks, at the same time invoking the gods Wosit and Allat, i.e., according to Herodotus, Baebus and Urania. Among the people of Calchis, the confirmation of alliances is said to be effected by one of the princes offering his wife's breast to the other to suck, which he was obliged to do till blood flowed.

It has been disputed, whether the states of the empire have a right of making alliances without the emperor's participation; and whether the king of England be vested with absolute power of making alliances at discretion, without consent of parliament. Dr. Davenant affects the negative. According to him, the contrary opinion owes its rise to the mere flattery of modern courtiers, having no foundation in the ancient laws and constitution of the kingdom. King John and Richard II. were, according to this author, the first that attempted any thing like it. It is certain there occur numerous instances in history, where the king has asked, or the parliament have offered, their advice, concerning the alliances to be made; but there are many others, at least of later times, wherein no footsteps of any such consultation appear. There are instances likewise where the parliament have declined giving any advice concerning such arduous matters.

Alliance, in a figurative sense, is applied to any kind of union or connexion; and in this sense the late Bishop Warburton has used the term in his treatise, entitled, "The Alliance between Church and State," published in 1736. Some persons, however, who are advocates for a religious establishment, have objected to this use of the term; alleging, that alliance implies a contract formed by two or more independent powers; whereas the established church, being a part of the state, or one of its members, cannot properly be represented as entering into alliance with it. "The notion," says Lord Belingbroke (Works, vol. iv. p. 515.) "of a formal alliance between the church and the state, as between two independent distinct powers, is a very groundless and whimsical notion." He informs us, that Dr. Senior, preaching before King Charles II. at Newmarket from Exod. iv. 14, 15, 16, established on these texts a supposed alliance between the church and the state, or rather between the church and the king. "Warburton," he says, "took his hint possibly from it;" but of this we have no evidence besides his lordship's assertion. Others have objected to the sentiment implied in the expression. "Every other idea" of a church establishment, besides that of a scheme of instruction, and "every other end" that has been blended with that of the preservation and communication of religious knowledge, "as the making of the church an engine, or even an ally of the state; converting it into the means of strengthening or of diffusing influence; or regarding it as a support of regal in opposition to popular forms of government, have never only to degrade the institution, and to introduce into it numerous corruptions and abuses."

Luky's Principles of Moral and Political Philosophy, vol. ii. p. 305; ed. 5th. See RELIGIOUS ESTABLISHMENT.

Alliance Island, in Geography, an island in N. lat. 80° and E. long. 100°, discovered by a ship so called from Philadelphia in 1787.

Alliarria, in Botany, a species of Erysimum.

Allica, in Entomology, a species of Papilioymphalis, with wings dentated and of a dark yellow colour; with numerous black points intermixed with white; found of a small size, in Siam.

Allieni Forum, in Ancient Geography, a city of Italy, now generally thought to be Ferrara.

Allier, in Geography, a river of France, which gives name to one of the departments. It rises near Chateau Neuf de Randon, in the department of Lozere, and joins the Loire three miles west of Nevers.

Allier, Department of, is formed of the ancient province, Bourbonnais. It is bounded on the north, by the departments of Sone and Loire, Nièvre and Cher; on the east, by the Sone and Loire; and the Loire; on the south, by the Loire, Puy de Dome, and Creuse; and on the west, by the Creuse and Cher. Its superficial is about 1454,341 square acres, or 742,272 hectares; its population about 266,105 individuals; it is divided into four communal districts; and its chief town is Moulins.

Alligati, in Antiquity, the bailiwick and worth kinds of slaves, whom they kept locked up, or with fetters on.

The Romans had three degrees, or orders, of slaves or servants; the first employed in the management of their estates, the second in menial or lower functions of the family, the third called alligati, above mentioned.

Alligation, in Arithmetic, a rule or operation by which quantities are resolved, relating to the mixture of diverse commodities or ingredients together, with the value, effect, &c. thereof in composition.

The word is formed of alligare, to tie together, by reason, perhaps, of a sort of vincula, or circular ligatures, ordinarily used to connect the several numbers together.
Alligation is of two kinds, medi@l and alternate; to which some add a third, called partial.

Alligation medialis teaches how to find the mean rate of a mixture, when the particular quantities that are mixed or compounded, and their respective mean rates, are given.

The several cases will come under the following rules.

I. The quantity of the ingredients, and the prices of each being given; to find the price or value of some part of the mixture.

Rule. As the sum of the quantities given,
Is to the sum of the products of each ingredient
by its price,
So is any quantity of the mixture,
To its value.

Example 1. A reiner, or goldsmith, hath $\frac{3}{4}$ of gold at 4\$. per 3d., $\frac{5}{6}$ at 4\$. per 5d., $\frac{7}{9}$ at 4\$. per 5d., and $\frac{3}{2}$ at 4\$. per 5d.; what is the ounce worth of all these melted together?

\[
\frac{3}{2} \text{ of gold} \quad l. \quad s. \quad d. \\
12 \times \quad 4 \quad 0 \quad 0 \quad \text{the product is 48} \\
8 \quad \times \quad 4 \quad 5 \quad 0 \quad \text{44} \\
3 \quad \times \quad 4 \quad 8 \quad \text{13} \\
9 \quad \times \quad 13 \quad 4 \quad \text{114} \\
\frac{32}{32} \text{ total} \quad 137 \quad \text{sum.}
\]

Then as $\frac{32}{32}$ \(=\frac{32}{32}\) is to \(\frac{137}{32}\), or to \(\frac{41}{8}\) \(=\frac{41}{8}\). By the same rule the value of any other quantity of that composition is to be found as supposing \(\frac{32}{32}\).

For as $\frac{32}{32} = \frac{7}{20}$, \(\frac{7}{20}\).

Example 2. Suppose it were required to mix 6 gallons of wine at $\frac{3}{4}$ a gallon, 8 at $\frac{5}{4}$, and 4 at $\frac{7}{4}$; what would be the value of the mixture per gallon?

\[
\begin{align*}
6 \times \frac{3}{4} &= 4.5 \\
8 \times \frac{5}{4} &= 10 \\
4 \times \frac{7}{4} &= 7 \\
\text{Whole compound, 18} &\quad \text{11. sun of products}
\end{align*}
\]

Then \(18\) \(=\frac{18}{18}\) is the value sought.

II. The prices of the several ingredients, and the sum paid or received for the mixture being given; to find what quantity of each was bought or sold.

Divide the sum paid or received, by the sum of the particular prices; the quotient is the answer.

Example. The compound in the foregoing instance is required to be augmented to \(\frac{48}{32}\) \(=\frac{48}{32}\); that is, 16 is to be added to 32, how much of each ingredient must be taken?

\[
\begin{align*}
12 &\quad \{12 \quad : \quad 6 \quad 3 \\
8 &\quad \quad 8 \quad : \quad 4 \\
3 &\quad \quad 3 \quad : \quad 1 \quad \frac{1}{2} \\
9 &\quad \quad 9 \quad : \quad 4 \quad \frac{1}{2} \\
32 &\quad \text{sum.} \quad 16 \quad \text{sum.}
\end{align*}
\]

So that there must be \(\frac{32}{32}\) of gold at \(\frac{4}{0} =\frac{4}{0} \text{ per } \frac{3}{2}\).

\[
\begin{align*}
\frac{12}{32} &\quad 4 \quad 0 \quad 0 \\
\frac{4}{4} &\quad 4 \quad 5 \quad 0 \\
\frac{4}{4} &\quad 4 \quad 6 \quad 8 \\
\frac{3}{3} &\quad 4 \quad 13 \quad 4
\end{align*}
\]

Sum = \(\frac{48}{38}\) for proof of the operation.

IV. The nature, quality, &c. of the several ingredients of a mixture being given, to find the temperament or degree of fineness resulting from the whole. Place the several quantities of the mixture in rows; against which place orderly their several qualities or fineness; and multiply each quantity by its own quality or degree of fineness; then, as the sum of the quantities is to the products, so is unity to the quality or fineness of the mixture.

V. The quantities of a mixture being given; to find the particular quantities of any ingredient in any part of the mixture.

Rule. As the total of the composition,
Is to the quantity of any fimple in that composition,
So is the total quantity proposed, to be proportionally compounded,
To the quantity of each simple to be in that proposed quantity.

Example. How much of each ingredient (or price of gold mentioned in the first case) is in a pound, or \(\frac{32}{32}\) of the \(\frac{32}{32}\), being the compound given?

\[
\begin{align*}
&\quad \frac{12}{32} : 4 \frac{1}{2} \quad \text{at} \quad 4 \quad 0 \quad 0 \quad \text{per } \frac{3}{3}.
\end{align*}
\]

\[
\begin{align*}
&\quad 8 \quad : \quad 6 \quad 0 \quad \text{at} \quad 4 \quad 0 \quad 0
\end{align*}
\]

\[
\begin{align*}
&\quad 3 \quad : \quad 3 \frac{1}{2} \quad \text{at} \quad 4 \quad 13 \quad 4
\end{align*}
\]

\[
\begin{align*}
&\quad 9 \quad : \quad 4 \quad \text{proof.}
\end{align*}
\]

VI. Given the total of a mixture, with the whole value, and the values of the several ingredients; to find the several quantities mixed, though unequally.

This case admits of two varieties: first, where the mixture is of two simples; and, secondly, when it consists of more than two. For the first, the rule is—Multiply the total of the mixture by the least value, subtract the product from the total value, and the remainder is the first dividend; then take the said least value from the greatest valued ingredient, and the remainder is the first divisor. The quotient of this division shows the quantity of the highest-priced ingredient, and the other is the complement to the whole.

Thus, still referring to the first example, and assuming the two first terms of it:

Gold at \(\frac{4}{4}\) per \(\frac{3}{3}\).

Ditto at \(\frac{4}{4}\) per \(\frac{3}{3}\).

Total of the composition \(=\frac{20}{32}\). Total value \(=\frac{32}{32}\).

\[
\begin{align*}
&\quad \times \quad 4 \quad \text{per } \frac{3}{3} \\
\frac{32}{32} &\quad \text{by } \frac{3}{3} \quad 2 \quad \text{(the quantity of the highest-priced ingredient).}
\end{align*}
\]

Secondly, when the quantities are more than two in number.

These kinds of questions, as in those of alligation alternate, admit of various answers, all of them true, and are called indeterminate problems. They are best done by parcel, two at a time, as in the preceding operation.

Alligation alternate is the method of finding the quantities of ingredients or simples necessary to form a compound of a given rate or quality; and it is the converse of alligation medialis.

Alligation alternate shows the due proportion of several ingredients; and counterchanges the place of such excels or differences as arise between the mean price and the extremes; affording that to the greater extreme which proceeds from the leffer; and contrarily.

The rules which obtain in alligation alternate are as follows: every greater extreme is to be linked with one leffer. If either of the extremes be single, and the other extremes plural, the single extreme is to be linked to all the rest.
If both greater and lesser extremes be not plural, they may be linked to differently that several differences may be taken and a variety of answers may be made to the question, yet all true; but if one of the extremes be single, there can be but one answer.

The numbers being linked, take the difference of each from the mean or common price; and place this difference against the number it is linked to, alternately.

Every number, linked with more than one, must have all the differences of the numbers it is linked to, set against it.

These differences resolve the question, when the price of every one of the ingredients is given without their quantities: and the demand is, to mix them so as to sell a certain quantity at a mean rate.

Example 1. A person would mix wheat at 4d. a bushel with rye at 2s. 8d. fo as to sell the mixture at 3s. 6d. a bushel, how much of each must he take?

Thus:

\[
\begin{array}{|c|c|c|}
\hline
\text{Wheat} & 42 & 48 \text{ bushels of wheat} \\
\text{Rye} & 32 & 6 \text{ bushels of rye} \\
\hline
\end{array}
\]

\[\text{Answer.}\]

Example 2. A vintner would mix Malaga, at 7s. 6d. a gallon, with Canary at 6s. 9d. and white wine at 4s. 3d. fo as to sell the compound at 5s. 2d. a gallon: what quantity of each must he take?

\[
\begin{array}{|c|c|c|c|}
\hline
\text{Wheat} & 62 & 81 & 11 \\
\text{Rye} & 51 & 11 & 9 \\
\text{Barley} & 19.28 & 47 & 11 \\
\hline
\end{array}
\]

\[\text{Answer.}\]

N. B. The difference between 62 and 51 is 11, which is set against 81, and also against 90; the difference between 62 and 81 is 19, placed against 51: the difference between 62 and 90 is 28, which is also set against 41. Then 19, added to 28, is 47: and therefore the differences required are 11, 11, 47.

But, in Alligation partial, when the quantity of one, with the price of all the ingredients, is given, and the demand is to know the quantities of the other ingredients; then, the rule of three is to be used.

Say, as the difference standing against the price of the given quantity is to the given quantity, so are the several other differences to the respective quantities required.

Example 1. If it be desired to mix 10 bushels of wheat, at 5s. with rye at 3s. 6d. and barley at 22. 4d. fo as to sell the mixture at 3s. per bushel, how much rye and barley must be taken?

\[
\begin{array}{|c|c|c|c|}
\hline
\text{Wheat} & 60 & 6.20 & 26 \\
\text{Rye} & 42 & 12 & 12 \\
\text{Barley} & 28 & 12 & 12 \\
\hline
\end{array}
\]

Then 26 : 10 : 12 : 4s. 8d. bushels of rye and of barley.

Example 2. How much Malaga at 7s. 6d. a gallon, Sherry at 5s. white wine at 4s. 3d. must be mixed with 24 gallons of Canary at 6s. 9d. fo that the whole may be sold at 6s. per gallon?

\[
\begin{array}{|c|c|}
\hline
\text{Malaga} & 90 \\
\text{Canary} & 81 \\
\text{Sherry} & 60 \\
\hline
\end{array}
\]

Or thus:

\[
\begin{array}{|c|c|}
\hline
\text{Malaga} & 90 \\
\text{Canary} & 81 \\
\text{Sherry} & 60 \\
\hline
\end{array}
\]

Then, the quantity of Canary being given, say, by the first method 21 : 24 : each difference its respective quantity; that is,

\[
\begin{array}{|c|c|}
\hline
\text{Malaga} & 12 \text{ 15} \frac{1}{2} \text{ gall. Malaga.} \\
\text{Sherry} & 18 \text{ 20} \frac{4}{6} \text{ Sherry.} \\
\text{White wine} & 9 \text{ 10} \frac{1}{2} \text{ White wine.} \\
\hline
\end{array}
\]

\[\text{Answer.}\]

Or, by the second method:

\[
\begin{array}{|c|c|}
\hline
\text{Malaga} & 21 \text{ 22} \frac{1}{4} \text{ gall. Malaga.} \\
\text{Sherry} & 9 \text{ 18} \frac{3}{4} \text{ Sherry.} \\
\text{White wine} & 18 \text{ 36} \text{ White wine.} \\
\hline
\end{array}
\]

And, in Alligation total, when the price of every ingredient is given, without any of their quantities, and the demand is to make up a certain quantity to be sold at a mean rate; then all the differences added together will be the first number in the rule of three; the whole quantity to be mixed, the second number; and each difference apart, the several third numbers; and so many farts as are mixed, fo many operations must there be of the rule of three.

Example 1. A goldsmith would mix gold of 24 carats with some of 21, and with another fort of 19 carats fine, and with a due quantity of alloy, so that 190 ounces might be of the fineness of 17 carats; how much of each lost must be taken?

N. B. Alloy is reckoned at 0 carat.

\[
\begin{array}{|c|c|}
\hline
\text{24} & 17 \\
\text{21} & 17 \\
\text{19} & 17 \\
\text{0} & 2.47 \\
\hline
\end{array}
\]

Then 64 : 190 : 17 : 50 \frac{1}{3} \text{ of the three sorts of gold.} \\
\text{13 : 38} \frac{1}{3} \text{ of all alloy.}

Example 1. A mixture of wine is required to be made of 130 quarts from 5 sorts, whose prices are 7d. 8d. 1cd. 14d. and 15d. quart respectively, and the whole is to be sold at 12d. a quart; how much of each is necessary? As there are five quantities, they will admit of several alternations.

First Method.

\[
\begin{array}{|c|c|c|}
\hline
\text{15} & 5 & 5 \\
\text{14} & 4.2 & 2 \\
\text{13} & 2 & 2 \\
\text{12} & 3 & 3 \\
\text{11} & 3 & 3 \\
\hline
\end{array}
\]

Second Method.

\[
\begin{array}{|c|c|c|}
\hline
\text{15} & 4.2 & 6 \\
\text{14} & 5 & 5 \\
\text{13} & 3 & 3 \\
\text{12} & 3 & 3 \\
\text{11} & 2 & 2 \\
\hline
\end{array}
\]

Third Method.

\[
\begin{array}{|c|c|c|}
\hline
\text{15} & 2.45 & 11 \\
\text{14} & 2.45 & 11 \\
\text{13} & 3.2 & 5 \\
\text{12} & 3.2 & 5 \\
\text{11} & 3.2 & 5 \\
\hline
\end{array}
\]

The operation by the last method is as follows:

\[
\begin{array}{|c|c|}
\hline
\text{11} & 38 \frac{4}{5} \text{ quarts of wine at 15d. and 14d.} \\
\text{10} & 5 \text{ at 1cd. 8d. and 7d.} \\
\hline
\end{array}
\]

\[\text{The}\]
The rule for this kind of alligation may be otherwise expressed and applied to all the cases above enumerated, thus: Having coupled the rates as before, then for any pair of differences, take their equimultiples, or multiply them by any number at pleasure; proceed in the same manner with any other pair; and you will thus have a new set of differences with which to work.

Example 1. A grocer would mix 12 lb. of sugar at 10d., with two other forts at 8d. and 5d., so that the mixture may be sold at 7d.; how much must he take?

**Common Method.**

\[
7 \\
\| 10 \| 2 \| 2 \\
| 5 \| 2 \| 2 \\
\| 1.3 \| 4 \\
\]

The pair of differences against 10 and 5, being 2 and 1, are multiplied by 2, and they become 4 and 2; those against 8 and 5, being 2 and 3, are multiplied by 3, and they become 6 and 9; so that 4, 6, 11, will be the new set of differences.

Then, \[4 \div 12 \times 6 = 8 \text{ lb. at 8d.}\]

**Example 2.** A farmer would mix wheat at 42d. with rye at 3d. and barley at 2s. and oats at 1s. per bushel, in order to obtain a quantity of 120 bushels, to be sold at 2s. 4d. per bushel; how much of each must be taken?

\[
28 \begin{array}{ccc}
\text{Wheat} & 42 & 16 \times 3 \\
\text{Rye} & 30 & 4 \times 5 \\
\text{Barley} & 24 & 8 \times 5 \\
\text{Oats} & 12 & 20 \times 3
\end{array} \]

Then 168 \[120 \div 48 = 34 \frac{2}{3} \text{ bushels of wheat,}\]

\[20 = 14 \frac{1}{2} \text{ bushels of rye,}\]

\[40 = 28 \frac{1}{2} \text{ bushels of barley,}\]

\[60 = 42 \frac{1}{2} \text{ bushels of oats.}\]

But all questions of this kind are most easily and accurately solved by common algebra, which will enable us to determine their limits; as they form a sort of indeterminate problems, and admit of many, or an indefinite number of answers. For a further explanation of this rule and examples, we refer to Ward, Wallis, Malcolm, Emerson, and other writers on arithmetic and algebra.

We shall add an example, wherein both the kinds of alligation have place. Suppose a mixture of wine of 119 quarters, required to be made of wines of the following prices, 7d., 14d., and 15d., per quart; and so as that the whole may be afforded at 12d. per quart.

Having linked 8 to 14, and 7 to 15, and counterchanged their differences from the common price, 12d., the sum of their difference is found to be 14; by which dividing 119, the quotient is 8 \(\frac{2}{3}\) or 8 \(\frac{1}{3}\), or for convenience in operation \(\frac{1}{3}\).

**Quarts.**

\[
8 \begin{array}{l}
\frac{1}{2} \times 2 = 3 \frac{1}{2} = 17 \\
14 \frac{1}{2} \times 3 = 5 \frac{2}{3} = 47 \\
7 \frac{3}{4} \times 4 = 3 \frac{1}{4} = 36 \\
15 \frac{1}{2} \times 5 = 7 \frac{1}{2} = 42 \frac{1}{2}
\end{array} \]

119

**ALLIGATOR.** In **Zoology**, a name given to the American crocodile, a species of **Lacerta**, under which article it is described.

**ALLIGATOR Pear.** In **Botany.** See **Laurus**.

**ALLIONIA.** In **Botany**, so called in honour of Charles Allioni, professor of botany at Turin, a genus of the **te-**

**ALLIOTICUM**, from **alliot**, alias, and **alot**, and literally denotes a horce. The Arabs give this name to each of the three stars in the tail of the Great Bear, on account of their appearing like three horses, ranged for the drawing of the waggon, represented by four stars, called Charles's wain.

**ALLIOTICUM**, from **alot**, to **vary**, a Galenical medicine, which alters and purifies the blood,confuting chiefly the roots of dandelion, fescue, fennel, and raisins; with the herbs endive, common ox-eye, lettuce, fennel, fumitory, &c. See **ALTERATION.**

**ALLITERATION**, in **Rhetoric**, is a figure or decoration of language, chiefly used in poetry, and consisting in the repetition of the same letter or letters at certain intervals, whence its name is derived. This figure has been generally regarded either as trivial in itself, or as an instance of false refinement; but for the use of it we might refer to the poet's authority, and it unquestionably facilitates the recitation of verse, contributes to both its sweetness and energy, serves to enforce the sentiment which it expresses, and aids the memory in retaining it. Pontanus, one of those ingenious Italians who flourished upon the revival of literature in Europe, has particularly described this figure, and furnished instances of it both from poetical and profane writers. It occurs in the repetition of the same letters, syllables, or words; and when it takes place in the first and last syllables, and even in the middle ones, it is, he says, wonderfully pleasing. The instances which he produces from Virgil are such as follow: "*Iams edens super arma.*"—"*Tales catus Caffandra canebat.*"—"*Incontinent infando indicio.*"—"*Longe sole fansa tonsabant.*"—"*Magnae miferi murmurum pontum.*"—"*Quaque lacus laeti liquidos.*"—In the following instance, cited from Lucretius, it is continued from one verse to another:—

"—Adverso flabra feruntur
Flumine."

Cicero (in Brut.) uses this figure:—"Nulla res magis penetrant in animos, coque fingit, format, flecit:" and also (De Orat.): "Quodque me follicitare flamma folet." For the use of this figure we may add to that of Virgil the superior authority of Homer. II. § 201.

---

1. *Προ το ε καπηλειον το Άλιον εστι Άλιον.
2. *Συμφορική, τοις Άλιοντι Άλιονι.
3. *Hermogenes*
Hermogenes quotes these lines as an example of the figure now described, which he calls by a Greek name, παραρθέσις, paro- 
thesis, and declares to be beauty in similar words, which under a different signification found the same. Aristotle called 
this figure παραρθέσις, paronomasia; and the Latin rhetoricians 
called it Annomatoio. Giraldaus Cambrensis informs us, that 
in the time of Henry II. the English and the Welsh 
were so attached to this verbal ornament in every highly 
finished composition, that nothing was by them esteemed 
elegantly delivered, no dictio considered but as rude and 
rudic, if it were not first amply refined with the polishing 
art of this figure. From this national taste may probably 
be derived some of our proverbial similes, which, independ- 
ently of the found, have no other merit.

Spencer and Shakspere adopted this practice. Spencer 
says—

"For not to have been dipp'd in Lethe like 
Could save the Son of These from to die; 
But that blind bard did him immortal make 
With verbs, dipp'd in dews of Callalston."

Thus Shakspere:—

"Had my sweet Harry bad but half their number, 
This day might I, hanging on Holpfin's neck, 
Have talked."—Hen. IV. part 2. act 2.

Milton also followed them:—

"For eloquence, the soul; song charms the sense."—P. L. ii. 556.

Again:—

"Bebemoth, biggest born of earth, upheav'd 
His vaults——"—P. L. vii. 471.

Dryden employed this figure frequently, and, like Virgil, 
with singular simplicity and strength. E. C. G.

"Better to hunt in fields for health unbought, 
Then see the dollar for a saucious draught. 
The wife for cure on exercise depend; 
God never made his work for man to mend."—Fables.

Pope adopted the same figure, as in the following couplet:—

"External beauties grace the shining scene; 
Fields ever first, and groves for ever green."—

Gray, who professed to have learnt his verification from 
Dryden, seems also to have paid particular attention to this 
ornament, as in the following inferences:—

"Rain feize thee, ruthless king!" 
"To highborn Hoel's harp, or loft Llewelyn's ly." 
"Weave the warp, and weave the woof." 
"Stamp we the vengeance deep, and ratify his doom." 
"Regardles of the facegning whirlwind's way." 
"Eyes that glow, and fangs that grin." 
"Thoughts that breathe, and words that burn." 
"Hanbork crafs, and helmet ring!" &c. &c.

apud Ald. 1519. Harris's Philological Inquiries, p. 94—

ALLIUM, probably from αλιομ, to avoid, because some 
persons avoid the plant on account of its very disagreeable 
smell, or from αλιομια, exilire, from the quickness of its 
growth, or from σγωμια, which signifies a head of garlic,

Garlic, in Botany, a genus of the hemianthes monogynia 
clads and order, of the natural order of the families and of the 
families of the order Jov. Mercurialis: its characters are, the 
covela is a common 
flowers or flesh, roundish, shining, and many-flowered; 
the corolla consists of six oblong petals: the flowers have six 
filaments, labellum, generally of the length of the corolla, 
the anthers are oblong and upright: the fruit is a 
garlic, of a gern, 
ior, short, bluntly three-cornered, the corners being 
marked with a grooved line, lyle simple, stigma acute: the 
pericarpium is a capsule, very short, broad, three-lobed, 
three-layered, and three-valved; and the seeds are many and round. 
Prof. Martyn enumerates 43, Glanein and Wilkenson 53 
species, distributed into several divisions. 1. Thoe with 
flute and leaves flat, and umbel capule-bearing. 1. ampe- 
loplafum, great round-headed garlic; has umbel globose, 
flament three-cuped, and petals with a rough keel: its item 
is a foot or more in height, having leaves at the bottom, 
glanaceous and succulent: the spathae is conical, one-leaved, 
and deciduous: it flowers in a close ball on peduncles which 
are about an inch in length: the flaments are somewhat 
longer than plural, which is a part of the corolla: this is eaten 
along with other pot-herbs; it communicates its flavour to the milk and butter of cows that eat it: 
it grows naturally in the East, in Switzerland, on the 
Homs island in the mouth of the Severn, &c. is perennial, 
and flowers with us in July. 2. A. porrum, porrum fatum of 
Ray and Miller, common leek, has umbel globose, 
flament three-cuped, petals with a rough keel, root coated: 
it has a rather high item, leafy at bottom, spathe shortly 
conical, deciduous: flowers in clove large balls on purple 
peduncles in April or May: it is very like the former spee- 
cies, and probably only a variety: it has been generally 
upspot that there are two sorts of leeks; but Martyn has 
made trial of both, and found that they were the same; 
the difference being occasioned by faving the seeds from old 
roots, and not from the feeding leeks, whereby they have 
degenerated, and become smaller and more narrow-leaved: 
this species was cultivated by Gerard in 1597, and probably 
at an earlier period; but its native place is not ascertained: 
it is highly esteemed in some places for culinary uses. 
3. A. linearis, linear-leaved G. with umbel globose, flaments 
three-cuped, twice as long as the corolla; grows naturally 
in Siberia, and is called by Miller, who cultivated it in 1568, 
porrum ampeleopramus. 4. A. faurolebus, with umbel capi- 
tated, and flaments awl-shaped, twice as long as the corolla; 
grows in Austria. 5. A. deflexum, has three-cuped 
flaments, of the length of the corolla, leaves narrow and linear, 
and stalk declined. 6. A. rotundum, great round-headed G. 
with umbel sub-globose, flaments three-cuped, and leaf- 
flowers nodding; has the fruit and seeds of the second spee- 
cies or leek, and is of a native of the southern parts of Europe. 
7. A. villarum, long-rooted G. with umbel rounded, 
flaments lanceolate, longer than the corolla, and leaves elliptic; 
grows on the mountains of Switzerland, Italy, Austria, 
Sicilia, and Savoy; cultivated in 1730 by Miller. 8. A. sub- 
biurus, hairy G. or Dialcoris's Moly, with flaments awl- 
shaped, and lower leaves hirtate, is a native of Italy, Spain, 
Afric, and the Levant; was cultivated by Gerard in 1596; 
flowers in May. 9. A. majus, Flower's G. or Moly, 
with simple flaments and bulb-bearing branches, was culti- 
vated in 1596 by Gerard, and is preferred in gardens for 
the sake of variety; but it has a very strong scent. 10. A. obli- 
quum, oblique-leaved G. with filiform flaments, thrice 
as long as the flower, and oblique leaves, is a native of 
Siberia, and cultivated here before 1768 by Miller. 11. A. ranunculorum, branched G. with globose umbel, flaments 
awl-shaped, longer, leaves linear and sub-convex, grows naturally
to Siberia, whence the seeds of this and the former sort were sent to Peterburgh, and from them the botanic garden, in which they are preferred for the sake of variety, was supplied. 12. A. Taracium, Tartarian G. with umbel flat, flaments simple, and leaves semi-cylindrical, is a native of Siberia, and introduced into Kew gardens in 1787 by Mr. Haneman. 13. A. recusum, rose G. with umbel flat-topped, petals emarginate, and flaments very simple, grows naturally about Montpellier and in Piedmont, in the fields, olive-gardens, and vineyards, and was cultivated in 1752 by Miller. 14. A. cerasturn, has a globose umbel, simple flaments, linear leaves, and prickly flhenes. Grinn. 15. A. with flamen-leaves flat and umbel bulb-bearing. 16. A. fativum, common G. with compound umbel and thrice-cuped flaments, is said to be found wild in Sicily, and cultivated in 1751, or probably at a much earlier period. 16. A. Scordopram, Roscambale, with three-cuped flaments, crenulate leaves, and two-edged flhenes, is found wild in Sweden, Denmark, Germany, and Hungary, and cultivated here by Gerard in 1596; it has compound bulbs, but much smaller than those of garlic: the root is heart-shaped, solid, and generally stands sideways of the falk: the leaves are rather broad and crenated at the edges; the flowers, which are collected in a sort of globular head, are of a pale purple colour: the flmen generally rifes from two to three feet in height, and produces many small bulbs at the top, that may be made use of as well as those of the root. 17. A. amarnum, A. scorodopramum of Flor. Dan. 290, said G. with three-cuped flaments, columnar falks, awnles fpathe, and petals slightly rough in the keel, distinguished from the last species by its round fhenes, and by its growing always in a sandy soil: bulbs, which are numerous, and blossoms, are blue: flaments a little longer than the blossoms; leaves three or four, lower ones quickly withering, broad, edges hairy, or rather finely toothed, teeth not discernible without a glafs; leaf-flhenes strongly keeled; flmen two to five feet high; flowers few, on short flalks, small, purple, marked with a deeper line: it grows wild in Thuringia, Scania, Denmark, Switzerland, Italy, and in the wood and mountainous parts of the north of England, particularly about Lowther in Westmorland, Castle Howard in Yorkfhire, Thorp-arfch, and HeUington-fields near York. It is perennial, and flowers in July. 18. A. carinatum, amplefopramum floriferum of Lob. 1c. 155, Molly montanum fecundam Chufi, mountain G. with awl-shaped flaments, very long (acute, Smith) fpathe: flmen, when cultivated, four feet high; leaves a foot long, not half an inch broad, flhenes-two, awl-shaped, unequal: umbel has few flowers, but many bulbs; blossom of a dull brown yellow colour, often changing to purple: the plant has but little of the garlic smell: it is found wild in Scania, Germany, Carniola, Italy, and Switzerland, and also in the rocky and mountainous parts of the north of England, near Settle in Yorkshire, in HeUington-fields near York, and about Knarrborough, on the rocks about Longfledale in Westmorland, near Ramflgate in the ifle of Thanet, and between Sandwich and Deal: it is perennial, and flowers in July. 19. A. gherisaphallum, Molly montanum with a purple flower of Chufi, small round-headed G. with three-cuped flaments, longer than the corolla, and semi-columnar leaves, is a native of Switzerland, Italy, Germany, and Siberia, was cultivated in 1759 by Miller, and is thought by Haller not to be specifically distinct from A. defcendens. 20. A. parviforum, small-flowered G. with globose umbel, simple flaments, longer than the corolla, and awl-shaped fpathe, is a native of the south of Europe, and introduced into Kew gardens in 1781 by M. Thouin. 21. A. defcendens, purple-headed G. with three-cuped flaments, and outer peduncles shorter, is a native of Italy and Switzerland, and cultivated in the Oxford garden in 1766: this species has two bulbs at the origin of the falk, the leaves being filiform and channelled above, the flalk generally two or more feet in height, the fheath quadrifid. 22. A. moraratum, multi-cuping G. Moly of Baulin and Rudbeck, with umbel flat-topped, mostly small-flowered, acute peduncles, simple flaments, and petalous leaves, grows wild in Provence, Narbonne, and Spain; brought by Saltmaann, according to Cap. Bauhin, from the bulbs about Montpellier in 1598, and cultivated in his garden. 23. A. flavum, sulphur-coloured G. with yellow flowers, pendulous, ovate peduncles, and flaments longer than the corolla; thought by Gerard and Gouan to be a variety of the last species; is a native of the south of France, Italy, and Austria, and cultivated in 1768 by Miller. 24. A. deferta- ram, with awl-shaped flaments, and petals marked by a dark line in the middle. Fork. Fl. Àeg. Arab. p. 72: doubtful whether it is a distinct species. 25. A. pallens, pale-flowered G. with flowers pendulous, truncate; flaments simple, equalling the corolla; is a native of Italy, Spain, Montpellier, and Hungary; and introduced into the Kew garden in 1779 by Abbé Pontre. 26. A. poiculatum, panicled G. with peduncles capillary, spread out, flaments awl-shaped, and very long spathe, joined by Gerard to the preceding, is a native of Italy, Austria, Switzerland, Carniola, Siberia, and the extreme of Russia: and introduced into the Kew garden in 1780 by Sign. Giov. Fabroni. 27. A. (fa-fil, A. fylvfretre of Ray and Gerard, crow G. with three-cuped flaments; bulbs tapering, bowkcked, often running into long hair-like points, compacted into a close head; blossoms small, violet; flaments with two long bristles, projecting beyond the flower; item about two feet high; leaves smooth, hollow, slender, and very long; umbel three-leaved of one leaf, broad at the base, ending in an awl-shaped point about an inch long, coarsely with green lines; bulbs numerous, white; and blossoms few, small; there is a variety with a double head of bulbs: this species is a native of Switzerland, Germany, Italy, &c. and with us is frequent in dry pastures, communicating its rank taste to the milk and butter, and growing in old walls and among corn, chiefly in calcareous soil, near Worcsrider (Stokes): it is perennial, and flowers in July. 28. A. brascum, purple striped, or streaked, field or wild G. with flaments simple, leaves rough, (not rough), Withering; semi-columnar, furrowed underneath; the root a solid bulb, stems two or three feet high, upright or a little bent towards the top, smooth, not scored, solid; leaves hollow, bulbs numerous, egg-shaped, forming a roundish knob, between which arise several thread-shaped fruit-flalks, each supporting a single flower, which is drooping, cylindrical, but somewhat bell-shaped; blossom white, with three dark purple streaks on each petal, or pale with purple lines; german prism-shaped, six-angled; style slender, longer than the blossoms; flaments shorter than the petals; with minute white dots, hardly visible to the naked eye, scattered over the whole plant: it is a native of Sweden, Germany, Switzerland, Italy, and Ingrina; and with us in Westmorland, near York, near Brifol, at Fincham, Norfolk, and Black Notley, Efeus, and Baydale near Darlington, among corn, and about the borders of fields. It is perennial, and flowers in July. 29. A. Pallassis, Pallais's G. with umbel disform, flaments simple, equalling the corolla, and style very short; three-cornered capsule; is a native of Siberia. IV. A. with leaves radical and flmen naked. 30. A. mutans, porrum of Gmelin, flat-linked G. with scape two-edged,
edged, leaves linear, flat, and three-clefted flamen: is a native of Siberia, and introduced into Kew garden in 1785 by Dr. W. Pitcairn. 31. A. acaule, toga: acaule of Morfon, tetris of Banthin, miller, and esculent, with scape columnar, leaves awl-shaped, umbel globose, and three-clefted flamen: this species has a conglabate root consisting of numerous oblong parts bound together by means of a thin delicate membranaceous covering, each of which lends forth two or three long filiform awls, China. It arises from a sheath nearly like those of the common onion; the flower-heads from membraneaceous sheaths, are round, nearly naked, and terminated by globular umbels of flowers, that have erect awl-shaped petals, of the length of the flamina, and of a purpled colour: the roots are very pun- gent, have a strong but rather pleasant smell, on which account they are generally preferred to the onion for various purposes of cookery; was found by Halfefqult, native, in Palestine, and cultivated here in 1673. 32. A. fœnscent, Narcissus-leaved onion or G. with scape two-edged, leaves linear, convex beneath, smooth, umbel roundish, and awl- shaped flamen, joined by Haller and Scopoli to the A. anguïulatum, is a native of Siberia, the Alps, Silecia, and the island of Sicily, and cultivated by Gerard in 1596. 33. A. hyacinthum, with a columnar scape, leaves linear-lanceolate, flat, umbel flat-topped, and awl-shaped flamen, grows naturally in the vine and olive yards of Austria. Oceanow. 34. A. edrum, sweet-smelling G. with scape nearly columnar, leaves lanceolate, convex beneath, umbel flat-topped, is a native of the south of Europe, China, Japan, &c. 35. A. inodorum, Carolina G. with scape naked, subfrustubose, leaves linear, flat, keeled beneath, umbel flat-topped, and simple flamen, is a native of Carolina, introduced in 1776 by the Duke of Devon, and cultivated in March and April. 36. A. anguïulatum, cega of Melin, angular-scaped G. with scape two-edged, leaves linear-channelled, somewhat angular beneath, and flat-topped umbel, is a native of Siberia, Italy, Austria, Switzerland, and Germany, in moist places. 37. A. fœtida. with a three-cornered scape, linear leaves, frituated with furrows beneath, fagiculated umbel, obtuse petals and simple flamen, is a native of the Cape of Good Hope. 38. A. nariens, with a columnar scape, linear awl-shaped leaves, fagiculated umbel, or umbel terminal inclined, pointed petals, or petals lanceolate, and simple flamen, shorter than the corolla, is a native of the mountains in the western parts of France. 39. A. pedemontanum, with a four-cornered scape, linear obtuse leaves, and few-flowered umbel, is a native of the Alps of Piedmont. 40. A. nigrum, A. multibulbiform of Jacquin and Murray, A. montiflourum of Gouan, both of which are in Gmelin's Linnæus characterized as distinct species, black G. with scape columnar, leaves linear, (lanceolate, Willd.) umbel hemispherical, petals erect, (patent, Willd.) spathe pointed and bifid, (flamen simple, Willd.) is a native of Provence, Italy, Austria, and the neighbourhood of Algiers, and cultivated in 1759 by Miller. 41. A. Canadæ, Canada tree onion, with scape columnar, leaves linear, and head bulb-bearing, is a native of North America; this species has a perennial root; smooth, flat, straight leaves, six or seven inches in length; stem cylindrical, smooth, nearly naked, hardly longer than the leaves, spathe ovate, flat, pointed, flowers few and white, petals oval, the flaminces simple, nearly of the length of the corolla, having brownish red anthers. 42. A. frisionum, A. fyléire lathifolium of Ray, broad-leaved G. or Renouf, with scape three-fidged, (semi-cylindrical, Smith,) leaves lanceolate, petiolate, and flat-topped umbel, flowers large, numerous, and white; is a native of Sweden, Denmark, Germany, Switzerland, and Italy, in woods and moist shady places, and with us in England it is frequent in such situations. It is perennial, and flowers in May and June: the smell and taste, according to Haller and Scopoli, are very acid: Dr. Smith says, that the plant has a strong smell of garlic, and that it affords to sheep and cattle a purgative not disagreeable; the milk is of course nauseous and fetid; and other plants near it do not flourish. 43. A. Chiffarum, Moly and the Chiffarum, and the Dutch Moly, six-cornered scape, linear, flat, ciliate leaves; few-flowered umbel, and oblong or ovate petals; a native of the southern parts of Europe. 44. A. triplicatum, three-cornered Moly, Moly of Parkinson and Ray, with scape and leaves three-fidged, and simple flamen, is a native of Italy, and Spain about Narbonne, and cultivated in 1765 by Miller. 45. A. cepa, cefa of Miller and Bium, common onion, with scape swelling out below, and longer than the columnar leaves, is well known by its futilar leaves and swelling flanks: it differs from the garlic only in having a swelling pipy stalk, that is considerably larger in the middle than at the extremities: the Latin name cepa, says Mr. Martin, is derived from cepa, a head, on account of the form of its bulb, and for the fame reason the Greeks called it κραπος. Others derive it from γαρνιον ρυπος γαρνιον, or from γαρνιον γαρνιον ρυπος γαρνιον. The English and French name are deduced from the Latin cepa, because the bulb never throws out any off-sents: the varieties of the common onion are, the Strafo, or common oval; the Spanish, silver flaked and red flaked; the Portuguese great oval onion; and the Tripoli: all these vary from seeds, and there are se- veral intermediate differences not worth enumerating. 46. A. Moly, yellow Moly, with scape sub-cylindrical, leaves lanceolate, fuscis, and umbel level-topped, is a native of Hungary, on Monte Baldo, about Montpellier, and on the Pyrenees, and cultivated in 1623 by Edward Lord Zouch: it was formerly preferred in gardens for the sake of variety, but most persons have rooted it out on account of its very strong garlic taint. 47. A. trilobatum, three-edged G. with scape naked, semi-columnar, leaves lanceolate-oblong, flat, smooth, umbel globular, and seeds solitary, is a native of North America, and introduced in 1770 by Mr. W. Young. 48. A. fæliaum, Welch onion, or ciboule, with scape equaling the columnar swelling leaves, is perennial, and does not form bulbs like the common onion: it was cultivated in 1629: the A. altaicum of Pallas, a native of Sibe- ria, is of a smaller size, and a variety of this species: in Gmelin's Linnæus it is made a distinct species. 49. A. fælofus, cives or chives, or G. with scape equal- ing the columnar awl-shaped leaves, is a native of France, Switzerland, Sweden, and Siberia; where a variety of this plant has been found and figured by Gmelin, in which the leaves are reflected, whereas in the common form they are straight: it has been found with us very rarely in meadows and pastures, near Fast-castle on the borders of Berwickshire, in Argyle-kilh, in Wellowmore, and near Kirby Moor-side, Yorkshire, and Cartmel Fell, in a small rivulet called Chivey Syke: this is a very small plant when compared with the former, the items naked and feldom exceeding five or six inches in length, the roots producing little or no bulbs, and the leaves hollow and awl-shaped: it has a very strong smell. 50. A. Silicarium, Siberian G. A. fælofus, fælofus of B. Linn. spec. 433. Murray, Gotting. Com. 1755, t. 4. Cepa paludosa ineiformis of Bush: and cepa paludosa tenuior of Tournefort: with scape columnar, leaves semi-cylindrical, flamen awl-shaped, petals lanceolate acute, it is found in Siberia and the mountains of Silecia, and was introduced into the Kew garden in 1777 by Cheval- ler Murray. 51. A. Tellurens, with a columnar scape, semi-cylindrical
femt-epidymic leaves, dense umbels, and subulatd flaments longer than the corolla, is a native of Siberia, near the river Jenica. 52. A. capillare, with columnar scape, capillaceous leaves, few-flowered umbel, and petals lanceolate acute. 53. A. tenirfiflum, slender-leaved G. with scape columnar, empty; leaves awl-shaped, flliform; and heads loofe and few-flowered (G. melin), or columnar scape; leaves linear, awl-shaped; umbel few-flowered; and petals roundish-ovate obtuse (Wildenow); is a native of Siberia: it is much eaten by the field-mice, and they lay up the roots for their winter food: the flaments in this and the preceding are shorter than the corolla. 54. A. Chama-Moly, ballard G. with scape fearceely any, naked, capsules drooping, leaves flat ciliate, is a native of Italy and Spain, and flowers in January. 55. A. gracile, Jamaica G. with scape naked, columnar, very long, leaves linear, channelled, flaments awl-shaped, connate at the base, is a native of Jamaica, was introduced in 1757 by Hinton Earl, Eqq. and flowers in February. 56. A. Neapolit.iiim, Naples G. with scape naked ancipital, leaves lanceolate channelled, umbel scattered, is cultivated in the gardens near Naples, begins to grow spontaneously about the city, and flowers in March. 57. A. ornithogalum, with scape columnar, umbel bearing and few-flowered, and leaves awl-shaped and flat. Walt. Flor. Carol. p. 121. Gmelin's Linnanea. Martyn's Miller. Wildenow's Linnanea. Smith's Flor. Brit. vol. i. p. 355. Withering's Bot. Arr. vol. ii. p. 332.

Allium, in Gardening, is applied to garlick, onion, and leek. Of the first or garlick-kind of plants, though there are a great number of species only few are valuable either for use or ornament in the garden. The kinds necessary to be taken notice of in this view are: 1st. The falfium or common garlick; 2d. Scardophyium or recombale, which are official or culinary plants. 3d. Helia or common yellow moly, 4th. Subsiburut or hairy white moly, 5th. Spherscopshalon or spherical headed purple moly, 6th. Roifum or rofe-coloured Montpellier garlick. 7th. Flireum or fraw-coloured pendulous moly, 8th. Moneum or great purple moly. 9th. Victorial or elliptical garlick. 10th. Descendens or oval purple-headed garlick: which are all of the flowering kind.

These different species are of the bulbous-rooted tribe, same having large bulbs, others not bigger than peas; they are perennial in root, but annual in leaf and stalk; they are all hardy plants, proper in almost any exposure and soil in the garden, and in general are very productive, but most of the sorts have a strong scent like the common garlick.

The common garlick has a large round white bulbous root, of an irregular form, with numerous fibres at the bottom, composed of many smaller bulbs denominated clones, which are included in a common membraneous covering; each of which being planted, grows, and in one season attains the size and structure of the parent bulb: the leaves are caulisne, or form a kind of stalk, which seldorn spindles, except when the fame roots remain in the ground two or three years, when they run up and bear a flower and small bulbs at the top. It deserves to be cultivated in the garden for the sake of its root, which is in great estimation for culinary and other domestic purposes. Indeed, the roots, as well as all the other parts of the plant, have a very acid taste, with an highly offensive smell, which has rendered its cultivation in gardens lefs desirable. It is a hardy plant, capable of growing in most sorts of soils and situations, and readily propagated either by roots or seeds.

Recombale has very small compound bulbs, which grow in clusters; the stalk generally spindling two or three feet high, with many bulbs at its summit, which, as well as the root bulbs, are useful for the same purposes as garlick, though much inferior.

The latter or the flowery kinds have the flower-flaments rising immediately from the root, growing erect and attaining different heights, from twelve to thirty inches; in some the leaves are radical, in others cauline, or elevated with the stalk, some are broad like those of a tulip, others long and narrow like a daffodil, and some taper and rush-like; but in all the sorts the flaments are terminated by a fort of sheath, from which is protruded an aggregate of many small flowers forming a kind of umbel. The flowers fingly are composed each of six petals, which, though separately small, from many being collected into large heads, are very confpicuous. The Allium moly, sublurpuntum, spherocarpon, roifum, and florum, generally grow from twelve to fifteen or eighteen inches in height, and their umbels often continue in bloom for the space of a month or fix weeks. But the magricus, victorial or elliptical garlick, rife about a yard in height, producing large highly ornamented umbels. They mostly flower in May, June, and July, ripen plenty of seed, and many small bulbs on the stalk and umbel in several of them.

Method of propagation. In all the sorts it may be effected with the utmost facility by off-sorts from the root, and in many of them by seed and the small bulbs contained on the stalk.

Common garlick is constantly propagated by the small bulbs that constitute the main root, which may be readily divided into a great number of separate cloves; these are to be planted in the spring, in beds four feet wide, a little raifed in rows lengthways, at from six to nine inches distance from each other, and fix inches in advance in each row, and two or three inches deep. The planting may be performed either by means of a blunt dibble or by drawing drills, and placing the cloves in them, afterwards covering them with the earth. When planted in this way they mostly shoot up their leaves in a month or six weeks, only requiring occasional small hoxing afterwards to kill the weeds that might arise.

About the end of July or beginning of August, the lubs are generally full grown, as is evident from the yellow appearance and withering of the leaves; they must be then taken up, cleaned and dried in the sun, and afterwards tied or plaited in bunches to be hung up and preferred for use.

Recombale may be propagated either by the off-sorts of its roots, or by the cloves produced on the top of the stalks, which may be planted in Spring or Autumn; but in the Autumn planting, as about October or November, they generally grow considerably larger than when planted in the Spring season. The seeds are to be planted in the manner directed for garlick, and are commonly fit for use about July or August, according as they have been put in early or late. But it may be observed that the roots never acquire any very large size.

The different flowering kinds propagate very rapidly by off-sorts, which may be separated any time after the decay of the flower, taking only such as are large and fine, and planting them at once in the borders where they flower the following Summer.

The propagation by feed is best accomplished in a shady border in Spring, the plants being fit to transplant in such cafes in the Autumn.

Of the second division, or the onion kind, the characters, &c. of which are the same as those of garlick; the species are, 1st. Cepa, or common onion, the best garden varieties of which are the Surfbrugh or common round onion, the oval long-keeping common onion, the Spanish large flat.
onion, the Spanish silver-skinned onion, the Spanish red-skinned onion, and the Portugal great roundish oval onion. 2d. Equisetum or the Ciboule or Welsh onion. 3d. Schinorrhoon, cives or chives. 4. Aolianum, etchalk or shallot. 5. Canadaeae, or Canada-tree onion. All the first species and varieties have large bulbous roots, and the plants are biennial, or being sown in the Spring arrive at perfection in the root the same year, and next year shoot up into falk, flower, and ripe seed; when the Falks quickly die, and the individuals are annihilated. But the second and third species never form any bulbs at bottom; they are, however, hardy and perennial, and may be continued many years by the roots according to the directions given below for them. And the fourth and fifth species are bulbous-rooted perennials, multiplying greatly by offsets, as is evident from their culture.

The method of propagation and culture in the onion kind. Common onion. Among the several varieties of the common onion, the Stralburgh is probably the best for general culture, having a hand dome bulb, mostly assuming a roundish oval shape. It is of firm growth, and generally keeps well for winter use. The Spanish onions are large and flat; the first fort is, however, of the mildest flavour; but all the varieties for the most part afford profitable crops, and none excel them for culinary purposes; but they seldom keep well after Christmas as the Stralburgh or oval fort of onion. The Portugal onion is a very large hand dome bulb, of a roundish oval shape, though it rarely attains the size here, as in that climate, as is obvious from those annually imported from that kingdom. If, however, seeds sown in Portugal be sown here, the bulbs will arrive at a much larger size than from such as are sown in this country, especially where preferred two or three years succes sively, in which cases they are often for figs degenerated, that the bulbs become flat, and not larger than the common onions. The mode of transplanting them at an early period, which is adopted in that country, may also have much effect in rendering the bulbs so large. From this form of onion being very mild, it is much esteemed for sauces and other culinary uses.

All these kinds are propagated by feed sown annually; which for the general crop should always be performed from about the twentieth of February until the latter end of March, though in cold wet stiff soils it may be proper to defer fowing entirely until towards the middle of the latter of these months. But in cases of omission in fowing at the times above recommended, it may be performed with tolerable success in the beginning or any time before the first of April, but the crops of the February or March sowing always bulb more freely and acquire a much larger growth than those sown at later periods.

The most proper situation for crops of this kind is an open exposure, and where the soil is moderately light and rich in vegetable matter. That sort of the bell mallow ground in the garden should always be chosen, with the addition, if possible, of a good coat of well rotten dung, dug well in, but not too deep, the surface being kept level, and while it is fresh stirred, well raked, and the seed sown, a point which is of importance to be attended to. The fowing when the surface is so wet or moist as to clog to the feet or rake in preparing it, should not however be performed.

The proper quantity of feed is in general about an oonce to every rod or pole of ground; but where it is not required to have them thick for cuttings, two oonces for three rods may be sufficient. Great care should be taken to procure fresh feed, as but very little of that which is kept more than one year will vegetate.

The feed may either be sown over the whole of the piece or plot of ground, or it may first be divided into beds of four or five feet in width, allowing foot-wide alleys between them. In fowing, the feed should be put in with a regular sown bed, and the surface, when very light, immediately trodden over evenly upon the feed; afterwards, where sown in beds, the alleys may be pared an inch or two deep and the earth call over them, proceeding directly to rake in the feed regularly with an even hand, trimming off all the stones, roots, &c. See Sowing Seeds.

The method of fowing them in beds is the most eligible, where it is desirable to draw or cut the young onions from time to time for market or family use; as, in such cases, a person can stand in the alleys without treading on the beds, which not only renders the surface hard, so as to injure the crop, but highly destructive, by trampling upon the plants themselves. It is likewise very convenient to stand in the alleys, in order to weed, thin, or hoe the crop as occasion may require. Although it is a common practice in the general culture of onions to sow them thick, in order to allow for culling or drawing out the superabundant plants, by degrees as they are wanted; it would no doubt be a better mode to sow a piece particularly for general culling, exclusive of the main crop; because by daily thinning out the superfluous plants there is no avoiding treading upon, disturbing and loosening the remaining ones, by which they become littered in their growth, and by no means so fine. There is also another very common but injudicious practice, which is that of mixing other crops such as leek, lettuce, radish, carrot, &c. with these crops. It is productive of confusion, as well as obstruction to the chief crop, without producing any great advantage; nothing should therefore be admitted, except a very thin sprinkling of eofs lettuce in some cases. In about fifteen or twenty days after the feed is sown the plants generally appear, and in a month or six weeks after that, as in May and the beginning of June, they will be three or four inches high; when they should be well cleaned from weeds, and the main crop thinned to three or four inches distance. The weeding and thinning should be begun in due time, before the weeds branch and spread much, which may either be performed by the hand or small hoeing; the latter is the most expeditious method, as by it one man may do as much as three, and it is also the most beneficial to the plants; as by stinting the ground about them with the hoe, it greatly forwards their growth, as is mostly seen in a few days after the operation. This mode, however, is more particularly eligible for the larger principal crops, for which a good sharp one-hand hoe, about two inches, or not more than two and a half broad, is the best, taking the opportunity of dry weather for performing the bulbine and carefully cutting up all weeds. Where the onions stand too close they should be cut out in a regular thinning order to about three inches distance; or in such crops as are not wanted for occasional cutting, they may be hoed out at once to about four or five inches, having regard to leave the strongest plants, as much as possible, for the continuing crops.

In the course of two or three weeks or something more, it will generally be proper to run over them again in the same manner, in order to cut up all advancing weeds, and any superabundant plants that may have escaped in the first hoeing; after this they seldom require any further culture, than that of pulling out such casual stragglng weeds as may arise.

But where the crops are small, or where they are required for thinning or culling by degrees, for use in their young green state and in small bulbs, the weeding and requisite thinning where they are in clusters, may generally be well performed by
by the hand. In the advanced growth of the crop, when the superabundant plants are occasionally thinned out for use, as wanted, they should be drawn somewhat regular, so as to leave a sufficiency of the strongest plants remaining at moderate distances for a full crop to attain their full growth in large bulbs.

It is highly necessary to continue to keep the different crops very clear from harmful weeds in their advancing growth during the months of May, June, and July, which being their principal growing feasts, if they are not kept free from weeds, and sufficiently thinned to proper distances in due time, they draw one another up, weak and slender, which much retards their bulbing. About the middle or latter end of June the continuing crops begin swelling a little at bottom in their bulbing order, but more fully in July; and in August the bulbs arrive to full growth, and are proper for taking wholly up. Towards the middle of August the crops in general should therefore be examined, and when the necks shrink and fall, and the leaves wither, it may be concluded that the bulbs are arrived at maturity, and have done growing.

They should then be pulled up, cleaned, dried, and hove for sale; this being done in dry weather on a piece of the ground bold, raked, and cleaned, in order to spread them on as they are pulled up, to dry and harden. They should lie in this way a week or a fortnight, being turned every day or two, when, if the weather proves dry, they will be duly prepared for keeping; the first opportunity should then be taken to hove them. The bulbs must be first divided of all adhering earth, loose skins, and the gross leaf parts of the leaves and neck, rejecting all infectious and bruised ones, and then they may be carried into any dry upper room, out of the damp, spreading them on the floor as thinly as convenient. The closer the room is kept the better, but care must be taken to turn them over once in three weeks, and to clear out such as have any tendency to infection.

As in the culture of onions it frequently happens, that through badness of feed many are disappointed of a crop, by waiting in expectation of the plants rising till it has been too late to sow again; in such cases recourse may be had to transplantation from other gardens, as a neighbouring one, where there are superfluous crops, or a bed or such part of one as is necessary may be purchased from a market gardener. This husfancs should be done in May or early in June, and if possible in moist weather; having a spot of well-dug and ground prepared, take up the plants with good roots, and plant them in rows six inches distant, and four inches asunder in each row, inferring the roots but moderately into the ground, for if planted too deep, they do not bulb well; giving them a good watering as soon as transplanted. By repeating the waterings occasionally for a week or fortnight, the plants will generally grow freely, and form tolerably handsome bulbs.

Onions for pickling are in great request in many places: such as are proper for this purpose should not be bigger than common round buttons, therefore in order to procure them in due quantity, some feed should be sown late, in a spot of light poor land; about the middle of April is probably the best time. It should be sown moderately thick, the plants requiring little thinning except where they rise in very thick clusters. They bulb in June and July, and are generally fit to take up in August. In the Spring many of the keeping onions will unavoidably grow as they lie in the house; these may be planted out in rows, at six inches distance, and will serve to draw by way of ications.

The Autumn or Michælinus crop, is generally sown in August, and the plants rise before Michælinus; and the Winter, come to be drawn occasionally for use in that season, but principally intended for Spring use, to be drawn up young for fallads, &c. and likewise where the Strauburg or any other variety of the common onion are sown, they, if permitted to stand, bulb to a tolerable size in June, and supply the kitchen or market as headed onions, till those of the Spring crop are bulbed.

But as the common onion is liable to be cut off in severe winters, it is always necessary to sow at the same time some beds of Welsh onions, which bid defiance to the most rigorous Winter frosts. August is the best season for sowing these crops, for if sown sooner they are not only apt to get too far in growth before Winter, but to run up for seed earlier in the Spring; and therefore the proper time to sow the main crop is the first or second week of that month, or in the third week for a late standing one, sowing them in beds four feet wide, with twelve inch alleys between; low and rake in the seed as directed in the Spring crop, only let a much larger quantity be sown in this case. The plants generally appear in a fortnight, and numerous words, to which early attention must be had to clear them out by hand before they begin to spread, so that the plants of this crop are not now to be thinned. But in November and December if they stand very thick, some of the largest may be occasionally thinned out for various uses.

Sowing Seed. February is the proper time to plant onions in this view, though this is often done in October by those that save great quantities for sale. For this purpose, make choice of a due quantity of the largest and handsomest bulbs, rejecting all blemished ones, and such as have already made any effort to grow, and having made choice of a spot of ground well exposed to the sun, which being dug, proceed to plant the onions, in a line, and with a hoe or spade open three drills, twelve inches asunder, and six deep, place the bulbs therein nine inches distant, and rake the earth over them; measure off two feet for an alley, and plant three more rows as above, and in that manner proceed to the end; the wide space of two feet is by way of alley to go between, to hoe and clear off weeds as well as to flake and support the plants as the thinning may be necessary. In June the flower-flanks will be shot to their full height, and the flower heads will be formed at top, to secure which in an erect position, drive some stout flanks in the ground along each row, at two yards distance, and from flake to flake fall double lines of packthread; and if these are tied together in the interval, between the stems of the plants, it will effectually secure them. About the latter end of August the seed will be ripe, which is known by the capsules opening, and the black colour of the seed; the heads should be cut in a dry day and spread upon cloths in the sun, care being taken to remove them under cover in cace of wet and at night; and when perfectly dry, beat or rub out the seed; cleaning it from the rubbish, and putting it up in bags for use.

As it is of the utmost importance to have good fresh seed, some to try its goodness, before they venture their general crop, grow a little in a pot, and place it in a moderate hotbed or near a fire; a more expeditious method however is to tie about a thinmellfull of the seed, loosely in a piece of linen rag, and put it into a vessel of hot water, suspended by a thread; in ten to fifteen or twenty minutes, pull it out, and if the seeds are good, they will, in that time, have germinated or sprouted, perhaps to the extent of a quarter of an inch in length.
As leek-feed is familiar in its nature it may be tried by the name means.

Cibonie or Welsh onion. This is a perennial plant, which never forms any bulb at bottom; therefore deserves to be cultivated only to be drawn as young green onions for falladis, &c. in Spring; but on account of its strong taste it is greatly inferior to those of the common onion. From the plants being so extremely hardy as to survive the severest Winter, in which though their blades be cut off, the roots remain found and shoot forth with great vigour early in Spring, furnishing feomable supplies till May, when they generally run to seed; from this singular hardness they may be cultivated more or less as a winter-standig crop, with advantage, for Spring use. They are perennial in root which increase by off-ssets into great clusters, but not to be propagated thereby for general use, but by seed, the same as the former sorts of onion. The best season for sowing them is August, in the manner of the Autumn onion crops.

The plants mostly appear in twelve or fifteen days after being sown, and towards Michaelmas she should be carefully hand-weeded. It is a peculiarity in this species of onion to lose their tops in November or December, and remain divined thereof till towards Candlemas, when the roots shoot forth again; at that period it is proper to dig the alleys, and spread about an inch depth of the earth evenly over the surface of the beds, by which vigour is given to the roots, and the plants are made to rife strong, and at the same time the part within the earth blanched white and rendered more tender and mild for eating as well as more agreeable. Where the sowing of a Michaelmas crop has been omitted, some have fown seed towards the end of January, when the plants will rife in February or March, and being hardy, continue growing, and be fit for drawing in the early Spring. In order to have plenty of seed of this species of onion, it is necessary to retain some plants for fowls. In the end of March a parcel of strong young plants may be put out nine inches distant, which produce feed in August. If the roots be let remain in the following years they produce treble the quantity; but as they increse into great bunches, the fowls should be removed and separated every second or third year.

Cives or Chives. This is the smallest of all the onion kind, rising but a few inches high; but its roots are perennial, and increse considerably into chuffers, from which large tufts of slender awl-shaped leaves issue, which are the principal part used, the roots never forming any bulb, at least not bigger than small peas. This is a hardy plant which merits a place in every garden; its clusters of leaves rife early in Spring, and are useful both in falladis and for culinary purposes, in default of onions. The method of gathering it is to cut the leaves off near the ground, by which a fresh supply is soon produced from the bottom; or occasionally the plants in clusters may be flapped quite to the root in separate little plants, resembling young onions, and used as subflutes for them. It is easily increased by dividing the roots in Spring, and planting eight or ten of them together in holes at fix inches distance; in this way by Autumn they will multiply into bunches of a large size.

Efscolet, or Shallet. This is a species of onion which is bulbous-rooted, and which increas greatly by off-ssets, the largest of which are the proper parts of the plant for use. The bulbs are oblong, irregular, and seldom grow large; as they generally increse into chuffers they do not swell like roots that grow fingly. From the roots are produced many long, narrow, infirm leaves in the Spring, and which wither in July or August, when the roots are full grown; they are then taken up, made dry and houfed, when they keep in good perfection till the following Spring.

In the propagation of this plant the smaller roots or off-ssets are the best; these may be planted out in Autumn or early in Spring: the end of October, or beginning of November, for the Autumn planting, and February and March for that of the Spring, but not later than the beginning of April. The Spring is the most general season of planting them, but when planted in Autumn, in a dry light soil, they often grow larger, and sooner attain full growth the following Summer; they are to be planted in beds four feet wide, in rows lengthways, the beds six inches asunder; each off-set infested fingly, either by means of a dibble or placed in drills not more than two or three inches deep; and the distance as above in each row. They shoot up in leaves in March or April, and the roots increse in growth till July or August. The only culture which they require is that of keeping them clean from weeds, by occasional hand weeding or hoeing. Towards the end of July or beginning of August the bulbs will have attained their full growth, as is seen by the withering of the leaves. They should then be taken up in a dry day, and spread in the sun to harden; the largest, cleaned and houfed for use, and the smaller off-ssets reserved for propagation.

As shallots are sometimes required early in the Summer time for immediate use, in such cases as will have formed small bulbs towards the latter end of May or in June, a few may occasionally be taken up for present supply; permitting a principal crop to remain in order to attain their full growth.

Canada or Tree Onion. This deserves to be cultivated both as a curiositie in producing the onion at the top of the stalk; and for the use of the onions, especially for pickling, in which they are excellent and superior in flavour to the common onion. It is perennial, and propagated by planting the bulbs in Spring or Autumn; either the root bulbs, or those produced on the top of the stalk, being planted in a bed or beds of any good earth, in rows a foot asunder, fix inches distance in each row, and two or three inches deep; they shoot up leaves and stalks in the Spring and Summer, and produce the bulbs for use in July or August; and the root-bulb remaining, furnish a production of top bulbs, annually in that season; the root-bulb increasing by off-ssets, may be taken up occasionally at the time the stem decays, in Autumn; or once in two or three years, in order to separate the off-ssets and replant them when necessary.

The leek is the third division of the genus, the general characters of which are the same as before described, and the species and varieties are the Porrum or common leek; which may be said to be an annual-biennial plant, for although the roots often survive, after perfecting seeds, yet the plants always attain perfection the same year they are sown, and the year afterwards run up to stalk and become unfit for use. The feed-stalk of this plant does not belly like that of the onion.

The bell of the varieties of this plant for general culture, is the broad-leaved or London leek, which attains a large growth, the neck acquiring a thick substance, in length from fix to nine or ten inches, dividing upwards into many large, long, thick leaves, arranging themselves in somewhat a fang-shape.

The narrow-leaved leek runs up with a long thin neck, and narrow thin fragging leaves, which, as a degenerate variety, does not relieve culture; and the frilled-leaved kind
is retained merely for variety, which may be continued by suckers rising from the old roots.

*Propagation, Culture, &c.* The common leek is raised annually from seed sown in the Spring; the proper time, for the general crop for Autumn and Winter use, is the same as that recommended for the onion, as from the twentieth of February to the end of March; but for later crops to stand for Spring use, any time in April may answer, or for a small crop to stand as late in the following Spring as possible, without running to seed, the beginning of May.

It is a common practice from the notion of making the most of the ground, to see leeks along with the crops of onions; which should not by any means be recommended, as experience has shewn it to be considerably the best culture to keep them separate. It is often practiced by the market gardeners, when intending to call out the onions from time to time for market, to that by a daily thinning, they are mostly all cleared off by the end of July; and those being gone, the same ground remains occupied by a crop of leeks. This method cannot be practiced to equal advantage in the main crops of onions that are to stand to grow to full size for keeping. The best culture, therefore, for the general crops of leeks, is to sow them pretty thick in a spot by themselves to be afterwards transplanted, either wholly or the greater part thinned out regularly and planted; the others being left at good distances for full growth, and the same situation, soil, and method of growing are to be adopted as directed for the onion. In June, July, and August, the plants will be of a proper size for transplanting; in doing which make choice of an open spot of the best ground; if dunged it will be of much advantage, digging in the dung one spade deep; then drawing a parcel of the large leeks, and trimming their tops and the extreme parts of their root fibres, proceed to plant them by line and cliffer in rows, which for the early crop should be twelve inches distant, and eight or nine inches apart in each row; and for better crops nine inches between the rows and six the other way, putting them three or four inches in the ground, or nearly to the length of their necks, and watering them immediately. The only culture they require afterwards is to be kept clear from weeds, which may be done either by hand weeding, or more expeditiously by applying a sharp hoe in a dry season.

The leeks thus cultivated are generally finer than those that remain where sown, their necks, which is the principal excellent part, are much longer, and all the part within the earth is finely whitened and rendered milky and tender, which is a desirable property in this plant. However, when it is intended to raise a crop of leeks in good perfection, to remain where sown till their full growth, the seed should be sown much thinner; and when the plants are somewhat advanced, as in June or July, they should be regularly thinned to about ten or twelve inches distance; those thinned out being planted in another compartment of the garden. The remaining plants will by this means attain a larger and thicker growth below, with large spreading tops of thick fleshy leaves.

This is a valuable family plant from Autumn till Spring, for soups, broth, &c. and for boiling the neck part and top leaves together, to use as greens, in the manner of cololettes, &c. to eat with fish meat. It is in perfection from September till May, when it shoots up to stalk for feeding.

In order to save the seed of this plant, a quantity of the finest plants should be transplanted in February into a sheltered sunny bed or under a south wall, paling hedge, or other fence. This is mostly necessary, as the seeds ripen late in the Autumn, and unless afflicted by such situation and shelter, seldom ripen freely in this climate. In this view it would be of particular advantage to plant some in a row close under a south fence, at ten or twelve inches distance, they will then shoot up their stalks considerably in May; and in June attain two or three feet in height, when they should be supported, and continued in an upright growth. In July the flowers protrude from their sheath at the summit of each stalk, and form a large globular head; and in September the seeds begin to ripen. After this is effected, cut off the heads with a part of the stalk and tie them in small bunches, hanging them across lines in a dry airy apartment, two or three months, when the seed will be hardened, and the capsules readily break by threshing or rubbing, and thus discharge it more readily from the cells in which it is lodged.

**Allium,** dietetic and medical qualities of several species of. The culinary uses of several species of allium are well known; and it is needless particularly to describe them. They are referred by Dr. Cullen to a particular head under the title of *Alienace,* and he considers them more as condiments than as aliments. Of this order the leek and onion are most commonly employed with the last intention, and they afford a large proportion of alimentary matter. In their boiled state, when their acrimony is exhaled, they manifest, with some sweetness, a large proportion of mucilaginous matter; and even in their recent state, and especially when young, their acrimony is not so strong as to prevent their being used among the lower classes as a delicious part of their food. But by those of superior rank, it is the onion only that is taken in its young and recent state; but hardly in larger quantity than may be regarded as a condiment. Deprived, however, of their acrimony by boiling or roasting, they are used by persons of every condition more freely. Nevertheless it is to difficult to deprive them entirely of all peculiar tastes, that many persons, from a particular idiosyncrasy cannot bear them even in a boiled state. The garlic, *runcinante* and *sillole* contain also alimentary matter; and when the garlic in certain warmer climates is produced with less acrimony than it is with us, and of course is much milder both in smell and taste, it is more frequently and more largely employed as a part of diet. As condiments, those of the milder kind, more especially when deprived of their acrimony, are very lafe and proper; and even the more acrid, as garlic, which is almost solely employed as a condiment, serves, if the odour and taste can be admitted, to stimulate the stomah very powerfully, and to promote digestion. As promoting perspiration and urine, all these vegetables are properly joined with our animal food, and may also be jufly reckoned among the antiscorbutics. In the eastern nations, amongst the Jews, ancient and modern, and also in Russia, Hungary, Spain, and France, the several species above enumerated, have been freely used both as aliments and condiments. In Egypt, onions have been from time immemorial a part of their conftant food; they are sweet and soft, and used in their soups, and roasted with their meat, so as to make a dish, called by the Turks *kebab," of which they are very fond. Onion, and particularly garlic, which is more powerful in its effects, by stimulating the stomah favour digestion; and as this stimulus is more readily and quickly diffused through the whole system than that of almost any other known substance, they may be considered as useful condiments, with the food of phlegmatic people, or those whose circulation is languid, and secretions interrupted; but for those who are subject to inflammatory complaints, or where great irritability prevails, their roots, especially in their acid state,
The medical virtues of *A. sativum* or *garlic*, are very various. The whole of the plant possesses similar qualities; but the root, which has a strong pungent odour and a very acrid taste, is the only part employed in medicine. These qualities depend upon a very volatile part, which is readily diffused by digesting, if the roots be bruised and the interior parts be exposed to the air, or by boiling in water. On drying, says Dr. Lewis, the root loses almost nine parts in 15 of its weight, without losing much of its taste or smell; and hence, he says, fix grams dried may be considered as equivalent to 15 grains of the fresh root. Dr. Cullen, however, thinks that the virtue of garlic is not modified by drying, and that it is possible to diffuse it entirely; and he is of opinion, that Dr. Lewis improperly proposes the dried garlic to be used in any proportion as a medicine. The volatile substance of this root is at least in part an effsnial oil, which exudes along with the steam of boiling water; and therefore the garlic should never be boiled either with vinegar or with watery liquors. This oil, which is of a pale yellowish colour, and of a thick, syrupy consistence, may be obtained by distillation; and that of many of the filiqoese plants, it sinks in water. The virtues of the root may more readily and more perfectly be extracted by rarefied spirit of wine, digested upon it when dry, than by either water or vinegar; and with this menstruum the active matter of the garlic does not easily exhale; and nearly the whole of its virtue remains in the infused extract. Both the fresh and dry root give out their virtue to water by warm infusion. A quart of water poured boiling hot upon a pound of the fresh root, cut in slices, and suffered to stand upon it in a close vessel for 12 hours, forms an infusion, which, with a proper quantity of sugar, was the syrup of garlic of the shops; and the oxymel of garlic was prepared by infusing an ounce and a half of the fresh root in half a pint of vinegar, and dissolving in the strained liquor, by the heat of a water-bath, 10 ounces of clarified honey; and in order to cover the ill-smell of the garlic, carraway and fennel seeds bruised, of each two drams, were boiled in the vinegar before the garlic was put into it. But the syrup and oxymel are now expunged from the British Pharmacopoeias. The odour of garlic is extremely penetrating and diffusive; infomuch that when the root is taken into the stomac, the alliaceous scent impregnates the whole sytem, and is diffusible in the various excretions, as in the urine, perspiration and milk. According to Bennett the discharge of stumps and ulcers becomes imbued with this odour very soon after it is taken; and Haller says, that on being applied to the feet, the alliaceous taste has been perceived in the mouth. Garlic has been long in effemination as an expectorant in putrefactive and spasmodic affections, and other pulmonary affections, unattended with inflammation. Dioscorides mentions its use in moderate coughs. Celius employed it mixed with honey in these complaints. Rosenfelsen recommends it to be boiled in milk, and a pint to be taken night and morning. Dr. Cullen allows what has been affented, that even in its external application to the soles of the feet, it has been useful in these diseases. Its utility as a diuretic in dropsies is attested by unquestionable authorities. Dr. Sydenham found some dropsies cured by garlic alone; and as a warm strengthenner it has been serviceable not only in the beginning of dropsies, but for preventing a new accumulation of water after evacuation. Dr. Cullen says, there can be no doubt of the *A. sativum* being a remedy for the scurvy. Dr. Lind also commends it both as a preparative and a cure for this complaint. Its febrifuge power has been experienced in preventing the paroxysms of intermittent;
AL. L

Beggins says, that he has seen even quartans cured by it in many instances. He recommends to begin with a single small bulb morning and evening, and one bulb to be added, till the patient takes four or five at a time. If the fever subside, the dose is to be diminished; and it will be sufficient as the preventive of a return, to take one or two bulbs, morning and evening, for several weeks. Some have held it in great esteem as an antidote to the contagion of pestilential and putrid disorders, whence it received the name of "Theriaca rustica;" and with a view of subduing the plague, it is to be administered in such a quantity as to excite a copious diaphoresis. The virtues ascribed to it of obviating and refilling contagion appear to Dr. Cullen very doubtful; though he allows the probability that, in the plague, which is commonly attended with a lower fever, it may have been useful. Another virtue ascribed to garlic is that of an anthelmintic; for this purpose the common people boil it in milk; and Hoffman confesses it as one of the capital medicines of that class. In calculous disorders it is also said to have been found very beneficial, not only as a diuretic, but as poising a lithotriptic power. The penetrating and diffusive acrimony of garlic renders its external application useful in many disorders, as a rubeficient, and more especially as applied to the soles of the feet, to cause a revulsion from the head and breast; and thus it was successfully practised and recommended by Sydenham, especially in the confluent small-pox about the eighth day. When it occasions pain, as it sometimes does, this, he says, may be relieved by a cataplasm of bread and milk. Dr. Cullen remarks, that though when bruised and applied to the skin it produces inflammation, and frequently vellebrates the part, its effects are not so permanent nor so flow in healing as those of mustard and the other filiqueous; and that it is more capable of absorption, and of extending its action to remote parts. It has, therefore, been variously employed externally in evacuations and cutaneous diseases: and in many infirmities of the feet, particularly of the rheumatic kind, a clove or small bulb of this root, wrapped in gauze or muslin, and introduced into the meatus auditorius, has been found an efficacious remedy. Bergius recommends for this purpose the juice of garlic dropped in cotton. Garlic may be administered in various forms; swallowing the clove entire, after being dipped in oil, is recommended as the most efficacious; or, where this cannot be done, it may be cut into pieces without bruising it, and this may be found equally beneficial, without producing any uneasiness in the stomach. On being beaten up, and formed into pills, the active parts of this medicine soon evaporate.

Several other species of allium, as the A. perrum, A. afcalonum, A. filifolium, and A. feroxoporum, are employed in diet, but hardly in medicine, as their qualities are in a less considerable degree than those that have been already mentioned. In Ramphicata the wild garlic is useful both in medicine and food. It is gathered by the Ruffians and natives, for Winter supply, and formed into a rapt with mustard seeds, and ground into a powder, as a remedy for the scurvy. Pennant in his Tour in 1772, p. 175, says, that an infusion of A. urinum in brandy is esteemed a good remedy for the gravel. The young shoots of A. vineae are eaten in falladas, or boiled as pot-herbs. Lewis, Mat. Med. p. 32. 214. Cullen's Mat. Med. vol. i. p. 272.—429. vol. ii. p. 172.—178. Bergius, Mat. ALLIUM. See Hyacinthus, Hypotis, and Tradescania.

A. L. P. in Biography, a learned divine of the church of England, and an eminent writer, was born in the year 1641, at Alençon in France; and after receiving a liberal education, became minister of the reformed church at Rouen. In this situation he acquired great reputation by his excellent writings on the subject of the Eucharist. From hence he removed to Charenton, which was the resort of the most distinguished protestants in France, and where he had the charge of the principal church belonging to the reformed in that country. Having now an opportunity of essentially serving the protestant cause, he preached several sermons in its defence, which were designed to counteract the attempts of the bishop of Meaux, who was one of its most able opponents. Twelve of these sermons were printed at Rotterdam in 1685, which were highly commended by Bayle, and contributed to increase the reputation of the author. Upon the revocation of the edict of Nantes in 1685, Mr. Allix was obliged to quit France, and to seek an asylum in England. His first object was to acquire a competent knowledge of our language; and in this he succeeded to such a degree, that in 1688, he published a defence of the Christian religion, in a work, entitled, "Reflections upon the Books of the Holy Scripture, to establish the Truth of the Christian Religion," to which he prefixed a dedication to King James II. acknowledging, in very respectful terms, his personal obligations to that prince, and expressing his sympathy and concern for the dispossessed fugitives in general. "I could wish, Sir," says he, towards the close of this dedication, "that this work, which I now present to your Majesty, might be so happy as to pass for a pious protestant character of our acknowledgment; and that it might stand as a faithful record for ever, to perpetuate the memory of that lively measure of your bounty, which is implanted in all our hearts." The author was so well received in this country, that he was soon complimented with the degree of doctor of divinity, to which his character and writings gave him a just claim; and in 1700, he was made treasurer of the church of Salisbury. The learned talents of Dr. Allix were diligently employed in writing several valuable treatises in defence of the reformed religion, which he vindicated both from reason and authority, from the practice of early ages, and also from the precepts of the Gospel; alluding against the church of Rome, which he treated others with the opprobrious name of heretics, she had herself invented new articles of faith. From the defence of religion in general, and of the protestant cause, he proceeded to that of the doctrine of the Trinity against the Unitarians, who maintained that the notion of the divinity of Christ had originated with Julianus Martyr. This work exhibits a great display of Greek and Hebrew literature; and it was intended, not merely to refute the assertions of the Unitarians, but to prove, that the Trinitarian doctrine was held by the ancient Jewish church. At a time when the disingenuous reputation of our author was universally acknowledged, he incurred some raillery and cenfure, particularly on the part of Mr. Bayle, who had before expressed sentiments of the highest respect for his abilities and erudition, by a publication, in which he hazarded a conjecture concerning the second advent of Christ, the period of which, deduced from an erroneous explication of Scripture prophecies, he fixed to the year 1720, or, at the latest, to 1736. His character, however, for eminent talents, indefatigable industry, extensive littera-
...and various services which he had rendered to religion and the reformation, was not depreciated in the estimation of the best judges. Having protracted his useful life, and enjoyed an uncommon share of health and spirits to the 76th year of his age, he died at London, Feb. 21st, 1717; "leaving behind him the reputation of a man equally affiduous in the right discharge of all the offices of public and private life, and every way as amiable for his virtues and social qualities, as venerable for his uprightness and integrity, and famous for his various and profound learning."

Mr. Bayle highly commends the learning, candour, and abilities of Dr. Allix; and in speaking of his sermons he says, "that they contain a thousand beautiful passages, equally strong in sentiment, and delicate in their turn and expression." His works were numerous, and they were written in Latin, French, and English. Those of the first class were "A Dissertation on the first rite of the Trifagium or Doxology," 8vo, Rouen, 1674; "On the Blood of our Lord Jesus Christ," 8vo; "On the Life and Writings of Tertullian," 12mo, Amsterdam, 1701; "On the authority of certain Councils," 8vo. 1680; "Anathasis's twelfth Book of Contemplations on the Six Days Work of the Creation, &c. from the Version and with the Notes of Andrew Dacier, with an expolutorial Preface, &c." 4to, London, 1682; "An historical Preface, as to the Doctrine of Tranubilantiation, to the Determination of Brother John Paris, Jacobin, as to the mode of our Lord's Body existing in the Sacrament of the Altar, &c." 8vo, London, 1686; "Of the two Advents of the Messiah, in as many Difertations against the Jews," 12mo, London 1701; "Nectarius's Confutation of the Pope's Authority in the Church," a translation from the Greek original, printed in 1672 in Moldavia, 8vo, London, 1702; "A Preface to Augustus Herman Francke's Introduction to the Reading of the Holy Scriptures," 8vo, London, 1705; "A Dissertation on the Year and Month of the Nativity of our Lord Jesus Christ," 8vo, London, 1707, and 1710. In French, Dr. Allix published, "An Answer to a Dissertation of Anfelm on Bertram and John Scot," printed at the clofe of Claude's answer to Arnaud, Quevilly, 8vo, 1670; "Ratramn, or Bertrand, the Priest, on the Body and Blood of our Lord," in Latin and French, 12mo, Rouen, 1672; "Twelve Sermons on several Texts," 12mo. Rotterdam, 1685; "The Maxims of a good Christian," Amsterdam, 1687; "St. Paul's Farewell to the Ephesians," 12mo. Amst. 1688; "Preparations for the Lord's Supper," 8vo, often printed at Geneva. In English we have by Dr. Allix, "Reflections upon the Books of the Holy Scripture, to prove the Truth of the Christian Religion," 2 vols. 8vo, London, 1688; "Some Remarks upon the Ecclesiastical History of the Ancient Churches of Piedmont," 4to. London, 1690; in answer to the "History of the Variations of the Protestants in Matters of Faith," by the bishop of Meaux, which was penned to facilitate the design of Lewis XIV. to oblige all his subjects to be, or seem to be, of one faith; "Reflections upon the Ecclesiastical History of the Ancient Churches of the Albigenes," 4to. London, 1692; "The Judgment of the Ancient Jewish Church, against the Unitarians in the Controversy upon the Holy Trinity, and the divinity of our Blessed Saviour," 8vo. London, 1689; "Preface and Arguments on the Psalms," in which the author disapproves of the notion of a double completion of the prophecies contained in them; "The Prophecies which Mr. Whilton applies to the times immediately following the appearance of the Messiah, considered and examined," 8vo. London, 1707; "Remarks upon some Places of Mr. Whilton's Books, either printed or in MS." 8vo. London, 1711. Digg. Brit.

ALLOA, or Alloway, in Geography, a sea-port town of Scotland, situated in the Frith of Forth, about 10 miles above Leith, and five miles east of Stirling. The town is populous, has two market days in the week, and is remarkable for its fine castle, the seat of the Earl of Mar, and for its adjacent coal-mines. The harbour is commodious, having a good depth of water for ships of burden, and vessels are expeditiously loaded with coal, conveyed from the pits by a waggon-way in carriages of such caily draught, that one James may draw three waggons, each containing one ton and an half. A dry dock has lately been erected, and there is a glass-house in the town, from which any quantity of bottles may be supplied at the shortest notice.

The Frith at this town first becomes a copious and navigable river. N. lat. 56° 10'. W. long. 3° 45'. The tower and lands of Alloa were exchanged by David king of Scots in 1355, with Thomas Lord Erkline, for the lands and estate of Strathgarnay, in Perthshire, and since that time the castle has been the residence of the family of Mar. The situation is beautiful, and the gardens, containing about 40 acres, were laid out under the direction of Le Nature, and the plantation was begun in 1706. The tower of Alloa is 89 feet high, its walls are 12 feet thick, and it was built towards the close of the 15th century. The laft heir of the Scots monarchy, who was nurtured here, was Henry prince of Wales; of whom some youthful relics are preserved, as is also the private signet of the unfortunate Mary, after she was obliged, by the treaty of Edinburgh, to yield from wearing the arms of England in the first quarter, the chair of James VI. her son, and the selle chair of Thomas Lord Erkline, the second earl of Mar of that name, with an inscription:

"Soli deo honor et gloria."

ALLOBROGES, in Ancient Geography, the inhabitants of that part of Gallia Narbonensis, which was situated between the rivers Ifara to the south, and Rhodanum to the north, and the lacus Lemanus, comprehending a great part of the countries since known by the names of Savoy, Dauphine, and Piedmont. Polybius, Plutarch, Dion, and Appian write their name, Allobreges, and Ptolemy and Stephan. Dyz. Allobroges; but the true orthography, establishe by two inscriptions, is Allobrogia. Their metropolis was Allobroges, in Vien- na. The Allobroges were inferior, neither in strength nor riches, to any of the inhabitants of Gaul. When Hannibal passed the Rhine into their country, he found two brothers contending for the crown, and took part with the elder. This people, whose country bordered on that of the Salyes, and with whom they were in amity, were dispofed to succour them against C. Sextius Calvinus, who had overcome Tectomolius, their king. But after Domitius had, during his consulis, settled the country of the Salyes in peace, a work which had been happily begun by Sextius, three years before, the Allobroges, being uneasy at the settlement of the Romans in their neighbourhood, prepared to make an attack upon the Roman colony at Aquae Sextiae. Domitian, in order to prevent the Arverni, a powerful people, from joining the Allobroges, formed an alliance with the Eedu, one of the most considerable nations in Transalpine Gaul. In confederation of this con-
and the Roman general took occasion, from this circumstance, to force a passage into the country of the Arverni, whose king sent a deputation to the general, attended by a number of large dogs, and a bard or priest, who chanted the praises of his king, the people, and the ambassador. The envoy, after being received with respect by Domitius, assuming an imperious air, commanded him, in the name of his master, to forbear modelling the Allobroges, and immediately to retire from Gaul. Domitius, unmindful of this address, gave orders for his troops to march into the fruitful plains of the Cavari, in the neighbourhood of the present Avignon. Whilst he was encamped near a village, called Vindalia, he was attacked by the Allobroges; but they were easily routed by his regular and well disciplined troops. We are told that 20,000 Gauls were killed on the spot, and 3,000 made prisoners of war. The Allobroges, after this defeat, and another victory gained by Fabius Maximus over the Arverni, submitted; and so important was this event deemed at Rome, that Fabius took from this occasion the surname of Allobroges. At length the Romans made themselves masters of their whole country. Cicero, (Catil. iii.) commends the Allobroges for their fidelity; but Horace (Epod. xvi.) reproaches them, on account of their fondness for novelty:

“Novisque rebus infidelis Allobroges.”

**Allocation, Allocatio,** the admitting or allowing of an article in an account; and palling it as such. Allocation is also an allowance made upon an account; used in the exchequer. Hence,

**ALLOCATIONE facienda,** a writ directed to the lord-treasurer and barons of the exchequer, upon the complaint of some accountant; commanding him to allow him such sums as he hath in execution of his office lawfully expended.

**ALLOCATÓ comitatus,** is a new writ of exigent allowed, before any other county-court holden, when the former has not been fully served, or complied with, &c. Fitz. Exig. 14.

**Allocation.** See Adlocution.

**Alodial, in Ancient Customs.** See Alodium. Alodial tenure of lands, in Agriculture, a sort of free tenure still existing in some parts of Scotland, under which the tenant is not required either to pay any quit-rent, or acknowledge a superior.

**Alodialiarius,** the owner or proprietor of an alodium, or alodial lands; also used to denote a lord paramount of a manor.

This is otherwise written abdarius, abdarius, abarius, aber, abarius, and aladier.

**Alodium, or Aluev,** land held by a man’s own right, without acknowledgment of service, or payment of any new rent to another; and this is property in the highest degree; but feu-doom or feu-doom, is such land as is held of another for which service is done, or rent is paid, as an acknowledgment thereof. When the barbarous nations over-run Europe, and settled in the countries which they had subdued, in the fifth and sixth centuries, the victorious troops divided the conquered lands. The portion which fell to every soldier was seized by him as a recompence due to his valour, as a settlement acquired by his own sword. He took possession of it as a freeman in full property. He enjoyed it during his own life, and could dispose of it at pleasure, or transmit it as an inheritance to his children. Thus property in land became fixed. It was at the same time alodial; i.e. the possessor had the entire right of property and dominion; he held of no sovereign or superior lord, to whom he was bound to do homage, and perform service. How it afterwards was converted into feudal possession, will appear under the articles Beneficium, Feud, and Feudal System.

In several parts of Europe this change had taken place, or alodial property had become almost entirely feudal, before the beginning of the 12th century. The former species of property seems to be so much better and more definable than the latter, that such a change seems surprising, especially when we consider that the alodial property was frequently surrendered, by voluntary deed of the possessor. The motives which led to a choice so repugnant to modern ideas concerning property have been investigated and explained, with his usual discernment and accuracy, by Montesquieu in his Spirit of Laws, lib. xxxi. c. 8. vol. ii. Thoese who were seized of it, says this writer, (p. 431.) enjoyed very great advantages. The composition for the injuries done them was greater than that of freemen. It was a privilege belonging to the king’s vaifer, established by the Salic law, and by that of the Riparians, that whoever killed him should pay a composition of 600 sous; whereas they gave but 200 for the murder of a person freeborn, if he was a Frank or Barbarian living under the Salic law, and only 100 for a Roman. Besides, when a man was summoned in court, and did not make his appearance, nor obey the judge’s orders, he was appealed before the king; and if he perjured in his contumacy, he was excluded from the king’s protection, and no one was allowed to entertain him, or even to give him a morsel of bread. If he was a person of an ordinary condition, his goods were confiscately surveyed and sold, by a voluntary deed of the owner. The first by his contumacy was deemed sufficiently convicted of the crime, the second was not; the former for the smallest crimes was obliged to undergo the trial by hoiling water; the latter was condemned to this trial only in the case of murder. Moreover, the king’s vassals could not be compelled to swear in court against another vassal. These privileges augmented daily, and the capitation of Charlemagne does this honour to the king’s vassals, that they shall not be obliged to swear in person, but only by the mouth of their own vassals. When a person who had these honours did not repair to the army, his punishment was to abstain from flesh-meat and wine, as long as he had been absent from the service; but a Freeman who neglected to follow his count, paid a composition of 60 sous, and was reduced to slavery till he paid it. When these several circumstances are considered, it is natural to think that these Franks who were not the king’s vassals, and much more the Romans, became fond of entering into the state of vassalage; and that they might not be deprived of their domains, they devised the usage of giving their alodium to the king, and of receiving it from him afterwards as a fief, and of nominating to him their heirs. This usage was always continued, and took place especially during the different orders of the second race, when every body flocked in need of a protector, and wanted to incorporate himself with the other lords, and to enter, as it were, into the feudal monarchy, because the political no longer existed. This continued under the third race, as we find by several charters; whether they gave their alodium and refumed it by the same act; or whether it was declared an alodium, and afterwards acknowledged as a fief. These fees were called fiefs of reversion.
In those times of anarchy and disorder, which became
general in Europe after the death of Charlemagne, it
became necessary for every man to have a powerful protector,
under whose banner he might range himself, and obtain
security against enemies whom he could not tingly oppose.
For this reason he relinquished his allodial independence,
and subjected himself to the feudal services, that he might
find safety under the patronage of some respectable superi-
or. In some parts of Europe this change from allodial to
feudal property became so general, that he who possessed
land had no longer any liberty of choice left. He was
obliged to recognize some liege lord, and to hold of him.
Upon this principle was formed the maxim, which, at
length, became general in the law of France, "Nulle terre
sans seigneur." During the 9th, 10th, and great part of
the 11th century, the property in the province of Languedoc
feems to have been entirely allodial; and during these
centuries, the state of property seems to have been alike
in Catalonia and the country of Rouffillon. In the Low
Countries allodial property continued to a later period; for
during the 11th, 12th, and 13th centuries, this species of
property appears to have been of considerable extent. Some
vestiges of it appear there as late as the 14th century.
It appears also by several facts, that allodial property subsisted
in different parts of Europe long after the introduction of
feudal tenures. Whilst some persons were fond of relin-
quishing this kind of property, in order to hold it by feudal
tenure, others were licentious to convert their fiefs into
allodial property; of which instances occur in a charter of
Louis le Debonnaire, again in 1299, and fo late as the year
1337.

In Italy, allodial property continued longer in estimation
than in France. Many of the charters granted by the
emperors in the 9th century, conveyed an allodial right to
land. But in the 11th century, there are found examples of
persons who resigned their allodial property, and received
it back as a feudal tenure. In Germany, the imperial vassals
did not aspire so early to independence as in France, nor
did they so soon obtain the privilege of obtaining their be-
nefices by hereditary right. Conrad II. or the Salic, who
began his reign A. D. 1024, is said to have been the first
emperor who rendered fiefs hereditary. In Germany, as
well as in France and Italy, a considerable part of the lands
continued to be allodial long after the feudal mode of tenure
was introduced. Robertson's Charles V. vol. I. p. 255.

Hume's Hist. vol. II. p. 106. 8vo.

All the lands in England, except the crown-lands in the
king's own hands, in right of his crown, are of the nature of
feudum, or fee; for although many have lands by
defect from their ancestors, and others have bought land,
but cannot come to any either by defect or purchase, but
with the burden that was laid upon him who had novelty
or firet of all received it from his lord; fo that there is no
peron hath directum dominium, i. e. the very property
or demesne in any lands, but the king in right of his
crown.

The origin of the word is controverted. Caffeneve says,
it is almost as obscure as the head of the Nile. There are
few of the European languages, from which one etymo-
logist or other has not derived it; yet some, not im-
probably, take it for a primitive French word without
cymon.

Wachter (Glosar,Germanic voc. Allodium) makes it a com-
 pound of the German particle au and lot, i. e. land obtained
by lot; and it appears from the authorities cited by him, and

by Du Cange (voc. fort) that the northern nations divided
the lands which they conquered in this manner.

Bollandus explains allodium, to be præxium, seu quavis
poffessio libera, jurisprue propriis, & non in feudam clientelari
once accepta.

After the conquest of the Gauls, the lands were divided
in two ways: viz. into benefices, beneficia; and alodium.—
Beneffes confeimed in lands given by the king to his officers
and fidders; either for life, or for a time fixed. See Be-
neficia. Allodium.

Allodium, or alodium, were such lands as were left in prop-
erty to the ancient possessors; fo that land possessed in prop-
erty, which is mentioned in the law of Charlemagne, was,
according to the title of that age, allodial land; alodice
and proprietas, allodium and proprium being terms perfectly
ynonymou. The clearest proof of the distinction between
allodial and benefiary possession is contained in two charters,
published by Murafood, by which it appears that a person
might posfeff one part of his estate as alodial, while he
could dispose of at pleasure, the other as a benefice, of
which he had only the usufruct, the property returning to
the superior lord on his demise. Antiq. Ital. medi. xvi. vol. I.
p. 559. 565. The fame distinction is pointed out in a cap-
p. 491. In the curious testament of Count Everard, who
married a daughter of Louis le Debonnaire, by which he
disposed of his estate among his children, he distinguishes
between what he posfeffed proprietas, and what he held
beneficia, and it appears that the greater part was alodial.
p. 258.

The sixty-second title of the Salic law, is de allodium;
where the word signifies hereditary lands, or those derived
from a man's ancestors. Whence allodium and patrimonium
are frequently used indiscriminately.

In the ancient capitulars of Charlemagne, and his suc-
ceffors, we find allodium constantly opposed to fee; but, to-
ward the period of the second race of kings, it loft the
prerogative; the feudal lords obliged the proprietors of
allodial lands to hold of them for the future. The fame
change also happened in Germany, &c.

In the confummary laws of France, we find mention made
of two kinds of allodium, viz.

Allodium noble, alio noble, to which jusficia or jurifdiiction was annexed; and which was alfo free from all
homage and service.

Allodium villanum, alio raturier, to that which no jurif-
diction was annexed.

ALLOGIA, in Antiquity, denote winter-quarters ap-
pointed for the folidary.

Some will have the word of French origin, from lagement;
others, with more probability, from the Italian allaggio,
formed of loco, plate.

ALLOISI, Bialdare, called Galaino, in Bio-
graphy, an eminent painter, was born at Bologna, in 1758,
and educated in the celebrated school of the Carace, whose
style he retained in all his compositions. Being of a me-
ancholy disposition and fond of retirement, he devoted him-
sfelf to the study of his art; but by his attachment to foot-
tude, he became fo indigent as to be under a neceffity of
procuring a subsittance by painting portraits. In this de-
partment of his profession he excelled to fuch a degree, as
to gain very high efteem, not only for striking refemblance,
and the beauty of his colouring, but for a new and unufual
tolfeis
boldness of manner, by which his portraits seemed absolutely to breathe. He was allowed to be superior to all his contemporaries; and the Italian writers place him in the same rank of merit with Vanderlyn. As an engraver, Mr. Strutt mentions one print done by him, which is a copy of Guido’s beautiful etching from Ammi. Caracci, where, “St. Rock is giving charity to the poor!” but the copy, he says, is far inferior to the original. He died in 1638. Pilkington and Strutt.

**ALLOM.** See **ALUM.**

**ALLONGE.** In **Fencing,** a thrust, or pass at the enemy. The word is French, formed of the verb, allonger, to lengthen out a thing.

**ALLOPHILY,** denoting Strangers, in **Ancient Geography,** a name given by Sulpicius Severus, and also in the Septuagint, to the Philistines.

**ALLOPHYLUS,** in Botany, a genus of the olindria monogynia class and order, and of the natural order of guthieres, Jull.; the characters of which are, that the calyx is a four-leafed perianthium, leaflets orbiculate, exterior, opposite, letter by letter; the corolla has four petals, less than the calyx, orbiculate, equal, claws broad, of the length of the two smaller leaves of the calyx; the filaments consist of filaments of the length of the corolla, anthers roundish; the pistillum has a germ superior, roundish, twin, style filiform, longer than the filaments, stigma bifid, with the divisions rolled back, quadrifid (Linn. Syll.). N. B. The flowers of Rhus Comina and Cobbe agree with the character of this genus; and Aperature of Forlir should be referred to it. Swartz. Martyn enumerates five, and Gmelin in his system of Linnæus three species. 1. A. cylindrica, with leaves oval acuminate quite entire, racemes axillary, very short. This is a tree having the appearance of Persea, and a native of Ceylon; its fruit is yet unknown. 2. A. rigida, with leaves simple, decurrent and spinous, and flowers in racemes. 3. A. racemosa, with leaves ternate, flowers in racemes. These and the last species are natives of Hispaniola. 4. A. comina, Rhus comina of Linnæus, &c. Rhus comina of Brown, and toxicodendron arborescens of Tournefort, has leaves ternate, and flowers in panicles, rises 50 feet in height, with a stem of the thickness of a man’s thigh, and smooth athercoloured bark, with numerous white yellow flowers, to which succed finally orange-coloured, smooth berries, about the size of a pin’s head, with a brittle shell and large kernel, and grows plentifully in Jamaica. It was introduced into Kew Garden in 1778, by Dr. Clark. 5. A. ternatus, with leaves ternate, ferrate, and racemes long terminating, is a shrub five feet high with spreading branches, and small white flowers with hairy petals, and a coryza of four glands, and bifid style. It is a native of Cochinchina, by the banks of rivers; and the inhabitants use the leaves as a catapult in contumaces.

**ALLORI,** Alessandro, called **BRONZINO,** in Biography, a painter of history and portrait, was born at Florence in 1535, and was the disciple of Agnolo Bronzino, who, by his affectionate attention, supplied the place of his father, whom he lost when he was five years old. He was industrious in his application, and imitated the manner not only of his master, but the different manners of other most eminent masters. His first work was a crucifixion, intended for an altar-piece, conflating a variety of figures well-grouped, beautifully coloured, and distingugished by good expression. In painting portraits he was much encouraged, and devoted much of his time to this branch of his profession. His picture of the “Laft Judgment,” after the manner of Michael Angelo Buonarotti, whose works he studied with peculiar attention and pleasure, is still preferred at Rome, and will perpetuate his honour. He died in 1627. Pilkington.

**ALLORI, CHRISTOFARO,** called **BRONZINO,** the fon and disciple of the former, was born at Florence in 1577; and having studied design from the works of Santi di Titi, and colouring from the lively and elegant tints of Cigoli, he acquired a manner very different from that of his father, which he first followed. He executed several designs for altars; but he excelled in small pictures, into which he introduced a number of minute figures, so correctly drawn, so round and relieved by the colouring, and so delicately touched, that it was surprising how the hand or eye could execute them. His portraits, as large as life, were highly valued for the expression and the attitude. Pilkington.

**ALLORIA,** in **Ancient Geography,** a town of Crete. Steph. Byz.

**ALLOS,** in Geography, a town of France, in the department of the Lower Alps, and district of Barcelonette, four miles north of Colmar and nine south of Barcelonette.

**ALLOSYGNE,** in **Ancient Geography,** a sea-port town of India, on this side the Ganges.

**ALLOTRIGAE, or ALITRIGAE,** a people placed by Strabo in the northern part of Spain, and probably the same with the Allograe of Ptolemy, and Antilograe of Pliny.

**ALLOTING,** or **ALLOTMENT** of goods, in matters of Commerce, is when a ship’s cargo is divided into several parts, bought by divers persons, whose names are written on as many pieces of paper, which are applied by an indifferent person to the several lots or parcels; by which means the goods are divided without partiality; every man having the parcel to which the lot with his name upon it is appropriated. See **INCH OF CANDLE.**

**ALLOTMENTS** of lands, in Agriculture, are such portions of ground as are allotted to claimants on the division and inclosure of commons or other waste lands, and which are generally proportionate to the extent of the right which they enjoy upon them, from the possession of lands, tenements, &c. in the same parish in which they are placed.

**ALLOUE,** in Geography, a town of France in the department of the Charente, and district of Confolent, on the Charente, two leagues west of Confolent.

**ALLOVIA,** in Botany, a species of **MARANTA.**

**ALLOW,** a river of England in Northumberland, which runs into the Tyne, between Hexham and Newcastle.

**ALLOWANCE** of Franchise, in Law. See **FRANCHISE.**

**Allowance of Pardon.** See **PARDON.**

**Allowance of Writs of Error.** See **ERROR** and **JUDGMENT.**

**Allowance to Bankruptcy.** See **BANKRUPT.**

**ALLOWAY Creek,** in Geography, a creek of America, in the county of Salem, and State of New Jersey, which empties itself into the Delaware. It is navigable 16 miles, with the interruption of drawbridges.

**ALLOY** of **ALLY,** Alligation, Fr.—**Legieren Metallverleihung,** Germ.—**Legno,** Ital.

The true origin of this word is probably derived through the medium of the French, from the Latin adligatio, signifying the act of tying, or binding, or connecting together; since, however, the term was formerly almost wholly confined, in England, to the goldsmiths and the mint, where it was
was appropriated to the lowering the purity of gold or silver by mixture with copper, previously to its being coined or manufactured, it seems gradually to have assumed the orthography and meaning of the English verb to alloy, i.e. to abate, to lower. All the other known combinations of metals with each other were simply called mixed metals. But as increased attention has been paid to the accuracy of chemical Nomenclature, the term alloy has at length comprised all the binary and more complicated metallic compounds, for which mercury makes a part, being indeed more generally known by the name amalgam.

An alloy, therefore, may be defined, a combination of any two or more metals, into one homogeneous mass; to the express exclusion of mere mechanical mixtures, which, however, in some cases, are not easily distinguished from genuine alloys. The most valuable and useful of these have acquired peculiar names, such as brass, type-metal, tutenag, bronze, speculum-metal, &c. all of which will be described in their proper places hereafter; the object in this article being confined to the statement of such general facts and inferences as are deducible from a comparison with each other of those experiments on the combinations of metals that have been made with sufficient accuracy, the number of which is unfortunately very small.

As no metal, except mercury, is fluid at the common atmospheric temperature, and as without the fluidity of one at least of the ingredients, no metallic combinations can take place, it is necessary to expel the materials in a crucible, or other proper vessel, to a heat somewhat greater than is required for the liquefaction of their most fusible part; but as this diminution of cohesion is equally favourable to intimate mixture as to chemical combination, and since all tendency to separation ceases, the very moment of the congelation of the mass, it is not doubt often happens that these two circumstances are confounded together, and thus cause many of the anomalies and peculiar difficulties with which the subject is encumbered.

The method that is given in most chemical books for ascertaining whether a mass of metal is a real alloy, or only a mechanical mixture, consists in fusing it with as little heat as possible, and keeping it in this state till its component parts separate from each other, like oil from water, according to their respective specific gravities; and perhaps there is upon the whole no other way equally simple and practicable of effecting this; at the same time that it is liable to a number of errors. In the first place, when experimenting at high temperatures, it is very difficult and indeed impossible to preserve an equal degree of heat through the process, and it is highly probable that a metallic combination may take place at a mere melting heat, which is decomposed by a higher one, or vice versa.

If this may happen in alloys that consist of only two materials, it is still more likely to do so when three or a still greater number of metals are united into one mass. Thus, if an alloy made of one part zinc and two parts of mercury be mixed with another of one part bismuth and one mercury, the whole may be fused together by a heat just sufficient to make them flow, may be kept in fusion for a considerable time, and then poured into a melting cone without any separation of the constituent parts; but when the alloy is heated so as to make the mercury boil, the greater part of the zinc immediately rises to the surface and separates, owing to the destruction of the equilibrium between the antagonistic affinities, by the presence of a certain quantity of caloric.

Again, supposing no change in the affinities to take place, if the mixed metals are nearly of the same fusibility and specific gravity, a spontaneous separation by fusion is scarcely to be expected: so also, if they differ in these two particulars, and the metal of least fusibility is of the greatest specific gravity, as in an alloy of copper and lead, where the two parts are in equal proportions, the first effect of the heat will be the separation of part of the lead before the mass enters into fusion, this will occupy the bottom of the crucible, and the fusibility of the alloy decreasing by the gradual separation of the lead, a temperature nearly equal to the melting point of copper will be required to bring the whole mass into a fluid state; when this is effected, the lead receiving the first impulsion of the heat as it enters the crucible from below, being also covered with melted copper, will be made to boil, and in consequence will be continually thrown up into the copper notwithstanding its superior specific gravity.

The only way, therefore, of determining with certainty the difference between an alloy and a mere mixture, is by a comparison of the properties of the compound with those of its elements, if which, if they are not intermediate, nor caused by mere mechanical action on each other, may be received as adequate evidence of a proper chemical union. Here, however, a number of difficulties and doubts, as yet wholly uninvestigated and incapable of being resolved by common cures of analysis, require examination.

If two metals being fused together produce a mass, whose specific gravity is either greater or less than the mean specific gravity of its elements, the result is said to be an alloy, or proper chemical combination. How few however, if any experiments for the purpose of ascertaining this have been made with sufficient care? It is not enough that the specific gravity of each of the simple metals should be taken and compared with that of the alloy; but they ought to have been previously melted by themselves, and cooled in the same circumstances to which the alloy was afterwards to be exposed. For example, if a piece of an alloy to be made of copper and gold, equal parts; the copper to have been cut off from a piece of hard wire, and the gold to have been laminated, the specific gravity of the first will be nearly 8.97 and of the latter 19.35; the two metals being thoroughly mixed by fusion, and either left to cool in the crucible or poured into a melting cone, are then weighed in the hydrostatic balance, and the difference or agreement between the specific gravity of the alloy and the mean gravity of the materials, is considered as a fair ground of inference for the reality of chemical combination, or the contrary. But the specific gravity of copper cooled slowly and not wiredrawn is only 7.78, and that of gold in the same circumstances 19.25; now the alloy is precisely in this state, having been merely melted and cooled gradually; if therefore no chemical combination whatever had taken place, yet the specific gravity of the alloy, instead of being = 14.11, as deduced by calculation from that of the materials, would be = 13.51, merely from the circumstance of slow cooling without compression. By cooling a malleable metal suddenly, as by pouring it into cold water, it becomes hard, and in some degree brittle, resembling in this respect a piece of the same metal that has been laminated without subsequent annealing; the specific gravity of the laminated metal is increased, and probably the same effect is produced by the sudden cooling; thus a great seeming change in specific gravity may exist where there is none in fact. Besides, it is possible that a real alteration of specific gravity may appear in a mixture of two metals, which, instead of being an evidence of chemical combination shall be merely the effect of the hardnefs and tenacity of one of them. It is well known that all metals expand by heat, and alter their dimensions when passing from
the fluid to the solid state. Let $A$ then be a binary mixture of three parts $A$, and one $B$; $A$ is the least fusible of the two and contracts least in cooling; it will necessarily happen therefore, upon the supposition that no chemical affinity subsists between them, that they are well mixed by fusion and then allowed to cool, $A$ will harden first, and by its excess in quantity will entirely envelope all the melted particles of $B$ with a crust impenetrable to the air, and capable of supporting the whole atmospheric pressure; afterwards $B$ will become solid and contract, leaving part of the cell which it occupied while fluid, a perfect vacuum, at the same time that those pores may easily be invisible even to common magnifiers; hence the result will be a mixture of less than the mean specific gravity.

The change that takes place in the ductility of metals when mixed together is generally brought forwards as one of the most striking proofs of chemical combination; even here, however, difficulties occur that have not yet been explained. Macquer lays it down as a constant fact that alloys are less ductile than the metals of which they are composed, and Gellert in his Chémie Metallurgique infers, that the mixture of gold with silver is not a true alloy on account of its perfect ductility; from the want of accurate experiments it is perhaps impossible at present to determine the question; but, so far from the position of Macquer and Gellert being universally true, the general result of the facts which have been heretofore ascertained, if rightly understood, seems to render the direct reverse highly probable; and that the brittleness of alloys from ductile materials is in all cases a proof of supersaturation, or of mere mechanical mixture. When to any quantity of pure copper one third of zinc is added, the alloy called brass is produced; and that this is a chemical combination between the two metals may be inferred from the remarkable change of colour and fusibility of the mafs; the ductility however of brass is fully equal to that of copper. But if the proportion of zinc is increased to an equality with the copper, the colour of the alloy, instead of being yellow like gold, will be nearly a medium between that of brass and of zinc, and its ductility will be destroyed; thus flowing, that the point of mutual saturation of these metals is between one third and a half of zinc to two thirds and a half of copper, and also that brass has little or no affinity with zinc. The ductility of any metal depends on the strong cohesive attraction of its particles, which slide upon each other when impressed by any external force instead of separating; now it may readily be conceived that two ductile metals being intimately mixed to as every particle of the one is in contact with a particle of the other, provided no very powerful affinity subsists between them, may be broken by a blow which would only have slightly altered the relative position of homogeneous cohering particles; and therefore, that a brittle mixture of two ductile metals does not necessarily infer a chemical combination between them.

Change of colour, in the few cases in which it occurs, provided it is not intermediate between those of the elements of any alloy, may be considered as a very probable evidence of chemical union; of this kind is the golden colour of brass, and the silvery white of arsenicated copper. But the general similarity of colour between all the white metals and their alloys, confines the application of this external character to a very few instances.

One of the most striking proofs of actual combination between the parts of an alloy, or at least what is the most difficult of explanation upon the theory of mere mechanical mixture, is a remarkable increase of fusibility; this, in almost all cases, is much greater than could be inferred from the mean fusibility of its component parts; thus equal parts of tin and iron will melt at the same temperature as is required for equal parts of tin and copper, or bronze, notwithstanding the great difference between the fusing heat of copper and iron, when they are each of them pure. So also an alloy of tin, bismuth and lead, will melt in boiling water, which is a less heat than is necessary for the liquefaction even of bismuth, the most fusible of the three.

The oxydableness of an alloy is generally either greater or less than that of the simple metals. Tin and lead for instance being mixed together and exposed to a low red heat take fire and oxidate almost incessantly.

Elective affinity takes place in the combinations of metals, as in those of all other substances; thus an alloy of copper and silver is decomposable by lead. Again certain metals refuse supersaturation, while others may be mixed in almost all proportions, as cobalt may be combined with a certain proportion of lead, but cannot even be mixed with a larger quantity. These enquiries, however, though highly interesting and intimately connected with many of the useful arts, have been almost wholly neglected during the last fifty years; and the experiments of Gellert, Kraft and Lewis, still continue to be our only authorities. Many peculiar difficulties attend the investigation of the general principles, according to which metals act on each other, and the general phenomena necessarily attending such action; it is a subject that may demand the abilities, and will recom pense the attention, of the greatest and most accurate philosophers, and which unfortunately has hitherto received less notice than any other branch of chemical enquiry.

**Alloy of coinage.** See Assay.

**ALL-SAINTS,** in Geography. See All-Saints.

**ALL-SEED,** in Botany. See Linum and Chenopodium.

**ALL-SPICE.** See Myrtus.

**ALLSTADT,** or Allstatt, in Geography, a very ancient town of Germany, in the circle of Upper Saxony, and principality of Eifenach; 26 miles north of Weimar, and five south-south-east of Sangerhausen. The emperor Ortho had a palace in this town, and held a diet here in 974. It belongs to a bailiwick of the same name, lying between that of Sangerhausen in the electorate of Saxony, the principality of Querfurt, and the bailiwick of Bocklode, in the county of Mansfeld.

**ALLUDSJE,** a town of Arabia, 14 miles east-north-east of Beitel Fakili.

**ALLUM.** See Alum.

**ALLUMBADDY,** in Geography, a town of Hindoostan, in the country of the Mylore, 63 miles east of Sringapatam, and 50 south of Bangalore.

**ALLUM BAY,** lies round the Needles point, or north east from the rocks for a mile, at the west end of the Isle of Wight, on the coast of Hampshire. It has good anchorage, and a sufficient depth of water, not far from the bottom of the bay, and out of the strong run of the tide, which is frequently very rapid, and accelerates or retards the motion of a vessel, as a ship fails with or against its direction, to an astonishing degree.

**ALLUMETÆ,** Fr., in Heraldry, a term applied to the eyes of a bear, or other beast, when they are drawn sparkling and red.
AIL.

ADUMETE, in Ancient Geography, the name of an ancient people of Arabia Felix.

ADUMINOR, from the French allunor, to lighten, is used for one who coloureth or pav'tach upon paper or parchment; and the reason is, because he gives light and ornament to his colours to the letters, or other figures. Such ornaments are styled illuminations. The word is used in Pat. Rich. III. cap. 9. But now such a person is called a limner.

ADUMINOUS, any thing that contains allum, or partakes of the nature and qualities of that salt.

Grew describes some extraordinary kinds of alluminous earths in the repository of the Royal Society.

ADUMNOUS waters, are those impregnated with the particles of that salt.

Alluminous waters make a species of those called mineral or medicinal waters.

We have also factitious waters, under the denomination of alluminous; such as called in the shops aqua alluminosa macleris.

Its preparation is thus: take of rock-allum, and white sublimate, ana 5 ii. boil them in robe and plantain water, and half is consumed; filter the remainder, and keep it for use.

This is prescribed against deformities of the skin, and often for the itch; but it is an uncertain remedy, and not to be used without caution.

ADUSSH, or ALLUS, in Scripture Geography, a city of Idumea, which was one of the stations of the Israelites, between Dophkah and Rephidim, in their migration from the wilderens of Sin to that of Sinai. Numbers, xxxiii. 13, 14. Eucl. and St. Jerom fix Allush near Gabala, i. e. Petra, the capital of Arabia Petraea. In the accounts of the empire, it is situated in the third Palestine, and by Pтолемy among the cities of Idumea. It is also called Eluza or Chalnua. The Jerusalem Targum, in Gen. xxv. 18. and in Exod. xvi. 22. translates the defect of Seir by Allush. Calmet.

ADUSSION, or ALLUSIO, formed of ad, and ludere, to play, in Rhetorics, a figure whereby something is applied to, or subtrahio of another, by renunt of some similitude of name, or found.

Camden defines allusion a dalliance, or playing with words alike in found, but unlike in sense; by changing, adding, or subtrahio a letter, or two; whence words resembling one another become applicable to different subjects. Thus the Almighty, if we may use sacred authority, changed Abram, i. e. high father, into Abraham, i. e. father of many. Thus the Romans played on their tipping emperor Tiberius Nero, by calling him Biberius Nero; and thus in Quinphilian the four fellow Placidus is called Acidus.

Allusion is a species of Comparison, not extending to a Simile, and confining chiefly in comparing one fact with another. The most fanciful and poetical is, when two facts, bearing a remote remembrance in a few circumstances, are compared; of which we have a beautiful example in one of Dr. Ogden's femons. "If it be the obscure, the minute, the ceremonial parts of religion for which we are contending, though the triumph be empty, the dispute is dangerous; like the men of Al we pursue, perhaps, some little party that flies before us, and are anxious that not a straggler should escape, but when we look behind us we behold our city in flames." Lowth's Lectures by Gregory, vol. i. p. 251.
have given our sovereign the prerogative he enjoys, that whatever hath no other owner is yielded by law in the king. Blackft. Com. vol. ii. p. 262, 8vo.

Great alterations are made in the face and limits of countries, by alluvions of the sea, rivers, &c. Whole plains are sometimes formed by alluvions. It is controverted whether alluvions should be considered as fruits, and as such accruing to us.

**ALMÁNA. See Almána.**

**ALMAGEST,** the name of a celebrated work, composed by Ptolemy, and consisting of 13 books; being a collection of many of the observations and problems of the ancients, relating both to geometry and astronomy. It contains a catalogue of the fixed stars with their places, besides numerous records of eclipses, the motions of the planets, &c. being the first work of the kind that has been transmitted to us, it is valuable to astronomers.

In the original Greek it was called *organon phonon, q. d. greatfull connotation, or collection*; which last words, *megallé,* joined to the particle *al,* gave occasion to its being called *almagèst* by the Arabians, who found it at Alexandria, in Egypt, on their capture of that kingdom, and transliterated it into their tongue about the year 827, by order of the caliph Almamun.—The Arabic word is *almagèst.* It was first translated into Latin about the year 1230, by favour of the emperor Frederic II. But the Greek text was not known in Europe till about the beginning of the 15th century, when it was brought from Constantinople, then taken by the Turks, by George, a monk of Trebizond, who translated it into Latin; and this translation has been frequently published.

Riccioli also published, in 1651, a body of Astronomy, which he entitles, after Ptolemy, the new *Almagest:* being a collection of ancient and modern observations and discoveries in that science.

We have also a botanical *Almagest,* composed by Plukenet, being a kind of *pinax,* or general index of plants, containing the proper and descriptive names of upwards of 60 thousand. To which, in a supplement, since published by the same author, have been added above one thousand others. Almagestum Botanicum, sive Phytographia Plukenetiana Omnifici, &c. Lond. 1696. fol.

**ALMAGRA,** in *Natural History,* a name given in later ages to an earth of the *ochrs* kind, called *fil atticum* by the ancients. It is an ochre of a fine and deep red, with some admixture of purple, very heavy, and of a dense yet friable structure, and rough dusty surface. It adheres very firmly to the tongue, and melts freely and easily in the mouth, and is of an auftere and strongly aromatic taste; it stains the skin in touching it, and ferments very violently with acid menftreums; by which single quality, it is sufficiently distinguished from the *fil ferricum,* to which it has in many respects a great affinity. It is found in immense quantities, in many parts of Spain; and in Andalusia there are in a manner whole mountains of it. It is used in painting, and in medicine, being a very valuable astringent.

**ALMAGRO, Diego de,** in *Biography and History,* one of the colleagues and rivals of Francisco Pizarro, and Ferdinand de Laufe in the conquest of Peru, was probably a foundling of obscure birth and unknown parentage, and derived his name from the village in which he was born, about the year 1463. Although he was unmanscured in reading and writing, he advanced himself by military service; and having acquired wealth and influence in Panama, he formed an association with the perouns above-mentioned in 1544, for discovery and conquest on the coast of Peru. Each engaged to devote his talents and his whole fortune to the adventure, and their confederacy for this purpose was authorized by Pedrarias, the governor of Panama. The province assigned to Almagro was that of conducting the supplies of provifions and reinforcements of troops, as Pizarro might need them in the prosecution of their enterprise. This office he performed with persevering fidelity, though their first attempts in 1525 and 1526 were attended with difficulties, which would have deterred adventurers of less ardent than themselves from renewing
ing their efforts. At length, however, they discovered the coast of Peru, and landed at Tumbes, a place of some note, about three degrees south of the line, distinguished for its picturesque, and a palace of the Incas, or sovereigns of the country. Having in 1532 settled some preliminaries, and adjusted among themselves that Pizarro should claim the title of governor, Almagro that of lieutenant governor, and Luque the dignity of bishop in the country which they determined to conquer, Pizarro was deputed as their agent to Spain, in order to negotiate and to obtain further powers and supplies. In this negotiation Pizarro, principally concerned about his own interest, neglected his associates; and though he obtained for Luque the ecclesiastical dignity to which he aspired, because it did not interfere with his own pretensions, he claimed for Almagro only the command of the fortresses which should be erected at Tumbes. On his return from Spain and arrival at Panama in 1530, he found Almagro so much exasperated at the manner in which he had conducted the negotiation, that he refused to act with such a pernicious companion, and determined to form a new association. Pizarro, however, temporized for the present; and by offering voluntarily to relinquish the office of Adelantado, and promising to concur in fulfilling that title, with an independent government for Almagro, he gradually mitigated the rage of an open-hearted fellow, which had been violent, but was not implacable. The confederacy was again renewed on its original terms; and it was agreed, that the enterprise should be carried on at the common expense of the associates, and that the profits accruing from it should be equally divided between them. With an armament of three small vessels, and 180 soldiers, Pizarro sailed for Peru in February 1531, leaving Almagro at Panama with instructions to follow him with such reinforcement as he should be able to muster. Having succeeded in the province of Coaque, and obtained from a principal settlement of the natives rich spoil, he instantly dispatched one of his ships to Panama, with a large remittance to Almagro, by which means he was enabled to complete his reinforcement, which almost doubled the number of Pizarro's followers, and to land with them at St. Michael towards the close of the year 1532. The Inca Ahuanalpa was now in the hands of the Spaniards, and when they had received the sum which had been paid for his ransom, Almagro and his followers demanded an equal share of it; and in order to secure this object, they eagerly petitioned the Inca to death. According to custom and expectation, instead of Pizarro was deputed to fail for Spain with an account of the successes of the adventurers, and with remittances of great value; in consequence of which his brother's authority was confirmed and enlarged, and Almagro received the honour which he had so long desired. The title of Adelantado, or governor, was conferred upon him, with jurisdiction over 200 leagues of country, fretting beyond the limits of the province allotted to Pizarro. As soon as Almagro was informed, that he had obtained the royal grant of an independent government, he attempted to make himself master of Cuzco, the imperial residence of the Incas, under a pretense that it lay within the boundaries of his territory. This produced new dissensions between him and Pizarro; but a new reconciliation took place, to which was annexed a condition, that Almagro should attempt the conquest of Chili, and that if this province did not afford an eligible settlement which he thought adequate to his merit and expectation, Pizarro engaged to yield up to him a part of Peru. Almagro in 1535 began his march towards Chili, at the head of 570 men, and here he suffered by purrying a wrong route very great hardships and losses. Whilst he was contending with a more vigorous resistance than the Spaniards had experienced in other countries, and pursuing his conquests, he was recalled to Peru by the intelligence that Cuzco, as well as Lima, were invested by the natives, who had assembled in great numbers to repel themselves from their oppressors. In order to heal his return he purveyed a new route; and in marching through the sandy plains on the coast, he suffered from heat and drought calamities, though of a different kind, little inferior to those in which he had been involved by cold and famine on the summits of the Andes. He arrived at Cuzco in a critical moment, and resolved to occupy the place both against the Indians and his Spanish rivals, who were preparing to supplant him. Having gained a decisive victory over the Peruvians, he proceeded to the gates of Cuzco without further interruption; but the Pizarros attempted to obstruct his entry. Almagro, however, whole open, affable, generous temper, had gained an accession of many adherents of the Pizarros, who were disgusted with their harsh domineering manners, advanced towards the city by night, surprized the sentinels, and surrounded the house where the two brothers resided, and compelled them, after an obdurate defence, to surrender at discretion. Almagro's claim of jurisdiction over Cuzco was universally acknowledged, and a form of administration established in his name. This event was the commencement of a civil war; and it was soon followed by more bloody scenes. In the first attack of a body of soldiery, deputed by Francis Pizarro for the relief of his brothers, and which were commanded by Alfonso de Alvarado, whose fidelity Almagro in vain endeavoured to corrupt, Almagro succeeded, and took the commander and his principal officers prisoners; but neglecting to improve the advantages he had gained, he marched back from this victory to Cuzco, and there waited the approach of Pizarro. Pizarro practised his usual artifice, and Almagro was weak enough to suffer himself to be amased with a prospect of terminating their differences by amicable accommodation. The negotiation between them was protracted, and whilst every day was precious to Almagro, several months elapsed before they came to any final agreement. In the mean while one of the Pizarros and Alvarado found means to bribe the soldiers to whose custody they were committed, and not only secured their own escape, but perjured 60 of the men who had guarded them to accompany them in their flight. The other Pizarro was also released by the governor. Whilst Almagro was thus deluged by a pretended treaty, Pizarro was preparing for open hostilities, and he determined to settle the domination of Peru, not by negotiation, but by arms. In 1538 an army of 500 men was ready to march for Cuzco; and Almagro, instead of obstructing their progress in the difficult passes of the mountains through which they marched, waited their arrival in the plains of Cuzco. When the two armies met, Almagro, worn out with the fatigues of service and declining age, was unable to exert his usual activity; and obliged to commit the conduct of his troops to Orgogozo, who, though an officer of great merit, did not possess the fame attendant either on the spirit or affections of the soldiery, as the chief whom they had been long accustomed to follow and revere. The conflict was fierce, and maintained by each party with equal courage. Orgogozo was wounded, and the route of Almagro's troops became general. This officer and several others were mangled in cold blood, and above 140 soldiers fell in the field. Almagro anxiously observed from an eminence, to which he was conveyed on a litter, the progress of the battle, and when he witnessed the total defeat of his own troops, he felt the
the passionate indignation of a veteran leader, long accustomed to victory. Although he endeavored to save himself by flight, he was taken prisoner; and after remaining for several months in custody under all the anguish of suspense, he was impeached of treason, formally tried and condemned to die. Humble and dispirited in the approach of an ignominious death, he earnestly supplicated life; but all his entreaties, which were abject in a degree unworthy of his former fame, and all the arguments by which they were enforced, proved ineffectual. The Pizarros were inflexible. As soon, however, as Almagro knew his fate to be inevitable, he met it with the dignity and fortitude of a veteran. He was strangled in prison and afterwards beheaded. He suffered in the 7th year, A. D. 1538, and left one son by an Indian woman of Panama, whom, though at that time a prisoner in Lima, he named as successor to his government, in pursuance of a power which the emperor had granted him. Almagro blended with the qualities of intrepid valour, indefatigable activity and infurmountable tenacity, an openness, generosity and candour, that are natural to men whose profession is arms; he was, therefore, beloved by his followers, his misfortunes excited their sympathy and pity, and his death was sincerely regretted not only by them, but by the Indians in general, who regarded him as their protector against the rigours of the odious Pizarro. After his death the attachment of his friends was transferred to his son, who was now advanced to the maturity of manhood, and who possessed all the qualities which captivate the affections of soldiers. Of a graceful appearance, dextrous at all martial exercises, bold, open, and generous, he seemed to be formed for command; and as his father, conficious of his own inferiority from the total want of education, had been very attentive to his instruction; and the accomplishments which he had acquired heightened the respect of his followers, who were illiterate adventurers; urged likewise by the feelings of delight, as well as by sentiments of affection, they ranged under his standard, and fought deliverance by his skill and valour from the oppressions of Pizarro. Their confutations, whilst Pizarro confined in his own security, were directed by Juan de Herrera, an officer of great abilities, who had the charge of Almagro's education, with zeal and authority which contributed to their prosperous issue. A conspiracy was formed against Pizarro, the accomplishment of which, notwithstanding his vigorous resistance, terminated in his death. The affinns, triumphant in their successes and waving their bloody swords, proclaimed the death of the tyrant, and compelled the magistrates and principal citizens of Lima to acknowledge Almagro as lawful successor to his father in the government. His triumph, however, was of no long duration. In 1541 Vaca de Castro arrived at Quito, and produced the royal commission, appointing him governor of Peru, with the privileges and authority of the deceased Pizarro. His talents and influence overpowered the interest of Almagro; who receiving the rapid progress of affection to his cause, and wishing to check it before the arrival of Vaca de Castro, set out at the head of his troops from Cuzco, where the most considerable body of opponents had erected the royal standard, under the command of Pedro Alvarez Holguin. During his march, Herrera, the guide of his counsels, died; and from that time his measures were conspicuous for their violence, but concerted with little sagacity, and executed with no address. At length Almagro and Vaca de Castro met at Chupas, about 220 miles from Cuzco, on Sept. 16, A. D. 1542; and victory, after long remaining doubtful, declared at last to the new governor. Almagro conducted the military operations of the day with a gallant spirit, worthy of a better cause and defending another fate; and his followers distinguished themselves by their valor. The carnage was great in proportion to the number of combatants; of 1,100 men, the total amount of combatants on both sides, 500 lay dead on the field, and the number of the wounded was still greater. Almagro escaped, but being betrayed by some of his own officers, was publicly beheaded in Cuzco; and in him the name of Almagro, and the spirit of the party, were extinct. Med. Un. Hist. vol. xxiv. p. 387—480. Robertson's Hist. of America, vol. iii. p. 4—114, 8vo.

Almagro, in Geography, a town of New Castile, in Spain, and capital of the district of La Mancha, called Campo de Calatrava, and situate three leagues south-east of Ciudad Real. It was built by the archbishop Rodrigo, of Toledo, who garrisoned it in 1124, in order to restrain the incursions of the Moors. Its environs are level and fertile, and near it are medicinal springs.

Almaguer, a town of South America, in the country of Popayan.

Almain, James, in Biography, a scholastic divine, was born at Sens, and became professor of divinity at the college of Navarre, in Paris, in the year 1508. He was a subtle logician and metaphysician, and a strenuous advocate for the principles of Scotus and Oecam. In 1512 he was employed in explaining the book of Sentences, and also in writing on behalf of Lewis XII. against pope Julius II., and in vindicating the authority of councils against a book published by cardinal Cajetan. He died at an early age, in 1515. His philosophical works were, "A Treatise on Physics," printed in 1503; "Four Treatises of Ethics," printed in 1510; several treatises on school divinity, and others concerning the power of the church. Ludgamus collected and published them at Paris in 1516. His skill in the art, he said, was equal to his learning; and his application to indefatigable, that he ever spent to much as one hour of a whole day without reading, writing or teaching. Dupin, 16th cent. vol. vi. p. 254. Cave Hist. Lit. vol. ii. p. 242. Gen. Dict.

Almajorofasgo, in Commerce, a term in the Spanish American calem, denoting a duty paid in America on goods imported and exported, and amounting on an average to 15 per cent.

Almaleci, in Medical History, a celebrated work containing a system of the ancient Arabian phvsic.

The word imports as much as the royal work.

Concerning the history, contents, &c. of the almaleci, see Fried's Hist. of Phys. p. i. p. 36.

Almon, James, or Manon, called also Abdallah, in Biography, caliph of Bagdad, and an eminent philopher and astronomer, was the son of the caliph Harun Al Rashid, and great grandson of Almamun. He was born on the day when his father succeeded to the caliphate, A. D. 786. At the time of his father's death, A. D. 809, he was governor of Kharasan; and he was appointed, by an express declaration of Harun, rendered public and solemn by being hung up in the Caaba, to be the successor of his brother Al Amin, who was now caliph. Al Amin, however, conceiving a prejudice against him, formed a design to exclude him from the succession, and ordered the forces in Khorasan to march immediately to Bagdad. Almamun, notwithstanding this unprompted insult, was faithful to his brother, and obliged the people of Khorasan to take the oath of allegiance to Al Amin upon his accession. The new caliph added himself to drunkenness and gaming, and entrusted the concerns of government to his prime vicer. Milled by
by this minister, Al Amin proceeded to sow his enmity against his brother by acts of open hostility, and at length invaded Khorasan with an army of 60,000 men. As he was advancing to the frontiers of the province, Almamon prepared to receive him, and appointed Thafer ibn Hosein, one of the greatest generals of the age, to the command of his army. The caliph's invading army was soon dispersed. Almamon assumed the title of caliph, and determined to maintain it. Thafer pursued the war with vigour and success; and such was the rapidity of his conquests, that the provinces of Egypt, Syria, Hejaz and Yemen, abandoned the interest of Al Amin, whose character was generally detestable. Almamon was restored to his dominions.

The defection of these provinces was soon followed by a complete revolution. Al Amin was formally deposed at Bagdad, and afterwards assassinated; and his brother succeeded to the caliphate without any further opposition, A. D. 813. The commencement of his reign, however, was attended with commotions; and as he favoured the sect of Al, his enemies multiplied, and it was with difficulty that the dissatisfaction, which began to manifest itself, was prevented from breaking out into a civil war. Whilst the agitation continued, Thafer, the caliph's general, availed himself of the opportunity of Almamon's absence to acquire the sovereignty of Khorasan, where he formed a dynasty, which subsisted for 60 years. As soon as tranquillity was restored, Almamon presented the plans he had formed for introducing literature and science into his dominions, and for thus laying the foundation of that distinguished honour with which his name has been decorated to posterity. Whilst he resided in Khorasan he had assembled a number of learned men from various countries, and formed them into a society or college, over which he appointed, as president, Mefue of Damblis, a famous Christian physician. When his father renounced against this appointment, because Mefue was a Christian, he replied, that he had chosen him, not as a teacher of religion, but for the instruction of his subjects in science and useful arts, and that his father well knew, that the most learned men and skilful artists in his dominions were Jews and Christians. Upon his accession to the caliphate, he made Bagdad the seat of learning, by forming in it an academy, and inviting thither eminent men from all quarters. He likewise caused translations to be made into Arabic from many valuable books in the Greek, Persian, Chaldean and Coptic languages, among which were the works of Aristotle and Galen. He visited the schools which he had established, treated the professors with respect, and thus encouraged by his example and patronage, every species of mental cultivation. In various parts of knowledge, and particularly in mathematics, astronomy and philosophy, he himself was a considerable proficient. He caused Poleny's Almagest to be translated in 827, either by Isaac ben Honain, according to Herbelin or, according to others, by Alhazen ben Joseph, and Sergius. He also employed the most skilful astronomers to compose a body of astronomical science, which filled voluminous amongst oriental manuscripts, entitled, "Astronomia elaborata à compluribus, D. D. juxta regis Maimon." History records two observations of the obliquity of the ecliptic, which were made either by Almamon himself, or under his immediate auspices, one at Bagdad, and the other at Damas. In the former, conducted by Jafia ben Abilmefar, Seneb ben Alis, and Abbas ben Said, the greatest declination of the ecliptic was found to be 23° 33', according to the report of Iba Jouini; but according to Alfragan, 25° 35'. The other observation was made in the year 233 of the Hegira, at Damas, by Chalid ben Abd-Imelie, Abultib, Seneb ben Alis, and Alis ben Ifa, and the result of it was 25° 33' 52".

This caliph also employed able mathematicians to measure a degree of the meridian, upon an extensive plain in Mesopotamia, called Singiar or Sandjar; and they found it to contain 563 miles, each mile being determined by six grains of barley placed sideways; but Thevenot says, that 144 grains of barley placed in this manner, would give a length equal to 1 mile. 25, 441, and therefore four cubits would be equal to one toise and 9 inches, and therefore 4000 cubits, i.e. 563 miles, would give 65,750 toises. But if the ordinary or royal cubit of 25 inches was applied, the calculation is to be referred, the degree in this estimate of it would contain 56,666 toises. But according to Maffoudi's valuation of a cubit, this measure would consist of 53,123 French toises.

In consequence of the encouragement afforded to science by Almamon, the Saracens began to acquire a degree of civilization and refinement, which distinguished them at a period of very general ignorance and barbarity. But the Mahommedan zealots were alarmed; and the scientific Almamon has been reproached by the Sottites, or orthodox Mussulmans, as little better than an infidel. It must be acknowledged that he manifested an undisguised inclination towards the party of the Mosntzalelies, who denied the eternity of the Koran, and maintained the doctrine of the free-will of man. Some have said, that in order to quiet the murmurs which prevailed against him on this account, he once determined to enclose his zeal for religion by establishing a kind of inquisition, which should compel all his subjects to profess Islam fir; but if this were the case, his compellative plan did not comprehend his Christian subjects, and the influence of his experiment was the introduction of universal toleration.

In the progress of his reign he assisted Thomas, a Greek, who, in 822, made war against Michael the Stammerer, emperor of Constantinople, and besieged his capital; but the expedition was on his part unjust, and terminated in the imprisonment and death of Thomas. In his war against the Greeks, in 829 and 830, he was more successful, took several places, and widely ravaged their territories. In 831 he made an expedition into Egypt, and there suppressed a rebellion. Here he discovered a great treasure which had been buried under two columns by Merwan, the last caliph of the house of Ommiiah. He displayed his love of science by erecting a new mosque, or millimeter, for measuring the increase of the Nile, and repairing one that was decayed. In his return from Egypt, in 833, he penetrated into the territories of the Greek emperor, as far as Tarfus in Cilicia; and in his way towards Bagdad, he encamped on the banks of a river Badandun, and quenched his thirst by drinking freely of its cool waters; and he also partook plentifully of some dates, to which he had access. This repast brought on a fever which endangered his life. In the prospect of dissolution, he wrote letters to the provinces, declaring his brother Mufaid his successor, and then waited the event which he apprehended. After a long struggle, he exclaimed, "O thou who never diest, have mercy on me, a dying man!" and then expired at the age of 48 or 49 years, after a reign of twenty years and some months. His body was buried at Tarfus, and this circumstance some zealots interpreted as a token of reproduction.

Sciencehumanized the temper of this Saracen caliph; and in contemplating his character, we cannot do less than admire his liberality and beneficence. As an instance of his clemency and magnanimity, his conduct towards his uncle and rival, Ibrahim, deserves to be recorded. When he was discovered, after having been concealed for some years, and brought
brought to the caliph, under an unanimous sentence of condem-
nation by the council: "Your counsellors (said Ibra-
him), judged according to the customary rules of political
government: if you pardon me, you will not, indeed, judge
according to precedent, but you will have no equal among
sovereigns." The caliph then tenderly embracing him, re-
p lied, with great emotion, "Uncle, be of good cheer; I
will not do you the least injury," and he not only pardoned
him, but granted him a rank and fortune fittable to his birth.
Upon being complimented by his counsellors for this generous
act, he exclaimed, in the fulness of his heart, "Oh! did
men but know the pleasure I feel in pardoning, all who have
offended me would come and confess their faults!" Modern
matiques, tom. i. p. 356—359.
ALMANA, in Ancient Geography, a town of Macedonia,
mentioned by Livy, situate on the river Axios, and probably
not far from Bytazo.
ALMANAC, a calendar or table, in which are set down
the days and feasts of the year, the rising and setting of the
sun, the course and phases of the moon, the eclipses of both
luminaries, &c. for each month of the year.
The original of the word is much controverted among
grammarians.—Some derive it from the Arabic particle al
and manah, to count; whence is naturally enough derived al
manah, the diary. Others, and among them Scaliger, rather
derive it from al, and manah, the course of the months:
which is contradicted by Colinus, who advances another op-
nion. He says, that, throughout the East, it is the custom
for subjects, at the beginning of the year, to make presents
to their princes; and, among the rest, the almanacs present
them with their ephemeredes for the year ensuing; whence
those ephemeredes came to be called almanah, i. e. hand-
fuls, or new-year's gifts.—To say no more, Verlegian writes
the name almanat, and makes it of Saxon original. Our
ancestors, he observes, used to carve the courses of the moon,
of the whole year, upon a square flock, or block of wood,
which they called al-monught, q. d. all-moonbeed.
The use of almanacs or diaries, containing a great variety
of almanacs and additional records, and of other functions
by a prevalent superstition, was very common among the
Arabians; and it is natural to imagine, that from them, by
means of the Saracens, it was introduced into European na-
tions. The present form and method of almanacs have been
attributed to Regiomontanus, who is said to have first publish-
ed, in 1475, an almanac, resembling that of the moderns,
and containing the characters of each year and month, predic-
tions of eclipses and other celestial phases, calculations of
the motions of the planets, &c.
The modern almanacs answer to the Fasti of the ancient
Romans.
For the construction of an almanac: 1st. Compute the
fun's and moon's place for each day of the year; or take
them from ephemeredes. 2d. Find the dominical letter, and,
by means of it, distribute the calendar into weeks. 3d.
Compute the time of Easter, and thence fix the other move-
able feasts. 4th. Add the immovable feasts, with the names
of the martyrs. 5th. To every day add the sun's and moon's
place, with the rising and setting of each luminary; the
length of day and night; the twilight, and the aspects of
the planets. 6th. Add, in the proper places, the chief
phases of the moon, and the fun's entrance into the cardinal
points, i. e. the solstices and equinoxes: together with the rising
and the setting, especially the last of the planets, and chief
fixed stars; means for each of which will be found under
the proper heads. The duration of the twilight, or the end
of the evening and beginning of the morning twilight; to-
gether with the sun's rising and setting, and the length of days,
may be transferred from the almanac of one year into that of
another; the differences in the several years being too small
to be of any consideration in civil life.
Hence it appears, that the construction of an almanac is
neither mysterious nor difficult; if access be had to the tables
of the historically motives and eclipses, some divide almanacs into public and private, perfect and
imperfect, heathen and civil an, book-almanacs and sheet-
almanacs. Public almanacs are those of a larger size, such
as fleet almanacs, usually hung up for common or family use;
private are those of a smaller form, of which there is a great
variety, to be carried about either in the hand, inscribed on a
sheet, or in the pocket; perfect almanacs are those which have
the dominical letters, as well as primes and feasts inscribed
on them; imperfect are those which have only the primes
and immovable feasts. Till about the fourth century, al-
amacs bear the marks of heathenism; from that age to the
seventh, they are generally divided between heathenism
and christianity; and from that time they have been altogether
christian.
Almanacs vary in their contents and the mode of their
composition; some containing more points, others fewer.
The essential part is the calendar of months and days, with
the risings and settings of the sun, age of the moon, &c. To
these are added various paragraphs, almanac, astrological,
meteoro logical, chronological, and even political, rural, medi-
cal, &c.; as calculations and accounts of eclipses, solar in-
greets, aspects and configurations of the heavenly bodies,
seasons, heliocentrical and geocentrical motions of the pla-
nets, prognostics of the weather, and predictions of other
events, tables of the planetary motions, the tides, points, in-
tervals, twilight, equation, kings, &c.
Henry III. of France very prudently decreed, by an or-
dinance of 1579, that no almanac-maker should presume
to give predictions relating to civil affairs, either of flates,
or private persons, in terms either express or covert.
The almanac, annexed to the book of Common Prayer,
is part of the law of England, of which the courts must take
notice in the returns of writs, &c. For ascertaining many
circumstances relative to a particular day past, the court hath
determined by an inspection of the almanac. Upon a writ
of error from an inferior court, the error assigned was,
that the judgment was given on a Sunday, the day being 26
Feb. 1612.; and it appearing, by inspection of the alman-
ac of that year, that the 26th of February actually
fell upon a Sunday, this was held to be a sufficient trial,
and that a trial by Jury was not necessary, although it was
an error in fact; and so the judgment was reversed. But in
all these cases, the judges, if they conceive a doubt, may or-
der it to be tried by Jury. Blackst. Com. vol. iii. p. 333.
For every almanac or calendar for one year or less, the fol-
lowing stall duties shall be paid, viz.

<table>
<thead>
<tr>
<th>Item</th>
<th>Amount</th>
</tr>
</thead>
<tbody>
<tr>
<td>1d</td>
<td>9 Ann. c. 23. §. 23.</td>
</tr>
<tr>
<td>1</td>
<td>30 Geo. II. c. 19. §. 1.</td>

<tr>
<td>2</td>
<td>21 Geo. III. c. 56. §. 1.</td>
</tr>
<tr>
<td>4</td>
<td>37 Geo. III. c. 90. §. 1.</td>
</tr>
</tbody>
</table>

In the whole amount the stall duty is 8d. And for every
almanac serving more than a year, the same duty shall be paid
for each year; but perpetual almanacs pay for three years
only. 9 Ann. c. 23. 30 Geo. II. c. 19. and by 10 Ann.
c. 19. all books and pamphlets serving chiefly to the pur-
pose of almanacs, shall be charged as such. If an almanac
contains more than one facet, one facet only need be flamped;
and every almanac shall be so printed that some part of the
print shall be upon the stall. 9 Ann. c. 23. §. 26. 21 Geo.
III. c. 56. §. 3. Selling almanacs unstalled incurs a pe-
alty,
aly, upon condition before one justice on the oaths of one witness, of commitment to the house of correction for a term not exceeding three months; and the person apprehending such an offender, shall receive a reward of 20 shillings. 16 Geo. II. c. 26, § 5; 50 Geo. II. c. 19, § 26.

In the Philosoph. Collect. we have a perpetual almanac, devised by Mr. R. Wood.

Many forms of a lead-almanac have been proposed in some of our periodical publications; but the following differs will very well answer the purpose:

"At Dover Dwell George Brown Esquire; Good Christopher Finch, And David Frier."

The twelve words answer to the twelve months; the first letter of each word stands in the calendar against the first day of the corresponding month; and if the dominical letter is known, it is easy to find on what day of the week any day of the month will fall throughout the year. In 1802, C being the dominical letter, Dec. 23 is Saturday, because the first day denoted by C is Wednesday.

ALMANAC, among Antiquries. See Runes Staff.

ALMANAC, nautical, and astronunical ephemeris, is a kind of national almanac, published annually, by anticipation, under direction of the commissioners of longitude. Besides every thing essential to general use that is to be found in any almanac hitherto published, it contains many new and interesting particulars; more especially, the distances of the moon from the sun and fixed stars for every three hours of apparent time, adapted to the meridian of Greenwich, by comparing which with the distances carefully observed at sea, the mariner may readily, and with little danger of mistake, infer his longitude to a degree of exactness, that may be thought sufficient for most nautical purposes. And the publication of it is chiefly designed to facilitate the use of Mayer's lunar tables, by superceding the necessity of intricate calculations, in determining the longitude at sea. It began with the year 1757, has been continued ever since, and greatly contributes to the improvement of astronomy, geography and navigation. In this almanac the sun's longitude, and every thing relating to it, have been always inserted, as computed from Mayer's tables, printed under the inspection of Dr. Maskelyne, the almanac royal, and published in 1759; and both the sun's place and the moon's place are inserted in the almanacs from the year 1791, as computed from Mayer's tables, and Mr. Mason's tables of 1780, duly corrected. In the ephemeris of 1803, the latitudes as well as longitudes of the stars are propounded to be thoroughly corrected; and the moon's distances from them computed by the late Mr. Taylor's accurate tables of logarithmic sines and tangents to every second of the quadrant. The calculations of the planets' places have been made for every ephemeris, beginning with that of 1780, from M. De la Lande's tables, contained in the second edition of his astronomy; and those of the eclipses of Jupiter's satellites were made from Mr. Wargentin's tables, annexed to those of de la Lande, those of the second satellite excepted, which are inserted from new tables of Mr. Wargentin annexed to the nautical almanac of 1779. To the nautical almanacs from 1795 to 1804, both inclusive, are added the eclipses of Jupiter's satellites, computed to mean time, from M. De Lambre's new tables, annexed to the third edition of M. De la Lande's almanac. To the almanacs of several years, since the commencement of this useful publication, many valuable papers have been added, which are more directly or indirectly connected with its general contents and principal object. The articles of the ephemerides are enumerated and explained, together with those of the "Requisite Tables," connected with them, but separately published, and examples of their use are added in the appendix annexed to them. See Longitude.

ALMANAR, in the Arabians Aprosogey, denotes the preeminence, or prevalence of one planet over another.

ALMANDIN, or ALMANDIN, a precious stone of the ruby kind, something softer than the oriental ruby; and, as to colour, partaking more of that of the granite than the ruby.

It is ranked among the richest of stones, and takes its name from Allebana, a city of Caria, whence Pliny says it was brought.

ALMANSOR, ALMANSUR, or ALMANZOR, the ibadites, in Biography and History, the surname of Abu Ja'far, second caliph of the house of Al Abbas, or the Abbasides, succeeded his brother Alab Abbas Al Safihi, A.D. 753, in the year of the Hegira 136, and was inaugurated at Al Hafemiyah in the following year. His right of succession, though Al Safihi had declared him presumptive heir of the crown, and he had been proclaimed caliph in the imperial city of Amur, then the capital of the Moslem empire, was, immediately upon his inauguration, disputed by his uncle: Abdallah bcn Ali, who called himself to be recognized as caliph at Damascus. In order to support his pretensions, he collected a numerous army in Arabia, Syria and Mesopotamia, and marched to the banks of the Tigris, near Nimibis, where he encamped. Here he was harried for five months by Abu Molem, who had the command of Almansor's forces, assembled in Peria, Khorasan, and Irak; and at length, A.D. 754, totally defeated. After this victory, and notwithstanding the services which Abu Molem had rendered to the family of Al Abbas, he became an object of jealousy, and was assassinated by order of Almanor in his own presence. See Abu Molem.

The death of Abu Molem was succeeded by the rebellion of Simon, a magian, who having feiz'd on the treasures of the deceased governor of Khorasan, excited the people of that country to a revolt; but this insurrection was soon quelled by Jamhour bcn Morad, the general of Almanor. The spoil obtained by this victory was lavishly feiz'd by the caliph, and the outrage so incensed Jamhour, that he immediately turned his arms against his master; but he was soon defeated by the caliph's forces. About this time Theodorus, patriarch of Antioch, having been detected in an illicit correspondence with the Grecian emperor, was banished into an obscure part of Palaestina, and the Christians in the dominions of the caliph were prohibited from building or repairing any churches, and laid under several other restraints.

In 757 Almanor sent a large army into Cappadocia, fortified the city of Malatia or Meltene, garrisoned it with 4000 men, and deposited in it a great part of his treasures. But in this year he was attacked by the Rawandians, a sect of believers in the Metempsychofs, so called from their head or founder Al Rawand. The followers of this chief assembled at Al Hafemiyah, where the caliph refited, and by the ceremony of going in procession round his palace, as the religious Molems go round the Caaba, intimated their purpose of invoking him as a deity, and paying him divine honours. The caliph provoked, as it is said, by their impertinence, ordered several of these sectaries to be imprisoned; upon which their resentment was roused, and they formed a design of afflaiinating him. Their intention, however, was defeated by the generous interposition of Marn bcn Zaidet, an Ommiyan chief, who had been under a necessity of concealing himself from the caliph's resentment. Notwithstanding his release, the infult he had received in his capital induced him to build a new city on the banks of the Tigris, and there
to fix his residence. This circumstance gave occasion to his building the city of Bagdad, A.D. 762. In the preceding year he received information that a design had been formed to dethrone him; but the plot being discovered, all who were directly or indirectly concerned in it were fiercely punished; and most of them were by cruel treatment put to death. His uncle Abdallah shared the fate of other rebels; for having been allure to his court by assurances of pardon and protection, he placed him in a building, which was set on fire, and found him in its ruins. Soon after Almanzar had fixed his residence at Bagdad, A.D. 768, he was cured of a dangerous disorder by the advice of a famous Christian physician, whose name was George Ebu Balthibua Al Jondisibari. The caliph, as a recompense, presented him with three beautiful Greek girls, and a considerable sum of money; but the girls were sent back, with a declaration on the part of George, who was married to a wife old and infirm, of which Almanzar was previously apprised, that it was not lawful for a Christian to have more than one wife at a time. The physician's conduct on this occasion, whilst it surprised the caliph, raised him in his esteem, and was followed by a profusion of favours. Almanzar in his succeeding military transgressions was generally victorious. Towards his Christian subjects he exercised much severity. In the year 744 he sent out on a pilgrimage to Mecca; and being feized on his journey with a disease which threatened danger, he sent for his son and intended successor, Al Mohiz, and gave him salutary advice. "I command you," said he, "to treat publicly your relations with the greatest marks of distinction, since this conduct will reflect no small degree of honour and glory upon yourself. Increase the number of your freedmen, and treat them all with kindness, as they will be of great service to you in your adversity; but neither this, nor the other injunction will you fulfill. Enlarge not that part of your capital erected on the eastern bank of the Tigris, as you will never be able to finish it; but this work I know you will attempt. Never permit any of your women to intermeddle in affairs of state, or to have too much influence over your counsellors; but this advice I know you will not take. These are my last commands; or, if you please, my dying advice; and to God I now recommend you." They then parted, and were both in tears. He pursued his journey to Bir-Maimun, i.e., the well of Maimun, where he expired, in the 63rd year of his age and 20th of his reign. His remains were interred at Mecca. The character of Almanzar seems to have been formed of very heterogeneous and even contradictory qualities. In private his temper was mild, and conciliatory affection and attachment; but in public, his aspect and demeanour inspired terror. He was prudent and brave, engaging in discourse, confidant in all the acts of government, and addicted to study and literature, and particularly to philosophy and astronomy; but he was extremely covetous, perfidious, cruel and implacable. Mod. Un. Hist. vol. ii. p. 100—135.

ALMANSOR, in Geography, a town of Africa, in the kingdom of Fez, situate on the river Guir.

ALMANSPACH, a small town of the circle of Suabia, between the lake of Zeli and that of Constance.

ALMANZA, a small town of Spain, in New Castile, on the frontiers of Valencia, situate in N. lat. 38° 54'. W. long. 10° 21'. In the plain adjoining to this town marchal Derwick defeated the allies in 1707, under the marquis de los Minas and the earl of Galway.

ALMARAZ, a town of Spain, in the province of Extremadura, situate in a fine plain, on the north side of the Tagus, eight leagues south-east of Coria.

ALMARIA, of Armaria, in our Ancient Records, denote the archives of a church, or library.

ALMARIA, in Geography. See Villa Rica.

ALMAS, or Almasch, a small town of Hungary, in Transylvania, with a district dependent on Claufernburg. The district lies between Burglos and Claufernburg, and consists of mountains, in which are found many caverns. Almas is a small place, giving name to the adjacent country in the canton of Temesvar, and also a river upon which is situated the fortress of Sigeth.

ALMAZAN, a small town or village of Spain, in Old Castile, at the foot of the frontier mountains of the province of Aragon, where is a relic, which is the object of devotion, as the head of the proto-martyr Stephen, and near which was settled the treaty of peace between Henry, king of Castile, and Peter IV., king of Aragon, in 1375. N. lat. 41° 30'. W. long. 2° 16'.

ALME, a river of Germany, which runs into the Lippe, near Ellen, in the bishopric of Paderborn.

ALME, in Modern History, singing or dancing girls in Egypt, who, like the Improvisatori of Italy, can occasionally chant unpremeditated verse. They are thus called, because they have received a better education than other women, and they form a celebrated society in this country. The qualifications for admission are a good voice, a knowledge of the language and of the rules of poetry, and an ability to compose and sing couplets on the spot, adapted to the circumstances. The above know by heart all the new songs, and their memory is furnished with the most beautiful melodies, i.e., elegiac hymns, bewailing the death of a hero or the misfortunes incident to love, and the prettiest tales. They attend every festival, and, placed in a rostrum, sing during the repast; and then descending into the fałoon, dance a kind of pantomime ballets, that represent the ordinary occurrences of life, and the mysteries of love. Their bodies are artfully enveloped, and their features so flexible, that they can exhibit at pleasure the different characters they assume. The indecency of their attitudes and of their discourses is often carried to excess; their legs are regulated by the sound of the flute, of saltarets, of tambour de basque and cymbals, which accelerate or retard the measure; and they are also animated by words adapted to the scenes. They appear in a state of intoxication, and are the bacchantes in a debauch. These nuns are sent for into all the harams, where they teach the women the new airs, amuse them with amorous tales, and recite poems, rendered interlacing by furnishing a lively picture of their manners. By these they are initiated into the mysteries of their art, and taught lascivious dances. As their underprivileges are cultivated, their conversation is agreeable. They also speak the language with purity; and are habituated to poetry, the softest and most generous expressions are familiar to them. They repeat with much grace, follow nature in singing, and excel in the pathetic. Even the Turks pass whole nights in hearing them. When two fag together, it is always with the same voice; and in the orchestra, all the instruments playing in unison execute the same part. These nuns are at the marriage ceremonies, and march before the bride playing on instruments; and they attend funerals, accompanying the procession and singing sorrowful airs. They are paid at a high rate, and feldon wear except among the grandees and rich men. However, the common people have also their almas, who are girls of an inferior class, and strive to imitate the former, without their knowledge, elegance and graces. The public places and walks about Grand Cairo abound with them; nor will decency

ALMEDINA, in Geography, a town of Africa, in the empire of Morocco, between Azamer and Safie, on the north of the city of Fez. It was once rich and populous, but now lies in ruins.

ALMEDESSOS, in Ancient Geography, a city of Thrace. Pline, iv. 18.

ALMEHRAB, among Mahometans, denotes a niche in their mosques, which directs to the keiba, that is, to the temple of Meca, to which they are obliged to bow their faces in praying.

ALMENDAR or ALMBOB, in Geography, a fortified town of Portugal, in the province of Bera, on the river Coa, on the frontiers of the kingdom of Leon. It is seven leagues from Ciudad Rodrigo, and four south-east of Plasdel. N. lat. 40° 5'. W. long. 5° 24'.

ALMESTAR, a celebrated game among the ancient Arabs, performed by a kind of calling of lots, with arrows, strictly forbidden by the law of Mahomet, on account of the frequent quarrels occasioned by it.

The manner of the game was thus: a young camel being brought and killed was divided into a number of parts. The adventurers, to the number of seven, being met, eleven arrows were provided without heads or feathers; seven of which were marked, the first with one notch, the second with two, the third with three, &c. the other four had no marks. These arrows were put promiscuously into a bag, and thus drawn by an indifferent person. Tho' to whom the marked arrows fell, won shares in proportion to their lot, the rest to whom the blanks fell were entitled to no part of the camel, but obliged to pay the whole price of it. Even the winners tailed not of the Bhebi themselves, more than the losers; but the whole was distributed to the poor.

ALMELLETU is used, by Avicenna, for a purgative treatment, and a natural kind of heat, a degree more remiss than that of a fever, and which sometimes remains after a fever is gone.

ALMELOO, in Geography, a town of the United Netherlands, in the county of Overfijl, situate on the Veche, not far from the Regge, eight leagues east-north-east of Dender. N. lat. 52° 25'. E. long. 6° 22'.

ALMELOVEEN, THEODORE JANSEN, in Biography, born in the year 1657 in the province of Utrecht, was originally intended for the church; but disgusted, we are told, at the disputes among the clergy, which at that time ran very high, he applied himself to the study of medicine, in which he was made doctor in the year 1681, and in 1695 professor of the Greek language, of history, and of physics, at Harderwick. He became more known, however, from some excellent works he published, as editor or author, than from his practice of medicine, which does not appear to have been very extensive. The principal of his works are, "De vita Stephani," first printed at Amsterdam in 1687, 12mo. "Exponaticon rerum inventarum," Catalogue of Inventions in 1694, 12mo. "Bibliotheca promilla et latens," The promised and concealed Library, in 1692, 12mo. "Amenitates theologico-philologicae," in 1694, 8vo. "Faëli Confutares," Amst. 1740, 8vo. "Plagiarorum Syllabus," List of Plagiarists. He also published editions of the Epitaphs of Hippocrates, of the works of Celsus, and of Celsus Aurelianus, which are held in very high estimation. He died in the year 1712, and 1742, as stated by mistake in the Biographical Dictionary, and in the General Biography now publishing, as may be seen by referring to a later edition of Celsus, published by Vulpis, at Padua, in the year 1722, founded on that edited by Almeleven. As he had no children, he left his collection of the different editions of Quintillian to the University at Utrecht. His library, which was extensive, was sold the following year at Amsterdam. See Haller's Bib. Med. et Anat. Eluy Dict. Histor.

ALMEN, in Geography, a town of the United Netherlands, in the country of Zutphen, on the Ijssel, two leagues east of Zutphen.

ALMENAR, JOHN, M.D. in Biography, a Spaniard, published in 1512, "Libellum de Morbo Gallico, septem capitis libertatem," which has since passed through several editions, and is included in the collection of treatises on the subject by Luifinus. He is the first Spanish author who wrote on the disease, in which he appears to have had considerable experience. As he depended, for the cure, on warm bathing and mercurial frictions, it is clear that the frictions were not used, or an alternative syrup. The disease might be occasioned, he says, either by the influence of a contaminated and corrupted atmosphere, to which cause we are told to attribute it, when it affected persons dedicated to the church, (Aphrodus. Luifinus, p. 364.) or by contact; in which case, however, the name procels is recommended in the cure. When falivation arises from the use of the mercurial frictions, he directs it to be checked and moderated by the exhibition of glysters and purgatives. "Vide Aphrod. five de Morbo Gallico, Luifinus, p. 360. Ataurc de Morbis Gallicis, p. 614." Haller, Bib. Med. &c.

ALMENARA, in Geography, a small town of Spain, in the province of Valencia, near the river Polencia, and not far from the sea. N. lat. 39° 41'. W. long. 1° 16'.

ALMENDRA, a small place of Portugal, in Bera, containing about 750 inhabitants.

ALMENDRO, a town of Spain, in Seville, six leagues north-north-east of Ayamonte.

ALMENDROLEJO, a town of Spain, in the province of Elbavada, four leagues south of Merida.

ALMENE, a name given, by some of the Arabian writers, to the prickly lots of Africa, called by some of the ancients lots acanbata, and by Virgil acanbata only.

ALMENE, in Commerce, a weight of two pounds, used for weighing sapphire in several parts of the continent of the East Indies.

ALMENHAUSEN, in Geography, a town of Pruffia, in the province of Natangen, five leagues south-east of Konigberg.

ALMÉRIA, a fea-port town of Spain, in the province of Granada, agreeably situated on a spacious bay, sometimes called Helena Bay, at the mouth of the river Almeria, in the Mediterranean, the seat of a bishopric, and of Granada. N. lat. 36° 51'. W. long. 2° 15'. The country about it is fertile, particularly in fruits and oil, and near it the land projects eastward into the sea, forming a cape called by the ancients Charidame, and by the moderns Capo de Gastes. Almeria is supposed to have risen upon the ruins of the ancient Abdara, and was formerly a place of great importance. It was taken from the Moors by the emperor Don Alfonso, in 1147, with the assistance of the French, Genoese, and Pisans. At that time it was the strongest place belonging to the Moors in Spain; and its privateers, which were numerous, not only troubled the coasts inhabited by their Christian neighbours, but gave equal disturbance to the maritime provinces of France, Italy, and the adjacent islands. When the place, which was strongly fortified and garrisoned, was taken by storm, the best part of the plunder was distributed among the allies, and all the inhabitants, who were found in arms, were put to the sword. The Genoese particularly acquired here that emerald veil which still remains in their treasury, and is deemed invaluable. After its reduction by the Christians, Almeria became a bishopric; and though frequent
frequent mention of it occurs in the history of Spain, it gradually sunk in consequence, and retains few traces of its ancient greatness. Its situation and climate, and the various vegetable and mineral productions of its environs, have been highly extolled by ancient and modern travellers. ALMERICANS, in Ecclesiastical History, were the followers of Almeric, or Amauri, in the thirteenth century. They maintained that every Christian was obliged to believe himself a member of Jesus Christ, and attached some extravagant and fanatical ideas to this opinion, and also that the power of the Father continued no longer than the Mosiac dispensation; that the empire of the Son extended only to the thirteenth century; and that then the reign of the Holy Ghost commenced, when all sacraments and external worship were to be abolished, and the salvation of Christians was to be accomplished merely by internal acts of illuminating grace. Their morals were as infamous as their doctrine was absurd; and under the name of charity they comprehended and committed the most criminal acts of impurity and licentiousness. Their tenets were reprobated by a public decree of the council of Paris, in the year 1209, when many persons of this sect were condemned, and afterwards burnt by the order of king Philip. Dupin 15th Cent. vol. v. p. 144. Mofr. Excl. Hist. vol. iii. p. 157.

ALMERY. See AMBRY.

ALMEYDA, Don Francisco, in Biography and History, Count d'Abrantes, having served King Ferdinand of Castile with great reputation, was nominated by king Emanuel of Portugal, first viceroy and governor-general of the newly conquered countries in the East Indies; and had affixed him guards for his person, a number of chaplains, and every other appendage to his office, which was thought necessary to give it dignity and influence. He fell fat with a fleet from Lisbon in March 1505-6, touched at the Cape Verd islands, doubled the Cape at a considerable distance to the south, and arrived safely at Guiloa. From thence he proceeded to Mombaza, a small, well fortified city in an island, which he reduced; he proceeded to the Anguedes islands, not far from Goa, where he built a fort; he also erected and garrisoned another fort at Cannanor; and, arriving at Cochin, secured it in the interest of Portugal. At this time the island of Madagascar was discovered; and, during his government, his son Don Lorenzo Almeida surveyed the Maldives islands, and discovered the great island of Ceylon, the chief monarch of which he compelled to submit to the protection of Portugal. This young warrior, after returning from this expedition, was employed in the fleet destined against Calicut, but lost his life in a naval engagement against the Samorin, on which occasion the victory achieved with great heroism, acquitting him in the defeating event with this reflection: "All men must die, and Lorenzo could not die better than in the service of his country." Almeida, however, manifestly an unbecoming jealousy on the arrival of Alphonso Albuquerque, who was appointed as his successor, and confined him in the citadel of Cannanor, under pretence of misconduct. Before he surrendered his command he engaged the whole power of the Mahometans at sea, and gained a complete victory, by which he contributed in a great measure to break that formidable league, from which the Samorin was in hopes of compelling the Portuguese to abandon their Indian conquests, and to facilitate the enterprises of Albuquerque, his successor. In his return home with the wealth he had acquired, he touched at Saldhana point, on the coast of Africa, in order to procure some fresh provisions; and some of his followers, quarrelling with the natives, occasioned a fray, in which Almeida was induced imprudently to interfere. When his officers urged him to go abroad on this hazardous enterprise, "Whither do you carry my 63 years?" said Almeida, on leaping into his boat. The natives assembled in a very numerous body, and Almeida, with 57 of the 150 men who accompanied him, fell victims to this rash and un-Jut attempt. Mod. Un. Hist. vol. viii. p. 40—43.

ALMEYRIM, or ALMERIN, in Geography, a town of Portugal, in the province of Estremadura, one league south-east of Santarem.

ALMIA, in Ancient Geography, a town placed by Ptolemy in Asia Minor.

ALMIGGIM, or ALMUGGIM wood, a word used in the Scriptures to signify a beautiful and light fort of wood. It has been conjectured to be several forts of wood now in use; others think it has been lost long since. Mebonius infers, from the accounts of Josephus, that it was the wood of the Indian pine-tree, or fir-tree. But it has been alleged, that as this tree was common in Judea, it could not have been searched for as far as Ophir. The Vulgate renders it hymnum thymum; and, according to Theophrastus, the thymon-tree grows in Africa near the temple of Jupiter Ammon, and resembles the cypress. It was much esteemed among the Heathens for doors and images, because it would not rot. Dr. Shaw (Travels, p. 422.) supposes that the albug was the cypress, and he observes, that the wood of this tree is still used in Italy, and in other places, for violins, harp-chords, and other musical instruments. Hiller, in his Hierotheicum, confiders almuggim as a general name for the wood of the gum-bearing trees, and for the trees themselves. But as the cedar and fir-trees are joined with the albug, it is more probable that some particular species, rather than the whole genus, was here intended. This wood was excellent for its whiteness, as well as remarkable light, and therefore was used in musical instruments.

ALMINA, in Ancient Geography, a country of Epirus, according to Ptolemy, between Thesprotia to the west, and Doloplia to the north.

ALMINA, AMISSA, the fame with Pegantium. See Almissa.

ALMIRA, a town of Phoenicia of Libanus.

ALMIRIJE, or ALMIRIJE, a district of Africa, in the Marcotas, according to Ptolemy.

ALMIRANTE islands, in Geography, are a group of small islands in the South Indian ocean, off the coast of Zanguebar in Africa, extending from west-south-west to east-north-east, from S. lat. 5° 45' to 5° 30', and from E. long. 51° 40' to 52° 50'.

ALMIRON, a town of European Turkey, in the isle of Candi, six miles north-west of Retimo.

ALMISSA, ALMISIA, the ancient Pegantium, an episcopal city of Dalmatia, is situated in the duchy of Chlumi, on a rock between two high mountains, at the mouth of the Tetta, and was formerly notorious for its piracy. It has been reduced by the Venetians. It is 20 miles east of Spalatro, and called by the Turks Omnic. E. long. 18° 14'. N. lat. 43° 50'.

ALMO, or ALMOK, in Ancient Geography, a river of Latium, which rising near Sibylla, took a northern direction, and discharged itself into the Tiber, to the south-west of Rome. The Latin poets, personifying this river, gave it a daughter named Lar, who, divulging the amours of Jupiter with the nain Juturna, was condemned to eternal silence, and dismissed to the infernal regions. In her way thither she attached the affection of Mercury, and became the mother of two children, under the appellation of the Dil Lieve, and the mother was called the goddess Muerta, or Muta. This river is now Dachia and Il río d'Appio, as it runs from the Apennine way into the Tiber, or from a corruption...
tion of Aquataccio, or Aqua d’Acio. On the place where
this river crossed the Appian way, the priests of Tybule per-
formed the annual ceremony of washing the statue of the
poddles, and they celebrated with sacrifices. Ovid describes
this ceremony; Fast. iv. 337.

“Et locus, in Tiberin quae lucubres infultus Almus,
Et molens magnum perdit in anuum minor,
Hic purpurae canus eum volpe faciendos
Almonus dominam, fœacula laevi aquam.”

ALMODARIN, a small town of Spain, in New Cat-
tile, north-north-east of Merida, and south-east of Alcan-
tara. N. lat. 37° 10’. W. long. 14° 46’.

ALMODVAR, or Almoduvar, a small town of Spain,
in Aragon, three leagues south-west from Huesca.
The adjacent country abounds with grain, wine, and
fafron.

ALMODA Val de Canyo, a town of Spain, in New Cat-
tile, situated in a pleasant valley at the foot of Mount Mo-
renes, and defended by a cattle, six leagues south of Ciudad
Real.

ALMODAVAR, a town of Portugal, in Alentejo, contain-
ing within its district five parishes.

ALMOENA, in Ancient Geography, a town of Africa,
placed by Ptolemry in Bithiax, ten leagues to the east-
fourth-call of Tichufa. Almoena is now Teleman, and Ti-
chufa, Teghewa. Shaw’s Travels, p. 126.

ALMOGIZA, among Arabic Writers, denotes the
limb or circumference of the astrolobe.

ALMOWARR, in Ancient Chronology, was the first
month of the Arab year. On some occasions the observance
of this month was put off to the following month Safar.

ALMOHEDES, in History, the name of an African dy-
mally which succeeded that of the Almoravides in Bar-
bary, in the commencement of the 12th century. It took
its rise in the 25th year of the reign of Al Ahmads, or
Brahm, who succeeded his father Ali, A.D. 1145; and
dervived its name from an obscure founder, called Al Mo-
hadi, or Al Mohedes. This person was a Berber, of the tribe of
Muzamada, named Abdallah, and was a famous preacher
among those of his tribe, who were bent upon Mount Atlas.
In order to secure success to the design he had conceived, he
assumed the title of Mohadi, or Mohed, and set up for the
head or leader of the Orthodox, or Unitarians, who were
now become so numerous by his preaching, that he pre-
sumed to bid defiance even to his sovereign. Brahms was
so much immersed in pleasure to regard the revolt, and too
confident of his own security to apprehend any danger from
the insurrection of a party composed of perfons whom he
looked upon with contempt. But their unexpected inca-
veral armament, and he prepared for subduing them. His force,
however, was insufficient for the purpose, and in his first
engagement he was totally defeated. Abdallah was wary, and
secured the capital; so that Brahms, purified as a fugitive
by Abdolmomen, one of the party, was obliged to seek re-
riage in the city of Fez. But the colleges of the city were not
only fluent against him, but opened to receive his pursuers.
The next place to which he repaired was Auran, or Orn,
but the city was soon invested by Abdolmomen, and threat-
ened with fire and sword. The magistrates, unable to de-
fend themselves, and dreading the consequences of an hostile
attack, urged him to leave the town. Under the shelter of a
dark night he, with his favourite wife on horseback behind him,
set out from Orn, but they were discovered and pursued; and
fearing to fall into the hands of his enemies, he spurred
his horse in a fit of despair, and leaped down a precipice,
where he and his wife were dashed to pieces. Such was the
fatal end of this prince, whose death put a final period to
the empire of the Almoravides. As soon as Abdolmomen,
vaftly called Abdullaman, was apprized of Brahms’s death,
he traversed the kingdom of Tremcen in his way to Mo-
roco, where, Abdallah being dead, he was declared his suc-
cessor by the chiefs of the party, and proclaimed king of the
Almohedes, under the title of Al Muh Al Mumin Abdallah
Mohammed Abdal Mumen Ebn Abdallah ibn Ali, i.e.,
chief or emperor of the true believers of the house of Mo-
hammed Abdal Mumen, the son of Abdal Mumen, the son
of Abdallah of the lineage of Ali. Abdallah’s reign was
long enough to allow his enacting some prudent regulations
for the establishment of his seat and his new kingdom,
which he left behind in his will. He appointed a council of
42 disciples of his faith, all of whom were preachers; some
of these were commissioned to regulate all public affairs, and
at proper seasons to itinerant preachers in the country,
for the diffusion of their doctrine; and others of them, to
the number of 16, were to act as secretaries. From the
former of these two classes the successors to the regal and
pontiffial throne were to be elected, for both these dignities
and titles were to be united in the same person. The disco-
ils of this sect were denominated Mohammdain, or Al
Mohaaddin; but by the Arabic writers they are styled only
preachers, and by the Spanish, Al Moheches; and the de-
decendants and successors of this tribe continued to retain
the appellation of Emir Al Muminin, or chiefs of the faithful
or true believers, as long as their dynasty lasted; and they
became very powerful both in Africa and Spain. As to
their religious tenets, if we except their specious pretence
unto orthodoxy, and strict adherence to the doctrine of
the unity of God, which they zealously inculcated, they had
little or nothing peculiar to themselves; but they were loud
in their reproaches against the tyranny of the Almoravides,
and their clangers for liberty; and thus they allowed the
greater part of the kingdom to revolt, and to embrace their
feet and doctrine.

The new sovereign, on his accession to power, ex-
nución the Almoravide line by threatening the son of
Brahms, and exterminated all the unhappy remains and adhe-
rents of this race. During the progress of this revolution,
several of the Almoravide governors, availing themselves
of the distraction and tumult that prevailed, created their
governments into independent principalities and petty king-
doms; and those who inhabited the mountainous parts es-
tablished a variety of lordships under their own chieftains.
The Nubians and Libyans took the lead, and others followed
their example; particularly the blacks of Barbary, Tripoli,
Alarwan, Tunis, Algiers, Tremcen and Bugesia, each of
which had its own sovereign. Abdolmomen, however, pur-
vised his conquests with success, and in a few years reduced
the Numidians and Gueltas in the west, and the kingdoms
of Tunis, Tremcen, and the greater part of Mauritania
and Tingitan under his subjection. He likewise made
Sahib, the chief city of Africa, and some others on the same
coast, and made other conquests both in Spain and Portugal.
He died in the seventh year of his reign, and was succeeded,
A.D. 1156, by his son Yufef, or Josep. Yufef was a valiant and
martial prince; and having established the kings of Tunis and Bugesia in their respec-
tive kingdoms as his tributaries and vassals, he prepared to
embark for Spain to aflift the Moorish princes, who solicited
his protection and succour. Yufef was succeeded by Yabub,
or Jacob, during Al Mansur, or the conqueror, who, after
securing himself against both the revolted and the plundering
Arabs, pursued his conquests with such speed and success,
that in a little time he became master of the whole country
lying
lying between Numidia inclusive, and the entire length of the
Barbary coasts from Tripoli to the kingdom of Morocco,
comprehending also those of Fez, Tiemcen, Tunis, and
Tripoli, and extending above 12,000 leagues in length, and
in depth from the Mediterranean to the sandy deserts of Libya,
above 450, excluding his Spanish dominions, where he
was acknowledged as sovereign by most of the Arabian
Moslem princes. The clime of this prince's history is wrap-
ped up in obscurity; for about the year 1200, having
quelled a revolt in Morocco, and violated his faith with the
governor of the capital which he reduced, and his adherents,
in the most perfidious and cruel manner, he disappeared;
and, as it is said, touched with remorse in the recollection of
his conduct, wandered about obscure and unknown, and at
last died a poor debilitated baker at Alexandria. He was suc-
cceeded in the kingdom by his son Mohammed, surnamed Al
Naker, who, on his accession to the crown, passed over into
Spain with a very large army, confounding of more than
150,000 horse, and 300,000 foot, and engaged the whole
force of the Christians on the plains of Tholofa, where he
was totally defeated with the loss of above 150,000 foot,
30,000 horse, and 50,000 prisoners. This famous battle
was fought, according to some Arabic writers, in the
year of the Hegira 609, A.D. 1212; but, according to the
Spanish and other historians, in 617, A.D. 1226. After
this defeat he returned to Africa, where he was received
with coldness and difficulty, and soon died of vexation, having
appointed his grandson Zeyed Arrax to succeed him. Al
Zeyed was soon afflicated by order of Garamanz Ebn
Zeyen, of the tribe of the Zeneti, a descendant of the Ab-
dolavates, ancient monarchs of the kingdom, but at this time
vassals to the Almohedes; and with him terminated the dy-
nasty or government of the Almohedes, after having held it
for about 170 years; which was succeeded by that of the
Benimerini, another branch of the Zeneti. These last, hav-
ing held the government during the space of 117 years, en-
larged their conquests, and enriched themselves by frequent
incursions not only into all the neighbouring kingdoms; but
even Nubia, Libya, and Numidia were at length swal-
lowed up by the general inundation of Mohammedan.

ALMOI, in Geography, a town of Trufia, in the pro-
cince of Natangen, eight leagues south-west of Rilla-
burg.

ALMOIN, in Law. See Franklin Almoin.

ALMON, in Ancient Geography, a town of Judea, in
the tribe of Benjamin, alligned by Josephus to the Levites of
this tribe who were of the family of Aaron.

ALMON, a town of Greece, in Beocia; and also a town
or district of Thessaly.

ALMONACID, in Geography, a town of Spain, in
Old Castile, three leagues south-east of Toledo.

ALMOND, Arabic, in Botany. See Brabeium.

Almond, Unson and Tree. See Amygdalus.

Almond, in the Materia Medica, is a kind of fruit which
is the produce of the almond-tree, or Amygdalus Communis.
There are two principal varieties of this tree, distinguished
by the quality of the fruit; and hence we obtain two kinds of
 almonds, viz. the sweet and the bitter. Neither the kernels
themselves, nor the trees that produce them, allowing for
some difference in the size of the flowers and fruit, are dif-
tinguishable by the eye; and it is said that the same tree
which in a wild state bore bitter almonds, have, when culti-
vated, afforded the sweet kind; and that the sweet, for want
of culture, have degenerated into bitter. The almonds
which we receive from Barbary, where the tree is indigenous,
are bitter; and those of Europe and of other parts, where it
is cultivated, are in general sweet. In the choice of these
kernels, particularly those of the sweet sort, care should be
taken, as they are very apt, on account of the oil with which
they abound, to become rancid in keeping, and to be preyed
upon by an insect, which eats out the internal part, and
leaves the almond apparently entire.

Sweet almonds are, for most purposes of medicine and diet,
blanched, or freed from the outer, thin, acrid skin, by steep-
ing them in hot water till it is sufficiently softened to be
peeled off. Sweet almonds are more used as food than as
medicine, and like others of the nucie olifae, or olive nuts,
they are considerab]y nutritious; but they are said to be of
difficult digestion, unless they are extremely well commo-
nated. Dr. Cullen suggests, that this inconvenience, not-
ticed by Dr. Lewis, may be in a great measure obviated by
a very diligent trituration, uniting very intimately the farinaceus
and the oily part. As medicines, they contribute, by their
soft succulent quality, to blunt acrimonious humours in the
first passages, and thus sometimes give present relief in
heart-burns and similar complaints. Their medicinal qual-
ties depend upon the oil which is blended with the farinaceus
matter, and which they yield, on expression, nearly in the
proportion of half their weight. Murray says, that 57
pounds of unpeeled almonds have yielded, by cold expres-
sion, one pound fix ounces of oil; and afterwards, on heat-
ing the almonds, three quarters of a pound. This oil is more
agreeable to the palate than most other expressed oils, and is
therefore preferred for internal use, in order to obtain
acid juices, and to soften and relax the solids; in tickling
coughs, hoarseness, colic, pyretic pains, &c. and ex-
ternally in tenion and rigidity of particular parts.
The milky solution of almonds in watery liquors, usually called
emulsions, poisons in a degree the emollient qualities of the
oil, and are prescribed with the same intention, particularly
in heat of urine and irritations; and they are also given as
diluents in acute diseases, and for supplying the place of ani-
mal milk, to which they bear a great analogy. These emul-
sions are formed of a due confluence, with the proportion of
an ounce of almonds to a quart of water, which should be
gradually poured in after the almonds have been finely
powdered; and the London College directs the ad-
dition of gum arabic, which renders it a still more useful
demulcent in catarrhal afflictions, irritations, &c. But if te
water is heated for an instant the solution of the gum, it
should stand to cool before it is poured on the emulsion,
otherwise the emulsion will be imperfect. Sugar, or some
other grateful material, is commonly added, in order to
make the liquor more palatable. The oil, after being ex-
posed for a few days in a heat equal to that of the human
body, becomes rancid and acrimonious. Emulsions, on
standing for some hours, throw up a white cream on the
surface, and the whey-like liquor underneath grows not ran-
cid but four. The latter are therefore preferred in inflam-
matory distempers, because they are not subject to become
acid and irritating by the heat of the body, but tend rather
to a flat in which they may serve to abate inflammation.
Acids, mixed with emulsions, separate the oily and ferrous
parts, and produce a thick curd, much after the same man-
ner as they do in milk. A more permanent emulsion may be
formed by triturating the pure oil with a thick mucilage
of gum-arabic, from which the oil will separate on standing
for some days, nor on the addition of water, though it may
be speedily disengaged by alka]ies, both fixed and volatile.
One part of gum, made into a mucilage with an equal
quantity of water, is sufficient for four parts of the oil. The
white
white or yolk of an egg, and a mixture of syrup, with a small quantity of volatile spirits, will render the oil in some degree soluble in water. Several substances, not miscible of themselves with water, may, by triturating with almonds in the proportion of about six times their quantity, be mixed with it, and thus fitted for medicinal use, as camphor, and various resins, and nitrous substanccs. Some reckon two kinds of sweet almonds, 1. Jordan, which are the larger, longer, and dearer kind, chiefly used to be cat with meats. 2. Valencian and Barbary almonds, or those from which the oil is produced. Houghton Collect. No. 474, tom. II. Better almonds yield a large quantity of oil similar to that of sweet almonds, and they are alike miscible with water into an emulsion. The oil has no bitter taste, and that of either fort is used indifferently for medicinal purposes; but the matter remaining, after the expression of the oil, is more powerfully bitter than the almond itself. Great part of this bitter matter diffuses by the assistance of heat, both in water and in rectified spirit, and a part also arises with both menstrua in distillation. These almonds, and emulsions of them, have been recommended as aperients, refolvents, diuretics, and anathemstics; but though they may in these respects be of some use, they are remedies of too dangerous a kind for common practice. When taken freely in subsistance, they occasion hebbness and vomiting; and they have been long known to be poisonous to various brute animals, as wolves, foxes, dogs, cats, and several sorts of birds; and from the sudden effects which this poison produces, and the convulsions and spavins that follow the exhibition of it, there can be no doub of its acting directly on the nervous energy. Some authors have alleged, that they are also deleterious to the human species. However this be, as their noxious quality seems to reside in that matter from which they derive their bitterness and flavour, it is probable that when this is separated from the farinaceous substance by distillation, and taken in a sufficiently concentrated state, it may prove a poison to man, as is the cafe with the common laurel, to which it appears very analogous. One small drop of this essential oil convulsed, and in two minutes killed a sparrow. These almonds were formerly eaten to prevent the intoxicating effects of wine; and Plutarch (Sympol. lib. i. apud op. tom. ii. p. 624) relates, that the physician of the Illyrians, son of Tiberius, took five or six bitter almonds for this purpose. John Baulin, from experiments made on paroephizer, denies their having this power; and from twelve of them, we are told, that Loary (De Venenis, p. 17.) experienced the effects of incineration. They are highly commended by Theophrastus (Nov. Act. Nat. Cur. tom. I. p. 181) for the cure of hydrophobia from the bite of a mad animal, who found them effectual in 12 cases, in which some were eaten every morning for one or two weeks. Bergius says, (Mat. Med. p. 433.) that bitter almonds, in the form of emulsion, cured obfinate intermittents, after the bark had failed. Having distilled two drams of foible tartar, and an ounce and a half of honey in a pound of water, he made an emulsion with this water, and one ounce of bitter almonds. Of this emulsion he gave, during the intermission, a pouf or two every day, and says, that by this remedy, the recurrence of the fits was prevented. In cases where this failed, and in which he had recourse to the bark, he mixed with the decoction of the bark the bitter emulsion: and he adds, that he had seen interminable fevers frequently recurring, and which had entirely relished the bark, at length totally cured by the bitter emulsion alone. This is a remedy, however, which should be used with great caution. Lewis, Cullen, Murray, and Woodville.

The kernels of bitter almonds give much the same relish in distillation as the kernel of the cherry; on which account some have used them in making a counterfeit cherry brandy. They are also frequently used instead of apricot kernels in ratafia.

Almonds give the denomination to a great number of preparations in confectionery, cookery, &c. of which they are the basis; as almond-cakes, almond-cream, crisped-almonds, almond-milk, almond-paste and powder, almond-flour, &c. Almond-milk is an emulsion or mixture made of one and a half ounce of sweet almonds, half an ounce of double refined sugar, and two pints of distilled water. The almonds are beaten with the sugar, then rubbing them well together, add the water by degrees, and strain the liquor. There is a preparation also called almond-butter, made of cream and whites of eggs boiled, to which are afterwards added blanched almonds, and the whole is set over a slow fire till it becomes thick.

Almond, in Geography, a river of Scotland which runs into the Frith of Forth, five miles west from Leith.

Almond, in Commerce, a measure by which oil is sold in Portugal, 26 almonds making a butt or pipe.

Almond is also a fruit which serves instead of small money, in several parts of the East Indies; particularly where the cowries, tho' small shells which come from the Maldives, are not current.

Almonds, amygdales, in Anatomy, denote two mucous glands, in rite, shape, and inequality of surface, not unlike a small almond. They are situatet in the posterior aperture of the fauces, or the opening by which the cavity of the mouth communicates with the bag of the pharynx. They are more commonly called tonsils, to which title we refer for further information.

Almond, or Alman-furnace, fontaine d'Allamagne, the common metal melting furnace of the German refiners. See Furnace.

Almonds, ammendis. Thus the French lapidaries and looking-glass makers call those pieces of rock crystal, or call crystal, which they cut with a wheel, giving them a figure something like that fruit. They are used to adorn branch-candlesticks, and other furniture made of glasses or crystal.

ALMONDBURY, in Geography, a village of the West Riding of Yorkshire, 10 miles from Halifax, and 185 from London.

ALMONDSBURY, a village in Gloucestershire, where Almound, father of Egbert, the first folk monarch of England, is said to have been buried. It has a Saxo fortification, with a double ditch, which commands an extensive view of the Severn. It is eight miles from Bristol.

ALMONER, anciently also written Amner, an officer in a king's, prince's, or prelate's household, whose business is to distribute alms to the poor.

The lord almoner, or lord high almoner, of England, is an ecclesiastical officer, usually a bishop; who is to visit and relieve the sick, poor widows, prisoners, and others in necessity, for which purpose he has the forfeiture of all dodeans, and the goods of felis de fis, which he is to dispose of to the poor.

He has likewise, by an ancient custom, a privilege to give the first dish, from the royal table, to whoever poor person he pleases; or, instead thereof, an alms in money.

He also distributes to twenty-four poor men, nominated by the parishioners of the parish adjacent to the king's palace of residence, to each four pence a day in money, and an alms of bread and small beer; each person first repeating the Creed, and the Lord's prayer, in presence of one of the king's
King's chaplains, deputed by the lord almoner to be his full-almoner, who is also to scatter new-coined two-pences in the towns and places through which the king passes in his progress. See Maundy Thursday.

He has also the charge of several poor pensioners to the crown below stairs; consisting of such as have spent their youth, and become superannuated, in the king's service; or the widows of such household servants as died poor, and were not able to provide for their wives and children, whom he duly pays. Chamberlayne's State of Great Britain, p. 98.

Under the lord almoner, besides the full-almoner, there is a yeoman, and two grooms of the almonry, chosen by his lordship.

The French kings used to have their great almoners, first almoners, ordinary or quarterly almoners, &c.

Great almoner, grand almoner, was the highest ecclesiastical dignity in that kingdom. To him belonged the superintendence of all hospitals, and houses of lepers. The king received the sacrament from his hand. He laid mails before the king, in all grand ceremonies and solemnities.

Almoner is also applied, in Ecclesiastical Writers, to the deacons of churches.

Almoner is also used, in Historians of the Middle Age, for him appointed by a person to distribute his alms to the poor. In this sense, almoner amounts to much the same with what has since denominated executor.

Almoner is also sometimes used for a person who left alms to the poor, by his last will.

Almoner is also sometimes used for a legatee.

In this sense, it is the rule, that the same person could not both be almoner and heir.

Almoner is also a more fashionable title given, by some writers, to chaplains. In this sense, we meet with almoner of a house, almoner of a regiment.

Almonry, or Aumery, the office or lodgings of the almoner; also the place where the alms are given. See Aumery.

Almonte, a neat town of Spain, in the country of Seville, environed with a forest of olives; 13 miles south-east of Moguer.

Almonte, a river of Spain, which runs into the Tagus, not far from Truxillo.

Almopia, in Ancient Geography, a country of Macedonia, inhabited by the Almopians, in which stood the cities of Europus, Albanopolis, and Apialus. Thucydides mentions Almopia, and Pliny the Almopii; and it is said to have derived its name from Almops, son of Neptune and Helle, the daughter of Athamas.

Almora, in Geography, a country of Asia, between the mountains of Thibet and Hindoostan, north of the province of Rohilkund. The principal towns are Rampoir and Coffsopour.

Almoravides, in History, a name given by the Spanish historians to an Arab tribe, which took possession of a district of Africa in order to live at their ease, and in a state of retirement, as they pretended to follow the dictates of the Koran more closely than others of their sect, from whence they took the name of Morabites, which the Spaniards changed into that of Almoravides. The first prince or chief of this nation was Abubeker Ben Omar, who is commonly called by Spanish authors Abu Texfien or Tezfin. This prince founded the dynasty of the Almoravides in Barbary, A. D. 1051, by the aid of a powerful army of malecontents in the provinces of Numidia and Libya, assembled by the influence of the Marabouts or Morabites, whence the appellation was derived. Texefian, as we have shown in the history of Algiers, was succeeded by his son Yufet, or Joseph, who, after having extended his conquests in Africa, and reduced the kingdoms of Tlemcen, Fez, and Tunis, to a state of tributary vassalage, took advantage of the intestine wars in Spain, and passed over, with a view of enlarging his conquests, into that country. Here he repulsed the Christians with great vigour; and though the Moorish princes did not afford him the assistance which he expected, he reduced the greatest parts of the kingdoms of Murcia, Granada, Cordova, Juen, and some few places in Valencia; and then returned into Africa, leaving his conquered dominions under the government of his nephew Mohammed, with a considerable part of his army. As soon as he arrived in Africa, he published a general gazzie, or religious war, and with a fresh and numerous army embarked at Ceuta for his Spanish conquests, and soon rejoined his nephew in Andalusia, which they ravaged with fire and sword. In 1107, five years after their assault, he made another descent, penetrated into Portugal, and reduced the city of Lisbon, with a great part of the kingdom, but left the cities of Algazir and Gibraltar, which he had taken before. Having been defeated at sea in his way to Barbary, he proposed a truce, which was agreed to on condition that he should submit to become the tributary of the Spanish monarch. Yufet, the Almoravide prince, was so exasperated that he vowed never to desist until he had utterly extirpated Christianity in Spain. Accordingly he prepared for a fresh descent; and landing at Malaga, led his army into the enemy's country with great fury and little prudence. The consequence of this hasty measure was a battle, famous in history, called the Battle of the Seven Courts, in which, though after great slaughter he gained a victory, he lost to great number of his own men, that he was obliged to return to Africa, where he died soon after, at his capital of Morocco, leaving the sovereignty to his son Ali, A. D. 1110. This prince, left warlike than his father, employed his thoughts in erecting spurious buildings, and in particular the great mosque of Morocco, whilst he neglected his Spanish conquests. Alphonso, king of Aragon, was daily recovering some considerable cities from him; and he was at last reduced to the necessity of passing over to Spain, for the succour of the Moorish princes. But he was unsuccessful in several expeditions; and in his last enterprise, though he had the vigorous concurrence of the Moorish chiefs, he was defeated and slain by king Alphonso, with the loss of 30,000 men, in the sixth year of his reign. He was succeeded by his son Al Abraham, or Brahem, who perforzed his pleasures, and oppressed his subjects with taxes, which occasioned dissatisfaction and complaint, and soon terminated in a revolution, by which the government was transferred from the tribe of the Almoravides to the Almohades, in the 27th year of his reign. Mod. Un. Hist. vol. xiv. p. 296-301.

Almout, in Geography, a town of Perfa, in the province of Taberistan, 32 leagues south-west of Ferbad.

Alms, eleemosyna, something given out of charity or pity to the poor.

The ecclesiastics anciently sufficed wholly on alms. — The alms of the primitive Christians were divided into three parts; one whereof belonged to the bishop, another to the priests, and a third to the deacons and sub-deacons. — Sometimes they divided them into four; the last of which went to the poor, and to the repairing of churches.

The Romans extend the term alms to that which is given to the church, or to other pious uses. — Hence, what the church holds on this footing is called tenure in alms.
Alms are of divers kinds.

Alms, pafchah, eleemosyna pafchah, were those distributed at the solemnity of Easter, attended, in some places, with other acts of humility, as washing of feet, &c.

Alms, sufficient, eleemosyna sufficientia, a certain portion of the effects of persons dying intestate, set apart for the use of the church and the poor.

Alms of plough-land, eleemosyna curvatum, or eleemosyna pro arboris, was a tax, anciently paid for the benefit of the poor, at the rate of a penny for each plough-land.

Alms of the king, denote what was otherwise called Peter's pence.

These were sometimes also called alms of St. Peter.

Alms are divided by Mahometans into voluntary and legal.

Alms, voluntary, are those left to every man's discretion, to give more or less, as he sees fit.

The voluntary alms are properly denominated by the Arabs fadakat, because they are a proof of a man's justice in the worship of God.

No religious system is more frequent or warner in its exhortations to alms-giving than the Mahometan. The Koran represents alms as a necessary means to make prayer be heard; for which reason the Caliph Omar Ebn Abd'alaziz used to say, "That prayer carries us half way to God, failing the rest is left to the door of his palace, and alms procure for us admission." The Mahometans esteem alms-deeds to be highly meritorious, and many of them have been illustrious examples of it. Hafan, the son of Ali, and grandson of Mahomet, in particular, is related to have lived in his life divided his sustenance equally between himself and the poor, and twice to have given away all he had; and the generality are so addicted to the doing of good, that they extend their charity even to brutes. Alms, according to the prescription of the Mahometan law, are to be given of five things, viz. cattle, i.e. camels, kine, and sheep; money, corn; fruits, i.e. dates and raisins; and wares fold. Of each of these a certain portion is to be given in alms; and that portion was usually one part in 40, or 2½ per cent. of the value. But no alms are due for them, unless they amount to a certain quantity or number, nor till they have been in possession 11 months; nor are alms due for cattle employed in tilling the ground, or in carrying of burdens. However, at the end of the feast of Ramadan, every Moslem is obliged to give in alms for himself, and every one of his family, a measure of wheat, barley, dates, raisins, rice, or other provisions commonly eaten.

Alms, legal, are those of indissoluble obligation, as being commanded by the law, which directs and determines both the portion to be given, and the kind of things of which it is to be given.

The legal alms are properly called by the Mahometans saccan, either on account of their increasing a man's store, or of their purifying the remaining part of his sustenance.

Some writers have given the denomination of tithes, but improperly; since, in some cases, they fall short, and in others exceed the proportion of a tenth. These legal alms were first collected by Mahomet himself, and employed, as he thought fit, in relieving his poor relations and followers, but chiefly in maintaining those who served in his wars, and fought, as he termed it, in the way of God. His successors continued to do the same, till, in process of time, other taxes and tributes being imposed for the support of the government, they seem to have been weary of acting as almoners to their subjects, and to have left the payment of them to their own confidences. In the Mahometan rules and practice with regard to alms, we may discover obvious traces of the resemblance of their system to that of the Jews. Sâk's Koran, p. 110.

Alms, charter of, charta eleemosynaria, that whereby a thing is given to the church.

Alms, alms-boxes, or tithes, and alms-men, among the French, is also used for a compulsory payment, imposed by way of punishment, to be converted to public charitable uses.

In all adjudications to the king's right, there is an alms reserved. This amounts to what among us is usually called forfeiture to the poor.

Alms-box, or chest, a small chest, or coffer, wherein anciently the alms were collected, both at church and at private houses. This is also in common use in several places.

The alms-chest, in churches, is a strong box, with a hole in the upper part, having three keys, one to be kept by the parson, or curate, the other two by the church-warden.

The erection of such alms-chest in every church was introduced by an act in 27 Hen. VIII.; and it is enjoined by the Book of Canons, as also the manner of distributing what is thus collected among the poor of the parish.

Almstend, or Almstond, among our Saxons ancestors, alm-money; that is, Peter's-pence, anciently paid in England on the first of August; called also romesfeo, romesfore, and houses-penny.

Almstäd, in Geography, a town of Arabia, 80 miles north-east of Haggan.

Alms-house, a poor hospital; or an edifice built by a patron in a private capacity, and endowed with a revenue, for the maintenance of a certain number of poor, aged, or disabled people.

Almstad, in Geography, a town of Sweden, in the province of Småland, three miles from the Baltic, and four east from Christianstadt.

Almucantars, or Almucantars, formed of the Arabic al ArgumentNullException, in Astronomy, are circles parallel to the horizon, imagined to pass through all the degrees of the meridian.

As the meridians pass through the several degrees of the equator, the almucantars pass through those of the meridian of any place, and they are the same with regard to the azimuths and horizon, that the parallels are with regard to the meridians and horizon.

They serve to shew the height of the sun and stars; and are described on many quadrants, &c. being also called parallels of altitude.

Almucantars, pafl, an instrument usually made of pear-tree or box, having an arch of fifteen degrees; formerly used to take observations of the sun, about the time of its rising and setting, in order to find the amplitude, and consequently the variation of the compass.

Almucium, or Almucium, in Middle-Age Writers, denotes a kind of cover of the head, part of it pendant over the neck and shoulders, worn chiefly by the ancient canons and monks.

The word is also written almucia, aumucia, almucella, armucia, and ameia.

The almucium appears to have been much the fame with what is otherwise denominated caputium. The almucium, though proper only to religious, was sometimes also afforded by laymen, princes, and even women of quality.

The part which covered the head was of a square form, making, as it were, four horns, as may be seen from the ancient pictures of canons. Hence appears the origin of the square caps, bonnets, &c. still retained in cathedrals and universities, which are no other than the upper part of the almucium, without the lower.

Almucia is also used, in some Ancient Writers, for the
furs or skins worn by the canons, on their left arms, in the manner of muffes.

ALMUDHERIS, in the Arabian *Astronomy*, a kind of dignity, or pre-emnience, according to a planet in some place, either from its disposition or benign aspect.

ALMUG-tree, a kind of wood mentioned in Scripture, imported by Solomon from Ophir, and used in the making of rails, or pillars of the temple. 1 Kings, ch. x. ver. 11, 12. 2 Chron. ch. ii. ver. 8. See *Almugnis*.

ALMUGEA, in *Astronomy*, denotes a certain configuration of the planets, in respect to the sun and moon, correspondent to that which is between the hours of those planets, and the sun's and moon's hours.

Thus Saturn would be in the *almanac* of the sun, when distant from him the space of five signs in faccession, or in the *almanac* of the moon, when he is at the same distance, only contrary to the faccession of the signs.

ALMUGNA, in *Geography*, a large handsome village of Aragon, in Spain, situate at the junction of the Grio with the Salon.

ALMUGNECAR, a sea-port town of Spain, in the province of Granada, situate on the Mediterranean, with a good harbour and strong citadel, eight leagues south of Alhama, and 18 east of Malaga. N. lat. 51° 50'. W. long. 3° 45'.

ALMUM, in *Ancient Geography*, a district of Mafia, upon the Danube.

ALMUS. See A. M.

ALMUTAZAPHUS, a magistrate of Aragon, whose office is to search houses for stolen goods, weigh the bread, measure the wine, &c.

ALMUTHEN, in the Arabian *Astronomy*, the planet which has the disposal of a place, that is, furnishes it with a good harbour and strong citadel, in number and efficacy of dignities, regard being had to the efiectual points, viz. exaltation, term, trigon, and phase.

This is otherwise called *almanente*.

ALNABATI, in *Materia Medica*, a name given, by Avicenna and Serapion, to the *Silwa dukis*, or carob-tree. They called both this and the *acacia* by the common name *charoph*, or *charab*; but they sufficiently distinguish this, not only by this appellation, but by telling us it was a gentle purge, whereas the other was astringent.

ALNAGE, or *Aulnage*, French, formed of *aune*, or *aune, an elle, q. d. ell-measure;* the measuring of woollen manufactures with an elle, and the other functions of the *alnager*.

All the attempts which our forefathers made for regulating manufactures, when left to the execution of any particular officer, in a short time resolved into a tax on the commodity without respect to the goodnss thereof.—As is most notorious in the case of alnaghe, which was intended for a proof of the goodness of the commodity; and to that purpose a test was invented, as a signal that the commodity was made according to their statute; which test is, it is said, may now be bought by the hundred, and put on what the buyers please. Sir Jos. Child's Diff. on Trade.

It is probable that the abuses here mentioned by Sir Josiah Child did, among other reasons, give occasion to the clause 11 and 12 Will. III. cap. 20. by which alnaghe duties are wholly taken away.

ALNAGER, Aulnager, or Aulneger, q. d. measure by the elle, signifies a sworn public officer, who, by himself or deputy, is to look to the affise of woollen cloth made through the land, &c. the length, width, and work thereof; and to the elle for that purpose ordained. The office of king's alnager seems to have been derived from the statute of Richard I. A. D. 1197, which ordained, that there should be only one weight, and one measure, in the whole kingdom; and that the custom of the alnager, or standard of weights and measures, should be committed to certain persons in every city and borough. This office is first mentioned in the statute-book, A. D. 1328; but it appears to have existed under this appellation, and to have been ordained by letters patent as far back as the 15th year of King Edw. II. A.D. 1322. His bounds were, for a certain fee, to measure all cloths made for sale, till the office was abolished by the statute 11 and 12 Will. III. cap. 20. In more modern times, instead of the alnager, they have in every clothing town and parish proper persons called *searbers*, appointed by the clothiers themselves, who examine the quantities and dimensions of the several kinds of cloth, agreeably to the statute of the 5th and 6th year of King Edward V. cap. 6. Anderson's *Com. vol. i. p. 191. ed.*

ALNAPES, in *Geography*, a mountain of Ireland, in the county of Donegal, 19 miles north-north-east of Ballyshannon.

ALNASI, in *Mahometan Law*, the transferring the observance of a sacred month to a profane month.

ALNE, in *Geography*, a river of England, which runs into the Stour in Warwickshire, on the borders of Worcester-shire, four miles north-east of Ewellham.

ALNE is also a river which runs into the north sea at Alnemouth.

ALNEMOUTH, or Alemouth, a sea-port town of England, for small vessels, in the county of Northumberland, which carries on a considerable trade with Holland, four miles south-east of Alnwick, and 15 north of Morpeth. N. lat. 55° 57'. W. long. 1° 35'.

ALNEY, an English island, in the river Severn and county of Gloucester, near the city of Gloucester, remarkable for an interview between Canute the Dane and Edmund Ironside.

ALNIDENA, in *Ancient Geography*, a town of Caria, mentioned in the council of Chalcedon.

ALNI EFFIGIE, in *Botany*. See CRATBERUS and MESPELUS.

ALNIFOLIA. See CLETHRA.

ALNI FRUCTI. See CONOCARPUS and THEOBROMA.

ALNUS, the elder. See BETULA and CONOCARPUS.

*Alnus nigra et betula.* See RHAMUS.

Alnus also denotes a part in the ancient theatres, at the greatest distance from the stage.

ALNWICK, in *Geography*, a market-town of England and county town of Northumberland, situate on the side of a hill near the river Alne. The town is populous, and in general well built: it has a large town-houfe, where the quarter-seions and county-courts are held, and members of parliament are elected. Its principal ornament is an old Gothic castle, belonging to the Percy family. It stands on the brow of a hill above the river Alne, fronting the north, and having a town immediately behind it. The late Duke of Northumberland, after his marriage with the heiress of this noble family, reduced this castle from its decay, and restored it to more than its former splendour. He repaired the surrounding towers, and supplied those that were wanting in all the several courts that encircle the mansion. He rebuilt the citadel in its original form, and converted it into a very superb palace, observing the Gothic exterior in every compartment, and uniting it with all the magnificence of the modern. The approach is extremely grand, through three gateways and two spacious courts, environed by the outworks, into a third court, which appears immured within the
the citadel. A light and elegant staircase, spreading in the form of a fan, introduces to the grand range of apartments, which are admirably contrived. The dining-room, drawing-room, salon, and library, are very noble rooms; and they are fitted up in a style which admirably corresponds with the structure. The richly ornamented chapel forms a splendid appendage to the castle. The ground in front of this building is well disposed, on each side of the Aine, which is crossed in flight by two handsome bridges, and the neighbouring hills are clothed with woods of the Duke's creation. On one of the highest summits he has erected a lofty tower, commanding an extensive prospect over a bleak country towards the Cheviot hills on one side, and the coast on the other. Hulme Abbey hangs beautifully over the river, and several neat apartments are intermixed, with judgment and taste, among the ruins. This town has been noted for a singular custom, which those who take up their freedom are said to be under a necessity of observing, which is that of jumping into a muddy well, called Freeman's Well; and this ceremony is conducted in a manner as singular. The freemen, on their return from this whilimical excursion, are received into the town by a procession of women dressed in ribbons, with bells and garlands, singing and dancing. This ceremony is said to be established by King John, who was mired in this well, as a punishment for their not keeping the roads in good order, and made a part of their charter. In this town Malcolm, king of Scotland, in his incursion into Northumberland, was killed, together with Edward his son, when his army was defeated by Robert Mowbray, earl of this county, A.D. 1094; and William, king of Scotland, when he invaded England in 1174, with an army of 50,000 men, was routed in this place, and made prisoner. The weekly market is on Saturday. The distance of Alnwick from London is 308 miles, from Morpeth 19, and from Berwick 30 miles. N. lat. 55° 24'. E. long. 1° 10'.
Alo

sembling the colour of soft soap; the flowers are of a beautiful red colour, and appear in August and September. A. aloifolia, common soap A., with leaves, broader, spotted, thorny at the edge, and flowers in spikes. This has broader leaves of a lighter green, with the edges and spines copper-coloured, &c. A. ferrulata, hollow-leaved perfoliate A., with leaves spotted, finely serrated at the edge and the tip of the keel. A. perferticata, upright perfoliate A., with leaves flat almost upright, thorny at the edge, and on the lower surface. A. depressa, short-leaved perfoliate A., with leaves embracing, thorny on both sides, and flowers in spikes. This faldom rises more than a foot high, and the leaves grow near the ground; they are of a fuscous colour, with some white spots; their edges are beft with sharp spines and the flowers grow in bole spikes, the tubular part being red, and the brim of a light green colour. A. humilis, dwarf hedge-hog A., with leaves upright, subulate, radicate, with weak spines all round. This plant is low, and never rises into stem; the leaves terminate triangularly, and are beft on their edges and surfaces with soft spines, whence the name of hedge-hog aloe. The flowers are feldom a foot high, below of a fine red colour, and of a pale green above. Wildenow makes a distinct species of this; ftemlefs, with leaves trigonous, subulate, and acutangular, and flowers racemose, reflex and cylindric; and he makes two varieties. A. miraformis, great mira A. grows to the height of five or fix feet; the leaves converge towards the top in the form of a mira, are fucculent, of a dark green colour, and have spines on their edges, with a few on the upper surface; the flower stem rises about three feet high, and the flowers form a globular spike at the top, which becomes cylindric; they have long pedicules, and the flowers hang downwards; they are cut to the bottom into fine unqual segments; three of the ftemotes are as long as the tube of the corolla, the other three are shorter: the tube is of a fine red colour, and the brim of a pale green. A. breviflora, small mira A.

3. A. arachnoides, cobweb A. Stemlefs, leaves three-cornered, culped, ciliolate, flowers in a fort of spike, upright, cylindric. The varieties are: A. arachnoides, common cobweb A. with leaves short, plane, fufculent, triangular at the end, and borders feri with soft spines. This never rief from the ground, but the leaves spread flat on the surface; the flower stem rises about a foot high, and has three or four fmall dilatent herbaceous flowers. A. arachnoides, ciliolate of Miller. A. arachnida, t. of Linn. 450, with leaves ovate-lanceolate, fufculent, triangular at the end, with numerous soft spines. This plant grows near the ground, the leaves are almost cylindric at their base, and angular near their ends, of a darker green colour than thoé of the former; and produces many fuckers on every side. From the feed of this Mr. Martyn has raised a variety, which has shorter, whiter, and fmoother leaves.

A. margaritiferum, A. pearl, A. puifita, t. t. of Linn. 450, stemlefs, with leaves three-cornered culped papillosome, and flowers in racemes drooping and cylindric. The varieties are: A. margaritiferum, great pearl A. B. marg. miniata, and B. marg. miniata, leafed pearl A. The pearl aloe is of humble growth; the leaves come out near the ground, and they are closely fludded with white protuberances, whence the name. These plants flower in several feasons of the year. A. verrucosum, A. dischicha, B. of Linn. 459, worted or pearl-tongue A. stemlefs, with leaves sword-shaped, acute, papillosome and dilatant, and flowers in racemes reflex or club-shaped. This species has long narrow tongue-shaped leaves, hollowed above, and keel-shaped below, closely fludded with white protuberances: the flowers form loose spikes, and are of a beautiful red colour, tipped with green. It flowers at different seasons, and produces plenty of off-lets. A. cornutum, A. dischicha, of Linn. 459, stemlefs, with leaves acinnicoform, papillosome, and flowers in racemes drooping, curved. The leaves are broader and thicker, not so concave, and with less protuberances than the last; the flowers are of a paler colour, and the leaves shorter. A. cornutum, A. dischicha, of Linn. 459, stemlefs, with leaves acinnicoform, smooth, painted, and flowers in racemes drooping, curved. There are two varieties. A. mac. pulchra, narrow-leaved, spotted A., with leaves fharp, and B. mac. oblonga, broad-leaved spotted A. with leaves blunt with a point. This species varies, with large, oblong, white confluent spots, and with small spots. It is a native of the Cape of Good Hope, and flowers in August. A. cylindrica, A. dischicha, of Linn. 459, stemlefs, with leaves tongue-shaped, ovate, dillant, and flowers in racemes, upright and cylindric. There are two varieties: A. liona angustifolia, A. dischicha, t. Linn. 459, common tongue A. with leaves narrower longer; and B. lingua aphylla, thick-leaved tongue A. This grows with its leaves, which are about fix inches in length, near the ground. The flowers are red below, and green above. It is a native of the Cape of Good Hope. There is a variety, with leaves much more spotted. A. pulchra, A. dischicha, t. Linn. 459, pulchra Medic. Thoé. Ian A. almost stemlefs, with leaves tongue-shaped, ovate, dillant, and flowers in racemes, pendulous and cylindric. It grows to the height of fix or seven feet, with a strong stem, on the upper part of which are produced, two, three, or four heads composed of long, compressed, phahle leaves of a fce green colour, which are placed in a double row: the flowers are red, and appear at different times of the year. A. tenuis, stamridge-bread A. almost stemlefs, with leaves in three ranks, painted, channelled, angular, cartilaginous, and flowers in racemes, cylindric. This is a low plant, seldom rising above eight inches in height: the leaves are triangular and reflex at their extremity, fufculent, with their edges slightly serrated, curiously veined and fpatched, like the breast of the partridge, whence the name. The flowers which grow on stalks about one foot high, are of a fine red colour, tipped with green. A variety of this was raised by Martyn, from seeds received from the Cape of Good Hope, with broader leaves, and not so beautifully spotted, with the flower stalks much taller. It is found in the clayey grounds of Ethiopia. A. eugenia, upright triangular A. sub-caulescent, with leaves imbricate, in three ranks, ovate, and flowers in racemes, drooping, and cylindric. It grows near a foot high, with triangular leaves from the ground upward, of a dark green colour, and the flowers are of an herbaceous colour, with their upper part reflex. It is a native of the fields of the Cape of Good Hope. A. febralis, spiral A. sub-caulescent, with leaves imbricate, in eight ranks, ovate, and flowers in racemes curved back. There are two varieties: A. febralis, imbricate, imbricated spiral A. and B. febralis, pentagona, five-folded spiral A. This grows like the 11th, with rounder leaves, ending in sharp points, and the flowers grow upon taller stems; a variety of this has been raised from seeds, much larger, with thicker leaves and taller stem. It is a native of the fields of Africa. A. retusa, cushion A. stemlefs, with leaves in five ranks deltoïd. These are short, thick and succulent, and compressed above like a cushion, whence the name. It grows close to the ground, and puts out suckers on every side: the flowers are of an herbaceous colour, and much resembhe theo of

Vol. I.
the fourth species. It grows in the clayey soil of Africa. 
14. A. spicata, spiked A. with flowers in spikes horizontal, bell-shaped, and 5-lobed, flat, embracing, and toothed. This much resembles the second species, but is very different in the spike and figure of the flowers. The flower is full of a purple honey juice. The bell and purplish hepatica aloes is obtained from this species. It is found in the interior regions of the Cape of Good Hope. 15. A. pila, painted A. caulecent, with leaves sword-shaped, toothed, painted and patent, and flowers in racemes, reflex, and cylindrical. There are two varieties: a. major, A. perfoliata, and 3. A. minor, A. perfoliata subsp. Linn. 458. A. perfoliata, f. japonica Aiton, Kew. 1. p. 467. It is native of the Cape of Good Hope. 16. A. ferox, caulecent, with leaves sword-shaped, minute-serrate and reflex, and flowers in racemes, erect and cylindrical. This is the A. perfoliata f. of Linn. 458, and it is suggested by Willdenow that it is the A. perfoliata var. barbae-mensis Aiton, Kew. 1. p. 466, and the narrow-leaved A. ferox, A. succulenta of Comm. Hort. i. p. 91, and the A. Americana, with the reddish flowers of manna, of Plukenet. It is a native of Barbados and the Cape of Good Hope. Martyn’s Miller, Gmelin’s Linnaeus, Willdenow.

La Maree enumerates 31 species, viz., A. purpurascens, or A. of Bourbon, originally brought from that island: when the leaves are cut, they yield a juice of a fetid smell. 2. A. succulenta. 3. A. vulgaris, Kandaku or Carvela of Reecd, growing in the sandy loamy soil of Madras, and many parts of India, and also in several provinces of America, as Mexico, New Spain, Brazil and Barbadoes; and yielding, by its purified juice, hepatic aloes, and from its dregs a less pure extract, called Calabash aloe. 4. A. vera, growing in India, of which the A. volubilis of Forks. Egypt. 74, 1. is a variety. 5. A. Aethiopica, that is called from Africa by Bruce, and larger and more reddish than the preceding species. 6. A. fruticosa, or arborecula of Miller. 7. A. ferox. 8. A. mitreformis, of which there is a variety, A. mitreformis angustifolia. 9. A. maculata, or the A. pila above mentioned. 10. A. tetradaphne. 11. A. perfoliata, of which there are reckoned two varieties, one commonly called A. with red spines, and the other artichoke A. 12. A. humilis, or A. with soft spines. 13. A. arachnoidea, with a variety commonly called the leaf aloe, growing in the fields and uncultivated parts of Ethiopia. 14. A. marginata. 15. A. retusa. 16. A. veen. 17. A. marginata. These are the A. africana, humilis, &c. of Comm. Fréel. The former yields an aqueous inodourous juice. They are natives of Africa. 18. A. triangulata, or A. vifcosa of Linn. native of Ethiopia. 20. A. variegata of Linn; the most beautiful of the genus, a native of Ethiopia. 21. A. acuminata, or A. aureoca of above-mentioned. 22. A. carinata. 23. A. longifolia, or A. lingua. 24. A. pleiocarpa. 25. A. longiseta. 26. A. liliifolia. 27. A. equilatera of Linn. from which La Maree thinks is erroneously referred to that genus, of which it has no character. 28. A. racemosa, which is a shrub five or six feet high, observed at the Cape of Good Hope, by Thunberg, and which, as La Maree fugitives, may be the same with the 24th species. 28. A. dichotoma. 29. A. Arabica, or A. variegata, called in Arabia Befal or Befil. 30. A. dependens, found by Forlk in Arabia. Gmelin queries whether this be a distinct species. 31. A. incarnata, found by Forlk. in Arabia, but akin to the 17th species. Encycl. Method. Bot. tom. i. 

All the aloes are natives of hot climates; and the place of growth of most of them is the Cape of Good Hope. The Hottentots hollow out the trunk of the fift species, or A. dichotoma, to make quivers for their arrows; and several of them are used for hedges. Among the Mahometans, and particularly in Egypt, the aloe is a kind of symbolic plant, and dedicated to the offices of religion, for pilgrims, on their return from Mecca, supped it over their doors as an evidence of their having performed that holy journey. The superstitions Egyptians imagine, that it has the virtue of keeping off apparitions and evil spirits from their houses, and it is hung over the doors of Christians and Jews in Cairo for this purpose. They also distill it from a water, which is fold in the flops, and recommended in coughs, althanas, and hysterics. Hallequin mentions a person who brought it to the Tuins in four days by taking two cupsful of it. The Arabians call it saflura. The negroes, as we are informed by Adanaka, in his voyage to Senegal, make very good ropes of the leaves of the Guinea aloes, which are not apt to rot in water. M. Fabroni, as we learn from the Annales de Chimie (vol. xxv.) procured from the leaves of the aloe succotrina angustifolia a violet dye, which refills the action of oxygen, acids, and alkalies. This juice, he says, produces a superb transparent colour, which is highly proper for works in miniature, and which, when diffused in water, may serve either cold or warm, for drying silk from the lightest to the darkest shade; and he reckons it one of the most durable colours known in nature. Aloe was used among the ancients, in embalming, to preserve bodies from putrefaction. Of this aloe, interpreters understand that to have been which Nicodemus brought to embalm the body of Christ. John, xix. 5.

Aloes, whose reinos part is not soluble in water, has been used as a preservative to ships’ bottoms against the worms, to which those that trade to the East and West Indies are particularly subject. One ounce of aloe is sufficient for two superficial feet of plank; about 12 lb. for a vessel of 50 tons burthen, and 300 lb. for a first-rate man of war. It may be incorporated with six pounds of pitch, one of Spanish brown, or whiting, and a quart of oil; or with the fame proportion of turpentine, Spanich brown, and tallow. Such a coat, it has been said, will preserve a ship’s bottom eight months, and the expense for a first-rate ship, will be about 181. The fame compotent may be used in hot countries for preserving rafters, &c. from the wood-ant. The efficacy of aloes, as a defence against worms, has been controverted. See ALOES, infra.

Propagation and Culture.—The soil in which these plants thrive best, is one half free, light earth, from a common; and if the turf is taken with it, and rotted, it is much better; the rest should be white sea-fand, and fitted line-rubbling, each of these two, a fourth part; mix these together or eight months at least before it is used, observing to turn it over often in this time. The middle of July is a very proper season to shift the plants; at which time you may take them out of the pots, and with your fingers open the roots, and shake out as much of the earth as possible, taking off all dead or mouldy roots, without wounding the young fresh ones; then fill the pot about three parts full of the above mentioned earth, putting a few stones at the bottom of the pot to drain off the moisture; and after dividing the roots in such a manner as to prevent their interfering too much with each other, put in as much of the same earth, as to fill the pot almost to the brim, shaking the plant so as to let the earth in between the roots, and settling it close to the roots with your hand to place it steady in the pot; then water them gently, and let them stand in a shady place, where they may remain for three weeks, giving them gentle waterings, if the weather be hot and dry.
Aloe Toward the latter end of September, in a dry day, remove them into the house again, observing to give them as much free open air as possible, while the weather continues warm; but if the nights are cool, you must shut up the glasses, and give them air only in the day; and as the cold increases, you must discontinue opening the glasses, only giving them gentle waterings till the middle of October, when you must abate them according to the heat of the house in which they are kept. For those plants which are placed in a place will require to be watered at least once a week, most part of the Winter, whereas those which are kept in a greenhouse, without artificial heat, should not be watered in the winter oftener than once in a month, and in summer they should not receive too much moisture.

The tender parts, as the viscosa, ferox, and cobweb aloes, should constantly remain in the floor, or be removed in the Summer to an airy glass-case, where they may have free air in warm weather, but be protected from the rain and cold. With this management the plants will thrive and increase; and such of them as usually bear flowers, may be expected to produce them in beauty at their season.

Most of these aloes are increased by off-sets, taken from the parent plant when they are shifted, and planted in small pots filled with the earth prepared for the old plants; and these suckers should be quite dry when they are planted, otherwise they will rot. After remaining in the shade for a fortnight, the tender kinds should be removed to a very moderate hot-bed, shading the glasses in the day, and giving them much air. Towards the middle of August, the young plants may be hardened by taking off the glasses in good weather, and admitting the air; and they should be removed into the house towards the end of September, and managed like the old plants. The African aloes generally afford plenty of suckers for increase; most of the others may be propagated by taking off some of the under leaves, laying them to dry for ten days or a fortnight, and then planting them in the foil already mentioned, by putting that part of the leaf which adhered to the old plant, about an inch or an inch and a half, into the earth, and settling the earth about them with a little water: the pot should then be plunged into a moderate hot-bed, preferred from the sun, and refilled with water once a week. The best season for this operation is June. The method of cultivating the aloe in the island of Barbadoes, described in the Medical Journal, (vol. viii. art. 8. p. 422.) is as follows. The flaky and shallow foil, which is in the vicinity of the sea, and subject to drought, and in which the fugar canes will not thrive, beli suits the aloe plant. When the flones have been picked up, and laid around the field as a fence, or piled in heaps upon the moist barren spots, the land is lightly ploughed and cleared from weeds; then lined in rows at the distance of a foot from one another, and the young plants are set like cabbages, about five or six inches apart from each other. By being thus set, they are easily kept free from weeds, which would obstruct the produce. They may be planted even in the driest season; as they need little or no rain; but the usual time is from April to June.

Aloe, Water. See Stratiotes.
Aloe, Truncifolia. See Yucca.

Aloes, in Medicine and Pharmacy, the insipid juice of various species of the Aloe above described. Of this there have been usually reckoned three kinds, viz. the fess-terine, hepatic, and caballine. 1. Socotrine aloes, so called from the island Socotra, from which it was first brought, though it was probably imported from the Cape by the Dutch East India Company, is obtained from a variety of the A. perfusuta of Linneus. This kind is the purest and most transparent: it comes to us wrapt in fkins, and is of a bright surface, and in some degree pullicid; in the lump of a yellowish red colour, with a purplish cast; when reduced into powder a golden colour. It is hard and friable in the Winter, somewhat pliable in the Summer, and softens between the fingers. Its bitter taste is accompanied with an aromatic flavour, but not sufficient to prevent its being disagreeable; the smell is not very unpleasant, and somewhat resembles that of myrrh.

2. Hepatic, Barbadoes, or common aloe, is obtained from another variety of the same species, viz. A. vera, vulgaris, folis spinafo confertis dentatus vaginatus plantis maculatis, called by Rheed kadumbo or cateuus, and reckoned by La Marec a distinct species, and it is usually brought to us from Barbadoes; that of the beef fort in large, gourd shells, an inferior kind in pots, and a still worse in casks. It is of a darker colour than the former, and not so clear or bright; generally drier and more compact; of a stronger and more disagreeable smell, and of an intensely bitter taste, with little or nothing of the aromatic flavour of the other. A tract of mountains about 50 miles from the Cape of Good Hope, is wholly covered with the aloes plants, which renders it unnecessary to plant them there; but they are now cultivated in Jamaica and Barbadoes, having been first brought to the former of these islands from Bermuda. They require two or three years standing before they yield their juice in perfection: and it is procured, says Dr. Browne, (Jamaic. p. 198.) in the following manner. The labourers go into the field with tubs and knives, and cut off the largest and most succulent leaves close to the stalk; these they put into the tubs in an upright position, that the loofe liquor may be drained from the wound. When this is almost wholly discharged, the leaves are taken out singly, and cleared of any juice that may adhere to them; and the liquor is put into shallow flat-bottomed vessels, and dried gradually in the sun, till it acquires a proper consistence. What is obtained in this manner is called socotrine aloe, and is the clearest and most transparent, as well as the highest in esteem and value. In the island of Barbadoes, according to the account of Mr. Millington (Med. Journ. vol. viii. p. 422.) after a sufficient quantity is drained from the leaves to make it an object for the boiling-house, and the juice with this view may be preserved for some weeks, without injury, three boilers of iron or copper are placed by one fire, though some have two and others only one; these are filled with juice, and as it is gradually insipidified by a regular fire, it is ladled from boiler to boiler, and fresh juice is added to that which is farthest from the fire, till the juice in that which is nearest to the fire, the smallest of the three, and called tatch, becomes of a proper consistence to be shipped or ladled out into gourds, or other small vessels, placed for receiving it. The proper time for ladling it out of the tatch is when it is arrived at a rein height, as it is termed, or when it cuts freely, or in thin flakes from the edges of a small wooden slice, that is dipped from time to time into the tatch for that purpose. A little lime-water is used by some aloe-boilers during the process, when the effusion is too great. This author adds, as to the fun-
dried aloes, which is most approved for medicinal purposes, very little is made in Barbadoes. The process, however, is very simple, though very tedious. The raw juice is either put into bladders, left quite open at top, and suspended in the sun, or in broad shallow trays of wood, pewter, or tin, exposed alo to the sun every dry day, until all the fluid parts are exhausted, and a perfect resin formed, which is then packed up for use, or for exportation.

Dr. Wright (Med. Journ. vol. viii. p. 219.) gives the following account, somewhat different from the former, of the method of preparing hepatic aloes in Jamaica. The plant, in its entirety, is carefully cleaned from earth or other impurities. It is then sliced and cut into pieces into small hand-baskets or nets. These nets or baskets are put into large iron boilers with water, and boiled for ten minutes, when they are taken out, and fresh parcels supplied till the liquor is strong and black. At this period the liquor is thrown through a strainer into a deep vat, narrow at the bottom, to cool, and to deposit its feculent parts. Next day the clear liquor is drawn off by a cock, and again committed to the large iron vats. At first it is boiled briskly, but towards the end the evaporation is slow, and requires constant stirring to prevent its burning. When it becomes of the consistency of honey, it is poured into gourds or caballine for sale. The focotone aloes, he says, may be prepared in the same manner.

3. Caballine, or horse aloes, obtained as some say, from the faces of the hepatic aloes, and according to others from a distinct variety of the aloe perfoliata, demarcated A. guineensis, caballina vulgaris fimbriata, festa tota maculata, is easily distinguishable from the two former by its strong rank smell. In other respects it agrees pretty much with the hepatic, and is not unfrequently sold for it. Sometimes it is prepared so pure and bright as scarcely to be distinguishable by the eye, even from the focotone, but its offensive smell soon betrays it; and if even this should be diluted by art, its wanton the aromatic flavour of the finer aloes will be a sufficient criterion. Some say, that its colour is also much darker, indicating a mixture of fordes and sand, and that it is of course much more compact and heavy. This aloes is not admitted into the Materia Medica, and is employed chiefly by Parrius. From the observations of Professor Murray it appears probable, that different species as well as varieties of aloe would furnish the various kinds of this drug, and that Linnaeus by referring these sorts to thse plants, the recent juice of which seemed to correspond respectively the nearest to them in taste, might easily be mislaid; for Murray, upon tasting the fresh juice of many different species of aloe, sometimes found it bitter, and at other times totally devoid of bitterness. This author found the bittercuff species to be the following, viz. 1. Aloe longifolia, floribons spiritatis tubuloso-triangularis, tubingentibus oblique dependentibus, folis aggregatis dentato-pinnatis; and he queries whether this is not the variety v. of the A. perfoliata of Linn. Spec. p. 53[8], and the aloe mentioned by Hughes and Brown. 2. A. Spatha, which is said to afford the health hepatic aloes.

3. A. linguaformis, which in the interior parts of the Cape is selected by some as producing the best and purgative aloes. M. Jussieu, who saw the three varieties of aloes prepared at Merriedro, in Spain, affirms us (fays Chapital, Elem. Chera. vol. iii. p. 86), that they are all obtained from the aloe vulgaris. The first variety, or focotone aloes, is obtained by making incisions in the leaves. Time is allowed for its impurities to sublime perfectly. The fluid is then decanted from the dregs, and left to become thick; after which it is put into leathern sacks for sale, under the name of focotone aloes. A juice of the same nature is obtained by expression from the same leaves, which, when clarified in the same manner, forms the hepatic aloes; and the caballine aloes is obtained by a stronger pressure.

Aloes is mentioned neither by Hippocrates nor Theophrastus; Dioscorides mentions two kinds, and Avicenna tells us, that of the different kinds, without naming them, the focotone is the best. Celcus, who frequently mentions aloes, and recommends it to be mixed with all cathartics, does not any longer recommend it. If, indeed, the account of J. Bauhin (Hist. Plant. tom. iii. p. 467.) be true, that the juice of the leaves forms itself spontaneously into three strata, the upper being the focotone, the middle the hepatic, and the lowest or faces the caballine; there may be some reason for the designation of the three names, that they have been uniformly appropriated to them.

All the kinds of aloes agree in this, that they consist of a refined matter, and a large proportion of a sub stance called gum; and that they diffuse in pure spirit, proof spirit, and proof spirit diluted with half its weight of water, the impurities only being left; and in boiling water they also diffuse, but when the liquor becomes cold, the reinos parts subside. The quantity of reinos in hepatic aloes appeared in experiments of Dr. Lewis to be 3d, in focotone aloes 4th, and in the caballine 6th. According to Boulduc, the focotone aloes contains no more than 4th of reinos, and the hepatic aloes contains half its weight; and therefore the hepatic aloes contains more reinos and less gum than the focotone, and this than the caballine. The reinos of all the forts, purified by solution in spirit of wine, have little smell; that of the focotone has scarcely any perceptible taste; that of the hepatic a slight bitterish relish; and that of the caballine a little more of the alocetic flavour. The gummy extracts are less disagreeable than the crude aloes; that of the focotone aloes has very little smell, and its taste is scarcely unpleasant; the smell of the extract of the hepatic is somewhat stronger, but its taste more agreeable than that of the focotone; the gum of the caballine retains a considerable share of the rank smell of this fort of aloes, but its taste is not more unpleasant than that of the extracts of the other forts.

Aloes is a well known purgative; and it acts not only when taken internally, but when externally applied; and its cathartic quality refines chiefly in the gummy part, for the pure reinos has little or no purgative virtue. Boerhaave declares it to be an effectual and safe cathartic: nevertheless in large doses it produces much heat and irritation, particularly about the rectum, from which it sometimes occasions a bloody discharge. To those, therefore, who are subject to piles, or of an hemorrhois diathesis, the plethoric and bilious, or even in a state of pregnancy, the exhibition of it has done much harm; but it is particularly adapted, by its stimulating quality, to perons of a phlegmatic temperament and sedentary life, to cachetic indisposition, and oppressions of the stomach by acid crudities contracted from irregularity. Although in purging doses, of half a dram or two scruples, it produces irritation about the anus and sometimes a discharge of blood; but in smaller doses of 10 or 12 grains, repeated once or twice a day, it not only unloads the first passages, but attenuates and diffuses viscid humours in the remotest parts, warms the habit, quickens the circulation, and promotes the menstrual and hepatic fluxes; and its continued use renders the blood sensibly more fluid. This, says Dr. Cullen, (ubi infra), appears to me improbable. We have frequently seen the blood drawn from persons using a good deal of aloes, and never could discover any change of its
its confidence: and if the experiments of Schenck may be trusted, aloes added to the blood, drawn out of the veins seems to coagulate rather than to dissolve it; besides the quantity of aloes taken in can hardly have any sensible effect upon the whole mass of blood. It has been urged, however, that by its dissolving power it proves an emmenagogue, and is hurtful in all morbid hemorrhages. Dr. Cullen observes, that he has seldom found the emmenagogue powers of this substance. If there ever be any appearance of such a power, it is probably to be ascribed, in his opinion, rather to its operation on the rectum, communicating a stimulus to the veins of the uterus, than to its action on the mass of blood. When aloes is not designed to act as a purgative, it has an action upon the stomach; and it has frequently been found an antispasmodic, in relieving pains of this organ. It is also useful in habitual colicenes, when taken in small doses. With respect to its ordinary operation, Dr. Lewis alludes, that its effects are more permanent than those of any other purgative; this Dr. Cullen (Mat. Med. vol. ii. p. 525.) does not admit; for we commonly find, he says, that notwithstanding the use of aloes, the state of colicenes will return at its usual period, and that it is often necessary to anticipate this by the use of the aloeetic. This bitter juice has been accounted destructive to worms, or to the matter which favours their production, either taken internally or applied in plasters to the umbilical region; and from its imagined efficacy in this respect, it has been used to preserve ships against the attacks of worms. But its antiseptic virtue has been disputed by Murray, who says that worms have lived for 20 hours in the bittered solution of focotorine aloes, and for many days afterwards in earth mixed with powder of aloes. In another experiment four worms were not destroyed on the fourth day. It is powerfully antiseptic; and commonly makes an ingredient in tinctures and balsams for cleaning and healing wounds or putrid sores. As to the choice of the different kinds of aloes, it may be observed, that the focotorine, which contains more gummy matter than the hepatic, purges with more certainty and greater irritation, and is therefore most proper where a stimulus is required, or for promoting the uterine discharge; but the hepatic is better calculated for the purpose of a common purgative; and as it contains more resin, answers better as a vulnerary, for external application. Aloes is seldom given alone. Aloes, says Dr. Cullen, acts as readily in substance as in any solution; and therefore this is never to be practiced but for the sake of more convenient exhibition; and it has been found to operate in substance in a smaller dose than in the vinum aloeeticum. Aloes hardly receives improvement by any addition; and the vulgar find as much effect from the aloes alone as from the pilula aloeeticum. Some benefit, however, is obtained by some division of the aloes before it is taken into the body, and the extract of gentin is properly enough employed; but Dr. Cullen is persuaded, that the Edinburgh college have not done right in withdrawing the whole of the saw poxycheaum from the aloeetic pill. In the pilula rubra the myrrh may be useful in dividing the aloes; but the addition of the sawpoxy is insignificant. Rhusbardi added to aloes can answer no good purpose. In the pilula flomachiae Ph. Ed. and in the elixir lacrum, the rhubarb, says Dr. Cullen, is an useless addition. The aloes, continues this author, is never properly joined with the dracca purgatives, as in the pilula colocyntidis sum aloes, and in the transcriptum colocyntidis compositum; for if such a medicine is intended to produce a liquid evacuation the aloes is superfluous; and if it is intended only to open the belly, the dracca are unnecessary. In the elixir proprietas, the sawpoxy is an insignificant ingredient: and on account of the medicament employed by the Edinburgh college, Dr. Cullen says, he has never employed it as an evacuant, but he often used it with success in affections of the stomach, and for putting it better to this purpose, the Edinburgh college have improved it much, by the medicament they have employed in their elixir aloes vitricum. Several preparations of it are directed in the pharmacopoeia, for which see Elixir, Extract, Hieratica, Pills, Powder, Tincture, and Wine. Lewis Murray. Woodville.

Aloe plica, is a preparation of the focotorine aloes, made by dissolving it in juice of damask roses, and evaporating it to the consistence of a paste. Then more juice is added, and the evaporation repeated, again and again. This has been held a gentler and safer cathartic than the aloes alone. If this be dissolved in a good quantity of the fresh juices of roses, violets, bugloss, and bugloss, mixed in equal proportions, and afterwards reduced by evaporation to its former consistence, the extract, thus prepared, is called aloe ficoticara, and with the addition of one third its weight of cream of tartar, aloe ficoticara tartaro.

Aloe violata, is prepared by means of the expressed juice of violet flowers; and mixed with half its weight of cream of tartar, it is called aloe violata tartarea. But preparations of this kind are obfolute.

Aloe is applied by some writers, to a kind of mineral juice produced in Judea. This is called gottle, mineral, or metallic aloe. Some dispute the existence of any such aloe. Others suppose it to be no other than the asphaltus.

Aloes, lignum. This wood, by the Indians and Portugese, is called calumba, or calumba, being the same with what is otherwise called by medical writers xylochar, and agallochum.

This wood is referred by Loureiro, as we have observed under the article Agallochum to a distinct genus called Alonum, belonging to the order of decandria; but it approaches to nearly to that of the Excoecaria agallocha of Linneus, that the latter has been field for it. The tree grows in Cochinchina, the Molucca islands, and several other parts of the East Indies; and was formerly held in very high estimation, on account of its fragrant odour, as a perfume, for which purpose it was applied to cloaths and apartments, and as a cordial medicine in fainting fits, and in cafes of paralytic affection. It is said also to be effectual in destroying the tineac and ascariades in children. By the Chinefe and Heathen Moors it was used as incense in their sacrifices; and employed for setting the most precious jewels that are wrought in the East Indies. It was formerly deemed in that part of the world of greater value than gold itself; and various fables have been invented as to the origin of the tree that yields it. Some have feigned, that it grew in Paradise, and that it was conveyed from thence by the rivers, which overflowed their banks and swept off the trees in their way. Others pretend, that it grows on inaccessible mountains, where it is guarded by wild bears, &c. The Siamese ambassadors brought a present of this wood from their emperor to the court of France in 1696; and thus it became known. Bauhin and many others reckon three sorts of it; viz. two kinds of Calambac and the aloes-wood, the agallochum of the hops, the tehiniheag of the Chinefe, themiiho of Canneli, pao de agua of the Portugese, and frequently called eagle-wood. This is oily, reconditious, compact, heavy, of a brown reddish colour, marked with grey veins, and often pierced with small holes, as if it were worm eaten.
A L O

Ecclesiastical History, a fest who denied that Jesus Christ was the Logos, or eternal Word; and on this ground also rejected the Gospel of St. John as iporous, and also the Re-valuation.

Some ascribe the origin of the name, as well as of the fest of Alogians, to Theodore of Byzantium, by trade a currier; who, having apostatized under the perfecution of the emperor Severus, to defend himself against those who reproached him therewith, said, that it was not God he denied, but only man. Whence his followers were called in Greek alogy, because they rejected the Word. But others, with more probability, suppose the name to have been first given them by Epiphanius in the way of reproaches. They made their appearance towards the close of the second century.

Philafer has also mentioned a hereby that rejected John's gospel and revelation, and ascribed both to Cerinthus. Dr. Lardner is of opinion that this is a fictitious hence; and that there never were any Christians who rejected John's gospel and ifit epitile, and yet received the other gospels, and the other books of the New Testament. Notice is taken of such by Ireneus, Eusebius, or any other ancient writer, before Philafer and Epiphanius; nor has Theoret given any account of this hereby. This hereby, says this indefatigable inquirer and impartial reporter, was, as he conceives, invented upon the occasion of the controversy of Caius and Dionyatus, and others, with the Millenarians in the third century; some of whom disputed or denied the genuineness of the book of Revelation, and ascribed it to Cerinthus. Hence some said that those enemies of the Millennium might as well reject also St. John's Gospel, and others said, that they actually did so, though they did not. In Philafer's catalogue this hereby follows next after the Millenarians, or Chiliomettes, as he calls them, and the order in Epiphanius leads us to the same time. Lardner's Works, vol. ix. p. 515.

A L O G O N I A, in Ancient Geography, a town of Messenia, south-east of Geronia; north-east of which were a temple of Bacchus and another of Minerva.

A LOGOTROPHIA, among Physicians, an irregular nutrition of some part, attended with a vicious figure or conformation thereof, as in the rickets.

If the bones of the vertebrae of the back receive too much nutriment on one side, as sometimes happens in children, an incurvation necessarily ensues, which, as Charleston expresses it, is produced by an alogotrophia.

ALOIDES, in Botany, a name used by fome for the elae polystis, or fresh-water aloes, called in some parts of England, water-soldier; and by Linnæus, frutesces.

ALOIJUM, in Ancient Geography, a town of Thessaly, near the valley of Temp, and founded, says Steph. Byz. by the Alodes.

ALOMAYO, in Geography, a town of South America, in the country of Peru, and jurisdiction of Guanacate.

ALON, in Biography, a celebrated personage whose memory is preserved in the Triads of the Welch Bards; and who flourished among the first colonies of this island, if not among the Cymry before their arrival here. This Alon, with Pennlynd and Goron, are recorded as the three who combined the institutes and privileges of the bards, Druids, and ovates, into a regular system, under the sanction of a national law. This event is said to have taken place in the time of Prydau, who is mentioned in the same Triads, as the first who digested a national constitution for the Cymry or Britons. Be this as it may, there is great reason to con-
chide, that Alon is the same person who is called Olen, Olenus, Ailinus, or Linus, among the different people of Greece and the adjoining countries, and even in Egypt; for it is remarkable that similar attributes are ascribed to him by those ancient nations, as in our Triads: according to Pausanias, Olen the hyperborean is said to have been the first prophet of Delphi; Beo the female hierophant is made to sing of Olen, as the inventor of verse, and the most ancient priest of Phoebus; and, indeed, all Greece chanted the fable of Olen; and this more particularly occurred in celebrating the completion of the vintage; for thus it is said by Homer, (II. lib. xviii. v. 570, &c.) in the description of the shield of Achilles:

"In the procession of the vintagers were groups of young damsels and youths, carrying baskets curiously twined, filled with presents of the most delicious fruits. In the midst of these was seen a young man striking from his lyre harmonious sounds; he sang the songs of Linus, with a voice most sweet; and the company joined in chants and thongs of joy, beating the earth in cadence with lively leaps."

Alos, in Ancient Geography, a river of Cilicia, near Scabyle or Lycus, a small island.

Aloa, or Aloa, a town on the eastern side of Spain, south of the mouth of the Tudor.

Aloa, or Halone, one of the Æolian islands.

Alone, a small island of the Propontis, south of the island of Proconesus, and north-west of Cyzicus. The name was given to it, says Steph. Byz, because its inhabitants had found out the art of making salt. This author says, that it was also called Nebris and Procon; but Pliny distinguishes the last of these two islands.

Alo, a town placed by some writers in Paphlagonia.

Along-side, in Sea-language, expresses side-by-side, or joined to a thin, wharf, &c.

Along-shore, a nautical phrase expressing along the coast, or a course which is in sight of the shore, and nearly parallel to it.

Along, Lying, denotes the state of a ship that is pressed down sideways by the weight of fail.

Alo, in Ancient Geography, a town of Asia, situated on the eastern banks of the river Zabas, near its entrance into the Tigris.

Alo, a people joined by Pliny to the Gordians, and placed near the Tigris.

Alonis, a town and island of Gaul, which Martin imagines to have been the town and island of Magdolena, formed by the retreatment of the first Celtic syllable Mag.

Alonion, a place of the island Cretse, in the territory of Gortyna.

Alonzo, in Biography and History. See Alphonso.

Alonta, a river placed by Ptolemy in Athisa Sarra.

Alonticicelli, a people of Bocica, near the river Menabas.

Alontium, Aluntium, or Haluntium, a town of Sicily.

Alof, in Sea-Language, denotes at a distance. See Luff.

Alope, in Entomology, a species of the Sphint, with destitute brown wings, the posterior being yellow and black at the apex, black abdomen, and interrupted pale-coloured bands, found in India.

Alo, or Aloa, in Ancient Geography, a name given to several towns. Aloa was a town of Thessaly. Homer mentions a town of this name, Supposed to be the same place, as he names it after Alos, a town of Phthiotis: it is supposed to have been so called after Aloa, the daughter of Cercyon, or of Acton. Aloa was also a town of Attica, and also of Pontus, between Myfia, Caria, and Lycia; another in Phoeis, and another among the Locrians.

Alopec, an island near the coast of Asea Minor, not far from Smyrna.

Alopec, or Alopec, was also a district of Attica, near Cynosarges, and distant about 11 or 12 stadia from Athens. The Lacedemonian general Anachimolus, who, by the suggelation of the oracle of Delphi, had been sent to drive the Phifiartides from Athens, died and was buried in this place; and Herodotus (lib. v. § 3.) says, that his tomb was near the temple of Hercules. This was also the birthplace of Aristides and of Socrates. Alopecia was also an island placed by Strabo in the Palus-Mozoi, and by M. d'Anville, near the mouth of the Tanais.

Alopecia, in Surgery, baldness in any part of the body, arising from disease, or from a natural defect of growth in the hair. This deficiency is sometimes produced by excessive venery, and has been known to be remedied by a person becoming chaste in his habits; but more frequently it is not connected with any evident external cause, and only indicates a faulty state of the fluids at the roots of the hair, or a want of due nourishment and moisture. Alopecia was formerly a common symptom of the laes venerea, but is now very rarely observed to occur in such cases.

Oily and gently stimulating applications to the head, with repeated shaving, are proper against the defect in question.

Alopecia is also used by Galen for the change of the hair to another colour.

Alopecias, in Ichthyology, a name of the culpes marina, or sea-fox.

Alopecosnesus, in Ancient Geography, a town of the Thracian Cheroneus, north of and near the gulf of Menanos. It was peopled by the Æolians, and taken by Philip, king of Macedon.

Alopecopithecus, in Zoology, a name derived from the Greek, and given by Aldrovand others to the Opossum.

Alopecos, in Ancient Geography, a hill of Barotia, in Greece, called also Orchalis.

Alopecuro-veronica, in Botany. See Mentha. Alopecuro, See Betonica.

Alopecurus, Alopecurus odoratus, fox-tail, a genus of the triandria digyna clas and order, and of the natural order of graminis, or grasses: its characters are, that the calyx is a glume one-flowered, two-valved; the valves ovate-lanceolate, concave, compressed, equal, connate at the base; the corolla one-valved, valve ovate, lanceolate, concave, with the edges united at the base, a little shorter than the calyx, about twice as long, with a bent joint, inserted into the base of the valve near the base, no nectary; the stamina have three filaments, capillary, flattened at the base, longer than the calyx, anthers forked at each end; the pistillum is a roundish germ, the styles are two, capillary, united at the base, longer than the calyx, and stigmatic villous; no pericarpium, the corolla incising the seed; the seed ovate and covered. Martyn and Willdow enumerate eight, and Gumil 12 species. 1. A. indusius, panicum indicum of Miller, panicum alopecuroideum of Linnaeus, Spec. pl. 8. 2. Indian fox-tail grass, with cylindrical spines, involucres flat, fimbriate, two-flowered, and villous pendentes, a native of the East Indies. 2. A. bulbosus, A. geniculatus. B, Hudson, gramine myosuroides nodosum of Dillenius, bulbous fox-tail, with culm erect, spike cylindric, (very simple, attenuated, smooth, glumes of the calyx dilininct and villous, Smith) and root bulbous. The bulbous epipiptike root emits fibres from its lower part, and has a brown, fimbriated, tunic membrane. The culm is botanically...
literate, scarcely a foot long, very simple, erect, a little decumbent at the base, foliose, bimodal, frilled, and smooth; the leaves smooth; the radical few and short; the cauline almost linear, plicate, and all the lengths of the leafblade: the glumes short and frilled: the spike feipenduncular, somewhat erect, very simple, slender, acute, and many-flowered; the glumes of the calyx a little unequal, acute, awnless, altogether separate at the base, villous in the nerves, and rudimentary carina; the glume of the corolla emarginated and awned at the base. This species is very different from the *A. geniculatus*, and has florets, says Dr. Stokes, longer, narrower, and much less hairy; and Dr. Smith observes, that in its spike, and the structure of the flowers, it is more nearly allied to the *A. agrestis*. It is found rarely in fell marshes; in those near Yarmouth, in the marshes of Cardifh in Glamorganshire, and near the Ault paffage, and in the vicinity of Northflext, in Kent. It is perennial, and flowers in July. 3. *A. pratensis*, meadow foxtail, g, with the culm erect and smooth, spike frilled, and the glumes of the calyx villous and connate at the base. The root is fibrous; the culm two feet high, cleft, foliose, smooth; the leaves somewhat smooth and glaucous, with a short, pubescent glume; the spike somewhat flat, feecally paniculate, dense, erect, about two inches long, soft, and many-flowered; all the glumes are green, lanceolate, prolonged, white, marked on both sides with two green longitudinal lines; those of the calyx, especially near the keel, silky-villous and awnless; the glume of the corolla smooth, except toward the apex of the keel, awned at the base, the awn geniculated, twice longer than the flower, and naked. This is a native of most parts of Europe, from Italy through France, Germany, Holland, Great Britain, to Denmark, Norway, Sweden, and Russia; and also in Siberia. It is found with us very common in pastures and meadows. It is perennial, and flowers in May. This is the best grafs to be fown in low meadow grounds, or in boggy places which have been drained. Sheep, hores, and goats eat it. Cows and swine are not fond of it; but Dr. Pulcefays says, this is the moft grateful of all the graffes to cattle. It polleffes, says Profefhor Martyn, the three great requifites of quantity, quality, and earlinares, in a degree superior to any other, and is therefore highly deferving of cultivation in lands that are proper for it. The feed may be eafily collected, as it does not root to the ground, and the wild fox-tail, *A. bulbosa*, is a veritable exclamation of a species of muscar, which are themefelves the prey of the cimex campestris, devour the feed fo much, that in many spikes you will fearefly find one perfect. Lewis Majendie, Esq., at Hedingham, has cultivatet it on a confiderable fcale, and found it to be an excellent grafs. 4. *A. agrestis*, field or flider fox-tail g, with culm erect, rough, spike very fimple and attenuated, glumes naked, connate at the base, and dilated at the keel. The root is fibrous and small; the culm half a foot long, erect, foliose, naked at the apex, and rough; the leaves rough above, the glume lanceolate and pubefcent; the spike almoft three inches long, erect, slender, acute, many-flowered, and of a purplifh colour; the glumes subequal, larger than the preceding, and lefs pubefcent, varied with white and green, and nerves prominent; those of the calyx villous at the base, connate, with a dilated pubescent keel, and awnless, the glume of the corolla smooth, awned at the base; the awn geniculated, twice longer than the flower; rough and recurved in drying. This grafs is a troublefome weed in cultivated ground, and among wheat it is exerated by the farmers, under the name of black bent; it is also common by way-fides as well as in cornfields, and in pastures in the fide of Wight. It has acquised the name of mouse-tail grafs in Englifh, and Myofuroides in Latin, from the great length and flendernefs of the spike, which resembles the tail of a mouse. It is annual, flowers in July, continues flowering till Autumn, and comes into bloom very foon after being fown. There is a variety, with a shorter spike, and recurved awns. It is small and brown, on account of its barren and fimmy fitation. 5. *A. geniculatus*, gramen fluviatilis plicatum of Gerard, *g*. aquaticum plicatum of Parkinson, and *g*. alepae. *Ae*. geniculatus. proeminent of Morfon, floating fox-tail g, with culm ascending and geniculated or knee-jointed, spike frilled and cylindric, and glumes blunted and hairy. The root confines of very long and fimple fibres; the culms natant, very long, geniculated, radiating in the inferior geniculi, affurgent in the apex, foliose, ramous, and smooth, the leaves smooth, the glume white, and very slender, the spike cylindric, short, feem what obtufe, divifible in lobes, many-flowered, purplifh, and in the variety *f*. white, the glumes twice lefs than the preceding, fubequal, and very obtufe, those of the calyx longer, hairy; three of the corolla crenated, smooth, awned toward the base, the awn geniculated, and of various length; the root in dry places is bulbous, with a culm feem what erect; and this variety Hudfon has confounded with the *A. bulbosa*. Dr. Smith mentions two varieties, *viz*. *g*. fluviatilis album of Dilleniis, and *g*. with a bulbous root of Hudfon. *g*. *A. pratensis*. A. Bulbofus. This is easily known in its common flatfe, by pools and in wet meadows, by the frequent joints of the culm or stem changing their direction, and appearing broken. It often puts out roots under water from the joints, and thus spreads itself; the leaves floating on the surface. From the deep colour of the spikes, it is called in some places black-grafs. It sometimes occurs in dry pastures, and then, according to Mr. Curtis, grows more upright; the spike is much more fieder, and the base of the ifkall swells out into a kind of bulb. It is perennial, and flowers in July. Cattle eat it, but it is not esteemed a profitable grafs. The variety *g*. is found in wells and a dry fcrill soil. Dr. Withering mentions four varieties; one of which, with awns, very fince and foft, not longer than the calyx, ftruit, little, ifacks branched, a fibrous root, and found in a marshy place near the Stews, in Edgbafton park, he fuppofes to be a di- ftrinct species. 6. *A. Harlotifum*, barley-like fox-tail g, with fimple raceme, and flowers intrenched with awns. This is an Indian grafs, and fometimes occurs in fields of barley. 7. *A. Mesafogynus*. This is very frequent in Holland, and the wild crab-graft, *A. villosus*; *A*. fleniferus, *A*. Hufdonicus. A. fleniferus. A fpecies of *A. pratensis*, very feveral and allied to *A. pratensis*. A. villosus. A small fpecies, usually known by its common flatfe, *A*. Hufdonicus. A. fleniferus. A very feveral and allied to *A. pratensis*. A. villosus. A small fpecies, usually known by its common flatfe.
spiked and erect, and ciliated glumes. A. carolinianus, with radiating culm, subspiked panicle, smooth glumes, and awned corolla. A. typicae, with simple raceme, and awnless broaden. A. concinnum, with spiked caudate panicle, and floresculent tinted with awns. A. ursinus, with panicle ovated, contracted, resembling a spike, and exterior petal awned before the apex. Willdenow, besides the A. indicus, A. bulboetus, A. pratensis, A. griseus, and A. geniculatus, describes the following species, viz., A. capensis, with cylindrical spike, and smooth awnless glumes, a native of the Cape of Good Hope. A. antarcticus, with erect culm, ovated spike, hairy glumes and awned corolla, the awns being longer than the calyx; brought from the Straits of Magellan. A. echinatum, with spikes, ovated panicle, punctuated, ciliated glumes, and geniculated culm, a native of the Cape of Good Hope. For the propagation and cultivation of this genus, see Grass. Martyn’s Miller, Gmelin’s Linnean, Withering, Arrang., vol. ii. p. 419. Smith’s Flor. Brit. vol. i. p. 72. Willdenow’s Linn. tom. i. p. 356.

Alopes, in Ancient Geography, one of the ancient names of Ephesus.

Alopec, in Entomology, a species of the Scarabæus Molonlonta, with yellow hair, the elytra reflex and emarginated, and the elytra smooth and black; found at the Cape of Good Hope.

Alopec, in Zoology, a species of the Canis, with a tail plain and black at the tip. This is less than the common fox, and has a thicker and daintler fur, though it is sometimes brighter and redder than that of the fox. A Pennsylvania bradt-fox, delivered by Mr. Pennant, was scarcely half the size of the common fox; with the nose black and thinner, the space round the eyes ferruginous, the forehead and upper parts of the body black, mixed with red, ash-colour, and black, and by the predominance of the ash-colour, appearing hoary, the belly yellowish, the tail black above, red beneath, and on the sides ash-coloured. The British variety of the fox with a black tip on the tail, says Mr. Pennant, is unknown in America; and therefore his bradt-fox must be either a variety of the other, or a distinct species. This species is found in Europe, Asia, and America. The alopec eurpeus, or coal-fox, the charbonnier of Buffon, is reckoned another variety. It inhabits Burgundy, is of a silver-grey colour, and the tail tipped with white like the common fox; but from the remarkable blackness of its feet and legs, seeming to have been produced by charcoal-dust, it is called charbonnier, or coal-fox.

Alor, in Ancient Geography, a river of Macedonia.

Aloritae, a people of Macedonia.

Alorus, a town of Macedonia, north-west of the Thermaic gulf, placed by Ptolemies in Pannonia, and by M. d’Anville in Pheria.

Alos, or Alos, a town of the Phitioi in Thessaly, east of the Peloponnesian, at the foot of Mount Othrys, upon the little river Amphipolis. It was built by Athamas, and so called in honour of one of his female domestics.

Alos was also a town of Peloponnesus, in the Argolid.

Alosa, in Ichthyology, a species of the Clupea, having the sides spotted with black, and the upper jaw bony. It is the thrus of Aulobe, Rondelius, and Ackward, the alonos of Gfener, the elophe of Willughby and Ray, and our Smelt.

Alosanga, in Ancient Geography, a town of India, beyond the Ganges, according to Ptolemy.

Alost, in Geography, a town of Flanders, situate on the river Dender, ten leagues south of Antwerp. This town contains a collegiate church, and several convents, in one of which, vis. that of Guillemins, is the tomb of Theodore Martin, who brought the art of printing out of Germany into the Low Countries. He was a friend of Erasimus, who wrote his epitaph.

This town, which is the capital of a county, was taken and dismantled by M. Turenne, in 1667; and abandoned to the allies in 1706, after the battle of Ramillies. N. lat. 59° 54'; Long. 5° 56'.

Alouste, in Zoology, a name given by Buffon to the Simia Semiluator, or long-tailed, bearded, red monkey, with prehensile tail, of the Linnaean System; the creator of Gomilla, Oronoko, tom. ii. p. 8. and the royal monkey of Pennant.

Some have considered this as a variety of the Simia Beelzebub, from which it differs by its very bright bay colour; but Dr. Shaw (Zool. vol. i. p. 71.) is of opinion, that it is a distinct species. From young animals in the Leverian Museum, he describes it as being about the size of a squirrel, and entirely of a very bright, ferruginous, or reddish chefum colour, with the face naked and black, surrounded on the lower parts by a fragilizing board of black hairs, and the tail strongly prehensible. This species is said to be rare in Brazil, but very common in Ceylon. Its voice and manners are the same with those of the Simia Beelzebub, which is common in Brazil, but not found in Guiana. By an account of a person who kept these animals in Ceylon, it appears that the allocates, or bowlers, as they are called, inhabit the moist forests in the neighborhood of waters or marshes. They are commonly found in the woody islands of large flooded savannas, and never on the mountains of the interior of Guiana. They go in small numbers, often in pairs, and sometimes singly. Their cry, or horrible scream, may well inspire terror, for it seems as if the foresters contained the united howlings of all its savage inhabitants together. This clamour is usually made in the morning and evening; but it is repeated in the course of the day, and sometimes in the night. The found is strong and varied, that one would imagine it to be produced by several animals at once, though it is emitted by only two or three, and sometimes one. In a state of captivity the animal loses its voice, or does not exert it in the same manner as it does when wild, and in this state he seldom lives long. The male is larger than the female, and the latter always carries her young on her back. In order to kill these animals it is necessary to fire several times; while any life remains, and after they are dead, they will remain clinging to the branches by the hands and tail. Their flesh, after all the trouble of purfling them, is not good; it is always tough, and never admitted to any tables but to those of indigent inhabitants and travellers, to supply the want of other food. This animal is said to be as large as a calf, and to live on the fruit of the banana-tree.

Alouchi, a kind of sweet-scented gum which runs from the tree that produces white cinnamon.

Alouette de Mer, in Ornithology, a name given by Buffon to the Tringa Hylophaga, or common Sandpiper.

Alouette, is also the name of the Alauda Arvensis.

Alos, in Ancient Geography, a town mentioned by Steph. Byz. and which belonged to Ilyria.

Alp, in Ornithology, an English name used by some for the Bull-finch.

Alpage, alpagium, in Ancient Writers, denotes the privilege of feeding cattle on the Alps or high mountains, or a sum paid for the perusal of such a right.

Alpaga, in Zoology, the Camelus Parus of the Linnaean System, and the Facos of Pennant.

Alpam, in Botany. See Alpam.

Alp Arslan, in Biography and Hisory, second Sultan.
fattan in the dynasty of Seljuk, in 1019 or 1020, the son of David or Jafar Beg, and great-grandson of Seljuk, who founded this dynasty, was born in the year of the Hegira 347, A.D. 1058. He succeeded his uncle Toghril Beg, A.D. 1063, and vested in him the two kingdoms of Khorasan and Iraq, with their dependencies; so that, at the commencement of his reign, he was sole monarch of all the countries lying between the rivers Jihan, or Amu, and the Dijlat or Tigris: that is, of all Iran, or Persia, in the conquest of which he bore a considerable part. Before he embraced Mahometanism he was called Turk, and afterwards he assumed the name of Mohammed, or Abu Shoja Mohammed; and his surname was Alp Arfkan, which signifies in Turkish, "the valiant lion." He was also distinguished, on account of his power and merit, by the appellation of Azzadin, or Ahadoddin, denoting, "the protector of the religion." He began his reign by putting down several rebellions among his subjects; and he derived great affluence from his vassals Nadham al Molk, or Nezam el Male, who was reputed to be the greatest man of his time, and who administered the affaires of the kingdom, in the reign of this prince and his successor, with the greatest integrity. Having succeeded in his enterprises for the security of his own dominions, and in an assembly of the states declared his son Malek Shah his heir and successor, causing him to sit on a throne of gold prepared for the purpose, and exacting from all the officers of the empire an oath of fidelity to him, Alp Arfkan crossed the Euphrates at the head of the Turkish cavalry, and entered Cardous, the metropolis of Cappadocia, to which he had been attracted by the wealth and fame of the temple of St. Basil. After plundering this city, he proceeded to the final conquest of Armenia and Georgia, A.D. 1065. In Armenia the title of a kingdom and the spirit of a nation were annihilated; and the artificial fortifications were yielded by the mercenary of Conflantinople; by strangers without faith, veterans without pay or arms, and recruits without experience or discipline. But the woods and valleys of Mount Caucasus were more inhumanly defended by the native Georgians, or Iberians, who were at length compelled to submit by the indefatigable exertions of the sultan and his son Malek; and who were punished for their obstinate resistance, by being obliged to wear at their ears iron horse-shoes as a badge of their slavery; many of whom, in order to avoid this ignominy, assumed the external profefion of Mahometanism.

In 1068 Alp Arfkan directed his arms against the Constantinopolitan empire, which was then governed by Endoeh. His progress alarmed the emperors, and induced them to give her hand and her sceptre to Romanus Diogenes, a brave folder, who was accordingly invested with the imperial purple. Although in the palace Diogenes was no more than the husband of Endoeh, yet in the camp he was the emperor of the Romans, and he adorned that character with feeble resources and invincible courage. By his fierce and furious the soldiers were taught to act, the subjects to hope, and the enemies to fear. In three laborious campaigns the Turks were driven beyond the Euphrates; and in the fourth and last Romanus undertook the delivery of Armenia. With an army of 100,000 men he marched to the siege of Malakzer, an important fortress in the middle way between the modern cities of Arranzum and Van. Alp Arfkan flew to the scene of action at the head of 40,000 horse, according to the statement of Elmacin, but reduced by Abulfaragius to 15,000, and by d'Herbelot to 12,000. The Greeks, though much inferior in number, were defeated and dismayed by his rapid and skilful evolutions; nevertheless, their principal general Dalilacus was defeated, Malakzer was reduced, and their forces were separated; in this moment of advantage he proposed peace to the emperor. The answer of Romanus was dictated in the tone of insult and defiance—"If the barbarian wishes for peace, let him evacuate the ground which he occupies for the encampment of the Romans, and surrender his city and palace of Riz as a pledge of his fidelity." Alp Arfkan insulted the vanity of the demand, but he kept in anticipating the death of so many faithful Medders; and, after a devout prayer, proclaimed a free permission to all who were desirous of retiring from the field. With his own hands he tied up his horse's tail, exchanged his bow and arrow for a mace and scimitar, clothed himself in a white garment, perfumed his body with musk, and declared that if he was vanquished, that spot should be the place of his burial. In the decisive and bloody battle that ensued, the Greeks were totally routed, great numbers of them were killed; and Romanus, after valiantly maintaining his station, when he had been defeated by the body of his army, was at length recognized by a slave, taken prisoner, and presented to Alp Arfkan. The successor of Conflantin, in a plebian habit, was led into the Turkish diwan, and commanded to kill the ground before the lord of Asia. He reluctantly obeyed; Alp Arfkan, flaying from his throne, is said to have planted his foot on the neck of the Roman emperor. This fact, however, is doubtful. He instantly raised the royal captive from the ground; and then clapping his hand with tender sympathy, afforded him that his life and dignity should be inviolate in the hands of a prince who had learned to respect the majesty of his equals, and the vicissitudes of fortune. Romanus was treated with attention and respect; and in the familiar intercourse of eight days, not a word nor a look of insult escaped from the conqueror. During the negotiation he was asked by Alp Arfkan what treatment he expected to receive? To which question Romanus, with calm indifference, replied—"If you are cruel, you will take my life; if you intend to spare me, you will drag me at your chariot wheels; if you confound your interest, you will accept a ransom, and relieve me to my country." But what continued the sultan, "would have been your own behaviour had fortune smiled upon your arms?" Had I vanquished, he fiercely said, "I would have inflicted on thy body many a stripe." The Turkish conqueror failed, at the influence of his captive; observed that the Christian law inculcated the love of enemies and forgiveness of injuries; and nobly declared that he would not imitate an example which he condemned. After mature deliberation, Alp Arfkan dictated the terms of liberty and peace, a ransom of a million, an annual tribute of three thousand pieces of gold, the marriage of the royal children, and the delivery of all the Melleans who were in the power of the Greeks. The treaty was authenticated by Romanus, and the sultan, after a courteous embrace, dismissed him with rich presents and a military guard; but his subjects having revolted, he was unable to collect and remit the stipulated price of his ransom. The generality, or perhaps the ambition of the sultan, disposed him to espouse the cause of his ally; but the accomplishment of his design was prevented by the defeat, imprisonment, and death of Romanus Diogenes. After this treaty, A.D. 1071, Alp Arfkan held the fairest part of Asia subject to his laws. 1200 princes, or sons of princes, flourished in his throne; and 200,000 soldiers marched under his banners. He determined to pursue the fugitive Greeks; but he meditated the more glorious conquest of Turkestan, the original seat of the house of Seljuk. His progress on this expedition, A.D. 1072, was impeded by Joseph Cuthal, a Karafinian, or Carnizian, the governor of Bursa, or Barza, who, after vigorously defending his fortress, was taken prisoner;
prisoner; and being reproached by the sultan for his obstinacy, in reply, by his incoherent replies provoked a cruel sentence, that he should be flogged by his hands and feet to four stakes, and left to expire in that painful situation. The desperado Joseph, drawing a dagger, rushed towards the throne; but Alp Arslan, the most skilful archer of his age, checked his zeal, and drew his bow; however his foot slipped, and the arrow miffed Joseph, who planted his dagger in the breast of the sultan, and was himself instantly cut in pieces. The wound was mortal, and the sultan expired, A.D. 1072, pronouncing an awful admonition to the pride of kings. "In my youth," said Alp Arslan, "I was advised by a facee to humble myself before God; to distrust my own strength; and never to despise the most contemptible foes. I have neglected these lessons, and my neglect has been severely punished. Yesterday, as from an enmity, I beheld the numbers, the discipline, and the spirit of my armies; the earth seemed to tremble under my feet; and I felt in my heart, 'Surely thou art the king of the world, the greatest and most invincible of warriors.' Thyse armies are no longer mine; and in the confidence of my personal strength, I now fall by the hand of an assassin." This prince reigned nine years and six months, and lived 44 years and three months; and his remains were deposited in the tomb of the Seljukian dynasty, at Maru, one of the four cities of Khorasan, with this inscription: "O ye who have seen the glory of Alp Arslan exalted to the heavens, repair to Maru, and you will behold it buried in the dust." The annihilation of the inscription, and of the tomb itself, says a popular historian, more forcibly proclaims the unfitness of human greatness. Alp Arslan commanded the respect of all who approached him by his stature, aspect and voice; his long whiskers fladed his face, and he wore a large turban in the form of a crown. His valor and liberality were equally renowned; and he was extolled for his piety and his attachment to the Mahometan faith and practice. He was succeeded by his son Malek Shah, who had been acknowledged during his life as the future sultan of the Turks; and who, by a triple victory over his uncle, cousins, and brother, each of whom disputed the inheritance, established his own reputation, and the right of primogeniture. Mod. Un. Hist. vol. iii. p. 394—401. Gibbon's Hist. vol. vi. p. 352—362.

ALPEDRINHA, in Geography, a small place of Beira, in Portugal, containing about 950 inhabitants, and one church.

ALPEDRIZ, a small place of Efremadura, in Portugal, containing about 600 inhabitants.

ALPEN, a town of Germany, in the circle of the Lower Rhine, and electorate of Cologne; eight miles south-west of Wefel, and fifty north-west of Cologne.

ALPENE, or ALPENUS, in Ancient Geography, the capital of the Locrians, on the south coast of Phœnix, east of Trachia, and above Thermopylae and Anthela.

ALPESA, a town of Eetica, according to Pline.

ALPHA, a river in the vicinity of Aquileia, near which Constantine was killed, and into which his body was thrown.

ALPHA BUCELIS, a town ascribed by Ptolemy to the Maris; probably the same with Alba Fucens.

ALPHA, the name of the first letter in the Greek alphabet; corresponding to our A.

The word is originally Hebrew, formed from alaph, the name of the first letter of the Hebrew alphabet.

Alpha, according to Plutarch, was placed at the head of all the letters, because, in the Phœnician language, it denotes an ox; which, with regard to use and service, is the first among beasts.

Alpha, in Composition, denotes, sometimes, privation, in the same sense with α, without; sometimes augmentation, as α, much; and sometimes union, as α, together. See A.

Alpha is also used as a letter of order, to denote the first; and of a number, to signify one; but when it was a numerical letter, a little stroke, or an acute accent, was drawn above it thus, Ά', to distinguish it from the mere Α, which was a letter of order.

Alpha and Omega, in the Divine Writings, signify the beginning and the end, or the first and the last, (πρ, before and after all things;) and therefore the hieroglyphic of God is formed of these two letters A and Ω.

These two letters were made the symbol of Christianity, and were accordingly engraved on the tombs of the ancient Christians, to distinguish them from those of idolaters.

Alpha is particularly used among Ancient Writers, to denote the chief, or first man of his clafs or rank.

In this sense, the word being contradistinguished from βeta, which denotes the second person.

Plato was called the alpha of the wise; Eratosthenes, keeper of the Alexandrian library, whom some called a second Plato, is frequently named beta.

Thus Martial, in imitation of the Greeks, who distinguished the rank of person by letters, says:—

"Quod alpha dixi, Codre, penulatorum,
Te supr, alqna, cum jocer in charta:
Si forte hilem movit hic tibi veritas,
Dicas labot beta me togatorum."

Epig. l. 5. ep. 26.

Alpha is also a title given by some ancient writers to the Jewish legislator Moses. The reason of the application is much controverted.

ALPHABET, the several letters of a language disposed in their natural or accustomed order.

The word is formed from the names of the two first letters of the Greek alphabet, alpha, beta; which were borrowed from those of the Hebrew, aleph, bethe.

In the English alphabet we reckon 26 letters, viz. a b c d e f g h i j k l m n o p q r s t u v w x y z. See each under its proper article, A, B, C, &c.

But as there is a much greater number of different sounds in our language, it is not without reason that some grammarians maintain, that there ought to be a greater number of letters: as also, that the double letters, x, y, and es, and the superfluous ones, k, and g, should be re-trenched.

The French alphabet contains only 23 letters. Paquier indeed maintains it to consist of 25, because he adds the two double letters é and ë for e and i for u; but those are only abbreviations. The Abbe d'Angelo, on better grounds, reckons 34 different sounds in the French tongue; and urges that the alphabet ought of consequence to consist of 34 different characters, setting aside the double letters x and y, and the superfluous one q.

The difference between languages with respect to the number of letters in their alphabet is very considerable: the Hebrew, Chaldee, Syriac, and Samaritan alphabets, have each 22; the Arabic 28; the Perisan 31; the Turkish 33; the Georgian 36; the Coptic 32; the Mino-Crete, or Ruffian, 41, of which some are only notes of accent in pronunciation; the Greek 24; the Latin 22; the Slavonic 27;
the Dutch 26; the Spanish 27; the Italian 20; the Indians of Bengal 21; the Brahmas 19.

The Ethiopic has no less than 202 letters in its alphabet, there being seven vowels, which they combine with each of their 26 consonants; to which they add 20 other aspibled syllables. The like is said of the Tartarian; each of their letters is a syllable, having one of their vowels joined to its consonant; as b, b, b. &.

The Chinese have no alphabet, properly speaking; except we call their whole language their alphabet; their letters are words, or rather hieroglyphics, and are in number about 80000. See Phil. Trans. vol. ix. an. 1769, N. 66.

In effect, alphabets were not contrived with design, according to the just rules of reason and analogy; but have been successively framed, altered, &c. as occasion offered. And hence have arisen many grievous complaints as to their deficiencies; and diveri attempts to establish new and more adequate ones in their places. Bishop Wilkins charges all the alphabets extant with great irregularities, with respect to the order, number, power, figure, &c. As to the order, it appears methodical, precarious, and confused; because the vowels and consonants are not reduced into clusses, with such order of precedence and subsequence as their natures will bear. Even the Hebrew order is not free from this imperfection. As to number, they are both redundant and deficient; redundant, either by allotting several letters to the fame power and sound; as in the Hebrew D and G; and the ordinary Latin e and a and f and b; or by reckoning double letters among the simple elements of speech; as in the Hebrew Y, the Greek S and Ψ, the Latin q, e, r, c, and the j consonant, or jod—Deficient in divers respects, especially in regard of vowels, of which there are seven or eight kinds commonly used, though the Latin alphabet only takes notice of five; whereof two, viz. i and a, according to our English pronunciation, are not properly vowels, but diphthongs.

Add, that the difference among vowels, in respect of long and short, is not sufficiently provided for: the ancients, we know, used to express a long vowel by doubling its character; as amasbam, naata, ree, feedes, samstifinim, though the vowel i, instead of being doubled, was frequently prolonged, as πάλιν, ριάνο, οίλα υνιος. The ways used in English for lengthening and abbreviating vowels, viz. by adding e quadient to the end of a word, for prolonging a syllable; and doubling the following consonants, for the shortening of a vowel, as amea amea, amea aure, &c. or else by inferring some other vowel, for the lengthening of it, as meet met, read red, &c. are all improper, because the sign ought ever to be where the found is.

As to their powers, again, those are not always fixed to the same signification: the vowels, for instance, are generally acknowledged to have each of them several founds: vocales ownes pluriones, says Lipsius; and Volatus affirms us, the ancients used their vowels in very different ways, aliquando tenuissimum efinus, cunon cunon, cunon intermedio fon. Thus the power of the vowel i is expressed in writing no less than in six several ways, viz. by e as in be, be, be, ye, ye by ee in threees, freer, wee; by ee in field, field, field; by e, in near, dear, bear; by e in people; by i in privilige. So is the power of the vowel a, as in all, aut, aut, sain, caign; which are only various ways of writing the same long vowel; besides the other distinct ways of expressing the same vowel which we used short; again, the power of the vowel o is written five ways: o, as in to, sain, move; o, as in doe; o, in floor, move, thumb; as in could, would; as in two; and so of the rest.—Nor are the consonants of more determine powers; witness the different pronunciation of the same letter e in the same word eiree, and g in negligence.

—To say no more, the letters f, t, z, are used alike, to denote the same power, and the letter f is commonly used for a, and, which is yet worse, some letters of the same name and shape are used at one time for vowels, and at another for consonants; as f, z, a, f, y; which yet differ from one another, says Bishop Wilkins, fuit corpus & anima.

From this confusion in the power of letters, there arise divers irregularities; as, that some words are distinguished in writing, which are the same in pronunciation, e.g. coffee and coffee, &c. and others are distinguished in pronunciation, which are the same in writing; as get, acquire, and get, acquire, &c. Hence also the Latin male is a difficult, and the English male is a monosyllable.

The names also, in most alphabets, are very improperly expressed by words of divers syllables; alpha, beta, &c. in respect, the Roman and our English alphabets, which only name the letters by their powers, have a great advantage over the rest.

Lately, their figures are not well concerted; there being nothing in the characters of the vowels answerable to the different degrees of aperation; nor in the consonants, analogous to the agreements or disagreements thereof. Wilkins's Eff. towards a real character, &c. b. i. c. 4.

All these imperfections are obviated in the universal alphabets, or characters, of M. Lodwick, Bishop Wilkins, &c. See Universal Characters.

In the French king's library is an Arabic worke, entitled Sephar Alcham, containing divers sorts of imaginary alphabets, which the author divides into prophetical, mythical, philosophical, magical, taslifanical, &c.

It is no wonder that the number of letters in most languages should be so small, and that of the words so great, since, from a calculation made by Mr. Prefet, it appears, that, allowing only twenty-four letters to an alphabet, the different words or combinations that may be made out of these twenty-four letters, taking them first one by one, then two by two, three by three, &c. would amount to the following number, 1391,724,888,807,552,699,425,51,484,934,027,000. See Combination.

It may be here observed, that every combination may make a word, even though that combination have not any vowel in it; because the e mute, or quiescent, infinuates itself imperceptibly between the consonants, or after the consonants, where they are but two, the latter of which would not be heard without it.—The use of this silent e is very remarkable in the Armenian, Welsh, and Dutch languages; wherein the generality of words have several consonants together.

Nor must it be omitted, that every single letter may make a word; which is very apparent, where the letter is a vowel; words of that kind being found in most languages. Thus, a and a make words in the Greek; a, o, in the Latin; a, o, in English; a, o, in Italian; a, o, in Spanish; a, o, in the Portugueze; o, in most languages, and even in the Dutch and Swedish. Any consonant also becomes a word, by adding an e mute to it in pronunciation.

In fine, though a considerable number of the possible combinations of twenty-four letters were retrenched, yet the number remaining would fill be immense, and vastly superior to that of the words in any language known.

Of all known languages, the Greek is looked upon as one
one of the most copious, the radices only of which are estimated about 32,44, but then it abounds exceedingly in compounds and derivatives. Bishop Wilkins thinks these may be moderately computed at about ten thousand. Hermanus Hugo, indeed, asserts, that no language has so few as 100,000 words; and Varro is frequently quoted by learned men, as if he affirmed that there are in the Latin no less than 5,000,000; but upon inquiring into the scope of the passage, Bishop Wilkins observes, that this number is not intended by him to express the just number of words in the Latin, but the great variety made thereof by the inflection and composition of verbs.—To this purpose he lays it down, that there are above one thousand radical verbs in the Latin, and that each verb admits of five hundred several varieties. He farther supposes, that each of these may be compounded with nine prepositions; as, cessit, rececssit, accedens, decedens, praecedens, procecessit, successit, &c. which amounts to five millions. See Word.

Concerning the origin and progress and various kinds of alphabetical writing, see Letters and Writing.

Alphabetical matters of Polygraphy, is a duplicate of the key or cypher, which each of the parties corresponding are to keep by them.

It is properly an alphabet of the usual letters disposed in their order; opposite, or underneath which, are the secret characters corresponding thereto, with the blank or unclefs letters, and the other signs or symbols serving to obscure and render it difficult to decipher. See Deciphering.

Alphabet, among Merchants and Traders, is a kind of index, with the twenty-four letters in their natural order, in which are set down the names and surnames of those with whom open accounts are kept; and which refers to the folios of the ledger, where those accounts are written, in the form of debtor and creditor; serving to find easily, and without any trouble, such accounts as are necessary to be turned to.

Alphabetic, among the French, signifies also those punchs or iron tools, which engravers upon metal use to engrave the several letters, or characters, which belong to their works, either for legends, or for other inscriptions. The book-binders have also small brass tools, which they call alphabets, and with which they cut the titles, and the number of the volume, on the back of books.

Alphabetical verbs. See Alphabetic.

Alphæa, in Entomology, a species of the Phalena Bombyx, with ferruginous wings, a white point in the middle, and a punctuated brown streak, found in New Holland.

Alphænix, white barley-sugar, to which is given an extraordinary name, to render it more valuable. This sugar, which is thought good for colds, is made of common sugar, which is boiled until it becomes easy to crack, when they pour it upon a marble table, grained with oil of sweet almonds, and mould it into various figures with a brass crotchet. It is easily falsified with flour.

Alpharabi. See Alphabetic.

Alphard. See Cor Hydrae.

Alpheratz, in Astronomy, a fixed star of the third magnitude in Aquarius. This is otherwise called alpharatz. Some also give the denomination cast alpheratz, and morabaz alpheratz, to two other stars in the right shoulder of Pegæus.

Alphery, Mikeper, in Biography, an English divine of the 17th century, was born in Ruffia, of the imperial line, and on account of the connexions of Ruffia, which happened towards the close of the 15th century, was sent to England with his two brothers. They were consigned to the care of Mr. Joseph Bidell, a Ruffia merchant, and by him entered at Oxford, where two of them died of the small-pox. The furious took orders in the English church, and was presented in 1618 to the rectory of Wodeley, in Huntingdonshire. During his residence in this situation, he was invited to return to his native country by some zealous friends, who promised to exert their utmost efforts in restoring him to the throne of his ancestors; but he declined the proposal, and preferred continuing in the humble, but perhaps no less honourable and useful, station of a parish priest. At the time of the civil wars, he endured great hardships from the republican party, and was ejected from his living. After suffering much insult and oppression from the misguided zealots of that distracted period, he made a small purchase in the vicinity of his living, built a house, and resided in it for some years. The presbyterian minister by whom he was succeeded encouraged and protected him; paid him the fifth part of the annual income of his living, the allowance made by parliament to ejected ministers; treated him with kindness, and did him all the services in his power. After the Restoration, he was replaced in his rectory; but his advanced age of 80 years, and attendant infirmities, obliged him to transfer the duty to a curate, and to retire to the house of his eldest son at Hammer smith, where he died, much respected, and affording a singular example of the virtuosity of the world. Biog. Brit.

Alphèsera, in Batavia, a name by which the Arabians, and some other authors, express the white Dryony.

Alphesi, Isaac, in Biography, a learned rabbi, who flourished in Spain in the 11th century, and who came over from the kingdom of Fez, in Africa, with the Morabites, or Almoravides. His epitaph, written in hexameters, was to this purpose:—"Let it be engraved on the stone, that the light of this world is gone out, and that the foundation of wisdom is deposited within this tomb. Daughters of Sion, come and weep! the world is buried, and riven with blindness. Weep and sigh, for the ark and tables of the law are broken in pieces with this doctor."

Alphèstis, in Ichthyology, the name of a fish called by others Cinæus, the Labrus cyanus of Cimilia's Linneus.

Alpheta, in Astronomy, a fixed star in the northern crown; otherwise called lucida coronæ.

Alphæus, in Ancient Geography, one of the names of Pías in Etruria, supposed to have been founded by the Eleans, who arrived thither from the banks of the Alpheus, in the territory of Elis.

Alpheus, a river of Elis, no less celebrated in mythology than recognized by geographers. The source of Alpheus was in the interior part of Peloponnesus, in the south-east of Arcadia. Its course was first to the north-west; and then turning to the east, it entered Elis, and ran by Pía and Olympia, discharged itself into the sea. The mythologists, who are fond of animating all fountain and rivers, pretend that Alpheus, falling in love with Arcia, pursued her to the sea, into which the plunged herself, and following the same course under the water, rejoined her at Syracuse, in the small island of Ortygias. Virgil, Æd. iii. v. 654. Accordingly it is reported that this river feeds under the sea, without mixing with the salt water, so as to pass quite into Sicily, where it mixes itself with the fountain Arche, near the city of Syracuse, so much that any thing which is thrown into the river on the side of Elis is said to come out at this fountain. The geographical relation and the poetic fiction are so blended, that it is not easy to decide which of them gave occasion to the
the other; but they are both founded on a notion which prevailed among the ancients, that rivers passed under ground for a considerable distance from one place to another. The Olympic games were celebrated on the banks of this river; and Orpheus was worshipped as a god at Olympia. Thus Pindar:

"Alpheus, thy immortal flood,
On his lord's triumphant brow
The Olympic wreath bellow'd."

Od. i. West's Pindar, vol. i. p. 7.

Panoptias (in Ebd. c. 6) informs us, that the Elekans had a law, which condemned to death any woman that should either appear at the Olympic games, or even cross this river, during that solemnity; and the Elekans add, that the only woman who transgressed it had disguised herself in the habit of a master or keeper of those games, and conducted her son thither; but when she saw him return victorious, her joy made her forget her disguise, so that her sex was discovered. She was, however, spared, on account of her father, husband, and son, who had gained the Olympic prize; but from that time an order was made that the keepers should appear there naked.

ALPHION lake was laid to be at the source of the river Alpheus, and that it derived its name from the property which the waters had of curing the leprosy, αλποιος denoting a leper.

ALPHITIDON, in Surgery, a species of fracture, wherein the bone is broken into a great number of small parts, αλποιος denoting a leper.

The word is formed of αλποιος, ιατρικος, bone; q. d. a bone ground to flour or powder.

ALPHITOMANTIA, in Antiquity. See Alphimos.

ALPHIUS, AVITUS, in Biography, a Roman biographer, who probably lived about the time of Alexander Severus, in the beginning of the third century. He wrote the History of the Carthaginian war. Vol. ii. Lat. c. iii.

ALPHIUS mons, in Ancient Geography, a mountain of Alpes, mentioned by Plutarch in his treatise of rivers, where he is speaking of Leucones, a river of Ετολία.

ALPHIGNIS is the name of a surgical instrument which was formerly used for the purpose of extracting foreign bodies, especially bullets, from wounds. The alpignis derived its appellation from its inventor, Alphius Ferrus, a Neapolitan physician of the 15th century, and consisted of three branches, which, by their elasticity, are separated from each other, but may be closely held together by means of a ring pushed forwards upon the branches. It is to be introduced to the bottom of the wound in its closed state; the ring is then drawn back, that the instrument may open and lay hold of the bullet; after which the operator replaces the ring, and withdraws the forceps, holding fast upon the extraneous body. See Wounds.

ALPHIGNIS Tablets. See Alphonsine and Tafers.

ALPHONSO I., or DON ALONZO ENRIQUEZ, in Biography and Heraldry, the first king of Portugal, was the son of Henry of Burgundy, Count of Portugal, and grandson of Don Alfonso, king of Leon and Castile, who granted to Henry part of Portugal, as the dowry of his wife Theresia. He was enticed by his father to the care of Egas Mnnit, who gave him an excellent education. But as his father died when he was entering into the third year of his age, A.D. 1112, his dominions were governed by his mother Theresia. As reports prevailed of his mother's familiarity with Don Ferdinand Perez, Count of Travesmar, and her intention to marry him, some of the Portuguese nobility, jealous of his growing honour and power, advised Don Alonzo, at the age of 18, to assume the sovereign authority. The queen and her party refuted; but though they had recourse to arms, they were speedily defeated, and Theresia was lodged in prison, where she was confined during the remainder of her life. After several conflicts with the Moorish princes, who possessed part of Spain and Portugal, in which he was generally successful, his conquests were restrained by Don Alonzo, King of Leon and Castile, who assumed the title of the Emperor of the Moors, by whose numerous army his country was laid waste. Having however, given him a temporary check, he proposed a treaty of peace, to which the emperor acceded, A.D. 1117; and as the Pope's legate interfered by his interest and influence to effect this accommodation, the Count Don Alonzo, under the impulse of gratitude and piety, declared himself tributary for all his dominions to the holy see, and promised to pay an annual sum of four ounces of gold. In 1139 the Moorish princes were reinforced by a powerful army from Barbary. The Count, though he had an opportunity of retiring, and was advised by his generals to adopt this measure of safety, determined to meet them in the plains of Ourique; and after an obstinate and bloody dispute, the Moors were totally routed. This glorious victory was gained on the 25th of July, and the anniversary of it has ever since been celebrated for preserving the memory of so signal a favour vouchsafed by Providence to the Christian arms. Immediately after this victory Don Alonzo was proclaimed king in the plains of Ourique; but the form and constitution of the monarchy were not settled till the state, consisting of prelates, nobility, and commons, were assembled at Lamagro, in the year 1145. This event was preceded by the conquest of Santaren; and it was sanctioned by the unanimous and cordial concurrence of the states. The king was crowned by the Archbishop of Braga, and it was declared that the regal dignity should descend to his heirs male. Eighteen statutes were framed with the advice of the prelates and nobility for the government of the kingdom, and they were assented to by the people. When the question was propounded, whether it was their pleasure that the king should go to Leon, do homage, and pay tribute to that prince, or to any other, every man, drawing his sword, loudly exclaimed, "We are free, and our king is free, and we owe our liberty to our courage; and if he shall at any time submit to such an act, he shall be accursed, and shall not reign either by himself, or by his sons." The king's coronation was next year followed by his marriage with Matilda, daughter of Audouard, count of Mauvienne and Savoy, and in 1147 by the recovery of Lisbon out of the hands of the Moors. In this conquest he was assisted by a number of adventurers, who were assembled from different countries at the mouth of the Tagus, in their progress to the Holy Land. The capture of Lisbon was followed by the accession of several other places to his dominions. By means of these acquisitions, Don Alonzo became master of four of the six provinces that compose the kingdom of Portugal, and the reputation of his arms was raised to a very high degree. He was no less provident in peopling and improving than enterprising in the acquisition of territories; and in all his great and good designs he was seconded by Matilda, a princess equally celebrated for her exquisite beauty, distinguished capacity and singular piety. By her he had a numerous offspring, which enabled him to strengthen his interests by great alliances. The marriage of his second daughter did not prevent his having disputes with his son-in-law, Don Ferdinand, king of Leon; who once made him prisoner, but restored him to liberty on the humiliating condition of coming in person to Leon to do homage.
homage for his dominions. His son, Don Sancho, inherited his father’s military disposition, took the lead on several occasions during the latter part of his reign, and in 1180 gained a glorious victory over Joseph, king of Morocco and emperor of the Almohades, who had advanced with a very large army as far as Sunturan. The conversion of the infidels, in consequence of this defeat, was so great, that they left the Portuguese at liberty to improve the interior part of the country, and to fortify their frontiers during the whole of next year. Alphonso needed repose and had retired to Coimbra, where, worn out with cares and fatigue, he departed this life on the eighth of December, 1185, after a reign of 57 years, in the 75th year of his age. His remains were deposited with great funeral solemnity in the church of the holy crosses at Coimbra. His gigantic size and strength, as he was no less than seven feet high, and his martial audour, have given occasion to many absurd and incredible stories concerning his military exploits, so that in the annals of chivalry, as well as in the record of martial achievements, he sustains a very conspicuous rank. He initiated two orders of knighthood, that of the Wings and that of Avis, which still flourish in that kingdom with honour. He was succeeded by his son, Don Sancho, in the 31st year of his age. Mod. Un. Hist. vol. xviii. p. 177-190.

Alphonso, or Alonso II, Don, surmounted the Fat, the third king of Portugal, succeeded his father Don Sancho I., at the age of 27, A.D. 1212. He began his reign with two very popular acts; he sent a body of infantry to the affittance of the king of Calife, who behaved with great reputation in the famous battle of Navas de Tolosa, and he gave the castle of Avis to the knights of that order; nevertheless the lustre of his reign was eclipsed in its dawn. His quarrels with his own family entailed upon him a variety of troubles, and subjected him to the interference, as well as the displeasure, of pope Innocent III. The pope, however, prevailed in producing a reconciliation with his fitters; but this calm was disturbed by the incursions of the Moors. However, an army of Germans and Flemings, defined for the holy land, feaconally arrived in the harbour of Lisbon, and enabled the king to take Alescaur-do-Sul, where the Moors had a fortres on a rock that was deemed impregnable, A.D. 1217, and also to defeat the Moorish army. Towards the close of his reign he quarrelled with his clergy, who refused a contribution of troops and money for defending the kingdom against the infidels; upon which, in 1221, the pope excommunicated him, and put his dominions under an interdict. Whilst he was negotiating with his subjects on occasion of the confusion produced by the pope’s sentence, he died on the 12th of March 1223, in the 12th year of his reign, and was buried with little ceremony, under a plain tomb, in the conventual church of Alcobaca. He was very brave and uncommonly strong; and is said to have been a great promoter of justice. Mod. Un. Hist. vol. xviii. p. 193.

Alphonso, or Alonso III, Don, king of Portugal, succeeded his brother Don Sancho II., A.D. 1248, in the 48th year of his age. Soon after his accession to the throne, he entered into a war with the Moors, and took Faro in the province of Algarve, which was deemed the capital of the Moorish territories, and also Loula, which was carried by storm; and he thus added a considerable district to the dominions of Portugal. His domestic administration was conducted with great prudence, so that his power and popularity were much increased, and he maintained a friendly intercourse with pope Innocent IV. In consequence of his marriage with Donna Beatriz, the natural daughter of Don Alfonso the Wise, king of Castile and Leon, whilst his first wife was living, he incurred the displeasure of pope Alexander IV., who put his kingdom under an interdict. But upon the death of his first queen, A.D. 1252, pope Urban granted a dispensation, legitimated the children of Donna Beatriz, and removed the interdict. In order to prevent all future disputes with the crown of Castile, the two kings defined the boundaries between their respective dominions by means of commissaries, and recognized this settlement by a solemn act. The king, encouraged by the prosperous state of the country and by the happy issue of his enterprises, extended the authority of the crown, and obliged the clergy to contribute to the welfare of the state; but this measure revived old disputes, and the kingdom was again, A.D. 1268, put under an interdict. Such was his policy, that he contrived to obtain from Castile an exemption of all claims upon the crown of Portugal, and to procure a declaration that its monarchs were free from every kind of homage. Before his death, he made a full submission to the church, and was reconciled to the pope and clergy; and having received abolition, he died February 16th, 1279, in the 52th year of his reign, and 60th of his life, leaving the kingdom of Portugal complete to his successor. This prince was of tall stature and engaging aspect and manners: magnificent in times of peace, and frugal when his affairs required economy; the friend of the poor, for he pawned his crown to provide them with bread in a time of scarcity, respected by the nobles, and obeyed by the clergy. Mod. Un. Hist. vol. xviii. p. 204.

Alphonso, or Alonso IV, king of Portugal, surmounted the Brave, was the son of king Denis, and succeeded his father in 1324. When he ascended the throne, hunting was his favourite diversion; and whilst he was giving a detail to his council of a month’s sports, one of his courtiers had the resolution to remonstrate, and to threaten, that if the grievances of his subjects were not redressed, they would look out for another and a better king. Alphonsus was at first highly displeased; but upon reflection, “I perceive,” said he, “the truth of what you say; he cannot long have subjects who will not be a king.” Remember, that from this day you have nothing more to do with Alphonso the sportsman, but with Alphonso, king of Portugal.” To this resolution he adhered; and he exercised the authority of a sovereign in a manner that awed his subjects, without conciliating their esteem. To his father’s memory he showed respect, and promoted those who had opposed himself with the greatest vehemence, regarding them, though enemies to him, as the true friends of the crown. He leaned much duty to his mother, and great affection for his consoled queen Beatriz; and commenced his reign with forming designs for the establishment of his family and the security of his dominions. He proceeded, however, against his brother, Alonso Sanchez, as a professed traitor, and thus drove him into rebellion; but he was afterwards reconciled, and received him into favour. He engaged in a war with Alphonso XI., king of Castile, which terminated in an alliance and in equal favours against the Moors. But no part of his conduct was more artful and cruel, and reflected greater disgrace on his character, than that which concerned Donna Agnes de Calatrav, the mistress and concealed wife of his son, Don Pedro. Inflituated by his courtiers, who were jealous of the influence of this favourite, he issued orders for the murder of this princess, and afterwards avowed and approved this horrid deed. The son by this act was driven into a civil war, but it was soon concluded by his submission, and by tokens of peculiar favour on the part of the father.

A L P
the termination of Alphonso’s reign and life approached, he
devoutly endeavored to compensate his past errors and misconduct by
acts of piety and charity, by redressing grievances, establishing
laws for the suppression and restraint of vice and immorality, dictating
justiciary maxims for ruling the state, and
affording from the memory of his son the infallible and
infallible, which he had received; at the same time he took measures
for removing those out of the way, who were likely to be
to become the objects of resentment after his death. Having
concerted measures of this kind he died in May 1357, in
the 32d year of his reign and the 67th year of his age, with
the character of an upright son, unnatural brother, and
coward monarch; but in many respects, of a great man and
a great king, brave and fortunate in war, but artful and
indirect in his political measures, attached to his subje&ts, first
in the administration of justice, attentive to the public welfare
and affinities in encouraging industry and enriching his
people. After all, he was rather revered for a right use
of power, than relied on as a public parent; and though
feared and even efteemed, he was not much honoured nor
beloved. His device was an eagle on the wings, with this
motto, “Alfonsa peto,” i.e., my hopes fly high.

Alphonso, or Alonso V., Don, king of Portugal,
appointed the African, on account of his heroic exploits,
born in 1325, and succeeded his father, king Edward,
at the age of six years. During his minority his uncle, Don
Pedro was regent, and though he conducted the administration
with reputation, and married his daughter to the young
king, he was treated as a traitor to the expiration of his
regency; and both he and several of his adherents were put
to death. The king, who on this occasion was overpowered
by the enemies of the regent, afterwards did justice to his
memory. And he manifestly attached to his queen,
who died in 1355, but without strong suspicions of poison
administered by her father’s enemies, by renouncing all
connections with the fel. Military glory was the chosen object
of his pursuit. With this view he turned his arms against
the Moors in Barbary, and in 1458 he passed over to Africa
with a fleet of 200 sail, and an army of 20,000 men. He
began his career with the capture of Alasser, which
he strongly garrisoned; and proceeded it, with various success,
till the year 1470, when, after reducing Arzila and Tangier,
he returned with great honour to his own country, and
acquired the distinguishing appellation of African. His heke
wife added to those titles which had descended to him from
his ancestors, that of lord of the coasts on both seas, and for
perpetuating the memory of his exploits caused them to be
elegantly wrought in tapestry. The war of Africa gave
occasion to the establishment of the order called Knights
of the Sword. Alphonso was engaged in another contest of
its fortunate issue against Ferdinand and Isabel, of Calife,
and in support of the claim of his niece Donna Joanna to
that crown. His failure of success induced him to take a journey
into France, in order to obtain the assistance of Lewis XI.;
but duped by this faithless monarch, he was so mortified
that he formed a purpose of reneging his crown and making
a pilgrimage to Jerusalem. During his absence, Portugal
was governed, with great ability, by the prince Don Juan;
and upon the king’s return, he was received by his son with
resplect and joy, and reinstated on the throne. Alphonso,
evertheless, opressed with melancholy, determined to withdraw
into a monastery; but in his way thither, he was feized at
Citna with the plague, and died there on the 13th of
August 1431, in the 49th year of his age, and the 43d
of his reign. Alphonso was much honoured and beloved by
his subje&ts, on account of his private character and public
conduct; his temper was condescending and affable, and he
was so much distinguished by his benignity, bounty, and
charity, which he particularly displayed in the ransom of
prisoners, that he acquired the popular title of the Redeemer
of Captives. He was eminently chaste and temperate, fond
of letters, and a patron of learning, and the first Portuguese
king who formed a library in his palace. Guinea was dis-
covered in his reign, under the auspices of his uncle, the
celebrated Don Henry; and a very lucrative trade was esta-
blished by the Portugal to that country, which Alphonso
vindicated against the claims and hostile attempts of the Spa-

Alphonso, or Alonso V., II. king of Portugal,
succeeded his father John IV. in 1656; and having been struck
with the palsy whilst an infant, and neglected in his education,
because of a fierce and untractable temper, so that he was
deposited and succeeded by Don Pedro. He died suddenly in
1683, in the castle of Citn, after having borne the title of
king almost 27 years, living 40, and being a prisoner

Alphonso, or Alonso III., surnamed the Great,
king of Asturias, Leon, and Oviedo, was born in 849, and suc-
cceeded his father Don Ordoño in 869. The rebellion of
Don Froha compelled him to retire from the kingdom, but
upon the death of this usurer he returned with universal
applause. He was an able and warlike prince, and in suc-
eellous combats with the Moors he reduced several places.
His attention to the lower classes of his subje&ts disgraced
some of the naughtiness, and occasioned disturbances
which he repressed. In an interval of tranquillity A.D. 900,
he held a general council of the clergy and state, which
enacted some useful regulations, and he directed his attention
to other objects, that contributed to the honour of his
kingdom and the happiness of his subje&ts. Whilst he was
employed in building and fortifying some of the towns,
which had been taken from the Moors, he was interrupted by
them, and reduced to the necessity of defending himself with
a considerable army; which he did with such effect, that
they were defeated with great loss. About the same time
he was disfavored by the rebellion of his son Don Garcia,
who had formed the design of deposing his father and
seizing himself upon the throne; but this rebellion was soon
suppressed. It was followed, however, by increasing dif-
contents, occasioned by the confinement of Guzman and the
oppression of taxes; in consequence of which Alphonso,
A.D. 916, assembled the states and all the grandees of
the country, and abdicating the crown, resigned it to Don
Garcia, who was declared king; and to his other son Don
Ordoño he assigned the province of Galicia. Soon after
his resignation of the kingdom, his son assembled a numerous
army in order to march against the Moors; and having
secured considerable advantage in 911, he was preparing for
another campaign. Alphonso aided him by his counsel, and
took pains to convince him, that incurring and conquests
were of little avail, if they were not conducted with no other
view beside that of enriching the soldiers and of gaining ap-
plause. His advice was regarded, and Alphonso himself offered
to take the command of the army that was raised for new
operations; and having made a glorious campaign in 912,
he returned with his army laden with spoil to Zamora.
Here he was soon feized with a disorder, which terminated
in his death, December 20th, in 912, two years after his
abdication, 49 years from the time of his being associated
with his father in the government, and when he was about
63, or as some say 65 years of age. He was deemed a

Prince
prince of great learning, and the patron of literature; and
much respected for piety and virtue, and all princely qual-
ities. It is said, that he composed a Chronicle of the
Spanish affairs from the death of king Reccesvihio to that
of his own father Don Ordoñez. This chronicle has been
incorrectly published by Simoviel, and the later editions
have been imperfect. This work was published to the world
under the name of Schalian, bishop of Orensa, at whose
request it was composed. Mod. Un. Hist. vol. xvi. p. 135,
141.

Alphonso, or Alonso X., surnamed the Hijo, king of
Leon and Castile, succeeded his father, May 30th, in the
year 1452, with the general approbation of the people, who
regarded him as a prince of great qualities and remarkable
merit; though the appellation with which he was
honoured was more the result of his learning and encour-
agement of science than of his royal talents and exploits. The
propriety of his reign was interrupted by the ill-concerted
projects of his ambition. His first attempt was directed
against Galcony, to which he pretended a better right than
Henry III. of England; but instead of succeeding in en-
forcing his claims, he confounded them, on con-
dition that Henry's son, afterwards king Edward I., should
marry his sister Eleonora. He also prepared for an expe-
dition against the Moors, in Barbary, at an expense which
drowned his treasuries and obliged him to deface his coin; but
he was diverted from attacking the Moorish princes, by
presenting claims, derived to him from his mother, to the diocese of Swabi.

He was thus led into communication with the German princes,
and became a competitor with Richard, earl of Cornwall,
for the imperial crown, a titular honour which coDl both
these rivals immense sums of money. The conspiracies of
several princes of the blood, as they were supported by the
Moors, demanded his serious attention; and he was success-
ful in retraining and defeating them. In 1268 he formed
a romantic design of visiting Italy, against which the states
repudiated, and which, in deference to their opposition, he
was under a necessity of relinquishing. This produced a
formidable conspiracy among his subjects, and the number of
male-content was so considerable as to overpower them, that a
compromise and reconciliation were not effected without
great reluctance on their part and contedction on that of
the king. After the death of Richard, earl of Cornwall,
and even when Rodolph of Hapbourg was actually elected
emperor of Germany, Alphonso adhered to his honour;
and, for the purpose of preventing the pope from confirming
his election, he took a journey to Bauxaire, in order to have
an interview with him; although in the mean while the
Moors, availing themselves of his absence, were ravaging
his dominions. This journey, whilst it was attended with
great expense, and productive of much confusion in his king-
dom, proved ineffectual; the pope was not to be convinced
of the justice of his claims; and he returned disappointed
and mortified. In this interval his eldest son died; and the
second, Don Sancho, claimed the crown against the children
of his elder brother. An assembly of the states was con-
vened at Segovias, and Sancho's claim was allowed; but the
cause of the children was maintained by their uncle, Philip
the Hardy, king of France; Alphonso was thus engaged in
a war; and his own queen, Donna Violante, refuted the
indignity offered to her grandchildren, and retired to the
court of her father, the king of Aragon. In addition to
these domestic disaffections, Alphonso, engaged in a war with
France, was compelled by the pope to renew the war with
the Moors, which proved disastrous; and having concluded
a truce with them, he was engaged in a conduit with the
king of Grenada. By these various measures his finances
were ruined, taxes were multiplied, and the affairs of the
kingdom were reduced to such disorder, that an assembly of
the states was held at Seville in 1251, in which the king
proposed, and the states acquiesced, to give a currency to
copper money. Another assembly of the states was held
at Valladolid, in consequence of the intrigues of Don San-
cho, A.D. 1282, which deprived Alphonso of the regal digni-
ty, and appointed Sancho regent. The king, reduced to
almost insupportable difficulties, sought the alliance of the
king of Morocco; solemnly curbed and dishonoured the Moors;
and by his last will in 1285 confirmed the act of exclusion,
and appointed, for the succession, the infants de la Cerda,
and upon the failure of their heirs, the kings of France.
At the commencement of the next year, when Alphonso
received information from Salamanca, that Sancho was dan-
gerously ill, and professed the most sincere sorrow for his
undutiful conduct to his father, he relented, pardoned his
son, revoked his curfes, and then died on the 3d of April
1284, in the 81st year of his age. He was buried in the
cathedral of Seville, and left behind him the character of a
learned man and a weak king. As a proficient in science
and a patron of literature, he fulfilled a high and honourable
rank. As a politician and legislator, he completed the code
of laws which his father, Don Ferdinand, had begun, known
by the title of Las Partedes; and he reformed the con-
structed in both proceedings, occasioned by intermixing Latin
with the vulgar tongue, by obliging his subjects to use their
own language. He also corrected many errors in the statutes
of the university of Salamanca; and compiled a general history
of Spain to be composed in the Castilian language, which
he took pains in polishing. But his favourite object was
astronomy; and to the improvement of this science his at-
tention and labour were particularly directed. With this
view he assembled at Toledo, during his father's life, a
number of the most celebrated astronomers of his time,
Christians, Jews, and Arabsians, from all parts of Europe,
for the purpose of examining the astronomic tables of
Ptolemy and correcting their errors. They were employed
in this business for four years, and in 1251, the first year of
Alphonso's reign, they compiled those tables which have
been denominated Alphonsine tables, from the name of this
prince, who encouraged the construction of them by his
libertiy. The sum, expended upon them, is immense; if
we may believe the report of those who state it at 400,000
ducats, or even that of others who reduce it to 40,000.
Some have ascribed the principal conduct of this work to
the Jewish Rabbi Isaac Aben-Said, whilst others, professing
to derive information from the MSS. of Alphonso, refer it
to Alcababius and Aben-Ragel. The other astronomers who
were employed on this occasion were Aben-Mufr, Moish-
med, Josep Ben-Ali, and Jacob Abuna, Arabians; Sa-
nuel and Jehuda El-Consco, Jews; but the names of the
Christians, if any such were actually engaged, are not known.
The epoch of these tables was fixed to the 30th of May,
1252, which was the day of his accession to the throne.
They were first printed at Venice in 1483; and there are
other editions in 1492, 1521, 1545, &c. He is also said
to have written a book, entitled, "The Treaufe," containing
treatises of rational philosophy, physics, and ethics; and
to have been well acquainted with astrology and chem-
istry, in which last science, as report says, there are two
volumes, compiled by him, still remaining in his Catholit
Majesty's library, in cipher. But considering the state of
this science at that period, they must be more curious than
useful. Alphonso has been charged with irreligion and im-
piety,
piety, chiefly on account of a laying of his, that is very well known, and that has been often repeated to his dishonour; vice that "if he had been of God's privy-council, when he created the world, he could have advised him better." If we admit the fact, that he used this expression, of which there is some reason for doubt, as it has been variously cited by different writers, it unquestionably indicates a degree of presumption and arrogance not very suitable to the character of a true philosopher. Candidly interpreted, it is to be considered as a kind of jesu d'esperit, or pleasant sarcasm that perplexing variety of eccentric cycles and epicycles, with which the later ages have been burdened; but the reflection might have been dictated in terms more decorous, and more consistent with that reverence of the Creator, which an enlarged contemplation of his works has a tendency to produce. "An indecent astronomer is mad." Young. Modern Un. Hist. vol. xvi. p. 343—365.

Alphonso, or Alonzo V., deservedly called the Magnanimous, king of Aragon and Naples, succeeded his father, Ferdinand the st, as sovereign of Aragon, in the year 1416. The tranquility of his reign was disturbed, soon after his accession, by the infortune of pope Benedict XIII., and by a conspiracy of several nobles among his own subjects against his life. The discovery of this treason was made just before its execution, and the king had an opportunity of exhibiting a signal display of magnanimity by tearing a paper in which the names of the conspirators were inscribed without reading it; declaring at the same time, "that he would at least force them to acknowledge that he had a greater regard for their lives than they had for his."

Having restrained all disturbance in Sardinia, he was preparing to advance to Sicily, when Joan of Naples, founder, was death of his son and heir, if he would assist against the pope, the duke of Anjou, and the confable Sforza, who had formed a confederacy to depose her. The king accepted the proposal, raised the siege of Naples by his army, and was immediately installed, by proxy, heir apparent of her kingdom and duchy of Calabria. The queen afterwards proving false to her engagement, he was expelled from Naples, which was taken possession of by Alphonso; but when the duke of Anjou made himself master of the greatest part of the kingdom, the queen renewed her application to the king of Aragon, and he prepared for a new expedition. In 1434 he again renewed his attempt for the conquest of Naples, and befegg ing Gata, he involved himself in a quarrel with the duke of Milan and republic of Genoa. In an engagement with the Genoese fleet, which was sent to relieve the place, Alphonso bolt all his ships, and was himself taken prisoner. At Milan, whether he was conducted, he was far ingratiated himself with the duke, that he became his friend and ally; and whilst his own hereditary states were liberal in their supplies, his power was greater than ever. In 1413 he made himself complete master of Naples, and in person assembled the states held first at Beguentorium and transferred to Naples, his sovereignty was acknowledged, his son Don Ferdinand, whom he had created duke of Calabria, was recognized as successor to the crown, and he was esteemed the great arbiter of peace and war through all Italy. Alphonso continued in Naples till the close of his life and reign; but his declining years were disputed by political intrigues and dissensions. Reckless and unwise, he was removed from one castle in Naples to another, and at length expired on the 22d of June, 1468; leaving to his natural son Ferdinand the kingdom of Naples, which he had acquired by arms, and to his brother Don Juan, king of Navarre, the crowns of Aragon, Valencia, Majorca, Sardinia, and Sicily, and the principality of Catalonia, with all their dependencies. Alphonso was, without doubt, the greatest prince that ever sat on the throne of Aragon, and he was accounted the ablest statesman and the most renowned military commander of the age in which he lived. He was in an eminent degree the patron of learning, and afforded an asylum to the Greek litterati when they were expelled from Constantinople; his device was a book opened, and it was his common saying, "that an unlettered prince was but a crowned ass." The perusal of Quintus Curtius cured him of a dissembler with which he was attacked at Cappa; he was brave and liberal, and in all his negotiations he displayed the mean arts of intrigue and dissimulation. He had in familiar intercourse with his subjects, whom he loved. "A father," he said, when walking unarmed and unaccompanied about his capital, "has nothing to fear in the midst of his children." When he was besieging Gaeta, he relieved and dismissed without injury the women and children that were turned out of the town, alluding, "that he had rather lose any city in his dominions than the reputation of humanity."

When one of his galleys, with its whole crew and a number of soldiers, was ready to perish, he leaped into a shallop for its relief, saying, "I had rather share than witness their calamities." Upon hearing an officer, who saw his treasurer bringing him 10,000 ducats, exclaiming, "I should only with that sum to make me happy?" "You shall be so," said Alphonso, and caused the money to be given to him. He expressed an extraordinary dislike of dancing, which he considered as a kind of infamy. His greatest failing was an attachment to women; and it was productive of several improprieties of conduct and pernicious consequences. Luceria Alana was one of his mistresses, and his fondness for her in an advanced period of life very much fulfilled his reputation; and connections of this kind led him to neglect his wife, who was faithful and affectionate, and very zealous and active in his interests. Mod. Un. Hist. vol. xvii. p. 240—254.

Alphonso's Island, in Geography, an island of the Indian Ocean, nearly south of the Almirante Islands, lying in a tract of sea, little traversed by European vessels. S. lat. 7° 30'. E. long. 52° 40'.

St. Alphonso's Island, is an island on the coast of Terra del Fuego, in the South Pacific Ocean. S. lat. 55° 51'. W. long. 60° 33'.

ALPONSIUS, Petrus, in Biography, a Spanish Jew, was converted to Christianity, A.D. 1165, baptized at Huesca, and had Alphonius, king of Portugal, for his godfather. He composed a treatise by way of "Dialogue between a Jew and a Christian," concerning the truth of the Christian religion, in which the arguments of the author against the Jews are arranged methodically and urged with clearness and fidelity of reasoning. This work was published at Cologne in 1531. Dupin, 12th century, vol. iv. p. 170.

Alphonsius Tortatius, a learned Spaniard and voluminous writer, flourished in the middle of the 15th century. He finished his studies in the university of Salamanca at the age of 22 years, and made great proficiency in those branches of knowledge that were in principal estimation at that period. He attended the council of Basile, became bishop of Avila, and was advanced to the chief offices in the kingdom of Spain. He died at the age of 40 years, A.D. 1454, and was interred in the church of Avila, with this epitaph:

"Hic diupor lo mundi qui feibile dictatu onem."

His works, written during his comparatively short life, amount
ALPHOS, in Medicina, a ditterem described by Celsus, under the name of withiga; wherein the skin is rough, and becomes sprinkled as it were with drops of white; and thence denominated luce. Where the spots are black, it is also called nigra; and melanc. It bears the same relation to the luce, as the sabbies to the lepra; the first is superficial and cutaneous, the second sinks deeper into the fleth. The alphas, melas, and luce, are but one and the same disorder, only differing in its degree of inveteracy.

ALPIFIJ. See BASSET.

ALPIGNAN, in Geography, a town of Italy, in the principality of Piedmont, on the Dora, five miles west of Turin.

ALPIN. See CISAIPINE.

ALPINI, in Ancient Geography, a people of Spain, mentioned by Aulus Gellius and Varro, in whose country were excellent mines of iron and silver. They were situated near the Ebro.

ALPINIA, in Botany, so called after PROSPER ALPINUS, a genus of the monandra monogyne chased and order, of the natural order of ficiaenex and canae of Jussieu; the characters of which are, that the calyx is a perianthium one-leaved, tubulofe, three-toothed, the leaflets equal, erect and acute; the corolla monopetalous, tubulofe, tube cylindraceus and short, border three-parted, and parts nearly equal and oblong; the nectary connate with the tube of the corolla, two-parted, the lower part forming the lower lip is larger and longer than the parts of the corolla, broad, spreading and often divided; the stamina have no proper filament, but along the upper division of the nectary, forming the upper lip, which is flatish and of the length of the corolla, grows a large anther, either deeply bided or entire; the fyllium has an inferior, oblong germ, style filiform, often inserted into the suffure of the anther, stigma incassate and obtuse; the pericarpium is an oval capsule, three-celled, crowned with the permanent calyx; the seeds are ovate, angular, and covered with a fort of berried aril. This genus differs from the fomium and collus only in the habit and the influenzae, which is racemed. Martyn reckons two, Willderow four, and Gmelin five species. They are as follow: 1. A. racemos, with raceme terminatig, spikod, flowers alternate, lip of the nectary trilid, and leaves oblong and acuminate. This is the A. jamaicensis of Gartner, the amomum pyramidal of La Marck, the amomum alpinia of Rothchel, and the zigiber sylvetrex minus, &c. of Skane. It is a native of the Weal Indies. With us it must be preserved in a flow, and the pot plunged into a tub of water; the leaves decay every Winter, and are pulled out from the roots every Spring. It may be increased by parting the roots, when the leaves decay. Gmelin mentions two varieties, A. ffolis of Koenig, and A. multicaulis of Aublet. 2. A. occidentalis, with raceme radical, compound, erect, nectary emarginate at the apex, three-capped capsules, and leaves lanceolate-ovate and very smooth. This is the amomum minus, with clothed stalk and spikod flowers of Brown, Jamaica. It is a native of the woods of Jamaica and St. Domingo. 3. A. spicata of Gmelin, who queries whether it be of this genus. See COSTUS. 4. A. langus of Gmelin, with palaunculated terminal flowers. He mentions two varieties, &c. Langus chinenis and L. aquatricum of Koenig.

5. A. jamaicensis, made by Gmelin a distinct species. 6. A. galhada of Wildenow, having a terminal lax raceme, with alternate flowers, the lip of the nectary emarginate and lanceolate leaves. This is the maranta galana, with a simple culm of other writers, the amomum galdana, &c. of Loureiro, the galhada of Rumphius, and the galhada of the 1hops. It is a native of the East Indies. 7. A. caryophyl of W. with a terminal tufted spike, bracts longer than the flower and coloured, and oblong-ovate pubescent leaves. The calyx is red; the corolla yellow; and the nectary yellow, truncated and quinque-lobed. It is found in Curaccas, in South America.

ALPINUS, PROSPER, or PROSPERO ALPINI, in Biography, born at Massereffa, in the states of Venice, in the year 1533, became celebrated for his skill in medicine and botany, which he cultivated with singular success. Having quitted the army, to which he was at first attached, he went to Padua, where he studied physic, and in 1578 was received doctor in medicine, and through the interest of his father, who was also a physician, was appointed in 1580 to attend the Venetian consul to Egypt. He remained there three years, during which time he applied himself with great industry to acquire a knowledge of the most remarkable plants, indigenous to that country, and of the practice of physic, or the methods used by the natives in curing diseases. These became the subjects of several learned and ingenious works, which he published on his return from Egypt. In 1586, he was appointed physician to Andrew Doria, at Genoa, whence, the reputation of his abilities increasing, he was called home by the states of Venice, and appointed professor of botany and curator of the phytic garden at Padua, which office he retained to the time of his death, which happened in November 1616. He was succeeded in the professor's chair, by one of his foars, who had probably been his assistant, as he is said to have been very inmum, and to have laboured under a difficulty of hearing, during some of the latter years of his life. The principal of his works, which have passed through numerous editions, and are in many hands, are, "De Medicina Asiae Egyptorium," lib. iv. first published at Venice, in 1511, full of ingenious information as to the diseases, medicine, surgery, and modes of life of the modern Egyptians; "De plantis Asiae, liber;" "De Balkomo, dialogus," a treatise on the famous bulb of Gilead. "De prefigianda vita et morte Egyptiainium," published in 1601, and consisting chiefly of a collection and arrangement of the prelages of Hippocrates; "De medicina methodica," being an attempt to elucidate and restore the ancient doctrine of the Methodid sick in medicine, published in 1611; "De Raphontico dipintasio inauguralis;" "De plantis exotici," all in quarto. He is also said to have left other works in manuscript, that have not been published. Ample accounts of these several works, and of the editions they have passed through, may be found in Haller's Bib. Med. Prat. and his Bib. Botanica.

ALPISTE, or ALPI, a sort of seed used to feed birds with, especially when they are to be nourished for breeding. The alpine seed is of an oval figure, of a pale yellow, inclining to an ifabel colour, bright and glossy. It is an article of the corn chandlers and farmers' trade. See PHALARIS.

ALPS, ALPE, in Geography, was a name given to a chain of mountains, which extended from the sea of Liguria to Itria, and forming a kind of crescent, separated the northern part of Italy from Gaul and Germany. The name is Celtic, and denotes highly elevated; or, as the author of a German book, entitled, "Rheinischer Antiquarius," lugglei,
suggests, it signifies mountains abounding in pellmary. Plutus is of opinion that the appellation was borrowed from *albus*, pronounced by the Sabines *alpna*, and signifying sablīs, because these mountains were always covered with snow. Others, recurring to a fabulous relation, derive it from a person of the name of *Albus*, the son of Neptune, who is said to have been killed by Hercules, in disputing his passage over these mountains. But the first etymology, adopted by Tilius, (Orig. lib. iii.) and Servius, (in Virgil, Æn. lib. iii.) is the most probable. The word *alp* signifies, among the ancient Scythians and Scandinavians, both a mountain and a mountain spirit; it being a perfunctio among them, that mountains and rocks were inhabited by Demons. Accordingly the Edda of Iceland, (Myth. 15.) mentions good and evil Alps.

This chain of mountains, commencing in the Vada Sabatia or Savona, and terminating near the Sinus Flanaticus or Flanonicus, now the Golfo di Canaro or Carnaro, in the bay of Venice, and the springs of the river Colapis or Kulpe, or reaching from the river Varus to the river Arva, in Illyria, has many irregular windings, so that its extent has not been accurately and uniformly ascertained; some of the ancient writers making it 800, and others no more than 250 miles. Its whole range may be more fairly computed at about 550 British miles; and may be considered as extending in a kind of semicircle from the gulf of Genoa, through Switzerland, which contains its central and most lofty parts, and terminating in the Carnic Alps, on the north of the Adriatic sea. It has been divided, both by ancient and modern geographers, into different portions, and these have been distinguished by different appellations.

The *Maritime Alp*, *Alpes Maritimes* or *Littoreae* of Ptolemy, arise from the gulf of Genoa, and reach from Vada or Vado, in Nice, to the springs of the Var, or to those of the Po. Some reckon their commencement at Monaco, on the Mediterranean, and trace them in their progress from south to north, between ancient Gaul to the west, and Genoa to the east, through the eastern part of the country of Nice, and between that and the marquisate of Saluzzo to their termination at Mont Vifo between Dauphine and Piedmont. Upon the summit of this ridge trophies were erected in honour of Augustus, at a place called Tropaeum, since called Turbia. The ancient capital of the *Maritime Alp* was Embrun, and the inhabitants of this district obtained from Nero, A.D. 63, the rights of Latium, that is, the rights and privileges which the Latins enjoyed when they were only allies and not citizens of Rome. The highest chain of these Alps, through which is the remarkable passage, called the Col de Tende, forms the exterior boundary of the country of Nice.

The next high ridge, called *Alpes Cottiae* or *Cottanne*, now Mont Genevre, in which is the spring of the river Durance, extends from the springs of the Var to the city of Susa, or from Mont Vifo to Mont Cenis, and separates Dauphine from Piedmont; having the *Alpes Maritimes* to the south, and the *Alpes Graiae* to the north or north-west. In the time of the Romans a petty prince called Cultura possessed an independent territory in this part of the Alps; and in order to maintain his independence paid court to Augustus, and engaged his protection. With this view he traversed these mountains, and formed commodious paves for the Roman troops. The territory of Cottias, a prince who reigned at Susa, and whose name was given to this ridge, continued, according to Pliny, of two independent cantons. Hence the passage of the Alps, which led from Briançon to Susa, was particularly denominated in the Theodorian table *Cottiae*. M. d'Anville, Holkham, and others, are of opinion, that it was by this part of the Alps Hannibal entered Italy. Some have thought that one part of his army crossed over the Cottian, and another over the Graian Alps. It has been said that he cut a passage through the folded rock; and if Livy may be credited, he located the rock by a fierce fire, and poured a great quantity of vinegar upon it, which penetrating into the fissures, produced by the intense heat of the fire, calcined and softened it. But this relation, although Pliny (lib. xxxii. c. 1.) takes notice of this quantity of vinegar, is rejected by many authors as fictitious. Polybius does not mention it. The capital of the Cottian Alps was Susa; and this territory was added by Nero, about the year Cirill 63, to the dominions of the Roman empire.

To the north of the *Alpes Cottiae* were the *Alpes Graiae* of the ancients, so called by Pliny and Nepos, as it has been said, from the passage of Hercules in his return from Spain; which is rejected by Livy (lib. v. c. 33.) as fabulous; these are now denominated the Little St. Bernard, and commencing at Mount Cenis, where the Cottian end, and running between Savoy and the Tarenteze to the west, and Piedmont and the duchy of Aosta to the east, terminate in Great St. Bernard.

The *Alpes Pennine* lay to the north-east of the Graiae, between the Velagi to the north, and the Sahali to the south. Some have sought the etymology of the name Pennes, Carthaginian, pretending that Hannibal passed into Italy by this mountain. But both the etymology and the fact are equally erroneous. The appellation *Pennine* formed from *pen*., head or high, signifies the height of these mountains; and the passage of Hannibal was probably over that part of the Alps, denominated Cottian. The *Alpes Pennine* consisted of the present Great St. Bernard, Mont Blanc, and the grand chain that extends on the south of the Rhone to the north of the modern Piedmont, and reached from west to east from St. Bernard to Adula or St. Gothard, separating between the Veltè, to the south, and the Malaente to the north; and the eastern part of this ridge was denominated the Lepontine Alps, from the appellation of a people who inhabit the country where the rivers Rhone and Téfino originate. From the *Alpes Pennine* proceed the *Alpes Helveticae*, which extend through the Grisons and the Tyrol, to the springs of the river Piave, of which a part called *Alpes Trigantinae* are situated to the north of Trent. With the Rhetic are connected the *Alpes Nervia*, to the east of the former, situated about the source of the river Tajaento; and joining to it the *Alpes Carnitana*, extending to the springs of the Save; and moreover, those four are the *Alpes Julia*, which reach to the source of the Kulpe. These last derive their name from Julius Cæsar, who formed a design, executed after his death by Augustus, of opening a road over this mountain into Illyria, which is separated from it by Venice. This part of the Alps is also called *Alpes Ventalis*, and *Alpes Pennonarii*. Some authors have extended the *Alpes* to the north of Dalmatia, and even through Macedonia into Romania, and as far as the coast of the Black Sea.

The principal passages of the Alps, of which the Romans availed themselves, when they were in the matters of Italy, as they are recounted by Martiniere, are the following. The first was through the maritime Alps along the sea coast; the second by the Grecian Alps, by which, according to Pliny, Hercules entered into Italy, and which, as Cælius Antipater, cited by Livy, says, was the track of Hannibal; the third by the Cottian Alps, by Embrun, Briançon and Susa, which, some say, was Hannibal's course; the fourth, more generally purfued by modern travellers, through the valley of Maurenne, by Susa and Turin: the fifth by the *Pen-
nine Alps, which, according to Polybius and Pliny, was
that of the Carthaginians, though Livy is of a different
opinion; this route is divided into that of the valley of Pe-
tina, which is the broadest, and that of the valleys of Aosta
and Bardo, which is the longest: the sixth, through the
Pennine Alps by Adula, or Mount St. Gothard, and Bel-
fon: the seventh, over the Rhetian Alps, by the Lake
Verbano or Cofino, which was the route of Druinus and
Tiberius, when they carried on the war in Rhetia, and also
of Silicho: the eighth, by which the Cumbrici entered into
Italy: the ninth, by the Carine Alps; and the tenth, by the
Julian Alps, which was the usual track of the Roman troops
into Pannonia and Illyria.

The central part of this chain of mountains, the most
extensive and lofty land in any in Europe, may be con-
ceived as composed of two ridges, which run almost parallel
from the south-west to the north-east. The first ridge is
that of the Helvetic Alps; and its most conspicuous summi-
ta are the Guinea, or Twins, the Schelenhorn, the Blumis,
the Geihorn, the Jungfrau or Virginhorn, the Eiger, the
Schreckhorn, the Grimsel, the Furca, the Badur, the Gla-
ciers to the north of the Rhine, and St. Gothard.

The highest mountain of the northern chain of the Alps
seems to be Jungfra; and the next in height are the
Eiger, and the Schreckhorn, and the Finlertarr Horn. According to Mr. Kirwan (Geo. Eff. 213, 217)"the height
of these mountains does not exceed 10,000 feet; and he
observes, that they consist of granular, or primitive lime-
stone. Saufure (vol. vii. p. 193) says, that the Schreck-
horn, and Finlertarr are about 15,215 feet high. Bournon
informs us (vol. iii. p. 104,) that the Schreckhorn is the
highest of the Swiss Alps. The summits consist of gra-
in
te; and on the sides appear red flate and calcareous maf-
fes. To the south are large deferts and glaciers, and on the north
is the romantic lake of Kander Steig, "whence (as we learn from a modern geographer) there is said to have been
a passage to Lautebrun amid singular glaciers, sometimes
refembling magical towns of ice, with palisads, pyramids,
columns, and obelisks, reflecting to the sun the most bril-
liant hues of the finest gems." The southern chain of
the central Alps extends from Mont Blanc, and other emi-
nences to the west, and bearing to the north-east compre-
hends the Great St. Bernard, Mount Maudit, Combin,
Cervin, and Mount Rosa. It traverses northward the
vicinity of the lakes Locarno and Como, under the various
denominations of Vogelberg, St. Bernardine, Splugger,
Albula, Bernini, &c. and stretching into the Tyrol, terminates
in the Brenner, or Rhetian Alps, on the south of the Inn,
extending even to Salzburg; and the first chain to the
north of that river separates Bavaria from Tyrol. This
chain of the Italian Alps, proceeding from Mount Rota,
through the country of the Grisons to the Glaciers of Ty-
rol, and terminating at the Salican Alps, should form the
boundary between Germany and Italy, as they pass through
the centre of Tyrol, and as the Italian Alps to the north of
the former Milancce and Venetian territories, are of com-
paratively small elevation. The highest of the Italian Alps
belong to the country of Piedmont.

"It was reserved," says the modern geographer already
cited (p. 583), "for this age of enterprise to disclose the
secret wonders of the Alps. The enormous ridges clothed
with a depth of perpetual snow, often crowned with sharp
obelisks of granite, filled by the Swiss horns or needles;
the dreadful chasms of fome thousand feet in perpendicular
height, over which the dauntless traumler sometimes stands
on a shelf of frozen snow; the glaciers, or seas of ice, some-
times extending 30 or 40 miles in length; the sacred
silence of the scenes before unvisited, except by the chan-
ons and goats of the rocks; the clouds, and sometimes the
thunder storm, passing, at a great distance below; the ex-
tensive prospects, which reduce kingdoms, as it were, to a
map; the pure clarity of the air, exciting a kind of in-
corporeal satisfaction; are all novelties in the history of hu-
man adventure."

From Saufure we learn, that the highest summits of
these mountains consist of "a large grained granite; the
mixture being white opaque felspar, greyish, or white fe-
rent glassy quartz, and micacin small brilliant scales, forming
what is called the white granite. The colours vary; and
sometimes hornblende, felspar, garnets, or pyrites are inter-
spersed. The construction seems to consist of flat pyramids
of granite, flincling vertically, difpofed like the fruit of the
artichoke; those of the centre being most upright, while
the others bend towards them. These flat pyramids com-
monly stand, like the grand chains of the Alps, in a north-
and south-west direction. Beneath, and incumbent on
the granite, especially towards the north, appear large maf-
ofs of flate, which are followed by exterior chains of high cal-
carcous mountains." For a further account of the Alps,
see Cooke's Switzerland, Saufure, Bournon, and the articles
Blanc, Gothard, Rosa, &c. in this Dictionary.

Alps, in Geography, beside its proper signification, by
which it denotes a certain chain of mountains, which sep-
ate Italy from France and Germany, is sometimes used as
an appellation to denote any mountains of extraordinary
height. In this sense, Antonius and others called the
Pyrenean mountains, Alps; and Gallus, the Spanish Alps,
Alpini Hispani. Sidonius gives the same appellation of Alps
to Mount Athos. Other authors speak of Norman Alps,
Alpes Arvernas, Alpes Alborrocetas, Alpes Dauphina, Alpes Ro-
manitas, Alpes Dauphinatus. The Apennines are also called by
Johannes Villeneuve, Alpi D'Aprea. Thus also the British
Alps denote the highest mountains in Britain; such are the
Granian hills, Ben Nevis, and other mountains of the High-
lands in Scotland; such are Snowden, &c. in Wales,
Snowdon, Sliddeow, and Crotfell, in England. To the
Atlantic Alps we may refer the Alsatian and Wetterian
mountains; and to the American the Alleghany and
Appalachian of North America, and the Andes of the
South.

Alps is also used to denote pavements on the mountains,
whereon cattle are fed in the Summer time; or rather in the
vallies, and spaces between the mountain tops. Some will
have this to be the primary signification of the word Alps,
which is supposed by these authors literally to denote the
frighten or apertures between hills.

Alps, Lower, Department of, is one of the four com-
poited out of the C-hevant Provence, in France. It is
bounded on the north by the department of the Upper
Alps, on the east by Piedmont and the department of the
Maritime Alps, on the south by the department of the Var,
and the north-east extremity of that of the mouths of the
Rhone, and on the west by the departments of Vaucluse and
the Drome. Its chief town is Digne. Its superficies is
about 1,459,699 square acres, or 7,45,207 hectares; its pop-
ulation comprehends 144,336 individuals; and it is divided
into five communal districts.

Alps, Upper, Department of, makes a part of Dauphine,
which contains three. It is bounded on the north by the
departments of Mont Blanc and Ifer; on the east by Pied-
mont, on the south by the department of the Lower Alps,
on the west by that of the Drome and part of that of Ifer.

a
Its chief town is Gap. Its superficies is about 1,084,614 square acres, or 553,626 hectares; its population comprehends 116,754 persons; and it is divided into three communal districts.

ALPS, Maritime department of, is formed of the country of Nice. It is bounded on the north by the Apenines and the departments of the Lower Alps, on the east by the Republic of Genoa, on the south by the Mediterranean, and on the west by the department of the Var and Lower Alps. Its chief town is Nice. Its superficies is about 623,619 square acres, or 322,574 hectares; its population amounts to 93,666 persons; and it is divided into three communal districts.

ALPSEE, a lake of Switzerland, being a continuation of the lake of Lucern.

ALP-STEIN, the denomination of a chain of mountains in Switzerland, which separate the canton of Appenzell from Toggenburg, the barony of Sax and the Rhenish. It was formerly the limit between the country of the Romans or Grisons, and the landgraviage of Turgovia.

ALPUERTE, a town and castle of Spain, in the kingdom of Valencia, to the west of Segorbia and the north-east of the river Guadalquivir. It is agreeably situated, and the territory is fertile. N. lat. 39° 55'. W. long. 1° 6'.

ALPUSARRAS, Las, are high mountains of Spain, in the kingdom of Granada, on the coast of the Mediterranean; their summits are visible not only from Gibraltar, but from the coast of Africa, between Ceuta and Tangier, and they extend from Velez to Almeria, and are about 17 leagues in length from east to west, and 11 leagues in breadth from north to south. This canton is one of the most populous and best cultivated in Spain; it is interspersed with villages, and covered with vines and other trees. It produces corn, wine, fruits, and good pasture, and also silk. The air and weather in this district are temperate and healthy. The inhabitants were originally Moors, and they are distinguished from the other Spaniards by the frugality of their manners, the rudeness of their language, and their diligence in labour.

ALQUIER, which is also called coton, a liquid measure for oil, used in Portugal. It contains six covasadas, or canadoras. Two Alquieres make an alcotes, or almarle.

Alquier is also a measure for grain, at Lisbon, containing a peck, three quarts, and a pint English.

ALQUIOU, or Aquifou, as the merchants spell it, is a sort of mineral lead, very heavy, easily reduced into powder, and hard to melt. When it is broken it parts into shining scales, much like the colour of needles of antimony. The potters use it to give their works a green varnish. In England it is commonly called potter's ore. It is found in Cornwall; the potters mix manganese with it, and then the varnish, or glazing, on their wares becomes of a blackish colour.

ALQUIVITE, or Queveto Coafl, in Geography, a part of the coast of South America, which is washed by the Pacific Ocean, extends from the Morro del Bonifico, at the entrance of Baldivia on the south distant 15 leagues to the river Imperial, on the north distant ten leagues. That on the south is the lowest and flattest land on the coast of Chili; but that to the north is higher, and in most places bold, with the exception of the shoals that run well south-west from the island Mocha, north-west by west from the river Imperial. Alquirite is in S. lat. 38° 40'. W. long. 76°.

ALRAMECH, or Aramek, in Astronomy, the Arabic name of a star of the first magnitude, otherwise called Arcturus.

ALRAUPE, in Ichthyology, a name given by the Germans, to the mytilus ferrugineus, or celpout, a species of the GADUS.

ALRED, Alfred, or Alured, in Biography, an ancient English historian, was born at Beverley, in Yorkshire, and educated in the university of Cambridge. Having acquired a considerable knowledge of divinity, philosophy, and history, he returned to his native country; became a secular prelate, and was appointed a canon and treasurer of the church dedicated to St. John of Beverley. His "Annals," containing the history of the Britons, Saxons, and Normans, were continued to the 26th year of Henry I. and he probably died in the year 1128 or 1129. From the preface to his work it appears that he was rather poor than rich, and much devoted to his studies. His abridgment of our history, from Brutus to Henry I. is one of the most valuable pieces that has escaped the rage of time, and the indiscretion of our first reformers. It is written in a concise, elegant, Latin style, with great perspicuity, and an uncommon attention to dates and authorities; so that he may be justly regarded as our English Horus. Leland has omitted Alfred, in his collection of British writers, because he considered his work as merely an abridgment of Jeffrey of Monmouth's British History; whereas, it is not only doubtful whether Alured ever left Jeffrey's history, but probable, from a variety of circumstances, that this history was published after Alured's Annals. The work was published by Mr. Hearne, at Oxford, in 1716, from a MS. which belonged to the famous Thomas Rawlinson, Esq., under the title of "The Annals of Alured of Beverley;" and in a preface to it, Mr. Hearne has vindicated the author from the charge of plagiarism, which has injured the reputation of this valuable compendium of British history. Although Huntington, Hoveden, Malmebury, and other writers have prefixed summaries of ancient history to the accounts they have left us of their own times, yet none of them, fays a very competent judge, are to be compared, in point of accuracy or elegance, with this history, which deserves to be translated and to be continued, with the same spirit, to later times. Besides this work, which has been mentioned under different titles, Alured wrote no other, except "The History of St. John of Beverley," a collection of records, which has never been printed, but is preserved in the Cotton Library, under the title of "Libertates Ecclesiae, S. Johannis de Beverlik, &c."

ALRESFORD, in Geography, a town of Hampshire, situate in the road from London to Winchester on a small stream, which, by means of a large pond as a revoir, with locks and aqueducts, was formerly navigable by barges and lighters to Southampton; but the navigation has for several centuries reached no farther than Winchester. It consists of about 200 houses, one church, and two principal streets; and has a small manufacture of linens. Its market is on Thursday. It is distant from London somewhat more than 57 miles.

ALROE, a small island of Denmark, in the bay of Horfens and prefecture of Aakir, belonging to the diocese or general government of Aarhus.

ALRUKAK, in the Materia Medica, a word used by Avicenna, and others of his nation, for what was called by the Greeks leptos libanotis, and manna lauris. This was the fragments of frankincense, which were broken off from the larger pieces in the collecting or packing up, and were most esteemed in medicine, as being the drier and purer kind.

ALRUM,
ALS

ALRUM, in the Botanical Writings of the Ancients, a name given to the tree which produces the E儒m. This gum was originally known to be the exudation of a tree growing in Arabia and the East Indies, and well known to Avicenna, and others, and by all of them called by that name.

ALRUNES, a name given by the ancient Germans to small figures of wood, of which they made their LASES.

ALSA, now Asea, in Ancient Geography, a small river of Italy, which passing by Aquileia discharged itself into the Adriatic. This river Confluent, the son of Confluentine the Great, fighting against his brother Conflantin, lost his life.

ALSACE, was before the revolution a province of France; bounded on the east by the Rhine which separated it from Swabia, on the south by Switzerland, and part of Franche Comté, on the west by Lorraine, from which it is separated by the chain of mountains called Walgrau or Les Voges, and on the north by the Palatinate of the Rhine; and comprehended between 47° 32', and 49° 8'. N. lat. and 6° 44' and 7° 24' E. long. This has been reckoned one of the most fertile and populous provinces in Europe, abounding in corn, wine, oil, flax, tobacco, fruits, and pulp, of various sorts, wood and excellent pasture. The part of this province that lies betwixt the rivers Ill, Haardt, and the Rhine, is of narrow extent, and less fertile than the other parts; but the district that borders upon Switzerland and Mount Saverne, and the levels about Straubing to the Rhine, are very fruitful and agreeable, and produce abundance of grain, tobacco, culinary vegetables, flax and hemp. The mountains towards Lorraine are high and covered with fir, beech, oak, and horn-beam. The forests of this province are numerous, and furnish great quantities of wood both for fuel and building; as well as plenty of deer and game of all kinds, and it is in general diversified with hills and vales, which render it fertile and productive. Alsace has mines of silver, copper, iron, and lead; and it has also various mineral waters and baths. Its rivers are numerous, of which the principal is the Rhine, and it has also several lakes. The number of inhabitants, who are mostly Lutherans and Roman Catholics, was formerly computed at about half a million; their common language is the German, though the French is generally understood and principally spoken by people of superior rank, and in the towns. This province was divided into Upper and Lower Alsace; the former contained 32 large and small towns, and the latter 39; and in both there are upwards of 1000 market towns and villages. By the late division of France, this province forms two departments, viz. those of the Upper and Lower Rhine, the capital of the former being Colmar, and that of the latter Straubing.

This province was anciently inhabited by the Rauraci, Segnami and Mediomatrici. Its name first occurs in the history of France under the Merovian kings; and it is most probably derived from the river Ill or Il, the inhabitants on the borders of which were called Elsafon, from whom the country itself was afterwards denominated Illas, in Latin Elfatiæ, Alisatia, and Alisatia. From the Celte it fell under the dominion of the Romans; from them it passed to the Germans, and after the battle of Tolbiac, or Zulpich, gained by Clovis in 496, it was possessed by the Franks. It was afterwards incorporated with the kingdom of Austria, and in 752 it was subject, like the rest of the monarchy, to the laws of Pepin and his successors. At the decease of Lewis Debonnaire in 840, his eldest son Lotharius obtained it, and he joined it to that part of the empire of the Franks which fell to him, and which was called the kingdom of Lotharingia or Lorraine. Lotharius II., his youngest son, inherited it; and after him in 869, it became a province of Germany, and was governed by dukes. About a century before the extinction of dukes, the provincial counts, who governed under them in Alsace, assumed the title of Landgraves, and the countries over which they presided were called Landgravates, one superior and the other inferior. In 1357 the half part of the inferior Landgrave was conveyed to the bishop of Strasburg, who filled himself Landgrave of Alsace. The government of Alsace was afterwards conferred by the emperors on several houses, till Ferdinand I. gave it to the German line of the Hohenzollern house; and accordingly it continued in the house of Austria. At the peace of Munster, in 1648, the emperor ceded for ever to the crown of France all right to the town of Brisé, Landgrave of Upper and Lower Alsace, Sundgau, and the district of the ten united imperial cities in Alsace, with the whole sovereignty belonging to them. By the peace of Ryswick, in 1697, the emperor and the empire ceded to France the perpetual sovereignty of the city of Strasburg, and of all its dependencies, on the left side of the Rhine.

ALSADAF, in the Materia Medica, a name given by Avicenna and Scrapiol, to a herbus odoratus, and also to the mures, or purple fish, of the shell of which it was supposed to be a part.

ALSAHARATICA, a name used in Botany, by some, to signify the partihernium de fervwvare.

ALSCHARCUR, in the Materia Medica, a name given by Rhazes, and some others of the old writers, to the Skor, a small animal of the lizard kind, formerly used in medicine as a cordial, and as a provocative to venery.

ALSCHAUSEN, in Geography, a free imperial village of Germany in the circle of Swabsia, in a commandary of the same name belonging to the Teutonic order, within the bailiwick of Alte and Burgundy. It has a caile which is the residence of the country commandary of this bailiwick, and it lies between the district of Altorf and the countries of Konigfleck and Scheer. The title of this place to jurisdiction in ecclesiastical and civil matters has been frequently contested by the Teutonic order.

ALSCHWANGEN, a town with a castle of Poland, in the duchy of Courland, and parish of Alsfahng.

ALSCHENFU, in Botany, a name used by some authors, for Wormwood.

AL SEGNO, in Mysia. These Italian words are used when a return is made to a former part of a movement, where this mark or character appears: " as who should say, return to this sign " S. This is an expedient to save the trouble of writing, or expense of printing certain portions of a movement that are to be repeated. Thus de copio implies that a whole strain is to be repeated from the beginning.

ALSCHWENEN, in Geography, an island of Denmark, situate in the lefser Belt, or entrance into the Baltic Sea, near the coast of Slefwick, to which it belongs; and separated from the main land by a narrow channel called Alten-fund. Its extent is about six leagues in length, and two in breadth; the soil is fertile, and produces plenty of fruit, and, wheat excepted, all kinds of grain, together with large crops of aniceps, used by the Danes as a carminative for soothing their food, and mixing with their bread. The island is sheltered by fine woods, which abound with game; and several of its lakes are well stocked with fish. It is divided into
into south and north Harle, called Sonderburg and Norbarg prelatures. It is about 100 miles west of Copenhagen.

ALS, a river of Germany, which runs into the Ill near Phleinstey.

Als, a town of Germany, in the circle of the Upper Rhine, and duchy of Deux-Ponts; 28 miles west of Worms.

ALSEND, a town of Germany, in the circle of the Upper Rhine, and principality of Naasau-Weiburg, seven miles south of Creutzach, and 40 north-west of Munich.

ALSFIELD, a very ancient town of Germany in the circle of the Upper Rhine, in Upper Hesse, in a prefecture of the same name. It lies near the river Schwalm, an old cattle and two churches; and it is the first town in Hesse which received the confederation of Hesse, being formerly more wealthy and populous than it is at present. N. lat. 50° 40'. E. long. 9° 9'.

ALSHASH, a beautiful city in Buckharia, supposed to be that which is now called Tashkunt, or Tashkand.

ALSHEDA, a parish of Smaland in Sweden, where a gold mine was discovered in 1738.

ALSHEIM, a town of Germany, in the circle of the Lower Rhine, 13 miles north of Worms.

ALSIMBEL, in the Materia Media, a name given, by Avicennan others, to the Spikenard of India. It is thus called from its having the appearance of a spike, or ear, and also simpalath, a word which signifies its being a compound of many spikes, or ears; and much is much of the name India, or Indian Joshua, that we receive at this day.

ALSINA, in Botany. See Theligionum.

ALSINANTHEMUM. See Arenaria.

ALSINASTRUM. See Costus and Elatine.

ALSINE, formed of A. nova, a groove, chickweed, Eng. marguerite, Fr. in Botany, a genus of the pentandria trigynia class and order, and of the natural order of Caryophyllaceae; its characters are, that the calyx is a five-leaved perianthium, leaflets concave, oblong and acuminate; the corolla has five equal petals, longer than the calyx; the stamina consist of capillary filaments, the anthers roundish; the pistillum has a subovate germ, styles filiform, and stigmas obtuse; the pericarpium is an ovate, one-celled, three-valved capsule, covered with the calyx; the seeds are very many and roundish. Martyn reckons three, and Gmelin five species. 1. A. media, holoceme Aline of Swarts, common chickweed, with petals bipartite, and leaves ovate-cordate. The number of stamens in the flower of the common chickweed is uncertain, from three to ten. This species in different soils and situations assumes different appearances; but it is distinguished from the cerasiferas, which it most resembles, by the number of petals, and by having the petals shorter than the leaves of the calyx, and from all the plants related to it, and particularly the stellaria nemorum, by having the calyx alternately hairy on one side only. Dr. Withering refers it to the stellaria, with which genus it agrees in various respects, and especially in the capsules opening with six valves. He observes, that it grows almost in all situations from damp and almost boggy woods, to the driest gravel walks in gardens; but in these various states its appearance are very different, so that those who have only taken notice of it as garden chicken-weed would hardly know it in woods, where it sometimes exceeds half a yard in height, and has leaves near two inches long, and more than an inch broad. In its truly wild state, he says, in damp woods, and hedge bottoms with a northern aspect, it has almost always ten filaments; but in drier soils and more shady situations, the filaments are usually five or three. Dr. Smith (Thor. Brit. vol. ii. p. 473.) also refers it to the genus stellaria, and characterizes it under the species of stellaria media, with ovate leaves and prominent flanks, having the lateral line slightly hairy. When the flowers first open, the peduncles are upright; as the flowers grow, they hang down; and when the seeds ripen, they again become upright. Dr. Withering observes, that the flowers are upright, and open from nine in the morning till noon; but if it rains, they do not open. After rain they become prand; but, in the course of a few days, rise again. In gardens or dunghills chickweed sheds abundance of seeds, which are round, compressed, yellow and rough, with little tubercles; and thus becomes a troublesome weed; but if it be not suffered to feed, it may be delayed, as it is annual, without much trouble. This species is a remarkable instance of the fleec of plants; for every night the leaves approach in pairs, including within their upper surfaces the tender rudiments of the new shoots; and the uppermost pair but one, at the end of the stalk, is furnished with larger leaf-stalks than the others, so that they can close upon the terminating point, and protect the end of the branch. The young shoots and leaves, when boiled, can severely be distinguished from Spring spinach, as equally wholesome. Some are very fond of it; cows and horses eat it; sheep are indifferent to it; and goats refuse it. It is a grateful food for small birds and young chickens. For medical purposes this herb was formerly employed in cataplats against inflammations; and its expressed juice, or decoction, given also internally, as an aperient, antiscorbutic, antiphlogistic; and as a reformativ, probably for abating hectic heats, in atrophies and consumptions. The virtues ascribed to it, says Dr. Lewis, do not appear to be wholly without foundation; though its active matter is so far divided and diluted in the herb, as scarcely to manifest itself after separated from the groffer parts. This plant is found wild in most parts of the world. It is annual, and flowers almost through the whole year. 2. A. gogitale, with entire petals, and awl-shaped leaves. This, according to La Chenal in Hall. Helv. is the same with the Arenaria tenelus. It is annual, and grows about Paris and in Piedmont. 3. A. nocturnata, with entire, short petals, letaceous leaves and awned calyxes. This is a native of France and Switzerland, and introduced into Kew Garden, in 1777, by Dr. Gounn. 4. A. profusa, with oblong leaves, and staminodes prostrate flake. Forth. Fl. Ae., ar. p. 207. 5. A. gymnophila, with lanceolate, rigid, hairy leaves, and erect three-flowered flake. Ardoin il. tomo. x. See Arenaria, Callitriche, Campanula, Centunculus, Cerastium, Corrigiola, Cu- cubalus, Draba, Frankenia, Glauk, Glinus, Gypsophila, Holosteum, Isandra, Linum, Linoidea, Linus, Lychmis, Moehringia, Molliace, Nama, Oldenlandia, Peplis, Pharnaceae, Samule, Sibthorpi, Silene, Spargula, Stellaria, Trientalis and Vero- nica.

ALSERELL. See Sagina.

ALSINOIDES. See Buronia and Montia.

ALSIRAT, in the Mahometan Theology, a bridge laid over the middle of hell, finer than a hair, and sharper than the
the edge of a sword, over which the people are to pass, after their trial on the day of judgment.

To add to the difficulty of the passage, Mahomet affirms, that the almirat, narrow as it is, is beset with briars and thorns; none of which, however, will be any impediment to the good, who shall fly over it like the wind; Mahomet and his Mussulmans lead the way; whereas the wicked, by the narrowness of the path, the entangling of the thorns, and extinction of the light, which directed the former to paradise, will soon mislai their footing, and tumble headlong into hell, which is gaping beneath to receive them. See Sale's Prelim. Difc. to Koran, fec. iv. p. 92. See MAHO-

METANS.

ALSiTz, in Geography, a river of the Netherland{s}, which passes by the city of Luxemburg, and runs into the Soar near Dietrich.

ALSIUM, in Ancient Geography, a city of Italy in Etruria, occupying, according to Cluverius, the spot where Palus now stands. If it was built by the Aborigines long before the Tyrian invaders Italy, as we are informed by Dionysius Halicarnassus, it must have been founded not long after the dispersion in the days of Peleg. Silius Italicus (lib. viii. v. 475.) refers its origin to the Trojan times, and says, that it was built by Alcides, the friend of Agamemnon; but some have conjectured, that Aleedes or Alfa, its founder, was Eliha, the son of Iava, mentioned in Scripture. Vellesius Paterculus (lib. i. c. 14.) relates, that it became a Roman colony, towards the end of the first Punic war. It was situated 18 miles from Portus Augufti, and south-east of Cere.

ALSELEBEN, in Geography, a town of Germany, in the circle of Upper Saxony and the principality of Anhalt-Dessau, and in the bailiwick of Great Alseeben, which has a princely palace built in 1666; nine miles south-west of Bernburg. N. lat. 51° 36'. W. long. 11° 29'.

Alser Druck is also a small town of Germany, in the circle of Lower Saxony and principality of Magdeburg, and in the bailiwick of Alseeben, situate on the Saale, and containing 108 houses. The revenues of the collegiate church have been transferred to the cathedral of Magdeburg. The old village of Alseeben lies so near the town walls as to seem to be a suburb of it. It is 22 miles south of Magdeburg.

ALSO-SAJO, a town of Hungary, in the Gespanschaft of Gomor, situate on the banks of the Sajo. A quantity of cinnabar is dug in its neighbourhood.

ALSO-DANY, a small town of Hungary, in the district of Ofzdin and Rewiichtye jurisdiction, to which belongs a mineral water.

ALSO, Anthony, in Biography, an English poet and divine, was educated at Westminster school, and from thence elected to Christ-church college, Oxford. He was soon after his admission to the university distinguished by Dean Aldrich, and published “Fabularum Aesopicarum delictus,” Oxon. 1668, Svo. with a preface, in which he took part with Mr. Boyle in the dispute between him and Dr. Bentley. He pafted through the gradation of offices to that of canter at the college with reputation, and had the care of several of the principal noblemen and gentlemen of the society; and in this situation he continued, till Sir Jonathan Trelawny, bishop of Winchester, appointed him his chaplain; and soon after gave him a prebend in his own cathedral, together with the rectory of Brightwell in Berks, from which no solicitations to a higher station could induce him to remove. In 1717 he was call’d in an action for the breach of a contract of marriage, with 2000l. damages; and on this occasion he left the kingdom. The duration of his exile is not ascertained; but his death, which happened, June 10, 1726, was occasioned by his falling into a ditch near his garden door. A 4to. volume of his was published in 1752 by Sir Francis Bernard, under the title of “Antonio Al sop, aedis Christi elimi alumni, Oedarum libri duo.” Four English poems, by Allop, are in Doddley’s collection, one in Lear’s, several in the early volumes of the Gentleman’s Magazine, and some in the Student. He was a pleasant and facetious companion, and not rigidly restrained by the forms of his profession. Mr. Allop is respectfully mentioned by the facetious Dr. King of the Commons, (vol. i. p. 257.) as having enriched the commonwealth of learning by “Translations of Fables from Greek, Hebrew, and Arabic,” and no less contemptuously by Dr. Bentley, under the name of “Tony Allop, a late editor of the Allopian Palladi,” Bib. Ditt.

ALSO, Vincent, an English Nonconformist divine, was born in Northamptonshire, and educated at St. John’s college, Cambridge, where he took the degree of master of arts. Having taken deacon’s orders, he settled at Oakham in Rutlandshire, as assistant in the free-school. Having imbibed the principles of nonconformity, he was ordained among the prebyterians, and exercised his ministry at Willes, in Northamptonshire, whence he was ejected in 1662. After this event he preached occasionally, and was imprisoned six months for praying with a sick person. Being known to the word by a book which he wrote in an honourable style against Dr. Sherlock, he was invited to settle with a congregation of prebyterian ministers in Westminster; and in this situation he fortunately escaped fines and imprisonment, because his christian name, which he rudely concealed, was not known to the informers. At the commencement of the reign of James II. Mr. Allop’s son engaged in treatable practices, and obtained the king’s pardon; and this act of clemency seems to have attached the father to the royal interest, to the address which was presented to the king for his general indulgence, and which is supposed to have been written by Mr. Allop, he entreats his Majesty to believe, “that loyalty is not entailed to a party,” and he professes for himself and his brethren, their gratitude and good wishes; to which address the king replied, that he was happy in observing two good effects of his declaration, the eating and pleasing of his subjects, and reforming God the empire over conscience; adding, “it has been my judgment a long time, that none has, or ought to have any power over the conscience but God,” and exquishing his hope, “to live to see the day, when you shall as well have Magna Charta for the liberty of conscience, as you have had for your properties;” closing with this admonition: “and now, gentlemen, do you so preach to your hearers, as they may be good Christians, and then I do not question but they will be good subjects.” After the revolution, Mr. Allop, though he retained a grateful respect for the memory of king James, became zealously attached to the government and interest of king William. He lived to an advanced age, and died May 17th, 1688. It is said, that though on grave subjects he wrote with a becoming seriousness, yet when wit might be properly flown, he displayed it to great advantage. To this purpose we are referred to his “Antifozzo,” in vindication of some great truths opposed by Dr. William Sherlock,” Svo. 1675. He also wrote, “Medius Inquirendum; in answer to Dr. “Goodman’s Compasionate Inquiry,” Svo. 1679; “The Miſchief of Impostures,” in answer to Dr. Stillingsfleet’s Miſchief of Separation, 1680, with several single sermons. Biog. Brit.
ALSTADT, in Geography, a town of Prussia, in the Oberland, near Preussischmark.

ALSTEDIUS, John Henry, in Biography, a German protestant divine, and one of the most voluminous writers of the 17th century. He was born about the year 1688, and was for so many years professor of theology and philosophy at Herborn, in the county of Nassau, and afterwards at Alba Julia, in Transylvania, where he died in 1638. He was one of the divines that attended at the Synod of Dort. He was an industrious compiler of systems of sciences. His principal work is his "Encyclopedia," printed in Lyons in two volumes, 1609; "Vollius speaks with commendation of this part, which comprehends arithmetic. This "Theolatria Chronologicus," has passed through several editions. His "Thesaurus Biblius," was written with a view of shewing, that all arts and sciences may be deduced from the Bible. His "Theologia Polonica," was answered by Himmelius, divinity professor at Iena. His other works are "Philosophia refutata," "Elementa Mathematica," "Methodus formandorum Studiorum," printed at Strasburg in 400, in 1610; "Templum Muficum, or Mufical Synophs," which is so formal as to resemble a logical rather than a musical treatise; and a treatise, "De Mille Annis," published in 1627, in which he maintains the Millenarian doctrine, or that of Chrift's reign on earth for 1000 years, and fixes the commencement of this reign in 1693. The character of this writer has been well comprized in a single grammatical word, "Sedulitas." Gen. Dio. 8.

ALSTER, in Geography, a river of Germany, which runs into the Elbe near Hamburg. It passes through the city, and forms a lake nearly half an English mile in circumference, which in summer evenings is covered with all sorts of pleasure-boats, affording to the spectators a very amusing spectacle.

ALSTON, Charles, (M. D.) in Biography, a botanical and medical writer, was born in the western parts of Scotland in the year 1683. He early applied himself to the study of botany, and opposed, with considerable ingenuity, the sexual fyllem of Linnaeus. When 33 years of age, he went to Leyden, and resided three years under Boerhaave. Returning thence with his friend Alexander Monro, he was materially instrumental in establishing a school of medicine in the College at Edinburgh, of which he was appointed professor of botany and the materia medica. In this poit he continued to the time of his death, Nov. 1760.

In the fifth volume of the Edin. Med. Essays, we have a short paper by Allston on the efficacy of the powder of tin in destroying or expelling worms from the bowels. He obtained the prescription, he says, of an empiric, who was famed for his skill in curing persons afflicted with those noxious infects. One ounce of tin, reduced to powder, and mixed with treacle, was given the first morning, and half an ounce each of the two following mornings; the patients were then relieved with the infusion of iena and manna. He speaks highly of the efficacy of this medicine, which has certainly considerable powers in these cases, and may be given to the most delicate subjects with perfect safety. His dissertation on the excellence of plants, in which he combines the doctrine of Linnaeus, was published in the year 1753, in the first volume of the Edinburgh Physical and Literary Essays. But the work principally calculated to secure his fame with posterity, is his Lectures on the Materia Medica, which was published in the year 1770, in two volumes, 40s. by his friend and successor in the professor's chair, Dr. John Hope. Although considerable additions and improvements have been made in this branch of science, yet this work will be always held in esteem for the number of curious and useful facts it contains. Haller Bibliotheca Botan. Alston-Moor, or Alstone, in Geography, a town of Cumberland, situate on a hill near the river Tyme, on the borders of Northumberland. The parish is small; but on account of the lead-mines in its neighbourhood very populous. The lands are part of the forfeited estates of the earl of Derwentwater, and are held on lease, granted for a thousand years, under the governors of Greenwich Hospital. The market is plentiful, and held on Saturday. The distance from London by Bernard castle is 277, and by Penrith 302 miles. N. lat. 54° 45'. W. long. 2° 40'.

ALSTONIA, so named from Dr. Allston, in Botany, a genus of the polyandra monotychgia class and order: its characters are, that the calyx is an inferior, imbricate perianthium, scales ovate, very obtuse and concave, the inner ones gradually larger, forming, as it were, a quadripartite or quinque-partite calyx; the corolla is one-petalled, shorter than the calyx, tube short, border spreading, divided into eight or ten parts, divisions equal, in a double row, alternately interior and exterior, obovate, obtuse, quite entire; the flamina have very many filaments, inserted into the tube, very short, imbricate, very smooth, the outer ones longer, linear, attenuated at the tip, anthers orbiculate and furrowed; the pistillum has a superior germ, ovate and small, style imple, of the length of the corolla, filiform and erect, the stigma capitata-obovate. The fruit is unknown, and the genus is imperfectly determined; it is nearly allied to Symphiloderis, and perhaps only a species of it. Swartz. There is one species, viz. A. theophoris, joined by M. P'Heritier with Hopsea and Cipsonia, under the same genus Symphiloderis. This shrub was found by Motis in South America. It is very smooth, and resembles the hohe tea in the leaves, the imbricate calyces, the situation of the flowers, &c. The dried leaves chewed gave a green colour to the saliva, and have the taste of Chinoe tea. The leaves Are alternate on short pedioles, elliptical in their form, and from the middle to the tip outfully ferrate, fliff and veined. The flowers are axillary, three or four together, and sessile; the calyx is very smooth, the scales rounded and green, with a membraneous edge; the corollas are white and spreading. Martyn's Miller. Trans. Linn. Soc. vol. i. p. 170.
beautifully stained and veined with purple and red; it flowers from June to October; and was introduced into Kew garden, in 1753, by Messrs. Kennedy and Lee. 2. *A. pulchella*, with erect stem, reflex-spreading and acute corollas, sessile leaves, and pedicles shorter than the involucre. This plant resembles the former in its structure and habit, but the leaves are narrower, and the stem terminated by an irregular involucre of larger petaloid leaves; the peduncles naked and one-flowered, flowers four or five rather nodding; the petals alternately lfts., whitish, red at the tip, streaked, or dotted with red at the base, filaments yellow, pistil red, and stigma trifid. This species is a native of South America. 3. *A. Ligust*, striped-flowered *A. with erect stem, flatulate-oblong leaves, peduncles of the umbel longer than the involucre, and two-lipped corolla. The barren items are clothed with awl-shaped leaves, and terminated with flatulate-oblong leaves, placed in a kind of roset.; the floriferous stem clothed with awl-shaped leaves, the peduncles few and naked; the three upper petals of the corolla larger, white, dotted at the base, and spotted at the tip with red, the three lower ones shorter and red; the filaments longer than the lower petals, ragged, the anthers twin and yellow; the pistil red. This plant, which is a native of Lima, is remarkable for the largeness of its flowers, and for their fragrancy, scarcely inferior to mignonette; it flowers in February and March, and was introduced here about 1776 by John Brown, Esq. 4. *A. Saltiff*, with twining stem, petiolate, lanceolate, acuminate leaves, branching umbel, peduncles longer than the involucre, bracted and hooved. The leaves are nerves, petioles naked, the involucre many-leaved, awl-shaped and reflex, the peduncles few, elongated, faltaining one or two flowers, the outer petal red, and the inner greenish. This is a native of Lima. 5. *A. multiflora*, with twining stem, petiolate, lanceolate, and acuminate leaves, simple umbel, peduncles shorter than the branches, and petals alternate and truncate. This species resembles the last in habit and structure; but the petioles are wrinkled at the edge, and the umbel is not peduncled, the many-flowered involucre consists of broader leaves, and the peduncles are simple and naked; the three outer petals are shorter, narrower, and entire, the inner truncate or emarginate, with a point; the colour is unknown. It is a native of South America. 6. *A. ovata*, with twining stem, lanceolate leaves, lamigno- nifer on the upper surface, lucid on the lower, and corollas tubular; or, according to Willdenow, with twining stem, petiolate, elliptic, acuminate leaves, above villose, ramose umbel, bracteate hooved peduncles, longer than the involucre, and bell-shaped corolla. The stem, twining contrary to the fun, is slender, and three feet high, the leaves are alternate and sessile; the flowers terminate in umbels, the petal proportionate to a tube, ovate-oblong, the three outer scarlet, green at the tip, the three inner green, flatted towards the top, and variegated with black dots; the flowers are fixed to the stem near the base of the petals, anthers ovate and brown; germ green without, marked with six longitudinal grooves, and terminated with six small notches, stile subulate, stigma capitate globular, an inch in diameter, six-grooved, six-notched at the edge. This species differs from the former in its woolly leaves, and tubulose flowers. It is a native of Peru. All these are flax-plants, and may be propagated by parting the roots in Autumn. The flax is more hardy than the third, and may be treated as a green-house plant, but it will flower and ripen its seeds better under the glafs of a hotbed frame, freely admitting air: it is more usually raised from seeds sown in the Spring in a pot of light earth, on a gentle hot-bed, either of dung or tan. Curtis Mag. Martyn's Miller.

**ALSUNGEN**, in Geography, a lake of Sweden, in the province of Halland, from which the river Falkenbergs flows, and by which river it communicates with the sea. **ALSANGEN**, a town of Poland, in the duchy of Courland, four leagues west of Gdalingen. **ALSWEDEN**, a district of the prefecture of Reineberg, in the principality of Minden, in Westphalia, consisting of five parishes, the inhabitants of which are employed in agriculture and the breeding of cattle. **ALSHA**, a small place of Turkey in Europe, belonging to a tribe of Tartars, betwixt the Nieper and Black Sea. **ALT**, a river of England, which runs into the Irish sea, 7 miles west of Omhirk, in the county of Lancastor. **ALT**, formed of al/us, high, in *Mafiz*, a term applied to the high notes in the scale. See also *Diagram*. **ALT-BUNZLAU**, Boleslawia vetus, in Geography, a town of Bohemia, in the circle of Bunzlaub, or Boleslawko, founded by Wratislau in 915, and improved by his son Boleslaw the Cruel in 937, but reduced by the troubadours in the 15th and 16th centuries to an inconsiderable place. The collegiate church of St. Cosmus and Damian is very ancient. **ALT-CLOSTER**, a town of Germany, in the circle of Lower Saxony and duchy of Brunswick, 12 miles south-west of Stade. **ALT-RANSTADT**, or Old-Raspladus, a town or parochial village of Germany, in the circle of Leipsic, two leagues from Leipsic, famous for a treaty concluded in 1706 between Charles XII. of Sweden, and Augustus II. king of Poland; and for the regulation with the Imperial plenipotentiary, Count Wratislaw, in 1707, on account of the religious freedom of the Protestant inhabitants of the duchy of Silesia. **ALTA**, a town of Sweden, in Helsingland, on the frontier of Gotland. **ALTEBA**, in Ancient Geography, a place of Africa, in Numadia. **ALTALI**, or Altay mountains, in Geography, are a chain of mountains in the northern part of Asia, ranking among the most extensive on the globe, and rising in length even with the Andes of South America, which extends from about the 70th to the 140th degree of longitude east from London, or about 5000 miles. The several ridges and branches of this immense chain of mountains are distinguished by different appellations, under which they will be noticed in the course of this work. The Altay mountains are called by the Chinese Altai-alin, and Ghin-allah, which signifies the Gold Mount. They are divided into the Great and the Lesser Altay. The former separates the Mongolian Tartary from the empire of the Soongorian Kalmuns, and a small part of Bukharia toward the west. This range proceeds in various windings toward the north-north-east, throwing out several considerable ridges, between which are the main sources of the Yenisei, Oby, and Irity, through Soongoria to the north-north-west, where they enter in conjunction with the Lesser Altay. The Lesser Altay separates Soongoria from the government of Karhiyan, through which the abovementioned streams pursue their course over a great extent of country. The great chain of the Altay mountains commences with Logdo, one of its highest points, passes over the sources of the Irity, north-westward between that and the lake Teletzkoi-Ozero, unites beyond the Yenisei with the Sayan mountains and those of Baikal, and in Daouria with the Argunian or Nertshinskoi mountains, fixing the limits between Siberia and
beria and the Chinese empire from the Irilfth to the Amur, and runs on, with divergent branches, to the mountains of Okhotsk, and to those of Kamtschatka, and of the Kuril and Aleutian islands, terminating in the promontories and rocky shores of Cape Tschutsins, the boundary of Asia; unless we suppose the mountainous and rocky island of Kurile and Japan connected with the mountains which reach from Tibet to China. The portion of the Altay mountains that properly belongs to Russia, may be divided into two parts; one of which comprehends the entire space between the Irilfth and the Oby, and the other the space between the Oby and the Yenfici. The former may be denominated the Kurilfian, and the latter the Kunzetzkii mountains. Both include the greater part of the government of Kolfiyaan; and the former half, might, on account of its mineral wealth, be called, by way of eminence, the Altay Ore-mountains.

That part of the Altayian chain, which separates the government of Kolfiyaan from the Chinese Soongoria, is divided into two great branches; one from the Irilfth to the lake Teletzksi and the head of the river Abakan, is properly the lesser Altay, or Khrebet Khalta, and the other, from the Abakan to the Yenfici, is called Sabinfki Khrebet. In the former are the greatest elevations of the Kolfiyaan, and in the latter those of the Kunzetzkian mountains; and these form the basis of all the ribs or ridges that extend out to the north-west and to the north, which at last lofe themselves towards the Icy or Frozen Ocean in extensive plains; while towards the south they continue to rise to an uncommon height over a long and broad extent of territory. In the middle of these lofty mountains, says Dr. Pallus, and on the frontier line between the Soongoria and Mongolian deferts, Bogo-Dola, or Bogo-Alim, g. d. the Almighty Mount, so eminenty famous among all these nations, lifts its pointed heads; which, if not one of the highest, is yet, by its craggy, steep, and irregular form, with the appearance of having been thrown up by some violent agitation of the earth, the most striking of the elevated mountains of this region. North-west from it the principal mountain as far as Altay-Kul, or Teletkoi-Ozero, is called the Golden Mountain. Eastward towards Mongole, more to the south, runs a large mountain Changan, and southwards a snow mountain Muffat, which connects either with the Tibetan, or with the northerly mountains in India. To the west the chief mountain throws out an arm, wholly bare of forests, and fiowed, as it were, with rocks, called Allakool, i.e. the chequered mountain, by the Tartars Ala-Tau, which joins with the Kirghizian Alginfki-Sirt. The Great Altay mountains are properly connected, as we have already observed, with the mountains of Tibet by the Muffat, or by other chains; for all the deferts between Siberia and India, and the eastern Bukharia, are merely alternate hills and plains, and very rocky. Besides, it is evident that the Altay mountains must make an uninterrupted partition between the Western Steppes and the eastern regions, because the Steppe animals, particularly the antelopes or Steppenouns, from the mountains, and even in Asia go no farther than to the western range of the Altai, and are come from it northwards to the woody regions of the Oby. The snow-mountain, which appears northwards on the Siberian frontiers from the Irilfthau between the Buktarma and the Katunia, and quite into the angle formed by the rivers Ina and Belna, which flow into the Tjirfh, is, as it were, a branch or nook of the Great Altai, and is by some usually called the Little Altay, and darts its stupendous pinnacles above the clouds. This mountain is bold and steep, and appears, especially in the vale where the Ina unites with the Tegerek, like a towering wall, behind which the mountains rise higher by irregular gradations, and at last strike up in separate points. The same steep vale parts the Schilhofo mountain from the Chalkifone mountain, which passes from hence northwards between the Ina and the Loteftka quite to the Tjhafari. Over the Schilhofo mountain the snowy summits rise conically out of a granite mixed with schorl and mica. The same granite flows itself again in chalky promontories, with the schilus lying upon it, and forms the Reunovaio Sopka, as it is called, at the same time, in the holm of the chaly mountains, the fill more elevated Saina Sopka. Granite appears likewise throughout in low, rocky, craggy mounts and single cliffs, between the rivers Ubo and Alay, where the mountain has already fallen deep towards the plain, and likewise about the lake Kolfiyaan. The rich ore-mountain of Kolfiyaan places itself immediately between and about this granite-lock, and thence arises an apparent confusion in the strata through the whole of the ore-mountain.

The principal part of the Altay mountains that belongs to Russia is the range of Kolfiyaan, or the proper ore-mountains of Altay; and these may be arranged into the Kolhyva-voiterse,i.e. the Kolhyva, the Auris-Khrebet, the Alaiskiav, the Oubinskoi, the Burtarminskoj, the Telethkoj, and the Tjharsikhkoj mountains. The second range of the Altayian mountains belonging to Russia, or the Kunzetzkii mountain, is still almost unknown and inaccessible. Its two subdivisions are the Kunzetzkii proper and the Krafnoyarkoi mountains, which together fill the whole large space between the Oby and the Yenfici. The summits of these mountains, between the sources of the Tom and the Yus, and on the Mafs, are covered with perpetual snow. Their inward constitution is not accurately ascertained; but various sorts of granite, porphyry, jaiper, breccia, fale, chalk, marble, with a granite, horn-flints, flint, scarlet, mountain-crystal, mica, and cornelians are brought from hence. On the Kondoma are productive iron-mines; about the source of the Tjhumsf the Salahirkii silver-mines continue to be worked with fanciane expectations; and at Krafnoryarki several copper-mines were formerly wrought, but are now abandoned. In the last-mentioned council is also an establishment for smelting iron ore. The highest mountains to the south are about the source of the Abakan, where the famous mountain Sabin, or Shabina Danbahn raises its snowy head to a stupendous height, and theItem on the borders of the brook Shantigry.

The greater part of the Altay mountains is more bald than woody. The largest forests are in the low country about the Altay, the Oby, and the Yenfici. The species of wood are the pinus fylvefris, the birch, the alpin, the pinus picea, the pinus abies, the alder, the willow, noble larch-trees, (pinus lirix) and cedars. The principal rivers of these mountains are the Irilfth, and its collateral streams the Buktarma, the Uba, and the Uba; the Oby, with its main rivers, the Alay, the Tjhafari, the Tjhulsyn, the Tom, the Katunia, the Yus, and the Abakan, which falls into the Yenfici. The upper regions of these mountains are uncommonly exuberant in waters.

The Altayian mountains contain rich gold and silver shafts, and also veins of lead, copper, and iron, impregnated with gold and silver. The most important silver mines in these mountains are those of Kolhyvaan. The copper-mine is also considerable; besides which the cupriferous silver ore yields a quantity of copper, the whole amounting to about 15,000 poold a year. In 1782 there were 100,000
ALT

18,793 pound of copper. We have before mentioned the iron fistalising-house of this mountain. In the Altay there are neither markets for provisions, nor any tradesmen and mechanics; and therefore the miner must provide himself with all necessaries, which he is enabled to do by means of the numerous court and church holidays, on which he is released from public labour. With this view the first object of his attention is to have a small house, with a garden and a cow-yard. When new shafts are opened, he makes a shift at first with a hovel constructed with a few stakes, and covered with fods; or he digs an habitation and a baking oven in the earth; when he has the prospect of being stationary, he erects a regular house to which he brings his cattle and his little property. Hence it often happens, that within forests apparently the most inaccessible, or in wild and dreary steppes, whole streets and villages spring up in a few years. The miners of the Altay are generally very ingenious and industrious; and they are excellent hunters, expert foresters, and in case of necessity, the best forgers. Tooke's View of Russia, vol. i. p. 118, &c. Vol. iii. § 10.

ALTALAT, a small district in the south-west part of Coréica.

ALTAMIRA, a village of Spain in Galicia, on the river Tames, which gives title to an earl and granee of Spain, five leagues west of St. Jago de Compostella.

ALTAMONT, or ALTOMONT, a town of Italy, in the kingdom of Naples, and province of Calabria Citra, near which are gold and silver mines, 10 miles south-west from Caffano.

ALTAMURA, a town of Naples, in the province of Barletta, at the foot of the Apennines, six miles north-east from Grativa.

ALTANUM, in Ancient Geography, a town of Italy, in the part of Magna Græcia, called Bruttium, situate on the eastern side, south of the gulf of Scylacentum, and north of Locri.

ALTAD, a town of Africa in Mauritania Cæfaricus, according to Ptolemy.

ALTAR, ALTARE, ARA, a place or pile whereon to offer sacrifice to some deity.

Altars are, without doubt, as ancient as sacrifices; and consequently their origin is not much later than that of the world. Gen. c. iv. Some attribute their origin to the Egyptians; others to the Jews; others to the patriarchs before the flood. Some remove them as far back as Adam, whose altar is much spoken of by Jewish and even Christian writers. Others are contented to make the patriarch Enoch the first who confebrated a public altar. Be it as this will, the earliest altars, of which we find any express testimony, are those of Noah, (Gen. viii. 20.) and of Abraham, (Gen. xii. 7.) In the patriarchal times altars were formed of rude materials, and they were of the inflammable construction, and temporary, appropriated to the purpose for which they were designed. The altar which Jacob set up at Bethel was merely the slime on which he rested, Gen. xxv. 8. Such was also the altar of Gideon, Judges vi.; and the first altar which Moses erected by the command of God was made of earth. Exod. xx. 24.

The principal altars of the Jews were the altar of incense, the altar of burnt-offerings, and the altar or table of shew-bread.

The altar of incense described, Exod. xxx. 1—10, was made of shittim wood, and overlaid with gold. It was one cubit square, and two cubits high, with an ornament of gold like a carved moulding round the top of it. It was carried about by two bars of the same wood, covered with gold, and palling through four golden rings. Its use was for burning incense every morning and evening; and it was also to be sprinkled with the blood of the sacrifices that were offered for the sins of ignorance, committed either by particular persons, or by the people in general. See Miscellany, Plate 1.

The altar of burnt-offering, described Exodus xxvii. and xlviii. was placed towards the east end of the court, fronting the entrance of the tabernacle, and at such a convenient distance from it, that the smoke of the fire which was constantly burning on the altar might not fully the furniture within the tabernacle. Its dimensions were five cubits, or about 10 feet square, and three cubits, or about five and a half feet high. It was made of hewn wood placed over with bres, and it had four brass rings, through which were put two bars, by which it was carried on the shoulders of the priests. It had four horns at the four corners; but critics have been divided as to the form and use of these appendages to this altar as well as to the former. Some have supposed that they were mere ornaments resembling the rays of the sun; the term translated borne signifying also a ray of light. Others imagine that the corners of the altar were in shape like the horns of an ox or ram, &c. that they served for the altar of incense to move and carry it about with the greater care and steadiness; and with respect to this larger altar, for tying the victims on them, according to the allusion of the Psalms, Psalms xxxviii. 27. Michaelis understood by the horns merely the corners, but this interpretation is incompatible with the context. They were evidently projections from the corners; the text, however, does not inform us whether they were upright, oblique or curved. Spencer, Le Clerc, Witius, and others, think that they were really horn-shaped, like those of the ara pacis of the Romans.

Josephus says expressly of the altar in his time: της ἤπειρος τοῦ ἱεροῦ, κωπίασεν περισσοτέρας ἡμέρας. De Bel. Jud. i. c. 5. n. 6. p. 324. ed. Beng. The fire of this altar was kept constantly burning, and never to go out. Lev. vi. 13. From hence probably the Chaldeans and Persians borrowed their notion of their sacred fire, which they preferred with religious care and attention; a custom which afterwards passed from them to the Greeks and Romans. This altar was beaten down and destroyed by the Babylonians at the burning of the temple, but it was replaced on the return of the Jews from captivity. Ezra iii. 5. It was now a large pile built of unhewn stones, 32 cubits (i.e. 48 feet) square at the bottom, and gradually decreasing to the top or hearth, which was a square of 24 cubits, and one cubit high, made of solid brazen, and hence called the brazen altar; for it is not to be imagined that it was all made of solid brass. The ascents to the altar was by a gentle rising on the fourth side, called the Kibbeh, 32 cubits in length, and 16 in breadth, and landed upon the upper benching-in next the hearth or the top of the altar. Prideaux's Conn. vol. i. p. 199. See Miscellany, Plate 1.

The altar or table of shew-bread, described, Exod. xxv. 23—30, was made of the same sort of wood with the altar of incense, and, like that, overlaid and ornamented with gold. Its dimensions were two cubits long, one broad, and one and a half high. It had a golden border, crown, or rim round it;
it; and upon it were placed two rows or piles of leavened or cakes of bread, six in a row or pile, which were changed for new ones every Sabbath. This table was also furnished with golden dishes, spoons, and bowls.

The Jews also gave the name "altar," to a kind of tables occasionally raised in the sanctuary of a field, on which sacrifices were offered to God. Thus we often read, that in such a place an altar was built to the Lord.

The altars of the Heathens were at first made of turf; they were afterwards made of stone, marble, wood, and even of horn, as that of Apollo in Delos. Before temples were in use, altars were erected in groves, in the highways, and on the tops of mountains; and it was customary to engrave upon them the name or attribute of the deity to whom they were consecrated. Altars were also of different kinds with regard to their qualities, the uses to which they were applied, and the objects to which they were appropriated. Accordingly we read of altars sacred to gods, heroes, virtues, vices, deities, &c. and of inner and outer, stationary and portable, public and private altars. They differed also in their figure, which was round, square, or triangular. All of them were turned towards the east, and generally adorned with sculpture, bas-reliefs, and inscriptions, expressing the gods to whom they were appropriated, or representing their distinguishing symbols. For a further delineation of Pagan altars, see Miscellany. Plate I. N° 1, represents an altar dedicated to Neptune, a trident, and two dolphins, the attributes of this deity being exhibited on its sides. N° 2, is a four-square altar, dedicated to the nymphs, as the inscription informs us. N° 3, exhibits a Basse-norm with a thyrus in his hand, which shows that the altar was erected to Bacchus; with two other sides it appeared triangular. Each side of N° 4, which was triangular, exhibited a genius, one of whom is seen carrying an onion upon his neck, which seems to indicate that it belonged to Neptune. N° 5, with the inscription "Artemesia," is of a round figure; the god is represented wholly naked, preferring the pallium on his shoulder, and holding in his left hand a trident, and in his right a dolphin.

Altars differed also in their height as well as in their figure and the materials of which they were formed.

According to Servius, (in Virg. Eccl. v. 66. Æn. ii. 515.) those altars set apart for the honour of the celestial gods, and gods of the higher class, were placed on some pretty tall pile of wood, as the altar of Olympian Jupiter, which was nearly 22 feet high; and for that reason were called alteria, from the word alter and arma, a short blade of iron. Those appointed for the terrestrial gods were laid on the surface of the earth, and called are—and, on the contrary, they dug into the earth, and opened a pit for those of the infernal gods, which they called séôpa andKA, k^TY,¿ÌÜ. But this distinction is not everywhere observed: the best authors frequently use are as a general word, under which are included the altars of the celestial and infernal, as well as those of the terrestrial gods. Vitn. Virgil. Eccl. v.

"——En quartor aras.

Where are plainly includes alteria; for whatever we make of Deipham, Phæbus was certainly a celestial god. So Cicero, pro Quint. "Aras dehbraquae Hecates in Graecia vidimus." In the great temples of ancient Rome there were commonly three altars. The first was placed in the sanctuary at the foot of the statue of the divinity, upon which incense was burned, and libations offered; the second was before the gate of the temple, and upon it they sacrificed the victims; and the third was a portable altar, upon which were placed the offering and the sacred vessels.

The Greeks also distinguished two sorts of altars; that

wherein they sacrificed to the gods, was called sêôpa, and was a real altar, different from the other, wherein they sacrificed to the heroes, which was smaller, and called séôpa. Pollux makes this distinction of altar in his Onomasticum: he adds, however, that some poets used the word séôpa, for which he allotted sacrifice was offered to the gods. The Septuagint version does sometimes use the word sekoupet, for a sort of little low altar, which may be expressed in Latin by rudimentum; being a hearth rather than an altar. The nympha, instead of altars, had aseôpa, caves, in which adoration was paid to them.

Altars and temples afforded an asylum or place of refuge for malefactors, and criminals of all descriptions among the Jews, Greeks, and Romans; chiefly to thieves, from the cruelty of their masters, to insolvent debtors and criminals, which where it was reckoned impious to touch them, and whence it was unlawful to drag them; but they sometimes kindled fire round the place, or shut up the temple and unroofed it. Hence "ara" is put for "refugium." Ovid, Trist. iv. 5. 2.

The altars of the ancient Heathens, as well as those of the Jews, were adorned with horns, to which the victims were fastened, and criminals who fled for refuge to the altar had hold of the horns. The ancients also, on solemn occasions, as in making alliances, and confirming treaties of peace, were accustomed to lay their altars before them. For classical authorities to these several facts, see Adam. Rom. Ant. p. 327. Harwood's Latin Ant. p. 116, &c.

The altar, bearing an inscription, "To the unknown God," found by the Apostle Paul, at Athens, and mentioned, Acts xvii. 23, has occasioned some difficulty to biblical critics. Jerom supposes, that the inscription on this altar was not, as St. Paul quotes it, "To the unknown God," but, "To the gods of Asia, and Europe, and Africa, unknown and strange gods;" and that the apostle has not quoted the inscription exactly, but dexterously applied it to his own purpose. Theophrastus and Oecumenius are also of opinion that the inscription was "to gods," &c. in the plural number. On the other hand, Chrysostom and Hieron of Pelium affirm, that the inscription was in the singular number, as St. Paul quotes it. Learned moderns, as well as ancient Christian writers, have entertained different opinions on this subject. Le Clerc says, that though the inscription was in the plural number, St. Paul was in the right to allude it in the singular number. The occasion on which this altar was erected, is thus related by Dioneus Laertius (in Epinom. i. 17. 60; ii. 70, 71.) About 600 years before Christ, "the fame of Ephesus, which was very great among all the Greeks, and he was appoised to be in great favour with the gods. The Athenians being afflicted with a pestilence, they were directed by the Pythian oracle to get their city purified by expiation. They therefore sent Nicias, son of Niceratus, in a ship to Crete, inviting Epididimus to come to them. He came accordingly in the 45th Olympiad, purified their city, and delivered them from the pestilence in this manner. Taking several sheep, some black, others white, he had them up to the aecopagus, and then let them go where they would; and gave orders to those who followed them, wherever any one of them should lie down, to sacrifice it to the god to whom it belonged, and to the plague ceased. Hence it comes to pass, that to this present time may be found in the heroules of the Athenians anonymous altars, a memorial of the expiation then made. By the God to whom it belonged some have understood, "the god next the place;" others have translated the passage, "to the proper god to whom that office belonged;" to him, whoever he was, who should remove the inflicted pestilence." Dr. Doddridge,
ALT

in loc.) understands the direction to be, "when the sheep lay down, to sacrifice them to the god near whose temple or altar they then were." Dr. Lardner has given a more satisfactory interpretation of this passage. "Epimenides," says this judicious writer, "took with him up to the Acherusian the sheep, the black and fome white; and when he let them go, he directed that they when they lay down, "should be sacrificed to the god to which it appertained or belonged." Black sacrifices were offered to some gods, white to others. Epimenides knew not by what god the piety had been inflicted upon the Athenians. When he was desired to purify the city, in order to its deliverance, he chose out sacrifices of different kinds, black sheep, and white sheep, and led them up to the Acherusian: and from that place, the cithadis or the seat of the senate, and of the court of judicature, he sent out the sheep, as in the name of the whole city or commonwealth to be sacrificed, in order to appease the offended deity, whoever he was. A sheep, with a black fleece, when it lay down, was to be offered to a deity who delighted in such sacrifices; a sheep with a white fleece was to be offered to a deity, to whom white sacrifices were acceptable. By this means he hoped to ingratiate the offended deity, whoever he was." From Laertius's relation Dr. Lardner infers, that there were several anonymous altars at Athens, and in the adjoining country, and that all these altars were in the singular number; for each sheep, when it lay down, was to be sacrificed to the god to whom it appertained. It appears from the testimonies of heathen authors, who lived whilst these altars had their inscriptions fulfilled, such as Diogenes Laertius, Pausanias, Philostratus, and the author of Philopatris, which Dr. Lardner has cited, that the inscription upon the altar at Athens was in the singular number: nor does it appear that there were any in the plural, "to unknown gods:" and this inscription seems to have been peculiar to the Athenians. To the same purpose it is observed, by the ingenious Mr. Hallett, that the Athenian altars were erected, not to the honour of Jupiter, Mars, Apollo, by name, but to that particular god, whoever he was, who had wrought out their deliverance. Nevertheless they thought, that this god, though unknown, was one of the idols of the heathen world. The truth, however, was, though they did not know it, that he, who delivered them by his providence from that disaster, was the one infinite supreme God. And therefore St. Paul mildly says, that the Athenians worshipped him; for they worshipped him who removed the plague, whoever he was; but the true God removed the plague; therefore they worshipped the true God. And yet, as the apostle observes, they worshipped him ignorantly, that is, they were ignorant of his majesty and power, and regarded him as no greater than one of their own idols.

ALT

of Adam, in Antiquity, is pretended by some rabbin's and others to have been erected by the first man soon after the fall; when, being overwhelmed with sorrow, a promise was made him by the ministry of the angel Haziel, that a Redeemer should be sent. In gratitude for this news, and for a perpetual remembrance thereof, Adam is said to have built an altar, and sacrificed on it a heifer.

The reliques of this altar have been mentioned by several writers of later ages.

Altars are sometimes also used among Christians for a sacrificial table, placed on the eastern side of the church, placed a little above the floor, and set apart for the celebration of the eucharist.

Its form is not borrowed either from that of the Heathen altars, or even from that of the Jews in the temple; but as the eucharist was instituted by Jesus Christ, at supper, and upon this table, the modern altars are made in form of a table: wherein it is more usual, and even more significantly denominated Communion Table.

In effect the denomination altar is founded on this supposition, that the eucharist is a proper sacrifice; which, though the standing doctrine of the church of Rome, is utterly denied by most of the reformed. Accordingly, Bishop Ridley, in the reign of Edw. VI. A.D. 1550, inserted injunctions for taking down all altars, and requiring the church-wardens of every parish to provide a table decently covered, and to place it in such a part of the church as should be most meet, so that the ministers and communicants should be separated from the rest of the people. The reasons alluded for this alteration were these: because our Saviour instituted the Sacrament at a table, and not at an altar: because Christ is not to be sacrificed over again, but his body and blood to be spiritually eaten and drunk at the holy supper, for which a table is more proper than an altar: because the Holy Ghost, speaking of the Lord's Supper, calls it the Lord's Table," 1 Cor. x. 21. The canons of the council of Nice, as well as the fathers St. Chrysostom and St. Augustine, call it the Lord's Table; and though they sometimes call it an altar, it is to be understood figuratively. An altar has relation to a sacrifice, so that if we retain the one we must admit the other, which would give great countenance to male-priests: there are many passages in ancient writers that shew that communion tables were not of wood, that they were made like tables, and that those who fled into churches for sanctuary did hide themselves under them; and the most learned foreign divines have declared against them, as Bucer, Oecolampadius, Zuinglius, Bullinger, Calvin, P. Martyr, Joannes Alacoque, Hedio, Capito, &c. and have removed them out of their several churches, and the Lutheran churches only retain them. Ridley, Cranmer, Latimer, and the rest of the English reformers were unanimously of opinion, that the retaining of altars would serve only to nourish in the minds of people the superstitious opinions of a propitiatory mals, and would minifier an occasion of offence and divulge the work of the godly. Some of the bishops, however, refuted to comply with the order of council, and suffered themselves to be deprived of their bisipricies for contumacy, October 1551. The practice of consecrating altars with their furniture was introduced and vindicated by Archbishop Laud in the reign of Charles I., but objected to by Pryme, as having no higher original than the Roman missal and pontifical, in both which there are particular chapters and set forms of prayer for this purpose; and it was alluded that the practice, as well as the arguments on which it was founded, have no foundation in reason or Scripture, and are contrary to the usage of the church of England, and the opinion of our first reformers. To the antiquity of altars it was replied, that though the name is often mentioned in Scripture, yet it is never applied to the Lord's table, but altars and prieaux are put in opposition to the Lord's table, and ministers of the New Testament, 1 Cor. x. 13, 14. It was added, that it cannot be pretended by any law or canon of the church of England, that it is called an altar more than once, Stat. 1 Edw. VI. c. i. which statute was repealed within three years, and another made, in which the word altar is changed into table. It was said, that from the unanimous suffrage of most of the fathers that lived within 300 years after Christ, and of our most learned reformers, it appears, that for above
above 250 years after Christ there were no altars in churches, but only tables; and that they were first introduced by Pope Sixtus II. and that the canons of the popish council of Aix, in 1583, are the only ones that can be produced for railing them in. The practice of bowing to the altar, charged on the archbishop as another innovation, was objected to as popish, superstitious, and idolatrous, being prescribed only by popish canons, and introduced to support the doctrine of transubstantiation, and having no foundation in antiquity, nor approved by any Protestant writers. Burnet’s Hist. Reform. vol. ii. p. 152—159. Strype’s Annals, vol. i. p. 160—162. Neal’s Hist. Puritans; vol. i. p. 44 &c. vol. ii. p. 135—145, 420.

In the primitive church the altars were only of wood, as being frequently to be removed from place to place. But the council of Paris, in 509, decreed, that no altar should be built but of stone.

At first there was but one altar in each church; but the number soon increased; and from the writings of Gregory the Great, who lived in the sixth century, we learn, that there were sometimes in the same church twelve or thirteen. In the cathedral of Magdeburg there are no less than 49 altars.

The altar is sometimes sustained on a single column, as in the subterraneous chapels of St. Cecilia, at Rome, &c. and sometimes by four columns, as the altar of St. Sebastian of Crypta Arenaria; but the customary form is, to be a masonry of stone-work sustains the altar-table.

These altars bear a resemblance to tombs: to this purpose, we read in church-history, that the primitive Christians chiefly held their meetings at the tombs of the martyrs, and celebrated the mysteries of religion upon them. For which reason it is a flanding rule to this day in the church of Rome, never to build an altar without inclosing the relics of some saint in it.

In lieu of proper altars the Greeks in process of time made use of antimensia.

Altar of Prothesis, is a name given by the modern Greeks to a smaller, preparatory kind of altar, wherein they blest the bread, before it be carried to the large altar where the solemn liturgy is performed.

F. Goar maintains, that the table of prothesis was anciently in the facelfy or vestry; which he makes appear from some Greek copies, where facely is made use of in lieu of prothesis.

Altar is also used, in Church History, for the oblations or contingent incomes of the church.

In ancient days they distinguished between the church and the altar. The tithes, and other settled revenues, were called the church, ecclesia; and the other incidental incomes, the altar.

Altar, in Astronomy. See Ara.

Altar-thane, in our Ancient Law Books, denotes a priest, or parson of a parish. In this sense the word is synonymous with church-thane.

Altarage, includes not only the offerings made upon the altar, but also the profit that arises to the priest on account of the altar.

Altarist, altarista, properly denotes the vicar of a church who serves the altar, and to whom the altarage or produce of the altar is assigned for his maintenance. Du Cange.

The altarista is sometimes also called altarius, sometimes altar priest.

Altarist is also used for chaplain.

Altasrif, in Literary History, the title of a medival book written in Arabic, describing the method of practice in use among the Arabs.

It was written by Allaharavius, an author in the fifteenth century, and translated into Latin by P. Riccius in 1519. Concerning the history and contents of the Altasrif, see Freind, Hist. Phys. p. ii. p. 124, 160.

Altavella, in Ebbayology, the name of a flat cartilaginous fish, which, in the Linnaean system, by Gmelin, is a variety of the Raja Papiluna; with its wings, as they are called, that is, its thin and flat sides, broad and obsolete towards their lower part. The fishermen, from the resemblance these flat sides have to wings, have an opinion that this fish can fly. The tail is very short, scarce being half the length of the body. Its flesh is solid and well tasted, and it always sells well in the markets. It is caught in the Mediterranean, and is frequently brought to market at Rome. Fab. Columna.

Altavella, in Geography, a town of Italy, in the kingdom of Naples, and province of Principato Ultra, seven miles south of Benevento.

Altavilla, a town of Naples, in the province of Principato Citra, eighteen miles south-east of Salerno.

Alta-her, a town of Hejaz, a district of Arabia Felix, situate above 60 miles east of Mecca, behind Mount Gazwan, where the air is very wholesome, but the cold more intense than in any other part of the district. Its territory abounds in fountains, and produces excellent raiins. The town is small, but surrounded with a wall.

Altchirck, or Altckirk, a town of France, in the department of the Upper Rhine, situate on an eminence near the river Ill, five leagues west of Bale, and nine south of Colmar. N. lat. 47° 8'. E. long. 7° 8'.

Altdorf, or Altorff, a large and handsome town of Swisserland, and capital of the canton of Uri, situate in the valley of the Reuss, and almost surrounded by steep mountains covered with trees, which throw a gloomy shade over the town. It has two convents, four churches, and several chapels, one of which was erected on the spot where was born William Tell, who is said to have shot the apple from his son's head in this town. Geller, a tyrannical governor, placed over the free inhabitants of Uri by Albert I., among other oppressive and irritating measures, set a hat on a pole at Altdorf, and required the same respect to be paid to it as to his own peron: but William Tell refusing to submit to this ignominiuous requisition, provoked the indignation of the governor, and was obliged to secure himself by flight. This circumstance, as some have reported, laid the foundation of the liberties of Switzerland, and occasioned an union of Uri, Schwitz, and Underwald, in 1384 for throwing off the Aufrian yoke; and in 1315 these three cantons formed a perpetual alliance. This town is 20 miles south-east of Luzern, and 33 south of Zurich. N. lat. 46° 55'. E. long. 7° 24'.

Alte, &c., in Middle Age Writers, denotes foreignty, or a thing done with the supreme power. Du Cange.

Altea, in Geography, a sea-port town of Spain, in the Mediterranean, on the south-east coast of Valencia, eight leagues north-east of Alicante, and 17 south of Valencia. It trades in wine, silk, flax, and honey. It was taken in 1705, in favour of the Archduke Charles, but lost after the battle of Almanza. N. lat. 38° 40'. W. long. 0° 16'.

Alten, or Altenbotten, a gulf of Norway, on the coast of Finnmark, in the government of Wardhus.

Altena, or Altona, a sea-port town of Germany, in Holstein, on the Elbe, in a situation favourable for commerce. It was burned by the Swedes in 1712, and afterwards
wards rebuilt and surrounded with walls. It is the port of the Danish East-India Company; half a league west of Hamburg. North lat. 54°. Wett long. 9° 39'.

Altenau, a small mine-town of Germany, in the principality of Grubenhagen, situated in the Hatz forest, near the source of the Oker, and surrounded by rugged mountains and rocks, eight miles south of Gollar. In this town there is a house for smelting silver.

Altenbecken, or Altenbeken, a town of Germany, in the circle of Wolfphalia, and bishopric of Pale- born, three miles east of Lippspring.

Altenberg, a town of Germany, in the duchy of Saxony, eight miles south of Wettburg.

Altenberg, a town of Germany, in the circle of Erzgebirg, and prefecture of Altenberg. It is a mine-town, and the tin supplied by it is reckoned the belt next to that of the English and Bohemian. The tin mine was discovered in 1458. Great quantities of lace are woven there. It has repeatedly suffered much from fire.

Altenburg, O-Var, a small well-built town of Hungary, with a castle flaring on a small branch of the Danube and Leitha, and secured by deep and wide moats. It has an annual fair, which lasts a week. It is 17 miles south of Pressburg, and 49 miles south of Vienna. North lat. 47° 35'. East long. 23° 15'.

Altenburg, a town of Germany, in the duchy of Slesia, on the Sann, eight miles south-west of Windisch Graatz.

Altenburg, or Oldenburg, a town of Germany, in the duchy of Holstein, on a river which runs into the Baltic, about three leagues to the east, 15 leagues north-east of Hamburg. North lat. 54° 18'. East long. 11° 4'.

Altenburg, a town of Germany, in the circle of Upper Saxony, anciently called Pilsen, the capital of a principality of the same name. It is large and populous, and has a castle seated on a rock, which was the residence of the former electors and dukes. It was anciently an imperial city, and the capital of the country of Pfeiflen. In this town are a place of education for young ladies of decayed families, a house belonging to the Teutonie order, a gymnasion illuslre founded in 1703, with a good museum and library, an orphan house, and a house of correction. It is 20 miles south of Leipzig, and 52 miles west of Dresden. North lat. 50° 59'. East long. 12° 52'. The principality of Altenburg is a part of the ancient Osterlands; and the soil is very fertile in corn, and affords good pasture. It has large breeds of horses, and plenty of wood; and its mines yield copper and cobalt, and other minerals. The flats of this principality are divided into those of the Altenburg, Saalfeld and Eisenburg circles, and consist of the nobility and towns of these three districts. Their provincial meetings are held at Altenburg. The religion of the country is Lutheran.

Altenburg, a town in the circle of the Upper Rhine, and bishopric of Spire, two miles north-west of Bruchsal, and nine south-west of Spire.

Altenburg, a town in the circle of the Upper Rhine, two miles north-west of Wetzlar, and two north-east of Brunswick.

Altenburg, a town in the county of Tyrol, nine miles north-east of Glurns.

Altenburg, a small village of Swiderland above Bruck, in the canton of Bern, situated on the river Aar, and known by its Roman antiquities, and the ruins of the ancient Benedictine monastery.

Altenburg, a town in the archduchy of Austria, two miles south-west of Horn.

Vol. I.
can only be changed by first changing the action of the fo-
lds, and this opinion is at present gaining ground.

In the third class may be placed such as act on the nervous
system, often called *Anodynes, Emollients, &c.*

If we employ the term *alteration* in a more extended sense,
to denote any means by which an alteration for the better can
be produced, we should be obliged to refer all diet and medi-
cines to this head, and even with the limitation, of "without
a sensible operation," we find it very easy to decide in all
cases what remedies should be included under alteratives.

We think a warm or cold climate may act as an alternat;
so may illnesses or fevers; others go so far as to say that ev-
cacants are the belt alteratives; others, on the contrary, af-
scribe even the salutary effects of evacuants to their alterative
nature; or this has long been alleged of mercury in the cure of
the venereal disease; and of it and ipecacuahia in the cure
of dysenteries; but it must be observed that these articles
succeeded bell when administered in *alternat dosis.*

The arrangement of the *Materia Medica,* as well as
the modus operandi of remedies, will furnish much diversity of
opinion for several centuries: it is, fortunately, a ground
of dispute that never has, nor ever will materially injure the
*propriety* of either medicine or surgery.

*ALTERATA,* in *Muffs,* a term used by the French as
well as the Italians, for temperation, in speaking of inter-
vals, and likewise of extreme confluence and diffusion:
as an extreme sharp 6th, a redundant 5th, an extreme flat
7th, &c.

**ALTERATE.** See *Sesquialterate.*

**ALTERATION.** *Alteratio,* in *Physic,* the art of
changing the circumstances and manner of a thing; its ge-
neral nature and appearance remaining the same.—Or it is
an accidental, and partial change in a body: without pro-
ceeding so far as to make the subject quite unknown, or to
take new qualities. This has been termed *alteration* there:
or, it may be defined, the acquisition or loss of such qualities as are
not essential to the form of the body. Thus a piece of iron, which before
was cold, is said to be *alterated,* when it is made hot; since it
may still be perceived to be iron, is called by that name, and
has all the properties thereof. By this, *alteration* is dislin-
guished from *generation* and *corruption,* those terms expres-
sing an acquisition or loss of the essential qualities of a thing.

The modern philosophers, after the ancient chemists and
physicallarians, hold all alteration to be effected by means
of local motion. According to them, it always confits
either of the emission, accesion, union, separation, or trans-
position of the component particles.

*Arithote* makes a peculiar kind of motion, which he calls
the *motion of alteration.*

*Alteration* is used, in *Medicine,* to denote a change in
the state and qualities of an animal body, in respect of tem-
perature or constitution, health or sickness.

In this sense, alteration includes both *emolvent* and *alteration.*

*Alteration* is more strictly taken for a change in the
quality of the body, contradistinguished from *excusation* and
*opposition.*

In which sense, alteration is the effect of medicines called
*alterants.*

Alteration is chiefly applied in respect of the fluids or hu-
mours of the body. When applied to the solids, it is chiefly
to affect the humours, or the motions of them.

*Alteration* is sometimes also applied in respect of the
vital motions of the body,

Thus specific are applied to alter and rectify convulsive and
other disordered motions. The alteration of the hu-
mours is either extrinsic, or intrinsic. The former is a change
produced in the sensible appearances, as colour, thickness,
and the like: and the latter is a change in the primitive
crude, or constitution of a fluid.

*Alteration* in a sense still more strict, denotes that
concession which the body undergoes, to render it nourish-
ment. In this sense alteration both includes the digestion
performed in the stomach, and the assimilation in the habit
of the body.

It is disputed among physiologists what the alteration is
which the body undergoes.—Some reduce it to a mere com-
mination or trituratian.—Others affect a total transubstantiat-
ation. See *Digestion.*

*Alteration of quantities,* among *Algebras,* denotes
what we otherwise call variation, or permutation.

*ALTERATIVE,* in *Medicine,* the name with *alterant.*

*ALTERATION,* a debate or contest between two
friends, or acquaintance. The word comes from *alterarii*
which anciently signified to converse, or hold discourse to-
gether. Thus we say, they never came to an open quar-
d; but there is continually some little alteration or other.

*ALTEr DO CHAO,* in *Geography,* a small town of
Portugal, in the province of Alentejo, 12 miles west of Pon-
telegrc, and 84 cwt. north-east of Lisbon. North lat. 39° 8'.
West long. 6° 58'.

*ALTERE,* a town of Flanders four leagues west of
Ghent.

*ALTERIO,* a town of Naples, in the province of Cala-
bria Cutra, 7 miles north-east of Cofenza.

*ALTER,* a town and castle of Germany, in the circle
of Upper Saxony, in the county of Mansfeld.

*ALTERTS,* a term used in *Trigonometry,* contradistin-
guished from *true altitude,* thus:—In an oblique triangle, the true
base is either the sum of the sides; in which case, the dif-
fERENCE of the sides is called the *relative base*; or the true base
is the difference of the sides; in which case, the sum of the
sides is called the *relative base*.

*ALTERANTHERA,* in *Botany,* a genus of the *tri-
andria monogyna* class and order; the characters of which are,
that the *calyx* has five leaves; *no corolla*; six filaments,
alternately barbary; the *fruits* bird, and the *seeds* solitary.
There is one species, viz. *A. repens.* Fork. Fl. Æg. Arab.
p. 28.

*ALTERATE,* or *Alternative,* is underfoot of
several things which succeed, or are disposed after each other
by turns.

We say, an *alterate,* or *alternative* office, or truth, which is
that discharged by turns; so, two general officers, who com-
mand each his day, are said to have the command *alterate.*

In *Botany,* the term *alterate* is applied to branches, leaves,
and flowers, when, instead of being opposite, they spring out
regularly one above another: such are the leaves of *burage,*
or chequered *dauboli.* See *Leaf.*

*ALTERATE,* in *Arithmetics.* See *Alligation.*

*Alternate angles,* in *Geometry,* are the internal angles
made by a line cutting two parallels, and lying on the op-
posite sides of the cutting line; the one below the first parallel,
and the other above the second.

Thus *x* and *y* are *alternate angles,* and these angles are equal
to another.

There are also two external angles, *alternately opposit* to
the internal ones. See *Parallel.*

*Alternate ratio or proportion,* is that which the ante-
cedents and consequents bear respectively to each other in
any proportion, which has the quantities of the same kind.

Thus, if *A* : *B* :: *C* : *D*; then, *alternately,* *A* :: *C* : *B* : *D.*

*Alternate,* in *Heraldry,* is used in respect of the situa-
tions of the *quarters.*

Thus in quarterly *cartae,* the first and fourth quarters
are
are alternate; and are usually of the same nature. And the like holds of the second and third.

ALTERNATION, in its primary sense, denotes a succession by turns.

ALTERNATION is more particularly used among the Cirellians, for disjunction, as in aying this or that.

ALTERNATIONS, in Arithmetic, a term sometimes used to express the divers changes, or alternations of order, in any number of things proposed. This is also called permutation, &c. and is easily found by a continual multiplication of all the numbers, beginning at unity.

If there be two quantities a and b, they admit only of \( 1 \times 2 \) or 2 changes, as ab, ba. If a third quantity c be added, this will admit of 3 changes with each of the two former; that is, it may be first, second or third in each of them; and therefore in this case the number of changes will be \( 1 \times 2 \times 3 = 6 \). A fourth quantity will admit of 4 changes with each of the preceding quantities; that is, it may be first, second, third or fourth, or the whole number will be \( 1 \times 2 \times 3 \times 4 = 24 \). If the number be n, multiply the feries of natural numbers \( 1, 2, 3, 4, 5, \ldots \), continually to n, and the last product will be the number of alternations required.

Thus, if it be required to know how many changes or alternations can be rung on six bells, multiply the numbers 1, 2, 3, 4, 5, 6, continually one into another; and the last product gives the number of changes. See CHANGES AND COMBINATION.

ALTERNATIVE, is particularly used for the choice of two things proposed.—In this sense we say, to take the alternative of two propositions.

ALTERNIA, in Ancient Geography, a town of Spain, belonging to the Carpathians.

ALTERS, or ALTARS, in Nautical Geography, are a flony shelf, westward of Langland Fort, about a cable's length and a half, on which there are no more than five or six feet of water at low water, so that ships should keep near the fort till they have passed it, and then edge off a point or two to the west, till they come athwart of the north point of Harwich. Malham's naval Gazetteer.

ALTES, in Ancient Geography, a town of Peloponnesus, situate on the Cylus, which fell into the river Alpheus.

ALTENANN, in Geography, a town of Italy, in the principality of Piedmont, three miles north of Turin.

ALTEREY, or ALTHEIM, a town and castle of Germany, in the Lower Palatinate, capital of a territory of the same name, situate on a small brook which runs into the Salzg, 15 miles south-west of Mentz, and 14 north-west of Worms. North lat. 49° 39'. East long. 8° 12'.

ALTHA, in Ancient Geography, a town of Babylon, upon the Tigris, and in dependence upon Apamea, according to Ptolemy.

ALTHEA, Alt. in Dioscorides, from αλθεα a remedy, or αλθηα to heal, or as Dioscorides fays σαν τον πωλολης; from its many excellent qualities, in Botany, a genus of the monadelphus polyandra class and order, or the natural order of Columnarias, and mankind of Jaffa: its characters are, that the calyx is a double perianthium, outer smaller, one-leafed, unequally novem-fid or nine-cleft, (6—12) divisions very narrow, inner feximquefus, divisions broader and sharper; the corolla is five-petalled, united at the base, obcordate, pernose and flat; the stamens have many filaments inserted into the corolla, anthers subreniform; the fief tillum has an orbicular germ, fole cylindrical and short, stigmas many (20), fectaceous, of the length of the style; the periemenium consists of arils not jointed, forming a flat ring about a columnar receptacle; they are deciduous and open on the inside; the seed is one, flat-kidney-shaped in each aril.

There are seven species, viz. 1. A. afficinata, common marsh-mallow, with leaves simple and downy, (subpulque-johd, Smith,) or with leaves undivided, angular and bottry (Verth.) the root fustiform, a gourd-shaped; the arils erect, almost three feet high, simple, cylindrical, slender like a twig, fuffle; the leaves alternate, petiolate, cordate, acute, subquincuncial, plicated and serrated; the panicles axillary, dense, many-flowered, shorter than the petals; the external calyx often ten-cleft, also twelve-cleft, the inner five-cleft; the corolla and flamina are purple fufi-coloured; the stigmas are numerous; the capsules compressed; the whole herb very softly pubescent or clothed with a very soft wool or velvet, with felled interwoven hairs. It is perennial and flowers from July to September. It grows plentifully in falt marshes, and on the banks of rivers and ditches in Cambricshire, Norfolk, and Suffolk, or the tea-flowers of Cornwall, in Holland, France, Italy, Siberia, &c. There is a variety of this, with the leaves rounder and not ending in a point, called by Ray A. vulgari fimiles, folio retus frond, and found in the isle of Ely; it varies also with lacinated leaves. 2. A. communis, hemp-leaved marsh-mallow, with the lower leaves palmate, dentated, (Gmelin,) upper digitate, (bifate, the middle lacinia of the leaf, Gmelin.) This has a woody stem, four or five feet high, which bears out many side branches; the leaves are alternate; the flowers axillary, less than those of the former species, but of a deeper red colour, and the calyx much larger. This feldom flowers the first year, except in a warm summer. It grows naturally in Hungary, Ifria, Aufrlia, Carniola, Italy, the south of France, &c. by the fides of wood; and was cultivated here by Gerard, in 1597. 3. A. hirfute, hairy marsh-mallow, with leaves trifid, hairy-hiñipid, smooth above; peduncles foltary and one-flowered. This is a low plant, its branches trailing on the ground, the flowers axillary, smaller than those of the common fort, and have purplish bottoms, the arils are woody, and seldom last more than two years; the outer calyx is eight-leaved, the inner as long as the corolla, and acuminate; the corolla crenulate. This species grows wild in Spain and Portugal, Italy, Aufrlia, Carniola, Germany, Switzerland, and France; and was cultivated in New garden M. 1685, by J. Sutherland. 4. A. ludoviciana, Ludwig's marshmallow, alike of Ray's herb, (Gmelin,) leaves lobed, naked on both sides, and peduncles collected and one-flowered. This resembles malva alea; the peduncles are axillary from two to five, the outer calyx eight-leaved, and leaflets lanceolate, the inner shorter, quincuncial, very rough, with white villous hairs. 5. A. Narbonensis, Narbonne marsh-mallow, with leaves tomentofe on both fides; the lower five-lobed, the upper three-lobed, peduncles folitary, one-flowered. The root is perennial, ftems are annual, from four to fix feet in height, round, and of the thickness of a finger, hoary with whitith fellite hairs; fipules fufihte, acute and ciliate; leaves alternate, petioloid, ferrate, bracts fubulate and fmall; the segments of the outer perianthium are fix or feven, deeply cut, lanceolate, and acaule; corolla purple-rofe-coloured, twice as long as the calyx; anthers dark-purple; fligmas white, and arils smooth; first discovered by Able Pouret near Narbonne, found also in Spain, flowers in August and September, and introduced into New garden in 1780, by M. Thouin. 6. A. carymbosa, with leaves fimple, cordate or angular, and smooth, peduncles and calyces hairy, and fowers in coryphys; a native of Jamaica. 7. A. racemosa, Pavonia fpicata of Cavan, and Gmelin, with leaves fimple, cordate, ovate, ferrate, fcarious on the upper furface, and raceme terminating and Erect. The ftems are thick, iff, five feet high, with many branches.
Leaves alternate on long petioles; stipules lanceolate and acuminate; outer calyx deeply eight-lobed, inner somewhat tabulate, with five notches; corolla yellow, double the length of the calyx; the petals oblong, almost entire, marked with deeper-coloured streaks; the fruit composed of five bivalve capsules, as a native of Jamaica. Instead of this species Gmelin inflict A. grandiflora, with cordate, angulated, tomentose, patulous leaves, and substriphloous peduncles. Martyn. Withering. Smith. Gmelin's Lin. Culture. The first species may be propagated either by seeds, sown in the Spring, or by parting the roots in Autumn, which is the best season for the purpose. It will thrive in any soil or situation, but grows larger in moist places than on dry land; the plants, whose roots spread wide, should not be nearer than two feet. The second species is propagated by seeds sown in the Spring, in a dry soil and sheltered situation; this root seldom continues longer than two years in England, but as the seeds ripen here, the plants may be had in plenty. If the seeds of the third species be sown in April, the plants will flower in July, and seeds ripen in September; and they should be sown where they are to remain.

Althaea, in the Materia Medica. The Althea officinalis seems to have been known to the ancients, called by Dioscorides A. Scirpus. by Galen, Erythera, and by Pliny Hibiscum. It is probably the Hibiscus of Virgil, Ecl. x. v. 30, and v. 71.

"Hedorumque gregem viridi compellere libifco."

It has been much used by medical practitioners in every country where medicine has been regularly cultivated. All its parts abound with a glutinous juice, with scarcely any smell or peculiar taste. The dry roots, boiled in water, give out half their weight of gummy matter, which is thought to be nearly allied to gum arabic, tragacanth, starch, &c. and dissolves murrh, and some other resinous substances more readily than gum; and, on evaporating the aqueous fluid, forms a yellowish mucilage. The leaves afford scarcely one-fourth of their weight, and the flowers and seeds still less. The mucilaginous matter is the medicinal part of the plant, and it is commonly employed for its emolient and demulcent qualities. It is recommended for obtunding and incrustating scrofulous thin fluids, in tickling coughs from delusions on the fauces and lungs, in hoarseness, crostions of the stomach and intestines, difficulty and heat of urine, the dyfenteries, colicines, and gonorrhea; and for lubricating and relaxing the passages in nephritic and calculus complaints. It has been given in powder, from a scruple to a dram or two, either by itself, or in conjunction with other substances of a similar nature; it is seldom administered in this form, but it is taken to better advantage in that of an infusion or decoction. Dr. Cullen observs, (Mat. Med. vol. ii. p. 411.) that demulents of this kind can have no effect as fuch in the mafs of blood, or in passing by various evasions. The Althea has been often applied in various external affections. The root boiled in honey and chewed by infants has mitigated difficult digestion; and milk, in which this root,igs, and a small quantity of saffron have been boiled, has relieved the gums. The decoction is said to be useful in ophthalmia; and a gargary made of the decoction of this root and figs has been serviceable in sore throats. The root, cut and boiled in water or milk, has formed a convenient and useful cataplasm for softening and ripening tumors; and it has been often added to glysters. The root was formerly used as an ingredient in several compounds of the pharmacopoeias, but it is now directed only in the form of a syrup. This is prepared by boiling a pound of the fresh roots bruised in a gallon of distilled water to one half, and precipitating the liquor when cold; and when it has settled for 24 hours, so that the fecundities may separate, the liquor is poured off, and four pounds of double-refined sugar being added to it, the liquor is boiled down to six pounds weight. This syrup is employed externally in some disorders of the breast, and for sweetening emollient decoctions in nephritic cases. Lewis. Murray. Woodville.

Althaea, See Hemsamia, Hibiscus, Lavatera, Malva, Melochia, Napea, Sida, and Waltheria.

Althaea Fruitus. See Hibiscus.

Althaea, Althea Olearium, Organ, in Ancient Geography, a town of Spain, belonging to the Occades; mentioned by Polybius under this name, but called Cartheia by Livy, in speaking of the exploits of Hannibal.

Althamerus, Andrew, in Biography, a Lutheran minister at Nuremberg, lived in the 16th century, and attended the conferences at Berne, in 1528, which prepared the way for the reformation in that country. He was so zealous an advocate for justification by grace, in opposition to the merit of good works, that he inveighed in a very indecent and outrageous manner against the apostle James, and gave him, almost, the lie direct. Grotius cites a passage from his "Annotations on James," printed at Straffburg, in 1527, in which he charges the apostle with running counter to Scripture, and opposing his authority against that of the Holy Ghost, the law, the prophets, Christ, and his apostles. Besides some works in divinity, he compiled a dictionary of the proper names in the Bible, "Sylvae Bibliorum nominum, &c," printed at Basl in 1535; "Conciliorum locorunm Scripturum," published at Nuremberg in 1535, and at Wittemberg in 1532; and notes upon Tacitus, "De Situ, moribus et pepulis Germaniae," printed at Nuremberg in 1529 and 1536, and at Amberg in 1609, 8vo. Gen. Dict.

AlTanUS, in Ancient Geography, a stream of Daunia, in Italy, the waters of which were said to cure all kinds of wounds.

AlTHEE, in Geography, a town of France, in the department of the Mayenne, and chief place of a canton, in the district of Crion, four leagues south-west of Laval.

AlTHEA, in Entomology, a species of Papilio, in the class of Nymphalidae, with dentated brown wings, and also a fafica and Nysa angular-dentated and white, found in Guinea.

AlTHEIM, in Geography, a market town of Upper Bavaria, in the district of Mauerkirchen, eight miles east of Braunau.

AlTHEPIA, in Ancient Geography, a small country, placed by Pausanias, in the Argolid, near Trezena, which had borne the appellation of Orca.

ALTHUSIUS, John, in Biography, a German civilian, towards the latter end of the 16th century, advanced free principles on political subjects, which gave great offence to some of his contemporaries. He was a Protestant; and from being a professor of law, at Herborn, he was raised to the dignity of fynic, at Bremen. The fundamental principles of his "Politics methodically digested," printed at Herborn, in 1605, are these, "that kings are mere magistrates; that the chief power of every commonwealth is in the people only; that it is lawful to depose a tyrant, to turn him out of the administration, and even to put him to death, if no other remedy can be found, and to choose another in his room. He also composed a treatise "De juridic平安tia Romana."
ALT

Romana; another "De Civilis Conuatione;" and other tracts. Gen. Dict.

ALTICA, in Entomology, a species of the Cantharides, with a red thorax, and violet unspotted elytra, found at the Cape of Good Hope.

ALTICAE, a class of the genus Chrysomela, distinguished as faltatory, and having their posterior tibiae incrusted.

ALTDIUM, in Ancient Geography, a place of Italy, in Umbria, north-east of Nocera.

ALTIKEN, in Geography, a prefecture of Zurich, in Switzerland, in which is a parochial village of the same name, not far from the Thur.

ALTILIA, a town of the kingdom of Naples, and province of Calabria Citra; six miles south of Cosenza.

ALTII.0, Gabriel, in Biography, was born in the kingdom of Naples, and flourishing about the end of the 15th century. He died about the age of 60, in 1501. He was preceptor to prince Ferdinand; and afterwards employed in state affairs, as he accompanied Jovianus Pontanus to Rome, in order to negotiate a peace between king Ferdinand and pope Innocent VIII. His reputation as a Latin poet attracted notice, and contributed to his promotion to the bishopric of Palermo. The distinguished excellence of his Latin verses led his contemporaries to regard him as a person who was intimately conversant with polite literature, and who had studied the ancients with great improvement. In the delicacy of his elegies and the sublimity of his heroics, he is said to have so much excelled, that in the opinion of Pontanus and Actius, he was equal to the ancient poets. Most of his poetical performances are lost; but some of them are preserved in the "Deliciae Poetarum Ital." Gen. Dict.

ALTIMETRY, Altimetria, compound of altus, high, and metra, to measure, the art of taking or measuring altitudes or heights, whether accessible or inaccessible.

Altimetry makes the first part of geometry; including the doctrine and practice of measuring both perpendicular and oblique lines; whether in respect of height or depth.

ALTIN, in Commerce, a money of account in Mudecay; worth three octa, one hundred of which make a ruble, worth four shillings and sixpence in English.

They have had occasionally altin coins, both of copper and silver. Those of the silver altins under Peter I. had on one side the eagle, and on the other, with the date of the year, the word Altinik. But for a long time no more altins have been struck; and those of silver are now seldom to be seen.

ALTIN, or ALTYN-NOOR, LAKE, in Geography, a lake of Siberia, in the government of Kolomna, is situated on a very considerable elevation of the Altaiian mountains, by which it is also entirely surrounded. N. lat. 49°. E. long. 102°. It is also called by the Ruffians Teltezk-ozer and Altain-kul. Its length is computed at 126, and its greatest breadth at 84 feet. It flows northward to the river Byar, which at its confluence with the Katun affirms the name of Ohy. The bottom of this lake is rocky, and at its northern part it is sometimes frozen so hard as to be passable on foot; but it is said, that the southern part is never covered with ice. The water on this lake and the adjacent rivers rises only in the middle of Summer; when the snow on the mountains is dissolved by the heat of the sun.

ALTIN, a town of Naples, in the province of Abruzzo Citra; nine miles south of Langiano.

ALTINCAR, among Minerals, a species of fatics used in the fation and purification of metals.

The altinar is a sort of flux powder. Divers ways of preparing it are given by Libavius.

ALTING, HENRY, in Biography, was born at Embden, in 1583, and, having devoted himself to the profusion of a divine, he was sent in 1612 to the university of Herborn, where he became a professor. In 1625 he was appointed preceptor to the electoral prince palatine, and in 1612 accompanied him to England, where he was introduced to the acquaintance, among others, of archbishop Abbot. In 1613 he returned to Heidelberg, where he took his degree of doctor of divinity, and was appointed director of the college of Wilmont. At the synod of Dort, to which he was invited in 1618, he distinguished himself by his prudence and eloquence. After his return to Heidelberg, he very narrowly escaped falling a sacrifice, when the city was taken in 1622, by count Tilly; for, as he was entering the house of the chancellor, one of the guards met him, and ignorant of his person, threatened his life; "with this battle-axe I have this day killed 10 men!" Altling, if I knew where to find him, should be the 11th." Altling replied, with a resolution and confidence of mind, and at the same time with an allowable mixture of terror, which said his life: "I am a teacher in the college of Wilmont." When the Jesuits took possession of the house, he concealed himself in a garret, and the air was secretly supplied with food, till he had an opportunity of making his escape, and of following his family to Heilbron. After the defoliation of the palatinate by count Tilly's forces, he retired to Schorndorf; but here, although situated among Protestants, he encountered new trials. The Lutheran ministers of Schorndorf, who were at variance with the professors of Heidelberg, were dissatisfied with the permission which the duke of Wirtemberg had given to one of these professors to reside among them; and by reason of their jealousy and intolerance, Altling was obliged to remove to Embden in 1623, from whence he followed his late pupil, who was king of Bohemia, to the Hague. Under the patronage of this prince, and in the office of tutor to his eldest son, he remained till the year 1627, when he obtained his permission to remove to Groningen, where he was appointed to the professorship of divinity, which he retained the rest of his life. Such were his talents and character and public services, that he lived in very great estimation; but the confusion and troubles of that period prevented his taking possession of the office of divinity; and for alt, to Heidelberg, to which he was appointed by prince Lewis Philip, administrator of the palatinate. Domestically, he was occupied by the loss of his eldest daughter and his wife, brought upon him a settled melancholy, which, after a few months, put a period to his life, in the year 1644. Altling, though he was no friend to the innovations introduced at this period by the Socinians, was of a moderate and peaceable temper, and indispersed to dispute and quarrel about trifles. "Adhering," as he judged, to the plain doctrine of scripture, he was equally deft to avoid sophistical subtlety and fanatical frapulosity." His works were, "Nota in Decem Problenatum; Johannis Behn," Heidelb. 1618; "Loco Commines;" "Probemata;" "Explicatio Catalogae Palatinae," Amstelod. 1601; "Exegetis Augustienni Confliti, &c. Amst. 1617; "Methodus Theologicie Didactice et Catechetice;" Medulla Historic Prophana," published under the name of Parvus. Gen. Dict.

ALTING, JAMES, son of Henry Altling, was born at Heidelberg, in 1618, and after finishing his studies at Groningen, became professor in that university. Attached to
the study of the oriental languages, he put himself, in 1638, under the tuition of a Jewish Rabbi, at Embden. Upon his visit to England, in 1642, he was admitted to clerical orders by Dr. Prideaux, bishop of Worcester; but he altered his purpose of continued residence in this country, as soon as he received an invitation to the Hebrew professorship, at Groningen. He returned to Germany in 1643, and obtained considerable distinctions of honour in the university.

In this situation a rivalry commenced between him and his colleague, in the professorship of divinity, Des Marets. The latter was addicted to the scholastic philosophy and plan of instruction; whereas the former devoted himself to the study of the Scriptures and Rabbincal learning; and acquired a degree of popularity, as a lecturer, which excited the jealousy and opposition of Des Marets and his adherents. A dispute between these colleagues, who were now become competitors and rivals, had for some time prevailed; and at length the decision of it was referred to the divines of Leyden. Thence supposes pronounced Alting innocent of hereby, but fond of innovation, and Des Marets deficient in modesty and candour. The civil power was at last obliged to interfere, and the penalty of deprivation was decreed against those divines, who should in any ecclesiastical assembly revive the Marefo-Altingian controversy. The magistrates proceeded by an usurpation of authority which did not belong to them, to prohibit even writing for or against the judgment of the divines of Leyden. This breach between the two professors was never thoroughly compromised; though, by the interpolation of friends, a kind of formal reconciliation was effected, while Des Marets lay on his death-bed. Alting did not long survive him, but was taken off by a fever, in 1679. He was reprobated, in consequence of his attachment to Rabbincal learning, with an inclination to become a Jew. His works were collected some years after his death, and published in five volumes folio, under the care of Bekker, minister at Amsterdam, by his cousin Menfo Alting, burgomaster of Groningen, who wrote a good description of the Low Countries, entitled, "Notitia Germaniae Inferioris." It is said that he preached well in three languages, German, Dutch, and English. Gen. Dict.

**Altitude**, in Geometry, the third dimension of body, considered with regard to its elevation above the ground—called also **height** or **depth**.

**Altitude of a figure**, is the distance of its vertex from its base, or the length of a perpendicular let fall from the vertex to the base.

Thus, K L (Plate 1. Geometry, fig. 2) being taken for the base of the right angled-triangle, KLM; the perpendicular KM will be the altitude of the triangle.

Triangles of equal bases and altitudes are equal; and parallelograms, whose bases and altitudes are equal to those of triangles, are just the double thereof.

**Altitude**, in Optics, is usually considered as the angle subtended between a line drawn through the eye, parallel to the horizon, and a visual ray emitted from an object to the eye.

For the laws of the vision of altitudes. See Vision.

If through the two extremes of an object, S and T (Plate 1. Optics, fig. 13) two parallels, TV and SQ be drawn; the angle TVS, intercepted between a ray passing through the vertex S, and terminating the shadow thereof in V, makes, with the right line TV, what is called, by some writers, the **Altitude of the Luminaries**.

**Altitude**, in Cosmography, is the perpendicular height of an object, above the plane of the horizon.

**Altitudes** are divided into **accessible** and **inaccessible**.

**Altitude, accessible**, of an object, is that whose base you can have access to, so as to measure the nearest distance between your station, and the foot of the object on the ground.

**Altitude, inaccessible**, of an object, is that whose base cannot be approached, by reason of some impediment; such as water, or the like.

There are three ways of measuring altitudes, viz. geometrically, trigonometrically, and optically. The first is somewhat indirect and unartful; the second is performed by means of instruments for the purpose; and the third by shadows.

The instruments chiefly used in measuring of altitudes, are the quadrant, theodolite, geometric quadrant, or line of shadows, &c. the descriptive, applications, &c. whereof, see under their respective articles Quadrant, Theodolite, and Quadrat.

**Altitudes, to take accessible.** To measure an accessible altitude geometrically. Suppose it required to find the altitude AB (Plate 1. Geometry, fig. 3) plant a staff, DE, perpendicularly in the ground, of such height as may be equal to the height of the eye. Then, laying a plumb on the ground, with your feet to the staff; if E and B prove in the same right line with the eye C, the length CA is equal to the altitude AB. If some other point, as F, prove in the line with E, and the eye, you must remove the staff, &c. nearer to the object; on the contrary, if the line continued from the eye over E, mark out some point above the altitude required; the staff, &c. are to be removed farther off, till the line EF raise the very point required.

Thus, measure the distance of the eye C from the foot of the object A, the altitude is had; since CA = AB.

Or thus: at the distance of thirty, forty, or more feet, plant a staff, DE (fig. 4) and at a distance from this, in C, plant another shorter one, so that the eye being in F, and E and B may be in the same right line therewith. Measure the distance between the two staves, GF; and between the shorter staff and the object, HF; as also, the difference of the heights of the staves, GE. To GF, GE, and HF, find a fourth proportional BH. To this add the altitude of the shorter staff, FC. The sum is the altitude required, A B.

To measure an accessible altitude, trigonometrically. Suppose it required to find the altitude AB (fig. 5) choose a station in E; and with a quadrant, theodolite, or other graduated instrument duly placed, find the quantity of the angle of altitude ADC. Measure the shortest distance of the station from the object, \( \text{tan} \), DC, and this of consequence is perpendicular to AC.

Now, C being a right angle, it is easy to find the side AC; since, in the triangle ACD, we have two angles, \( \text{tan} \), D and A its complement, and a side opposite to one of them, CD, the side opposite to the other may be easily found by this case. As the line of the angle A is to the given side opposite to it DC, so is the line of the other angle D to the side required CA. To this side, thus found, adding BC, the sum is the perpendicular altitude required.

Or say, as radius is to the distance DC, so is the tangent of the angle ADC to AC, the height of the object; and adding the altitude of the instrument above the ground, the whole height of the object is found. The operation is bell performed by logarithms. E. G. Suppose the angle ADC = \( 31^\circ 52' \), and the distance DC = 64 feet. Then it will be,

\[ \text{Radius} = \]
Radius \( 10 \text{,}000 \text{,}000 \)

Log. of \( DC \), or 64 feet \( 3.06180 \)

Tangs. of \( 51^\circ \) 52' \( 1.01519 \)

\( AC \) or 81 \( \frac{1}{2} \) feet \( 1.01519 \)

To which add four feet, the height of the eye, and the altitude required, or \( AB \), is 83 \( \frac{1}{2} \) feet.

This may also be resolved by projection, thus: draw \( DC \), on which let 64 feet from any scale from \( D \) to \( C \); erect the perpendicular \( CA \); and draw \( DA \), intersecting the perpendicular in \( A \), the top of the object. Then \( CA \) measured on the same scale, will give 81 feet.

If there happen an error in taking the quantity of the angle \( 2 \) (fig. 6) the true altitude \( DB \) will be to the false one \( BC \), as the tangent of the true angle \( DAB \), to the tangent of the erroneous angle \( CAB \).

Hence, such error will be greater in a greater altitude than in a lesser; and hence also, the error is greater, if the angle be lesser, than if it be greater. To avoid the inconveniences of both which, the station is to be pitched on at a moderate distance; so that the angle of altitude \( DAB \), may be nearly half right.

Again, if the instrument was not horizontally placed, but inclined, e. g. to the horizon in any angle, the true altitude will be to the erroneous one, as the tangent of the true angle to that of the erroneous one.

If the plane intercepted between the observer, and the object be inclined, as in fig. 7; two stations \( C \) and \( D \) must be selected, and their distances from the base of the object, reckoned. \( CA \) and \( DA \) must be measured. Then as the angular tangent \( ACB \) is equal to \( CDB + DBC \); the angle \( DBC \) = \( ACB - CBD \); and \( DB \) is equal to the supplement of \( ACB \); in either way the angles of the triangle \( BCD \) are known, and one side \( DC \) is given; then, the angle of \( BDC \); \( AC \); \( CDB \); \( BCA \); \( ADC \); and in the triangle \( ABC \), the two sides \( CA \) and \( CB \) being given together with the included angle, we shall have \( CB + AC : CA : \text{tangent of} \frac{A + B}{2} \)

\[ \frac{A - B}{2} \]

whence the angles will be determined.

And it will be easy to find \( AB \) the altitude of the object as before. Otherwise, measure the difference \( AC \) and the angles \( A \) and \( C \); and in the triangle \( ABC \), all the angles and one side \( AC \) are given, the other side \( AB \) will be easily found.

To measure an accessible altitude optically, by the shadow of the body, see shadow.

To measure the altitude of any object by optical reflection, place a plane mirror, or a vessel of clear water, horizontally at \( C \), (fig. 8), and retreat from it to such a distance as \( D \), that the eye \( E \) may just perceive the image of the top of the object, in the reflecting surface at \( C \); then, as these triangles, having two equal right angles, and the angle \( ACB = ECD \), because the angle of incidence is equal to the angle of reflection, are similar, we shall have \( CD : DE : CA : AB \), the altitude required.

To measure an accessible altitude by the geometrical quadrant or square, Suppose it required to find the altitude \( AB \) (fig. 6), choosing a station at pleasure in \( D \), and measuring the distance thereof from the object \( DB \); then the quadrant this and that way, till the top of the tower \( A \) appear through the sights.

If then, the thread cut the right shadows, say, as the part of the right shadow cut off, is to the side of the quadrant, so is the distance of the station \( DB \), to the part of the altitude \( AE \). If the thread cut the vertical shadow, say, as the side of the quadrant is to the part of the vertical shadow cut off, so is the distance of the station \( DE \), to the part of the altitude \( AL \).

\( AB \), therefore, being found in either case, by the rule of three, and the part of the altitude \( BE \) added to it, the sum is the altitude required. See quadrant.

To measure an inaccessible altitude, trigonometrically,—Choose two stations \( G \) and \( E \) (fig. 10), in the same right line with the required altitude \( AB \), and at such di stance from each other, \( DF \), as that neither the angle \( FAD \) be too small, nor the other station \( G \) too near the object \( AB \). With a proper instrument take the quantities of the angles \( ADC \), \( AFC \), and \( CFB \); and also measure the interval \( FD \).

Then, in the triangle \( AFD \), we have the angle \( D \), given by observation; and the angle \( AFD \), by subtracting the observed angle \( A FC \), from two right angles; and consequently the third angle \( DAF \), by subtracting the other two from two right angles; and also the side \( FD \); from whence the side \( AF \) is found by the canon above laid down, in the problem of accessible altitudes. And again, in the triangle \( ACF \), having a right angle \( C \), and observed angle \( CFB \), and a side \( CF \), the side \( AC \), is found by the same canon.

Lastly, in the triangle \( FCB \), having a right angle \( C \), observed angle \( CFB \), and a side \( CF \); the other side \( CB \), is found by the same canon.

Adding, therefore, \( AC \) and \( CB \), the sum is the altitude required, \( AB \).

E. G. Suppose \( AFC \) to be 88° and \( ADC \) 58°, and the distance of the stations \( FD \) to be 26 yards. Subtract \( ADC \) or 58° from \( AFC \) or 88°, and there remains \( FAD \) or 30°. Then, in the triangle \( DAF \), the angles and one side being known, we shall have sine of \( DAF \) = sine of \( ADF \) = \( \frac{FD}{FA} \) i. e. \( \frac{CD}{CA} \) = \( \frac{6}{8} \), a fourth, or by logarithms, 0.93107 0.67934 0.45067.

Again, in the triangle \( APC \), we shall have sine of \( ACP \) = sine of \( AFC \) = \( \frac{AP}{AC} \) = \( \frac{6}{8} \), a fourth, and by logarithms 0.93107 0.67934 0.45067.

Adding, therefore, \( AC \) and \( CB \), the sum is the altitude required, \( AB \).

To measure \( AB \) with the quadrant, choose a station at \( F \) and \( D \), so that the angle \( AFC \) may be 45°, and the angle \( ADC \) = 25° 34', the altitude \( AC \) will be equal to \( DF \) the distance of the two stations. For when \( AFC = 45° \), \( AC = CF = FD \), and \( DC = 2 AC \), as radius = natural tangent of \( 25° 34' \) = 1.50861.

We
ALT

We may hence deduce a method of finding the height of one object, as AC, supposing another HC. Find, first, the whole altitude AC, and then the altitude HC, as above, and their difference will be the altitude of AH, as e.g., of a fire above the tower of a palace. If the height of the tower HC be known, any distance DF in the horizontal line DC may be measured from H. This is the reverse of the preceding problem.

To measure the altitude of a balloon, cloud, or other moveable object, C; (fig. 11.) let two observers at A and B, in the same horizontal plane, take, at the same time, the angles CAD and CBD, and measure the distance AB between the stations; and then the altitude may be calculated as before. The height of a cloud may be found by its shadow in the following manner. Observe the cloud C, (fig. 12.) in its direct access to or recedes from you; and marking the instant in which the middle of the shadow is at some remarkable point upon the ground as at A, at that moment take the altitude ABC of the middle of the cloud. Then, take the fun's altitude at your station B, and that will be equal to the angle BAC, and measure the distance between your station and the place of the shadow. In the triangle ABC, as all the angles and one side are known, it may be easily projected, and the height of C above BA may be determined: or it may be resolved trigonometrically as follows:

fine of C : AB :: fine of B : AC = \frac{S \cdot B}{S \cdot C} \times AB; and

rad. : AC (\frac{S \cdot B}{S \cdot C} \times AB) :: S \cdot A : the perpendicular;
or rad. \times S \cdot C : AB :: S \cdot A \times S \cdot B : the height.

If the cloud be directly over your head at the time of observation, CBA will be a right angle; and rad. : AB :: tangent of the fun's altitude CBA : the height CB.

N. B. The cloud should be small, because the observation must be at a point. If the cloud be large, its edge as well as the edge of the shadow must be observed; and the stations must be upon a large plain or open ground.

To find an inaccesible altitude by the shadow, or the geometrical quadrat.—Choose two stations in D and H (fig. 9.) and find the distance DH, or CG; observe what part of either the right or verfed shadow is cut by the thread.

If the right shadow be cut in both stations, say, as the difference of the right shadow in the two stations, is to the side of the square; so is the distance of the stations GC to the altitude EA.—If the thread cut the verfed shadow at both stations, say, as the difference of the verfed shadow marked at the two stations, is to the lesser verfed shadow; so is the distance of the stations GC to the interval AE.—Which being had, the altitude EB is also found by means of the verfed shadow in G; as in the problem for accesible altitudes. Lastly, if the thread in the first station G, cut the right shadow, and in the latter, the verfed shadow; say, as the difference of the product of the right shadow into the verfed, subtracted from the square of the side of the quadrant, is to the square of the side of the quadrant into the verfed shadow; so is the distance of the stations GC, to the altitude required AE.

The utmost distance at which an object may be seen in the horizon, being given, to find its altitude.

Suppose the top H of a tower FH (fig. 13.) just visible at E, the distance EF being 25 miles; and suppose the circumference of the earth to be 25,000 miles, or the radius 3979 miles, or 21009120 feet. Then 25000 : 25 :: 360° : 21° 30' = the angle EGH; and radius : secant of the angle G :: EG : GH = 21009536 feet; and 21009536 - 21009120 = 416 feet or FH the height of the tower.

Otherwise.—In the right-angled triangle GEH, GHI or GH + 2GF \times FH + FH = GE + EH. But GE being EF, 2GF \times FH + FH = EH; or, FH being comparatively very small, 2GF \times FH = EH = EF, and FH = \frac{2GF}{2GF} but 2GF, or the earth's diameter, is 7958 miles, therefore \frac{EF}{7958} = FH in miles, and \frac{EF}{7958} \times 1760 = FH in yards.

Or, the altitude FH may more easily be found thus. The horizon dips nearly eight inches or \frac{1}{2} of a foot, at the distance of one mile, and according to the square of the distance for other intervals; therefore, as 1 : 1.25 = \frac{1}{2} :: \frac{1}{2} of 625 or 416 feet.

The method of taking considerable terrestrial altitudes, of which those of mountains are the greatest, by means of the barometer, is very easy and expeditious. This is done by observing on the top of the mountain how many inches, &c., the mercury is fallen below what it was at the foot of the mountain. When this is done, you will have its altitude by the help of a table calculated for that purpose. A very accurate table of this kind may be found in the Hist. de l'Acad. Roy. des Scienc. 1703, and 1705, calculated by M. Cassini; and also in the Phil. Trans. Eames's and Martyn's Abr. vol. vi. p. 34. See Barometer.

ALTITUDE of the eye, in Perspective, is a right line let fall from the eye, perpendicular to the geometrical plane. See Perspective.

ALTITUDE, in Astronomy, is an arc of a vertical circle, intercepted between the fun, moon, star, or other celestial object, and the horizon.

This altitude may be either true or apparent. If it be taken from the rational, or real horizon, the altitude is said to be true, or real; if from the apparent or sensible horizon, the altitude is apparent. Or rather, the apparent altitude is such as results from observations made at any place on the surface of the earth, and the true is that which has been corrected, on account of the refraction and parallax.

The true altitudes of the sun and fixed stars differ but very little from their apparent altitudes; because of their great distance from the centre of the earth, and the smallness of the earth's semidiameter, when compared with it. The quantity of refraction is different at different altitudes, and the parallax is different according to the distance of celestial objects; in the fixed stars it is too small to be observed; that of the sun is about 8\textdegree; seconds, and that of the moon about 52 minutes. The altitudes of the heavenly bodies are observed by a quadrant or sextant, or by the shadow of a gnomon, and by various other ways may be found without a quadrant, or any the like instrument, by erecting a pin or wire perpendicularly as in the point C (Astronomy, Plate 1. fig. 5.) from which point you have described the quadrant are AF. Make CE equal to the height of the pin or wire, and through E draw ED parallel to CA, and make it equal to CG; the length of the famous triangle, laid from C to D, intercept the quadrant in B; and B A is the arc of the sun's altitude, when measured on the line of chords.

The fun's altitude may be computed by the following rule, proposed by Mr. Lyons for nautical purposes. By the rules in the Nautical Almanac, for 1751, find the logarithm ratio; subtract it from the rising found answering to the given distance of time from noon, in the tables of the same Almanac; the remainder is the logarithm of a number, which
which subtracted from the natural sine of the sun's meridian altitude, leaves the natural sine of the altitude at the required time. For, finding the altitude of the moon or a star, he gives the following rule. From the tables above mentioned, take out the rising, corresponding to the hourly angle in the distance of time from the star's passing the meridian; add to it the logarithmic cosine of the star's declination, and the logarithmic cosine of the latitude of the place; the sum, abating twenty from the index, is the logarithm of a number, which subtracted from the natural sine of the star's meridian altitude, leaves the natural sine of the altitude at the given time. These rules are of great importance in determining the longitude at sea. See Naut. Alm. for 1778.

In taking altitudes from the visible horizon, where great exactness is required, an allowance is to be made for refraction, and the height of the observer's eye above the surface of the sea. To find the altitude of the stars, &c. by the globe, see GLASS.

An inequality has been observed in the apparent altitudes of the stars near the Meridian. On some occasions, when they are mounting towards the meridian, they appear to fall, and after passing the meridian, to rise. Hill, Acad. Science.

1719. p. 75.

M. Parent suggests a new method of taking altitudes at sea, by a common watch. It is obvious, that in an oblique sphere, the difference between the rising and setting of two stars, is greater, as they are farther distant from one another.

Now the astronomical table furnishing us with tables of the right ascensions and declinations for the fixed stars, it is easy, after observing the difference of time between the rising of two stars, to distinguish that part of the difference which accrues from their different position from that which arises from the obliquity of the sphere.—But such difference is the precise height of the pole of the place of observation.

Indeed, the ship not being immovable, but changing place between the two observations, seems to lay the method under some difficulty; but to this M. Parent answered, that a small alteration either of the ship's longitude or latitude, will make no sensible error; and that if she have gone a large distance between the two observations, it is easy reckoning how much it is, and accordingly allowing for it.

See SAILING.

Altitude, meridian. The meridian being a vertical circle, a meridian altitude, that is, the altitude of a point in the meridian, is an arch of the meridian intercepted between it and the horizon.

If HO (Astronomy, Plate 1. fig. 6.) be the horizon, and HZO the meridian, then the arc HE, or the angle HCE will be the meridian altitude of an object in the meridian at the point E.

To observe the meridian altitude of the sun, of a star, or other phenomenon, by means of the quadrant, see Meridian Altitude.

To observe a meridian altitude by means of a gnomon, see Gnomon.

Altitude, or elevation of the pole, is an arc of the meridian OP (fig. 6.) intercepted between the pole P and the horizon; or the angle OCP.

The altitude of the pole coincides with the latitude of the place; and may be found by observing the meridian altitude of the pole star, when it is both above and below the pole, and taking half the sum, after it has been corrected on account of refraction. O or the same may be found by means of the declination and meridian altitude of the sun.

Altitude, or elevation of the equator, is the complement of the altitude of the pole to a quadrant of a circle. Or, it is the angle HCE (fig. 6.) or arc HE of the meridian between the horizon and the equator at E, and equal to ZP, the co-latitude of the place.

Altitude of the tropics amounts to the same with what is otherwise called the solstitial altitude of the sun, or his meridian altitude when in the solstitial points.

Altitude of the horizon, or of stars seen in it, is variable by the refraction, according to the quantity of which the horizon is, more or less, either elevated or depressed.

Altitude of the nonagesimal, is the altitude of the 90th degree of the ecliptic, counted upon it from the point where it intersects the horizon, or of the middle or highest point of it which is above the horizon, at any time; and it is equal to the angle made by the ecliptic and horizon where they intersect at that time. See NONAGESIMAL.

Altitude, refraction of, is an arc of the vertical circle, as CE (Astronomy, Plate 1. fig. 7.) whereby the altitude SE, of a star or other celestial body, is increased by means of the refraction. This is different at different altitudes, being nothing at the zenith, and greatest at the horizon, where it is about 33°. See Refraction.

Altitude, parallax of, is the difference CB (fig. 8.) between the true and apparent place of a star; or the difference BC, between the true distance of a star AB, and the observed distance AC, from the zenith A. The parallax diminishes the altitude of a star, or increases its distance from the zenith. This arc, or the angle measured by it, is evidently less, as the celestial body is farther distant from the earth, and also less, for the same body, as it is higher above the horizon, being greatest there and nothing at the zenith. To find the parallax of altitude, &c. see PARALLAX.

Altitude of the cone of the earth's or moon's shadow denotes the height of the shadow of one or the other in an eclipse, and is measured from the centre of the body. It is found by this proposition: as the tangent of the angle of the fun's apparent semidiameter is to radius, so is one to a fourth proportion, which will be the height of the shadow in semidiameters of the body. The greatest height of the earth's shadow is 217.8 semidiameters of the earth, when the fun is at its greatest distance, or its semidiameter subtends an angle of about 11° 47'; and the height of the same is 210.7 semidiameters of the earth, when the fun is nearest the earth, or when its semidiameter is about 10° 11'; and between those limits it is proportional to the intermediate distances or apparent semidiameters of the sun. The altitude of the shadow of the earth and moon are nearly as 11 to 3, the proportion of their diameters.

Altitude, or exaltation, in Astrology, denotes the exceed of the five essential dignities, which the planets acquire by virtue of the signs in which they are found.

Altitude of motion, in Mechanics, is a term used by Dr. Wallis, for the measure of any motion, estimated according to the line or direction of the moving force.

Altitude, determinative, is sometimes used for the height, whence a falling body acquires, by acceleration, a certain velocity. Herman. Phoron. lib. i.

Altitude, in speaking of fluids, is more frequently expressed by the term depth.

The ingenious Dr. Hales, in his vegetable Statics, proposd a method of measuring unfathomable depths of the sea; on the principles by which Dr. Defagulieris contrived a instrument called a sounding, which was tried before the
the Royal Society; and is described in the Phil. Trans. N. 405. A more particular description of this instrument by Dr. Hales himself is as follows.

Suppose A B (fig. 1.) to be an iron tube, or mulek-barred, of any length, as fifty inches, having its upper end A well closed; if this tube be let down in this position about thirty-three feet into the sea, a column of water of that height is nearly equal to the mean weight of our atmosphere, and, conseqently, from a known property of the air's elasticity, it will be compressed into half the space it took up before, so that the water will ascend half way up the tube; and if the tube be let down thirty-three feet deeper, the air will be compressed into 4 of its first dimensions, and so on 1, 1/3, &c., the air being constantly compressible in proportion to the incumbent weight; whence by knowing to what height the water has ascended in the tube, we may readily know to what depth the tube has descended into the sea.

Now to measure the depth of one of these columns of sea-water: first, by a line let the iron tube, with a weight at its bottom, sink about thirty-three feet, which depth in salt water will nearly answer to the weight of the air at a mean height of the barometer; then draw up the tube, and observe how far the water rose. If thirty-three feet of water be equal to one atmosphere, then will the water rise so high as to fill exactly one half of the tube. But if the water rise higher or lower than half-way, then, by the rule of three, say, as the number to which the water rises is to one, so is thirty-three to the number of feet, measuring the depth of the column required. For example, suppose the water rises, when the tube is let down thirty-three feet, only 3/4 of half-way, then say, 4: 10 :: 33 : 5/4 feet, the depth of each column, which being once known, the number of columns of water is to be multiplied by this number of feet, whereby the depth of the sea in feet will be known.

But since, when the instrument has descended to the depth of 99 columns, or 99 times 33 feet, the air will be compressed into the 99/3 part of 50 inches, that is, into half an inch, the divisons both for some space below and also above that will be so very small, that the difference in depth of several columns of water will not be sensible. So that an instrument of no greater length than this would scarcely give an accurate estimate of half a mile's depth, that is, 2640 feet, or 80 columns depth of water. The lengthening of this instrument to 4, 5, or 10 times this length would obviate this defect, and make the difference of the degrees of depth much more sensible. But since it is impracticable to make a metal tube of so great a length, and if it were made, it would be so unwieldy as to be easily broken, the difficulty may be obviated in the following manner.

Let there be a globos metallic body of iron or copper, nearly of this form (fig. 2.) K, L, M, N, Q, whose capacity within may be equal to nine times the capacity of the metal tube, Z, K, L; let this globos body be firmly screwed to the metallic tube, at K, L, with a leathern collar, well corked in some aetherific matter at the shoulder, or joining, thereby to secure that joint in the most effectual manner. Let there be a small hole at X for the sea-water to enter freely in, and let some coloured oil be poured into the globos body, to fill it up to the hole X. Let there be also provided a fender rod d, screwed, or fastened into the metal tube s, which will also be made to screw in and out, thereby to take out the rod at pleasure; the rod must also have a small button d fastened to its upper end, which will prevent its being daubed by falling against the sides of the tube.

The capacity of the tube must be estimated by pouring water in, when the rod and metal line tube are fixed in their places.

Now since the lower vessel is supposed to contain nine times as much air as the tube Z L, which is the same thing as if the tube were nine times as long, therefore the air in the globos vessel will not all be forced within the capacity of the tube, till the vessel has descended to the depth of nine columns, or nine times 33 feet; for then the air will be compressed within one tenth of the space it first took up.

Supposing, therefore, the instrument to have descended to the depth of 99 columns of water, or 99 times 33 feet = 3287: then the air will be compressed within a 3/10 part of 500 inches (the capacity of the whole vessel being supposed equal to the tube of that length), that is, within six inches of the top of the tube; and, consequently, the rod d will be found tinging with the oil, within six inches of its top.

Suppose again the instrument to have descended to the depth of 359 columns, then the air will be compressed within a 7/10 part of the whole, that is, nearly within 21 inches of the top of the tube. In this case, the instrument will have descended 6567 feet; that is, one mile and a quarter, and 132 feet.

Suppose again the instrument to have descended to the depth of 399 columns, then the air will be compressed into a 7/9 part of the whole, that is, nearly within one inch and a quarter of the top of the tube. In this case the instrument will have descended two miles and a half, wanting 53 feet, which may probably be the greatest depth of the sea.

The larger the capacity of the vessel K, L, M, N, Q, the deeper will the gage be enabled to sink, the instrument being made stronger, and its joints being secured in proportion.

The instrument being thus prepared, a large buoy, i, must be fixed to it, which ought to be a solid piece of light wood, well tarred to prevent the water's being pressed into the fap-vessels; and as it may rise at a considerable distance from the ship, it may be advisable to fix on the top of the buoy broad fans of tin, properly painted, so as to be easily seen.

In order to sink the instrument, a weight must be fixed to it in the following manner. See the diagram. W is a weight of ballast, hanging by its fixed shank I, in the socket j j, which socket is screwed fast to N Q. The shank is retained in its place by the ketch k of the spring O, while the machine is descending; but as soon as W touches the ground at the bottom of the sea, the ketch O j sinking by the descending force, a little below the upper part of the hole k, is therefore at liberty to fly back, and so lets go the weight; then the buoy rises up to the surface of the water with the machine. Springs might also be fixed on the inside of the shank j j as to fly back in the same manner, when the weight touches the ground. It might be advisable to keep an exact account of the play of the machine under water, which might be done by a watch, or by a pendulum vibrating seconds. Dr. Hook found upon trial, that a leaden ball which weighed two pounds, fixed to a wooden ball of the same weight, and both let down in fourteen fathom water, reached the bottom in seventeen seconds, and the detached wooden ball ascended to the surface in nineteen more. See Phil. Trans. Lowthorp's Abr. vol. i. p. 278. Consequently if this machine descended and ascended greater depths with
with the same velocity, it would reach to the depth of a mile in seventeen minutes, and reappear in the like time. This, however, might be a vague estimate, until experience has furnished a rule.

This machine was tried in various depths in the Thames, and answered very well, always returning, and leaving the bailit behind. It was afterwards tried near the Bermudas, where several ships were in company; but though a good look-out was kept for three or four hours, it was not seen to return. Hali's Statics, vol. ii. p. 729.

Altitude of the sea's surface is not very near by the

which, as appears from the drift of currents setting against out of one sea into another.

Altitude of the mercuries, in the barometer, is marked by degrees placed on the face of that instrument, the variations of which are the chief object of barométrical observations.

The mean altitude of the mercury at London for every day in several years is about 29.87 inches, and its variations are computed between 31 and 28 inches. Some suggestions have been made, as if the altitude of the mercury were regularly greater in the morning than in the evening; at least something of this kind was observed to hold for a considerable time at Berlina. Hilt. Crit. Rep. Lett. tom. xiv. p. 239.

Altitude of the pyramids in Egypt, was measured so long ago as the time of Thales, by means of their shadow; which makes one of the first geometrical observations we have an exact account of. Phurach has given an account of the manner of this operation, which, according to this author, was done by erecting a staff perpendicular upon the end of the shadow of the pyramid; and by two triangles made by the beams of the sun, he demonstrated that there was the same proportion between the shadows as between the pyramid and the staff. Stuhl. Hilt. Phil. p. i. p. 9. See Pyramid.

Altitude, circles, parallels, and quadrant of. See the respective articles.

Altitude instrument, equal, is that used to observe a celestial object, when it has the same altitude on the east and west sides of the meridian, or in the morning and afternoon. This instrument consists of a telescope about 30 inches long (with two vertical, and three or five horizontal wires in its focus), supported at the end of an iron bar or axis, 30 inches long, and about an inch in diameter; the axis being sustained in a vertical position by passing through a hole in one end of a brass box, whose other or lower end sustains the lower joint of the axis. The box, which is about 21 inches long, with ends about four inches square, has only two sides, which are fixed at right angles. From one of these sides project four flat arms, with a hole in each, whereby the box is, by screws, fixed in a vertical position to an upright poll. On the lower end of the box lies a brass plate, which slides in grooves, and can, by means of a screw, be gently moved forwards or backwards; in this plate is a fine punched hole, to receive the smooth conical point, into which the lower end of the axis is formed. On the upper end of the box are two plates, which slide into grooves; and, by the means of screws, can be gently moved sideways, till their angular notches embrace the axis, which, in this part, is made perfectly cylindrical and very smooth. To the upper part of the axis is fixed, by its radius, a brass fastent (or arch of 63°, to a radius of seven or eight inches) with the arch downwards, so that the centre is just above the top of the axis: also a spirit-level is fixed at right angles across the axis, just under the arch, so as to be clear of the upper end of the box. To the under part of the telescope is fixed a brass fe-

micircle, of the same radius with the fastent, both arches having a common centre-pin. In the semicircle is a groove cut through the plate, parallel to its limb, to receive two screw-pins, which go into the fastential arch, near its ends; by these screw-pins the two arches may be preserved closed, and the telescope fixed in any desired elevation, which might be nearly ascertained by graduating the semicircle, and putting a maker's scale on the fastent.

When this instrument is used, the box is fixed to the poll, and the axis put into the box, letting the conical point drop into the punched hole; the level is screwed on, and the telescope is annexed, observing to infer the centre and arch-pins; then, by the help of the screw-plates at the bottom and top ends of the box, the vertical position of the axis is corrected, so that the same end of the air-bubble in the level may stand at the same point through the whole revolution of the axis, which will thereby be known to be then truly vertical, so that the telescope will describe a parallel of altitude. The tube, thus adjusted, is to be directed to the sun or star, and fixed at the desired elevation, by pressing the two arches together with the two screw-pins. This instrument is very useful in adjusting clocks, &c. and comparing equal and apparent time.

Altmanstein, in Geography, a market town of Upper Bavaria, belonging to the family of Abenberg, 12 miles north-east of Ingolstadt.

Altmore, a town of Ireland, in the county of Tyrone and province of Ulster. N. lat. 54° 34'. W. long. 7° 2'.

Altmuhl, a river of Upper Bavaria, which joins the Danube near Kelheim.

Altmuhlmünster, a commandery of the order of St. John, in Upper Bavaria, in the district of Rüdenburg.

Altobasco, in Geography, the name given to the ancient city of Colophon, in Ionia.

Altomünster, a market town of Upper Bavaria, which has an abbey of nuns of the order of St. Bridget.

Alto & Basso, or in Alto & in Basso, in Law signifies the absolute reference of all differences, small and great, high and low, to some arbitrator, or indifferent person.

Alto & Basso, or in Alto & in Basso, in Law, signifies the absolute reference of all differences, small and great, high and low, to some arbitrator, or indifferent person.

Altos, viols, or alto viola, the tenor violin, in opposition to the bas viol, to which instrument or violoncello, the tenor strings are tuned octaves; as C', G', D', A'. The following is the complete scale on the tenor:

This instrument has been rendered much more important of late years by quartets, and pieces made expressly for it than it used to be in the old overtures and concertos, in which it seldom had any melody assigned it. To fill up the harmony, by the refusé of other parts, was its only employment. But in the quartets of Stamitz, Boccherini, Giardini, and, above all, those of Haydn, it has been brought fully into action, and enjoyed equality.

Alto Relievo, in Sculpture, a representation of figures and other objects against a flat surface or back-ground; differs 5 H 2 from
from Bradford, we only in the work being much more relieved and brought forward.

To any representation half-relieved or more, if it be not entirely detached from the ground behind, sculptors apply the appellation of Alto Relleno.

ALTON, in Geography, a town of England, in Hampshire, on the rivers Wey. Its market-place consists of plain and figured herons, ribbed dragoons and fanges; and round the town is a plantation of hops. Its market is on Saturday, and it is distant from London 37 miles.

Alton is a village near Uttoxeter, in Staffordshire, in which are the ruins of a castle, supposed by Dr. Plot to have been erected by Theobald de Verdun in the beginning of the reign of Edward II. but by others apprehended to be prior to the Norman conquest.

Alton, a tract of land in Stafford county, New Hampshire, in America, north-east from Barnstable.

ALTONA. See ALTENA.

Altona, in Ancient Geography, a river of Britain, mentioned by Tacitus, and supposed to be the same with the Avona or Avon; but as there are many rivers of this name, it is conjectured that the Altona of Tacitus flowed by Northampton and Peterborough callwards.

ALTÖRF in Geography. See ALTOFF.

ALTÖRF, or ALTÖFF, a town of Germany, in the circle of Franconia, now small, but of great antiquity. It has an university with a valuable library, an anatomical theatre, chemical laboratory, and botanical-garden. It has undergone many revolutions from the year 912, when it is mentioned in some ancient records. It is subject to the house of Brandenburg, and is situated 12 miles east-south-east of Nuremberg. N. lat. 49° 25'. E. long. 11° 7'.

ALTRIMINGHAM, a town of England, in Cheffers, near the canal that passes to Warrington from Manchester, and about 8 miles from the latter town. The market is on Tuesday, and it is 179 1/4 miles from London. N. lat 53° 25'. W. long. 1° 30'.

ALTSOHL, a district and town of Hungary, five miles east-south-west of Neufohl.

ALTSTADT. See ALTSTADT.

ALTSTATT, a town of Germany, in the circle of Upper Saxony, and margrave of Mecklen, near Stolpen. ALTSTADT, a town of the circle of Westphalia and bishopric of Munster, five miles north-west of Ahns.

ALTSTETTEN, or ALSTETTEN, a town of Switzerland, in the Upper Rhine, seven miles east of Appenzell.

ALTUN-SOU, a river of Asia, which runs into the Tigris, 10 miles above T契, in the province of Kurdistan.

ALTUN-TASH, a town of Asia Minor, in the province of Notlia, 20 miles north-west of Kutaja.

ALTUR, or ALTUR, a sea-port town of Asia, in Arabia Petraea, frequent to the west of Mount Sinai, and towards the extreme of the western part of the Red Sea. The Greeks called it Raitho; the houses are built of white coral, which is found in great abundance on the coasts of the Arabian gulf. The inhabitants are partly Arabs and partly Christian Greeks. The monks of Mount Sinai have a convent in this place. Its port, like that of Suez, can admit no large vessels. N. lat. 25° 20'. E. long. 34° 19'.

ALTZENAU, a town of Germany, in the circle of the Lower Rhine, five miles east-south-east of Hanau.

ALTZER, ALZER, or ALTZHEIM, anciently ALEXI, a town of the Lower Rhine, in the Lower Palatinate, with a citadel, on the river Selz, and the capital of a prefecture of the name, three miles north-west of Oedernheim, and 14 north-west of Worms. N. lat. 49° 44'. E. long. 7° 55'.

ALVA DE ALISTA, a town of Spain, in Old Castile, not far from Zamora.

ALVA DE TORNES, a town of Spain, with a castle, in the county of Leon, and province of Salamanca, on the frontier of Estremadura, on the banks of the Tornes, eight leagues south-east of Salamanca.

ALVA DE TOLEDO, Duke of, in Biography and History, was born of an illustrious family in Spain in 1504; and having received military instruction under his grandfather, Frederic of Toledo, he was appointed a general, in 1538, by Charles V.; and, in 1542, defeated Perpigian against the besieging army of the Dauphine of France. When Charles V. determined to commence hostilities against the German Protestants, in 1546, the duke of Alva was appointed general-in-chief of the Imperial army; and in the following year, when the Elector of Saxony was defeated in the battle of Mühlbach, and taken prisoner, he was chosen to preside at the court-martial, which sentenced this unfortunate prince to suffer death by being beheaded. At the siege of Metz, in 1552, the chief command, under the emperor, was entrusted to the Duke of Alva; but neither the obstinate perseverance of Charles, nor the conquering affidance of Albert of Brandenburg, could avail against the vigorous defence of the Duke of Guise. The emperor, after varying the mode of his operation, and repeatedly renewing the attack, was at length constrained to yield to the solicitations of his generals, who conjured him to save the remains of his army by a timely retreat. "Fortune," says he, "I now perceive, refutes other females, and chuses to confer her favours on young men, while the forlorn those who are advanced in years." In this siege, which lasted 56 days, he lost upwards of 50,000 men, who either died of disease, or were killed by the enemy. In 1555, the emperor found it necessary to check the progress of the French forces in Piedmont by some vigorous measures; and with this view to employ a general of such reputation and abilities, as might counterbalance the great military talents of the Marechal Brissac, who was at the head of the French army. The Duke of Alva was pitched upon for that purpose, and he was invested with the dignity of the emperor's vice-general in Italy, as well as with the supreme command in all the Imperial and Spanish territories in that country. But though his authority was unlimited, the success of his operations was inconsiderable; and after having boasted, with his usual arrogance, that he would drive the French out of Piedmont in a few weeks, he was obliged to retire into winter quarters, with the ignominy of being unable to preserve entire that part of the country of which the emperor had hitherto kept possession. At the commencement of the ensuing year, Charles resigned to his son Philip the crowns of Spain, with all the territories depending upon them, both in the Old and New World; and though the Duke of Alva had advanced in the course of this year into the pope's territories, and reduced the whole of Campagna Romana, yet it was with reluctance that he pursued hostilities against the head of the church, which were no less repugnant to his own principles than to those of his new master. Having therefore made a truce, he afterwards negociated a peace with the pope; and, notwithstanding his haughty spirit, submitted to the humiliating condition of asking forgiveness of the pontiff whom he had conquered. After a general peace was established in Europe in 1559, the Duke of Alva was sent to Paris, at the head of a splendid embassy, to espouse, in the name of his master, Elizabeth, the daughter of Henry, king of France. The tyrannical conduct of Philip, and the perfecution measures which he had adopted with a view of restraining the progress
progress of the Reformation, had excited a very general dissatisfaction. Among his subjects in the Low Countries, and therefore, in 1567, he determined to send the Duke of Alva with an army to compel the discontented to submit to his will, and to punish them for their disobedience. No person could be a fitter instrument for the execution of his purpose. The duke not only approved, but advised and recommended, horrible measures. Notwithstanding the remonstrances of the regent, the Dukes of Parma, Philip persevered in his purpose; and the Duke of Alva, with a considerable army, directed his march to the Netherlands, and, after foraging the frontier towns, proceeded to Brussels, where he arrived in the month of August, A. D. 1567. His arrival spread great consternation and alarm throughout all the provinces. Many thousand persons had before this time left the country, among whom was the Prince of Orange, who would gladly have prevailed upon Count Egmont to accompany him. But he did not perceive the danger that awaited him. The prince took a sorrowful leave of him with these memorable words, which a disaffected event must soon have brought to his recollection: "You are the bridge, Count Egmont, by which the Duke of Alva will pass into the Netherlands, and he will no sooner pass it than he will break it down. You will repent of despising the warning which I have given you, but I dread that your repentance will be too late." One of the duke's first acts, after his arrival, was to call both Count Egmont and Count Horn into prison; and their imprisonment was soon followed by their trial, condemnation, and death. The Dukes of Parma, after repeated solicitations, obtained permission to quit the country, and the left Brussels in the beginning of the year 1568, much regretted by all, and particularly by the Protestants, to whom her administration appeared mild and gentle, compared with that which they had reason to expect under the present government. As soon as she was removed, the Duke of Alva fully disclosed his commission, and his powers appeared to be much greater than those of any former governor, and such as were inferiour of all the rights and privileges which Philip, as sovereign of the Low Countries, had at his inauguration solemnly sworn to maintain. But the pope had previously granted him a dispensation from his oath, so that his mind was quieted in every measure of detopism and cruelty, which he dictated or sanctioned. Alva's commission, besides the absolute command of the army, comprehended the presidency of the three councils of state, of justice, and of the finances, with ample powers to punish or to pardon crimes of every sort at his own pleasure. Allowing to the Reformers a month for leaving the country, he issued secret orders to the Inquisition to proceed immediately in the most rigorous execution of their edicts. For their affluence and encouragement he instituted a council of 12 persons, most of whom were Spaniards, and of which the duke was the president, called the Council of Tourists; but by the Flemings, justly denominated "the Council of Blood." Thus fortified and aided, the duke proceeded to build citadels at Antwerp, and in several other cities, and to spread his troops over the country in such formidable bodies, that the people, who could not endure their oppression and rapacity, either forsook their habitations, or abandoned themselves to despair. Above 20,000 persons escaped at this time into France, England, and the Protestant provinces of Germany. Some were seized in their flight, and innocent persons were overwhelmed with horror at the sight of the dreadful punishments inflicted on those who were charged with guilt; and all concurred in lamenting that a country, once eminently flourishing and distinguished by the mildness of its government and the happiness of the people, should now prefer to view no other object besides confiscations, imprisonments, and blood. In the space of a few months more than 18,000 persons suffered by the hand of the executioner; and yet Alva's thirst of blood was not satiated.

Like a beam of prey, this savage tyrant feared every secret recess; and his soldiers, accompanied by the inquisitors, were let loose among the Protestants, who were feated in the middle of the night in their beds, and from thence dragged to prisons and dungeons. Those who had been only once present in Protestant assemblies, although they declared their faith in the Catholic religion to be firm and unshaken, were hanged or drowned; and those who professed themselves Protestants, or who refused to abjure their religion, were put to the rack, in order to make them discover their associates; they were then dragged by horses to the place of execution, and their bodies being committed to the flames, their sufferings were prolonged with inguens cruelty. To prevent them from bearing testimony in the midst of their torments to the truth of their profession, their tongues were first scorched with a glowing iron, and then forced into a machine, contrived on purpose to produce the most excruciating pain. It is, indeed, shocking to recount the numberless instances of inhuman cruelty perpetrated by Alva and his associates; especially when we consider that the unhappy victims were generally persons of the most inoffensive character, who, having imbibed the principles of the Reformation, were too honest to disguise their sentiments; or, to say the word of them, who had been betrayed into indiscretions by their zeal for propagating truths, which they believed to be the highest importance to the glory of God, and the happiness of mankind. The hearts of even some members of the "bloody council" revolted against the repeated acts of cruelty to which their function was required; some of them fought a disimission, others abdented themselves, and of the 12 that composd the council, there were seldom more than three or four prefect. At this time the magistrates of Antwerp, whose behaviour had been uniformly obsequious during the whole of Alva's administration, presented an humble petition on behalf of some citizens whom the inquisitors had imprisoned. To this petition Alva returned a haughty reply, reproaching them for folly and presumption in applying on behalf of heretics; threatening them with tokens of his displeasure; and even affurting them, that if they persisted in such measures, he would hang them all, for an example, to deter others from similar presumption. Some of the Catholic nobility also remonstrated to the king against the governor's barbarity, and the pope exhorted him to greater moderation. But the inquisitors enforced the council of Vargas, who recommended perseverance, and Philip turned a deaf ear to the remonstrance which had been made to him; and the persecutions were continued with the same relentless fury. The people were reduced to circumstances of extreme distress, and they had no resource left but in the wisdom, public spirit, and extensive influence of the prince of Orange. Alva, soon after his arrival in the Netherlands, cited prince William to appear before him, but he was too sagacious to be deluded by promises of lenity, and refused to obey the citation, signing, at the same time, a variety of resols for his conduct. Several other nobles were cited to answer for their conduct; and, upon their refusal, Alva pronounced sentence against them, and confiscated their effects. The Prince of Orange at length had recourse to arms; but whilst he was employed in making levies, his brother Count Lewis arrived with an army in the Netherlands, and resolved to make his first attempt on Groningen. The Spanish army under Count Ambergen was sent to oppose him, but Lewis was victorious. However, Alva soon marched against him with a superior army, and totally defeated him. The Prince of Orange prepared for
for action by publishing a manifesto, in which he declared that
his religious sentiments were changed, and that he was now
convinced that the opinions of the Protessants were more con-
formable to the Scriptures, the rule and standard of Chrisean
faith, than those of the Romish church. William was a for-
midable enemy; and it required all the caution and valour of
Alva, and of his son Frederic of Toledo, to prevent him from
breaking in upon the Netherlands. Alva succeeded; and the
prince, disappointed in his expectation of supplies, was
under a necessity of disbanding his army. After this event
Alva marched in triumph to Brussels, and commanded a fo-
lemn thanksgiving for his successes to be observed through all
the provinces. He ordered a statue of himself to be formed
of brass, and medals to be struck. On one of these medals
he was represented riding in a triumphal chariot, with a Vic-
tory behind him, putting a crown upon his head. In his
right hand he held a sword, to signify that he had con-
quered Lewis by open force; and in the left an Aegis, to ex-
pres that wisdom of which he had availed himself against
the prince of Orange; and as a further emblem of his wisdom,
the chariot was drawn by owls, which, in the ancient Hen-
then superstition, were sacred to Minerva. His statue, which
was placed in the citadel of Antwerp, was the workmanship
of Jockela, a German artist, the most celebrated sculptor
of the age, and afforded a still more striking display of his
vanity and arrogance. He was represented trampling under
his feet the figure of a monster, having certain emblematical
figurs in different parts, which denoted the petition which
had been presented to the Dukes of Parma, the compro-
mise, and the insurrection and tumults which ensued. The
cube of the figure was a square pillar of marble, with the
name of the artist on one side, and with encomiums on the
Duke of Alva on the other sides, who is said to have had
extinguished heresy and rebellion, to have saved the church
from destruction, and restored justice and tranquility to the
Netherlands.

We learn from Grotius, that about this time the duke
enacted several useful regulations with regard to trade, the
coin, and the liberty of the press: but they failed in pro-
moting the purposes for which they were intended, and the
memory of them was soon effaced by the violence of the meas
ures which he afterwards pursued. He devoted the
interval of leasure which he now enjoyed to various acts of
tyranny; and to the accomplishment of his schemes for
reducing all the provinces to total slavery, and extinguishing
the reformed religion; and the executioner was fully em-
ployed in removing all those friends of freedom whom the
sword had spared. The emigrations from the Low Coun-
tries were, in consequence of Alva's violent and cruel meas-
ures, very numerous; and of those persons who were
exiles many came over to England, where they were all re-
ceived by queen Elizabeth. In this country they enjoyed
the free exercise of their religion; and amply recompened
the English for the protection that was afforded them by
introducing various branches of manufacture, with which
they had been before unacquainted. Alva's vanity was
flattered about this time by an embassy which was deput-
ted by the pope, to present him with a confrerated hat
and sword; and he was thus confirmed and encouraged in
the prosecution of those flagrant measres, which had pro-
curred him this distinguished honour. But such were the
abundance and folly, as well as the oppression and ty-
anny, into which his arrogance betrayed him, that he
adopted a measure which may be regarded as the chief
caule of all the difficulties which he afterwards encountered,
and of all those astonishing exertions which the people made
to emancipate themselves from the Spanish yoke. Head-
offs of the rights and privileges of the people, who had been
accustomed to be taxed by their own princes, he re-
olved, by his own authority, to establish numerous and
burdenome taxes, sufficient not only for supplying his pre-
ent exigencies, but to serve as a perpetual fund for defray-
ing all the expenses of his government. These taxes, by
their number, and by the mode of their imposition and en-
forcement, excited universal discontent. The states de-
clared and renonmated; but Alva was not only deaf to re-
monifance, but determined, after some temponing meas-
ures, to employ force for rendering effectual his arbitrary
requisitions. The states of Utrecht were refolute and firm
in their opifition, and though they incurred a confiscation
of their territory and revenues, their conduct was attended
with the most important confequences, and produced a
more general adherence to the taxes which the govern
imposed. In the mean while the prince of Orange was not
an unconfcrmed fpectator of these transactions. Having
returned from France, in 1569, to his country of Naflau in
Germany, he commenced preparations for trying his for-
tune once more against the Spaniards. The exiles also,
who had left the country on account of the perfecution of
Alva, united, and fitted out a great number of armed ves-
fels with which they feized all the Spanish ships which they
could meet with on the Flemifh or English coasts. Alva
perforved in fufing edicts for the payment of exorbitant
taxes; and, in order to intimidate the people into compli-
ance, he formed the barbarous resolution of putting to
death, before their own houses, 17 of the principal inhabi-
tants of Bruslfs. But before the time fixed for their exe-
cution, a messenger arrived with information that the exiles
had made a deffen on the island of Vorn, and got poffef-
sion of the Brille. This intelligence alarmed Alva, and
induced him to revoke his bloody orders, and to suspend,
for a time, the levying of taxes. An order had been iffued
by queen Elizabeth, in compliance with the requelt of
Alva, that all ships, belonging to fuch of the inhabitants of
the Low Countries, as had withdrawn their allegiance from
the king of Spain, should leave her harbours. This order
was an occasion of triumph to Alva, but, in the ifue it con-
tributed to the vigorous exertions of the exiles, to the cap-
ture of the Brille, and to that union under the prince of
Orange, which had the foundation of the independence of the
United Provinces. The spirit of reliance and revolt which was
spreading through the country was much encouraged by the
defeat of the Spanish fleet under Medina-Celi, in 1572, and
by the supply of money and military forces which the exiles
found on board the fhips that were taken. The revolt in
North Holland became general; Mons, the capitol of
Hainault, and one of the most populous and flourishing
cities in the Low Countries, was taken by Count Lewis;
the Spanish army was employed in endeavouring to recover it;
the people of Holland and Zealand were induftriously fecuring
themselves, by every precaution and preparation in their
power, from being again reduced under the Spanish yoke.
In contempt of the order iffued by Alva, for an assembly of
the States at the Hague, a meeting was held at Dort, and
it was determined to acknowledge the prince of Orange as
the only lawful governor or Stadholder of the provinces,
and commander in chief of all their forces both by sea and
land; and every possible exertion was made to furnish him
with necessary fupplies. Whilift the prince and the States
were employed in providing for the fecurity of Holland,
Frederic de' Toledo was making rapid progress in reduc-
ing the towns which had revolted in the other provinces;
but his progress was marked by various acts of oppression and cruelty, of fo horrible a nature as to be fiarrely credible, if they were not well authenticated by the most unquestionable testimony. But the pernicious cruelty of Alva and his son, after the siege and capture of Haarlem, exceeded, if possible, in atrocity every other measure of this savage administration. By the lowest computation, 900 brave men were executed, with every circumstance of igno-

miny and barbarity, like the vilest malefactors, who, truffing to Toledo's promise, had surrendered their arms to throw themselves upon his mercy. The confefion, however, of the length of this siege and of the lobs of men fhallaine by it, was a mutiny among the Spanish troops; and it was with difficulty, and after much negotiation, that they were induced to march against Alkmaar. Here they met with a repulfe, attended with great loss, and Frederic was obliged reluctantly to refiire. Alva's fleet was, about the fame time, defeated by the Zealhundrs, and the town of Gertruydenburg fafomipated by the prince of Orange. Alva, difpirited by these events, and declining in his health, by the anxiety and fatigue he had undergone, solicited a recall, and obtained Philip's leave to quit the Netherlands, and to return home. Philip, diffydent of the succefs of the cruel meafures that had hitherto been pursued, and detem-

ined to try the effect of a milder administration, configned the more readily with Alva's requelt. Accordingly, in December 1573, the duke and his fon fet out, by the way of Germany and Italy, for Spain; after having resigned the regency to his cucefor Requefien, who commenced his administration with demolifhing Alva's ftabe at Antwerp, and with reproving the infolence of certain garrifons, at whose enormities his predeceflors had condined.

In the review of Alva's administration we may obferve, that both the catholics and protestants regarded him as the chief fource of all the calamities in which the Netherlands had been involved. He had received his government from the duchefs of Parma, in a state of perfect tranquillity. By his tyranny he had thrown it into the moft terrible confufion, and kindled the flames of a deftructive war, which he was conscious of being unable to extinguifh, and he had, therefore, applied for liberty to retire. He is faid to have boated to Count Knowing, uncle to the Prince of Orange, at whose house he lodged on his way to Italy, that, during his government of five years and an half, he had confligned more than 18,000 heretics to the public executor; besides a much greater number whom he had put to the sword, in the towns which he took, and in the field of battle. During Alva's administration, the fitation of the Low Countries was truly deplorable. His oppreffion was not confined to protfeftants, but many catholics were put to death, and their effects forfeited, under a pretenfe of their having entertained heretics, or having held a corre-

fpondence with them in their exile. Wives were punifh-

ed with the utmost fervor for affenting thither to their husbands, whom the council of tumults had condemned; children for performing the like offices to their parents; and in Utrecht, a father was executed for allowing his fon, who had returned from banifhment, to lodge under his roof for one night. By forcing fo many thousands of the moft industrious inhabitants to leave the country, and by neglecting to pro vide a naval force to oppofe the exiles at sea, commerce was almost entirely ruined; notwithstanding which, he impofed upon the people more oppressive taxes, than they could have borne, if they had been in the most flourishing condition. In levying these taxes, the utmost rigour was employed. The people were often wantonly provoked, and tumults purposely excited, from which occa-

sion was taken to punish them with confifcation of their goods, and sometimes with both death and confifcation. From the confifcations and taxes large sums were raised; yet, by maintaining fo numerous an army, and by building citadels to keep the principal towns in awe, as he received little aflifiance from the king, who was engaged in other expensive enterprizes, he fell behind in the payment of his troops; and in order to keep them in good humour, he permitted them to live at free quarters upon the inhabitants, against whom they exercised, on many occasions, the most cruel and oppreffive capacity.

Alva, after his return to Spain, enjoyed for some time the favour and confidence of his master; but his fon Don Garcia de Toledo, having debauched one of the maidens of honour, under a promise of marriage, was put under arreft, and affifted by his father in making his escape. Alva, in order effectually to prevent the fulfilment of his obligations, enforced by the king's order, concluded a marriage between him and his confin, a daughter of the Marquis of Villena. Upon this Alva was banifhed from court, and confined to the castle of Uzeda. Here, notwithstanding many intercelfions in his favour by the pope, and some foreign princes, he remained for two years. But when Don Antonio affirmed the crown of Portugal, Philip made preparations for oppo-

fing him; and devoted on Alva the supreme command in Portugal, without forgiving his offence or admitting him into his prefence. Alva, notwithstanding his age and infirmities, accepted the command; repaired to the army in 1580, defeated Antonio, and reduced the whole kingdom of Portugal to Philip's authority. When Lisbon was taken, the suburbs, which were at that time no less confiderable than the town itfelf, were delivered up to be rafaced and plundered by the foldiers, without any difference between the friends and the enemies of the king. When Alva was required to give an account of the treafure which he had acquired on this occasion, he is faid to have replied; "If the king asks me for an account, I will flate to him kings-

doms preferved or conquered, signal victories, successful fieges, and 60 years' service." Philip made no further in-

quiries; but Alva did not live to enjoy the honours and emoluments resulting from this laft exploit. He died in 1582, at the age of 74 years. Robertson's Hist. of Charles V. vol. iii. and iv. Watfon's History of Philip II. of Spain, vol. i. and ii.

ALVACA, in Ancient Geography, a town of Media, according to Ptolemy.

ALVAH, the wood wherewith Moses sweetened the waters of Marah. Exod. ch. xv. ver. 25.

The name of this wood is not found in Scripture, but the Mahometans give it that of awab, and pretend to trace its history from the patriarchs before the flood. Jud. 14. 7, on the contrary, says, that Moses used the wood which he found next lying before him.

ALVALADE, in Geography, a small town of Portu-
gal, in Alentejo, fituate between two rivers, and containing about 1200 inhabitants.

ALVANIS, in Ancient Geography, a town of Mefopo-
tamia, according to Ptolemy.

ALVANNA, in Geography, a town of Spain, in the province of Guiuscoa, three leagues east of Tre-
vigno.

ALVAR, a town of Hinduftan, in the country of Mewat, 60 miles south south-west of Delhi.

ALVARA MARITIMA BAY, is situated on the coast of Loango, in Africa, in S. lat. 5°. and E. long. 11°. This bay
bays has a fine sandy strand, and good anchorage ground. On the south side of it are two villages.

ALVARADO, a town of America, in the province of Guazaca, situated at the mouth of a river of the same name, 30 miles south-south-west of Vera Cruz. N. lat. 18° 40'. W. long. 96° 37'.

ALVARADO, a river of New Spain, rises in the mountains of the Zapotecas, and making a circuit through the province of Mazatlan, and receiving several smaller rivers and streams, runs into the Gulf of Mexico, about the distance of 30 miles from Vera Cruz. The mouth of the river is about a mile wide; but for more than two miles from the shore it is almost choked up with sand.

ALVAREZ, a town of Arabia Felix, according to Ptolemy.

ALVARES, a town of Portugal, in Estremadura, containing about 1200 inhabitants.

ALVAREZ, Francis, in Biography, a Portuguese priest, was chaplain to Emanuel, king of Portugal, and sent by him as ambassador to David, king of Ethiopia and Abyssinia. Having continued six years in this country, he returned with letters to king John, the successor of Emanuel, and to pope Clement VII., and gave an account of his embassy at Bologna in 1533, in the presence of Charles V. He died in 1543, and the account of his embassy, with a description of the customs and manners of the Ethiopians, was printed at Lisbon, in 1545, in the same year, and translated into Latin by Goez, under the title "De foco, regione et moribus Ethiopum," and at Antwerp in 1558; in French, 1559. He was the first writer who gave any certain information concerning Ethiopia; but his account, though represented by some as true and accurate, is not entitled to implicit credit. Gen. Dict.

ALVAREZ, Emanuel, a learned Jesuit, was born in the island of Madeira in 1546. He became successively rector of the colleges of Coimbra, Lisbon, and Evora, at which place he died in 1582. His Latin Grammar, "De Institutione Grammatica," is much esteemed, and is still used by the Portuguese Jesuits in their colleges. It was published in 1602, in 1599, and has passed through several editions. Gen. Dict.

ALVAREZ DE PAZ, James, an eminent Jesuit of the 17th century, and author of several devotional treatises, was born at Toledo in Spain, and educated in the schools of the Jesuits, among whom he entered himself at 17 years of age. Having finished his course of theological studies at Alcalá de Henares, he removed to the kingdom of Peru, in South America, and read lectures in divinity and philosophy at Lima, which were much applauded. He was likewise rector of the colleges of Quito, Cuzco, and Lima, and governed the whole province for six years, connecting his public offices with the regular discharge of his private duties. At Potosí, where he was much revered, he was feized with a disease, which proved fatal, A. D. 1629, in the 66th year of his age. Gen. Dict.

ALVARID, among the Spanish Moors, denoted a judge. The word is also written alvarid, in this sense alvaridus amounts to much the same with what is otherwise called alcald.

ALVARIST, in Church History, a sect or branch of modern Thomists, denominate from Alvaris, whose method and principles they follow.

ALVARIS, as a name of one of the ancient Thomists, in that the former are alliterative of sufficient grace, the latter of efficacious grace. The former come near to the Jesuits, the latter to the Jansenists.

ALVARTO, James, in Biography, an eminent civilian, was born at Padua, and became professor of law in that city, in the 15th century. Besides other treatises, he wrote "Commentaria in libros Feudorum," printed at Frankfurt in folio in 1507, a work much esteemed, and often cited by the Italian lawyers.

ALVAYAZERA, in Geography, a small town of Portugal in the province of Beira, containing one parish, and near 1000 inhabitants.

ALUCITE, in Entomology, a subdivision of insects, with digitated wings, belonging to the genus of phalena, and of the lepidoptera order in the Linnean system; comprehending 12 species.

ALUCO, sacred owl, in Ornithology, a species of the owl, or striæ, with nutty head, black irides, and the primary wing-quills serrated at the edges. This species, the La Halloette of Buffon, the Ulula of Brill. Gen. and Aldr. the black owl of Albin, and the brown owl of Pennant and Lewin, is 15 inches long; its head is large and round, without tuft, and face fawn, as it were, within the plumage; the beak of a yellow or greenish white; the upper part of the body of a deep iron grey, mottled with black and whitish spots, the under part white, with longitudinal and transverse black spots or bars; and the legs white, sprinkled with black points. It flies lightly, and not rolling with its wings. The outmost feather of the wing is two or three inches shorter than the second, and this shorter than the third; and the longest of all are the fourth and fifth. Its cry is a kind of howl, resembling that of wolves, whence its name ulula, and the German bubo, or hoo-boo. It inhabits Europe and Tartary, and is said to be considered as sacred by the Cyprians, for having contributed to preserve the life of their great monarch, Jenghis Khan, though Mr. Pennant attributes this to another species. In summer it lodges in the hollows of decayed trees in the woods, and in winter approaches human habitations. Its most usual prey is field-mice, which it swallow whole. It generally lays four eggs, of a dirty grey colour, in the nests of other birds, such as buzzards, bullocks, crows, and magpies. Gmelin's Linna. Buffon's Birds, vol. 1. p. 291.

ALUCO, in Entomology, a species of Phalena Bombyx, with brown wings, cincereous at the apex, found at the Cape of Good Hope.

ALUCO is also the name of a species of the Phalena Notata, with dentated wings, brownish, indulated with black and three marginal spots, found in China.

ALUCO is also the name of a species of Murex, in the class of Vermae, with tuberculated spiral windings, the middle drawn spinose, the columnella uniplicate, and the tail ascending. There are several varieties of this shell. It is found in the Southern Indian Ocean, Red Sea, and Atlantic, about four miles long, white, sprinkled with caruncle or brownish dots, the windings transversely frigate, the lip roundish, and the aperture oval.

ALUDDA, or Aulcca, in Ancient Geography, a town of Asia Minor, in Phrygia Major, upon the confines of Lydia.

ALUDEL, Alucel, Fr.—Sublimirtappa, Germ.—Aludello, Ital.—Capella SUBLIMINARIA, Lat. The aludel of the chemists is a kind of pot or crucible, generally made of earthen ware, but sometimes of glass, open at both ends for the purpose of collecting the products of dry sublimations. The matras or cucubit, containing the sublimation to be sublimed being fixed in a sand bath, is covered with an aludel, so disposed that the neck of the cucubit may be received into the body of the aludel; this again is covered in like manner with another aludel, so on increasing the fire according to the volatilities of the substances operated
on, the neck of the upper alveol being either flopped with a cork or covered with an imperforated capulse. See Chemistry, Plate iii. fig. 14. A, the cucurbit, B, a series of alveols, C, the capital. It was in an apparatus of this kind, that those crystalline sublimates formerly called "flowers," as flowers of sulphur, of arsenic, of Benzoic, &c. used to be prepared, and having each telemitt and droogift manufactured three articles for his own use: but since the floops have been supplied for the most part from large wholesale laboratories, the alveol, together with various other vessels, has been discarded, and its place supplied by apparatus of more simplicity and greater expedition.

ALVEARÈ, in Conchology, a species of Trochus, with a plicated nudoloide shell, flattened transversely, and adorned with bands of concentenated points, funnel-shaped umbilicus, and eulated columnella. It is found in India; the shell is coloured with a mixture of green and white, within pearly, and finely annulated.

ALVEARIUM, in Anatomy, the bottom of the cowl, or hollow of the auricle, or outer ear. The alvearium auris is a cavity, terminating at the meatus auditory, wherein that bitter yellowish excroment is collected called cerumen, or ear-wax.

ALVEARIUM, also signifies a bee-hive. The word is formed of alveus, a channel, or cavity; in allusion to the alveoli, or cells, in bee-hives.

Some of the ancients use also the word alvearium for a bee-house, more usually called among us apiary.

ALVEARIUM is sometimes also used figuratively, to denote a collection.

In which sense, alvearium amounts to much the same with what we otherwise call thebirus, cornucopia, or the like. Vinc. Boeris has published an alvearium of law.

ALVEHZIT, among Arabian Writers, denotes what we ordinarily call falling-flares, or star-shot.

ALVENSELEN, in Geography, a bailiwick of Magdeburg, in Germany.

ALVEOLATE, in Botany, a term used in the same sense with favourum, or honey-comb, to express a part that is furrowed by oblong depressions.

ALVEOLI, in Anatomy, those little sockets in the jaws wherein the teeth are set. The alveoli are lined with a membrane of exquisite fineness, which seems to be nervous, and is wrapped about the roots of each tooth; from whence, and from the nerve, proceeds that pain called odontalgia, or tooth-ach. Of these alveoli there are usually 16 in each jaw.

ALVEOLI is more especially used, among Naturalists, for those waxen combs in the combs of bees, wherein their honey is deposited.

ALVEOLUS, Nautilus Orthocera of the Linnaean system, in Natural History, the name of a marine body, found frequently foillie, sometimes lodged in the cavity at the end of the belenmites, and sometimes loofe; and in this last case, often so large, that we cannot suppoae any belenmites ever to have existed so large as to have been able to contain it. We do not meet with theae at this day in their recent state, but what we find of them foillie are ever large at one end, and tapering to a point at the other, and are composed of several hemispherical cells, like to many bee-hives joined into one another, and having a flabellum, or pipe of communication, like that in the thick nautilus. These are sometimes found perfect and whole, but much more frequently truncated, or wanting a part of their smaller end.

Klein.

ALVERD, in Geography, a town of Perthus, in the province of Taberillan, 20 leagues south-south-west of Perbad. Vol. I.

ALVERNO, a mountain of Italy, in the duchy of Tuscany, 10 miles north of Borgo San Sepulchro.

ALVEROA, a small town of Portugal, in Estremadura, containing, within a district of one parish, about 400 houses, two leagues from Lisbon.

ALUESEN, in Botany, a name used by some for the faithful, or hug's-tunnel.

ALVEUS properly denotes a channel.

ALYVES is applied, by some Anatomists, to the timid lactic branches arising from the receptaculum chyli under the diaaphragm.

ALVES, when used in Antiquity, to denote a small vell, or boat, made out of the trunk of a single tree, by borying or cutting it hollow.

Such was that wherein Romulus and Remus are said to have been exposed.

ALVIDONA, in Geography, a small place of Naples, in Calabria Citra, nine miles north-east of Caffano.

ALVIDUCA, compounded of albus and ducis, I draw, openers of the belly, in the Materia Medica, a term used by some writers for laxative or purgative medicines.

ALVIGNANO, in Geography, a town of Naples, in the country of Lavora, 10 miles east of Capua.

ALVITO, a town of Naples, in the country of Lavora, six miles east of Sorrento.

ALVITO is also a small town of Portugal, in the province of Alentejo, containing about 2000 inhabitants, and a barony.

ALULA notia festiva, baiard or spurious wing, in Ornithology, is a kind of appendage to the true and principal wing, placed near its outer extremity, at the base of the primary quill-feathers, and consists of three to five small feathers of the quill kind.

ALUM, ores of, in Mineralogy. Under this head we include all those minerals which either contain alum ready formed, or are capable of yielding this salt by the process of manufacture. They may be conveniently divided into three families: 1. The salines, all the species of which are almost wholly soluble in water; 2. The airy-saline, in which the soluble particles are diffused into a large proportion of earth; 3. The earthy, which containing no alum but only the materials of it, are insoluble and deliquescent of that sweetish astringent taste, which is characteristic of the two former.

I. Family—SALINE. Taste aluminous, almost wholly soluble in water.

Species 1. Capillary alum.—Vitriolum halotrichum, Werner.—Haarzfels, Germ.—Terrae tinca, Hung.

The colour of capillary alum is either pure or yellowish white, palling into tabella yellow and grey, upon exposure to the air. It occurs in long very tender capillary crystals accumulated on an earthy base, or amorphous or tooth-shaped. Its external lustre is glasby and generally gimmering, advancing sometimes to the little-shining, in the pure white varieties approaching more or less to the mother of pearl lustre; internally it is shining or little-shining with a glasby lustre. The amorphous has a fine, t nut, or curved fibrous fracture. It flies, when broken, into indeterminate not particularly sharp fragments. It appears sometimes to contain slender columnar distinct concrections: is transparent, soft, and very brittle; though each separate crystal has a slight elasticity: fire, gravel, according to Scopoli 1835; has a sweetish astringent taste.

By the analysis of Scopoli, it is soluble in three times its weight of water, and coaguat of alum and sulphuric iron. It is met with at Creminitz and Chemnitz in Hungary, also in the quick-silver mines of Ydria, where it has generally been mistaken for white vitriol.

The Colour of this variety is yellowish or greyish white. Its external luster is dull, but sometimes glistening, or even little shining. It consists of slender irregular hair-shaped fibers, either single or accumulated, and slightly adherent to each other; it is seldom flaky or amorphous. It is usually opaque, but sometimes also transparent or semi-transparent. It excites the same taste on the tongue as the preceding species.

It is found efflorescing on bituminous schilus at Göttwig in Austria, on grey argillite in Carnithia, in clots and cavities on Stromboli, the Solfatara, the grotto of St. Germain, Mileno, and other places in Italy.

In Klaproth's Essay is a description of the native alun of Mileno, from which it appears, that 100 parts yield by simple solution and crystallization 47 of perfect alun, and 29 more by the addition of the necessary quantity of potash, the remainder being found with a little felspar, and a small trace of oxidized iron.

Species 3. Mountain butter.—*Vitrilum alunum butyratum*, Werner.—*Bergmutter, Germ.*

Its colour is that of a more or less dun isabella yellow, or yellowish brown. It occurs amorphous commonly overlaying the surface of aluminous schilus in lumps or clots. Internally it is shining, with a waxy luster. At first it is very soft, but by exposure to the air it becomes of a middle-consistency, between crumbly and compacted, and is then of a fibrous fibrous texture. Its fragments are indeterminate, bluish. Its distinct concretions are small and fine granular. It is transparent on the edges, and lightly elastic or fleshy. It leaves on the tongue an acridly sweetish alluring taste.

It occurs in many places where the aluminous schilus is plentiful, and exposed to the air, as at Muskh in the Oberlaufer: it is also found in Siberia.

It has not yet been analyzed, but probably differs from the preceding, in containing a larger proportion of clay and iron ochre.

11. Family. Earthy-saline. Talc alunum, very little soluble in water. All the ores that belong to the third family are occasionally found to have undergone a natural change, similar to what is produced in them by art at the alum manufactories; in consequence of which they often yield, by lixiviation, a variable proportion of alum, and exhibit the sweetish alluring taste peculiar to this kind.

Upon the purely sulphureous ores or alun-flake with its varieties, this alteration seems to take place by the action of sulphuric fire: alum is also probably formed in mere earthy compounds of flake and alum, which contain no sulphur when they overlie heated sulphureous strata, by which they are first cracked and then penetrated with sulphurous acid vapours.

Examples of both these occur in Italy at La Tolfa, not far from Civita Vecchia, and the Solfatara in the Neapolitan dominions; from 100 parts of which Bergman obtained by mere lixiviation eight parts of perfect alum. 2. The well known property of pyritic and pyritous-bituminous matters to heat, and afford vitriolic fells by the combined action of air and moisture, may also be traced, though in a slighter degree, in the aluminous ores of this description; hence it is that the upper strata of the foister aluminous schilus of the alum earth, and the sulphureous peats are occasionally impregnated with alum. The marly black soil of Arragon, that yields pure alum by lixiviation (Bowles's Spain, p. 383.), appears to be of this kind; also the aluminous turf of Helmborg in Scania (Bergen, Efl. ii. vol. i. 353.) and a vein of black earth in the Skeltland islands, containing alum and sulphated iron. Alum is also extracted from fossil wood in Helle; (Vogel. p. 322.) Springs in the neighbourhood of these strata sometimes hold a little alum in solution, as those near Halle (Chym. Ann. 1788, p. 374.)

Family 111. Earthy—no aluminous taste—not soluble in water.

Alum-flake is greyish or yellowish white, isabella yellow, or light smoky grey; amorphous. Its internal luster is dull, and sometimes glistening. Its fracture uneven, splintery. Fragments indeterminate or sharp-cornered. It has distinct conchoideal concretions, which might be mistaken for a fine fibrous texture. It is nearly transparent at the edges. It is half-hard palling into hard. Brittle, inpdip, feels meagre; and adheres flitely to the tongue.

Its fp. grav. according to Kirwan, is 2.424. It has an earthy smell, and when projected on a red hot iron it billes and gives out a black smock, a light sulphurous smock, and the residue acquires a reddish colour. According to Monnet's analysis, it consists of sulphur and clay. In nearly equal proportions, together with a little iron and potash. Bergman found it to contain about 43 sulphur and inflammable matter, 35 alumine, and 22 flake.

It is found in maizes and veins running through argillaceous rocks at La Tolfa, in the flates of the church, and in the ore from which the Roman alum is prepared. A volcanic origin has been generally attributed to it, but apparently without reason, as the veins of La Tolfa have been traced into the Apennines. It was formerly supposed to be mostly calcareous, as is evident from the Lyonins quoted above. La Metherie (Theorie de la Terre, vol. ii. p. 215.) has hazarded an opinion that it is principally alum superstitrated with alumine, and therefore earthy and inodorous. This is a notion which derives high probability from the recent analysis of this ore, by Vanquelin (An. de Chem. vol. xxii. p. 275.) who obtained from it

A similar kind of ore has been discovered in rocks near Polinire in Brittany.

Of this there are two varieties.

Its colour is bluish black, sometimes greyish black. Amorphous, or in concentric balls embedded in the strata. Its internal luster is glistening, or dull. Fracture flat or curved flat. It flies when broken into broad flakes, or trapezoidal fragments. Gives a grey smack; feels rather smooth but meagre. It is soft, brittle, and but little elastic.

Var. 2. Shining alum-flake. *Glansender alumoflakier, Germ.* *Argilla aluminaria sibelia nitida, Werner.*
It is of a bluish black colour, generally passing into the iron black—occurs amorphous, in large flints. The brittle of its parallel fracture is shining, or even brightly shining, with a fracture between common and semi-metallic; that of its cross fracture is dull, or at most glimmering. Fracture thick and curved flatly, seldom thin flatly. Its fragments therefore are sometimes thick and sometimes thin fibrous. It feels smooth; is half hard; brittle; and but little chafing.

Both varieties are found in Norway, at Whitby in England, in Sweden, in Saxony, and various other provinces in Germany. The alum of Great Britain and the north of Europe is almost entirely made of it, for which use the second variety is said to be the best adapted. It commonly occurs in the neighbourhood of coal, and seems to differ in no respect from the bituminous slate impregnated with pyrites.

It has a light or dark blackish brown, brownish black, or blackish grey colour. Occurs in large flints of earthy or irregularly matted mica. It is generally dull, but when containing scattered particles of mica, becomes occasionally glimmering. Its fracture is between compact earthy and imperfectly flat. Its fragments are partly flaky and partly irregularly blunted corners. Its streak has a feeble luster. It is very soft, and may be rubbed to powder between the fingers; is brittle, and of very little lability.

When placed among burning coals, it generally blaze a little; and when moistened and exposed to the air in large quantities, it heats and not unfrequently inflames. From 100 parts of it, after tereftication, Klaproth obtained 10 alum, 7.25 sulphated iron, 2.25 sulphated lime, and 1/6 sulphated magnesia.

It is found in alluvial and secondary flints, and is intimately connected with bituminous wood, alum flate, and coal flate. Is used in the manufacture of alum in Germany.

ALUM, Manufacture of.

In order to appreciate rightly the peculiar advantages or disadvantages of the several methods of manufacturing this salt, it will be necessary to enter into a previous enquiry concerning the nature and proportions of its elements, and the different chemical varieties of alum, which have hitherto been confounded under the same name.

S. Analysis and Composition of Alum.

The identity of the earthy bafe of alum with pure clay, was first ascertained by Geoffroy and Hellot, and the successive experiments of Pott, Margraf, and Macquer, upon the same subject, put an end to the controversy concerning the nature of aluminous earth, which has ever since been universally received as the same with pure clay or alumine, according to the reformed nomenclature. The acid in alum has always been considered as the sulphuric, and the only question among chemists on this head is whether the acid is necessarily in excess. A solution of alum reddens litmus paper, and exhibits other properties of an uncombined acid; but on the other hand it is contended by Morveau, that crystallization and edulcoration would effectually separate any such excess, and therefore that the change of vegetable colours is not an unequivocal proof of superabundant acid. Referring the consideration of this and similar cases till we come to treat of the nature of alums, it is sufficient to observe here, as indeed Bergman has clearly shown, that the acid exists in alum with two very different degrees of affinity. By the action of iron filings on a solution of alum, all the signs of uncombined or loosely adhering acid are destroyed, sulphated iron is produced, and a white earthy precipitate takes place, consisting of the alum deprived of a small portion of its acid, but still retaining the greater part, as may be proved by the further decomposition of it by a caustic alkali; and to this superabundant or slightly combined acid, is entirely owing the taste, the solubility, and most of the other external characters of the salt.

The component parts of alum, according to Bergman, are 38 sulphuric acid, 18 alumine, and 44 water of crystallization. Observing, however, that those solutions, which contained a great excess of sulphuric acid could not be brought to crystallization by the addition of a solution of potash or barytes; but only by means of potash or ammonia; finding also sulphat of potash in many species of alum, he appears often induced to believe that the alum of commerce is a triple salt consisting of sulphuric acid, alumine and potash. The subject remained in this state of uncertainty till it came under the notice of the most eminent analysts of modern times, the accurate and indefatigable Vaquelin, to whose admirable Memoir on the combinations of alumine with sulphuric acid, we are indebted for the final illustration of a question of equal importance to the chemist and manufacturer.

In order to ascertain the component parts of alum, and to determine the necessity and peculiar agency of alkalies in its preparation, he dissolved in pure sulphuric acid alone alumine equally pure; the solution was evaporated several times to dryness to drive off the excess of acid, and the dry and pulverulent residue being then re-dissolved in water, was brought by evaporation to various states of specific gravity for the purpose of crystallization; but, notwithstanding every precaution, a soft magma, consisting of crystalline flakes, was all that could be procured. The solution, which had thus constantly refused of itself to afford crystallized alum, began to deposit some immediately on the addition of a few drops of potash, and by gradually adding the alkali, drop by drop as the deposition of alum ceased, the whole was converted into pure alum, without the smallest mixture of sulphated potash.

Another portion of the same pure aluminous sulphat was mixed with carbonated soda, but without obtaining any crystals. Nor were lime or barytes more efficacious. Hence it appears plainly that the use of potash is not merely to engage the excess of acid, but also to have produced the same effect. Again, if potash and alumine unite only to the superabundant acid, the sulphat of potash and alumine should occasion no change in the pure aluminous sulphat; but, on the contrary, if they form an essential confluence part of alum, then they should produce the same effect when combined with sulphuric acid, as when pure. To ascertain this, a solution of sulphated alumine was mixed with a few drops of sulphat of potash, the immediate effect of which was the precipitation of octahedral crystals of alum. Sulphat of ammonia produced the same result.

It might still, perhaps, be objected that the action of these salts, as they are remarkably greedy of sulphuric acid, determined the crystallization of the alum, by the simple absorp-
tion of superfluous acid. In order to determine this, some uncrystallizable aluminous sulphat was mixed with acidulous sulphat of potash, and afforded as great an abundance of alum as when the neutral sulphat of potash was made use of. Hence, no doubt can remain concerning the influence and particular mode of action exercised by potash and ammonia in the manufacture of alum.

The experiments of Bergman and of several other chemists aforesaid, that when a solution of common alum is boiled with a quantity of pure alumine, this body combines with it, and forms a peculiar salt insoluble in water, known by the name of neutral aluminous sulphat, or alum saturated with its own earth. To this fact was added another of equal importance, by Vanquelin, namely, that the earthy part thus precipitated retains its potash or ammonia, for by digestion in dilute sulphuric acid, it is diffolved, and affords octahedral crystals of alum; it even appears from the memoir of this philosopher quoted above, that the presence of one of the two alkalies is necessary to the formation of this neutralized alum. To an uncrystallizable solution of sulphated alumine perfectly free from alum, he added some pure alumine, and found that a part of it was dissolved to the complete satura-
tion of the acid, but that no precipitation took place; hav-
ing then added a few drops of sulphat of potash, a precipitate was deposited shortly after, posssessing all the properties of the foregoing saturated alum. Hence is established the ne-
cessity of sulphated potash or ammonia, to enable alum, by combining with a larger proportion of its base, to pass to the earthy flate.

The alum of commerce always contains sulphat of potash either alone or mixed with sulphated ammonia, and as it is often of consequence to the manufacturer to know the abso-
lute and relative proportions of these salts, the following me-
thod of analysis may be had recourse to. First, let a small piece of the alum be reduced to powder, and mingled with a solution of caustic potash in sufficient quantity to decom-
pose it entirely: if then, upon gently heating, it gives out an ammoniacal odour, as is generally the case, this indicates the presence of sulphated ammonia. Having obtained this indication, let two or three hundred grains of the alum be dissolved in distilled water and put into a tubulated retort, and then add quick-lime, equal in weight to the salt: by making this mixture boil for about twenty minutes, the whole of the ammonia will be expelled, and may be con-
densed by cold water in the receiver, or a Woulfe's apparat-
s: this ammoniacal liquor, being then carefully saturated with sulphuric acid and crystallized, will shew the quantity of sulphated ammonia. The residue in the retort being mixed with warm water and filtered, a clear liquor will be obtained, containing the sulphat of potash, with some sele-
nite; this latter will be precipitated by boiling and evapora-
tion, and the remaining fluid will then deposit the sulphat of potash in a crystalline form. When the previous alloy does not indicate the presence of ammonia, the alum is to be decomposed by caustic ammonia, the precipitate is to be well washed, and the liquors being added together, are to be gently evaporated to dryness; the salt thus obtained is to be heated in a crucible tili it ceases to exhale white vapours of ammoniacal sulphat, and the residue is sulphat of potash.

§ 2. Manufacture of Alum from the saline-earthly ores.

The only place where this kind of ore is found in sufficient abundance to be worth working, is at the Solfatara, a few miles from Naples. The Solfatara, called by the ancients Forum Vulcani, Campi Leucosii, is a small plain, at the top of a hill, covered with a white foil, and exhaling sulphurous vapours which, during the night, emit a pale blue lambent light: the ground, even at the surface, is considerably warm, proceeding, no doubt, from subterranean fire. It has con-
tinued in nearly the same state from the age of Phiny to the present time, and is celebrated by this author in his Natural History (lib. xxxv. ch. 50) for its sulphur, but not for its alum, as the Abbé Mazeeus affirms. On the contrary, by his omission of the Campi Leucosii, when mentioning the various places from which alum was then procured, it is plain that the establishment of the alum works of the Solfatara is of more recent origin. The white clayey soil of this plain, being constantly penetrated by sulphurous vapours, and the exhalations during the night being for the most part mixed with the dew, and thus returned upon the surface, cause it to be covered with a light saline efflorescence. This, to-
gether with the earth to which it adheres, is daily collected and distributed into leaden cauldrons, so as to fill about two-thirds of their capacity; water is then added, till it stands about three or four inches above the surface of the clay, and this in a few hours, by the abstinence of the natural heat of the ground in which the cauldrons are set almost up to the brim, extracts the alum diffused through the clay, and de-
posits it in rough crystals on its surface. These crystals being taken out and washed in the mother liquor, are put with fresh water into other boilers, and again dissolved as before, by the natural heat of the ground; the solution is then run through a filter into large wooden coolers, and in a day or two affords a large quantity of pure colourless cry-
stals. Hence it appears that the alum exists ready formed in the earth of the Solfatara, and the whole of the manu-
ufacturing part is reduced merely to lixiviation and purifica-
tion. The proportion of salt must necessarily be very vari-
able, those parts that are exposed to the rain, and that lie above the general level, will contain the least. A specimen that was analyzed by Bergman yielded eight per cent. of alum. The Abbé Mazeeus, from six pounds of the earth, procured, by lixiviation, two pounds and a half of crystals, or about 41 per cent. The alum itself has not yet been analyzed; it seems probable, however, that its alkaline part is entirely potash.

§ 3. Manufacture of Alum from alum-flone.

It is at La Tolfa, not far from Civita Vecchin, in the Roman flate, that the manufacture of alum from this species of ore is principally carried on. All the alum known in commerce by the name of Roman alum is thus prepared, as well as the Levant or Smyrna alum.

The ore of La Tolfa forms veins of considereable hardness, which are separated by means of blasting from the rest of the rock; the pieces thus obtained are brought to the calcining oven, which is merely a hole dug in a rising ground, four or five feet in diameter, and from five to six in depth, with a lateral gallery, communicating with the open air, and the bottom of the furnace. The bottom being covered with faggots of brush-wood, the pieces of ore are skillfully laid over them, so as to form a kind of hollow vault, between the interlaces of which is an ample passage for the smoke. As soon as the fire is kindled and the flame begins to appear between the flines, a workman is at hand to regulate the combustion, that it may be neither too great nor too feeble; in the course of from three to five hours the smoke begins to decrease, and the fire burns brightly; this is allowed to go on till the finall of burning sulphur begins to be prevalent, which is a sign that the ore is sufficiently roasted. The fire is now raked out, and the flines are left to cool. The sign of this fire proceeds being well conducted, is, that the
the ore has now acquired the sweetish astringent taste of alum.

The second process begins by piling the calcined stones in long beds, on a sloping floor, the lower side of which is terminated by a ditch of water, extending along its whole length; from this ditch the beds are frequently sprinkled, and the water draining from them returns again into the reser voir. In about a fortnight the stones begin to crack and break down, and are at length, in forty days, more or less, overspread with a reddish efflorescence, and reduced into a kind of paste. A leaden boiler is now half filled with water, and when hot, fresh portions of the prepared ore are continually stirred in till a solution of sufficient strength is procured; the liquor as yet turbid is drawn off into another boiler, where it is subjected to a very gentle evaporation, at the same time that it becomes clear by the deposition of its earth. Having arrived at the point of crystallization, it is transferred by means of a pipe into a square wooden vessel, eight feet high by five wide, so constructed as to be readily taken to pieces; after remaining here for a few days, the mother water is poured out, to be boiled again with fresh alum ore in the birl cauldron, and the crystals, when dried, are ready for sale.

From this account of the process, by an eye-witness (the Abbé Mazaca), it would appear that no potash or alumina is added to the lixivium; it follows, therefore, that one or both these alkalies must be found in the ore, and this is actually the case, according to the analysis, by Vaquelin, already quoted in the preceding article.

The nature of this ore has been long misinterpreted, as well as the rationale of its manufacture, and the analyses of it undertaken by Bergman and Monnet have only served to perpetuate the error. Both these chemists found a large proportion of sulphur in it, while Vaquelin finds only sulphuric acid; this apparent contradiction, however, may easily be reconciled, by considering that the ore contains carbonaceous matter enough to blacken it, and to give out a light flame when powdered and spread on a hot iron; hence, if the analysis of Bergman and Monnet was begun by distillation in a close retort, as it probably was, the decomposition of the acid and production of sulphur is readily accounted for. Admitting then the proportions of this ore, as ascertained by Vaquelin, to be sufficiently correct, viz. alumine 43.92; sulphuric acid 25.4; potash 5.08; water 41; flex 24; it ought to be considered as a native faturated alum, with excess of earth and deficiency of alkali, intimately mixed with flex and inflammable matter. The action of the fire in the roasting is to drive off the inflammable matter, and from the sweet aluminous taste which is thus communicated to the ore, notwithstanding the loss by volatilization of part of its sulphuric acid, it seems also to effect a separation between the alum and the excess of earth. The subfrequent cracking and breaking down upon exposure to the air and moisture, is probably caused by the absorption of water of crystallization.

But though a considerable proportion of alum is thus obtained, without the addition of potash, it may be worth while to endeavor whether a larger quantity might not be procured by a trifling additional expense. The alum of La Tolla contains by Vaquelin's analysis

| 49 | sulphate of alumine |
| 7  | sulphate of potash |
| 44 | water |

And according to Kirwan, (on the proportion of real acid,

&c. 1792) 100 parts sulphate of potash are composed of 54.8 potash and 45.2 sulphuric acid; and 100 parts alum of 63.75 alumine and 36.25 sulphuric acid. Therefore, the 25 parts sulphuric acid in the ore require 37.1 alumine and 44.5 potash. But the ore only contains at most 3.68 potash, so that no more than 16 parts of sulphuric acid will be converted into alum; the remaining 9 will be left in combination with alum in the mother water; and this agrees with the observation of Mazaca, who speaks of an anhydrous acid, efflorescent falt bing left in the residue of the lixiviated ore. The 9 parts of acid that are thus lost, may, however, be converted into alum, by the addition of 1.42 potash, or about 3. sulphate of potash.

From these data the ore of La Tolla ought to yield by the present method of working it 78.5 per cent. of crystallized alum; or by the addition of 3 per cent. sulphate of potash, 12 per cent. of crystallized alum. In this calculation, however, no allowance has been made for the sulphuric acid volatilized in the roasting, and that portion of the salt which cannot be extracted by lixiviation in the large way from the prepared ore; both these circumstances will, no doubt, diminish considerably the produce of alum, but the proportions must vary much according to the skill and attention of the manufacturer.

§ 4. Manufacture of Alum from the Pyritic ores.

All the European alum, except what is manufactured at Solitata and La Tolla, as described in the preceding sections, is prepared from the alum slate or alum earth, and these containing only the remote principles of this falt, a much more complicated process is required than where the alum exists ready formed in the ore.

The only necessary ingredients in the pyritic-aluminous ores are clay, and pyrites, or sulphur of iron. Besides these, however, there is generally a variable proportion of bitumen, lime, and magnesia. The bulk of it is procured from the black micaceous species in which the pyrites is thoroughly diffused through the mass in such small particles as to be indistinguishable from the rest. Such, however, as contains even large nodules of pyrites, is very capable of being manufactured, much of the Swedish ore being of this kind.

The first thing to be done is to dip the pyrites to decompose into sulphate of iron, (green vitriol), and this at the manufacture of Fgone, in the department of Ource, in France, is brought about by simple exposure of the ore to the action of air and moisture; this ore, however, is of the very best kind, moderately soft, free from bitumen, and with the ingredients well mixed, and even with these advantages, the process requires three years. The more flinty and bituminous kinds, such as those of England and Sweden, are subjected to a previous roasting. For this purpose a layer of billet wood or coals is placed on a floor of rammed clay, and let fire to; upon this are thrown by degrees moderately small pieces of unburnt ore, till a stratum is formed, about half a foot in thickness; these presently take fire, by their own bitumen, and are then covered with a stratum of nearly the same thickness of ore that has been already roasted and lixiviated; to this succeeds a layer of unburnt ore, and thus alternate layers, eight or nine in number, are gradually added, till the pile is completed. Care is taken by protecting it from heavy rains, and covering those parts exposed to the wind, to keep up the heat of a moderate equable degree till the bitumen being consumed, the fire goes out of itself. If the ore is now examined it will be found to be of a reddish colour, containing a small quantity of sulphated iron and alumine,
alum, and in some of the Swedish manufactories is accordingly lixiviated without any further preparation. In the English and German alum-works, however, the roasted ore is watered lightly, and exposed for a greater or lesser time to the action of the air, by which the sulphur of the pyrites is more completely oxygenated, and in consequence a larger proportion of alum is obtained. In the manufactories of France, already mentioned, the singularly judicious practice is observed, of lightly roasting the ore after spontaneous efflorescence.

The acid being thus developed, and in part united to the alumine, the proces of lixiviation takes place. For this purpose the ore is thrown into large refractory vessels of stone or wood, furnished with a false bottom, to serve the purpose of a filter; water is then poured on, and remains for twenty-four or more hours, in which time it diffuses the greater part of the salts; this being let out by means of a cock fixed nearly level with the bottom of the resevoir, a fresh quantity of water is added, in order to exhaust the ore of all soluble matter. The second lixivium is weaker than the first, but is afterwards concentrated by being used instead of water for the first lixiviation of the next parcel of ore. The water with which the lixiviation is performed is cold, and it may seem at first to be an obvious improvement to make use of boiling water; the experiment has, however, been tried without the desired result, the increased strength of the lixivium not being adequate to the time and expence of fuel. Where the lixivium is kept in large resevoirs, exposed to the weather, much depends on the dryness of the feason, a few heavy rains weakening the liquor to such a degree, as to add considerably to the cost of boiling down. In Sweden and the northern countries, various attempts have been made to concentrate the liquor by freezing, but the success has not answered expectation; for a saturated solution of alum congeals at nearly the same temperature with common water.

The proces of boiling down succeeds to that of lixiviation, and is always performed in leaden boilers, copper being for the most part too dear a material, and iron being attended with the inconvenience of decomposing alum. The lixivium is mixed in the boiler with the mother-water of a preceding boiling, and this is done either by filling the boiler with a mixture of mother-water and liquor, and supplying the loss by evaporation with fresh liquor, or by filling the boiler at first with liquor, and supplying the waffle by the above mixture. The evaporation falls from twenty-four to forty-eight hours, according to the proportion of mother-water. In Saxony, where the proportion of mother-water is large, and the lixivium is brought to a high degree of concentration, the boiling continues without interruption for eight days. At the end of these respective periods the specific gravity of the liquor is asayed by a leaden hydrometer, or, with greater exactness, by filling a bottle of known size with the liquor, and then, by weighing it, to ascertain the comparative specific gravity between it and water. This being done, an alkaline solution is added, and the first crystallization is brought about. In the Saxon manufactories, where the liquor is uncommonly concentrated, as soon as the evaporation is finished the contents of the boiler are let out into a resevoir, where they are strongly agitated for half an hour, during which time a certain proportion of soap-makers lees and putrefied urine is added; and the liquor being then let into another vat, the crysflals of alum begin immediately to be deposited; at the end of a few days the mother-water is laded out, and the crysflals are collected and washed. The method followed in the English works differs somewhat from the Saxon practice; in thefe, when the liquor appears by the hydrometer to be sufficiently evaporated, the fire is withdrawn from the boiler, and a stream of impure alkaline lixivium, from kelp and soap-maker's ashes, is let into the liquor already in the boiler; at the same time the cock at the bottom of the boiler is turned, so as to allow the contents of it to flow into a resevoir, by which management the two liquors are speedily and effectually mixed. It remains in this resevoir for three hours, during which it deposits an earthy and ferruginous sediment by the action of the alkali, and becomes of a clearer fluid; it is then transferred into another large vat, and has its specific gravity again taken, according to which a greater or less quantity of putrid urine is added to lower it to the proper standard; being then agitated briskly for a quarter of an hour it is left at rest, and in the course of five days the crysflals are deposited. In some French and Swedish manufactories the liquor, after being boiled down, is merely agitated for some time without adding any alkali, and then passed into the crysflalizing vat. The rough alum being washed in order to separate it from the green vitriol which is deposited along with it, is put into a small pan with a little water, and when dissolved and boiling hot, some bullocks blood, or other similar substance, is usually added for the purpose of clarification: when this is effected, the liquor is run into casks, where the crysflals are deposited in large masses; after ten or twelve days the mother-water is poured out, and the salt, being then dried, is ready for sale. By keeping in mind the analysis and experiments in § 1. of this article, it is easy to understand the rationale of the manufacturies, as well as the advantages and faults of each process. As soon as the pyrites are converted into sulflphat of iron, whether by roasting or by spontaneous efflorescence, it begins to be gradually decomposed by the lime and magnesia which may happen to be in the ore, therefore the fels there is of these two earths, the greater celeris paribus will be the produce of alum. Clay is incapable of decomposing sulflphat of iron; but by exposure to the air, especially when affected by the action of heat, the metal becomes highly oxygenated, and is no longer combinable with the acid which then unites with the clay, as being the substance in the ore of next affinity. Hence arises the advantage of the practice at France of roasting the ore after the formation of the sulphat of iron. We have already seen in § 1. that sulphat of alumine, even with excess of earth, is soluble in water, but that it becomes insoluble on the addition of potash; on this account, therefore, coal, which contains little or no potash, is a far preferable fuel for roasting the ore than wood which yields a great deal, as all the alum, thus rendered incapable of extraction by lixiviation, is lost. The bitumen in the ores, however, diminishes the consumption of wood, and the lixivium confits of the sulphats of iron, of alumine, of lime, and magnesia. By long boiling and evaporation the iron becomes so far oxygenated, that the addition of an alkali will decompose the sulphat of iron, rather than the sulphat of alumine. If the alkali is ever too little in excess, the aluminous sulphat will be the next decomposed; this is therefore to be carefully avoided. Nor is the kind of alkali a matter of indifference, for since only amonia and potash are capable of forming crysflalizable alun, it would appear that the use of foda in the English manufacturies might be advantageously superceded by potash; indeed the chief use of the kelp leem to confit in the potash which this impure foda contains. The principal thing to be attended to in the boiling down is to bring the liquor to such a degree of concentration, that the alum shall be deposited with as little as possible of the other farts.

The mother-water, when thrown away, holds in solution sulphates of potash or foda, and sulflphat of magnesia, the extraction of which was made the subject of one of Lord Dun-
donald’s patents, but we believe the profits have not yet answered the expense.

The nature of alum, and consequently the true theory of its manufacture, has only been known since the publication of Vanquelin’s excellent memoir on the subject in the Annales de Chimie; it is not surprising, therefore, that all the long-established processes should be more or less defective. Perhaps the following method would be found to combine more advantages, and be subject to fewer inconveniences than any which has been hitherto put into practice. The ore should be first lightly roasted with coal to drive off the bitumen, and forward the decomposition of the pyrites, which may be further accelerated by moderate waterings, and exposure of fresh surfaces to the action of the air. When these efflorescences appear at the top of the heaps of ore, and their interior, upon being dug into, also forms penetrated with white faine particles, let the ore be disposed in alternate strata with coal, and again roasted, so as to decompose as much as possible of the sulphated iron, and combine the acid with the clay; the flower and more gently this process can be carried on, the more completely will its object be answered. The liquor obtained from this roasted ore will consist chiefly of sulphated alumine, nearly satu rated with earth, but, on account of the absence of potash, perfectly soluble. By the subsequent boiling and agitation, part of the sulphur of iron would be decomposed, and this oxidation of the iron might perhaps be still further effected, by pouring the liquor through heaps of faggots, exposed to the wind, as is done in the houses of graduation for brine in France and Germany. The ferruginous and selenic sediments being now allowed to settle, the clear liquor ought to be transferred into another revervoir, and there mixed with a hot solution of acridulous sulphate of potash, such as remains after the diffilution of aquafortis from nitre and sulpharic acid; crystals will be immediately deposited of an alum much purer than common; and thence, by a further clarification, may be made equal to that of La Tolfa.

§ 5. Manufacture of Alum by Chaptal’s process.

An attempt had been made, but with little success, at the manufactory of Javelle near Paris, to prepare alum by the direct combination of its constituent principles; but it was not till the admirable and decisive experiments, in the large way, by Chaptal, published by him in the genuine spirit of philosophic liberty, that the practicability of this method could be said to be established. According to the modern way of preparing sulphuric acid, the requisite proportions of sulphur and nitre being mixed together, are brought to combustion in a closed chamber lined with lead; the sulphur is thus acidified and converted into vapour, which by degrees unites with the water that overspreads the floor of the chamber, and forms a liquid, diluted sulphuric acid. A similar process was instituted by Chaptal, only substituting dried clay or brick for the water; the result of which was so favourable, that a large manufactory on the same plan was set on foot; which, having continued in full activity for several years, and producing alum only inferior to that of La Tolfa, merits a particular description.

The chamber in which the combustion is performed is 91 feet long, 48 feet wide, and 31 feet in height to the pitch of the roof. The walls are of common masonry, lined with a moderately thick coating of white plaster; the floor is a pavement of bricks, set in a mortar, composed of baked and unbaked clay; and this first pavement is covered by a second, in which the bricks are made to overlap the joints of the lower ones, and are themselves firmly connected to each other by a cement, composed of equal parts of pitch, turf, peat, and was, made boiling hot, and poured between the joints instead of mortar. The roof is of wood, and the beams are flat much less distances than common; they are also channelled with deep longitudinal grooves, for the purpose of receiving the planks that fill up the space between the beams; so that the whole of this great area of carpentry does not present a single nail. The chamber thus constructed was covered on the sides and top with a layer of the cement just mentioned, applied as hot as possible to as to penetrate into all the pores of the wood and plaster; three more successive layers were then laid on, and the hill was polished so as to present an uniform, even, solid face. In order to prevent the wood-work of the clading from warping, it was covered on the outside with a thick coating of cement, and a light roof of tiles was laid over the whole. By substituting this cement for a lining of lead, a vast saving was effected in the first expense; and it has been found, by long experience, to require much fewer repairs than even lead itself.

The clay ought to be of the purest kind, such as pipe-clays; that it may contain neither lime nor magnesia, and as little as possible of iron. It is to be tempered with water, and made into balls five or six inches in diameter; these being dried in the sun, are afterwards calcined in a furnace; the first effect of the heat is to blacken them, but soon after they become red hot, the carbonaceous matter which causes the blackness is burnt out. Being thus withdrawn from the fire and cooled, they are broken down into small fragments, and spread on the floor of the chamber. In this state they are exposed to the vapour of sulphuric acid from the combustion of sulphur and nitre; and in a few days the pieces are observed to crack and open, and to be penetrated with fonder faine crystals. The earth being at length covered with efflorescences, it is removed from the chamber, and exposed to the air under shelter of a shed, that the acid may obtain its biggest degree of oxygenation, and become thoroughly united with the earth. It is now liquefied, and the liquor contains, in solution, little else than acridulous sulphate of alumine; this being boiled down to the proper consistence, a solution of sulphated potash (being the residue in the pots of combustion from which the sulphuric acid was produced in the chamber, and of silting of the alkaline base of the nitre combined with some of the sulpharic acid) is poured in, and the liquor being then transferred into a large vat, perfect crystals of alum are shortly deposited, which are afterwards refined in the usual manner.

The advantages of this process are numerous. It may be carried on whenever a supply of proper clay can be had. The space taken up by the works is much less extensive than what is required according to the common methods. The whole manufactory is performed in a month one-third of the time usually necessary. A large quantity of fuel is saved. The extraneous farts in the mother-water are fewer; an important use is made of the residual sulphur of potash; and lastly, the alum itself is much purer, and almost equally well adapted to fix the delicate dyes as that of La Tolfa, the commercial price of which is generally about double that of the English alum.

§ 6. Brunswick Alum.

The dilute red colour of the rock alum, and the flesh-coloured efflorescences with which its crystals are covered, being its distinguishing character among the merchants, occasioned two brothers of the name of Gravenholt to manufacture, some years ago, a spurious imitation of it at Brunswick. We know not whether the manufacture is still carried on or not; but if it is, the public will be benefited by the communication of an easy method of detecting the counterfeit, more especially...
especially as the roch alum is the kind used in medicine, and the Brunswick imitation of it contains argillic. The external appearance of the two sorts differs but little. The taste of the Brunswick alum is less sappy than that of the roch alum, it is less soluble in water, and when heated to redness, it loses only 37.5 per cent. of its original weight, while the other loses 59 per cent. The roch alum, when exposed to the blow-pipe, becomes opaque, swells, foams, and is converted into a rufhing white mass. The Brunswick alum, on the contrary, swells, scarcely foams at all, but melts, and becomes of a green colour, exhaling at the same time an arzenical vapour. Again, the precipitate from a solution of roch alum by potash or soda, being mixed with borax, fuses before the blow-pipe into a white or yellowish white; whereas the Brunswick, by the same treatment, affords a violet-coloured globule: and in fact it is nothing more than common alum, containing a little cobalt and arsine.

The Roman alum, manufactured at La Tolfa, is the purest and dearest of all; it is in pieces about the size of a walnut, shining more or less of its crystalline form, and is opaque, on account of a farinaceous efflorescence with which it is covered. The Levant or roch alum appears in fragments of nearly the same size as the former, but in which the crystalline form is more obscure; it is externally of a dirty rose-colour, and internally exhibits the same tinge, but clearer. Smyrna is the place whence it is usually shipped for Europe; but it was anciently made at Rocca, or Edeffa, in Syria, whence its commercial name roch-alum. The French alum, that is, Chaptal's, described in § 5, is in small, clear, colourless crystals. The English is large, irregular masses, considerabler harder than the others. Equal portions of all these kinds, being exposed in a muffle to a red heat, were weighed after the intumescence was over, and the lofs by calcination in the Roman alum was 50 per cent.; in the Levant alum 40 per cent.; in the French alum 57 per cent.; and in the English 47 per cent. Of pure water, at 144° Fahr. Roman alum required 14 times its weight for solution; Levant alum required 12 parts; French alum 13 parts; and English 15 parts.

Equal parts of these four kinds of alum being dissolved separately in water, the same quantity of precipitated lime was added to each solution. That of the English alum became lightly blue at the end of a few minutes, as was also that of the French alum, though the tint was rather lighter; after some time the Roman alum became faintly blue; but the solution of Levant alum was only lightiy yellow, the natural colour of the precipitated lime. After two days an inappreciable quantity of blue precipitate was deposited from the English alum, rather less from the Roman and French, and only a few atoms from the Levantine; the three first solutions were of a bluish green tint, but the last was a very dilute yellow.

Equal parts of the four sorts were dissolved separately in pure water, and their earthy bate was precipitated by an excess of ammonia. The precipitate from the Roman alum was of a pure dead white; that of the Levantine and French was nearly equal to the Roman; but that of the English was of a jiff perceptible bluish tint. By calcination in a red heat, they all at first became blackish, and ended with being perfectly white.

Hence is apparent the superiority of the Roman alum, and the inferiority of the English, when used as standards for the most delicate colours: for other colours, and for the various ulcers besides to which alum is applied, each kind may be used indifferently. The English possesses less water of crystallization than the Roman or French; and a given weight of it will go farther than the same quantity of any of the rest, as 12 per cent. is to be deducted from the Levantine, on account of the reddish insoluble sediment with which it is contaminated.

§ 8. Historical notice of the introduction of alum-making into Europe.

The ancients appear to have been acquainted only with the native plume alum, which they procured from Lapari, and the neighbouring volcanic islands. In the 12th, 13th, and 14th centuries it was manufactured at Edeffa (Roccha) in Syria, in the vicinity of Conflantinopole, and at Phocea (Foya nova), not far from Smyrna. Bartholomew Perdis, a Genoese merchant, who had often visited Roccha, discovered, about the year 1459, a vein of alum ore in the island Ichia, and there established the first European manufacture of alum; soon after John de Casto discovered the body of ore at La Tolfa. Establishments were then made at Viterbo, Volaterna, and other places in Italy with such success, as induced Pope Pius II. to prohibit the importation of Oriental alum. In the 16th century this art was introduced into Germany and Spain; and a little before its conclusion the English alum-works at Whithby were instituted by Sir Thomas Chaloner, who had the honour of being personally communicated with the reigning pope on this very account. The earliest of the Swedish works dates no higher than 1657. Macquer's Chymisches wörterbuch von Leonharti, art. Alum. Amara de Chimie, vol. viii. xiv. xxii. xxix. Plini. Hift. Nat. lib. xxxv. c. 5. Bergman's Efftjs, vol. i. Memoires de l'Acad. Royale, vol. v. Encyclopedie Method. art. Alum.

ALUM, in Chymistry, Materia Medica, &c. See Sulphat of Alumine.

ALUMINE.—Pure earth of alum.—Pure clayey or argillaceous earth. Alumine.—Terre d'alum. Terre argileuse. Fr.—Thon-erde, Germ.

The word alumine has been adopted, without alteration, from the modern French nomenclature, by the majority of English chemists, as the technical name of pure argillaceous earth, on account of its being generally procured by the decomposition of alum, when required to be in a state of extreme purity.

Next to felds and lime, alumine appears to be the most commonly occurring earth in those fomy or earthy masses, of which the globe, as far as we are acquainted with it, is principally compos'd. It forms the effential, though seldom the greatest part of all kinds of clays, giving to them the property of ductility or plasticity when mixed with water. When in a state of more intimate combination with felds it loses its quality of plasticity, and gives to the minerals in which it enters, the characters of opacity, of hardnes inferior to that required for striking fire with steel, of that odour known by mineralogists under the name of earthly, and of that abence of crystalline form which is called amorphous; such are the innumerable masses of flate and argillaceous schistus that abound in almost all mountainous tracts, the holes, the colorific earths, the toad-bones and clay porphyries. Alumine, however, occasionally, though very rarely, enters in large proportion into crystallized minerals, and then in its external characters of hardnes, transparency and birefringence approaches very nearly to feld: such is the adamantine fpar, inferior only in hardnes to the diamond, and which contains from 80 to 90 per cent. of alumine: such also is the sapphire, which by the analysis of Klepruth appears to contain no less than 98 per cent. of pure
pure alumine. These, however, which are more properly the mineralogical than chemical characters of alumine, will be treated of more at large in the subsequent mineralogical articles.

Pure alumine, in a latter proper for chemical experiment, has hitherto never been found and proceeded in it is only of late that chemists have discovered the method of obtaining this earth sufficiently free from foreign admixture. The method of Bergman and his contemporaries was to decompose a solution of purified crysals of alum by an excess of carbonated potash, or soda, and to wash the earthy precipitate in repeated quantities of distilled water, till it came off perfectly taelles and pure; a white uniform soft matter was thus obtained, which was supposed to be carbonated alumine, and this by drying in a heat below that of redheat, was deprived of its acid and water, and was then extracted pure alumine. The insufficiency of this method had begun to be suspected for some time, however, particularly from the appearance of sulphated hydrogen, when alumine thus purified was heated with charcoal, and afterwards moistened with a diluted acid, and the admirable memoir of Vaquelin on alum, (which has already been referred to under that article) not only established the validity of these suspicions, but pointed out the method of avoiding the errors of his predecessors, and thus introduced a very important improvement in the difficult art of chemical analysis.

Alum has already been shewn to be a triple compound of alumine, potash and sulphuric acid in excess, and when this excess of acid is taken away, either by the addition of alumine or of an alkali; an insoluble salt is produced differing from alum only in the proportion of its earthy base; now the cafe with which a salt is decomposed depends very materially upon its solubility, when, therefore, we add gradually to a solution of alum a solution of carbonated alkali, the first effect is to neutralize the excess of acid, and the precipitate consists principally of the insoluble salt just mentioned; a further quantity of alkali, especially if assisted by heat, will effect the decomposition of part of the salt, but in proportion as this takes place the residue becomes mixed with the alumine, and thus is covered from the further action of the alkali. This being the case, it is obvious that no subsequent washings can do more than separate the sulphated potash; and therefore the residue, instead of being pure alumine, contains besides a variable proportion of earthy base, from which it may be removed by evaporation of the liquor obtained on heating it in a clove vessel with charcoal.

The only way by which alum can be made to yield its earth in a state of sufficient purity for delicate chemical experiments, is the following. Take any quantity of Roman alum, and diffuse it in lukewarm distilled water, filter the solution, and set it to crystallize. When by cooling and spontaneous evaporation, a sufficient portion of this purified alum is deposited, take it out and rediffuse in cold distilled water; to this solution add liquid caustic ammonia, a white precipitate will be thrown down, and continue the gradual addition of ammonia till no further precipitation takes place; heat the liquor then nearly to boiling for a few minutes, add more water, and throw the whole on a paper filter; in proportion as the fluid drains off add water, till it passes through quite talleles. The precipitate, while yet in a pulpy state, is to be removed into a flask, and digested with muriatic acid till it is dissolved. The muriatic solution being then concentrated by very gentle evaporation, till it has a length deposit crysals of alum, which are to be removed, and new liquor is to be continued till the liquor ceases to yield any more. Nothing now but pure alumine remains in the solution, the potash and sulphuric acid being got rid of, at the expense of a little of the alumine in the crysals, the liquor is therefore to be diluted with water; and ammonia fully sufficient for the decomposition of the muriated alumine being then added, the process of filtration and edulcoration is to be gone through as before, and the result will be pure alumine. On account of the length of this method and the possibility that even after all a very minute proportion of sulphated potash may still remain, it has been the practice of late with Vaquelin and Berthollet to procure their pure alumine from both of the natural clays as contain only flex and alumine, by digestion in muriatic acid and decomposition of the solution by ammonia.

Pure alumine, obtained by the above methods, is opaque, of a white yellow colour, a smooth somewhat unctuous feel, has no smell, even when breathed upon, or moistened with warm water, nor any proper taste; when placed upon the tongue, however, it abors all the moisture with which it finds itself in contact, and thus occasions a peculiar sensation of altrigency. It is readily diffusible, and remains for a long time suspended in water, but appears to be totally insoluble in this fluid. Its specific gravity is variously estimated, according to the degree of deleration, by Bergman it is reckoned 1:305, while Kirwan allows it as much as 2:10. After being thoroughly dried in a heat juft not sufficient to destroy its platicity, it is capable of absorbing 42 times its weight of water, with which it is allowed to be drop out, and the water thus mixed is retained more or less obliquely at the usual atmospheric temperature by alumine than by any other earth; a freezing cold however causes this earth to contract remarkably, and thus squeeze out a large proportion of its water.

Alumine is the only earth that poififes the property of platicity, or of being kneaded up with water into a soft coquet pate, capable of being formed by the hand or the potter's wheel into any shape that may be required; the platicity therefore of all the natural clays is owing to their alumminous part; nor is this property destroyed even by a very large admixture of other earths; the finer kinds of pottery in a fourth of the whole mass is pure alumine, and yet its platicity is unimpaired. If a piece of tempered clay is dried gently in the air, it retains its form, but becomes quite brittle; its former ductility may, however, be restored by again kneading it with water. If exposed to a red heat it hardens, contracts in all its dimensions, becomes more compact, and of greater specific gravity; and is no longer plastic, nor can its property of platicity be obtained by any other means than by solution and precipitation; hence bricks or pottery ware, after having been baked, if pounded ever so fine, are no more capable of forming a pate with water.

The action of caloric on alumine is accompanied by some interfering phenomena which deserve mentioning. If the purest plastic alumine is exposed to a low red heat, it becomes of a bluish black colour, especially on the inside, as is manifest by breaking a piece across that has been thus heated; as soon as this colour is perceived the platicity is destroyed, a fact that renders it probable that this property of alumine depends on something else than mere water. By a further increase of the heat with access of air, the carbonaceous colouring matter is burnt out, and the alumine acquires a splendid white colour, becoming at the same time harder, denser, and of less bulk; all these changes advance in gradual progression in proportion to the heat; and after it has thus experienced the full effect of our most powerful furnace, and reduced to nearly one half of its original bulk. Upon this last property is founded the use of Wedgwood's pyrometer, for measuring the higher degrees of heat. The
decrease of bulk is in part occasioned by the expulsion of the fluid particles of water; but from the augmented specific gravity of the alumine, it is plain that an actual condensation or approximation of molecule takes place, as is observable in various other porous substanances previous to fusion. Whether any artificial heat is able to bring this earth into real fusion is as yet dubious; for though Lavoisier, by means of a blow-pipe charged with oxygen gas, reduced a piece of alumine to a pasty semi-fluid state, yet it is possible, as the earth was obtained from alum, that a minute portion of potash might still be contained in it, and thus act as a flux.

Alumine has a strong affinity for metallic oxyds, especially the oxyd of iron; hence arises the difficulty, and indeed almost impossibility, of obtaining alum free from iron in the great way, because all natural clays and alumine ores contain more or less of this metal. The only way of accurately separating these two substanances is by digestion in caustic potash or soda, which will diffuse the earth, but not the oxyd.

These two substanances are also capable of acting on each other in the dry way at high temperatures; and some important experiments on this subject are recorded by Achard and Kirwan, from which it appears, that when the proportion of alumine exceeds that of the oxyd of iron, the mixture is in all cases very difficultly fusible; but that when the proportions of the ingredients are equal, and especially when the iron predominates, the result, after exposure to a heat of about 160° Wedgewood, is a dark-coloured vitreous flag.

The attraction too that subsists between alumine and vegetable or animal colouring matter, is singularly powerful. Thus, if, to a watery infusion of cochinal or madder, a few drops of a solution of alum are added, a decomposition shortly takes place, and the whole of the tinging particles unite, and are precipitated together with the alumineous base of the earthy salt, leaving the supernatant liquor wholly colourless. Fugitive colours also, by this combination, become of sufficient permanence to refit for a long time the changes to which they are subject: hence is explained the preparation of the Lake pigmenta, and the theory of Morgants in the art of Dying.

In the direct way sulphur appears to contract no union with alumine; and the hepatic gas that is separated by an acid from alum, after having been heated with charcoal, is no longer a decisive evidence of sulphur of alumine, since the discovery of the necessity of potash to the very constitution of common alum.

Upon the gaseous substanances alumine has not been observed to produce any change, although Humboldt has published (Annales de Chimie, vol. xxix.) a long and plausible memoir, to show that alumine absorbs the oxygen of the atmosphere, and hence produces an important effect in the economy of vegetation. It is true, indeed, that many natural clays will deoxide atmospheric air; but this is solely owing to the carbonaceous matter and oxyd of iron that they contain, it having been proved by accurate experiments, instituted for this purpose by Theod. Sauvire and others, that pure alumine has no effect whatever on oxygen gas or atmospheric air.

All the acids are capable, in particular circumstances, of combining with alumine; but these combinations are not accomplished with the same ease as those between the acids and alkaline earths. The stronger mineral acids will take up alumine from clay by digestion at a boiling heat, but the vegetable and other weaker acids will not readily effect a solution, except the alumine is precipitated to them recently precipitated by an alkali from sulphuric, nitric, or muriatic acid. All the aluminous salts are decomposed with precipitation of the earth by the caustic or carbonated alkalies, or alkaline earths. For further particulars see the facts under their respective acids.

Ammonia has not yet been observed to exert any action on pure aluminous earth; but both potash and soda, when caustic, will diffuse it without any difficulty. This may be done by evaporating to dryness, and igniting in a silver crucible, a mixture of caustic alkali and alumine, and then lixiviating the mass, or merely by boiling some freshly precipitated alumine in a watery solution of the alkali. This alkalyzed alumine has of late been recommended as a preferable mordant to common alum in the fixing of those colours that are injured by the presence of sulphuric acid. To separate alumine from its solution in caustic alkali, it is necessary to add nitric or muriatic acid in sufficient quantity to neutralize the alkali and diffuse the alumine, and then to precipitate the earth by caustic ammonia.

The action of barytes on alumine is analogous to that of the alkalies, yet presents some peculiar characters. When a solution of caustic barytes in water is added to a liquid muriat of alumine, the first effect is the appearance of a precipitate, owing to the decomposition of the salt by the barytes; if this last, however, is added in excess, the alumine is redissolved by it, and the liquor becomes clear.

Again, if equal parts of newly precipitated alumine and caustic barytes are boiled together in a quantity of distilled water sufficient to take up the barytes, about half the mixture will be diffolved, and upon analysis the insoluble residue will be found to consist of alumine, with a small proportion of barytes, while the solution will consist of much barytes and a little alumine. By adding to the liquor some muriatic acid, to engage the excess of barytes, a flocculent precipitate will be deposited, consisting of the two earths, nearly in the proportion of the original insoluble residue. Hence it appears that alumine combines with barytes into a salt which is insoluble in mere water, but is capable of being rendered soluble therein by the affinity of barytes. In the dry way, at about 150° Wedgewood, any mixtures of the two earths in which the alumine preponderates remain unaltered; but when the barytes is three or four times as much as the alumine, the powder concretes into a hard mass, without, however, flowing any signs of fusion. In order to decompose barytic alumine, diffuse the whole in muriatic acid, and add caustic ammonia; the alumine alone will be precipitated.

Strontian produces the same effect on alumine as barytes, but more feebly; the action of these two substanances in the dry way, on each other, has not yet been the subject of experiment.

It appears highly probable that lime has a similar affinity for alumine, as the rest of the alkaline earths possess; the only experiment, however, upon the subject, is one of Moreau’s; he mixed equal parts of muriat of alumine and muriat of lime in solution, and immediately a precipitate took place, which was insoluble by an excess of acid; this has been since repeated by Darraaq, a pupil of Vanquelin, without effect, the liquor remaining perfectly limpid; hence it is probable that the alumine of Moreau was not quite free from sulphuric acid, and that the insoluble precipitate was merely feldite. In the dry way lime and alumine in any proportions are insoluble, except by means of a blow-pipe, charged with oxygen gas.

The action of magnesia on alumine is not yet fully ascertained; it appears, however, from Mr. Chenevix’s experiments, that the ammoniac-magnesia triple faults, are formed with difficulty, when alumine is present, and that magnesia prevents, in any great measure, the solubility of alumine in the caustic fixed alkalies. This combination of the two earths
ALU

ALU, if green in other material clays pefted, the earthenware component upon matter, Wood Scheele, pure at it will acid, copious phuric and v.hcn remains may number the mix of fineft and liquor ftate of Alumine with then vitiated muriatic solution with the latter off, which is, therefore, indebted to Klaproth for flowing, that when to a solution of pure fílex in caustic potash is added a solution of alumine equally pure in the fame menstrum, the liquor immediately assumes a reddish brown colour, and after standing an hour or more, coagulates in a thick opaque whitish jelly. This jelly, by the addition of a little warm water, is resolved into a fluid, and being then mixed with muriatic acid, to the exact saturation of the alkali, a copious precipitate is deposited, confiding of the two earths, in a flate of combination; if now a slight excess of acid is dropt in, it will not separate as well as the alum will be perfectly dissolved. Carbamated potash will again cause the precipitate to appear, and this even when separated by filtration and dried, will be still entirely soluble in dilute sulphuric acid, without the smallest deposition of fílex. If the sulphuric solution is now gently evaporated, crystals of alum will be deposited, and the remainder will assume the form of a clear jelly, the surface of which, after a few days, will be covered with crystalline pyramids; and in order to show that it is really fílex mixed with alumine, which has thus repeatedly been dissolved in acids, nothing more is necessary than to mix this jelly with a large quantity of water, and digest it for some while in a moderate heat, stirring it repeatedly at the fame time, when the liquor will become turbid and pure fílex will be deposited. In the dry way, according to Kirwan, equal parts of alumine and fílex at 160° Wedge wood concrete together, but fíw no signs of fusion.

Alumine is as yet a pure chemical element, never having been composed or analysed. From its affinity with colouring matter, and its blackening in a low heat, Baron was of opinion that it was of a metallic nature. It was, however, entertained the idea that it might be a metallic oxyd, whose component elements were united together by a very powerful affinity. Beaumé considers the earth of alum as essentially the same with fílex, being led into this mistake by fusing rock crysâl repeatedly with potash, and always obtaining alumine; this experiment of Beaumé's was repeated by Scheele, who found indeed that it was true whenever an earthenware crucible was made ufe of, but perceiving the crucibles corroded internally after every procées, he conjectured that the alumine was furnished by the action of the alkali upon them; in proof of which he repeated the fution of fílex with potash in an iron crucible, and as might be expected, did not procure a particle of alumine.

The uses of pure alumine are wholly confined to the laboratory; it gives, however, their peculiar character to all clays, every thing; therefore, that depends on the cohesive-ness and placticity of these substances when fresh, and their hardnests after being baken, may be fairly attributed to the alumine which they contain; hence, it is the basis and material of all the arts of pottery, from the common brick to the finest porcelain, and these include more of the comforts and elegancies of life than are perhaps dependent on any other substance in nature.

ALUNT[, in Botany, a name given by some of the old Latin writers to the plant, otherwise called potan and cornella, and by the Greeks cynane. It was the same with our gentifolia tinntia, or dyers weed, and was used by the dyers, and by the ladies to tinge their hair yellow, the colour that was esteemed most beautiful in those times.

ALUNG, in Natural History, is a word of the Mala bar language, and the name given by the Malabarans to an animal resembling a large lizard, except as to head and tail, which are both pointed. It is a German eil and 4 long, and its breadth is half an eil. It is a species of the manis of Limneas, and belongs to the family of ant-eaters, which have no teeth, but a long round tongue, with which they catch the ants. Phil. Trans. vol. lxi. N° 9. an. 1700.

ALUNKAN, or ARRUKAGGE, in Geography, a town of Peru, in the province of Zaballitan, 100 miles south of Candahar.

ALUINT, ALOINT, or HALUNTUM, in Ancient Geography, a town of Sicely, on the deep eminence, near the head of the river Chebram. It is now in ruins; but from these arose the hamlet St. Philadelpio, in the Val di Demona. The inhabitants were called Haluntini.

ALVOR, in Geography, a small place with an earldom in the province of Algarve, between Villa Nova de Portimao and Lagos.

ALVOREDO, an island of South America, on the coasts of Paraguay, three leagues south of St. Catharine’s island. S. lat. 25° 23’. W. long. 49° 16’.

ALVORNINHA, or ALBURNINHA, a small town of Portugal, in Estremadura, containing about 1500 inhabitants.

ALURNUS, in Entomology, a genus of insects of the order of Coleoptera, with hiform antennae, fix very short palpi or feelers, and horny arched maxilla or jaw. There are three species, viz. 1. A. grandis, black, with crimson thorax and yellow elytra, found in South America and India. 2. A. feneratus, of a green reddish colour, with the hinder thighs and legs dentated, the tenebrio fermoatus of Drury, and the tenebrio viridis of Sulzer, found in India, with the antenne half the length of the body, and the hind legs black. 3. A. thoracicus, black, with the hinder thighs and legs dentated, found at the Cape of Good Hope.

ALUS, in Ancient Geography, a village of Palefline, in the vicinity of Nicopolis. Also an ancient town of Arabia Petrae, where was the 10th encampment of the Ifrâdites.

ALUSMA Caracannian, in Botany, a term used sometimes to express a plant growing in Carmania, and sometimes a preparation of that plant, or pigment made from it. The word frequently occurs in the writings of Avicenna and Scarpion.

ALUTA, in Ancient Geography, a river of Dacia, now called Alt, or Olth, which rises at the foot of the Carpathian mountains, and passes through the eait and south regions of Transylvania into Walachia, dividing it into the eastern and western parts. It discharges itself into the Iher.

ALUTA, a small village of Palefline, placed by Jerome near the river Chebron.

ALUTIE, a people of Ilyria.

ALUTRAENCES, a people of the Alps, according to Pliny.

ALVIS, among Anatomists, is sometimes used to express the lower belly, or venter.

ALVIS is more usually taken among Physicists for the
A L Y

date and condition of the faces, or excrements, contained within that cavity.

Thus, when a person is laxative, it is called albus liquida; and when colicky, albus adjurata.

They who are of a loose belly in their youth are generally colicky in their old age; and they who are bound in youth are often loose when old. A laxer state in youth, and rather loose than lax in old age, is most desirable.

Besides, the phenomenon of the belly are labour, fitting in a chair, fullers' clay laid over the body, diminution of food, eating once a day instead of twice, little drinking, and that only after a full meal, relf after meals. On the contrary, things which loosen the belly are, walking and eating more than usual, surising after meat, intermixing draughts with eating, and it ought to be observed, that a vomit binds a loose belly, and loosens a bound one; and that a vomit taken immediately after meat binds the belly, but, delayed until a considerable time after, loosens the same. Celsus.

ALWAIDII, a sect of Mahometans, who hold that all great crimes are unpardonable, and the criminals reproved to eternity. The alwaidi stand in opposition to the monci. They attribute less efficacy to the true belief in the salvation of men than the rest of the Muthlimen.

ALWELL, in Geography, a lake of Switzerland, in the canton of Bern, seven miles long, and one a half wide, seven miles south-east of Arau.

ALWEN, a river of North Wales, which runs into the Dee, seven miles north-east of Bala, in Merionethshire.

ALWOS, a large and populous village of Hungary, on the site of the Danube, in the district of Camaro, and famous for an aqueduct made there in 1747.

ALYATTUS, in Archaeology, the tomb, or rather burial-place of Alyattus, the father of Cretus, near Sardis, which was six fadisti in circumference.

ALYBA, in Ancient Geography, a town on the eastern part of Poutus, belonging to the Alyians, who inhabited this coast; suppos'd to be the Lyans with the Chalybes, whose country furnished metals.—Alfo, a mountain of Africa, the name with Alyba.

ALYCUS, a town of Peloponnesus which was either ofine Megaris, or near it.

ALYMNEN, a town of Afin Moro, situate towards the confines of Phrygia, Caria, Lycia and Phildia.

ALYMONHAN, in Geography, a town of Hindoostan, in the country of Guzerat, and circuit of Champaneer, 100 miles north-east of Surat, and 32 mile south-east of Champaneer.

ALYPIAS, in the Materia Medica of the ancients, a species of turbuch, prescribed for the purging of bile. Some write the word alipum, and define it by whiteurbath. Calen used alipum, alætum, for a minorative, or a medicine that gently purges.

ALYPUS is of Alexandria, in Biography, a Platonian philosopher, was much celebrated for the acuteness of his genius, and the subtlety with which he lectured upon the abstruse speculations of the Platonick school. Jamblichus, who was his contemporary, and who wrote his life, commends him highly on account of his exemplary virtue, as well as his distinguished talents. His stature was very diminutive, so that he was denominated a dwarf, but his mind was proportionably capacious and superior. He died at Alexandria in an advanced age. Gen. Dict.

ALYPIUS of Athens, a geographer of the fourth century, lived under the reign of Julian the apostate, and was sent into Britain as deputy-governor, where, says Mr. Gibbon, his humanity was tempered by severe justice and manly fortitude, and while he exercised his abilities in the civil administration of the country, heimitated, in his political composition, the harmony and softness of the odes of Sappho. To Alypius, Julian entrusted the execution of his plan for rebuilding the temple of Jerusalem. Ammianus Marcellinus informs us, that whilst Alypius, afflicted by the governor of Palæris, urged, with vigour and diligence, the accomplishment of the work, horrible balls of fire breaking out near the foundation, with frequent and reiterated attacks, rendered the place, from time to time, inaccessible to the searched and bladed workmen; and the victorious soldiers, encamping in this manner obstinately and resolutely bent, as it were, to drive them to a distance, the undertaking was abandoned.

On this relation Mr. Gibbon, in his usual manner, observes, that "Such authority should satisfy a believing, and must astound an incredulous mind. Yet a philosopher may still require the original evidence of impartial and intelligent spectators. At this important crisis, any singular accident of nature would assume the appearance, and produce the effects of a real prodigy. This glorious deliverance would be speedily improved and magnified by the pious art of the clergy of Jerusalem, and the active credulity of the Christian world; and, at the distance of 20 years, a Roman historian, careless of theological disputes, might adorn his work with the specious and splendid miracle." The impartial enquirer into the credulity of this event will derive greater satisfaction from the testimonies for and against it, cited by Dr. Lardner, than from the facile reflections of this popular historian, whose scepticism on the subject of religion has, in fact, perverted his judgment with regard to historical facts. Julian's attempt for rebuilding the temple, and the defeat of it by divine interposition, are mentioned by three contemporary writers, viz. Gregory Nazianzen, Chrysoforis and Umbrofis, bishop of Milan, all Christians; and also by Ammianus Marcellinus, a learned heathen; and afterwards by Rufinos, Socrates, Sozomen, Thedoret, and Philostratius, as well as by later writers. Some Jewish writers, as R. David Gaunius, and R. Geddelius, have also been alleged as bearing testimony to this event. The truth of the history, thus confirmed, has been maintained by Fabricius, Wiltius, bishop Warburton, and others of high reputation in the republic of letters. Bafnage has made some objections to this history, and Dr. Lardner, with his usual modestly, has suggested several reasons for doubting its authenticity. He hitherto argues, that Julian's own writings lead us to think that he never attempted to rebuild the temple at Jerusalem; it is also unlikely that he should give orders for this purpose, and allot money for it out of the public treasury, when he was setting out in his expedi- tion against the Persians; and though great terrors are laid upon the testimony of Ammianus Marcellinus, a heathen, and an impartial historian, yet he had his account from the Christians, which he seems to have taken up without examination, and it sufficiently appears from other circumstances, that he was credulous: besides, the history of this event, as it is related by Christian writers, is loaded with miracles, or pretended miracles, which appear to be incredible: nor was there at that time any occasion for such miraculous interpositions. And, lastly, there are several Christian writers, who have said nothing about this affair, but who were likely to have mentioned it if any thing of this kind had been done; such are Jerome, Prudentius and Orasius.

Whether Alypius was ever employed in rebuilding the temple or not, it appears that towards the latter part of his life, he was accused, with others, of practising magic. Hierocles, his son, was condemned to death, and he himself suffered confutation and banishment. They were charged with administering poison; but Ammianus represents their suffering as unjust. Alypius was the author of a treatise
in geography, of which Julian speaks favourably; but it is probably loll. Another treatise, published by Godfrey, in Greek and Latin, under the title of "A Description of the Old World," in 1620. He was probably not the work of Alypius, though some have ascribed it to him, because the author speaks of Britain from report, and not from his own observation. This work is thought to have been written in the reigns of the emperors Constantius and Constanus. Ammian, Marc. l. xxiii. c. 1; xxix. c. 1. Lardner's Works, vol. viii. p. 377-391. Gibbon's Hist. vol. iv. p. 105-109. 8vo.

Alypius of Tagafla, a town of Africa, was the intimate friend of Augustine, and baptized with him at Milan, in 388. On his return from Palestine, in 394, he was made bishop of his native place. Whilst Augustine was engaged with the Manichees, Alypius was induced to join them; but he afterwards avowed himself a zealous advocate for the catholic faith. He made successive attempts to convince the titles of their errors, and to recover them to an union with the church; particularly at the council of Carthage, in 403, and again in 411: but neither his arguments, nor the penal decrees of the emperor Honorius were sufficient to reclaim them. Alypius was also deputed by the churches of Africa about the year 419, to Honorius, in order to obtain severe decrees against the Pelagians, and in this office of perfecting zeal he so far succeeded as to break up their af
cen- tions and banish their ministers. He died about the year 435. He is honoured in remembrance for his Christian charity than his orthodoxy and zeal. Gen. Diet.

Alypius, in Biography, one of the seven Greek writers on music, that have been collected and published with a commentary and notes, in 1652, by Meibomius. It is difficult to ascertain the time of his existence. Caffendorus (de musica) placed him before Enclid and Ptolemy, and has ranged his tract, "Expoxy's musae," or Introduction to Music, between that of Nichomachus and Claudianus. The contents of this work furnish the most ample nomenclature of all the sounds of the several scales and modes of the ancient Greek music, that have come down to us. The characters for found used by the Greeks for their several modes in the three genera, amounted to 1620. These notes were formed of the twenty-four letters of the Greek alphabet, entire, mutilated, single, double, or lengthened; sometimes turned to the right, sometimes to the left, or lying horizontally, so that their corners or sides were turned upwards; and lastly, some were barred, and others distinguished by the grave and acute accents, which had likewise a place among these numerous discriminations.

This tract was first published by Murcurius, 1616, from the MS. of Joseph Scaliger, but not very correctly, according to Fabricius. Kircher has given extracts from Alypius in his Mafuripia, 1650; pretending that he had translated the whole into Latin; but the table which he has inserted from him of ancient musical notation, is so inaccurate, that Meibomius, who confuted not only the Greek MS. of Scaliger, but that of Bolesanus, Baroxius, Barberti, and Sellin, affirms, that he found in it more than 200 errors.

It is from the indefatigable labour of the learned Meibomius, in his commentaries upon the ancient Greek musicans, particularly Alypius, that we are able to decipher those characters; which, before his time, had been so much altered, corrupted, disfigured, and confounded, by the ignorance or inattention of the transcribers of ancient MSS., that they were rendered wholly unintelligible. See Greek Music, and Notation.

Alypon Musici Celi, or white turbin, in Botany and the Materia Medica. See Convolulus.
two feet, with woody stalks, dividing into several branches; the flowers are produced at the extremity of every shoot in round bunches, small and white; the spike is oval, and full of brown feathery spikelets; it grows naturally in the south of France, Spain and Italy, Germany, Austria, Sweden, &c. chiefly on rocky or gravelly soils, is perennial, and was cultivated here by Parkinson in 1652. 7 A. Minum, lead M. with spikes diffusely, leaves linear, downy, and spikelets compressed. This is annual, and grows wild in Spain: the petals are yellow and submarginate. 8 A. Calycium, calycine M. with filaments all toothed, and permanent calyxes. It is annual, and found wild in Austria, Carniola, France, Germany and Swiferland. The petals are small and yellow, becoming white with age: the spike has two seeds in each cell, one of which is commonly abortive: it was cultivated by Miller in 1768. 9. A. Montanum, mountain M. with spikes diffusely, leaves sub lanceolate, dotted and echinate. The branches trail, the leaves hoary, rough and alternate, the flowers produced in small clusters at the ends of the branches, and of a dark yellow colour; it grows naturally upon rocks in Burgundy, and some other parts of France, about Baill, in Germany, Austria, Carniola, &c. is perennial, and cultivated by Miller in 1759. 10. A. Campfera, field M. (omitted by Gmelin) with filaments guarded by a pair of bristles, and calyxes deciduous; resembles the 8th in leaves, leaflets, and petals, is annual, and a native of France, Germany and Sweden, and cultivated by Miller in 1768. 11. A. Cliffadium, buckler-podded M. with petal, spikes filiform, oval, compressed-flat, petals pointed and linear. This is a biennial (annual, Linn.) plant, and grows naturally in Spain and Portugal, and it was found by Tournefort, on Mount Libanus; it was cultivated by Gerard in 1596. To the division with spikes inflated, or calyxes oblong and closed, belong the following species. 12. A. Sinuaturn, finate-leaved M. with spikes herbageous, leaves lanceolate deltoid, and spikelets inflated. This is a low spreading plant, which divides into small branches, garnished with hoary leaves through the year; the flowers produced at the ends of the branches are of a bright yellow colour. It is annual, or biennial, and grows wild in Spain by the way-side, and in the sands of the Archipelago, and sufficiently hardy to bear the open air in England, in a dry soil and warm situation; it was cultivated in the Kew garden in 1680. 13. A. Creticum, cretan M. with petal, spikes pubescent, leaves lanceolate deltoid, and spikelets inflated and globular. This species fidelius continues longer than two years in England, and in a warm, dry situation, will live in the open air. It is a native of Spain and Crete, and was cultivated by Miller in 1759. 14. A. Ge- monamo, gemonan M. with spikes herbageous, branches divaricated, root-leaves obovate, rather downy, and spikelets inflated. This differs from the last in having divaricated branches, and smaller flowers of a deep yellow colour. The root is perennial; the spikes spread on the ground; the leaves are rough, and ash-coloured, about five inches long, and scarcely an inch broad; the perianthium is spreading, yellow and his- tate; the petals are twice the length of the calyx, obovate and emarginate. This species was discovered by Arudini in 1759, on the mountain Della Fontana, near Gemonan, in the district of Forli in Italy, in the crests of rocks: it flowers in May and June. 15. A. Uriculatum, bottle M. with spikes herbageous, erect, leaves smooth, lanceolate, quite entire, and spikelets inflated. This has the flower of buxaria, and resembles it, except in its inflated spikelets; it was found by Tournefort in the Levant, and grows in the vineyards of Savoy: it is a hardy and beautiful perennial, flowering from April to June, when it begins to form its curiously inflated pods; it is well adapted to the decoration of walls or rock-
AMA

river in Africa, according to Leo; and the roots probably had this name from their being found in great plenty on the banks of that river, the trees always growing in wet places.

ALZNA, in Geography, a province of Asia, in Great Armenia, towards the river Tigris, comprising nine very considerable districts, which extend along the river to Karannut or Diarbekir.

ALZON, a town of France, in the department of the Gard, and chief place of a canton, in the district of Vigan, 15 miles north-north-east of Lodève.

ALZON, a river of France, which runs into the Gard, about a league below Uzes.

ALZONNE, a town of France, in the department of the Aude, 2 1/2 leagues west of Carcassonne.

ALZUM, in Botany, a name given, to the ancients, to the tree which produces the gum BELLUM. It is also written alvum and aldum, which last denotes the proper way. The gum of this tree was called, by the Arabians, modi, and the same word modi is used as the name of a fruit of a palm-tree.

AM, in Geography, a famous city of Armenia, where they formerly reckoned 100,000 horses, and about 1000 mosques. It was taken by the Tartars in 1219, and is now considerably reduced. It is thought to be the present Ami.

AMA, in Ecclesiastical Writers, denotes a vessel wherein wine, water, or the like, were held, for the service of the eucharist: in which sense, the word is also written annula; sometimes also banua and bounula.

Anna is sometimes also used for a wine-measure, as a cask, pipe, or the like.

AMA, Amé, or rather Amés, anna, a sort of cake. Arceus used this word to express the quantity of helbore which is sufficient for a dose in strong constitutions, when given in the winter.

AMA, or Aman, in Geography, a town of Syria, once the celebrated city of Amana, now reduced to ruins.

AMA, or Hama, a town of Germany, in the circle of Westphalia, and bishopric of Liege, 8 miles south-west of Liege.

AMAAD, in Scripture Geography, a town of Palestine, on the borders of the tribe of Azer.

AMABYR, or Amabry, q.d., in ancient British, “the price of virginity,” in some Ancient Cymri, a sum of money to be paid the lord upon marrying a maid of his manor.—This custom is said to have anciently obtained in Wales, where amabry was paid to the prince: also in the honour of Chyn belonging to the earl of Arundel, till earl Henry, in the times of queen Mary, in consideration of sixty pounds, released it to all his tenants by the name of the custom of amabry and cheering.

AMACACHES, in Geography, a people of South America, in Brazil, inhabiting the vicinity of the territory that extends from St. Sebastian to Rio Janeiro.

AMACASTIS, in Ancient Geography, a town of India, on this side the Ganges, according to Ptolemy.

AMACCUR, a town of Africa.

AMACI, a people of Spain, whose capital, according to Ptolemy, was Aitoria Angula.

AMACK, in Geography, an island of Denmark, joined to Copenhagen, and consequently to Seeland, by two bridges over the channel that separates them. It is about one and one-half geographical mile in length, and above half a mile in breadth. It is level and without woods; the soil is uncommonly fertile, so that it is considered as the kitchen-garden and flour-house of the city; and the inhabitants supply it twice every week with all sorts of eculent vegetables, and also with milk, butter and cheese. The present inhabitants occupied it in 1516, being invited hither by Chrithian II. from the province of Water-land, in North Holland. The whole island contains about 800 families, and is divided into two parishes. The dialect of the people is a medley of the low Dutch, German, and Danish languages; their mode of dres, and of living is peculiar to themselves. In the Summer they drive their cattle for pasture to a small neighbouring island, called Saltholm. There are excellent quarries of flone for lime and building on this island.

AMACORE, or AMACURE, a river of south America, which waters the Carrhana, and runs into the Northern sea, near the mouth of the Oroonoko.

AMACOQUE, in Ornithology, a name given by Fernandes to a Mexican bird, supposed by Buffon to be a species of Cucullarius or Pluvialis. It is a noisy bird, the plumage is mixed with white and black, and it has a double collar. It is seen the whole year on the lake of Mexico, where it lives on aquatic worms.

AMACUSA, in Geography, an island and province of Japan, with a town of the same name, that borders upon that of Oyanan, and is south-west of the island of Karabu. It is between 31° 30' and 32° N. lat. and E. long. 129° 20'.

AMADABAD. See Ahmedabad.

AMADAN or Hamadan, a town of Persia, in the province of Irac-Agemi, between Bagdad and Isphahan, about 80 leagues from one and the other. It is seated at the foot of a mountain, whence issue streams that water the country; its extent is large, as it encloses waste and cultivated land, though it has but one tolerable street formed of houses, that are built of brick, hardened in the sun. The adjacent country is fertile, and productive of corn and rice; the air is fabulous, but in Winter the cold is intense. The Armenians have a church in this town, and the Jews have a synagogue, near which is a tomb, where, according to report, Esther and Mordecai were interred. The place is reforted to by several pilgrims from all parts of the Levant; and in its vicinity is a mountain called Nohana, abounding with various herbs, and the sick repair hither to recover their health by imbibing its salutary effluvia. Amadan is an ancient city; and it is said that it was destroyed by Nebuchadnezzer, and rebuilt by Darius. The kings of Persia retired to it in the times of its delightful situation, and hence it obtained the name of the “Royal City.” It was reduced by the Caliph Othman, and was nearly destroyed by Jenghis Khan in 1220. Its castle and walls are now in ruins; and it is merely distinguished by its gardens and springs. N. lat. 35° 15'. E. long. 47° 30'.

AMADANAGEN, a town in the Hither Peninsula of India, in the province of Decan. It was taken by the Moguls in 1598. N. lat. 18° 10'. E. long. 74° 15'. See Ahmednagar.

AMADEUS V., count of Savoy, in Biography and History, succeeded to the sovereignty in 1285, and obtained the surname of “The Great,” by his wisdom and successe. His possessions were much enlarged by marriage, purchase, and donation. In defending Rhodes, against the Turks, in 1311, he gained distinguished honour; and in memory of this service, he and his successors took for their device, F. E. R. T. the initials of the Latin words “Fortitudo ejus Rhodium tenus,” i.e. his valour preferred Rhodes. The grand master of the knights of St. John, to whom Rhodes belonged, granted him a palace at Lyons, as a reward of his effectual succour. He died after a reign of 38 years, in 1323, at Avignon, where he was soliciting pope John XXII. to publish a crusade in favour of Andronicus, emperor of the East, who had married his daughter. He was much loved and honoured by all the sovereigns of Europe, and was generally the mediator in all their differences. Mod. Un. Hist. vol. xxxiv. p. 16.

AMADEUS
Ama

Amadeus VIII., count of Savoy, succeeded his father Amadeus VII., in 1391, and acquired the titles of the "Pacific," and "the Solomon of the Age." Savoy was erected by the emperor in 1416, into a dukedom; but after this elevation, Amadeus formed the resolution of retiring from his throne and family into a religious house at a place called Ripaille. In this retreat, which he had fought according to the opinion of the world from religious motives, he devoted himself to every kind of pleasure and luxury, so that faire repaillère became proverbial to signify a life of exquisitely gratification and indulgence. Here he instituted the order of St. Maurice, or the Annunciata, consisting of a number of hermits, who excluded women from their community, but in other respects maintained the character of Epicureans and votaries of pleasure. In this retreat Amadeus aspired to the papacy, and employed large sums of money at the council of Basill, to secure the object of his ambition. Accordingly, in 1439, this council, having deposed pope Eugenius IV., conferred the triple crown on Amadeus, under the name of Felix V., though he had never taken holy orders. A schism was the consequence of this extraordinary election; and Eugenius at length excommunicated his rival. On his death Amadeus was persuaded to abdicate, and a new pope was chosen in his room. But his resignation was only recomposed by the dignitaries of that day, bishop and apostolical legates, and by his being allowed to retain most of the pontifical insignia. He died at the age of 69, in 1451, at Laufanne, which, during the latter part of his life, he had chosen for his residence, and was succeeded by his son Lewis, to whom, in his life-time, A.D. 1433, he had resigned the title, but few or none of the revenues of the dukedom. Mod. Un. Hist. vol. xxxiv. p. 78.

Amadeus IX., count of Savoy, was famnname the "Happy," on account of his virtue and piety, his readines to forgive those who offended, his love of justice, and his study to promote the welfare of his subjects. He succeeded Lewis in 1464, and though his bodily infirmities prevented his engaging in any great exploits, he acquired and maintained a very exemplary character. He was eminently distinguished by the benevolence of his disposition. Being once asked by a courtier, whether he kept hounds; he pointed to a great number of poor people, who were fed at tables, eating and drinking, and replied: "those are my hounds, with whom I go in chase of heaven." When he was told that his alms would exhaust his revenues, "take the charge of my order," he said, "sell it, and relieve my people." He married Isabeau of France, who concurred with him in all his good deeds. His death, in 1472, at the age of 37 years, and after a reign of seven years, was universally regretted. Mod. Un. Hist. vol. xxxiv, p. 82.

Amadia, in Geography, a fortified and trading town of Asia, in the province of Kurdiran, situate upon a high mountain. Its environs produce tobacco and gall-nuts, which furnish means of commerce. It is the residence of a bey, who governs the whole country. N. lat. 36° 25'. E. long. 43° 1'.

Amadoar, in Ancient Geography, a town of European Sarmatia, inhabited by the Amadoar, and whose habitations sometimes were also on mountains of the same name, between the Roxanae and Baffareas.

almādīs, in Natural History, a species of the Conus, in the Vermes Testacea, with a shell dilutely brown, broad fuscia, and articulated bands above and below; and an acute, crowded spire, finely and transversely fluted.

Amadow, a kind of black-mash, tender, or touch wood, which comes from Germany. It is made of a sort of large mushroom, or fungous excrescences, which commonly grow on old trees, especially oaks, as, and firs. This mushroom being boiled in common water, and afterwards dried and well beaten, is then put into a strong ley prepared with salt-petre, after which it is again put to dry in an oven. The druggists sell this match wholesale in France, and several hawkers retail it. See Agaric.

Some give to the amadow the name of pyrotechnical spurge, because of its aptness to take fire.

Amadowry, a kind of cotton which comes from Alexandria, by way of Marseilles.

Amēa, or Ammēa, in Ancient Geography, a town of Lydia, inhabited by the Ammienes, between the Elbas and Tagus.

AMAGETORIA, now Bréis, an ancient town of Gaul, mentioned by Caesar, placed by M. d'Anville on the Arar, to the south of Segobodum, and to the west of Vefontio.

Amagor, in Geography, a town of Africa, in the empire of Morocco, and province of Haoua.

Amaguana, the name of one of the Lucayan or Bahama islands, called also Mayaguana.

Amal, or Amaggia, formerly Varegia and Nativicia, a town of Spain, belonging to the Cantabric, on the confines of Albyritus, about three leagues from Villa-Diego, at the foot of a high mountain.

Amallillo, a town of France, in the department of the Two Severs, and chief place of a canton, in the district of Partenay, three leagues south-east of Bressefor.

Almain, or Amaye, a sea term, used by a man of war, to his enemy; and signifying yield.

Hence, to strike amain, is, to lower, or let fall, the top-fails. The word is also written amayn. — Waving amain, is to make a sign to another vessel, by waving a bright sword, or other thing, as a demand for striking its top-fails. — This is commonly done either in the foremost, or on the poop. Amain is also a term used in letting down a thing, by a tackle, into the hold, or elsewhere, in the lowering a yard, or the like, to denote, that the sailors are to let go that part of the rope which they held before, and let down the thing easily, and by degrees. Amain is also used to denote at once and instantly; as let go amain.

Amak, called also Abulnasir Al-Balkari, in Biography, a celebrated Persian poet, was a native of Bokhara, and flourished towards the close of the 11th century, under the sovereigns of the Seljuk race. He was at the head of an academy, consisting of about 100 men of letters, with whom he held constant conversation. He was invited by Khedar Khandall, who reigned in the Tranoxian provinces, and who was a very munificent patron of letters, and particularly of poetry. This prince profited in the academy, seated on a throne, at the foot of which were four large basons of gold and silver coin, which were intended for the recompense of those poets who obtained his approbation. Amak was a distinguished favourite, lived by the bounty of his patron in great affluence, and kept a number of slaves, and thirty richly caparisoned and trained horses. Thus favoured, he became the object of envy, and Raflchidi, whom he had recommended, endeavoured to supplant him. Amak and Raflchidi were appointed to contend for poetical victory in the sultan's presence; and the fatalical veres of the latter gained the prize, very much to the mortification of the former. Amak lived nearly a century. His principal work is the "History of the Loves of Joseph and Zoleifla," a romance, founded on the account of the patriarch Joseph, in the Koran. He was most distinguished for his elegies. When sultan Sangiar was incomparable for the death of his letter, and disregarded all the elegiac veres of other poets, Amak was sent for to fothe him; and an elegy transmitted by him, when he was too aged
aged and infirm for travelling, obtained a decided preference.  

AMAL, Amalia, in Geography, a town of Sweden, in the province of Thulland or Dalland, seated on the Wenerlake, which divides the town and the market place into two parts. The town was founded in 1640; it has a good harbour, and carries on a considerable trade, particularly in timber, deals and tar. It is the 80th town of those that vote in the dist. N. lat. 58° 50’. E. long. 12° 30’.

AMALAEVA, a river of Siberia, which runs into the Frozen Ocean. N. lat. 71° 10’. E. long. 128° 14’.

AMALAGO, in Botany. See PIPER.

AMALANCHIER. See Mesophilus.

AMALARIC, or AMALRY, in Biography and History, king of the Visigoths, was the son of Alaric II.; but being an infant of five years, at his father’s death, in 506, the throne was usurped by Genilac, the natural son of Alaric. Amalaric in the mean while retired into Spain; and the Visigoths were governed by his grandfather, Theodoric, king of the Ostrogoths, who expelled Genilac from the throne, till his death in 526, when Amalaric assumed the government. This prince was zealously attached to the Arian doctrine and cause, and as he had married Clotilda, the daughter of Chlovis, who inherited the piety and orthodoxy of her mother, he used various means, and as the Catholic historians say, those of violence, to prostrate her to his own opinion and party. In process of time, after patiently enduring the wrongs she suffered, he communicated an account of them to her brothers, and testified the truth of her relation by accompanying it with a handkerchief stained with blood. In consequence of this complaint, his brother Childeric, king of France, marched with a numerous army into the territories of Amalaric, defeated him in an engagement, and forced him to take refuge on board his fleet. But recollecting that his treaures were left in the city of Narbonne, he went on shore again, in order to recover them; but had no sooner entered the city than he was surprized by the enemy; and feeking safety in a church belonging to the Catholics, a common soldier run through with a spear, A.D. 531. Some say, that he retired to Barcelona, and was assassinated by his own subjects; but it is more probable, that the assassin was either a Frank or some person employed for this purpose by Theudis, who succeeded him. Mod. Un. Hist. vol. xvi. p. 10.

AMALASONTHA, regent and queen of Italy, was the daughter of Theodoric the Great, king of the Ostrogoths, by Audeleda, the sister of Chlovis, and united in her person the two most illustrious families of the Barbarians. She was born about the year 483, and in 515 married to Eucharis, the tall heir of the royal race of the Amali, whom her father had sent from Spain, and designated for his successor; and as the son of his daughter excluded her from the Gothic throne. Eucharis soon died and left an infant son, Atalaric, and Amalasontha assumed the guardianship of her son and of the kingdom of Italy. Her beauty was admired by many men, activity, and resolution. Education and experience had cultivated her talents; her philosophical studies were exempt from vanity; and though she expressed herself with great elegance and ease in the Greek, the Latin, and the Gothic tongues, she maintained in her counsels an impenetrable silence. By a faithful imitation of the virtues of Theodoric, she revived the prosperity of his reign; and she alio troved, with pious care, to expiate the faults, and to obliterate the least favourable remembrance of his declining age. The children of Boethius and Symmachus were restored to their paternal inheritance; she inflicted neither corporal nor pecuniary penalties on her Roman subjects; and she despised the clamours of the Goths, who, at the end of 40 years, considered the people of Italy as their slaves or their enemies. The measures of her administration were directed by the wisdom, and also celebrated by the eloquence, of Cassiodorus; the solicited and deferred the friendship of the emperor, and the kingdoms of Europe respected, both in peace and war, the majesty of the Gothic throne. The education of her son engaged her particular attention; and the employed three venerable Goths to infill into his mind the principles of honour and virtue, whilst he was diligently instructed in all those arts and sciences, which might be either useful or ornamental to a Roman prince. But the queen’s solicitude for her son’s improvement and good conduct, produced a degree of vigilance and discipline, against which his untractable disposition recoiled, and which his subjects disapproved. At length when the Goths were assembled on a public occasion, in the palace of Ravenna, the youth escaped from his mother’s apartment, and complained with tears of pride and anger of the chaffiment, which his stubborn temper had induced her to inflict. The indignation of the Barbarians was roused, and they accused the queen regent of conspiring against the life and crown of her son; and proceeded to demand, that he should be rescued from his present tuition, and educated, like a valiant Goth, in the society of his equals. Amalfontha was compelled to submit; and the young prince became dissolute and licentious, despised his mother, and counteracted the salutary measures which she had been pursuing. In these circumstances she entered into a negociation with the emperor Julian, and prepared for retiring from a scene of discontent and faction. In the mean while she yielded to the impulse of ambition and revenge; three of the most dangerous malecontents, who had been separately removed to the frontiers of Italy, were affianced by her private emissaries; and this act increased the popular dissatisfaction and complaint. At this time the death of her son, at the age of 16, in consequence of premature intemperance, left her destitute of any firm support or legal authority. Instead of submitting to the laws of her country, and retiring to a private station, she conceived the design of sharing, with one of her cousins, the regal title, and of resorting in her own hands the substance of supreme power. The eloquent Cassiodorus announced to the senate and to the emperor, that Amalfontha and Theodatus had ascended the throne of Italy. The issue of this scheme of ambition soon proved disastrous and fatal. Infligated by the principal Goths, Theodatus caused the queen to be imprisoned in a small island, in the lake of Bolsena, where, after a short confinement, she was strangled in the bath (A.D. 555) by the order, or with the connivance, of the new king. Gibbon’s Hist. vol. vii. p. 206-210.

AMALEK, in Scripture History, was the son of Eliaphaz, Efun’s eldest son, by his concubine Timna. Gen. xxxvi. 12-16. 1 Chron. i. 36. He succeeded Gatam, who was one of the dukes in the land of Edom; and was the father of the Amalekites, who inhabited that part of Arabia Petraea, which lay east of the Edomites, with Median on the north, Arabia Petraea on the south, Arabia Deserta on the east, and extended almost as far north as the Dead Sea, and southward to the Red Sea, or between Havilah and Shur, 1 Sam. xv. 7. These people had no constant dwelling, nor do they seem to have had any cities; but they changed their abode, like the Arabs, and lived in tents or booths, as they migrated from one part of the country to another, and sometimes in subterraneous caverns. It is not, therefore, easy to ascertain the limits of their country. Mr. Reclus 5 L places
places them between the defeats of Kadesh and those of Engedi, though somewhat nearer to the Mediterranean. Josephus, in one place, affirms, that they extended from Pelusium to the Red Sea, and in another place he fixes them between Capholitis and Petra. Antiq. lib. vi. c. 8. Ibid. lib. iii. c. 2.

As soon as the Israelites had crossed the Red Sea, the Amalekites determined to cut them off; and with this view they fell on their rear, as they were marching from Rephidim to Mount Horch, and flew those who, through weaknesses or fatigue, were left behind. But this unprovoked assault was very justly and severely avenged upon themselves by Joshua, who defeated them with great slaughter, A. M. 2517, B. C. 1487. Between the Amalekites and the Israelites, there seems to have subsisted an irremediable enmity; and it has not been improbable traced to their progenitor's having been deprived of his birth-right and blessing by Jacob. Under the Judges, they joined with the Midianites and Moabites against Israel, who were delivered from the former by Ehud, and from the latter by Gideon. Judges, vi. 3. 11. 13. Saul, soon after he was advanced to the throne of Israel, marched against the Amalekites with a large army; advanced to their capital; flew a great number of them, and laid waste their country; but by retreating to himself the best of the cattle and moveables, in violation of the divine command, he laid the foundation of the calamities that afterwards befell him, B. C. 1093. Some fugitives escaped; and we find that some years after this event a troop of Amalekites pillaged Ziklag, which then belonged to David; but he pursued and dispersed them, and recovered the captives and treasures which they had taken. 1 Sam. xxx. The Amalekites were thus gradually reduced; and at last, in the days of Hezekiah, king of Judah, who began his reign, B. C. 726, they were utterly destroyed and scattered by the sons of Simeon, who took possession of their country. 1 Chron. iv. 40-43. Thus the declaration of Balaam, recorded Num. xxiv. 20, was literally fulfilled: "Amalek was the first of nations; but his latter end shall be, that he perish for ever." According to the account of the Aranians, Amalek was the son of Ham, and grandson of Noah; he was the father of Ad, and grandfather of Schedad. Calmet inclines to this opinion; for he says, it is not easy to conceive how the Amalekites, if they were merely the pothouse of the son of Eliphaz and grandson of Esau, could be so numerous and powerful as these people are represented to be when the Israelites departed out of Egypt. Besides, when we call to mind the previous wars of the Amalekites with Chedorlaomer (Gen. xiv. 7); when we consider that Balaam calls them the first, or beginning, of nations; when we reflect, that Moses never flays them the brethren of Israel or Edom; that the latter never held any confederacy or friendly correspondence with them in all their wars, but suffered them to be invaded and butchered by Saul, without assisting them any assistance; and, lastly, when we find them always mentioned with the Amorites, Philistines, and other Canaanitish nations, and with them involved in the same curfe, we can scarcely forbear looking upon them rather as a tribe of those nations, than as the descendants of Esau, who probably formed but a small tribe, and not permanently conspicuous. Of the Amalek, destroyed by Saul, the Aranians give the following account. He was the father of an ancient tribe in Arabia, which contained only the Aranians called pure; the remains of whom were mingled with the pothouse of Joektan and Adman, and to become Moanames or Moctasarabes, i.e. Arabians blended with foreigners. They believe, that

Goliath, who was overcome by David, was king of the Amalekites, and that the giants who inhabited Palestine in Joshua's time, were of the same race; and that part of them retired into Africa, while Joshua was living, and settled on the coasts of Barbary. The son of Amalek was Ad, a celebrated prince among the Arabians, whom some make the son of Uz, and grandson of Aram, the son of Sham. Calmet. See ADITES.

AMALEK, in Geography, a mountain in the land of Ephraim, on which the town of Pirathon was situated, where Abdon, son of Hiffel, judge of Israel, was buried, A. M. 2548, B. C. 1156. Judges xii. 14, 15.

AMALFI, or AMPHLI, an ancient sea-port town and archiepiscopal city of Italy in the kingdom of Naples, and Principato eitra, situate on the west coast of the gulf of Salerno. N. lat. 40° 35'. L. long. 15° 20'. The most generally received opinion of the origin of this city is, that about the middle of the 4th century a considerable number of Roman families, either with views of emolument or by compulsory orders of the emperor, left Rome, and embarked for Constantinople, but meeting with adverse forms, they were cast away on the shore of Salerno, and determined to form a settlement on the present site of Amalfi. This seafea and rising colony was guarded by impious mountains and inaccessible coasts, from the first fury of the Lombards, who seldom attempted the conquest of a maritime people. In the year 825 this small republic, under the patronage of the eastern emperor, attained a degree of wealth and reputation which invited the attack of Sicily, prince of Salerno, who marched a body of troops by night, surprized Amalfi, and carried off the greatest number of its inhabitants to supply the place of those, of whom Salerno had been deprived by an epidemic disorder. The Amalians taking advantage of the absence of the chiefs of Salerno, in an expedition against the Beneventans, armed themselves, and, after burning and plundering Salerno, marched back in triumph to their native abodes. Being thus restored to their country, they formed a better constitution and code of laws, and adopted various measures likely to prevent internal discord, and the assault of foreign enemies. Under these new regulations Amalii rose to the summit of its military and commercial glory. Pope Leo IV. found the Amalians an useful ally in his war with the infidels, and conferred upon the commonwealth the distinguishing title of defender of the faith. The Neapolitans fought their friendship, and the muslimen courted alliance with them. Their situation was favourable for commerce; and their attention to naval affairs induced the emperor of Constantinople to establish a court at Amali for the decision of all maritime disputes, and the code and reports of this court obtained authority through this part of Europe. The merchants of this town engaged the trade of the Levant, and transcended the commercial business of the world in a lucrative and exclusive manner. The importance of Amalfi, in its various maritime and commercial connections, led to the establishment of the order of knighthood, under the patronage of St. John of Jerusalem, the members of which were afterwards called knights of Rhodes, and since of Malta. The charitable traders of this port obtained leave of the muslimen chief at the caliph's court, in 1020, to erect two small hospitals and a chapel for the use of votaries coming from the western parts of Europe. From Pafitano, says Mr. Swinburne, in the neighborhood of Amalfi, was derived the first knowledge of the mariner's compass.

The flourishing state of the Amalians exposed them to various assaults; but they derived from the holy war temporary
porary refuge from the hostile attacks of their enemies, and thus were in some degree compensated for their charitable zeal on behalf of the pilgrims and sojourners in Pal-

stine. From the year 1100, when duke Roger took pos-
session of this state, and abolished even the shadow of its republic constitution, it has been exposed to the attacks of every power at variance with its new masters. The pil-
illage of it by the Pisans forms an intersecting epoch in its his-
tory; for they carried away the Pandects, a copy of the
Code which was formed by Justinian the first; a mer-
chant had brought it as a curiosi from Greece, but it had
obtained no authority at Amalfi, where the Theodorian
code was in force. Amalfi, after the destruction of its li-
iberty, found that its commerce declined. Trade was en-
tirely left to this confi in the reign of Jean the first. The
alienation of its lordship to feudal proprietors was without
doubt a circumstance that hastened its dissolution. The
brother of pope Martin V. (Colonna) had the first grant of
Amalfi; the Sanferventini the next; then the Orini acquired
possession; and lastly, Piccolomini enjoyed it in the

title of duke.

Amalfi is now merely a shadow of what it was in mag-
nitude, connections, and real importance, when it was in its
flourishing state; when, from a narrow, though fertile, ex-
tent of land, by means of an accessible and open sea, it
supplied the western world with the manufactures and pro-
ductions of the east; when 50,000 citizens were numbered
within its walls; when it was more abundantly than any
other city provided with gold, silver, and the objects of
precious luxury; and when its settlements in Constantinople,
Antioch, Jerusalem, and Alexandria, acquired the privileges
of independent colonies. Its buildings are not remarkable
for elegance and size, and contain at most 4000 inhabitants,
who seem to be in a poor condition. It presents few objects
that can recall any idea of its ancient prosperity. The ca-
tedral is not an agreeable building; under the choir is
the chapel and tomb of the apostle St. Andrew, in whose ho-

our the edifice was dedicated, when cardinal Capuano, in
1208, brought his body from Constantinople. Swinburne's

ALMAGAM, Almagame, Fr.—Alamagama or Quickbres,
Germ.—Almagama, Ital.

The word amalgam, from σωμα and γαμμα, coniunctum, is a
metaphorical term invented by the ancient chemists, and re-
tained by the moderns to signify any metallic alloy, of
which mercury forms an essential constituent part. Hence,
as mercury remains fluid at the usual atmospheric tempe-
rate, the theory and general phenomena of amalgamation
may be said to be those of the solution of metals in mercury.
All that is peculiar to the several amalgams, such as the
method of preparing them, their characteristic physical and
chemical properties, and the uses to which they are appli-
cable will be detailed hereafter in the article MERCURY; but
besides these there remain to be described a number of ge-

deral facts and appearances common to all amalgams, which
may be treated of with more propriety here than else-
where.

The knowledge of the solvent power which mercury exer-
cises over various metals, especially gold, was not only
known by the ancients, but, as we learn from Pliny, was ac-
tually employed by them in the separation of gold from
the bafer metals and in the gilding of silver. Velaeso and
Alonzo Barba, in the 16th century, applied the process of
amalgamation in the great way to the extraction of silver
from the ores of Peru and Mexico; but of the early che-
nists, Borrichius, Ofander, Beecher, and Stahl, are the
only ones who have treated of various amalgams with the
view of comparing their resemblances, of noting their pecu-

liarities, and thence deducing a few general axioms for the
benefit of science. Rouillé and Fuchs, following the
steps of their predecessors, discovered the crystallizability of
metals from their solutions in mercury, and Sage has
since enriched this department of chemical philosophy with
a vast number of curious, correct, and important observa-

ions.

§ 1. Methods of preparing Almagnams.
The precautions required in the preparation of an amal-
gam depend considerably on the degree of affinity ful-
filling between the mercury and the metal made u of. Where
the affinity is very powerful, as in the case of gold and
silver, the fluidity of the mercury without any further con-
dition will effect a combination even at the usual atmos-
pheric temperature. Thus leaf-gold, by simple trituration
with mercury will form an amalgam in a few minutes; and
pieces of gold, silver, or tin, even of considerable thickens-

ess, by being immersed in pure mercury will, in a few days
without trituration, be wholly dissolved. Other metals of
stronger cohesion or weaker affinity require the affinities
of heat to make them amalgamate, such as zinc and antimony;
for this purpose the zinc is melted in a crucible, and being
then withdrawn from the fire is allowed to cool till it is
upon the point of becoming solid, at this instant the mer-
cury, previously heated to boiling, is stirred in, and the mix-
ture is kept fluid by a gentle heat till the combination ap-
pears to be perfect: it is of consequence to the safety of
the operator, and the success of the experiment, that the
mercury should be previously heated, otherwise the dif-
ference of temperature between the two metals at the time
of mixture will be very apt to produce an explosion. The
actual fusion of the zinc or antimony is, however, by no
means absolutely necessary: the metal in small pieces being
put into a crucible, the proper quantity of mercury is then
to be added; the interfaces will thus be filled up, and the
mats being then exposed to a heat a little less than that
required for the volatilization of mercury, the amalgamation
will in a short time be completely effected. Those metals,
however, that require a full red heat for their fusion, will
volatilize with explosion any mercury that is attempted to
be mixed with them while in this state, such, for example,
is copper. This is, therefore, best amalgamated in the
most way; for which purpose take a boiling hot faturated
solution of sulphat of copper, pour it into a glass or Wedge-
wooden mortar, and add mercury and iron filings; the
iron will decompose the sulphat of copper, and precipitate
this latter metal in a finely divided state, which by the heat
and moderate trituration will unite with the mercury, and
the combination may afterwards be perfected by fusion at a
gentle heat in a crucible. Almagnams may be made either
solid or fluid, according to the proportion of mercury that
enters into their composition; the quantity of this last,
however, that is required to give the amalgam a fluid state,
is different for each metal, for the more powerful the affinities
the less is the quantity of mercury required.

§ 2. Phenomena observable during Almagnamation.
All the appearances that happen during the combination
of metals with mercury indicate a real solution of one in the
other, owing to the chemical attraction between the bodies
so uniting. In proportion to the readiness with which any
metal tends to amalgamation is the force with which it ad-

dores
heres to mercury when applied to its surface; and, when a
plate of this, suspended to the arm of a balance, is brought
in contact with mercury, a greater or less counterpoise will
be required to break the adhesion, as the chemical affinity
between the two is stronger or weaker. (See Adhesion.)
Nor is this adhesion an effect taking place merely at the
place of contact, but an actual penetration or absorption of
the mercury is produced by the other metal; thus, when a
plate of gold is placed in contact with mercury, not only the
surface of adhesion is whitened by the mercury, but, after
remaining in this state a few hours, the gold will become
brittle, and particles of mercury may be observed through
its minute pores by the force of chemical attraction.
During amalgamation, as is the case in all other instances
of simple solution, a considerable quantity of caloric is ab-
soved, producing the sensation of cold, and lowering the
thermometer. This is rendered very sensible to the touch,
by rubbing together in the palm of the hand equal parts of
an amalgam of bismuth and an amalgam of lead; the two
solids will almost immediately become fluid, and a very
considerable cold will be produced. This may be shown
by the thermometer; if a quantity of mercury is heated to
about 80° Fahr., and the bulb of a thermometer wrapped
round with tinfoil is then immersed in it, a speedy solution
will take place, and at the same time the mercury in the
thermometer will descend a few degrees.
Another remarkable phenomenon of amalgamation is the
diffusion to oxide which both metals exhibit while the so-
lution is going on, and even after it is completed; it is im-
possible to combine bismuth, tin, or lead, with mercury,
without observing as the process advances the formation of
a quantity of black powder, which rises to the surface of the
metals, and is a compound oxide of mercury and the other
metals. Upon this also depends Dr. Priestley's simple and
ingenious method of separating from mercury a large pro-
portion of the lead, &c., with which it is usually contami-
nated; for this purpose nothing more is necessary than agi-
tation of the mercury in a bottle, with a little water, till it
ceases to be discoloured, or, in other words, till the amal-
gam is almost wholly decomposed. Hence too is explained
the observation of Isaac Hollandus, that gold and silver may
be calcined in a reverberatory furnace, if they have been
previously mixed with mercury.
§ 3. General Properties of Amalgams.

The specific gravity of amalgams, as of all other alloys,
is different from the mean specific gravity of their com-
ponent parts: sometimes it is greater, at other times less;
and, according to Gellert, the amalgam of silver is of supe-
rior specific gravity even to mercury, the weight of the
two ingredients. This takes place, however, only at a low
temperature; for it was found by Sage that the amalgam of
silver, when heated, floats on the surface of mercury.
The more decidedly crystalline form of amalgams, owing
to their soft or semi-fluid state, at a moderately warm tem-
perature, is a circumstance that remarkably distinguishes them
from the pure metals. Any metal, when melted and cooled
very slowly, will exhibit in its fracture a crystalline structure,
and the crystals of which it is composed may, by particular
management, be exhibited in a state of separation from each
other; but similar appearances may be produced with much
greater ease in amalgams. All amalgams are brittle, and
any of them, being broken, will exhibit a granular or lam-
nated texture, which, by the microscope, will be found to
be owing to a multitude of minute crystals, applied by their
surfaces to each other, but not adhering with any consider-
able force. Induced by these appearances, M. Sage, after
many trials, succeeded in obtaining regular crystals of most
of the amalgams by the following method. Having pre-
pared a very fluid amalgam, by adding four, five, or six
times a greater quantity of mercury than of the other met-
al, he put it into a retort, and proceeded to distillation in
a sand-bath, till a fourth, or even a third, of the mercury
had been driven off; the residue, being then allowed to cool
very gradually, was found regularly crystallized at the bot-
tom of the vessel. He thus obtained silver amalgam in the
form of articulated tetrahedrons and aluminiform octah-
drons, resembling the native dendritic silver. In the same
manner the amalgams of gold, bismuth, tin, and zinc, af-
formed the form of regular crystals, but those of copper,
arsenic, and antimony, refused to crystallize.

Amalgams may be decomposed by heat, but the last por-
tions of mercury are not driven off without a much greater
heat than is required for the volatilization of pure mercury.
Hence a large proportion of the volatile metals, such as
zinc and arsenic, unites with the mercury, and is carried
over with it, and even the more fixed ones, as gold and sil-
ver, are thus rendered in part volatile.

As each metal has its peculiar affinity for mercury, it is
obvious that an amalgam may be decomposed by the addi-
tion of a metal that has a stronger attraction to mercury
than that of which the amalgam is composed; upon this
subject, however, no accurate experiments have as yet been
made, which is the more to be regretted, as it would much
afold the investigation of the difficult but important subject
of metallic alloys. One amalgam may even decompose an-
other in a great measure, as is the case with the amalgams
of lead and bismuth; these being made separately, with a
quantity of mercury equal to the other ingredient, will be
solid and friable, but, upon mixture, will combine into a
fluid scarcely to be distinguished by its appearance from pure
mercury: by floating some days, however, in a temperature
not exceeding 40° Fahr., cubic crystals will be deposited of
almost pure bismuth. For other particulars see the several
amalgams under the word Mercury. Encycloped. me-
thod. art. Almagame.

AMALGAMATION, in Metallurgy. See Silver.

AMALI, in Ancient Geography, a people comprehended
under the appellation of Getæ.

AMALIA, in Entomology, a species of Papilio in the
Nymphalidae section, with indented wings: upper side brown,
under side yellow with two fæte and spots of blue, the lower
ones marked with black dots. Fabr. Ent. Syst. tom. iii.
p. 1. p. 129, fp. 398. Obs. In addition to this specific
character Fabricius says, above the brown colour of the
wings inclines to fulvous, and the posterior pair is marked
with an obsolete row of fulvous spots. Beneath, the apex
of the anterior wings has a black mark, and two blue spots
with a black character in the middle of each; the exterior
margin, two fæte, and seven spots on the posterior wings
are blue, the latter with black dots in the middle. Inhab-
bits Sierra Leon.

AMALLOBRIGA, in Ancient Geography, a town of
Spain, upon the Darius, to the south-east of Pallentia.

AMALRIC, Auger, in Biography, an ecclesiastical
historian of the 14th century, dedicated to pope Urban V.
a history of the popes, under the title of "Chronicon Pen-
tificale," brought down to pope John XXII, and said to be
collected from more than 200 writers.

AMALTHEA, in Mythology, the Cumean Sibyl, who

is
is said to have come from a far country to Tarquinius Superbus, and to have offered for sale nine books of Sibylline, or prophetic oracles. Upon Tarquin's refusal to give her the price she asked, she went away and burned three of them. Returning soon after, she demanded the same price for the remaining five. The king ridiculed her for her folly, upon which she went and burnt other three; and returning asked the same price for the three which remained. A. Gellius (i. 19.) says, that the books were burnt in the presence of the king. Tarquin, surprised by this strange conduct, consulted the augurs, who, regretting the loss of the books which had been destroyed, advised the king to give the price, which the woman required. Amalthea, having surrendered the books, with a desire that they might be carefully kept, disappeared, and was never afterwards seen. Dionys. iv. 62. Lactantius, i. 6. Gell. i. 19. Pliny (xiii. 13. f. 27.) says, that she burnt two books, and only preserved one. See SIBYLS.

AMALTHEA, the daughter of Melissus, king of Crete, and nurse of Jupiter, whom she is said to have fed with goat's milk and honey. According to others, Amalthea was a goat which nourished Jupiter, and whom, in recompence for her attention, he translated into the heavens, and thus she became the constellation which bears this name. It is added, that one of the horns of this goat was given to the daughter of Melissus, as a reward for their kindness, and that it had the peculiar property of furnishing them with whatever they wished for; and hence the Greeks formed of it their cornucopia, or horn of abundance.

AMALTHEA, in Biography, the name of a family of the 16th century, celebrated for literature, originally from Porleone in Friuli, and branched out into several places in that province. In this family there were poets, physicians, and professors of belles lettres. The most distinguished were the sons of Francisco Amalthea, professor of belles lettres in Sacile; viz. Girolamo, or Jerom, born in 1507, at Oderzo in the Trevisan, who was solicited by the queen of Poland to be her physician, but declined it. He taught medicine at Padua, and practised as a physician in several towns of Friuli, till 1574, when he died at Oderzo highly honoured by his townsmen. He so much excelled in Latin poetry, that he is placed by Muretus at the head of all the Italians who excelled their talents in this way. The famous epitaph of "Aeon and Leonilla," is by this author. Simondia, or John Bagdy, was born at Oderzo in 1525, educated at Padua, and at the age of 20, called to Venice to instruct the youth of the Lippomana family in polite literature. His own studies comprehended, besides the Greek, Latin, and Italian languages, philosophy, jurisprudence, and theology. In 1554 he accompanied the Venetian ambassador, Michele, to England; he was afterwards secretary to the republic of Ragusa, and accompanied the cardinals deputed to the council of Trent, as first secretary to pope Pius IV. He died at Rome in 1573, much lamented by the learned men of his time, by whom he was highly esteemed for his genius and erudition. His Latin poems, first printed in 1550, gave him a reputation equal to that of his brother; and he likewise wrote poems in his own language that are much valued. The Latin poems of these two writers, and of another brother named Cornetta, who was a physician, are contained in the first volume of the "Delizie Poet. Italor," and were published in a separate volume, at Venice in 1627, and at Amsterdam, in 1689. Gen. Biog.

AMAMA, SIXTIMUS, an eminent biblical critic of the 17th century, was born in Weft Friefland, educated under Drusius in the university of Francker, and obtained a very considerable acquaintance with the oriental languages. Wood (Athen. Oxon. n. 612.) says, that about the year 1613, he visited Oxford, resided in Exeter college, and taught Hebrew in the university. Upon his return to his native country, he was appointed professor of the Hebrew language in the university of Francker, where he continued, notwithstanding earnest solicitations for his removal to Leyden, in order to succeed Erasmus, till his death, which happened in December 1629. His first work was a criticism on the Vulgate translation of the Pentateuch, printed in 1606, in Francker, and entitled, "Concilia Vulgata Latina Editionibus Pentateuchis." This was part of a plan which he had formed with a view to a "General Concilium of the Vulgate Version of the Scriptures," which the council of Trent had declared authentic. But his attention was diverted from the completion of his design, by a collation of the Dutch version of the Scriptures, with the originals, and the most approved translations. The result of this collation was published in 1603, in the Dutch language, under the title of "Bybelsche Conferentie." Whilil he was thus engaged, he received information that father Merfennius, in vindication of the Vulgate, had written a refutation of his criticism on the first four chapters of Genesis, and he, therefore, returned his original design; and, in 1627, published a letter to Merfennius; and in 1628 a work, entitled, "Anti-Barbarus Biblium!" or containing a farther reply, together with a catalogue of the Vulgate on the historical books of the Old Testament, on Job, the Psalms, and the books of Solomon, to which are added, dissertations on particular subjects. This book was reprinted at Francker, in 1636, with a criticism of the Vulgate upon Isaias and Jeremiah. Amama also wrote a learned dissertation, "De Nomine Tetragrammaton," which was published in 1615, at Francker in 1620. So successfully did he expose the defects and errors of the Vulgate, and so earnestly did he recommend the study of the original languages of the Bible, that it was decried by some synods, that those only should be admitted to the ministry, who understood, at least in some degree, the Hebrew and Greek texts of the Scripture. Amama also evinced his solicitude for the honour of the university at Francker, by his attempts to reform some irregularities of conduct that prevailed in it. He was so much respected by his countrymen, that, after his death, they testified their regard for his memory by their liberality to his children. Gen. Diet.

AMAMASSIUS, in Ancient Geography, a town of the island of Cyprus, in which they worshipped Apollo Hyentes.

AMAM-SAMA, a town of Judea, in the tribe of Judah.

AMAN, in Commerce, a sort of blue cotton cloth, which comes from the Levant by the way of Aleppo.

AMAN, in Ancient Geography, a town of Paleline, in the southern part of the tribe of Judah.

AMAN, in Geography, a sea-port town of Africa, on the Atlantic, between Cape Ger and Cape Cantin, in the kingdom of Morocco.

AMAN, a district of Sumatra, about the centre of the island.

AMANA, in Ancient Geography, a mountain of Paleline, on the other side of Jordan, in the tribe of Manasseh.

AMANA, a town of Aifa, in Media, according to Plo- lemmy.

AMANCE, in Geography, a town of France, in the department of the Meurte, and chief place of a canton in the district of Nancy, three leagues south-west of Chateau-Salins, and 13 north-east of Nancy.

AMANCE is also a town of France, in the department of
of the Upper Saone, and chief place of a canton in the
district of Jufsey, two leagues east of Jufsey.

AMAND, MARK ANTHONY GERARD, SIEUR DE
SAINT, in Biography, a French poet of the 17th century,
was born at Rouen in Normandy in 1595. His father com-
manded a squadron of ships in the service of Queen Elizabeth
for 22 years, and his two brothers were killed in a battle
against the Turks. As for himself, his whole life was spent
in a succession of travels in Europe, Africa, and America,
which, whatever might be the annihilation of his fortune
he derived from them, were injurious to his fortune. His
works were chiefly miscellaneous poems, most of which are
of the comic or burlesque, and of the gallant or amorous
kind. Three volumes of his poems were published in 1610,
at Paris; the first in 1627, the second in 1643, and the third
in 1649, under the title of "Les Œuvres de St. Amand;" and
they have passed through several editions. His "Stan-
zas upon the Pregnancy of the Queen of Poland and Swe-
den" were printed in 1560; his "Moles faced, an heroic
Idyllium," Paris, 1653, 4to, and 1666, 12mo; his "Stan-
zas to Monf. Cornecille, upon his Limation of Jefus Chrift,"
Paris, 1656, 4to; and his "Rome ridiculis;" printed several
fames in 1610 and 12mo; and when it was printed clandestinely
at Paris in 1643, the printer was thrown into prifon.
The earlier part of Amand's life was licentious and debauched;
but towards the close of it he was reformed, in confequence
of the penury and diftrefs of his circumstances. M. Brifot,
in his notes upon Beliace, fays, that he wrote a poem upon
"the Moon," in which he complimented Lewis XIV.
upon his flill in swimming, in which he was accustomed to
exercise himfelf in the Seine; but the king could not bear
to hear this poem read to him; and this circumstance is faid
to have mortifed the author to fuch a degree that he did not
long survive. He died in 1661, at the age of 67 years.
He was admitted a member of the French Academy from
its first foundation in 1663; and he was excufed from mak-
ing a speech upon his introduction, on condition of his
compiling the comic part of the Dictionary which the Aca-
demy had undertaken, and collecting the grotesque and bur-
leque terms. Boileau reprefents the genius of St. Amad
as adapted to works of low humour and fatigue; but he adds,
that he fpots all by the mean and trivial circumstances which
he introduces. Geo. Dift.

AMAND, PIERRE, born at Riez in Provence, about the
middle of the 17th century, practifed midiftry with credit
at Paris. In the year 1697, he published "Nou-
velles Observations fur la Pratique des Accoucheurs,"
in 8vo, of which a second edition appeared in the year
1715. He relates the cafes of feveral women who had extra-
uterine ftreptes, and gives an account, accompanied with en-
gravings, of a kind of net he had invented for extracting
the heads of foetuses, when left in the uterus, separated from
the body. The invention is ingenious, but has long been laid
aside for the crotchet, by which the extraction is performed
with much greater care and certainty. Vide Effais Histo-
rigues fur l'Art des Accoucheurs, par M. Suc.

AMAND, St. in Geography, a town of France, in the de-
partment of Cher, feated on the river Cher, 20 miles south
of Bourges. N. lat. 46° 45'. E. long. 2° 30'.

AMAND, St. is also a town of France, in the depart-
ment of the North, in which was lately a celebrated abbey.
When the combined forces of Prufia and Austria invaded
France in 1792, it was taken by them, but evacuated afterwards in
their memorable retreat. It was given to France by the
bargain of Utrecht. It is feated on the river Scarpe, seven
miles north of Valenciennes. N. lat. 50° 27'. E. long.
2° 35'.

AMAND, St., a small town of France, in the diocese of
Auxerre.—Alfo a small town in the diocese of Clermont.

AMANDA, in Ancient Geography, a country of Indo-
alia, which, according to Pliny, contained various people, under
the denominations of Samarantb, Sanbrucus, Bilambrif, Olii,
Antiken, and Taxille.

AMANDAVA, in Ornithology, a species of Fringilla
that inhabits Asia, and is cynically defcribed by Linnaeus, as
being of a brown and redifh colour, spotted with white.
It is about the size of a wren, or four inches in length; the
upper part of the plumage brown, with a mixture of
dull red, the under part of the fame colours, but paler,
except the middle of the belly, which is darkf. Every
feather in the upper wing-coverts, breifs, and fides, has
a white spot at the tip. The bill is dull red, tail black,
and legs pale yellow. The female has a mixture of white
on the throat and fore-part of the neck, and the belly is
pale yellow.

This species is frequent in Bengal, and has been called
the Bengal finch (or Amaduva). In allusion to this, Brif-
fon names it Bengalus punctatus, and Buffon Bengale
piqueté.

There is a variety of this fpecies, the Amandava E.
of Linnaeus, hitherto found only in Bengal, which is
faid to be entirely brown, and without spots. This is
the Bengalus fulicus of Brifon, and Bengale Brun of Buf-
fon, pl. enl. 115, f. 2. but it feems this variety is not al-
ways immaculate. Some have a small white spot at the tip
of each of the wing covert feathers, and there is in general
a little white on the breast also. The female is brown, with-
out white spots: the legs, as in the preceding, yellow.

AMANDRA, in Ancient Geography, a town of Ethi-
opia, placed by Suidas in the territories of king Cepheus.
AMANGO Cape, in Geography, lies on the south-east part
of the island of Corica, and forms the limit of Bonifacio
Bay. It is easily known by a large castle, and two rocks,
which are situated just below the haven.

AMANGUCHI, a town of Japan, the capital of the
kingdom of Nagaro, and one of the richest towns of
Japan.

AMANIA, in Ancient Geography, a name given to Ara-
bria Felix, or to that part of it called Yemen.

AMANIBO, a town of South America, on the coast of
Guiana, between Paramaribo and Cayenne.

AMANICOLE, or AMANDIBULUM, port. or pule, in Ancient
Geography, denote defcifts in the mountain Amamus.

AMANITA, in Botany. See AGARICUS.

AMANNA. See ASMANNIA and PEPLUS.

AMANOA, in Botany, a genus of the pentandria monogy-
ous clafs and order. Its characters are, that the calypsis
is quinquem-partite; no corolla; the genus is triangular, the stig-
ma trigonous, concave, and fimbricated. There is one fpecies,
A. guianensis. Auebl. pl. gui.

AMANOBII, in Ancient Geography, a people placed by
Ptolemy in Sarmacia, in the vicinity of the Roxolane.

AMANOIDES, a promontory of Cilicia, between the
rivers Pyramus and Cidnus.

AMANTEA, a sea-port town and bishop's see of
the kingdom of Naples, on the west coast of Calabria
Citra, near the bay of Euphemia. N. lat. 39° 15'. E. long.
16° 21'.

AMANTHONTE, in Entomology, a species of Papil-
io in the fection Danae Candidi, with rotund wings, white
and black at the tips. The margin of the posterior wings
on the under side is brown. Inhabits South America.

AMANTIA, in Ancient Geography, a town in that part
of Epirus called by Ptolomy Oedipides, and since denomi-

A M A
AMA

Ama
ted New Epirus. It is placed by M. d'Anville in the in-
terior of the country, on the river Celidaus. The inhab-
tants were denominated Amantes, or Amantini.

AMANUS, the name of a mountain, situated at the eas-
tern extremity of the Mediterranean, near the gulf of Ifis,
and separating Cilicia from Syria. The defile or pass of this
mountain, which forms a communication between these
countries, is called Portus Amanusi, or Pyli Cilicia, the
Gates of Cilicia. The Persian army, under Darius, marched
through this strait, while that of Alexander was encamped
at Ifis, after having passed the Strait of Mount Taurus,
called also one of the Gates of Cilicia. This defile is also
famous for the victory gained by Septimius Severus over
Pescennius Niger. This mountain extends between the 37th
and 35th degree of latitude, and its direction is from the
north-east to the south-west. Some geographers have made
it a branch of Mount Taurus. Stephanus Byz. says, that it
took its name from the Greek word μανας, mania, because
Oroetes was delivered here from the furies which agitated
him after the assassination of his mother.

AMANUS, or OMANUS, in Mythology, the deity of the
ancient Persians, which they believed to be the sun, or the
perpetual fire, which they adored as an image or emblem
of the sun.

AMANZIRFIDIN, in Geography, a town of Arabia,
460 miles east of Mecca, and 384 north-east of Mocha.
N. lat. 20° 25'. E. long. 67° 30'.

AMAPALLA, a sea-port town in the province of Guat-
imala, in North America, situated on a gulf of the same
name, 220 miles south-east of the town of Guatimala. The
inhabitants of this town and its vicinity carry on a considera-
tble trade in cochineal, cocoa, hides, and indigo, and the other
commodities of the province. N. lat. 12° 30'. W. long.
86° 40'.

AMAPALLA Bay, or Gulf, lies on the western coast of
Mexico, in North America, south-east from Guatimala,
and north-west from Realejo, in the direction of the coast.
The entrance into the bay is between two peninsulas, which
approach near each other, and defend the bay from the
ocean; but within it is very spacious, extending from north-
west to south-east. It forms the harbour of the town of
Amapalla, sometimes called Fonfece or Penfece. The coast,
within the limits of the gulf, and without the bay, is free
from rocks and shoals, and affords good anchorage; on the
west side of the bay there is a hill, called the Hill of Ama-
palla, with a port at the foot of it called Martin Lopes.
In the Gulf of Amapalla are two islands: one, called Man-
gera, is a high round land, encompassed by rocks, with
a small sandy creek on the north-east side; and the other,
called Amapalla, and the largell, is about the distance of
two miles. The gulf, though it runs a great way beyond
this island, is not deep enough to receive ships of burden.
Malham's Gaz.

AMARA, in Ancient Geography, a town of Arabia
Felix.

AMARA INDICA, in Botany. See MOMORDICA.

AMARACUS. See ORIGANUM.

AMARANTE, in Geography, a considerable and pleasant
town of Portugal, in the province of Entre Mino, on
the river Tamega, 23 miles south-east of Braga, and 30 east-
north-west of Oporto. N. lat. 41° 15'. W. long. 6° 52'.
It contains about 4000 inhabitants, and is situated in a very
delightful country.

AMARANTH, an order of knighthood, instituted in
Sweden by Queen Christina in 1655, at the close of an an-
nual feast, celebrated in that country, and called期货
chaff.

This feast was solemnized with entertainments, balls,
masquerades, and the like diversions, and held from evening
the next morning. That prince, thinking the name too
vulgar, changed it into that of the "flour of the gods", because
each person here repented some duty according as it fell
to his lot. The queen assumed the name of Amaranthe, that
is, unfading, or immortal. The young nobility, drested
in the habit of nymphs and shepherds, served the gods at the
table. At the end of the feast, the queen threw off her
habit, which was covered with diamonds, leaving it to be
pulled in pieces by the maids, and in memory of so gallant
a feast, founded a military order, called in Swedish gejill-
chaff, into which all that had been present at the feast were
admitted, including sixteen lords, and as many ladies, be-
fides the queen. Their device was the cypher of amaranthe,
composed of two A's, the one direct, the other inverted, and
interwoven together on a jewel of gold adorned with dia-
monds; the whole inclosed by a laurel crown, with this
motto, dolor nulla memoria. The jewel was worn by the
knights either in a gold chain, or a crimson or blue ribbon.
Bulstrode Whitlock, the English ambassador from Cromwell
to the court of Sweden, was made a knight of the order of
amarante. On which account it seems to be, that we some-
times find him fand Sir Bulstrode Whitlock.

AMARANTHUS denotes a colour inclining to purple, derived
from the flower of this name.

AMARANTHUS, Gels, in Botany. See GOMPHRENA.

AMARANTHUS, Gels. See PHYMA.

AMARANTHUS AFFINI. See GOMPHRENA and ILLI-
CEBRUM.

AMARANTHIDES. See CELOSIA, GOMPHRENA
and ILLICEBRUM.

END OF THE FIRST VOLUME.
