Heat is well known to rarely and expand, and consequently to lessen the specific gravity of the air to which it is applied; and the diminution of its weight is proportional to the heat. To the observations that occur under Elasticity of Air, to this purpose, we shall here add, that one degree of heat, according to the scale of Fahrenheit's thermometer, incurs to expand the air about one hundredth part; and about 400, or rather 435, degrees of heat, will just double the bulk of a quantity of air. If, therefore, the air inclosed in any kind of covering be heated, and consequently dilated, to such a degree, as that the excess of the weight of an equal bulk of common air above the weight of the heated air, is greater than the weight of the covering and its appendages, this whole mass will ascend in the atmosphere, till, by the cooling and condensation of the included air, or the diminished density of the surrounding air, it becomes of the same specific gravity with the air in which it floats; and without renewed heat, it will gradually descend. 

If, instead of heating common air inclosed in any covering, and thus diminishing its weight, the covering be filled with an elastic fluid, lighter than atmospheric air; so that the excess of the weight of an equal bulk of the latter above that of the inclosed elastic fluid be greater than the weight of the covering and its appendages, the whole mass will in this case ascend in the atmosphere, and continue to rise till it attains a height at which the surrounding air is of the same specific gravity with itself. Inflammable air is a fluid of this kind. For the knowledge of many of its properties, we are indebted to Mr. Henry Cavendish; who discovered, that if common air is eight hundred times lighter than water, inflammable air is seven times lighter than common air; but if common air is eight hundred and fifty times lighter than water, then inflammable air is 10.8 times lighter than common air. See Phil. Trans. vol. liv. art. 19, and Inflammable Air or Hydrogen. 

The construction of air-balloons depends upon the principles above stated; and they are of two kinds, as one or the other of the preceding methods of preparing them is adopted. 

ÆROSTATION, history of. In the various schemes that Pp:
have been proposed for navigating through the air, some have had recourse to artificial wings; which, being constructed like those of birds, and annexed to the human body, might bear it up, and by their motion, produced either by mechanical springs, or muscular exertion, effect its progress in any direction at pleasure. This is one of the methods of artificial flying suggested by bishop Wilkins, in the seventh chapter of his Dedalus, or "Treatise on Mechanical Motions;" but the successes of it is doubtful, and experiments made in this way have been few and unsatisfactory. Borelli (De Motu Animalium, cap. 22, prop. 193 and 204, p. 196 and 208, ed. 1716), having compared the power of the muscles which act on the wings of a bird with that of the muscles of the breast and arms of a man, finds the latter altogether insufficient to produce, by means of any wings, that motion against the air, which is necessary to raise a man in the atmosphere.

Others, with greater probability of success, have proposed to attach the human body to some masts, which being lighter than air, might raise itself and the annexed weight into the regions of that element. This method has actually succeeded; though Borelli (ubi supra), as well as Leibnitz, denied the possibility of a man's flying by any of the means with which they were acquainted.

It is needless to recite any of the accounts relating to this subject, which have been transmitted to us by the ancients. Most, if not all of them, are fabulous. An ingenious writer, in a work cited at the close of this article, has given us the result of his enquiries into the records of antiquity; and he informs us, that the earliest account of any thing relating to flying, which has the appearance of authenticity, is that of the wooden pigeon, constructed by Archytas in the fourth century, before the Christian era, and of which Aulus Gellius (Nocetis Attic., lib. x. cap. 12.) relates, that it could fly by means of mechanical powers, and by an inclosed spirit. This spirit, or aura, our author apprehends, was nothing more than a sort of animation, which the machine appeared to be possessed of, in consequence of its extraordinary mechanism. Aerostation was, therefore, a subject either altogether unknown, or very imperfectly understood among the ancients; unless we suppose it to be one of those arts, of which the records are lost. In later times, the schemes which have been proposed by ingenious men seem to have terminated in speculation. The reader will find a brief account of some of them under the articles Atmosphere and Artificial Flying, and a more comprehensive history of the projects and achievements of different persons, in the work cited below. Upon the whole it appears, that the art of traversing the air is an invention of our own time; and the whole history of it is comprehended within a very short period.

Soon after Mr. Cavendish's discovery of the specific gravity of inflammable air, it occurred to the ingenious Dr. Black of Edinburgh, that if a bladder, sufficiently light and thin, were filled with this air, it would form a mass lighter than the same bulk of atmospheric air, and rise in it. This thought was suggested in his lectures in 1767 or 1768; and he proposed, by means of the allantosis of a calf, to try the experiment. Other experiments, however, prevented the execution of his design. The possibility of constructing a vessel, which, when filled with inflammable air, would ascend in the atmosphere, had occurred also to Mr. Cavallaro about the same time; and to him belongs the honour of having first made experiments on this subject, in the beginning of the year 1782, of which an account was read to the Royal Society, on the 20th of June in that year. He tried bladders; but the thinness of these, however scraped and cleansed, were too heavy. In using China paper, he found that the inflammable air passed through its pores, like water through a sieve; and having failed of success by blowing this air into a thick solution of gum, thick varnishes, and oil-paint, he was under a necessity of being satisfied with soap-balls, which, being inflated with inflammable air, by dipping the end of a small glass tube, connected with a bladder containing the air, into a thick solution of soap, and gently comprephing the bladder, ascended rapidly in the atmosphere; and these were the first sort of inflammable air-balloons that were ever made.

For balloons formed on a larger scale, and on the principle of rarefied air, we must direct our attention to France; where the two brothers, Stephen and Joseph Montgolfier, paper-manufacturers at Annonay, about 36 miles from Lyons, distinguished themselves by exhibiting the first of those aerostatic machines, which have since excited so much attention and admiration. The first idea of such a machine was suggested to them by the natural ascent of the smoke and clouds in the atmosphere; and the first experiment was made at Avignon by Stephen, the elder of the two brothers, towards the middle of November, 1782: Having prepared a bag of fine silk, in the shape of a parallelepiped, and in capacity about forty cubic feet, he applied to its aperture burning paper, which rarefied the air, and thus formed a kind of cloud in the bag; and when it became sufficiently expanded, it ascended rapidly to the ceiling. Soon afterwards the experiment was repeated by the two brothers at Annonay, in the open air, when the machine ascended to the height of about fifty feet. Encouraged by their successes, they constructed a machine, the capacity of which was about 650 cubic feet; which, in the experiment, broke the ropes that confined it, and after ascending rapidly to the height of about 600 feet, fell on the adjoining ground. With another machine, 35 feet in diameter, they repeated the experiment in April, 1783; when breaking loose from its confinement, it rose to the height of about 1000 feet, and being carried by the wind, it fell at the distance of about three quarters of a mile from the place where it ascended. The capacity of this machine was equal to about 23,430 cubic feet; and when inflated, it measured 171 English feet in circumference. The covering of it was formed of linen, lined with paper; its shape was nearly spherical; and its aperture was fixed to a wooden frame about 16 feet in surface. When filled with vapour, which was conjectured to be about half as heavy as common air, it was capable of lifting up about 450 pounds, besides its own weight, which, together with that of the wooden frame, was equal to 560 pounds. With this machine the next experiment was performed at Annonay, on the 5th of June, 1783; before a great multitude of spectators. The flaccid bag was suspended on a pole 35 feet high; straw and chipped wool were burnt under the opening at the bottom; the vapour, or rather smoke, soon inflated the bag, so as to distend it in all its parts; and this immense mass ascended in the air with such a velocity, that in less than 10 minutes it reached the height of about 6600 feet. A breeze carried it in an horizontal direction to the distance of 7068 feet; and it then fell gently on the ground. Mr. Montgolfier attributed the ascent of the machine, not to the rarefaction of the heated air, which is the true cause, but to a certain gas or aeriform fluid, specifically lighter than common air, which was supposed to be diffused from burning substances, and which has
has been commonly called Montgolfier's gas, as balloons of this kind have been denominated Montgolfiers.

As soon as the news of this experiment reached Paris, the philosophers of the city, conceiving that a new fort of gas, half as heavy as common air, had been discovered by Meffis. Montgolfier, and knowing that the weight of inflammable air was not more than the eighth or tenth part of the weight of common air, justly concluded that inflammable air would answer the purpose of this experiment better than the gas of Montgolpher, and resolved to make trial of it. A subscription was opened by M. Faujas de St. Fond towards defraying the expenses of the experiment.

A sufficient sum of money having been soon raised, Meffis. Roberts were appointed to construct the machine; and M. Charles, professor of experimental philosophy, to superintend the work. After surmounting many difficulties in obtaining a sufficient quantity of inflammable air, and finding a substance light enough for the covering; they at length contrived a globe of flinting, which was rendered impervious to the inclosed air by a varnish of elastic gum or caoutchouc, dissolved in some kind of spirit or essentia oil. The diameter of this globe, which from its shape was denominated a balloon, was about thirteen feet, and it had only one aperture, like a bladder, to which a stop-cock was adapted; its weight, when empty, together with that of the stop-cock, was 37 pounds. On the 23d of August, 1783, they began to fill the globe with inflammable air; but this, being their first attempt, was attended with many hindrances and disappointments. At last, however, it was prepared for exhibition; and on the 27th it was carried to the Champ de Mars, where, being detached from the cords that held it down, it rose before a prodigious concourse of people, in less than two minutes, to the height of 3123 feet. It then entered a cloud, but soon appeared again; and at length it was lost among other clouds. This balloon, after having floated about three quarters of an hour, fell in a field about fifteen miles distant from the place of ascent; where, as we may naturally imagine, it occasioned much astonishment to the peasants. Its fall was owing to a rent, occasioned by the expansion of the inflammable air in that rare part of the atmosphere to which it ascended. When the balloon went up, its specific gravity was 35 pounds less than that of common air.

In consequence of this brilliant experiment, many balloons were made on a small scale; gold-beaters skin was used for the covering; and their size was from 9 to 18 inches in diameter.

Mr. Montgolpher repeated an experiment with a machine of his construction before the academies of the Academy of Sciences on the 11th and 12th of September. This machine was 73 feet high, and about 43 feet in diameter. When distended, it appeared spherical. It was made of canvas, covered with paper, both within and without; and it weighed 1000 pounds.

The operation of filling it with rarefied air, produced by means of the combustion of 50 pounds of dry straw, and 12 pounds of chopped wool, was performed in about nine minutes; and its force of ascension, when inflated, was so great that it raised eight men who held it some feet from the ground. This machine was so much damaged by the rain, that it was found necessary to prepare another for exhibition before the king and royal family on the 19th. This new machine consisted of cloth, made of linen and cotton thread, and was painted with water-colours both within and without. Its height was near 60 feet, and its diameter about 43 feet. Having made the necessary preparations for inflating it, the operation was begun about one o'clock on the 19th of September, before the king and queen, the court, and all the Parisians who could procure a conveyance to Versailles. In eleven minutes it was sufficiently distended, and the ropes being cut, it ascended, bearing up with it a wicker cage, in which were a sheep, a cock, and a duck. Its power of ascension, or the weight by which it was lighter than an equal bulk of common air, allowing for the cage and animals, was 606 pounds.

This balloon rose to the height of about 1442 feet; and being driven by the wind, it descended gradually and fell to a wood, at the distance of 10,290 feet from Versailles. After remaining in the air about eight minutes, the animals in the cage were safely landed. The fowl was found feeding; the cock had received some hurt on one of his wings, probably from a kick of the sheep; the duck was perfectly well.

The success of this experiment induced M. Pilatre de Rozier, with a philosophical intrepidity which will be recorded with applause in the history of aeronautics, to offer himself as the first adventurer in this aerial navigation. Mr. Montgolpher constructed a new machine for this purpose in a garden in the Faubourg St. Antoine. Its shape was oval; its diameter being about 48 feet, and its height about 74 feet. To the aperture at the bottom was annexed a wicker gallery about three feet broad, with a balustrade about three feet high. From the middle of the aperture was suspended by chains which came down from the sides of the machine, an iron grate or brazier, in which a fire was lighted for inflating the machine; and ports-holes were opened in the gallery, towards the aperture, through which any person, who might venture to ascend, might feed the fire on the grate with fuel, and regulate the dilatation of the inclosed air of the machine at pleasure. The weight of this aeronaut was upwards of 1650 pounds. On the 19th of October, the fire being lighted and the machine inflated, M. P. de Rozier placed himself in the gallery, and ascended, to the astonishment of a multitude of spectators, to the height of 84 feet from the ground, and there kept the machine afloat during 4½ hours, by repeatedly throwing straw and wool upon the fire: the machine then descended gradually and gently, through a medium of increasing density, to the ground; and the intrepid adventurer afforded the spectators that he had not experienced the least inconvenience in this aerial excursion. This experiment was repeated on the 17th, and on the 19th, when M. P. de Rozier, in his descent, and in order to avoid danger by reascending, evaded to a multitude of observers, that the machine may be made to ascend and descend at the pleasure of the aeronaut, by merely increasing or diminishing the fire in the grate. The balloon having been hauled down, M. Girand de Villette placed himself in the gallery opposite to M. Rozier; and being suffered to ascend, it hovered for about nine minutes over Paris in the sight of all its inhabitants at the height of about 330 feet. In another experiment the marquis of Arlandes ascended with M. Rozier much in the same manner. In consequence of the report of the preceding experiment, signed by the commissaries of the Academy of Sciences, it was ordered that the annual prize of 600 livres should be given to Meffis. Montgolpher for the year 1783. In the experiments above related the machine was secured by ropes; but they were soon succeeded by unconfined aerial navigation. Accordingly the balloon of 45 feet in height, above mentioned, was removed to La Muette, a royal palace in the Bois de Boulogne; and all things being ready, on the 21st of November M. P. de Rozier.
AEROSTATION.

Rozier and the marquis d'Arlandes took their respective polls in the gallery, and at 54 minutes after one the machine was absolutely abandoned to the element, and ascended calmly and majestically in the atmosphere. The aeronauts, having reached the height of about 230 feet, waved their hats to the astonished multitude; but they soon rose too high to be distinguished, and are thought to have soared to an elevation of above 3000 feet. They were at first driven by a north-west wind horizontally over the river Seine and over Paris, taking care to clear the steeples and high buildings by increasing the fire; and in rising met with a current of air, which carried them southward. Having paddled the Boulevards, and defiling from supplying the fire with fuel, they descended very gently in a field behind the new Boulevard, about 5000 yards distant from the palace de la Muette. They were in the air about 25 minutes. The weight of the whole apparatus, including that of the two travellers, was between 1600 and 1700 pounds.

Notwithstanding the rapid progress of aerostation in France, we have no authentic account of any aeronautic experiments performed in other countries till about the close of the year 1783. The first experiment of this kind, publicly exhibited in our own country, was performed in London on the 25th of November, by count Zambeccari, an ingenious Italian, with a balloon of oil silk, 10 feet in diameter, and weighing 11 pounds. It was gilt, in order to render it more beautiful and more impermeable to the inflammable air. This balloon, three-fourths of which were filled with inflammable air, was launched from the Artillery-ground, in the presence of a vast concourse of spectators; at one o'clock in the afternoon, and at half past three was taken up near Petworth, in Sussex, 48 miles distant from London; so that it travelled at the rate of nearly 20 miles an hour. Its descent was occasioned by a rent, which must have been the effect of the rarefaction of the inflammable air, when the balloon ascended to the rarer part of the atmosphere.

The Parian philosophers having concerted and executed the first aerial voyage with a balloon inflated by heated air, determined to attempt a similar voyage with a balloon filled with inflammable air, which seemed to be preferable to dilated air in every respect; the expense attending it excepted. A subscription was opened to defray the charges, which were estimated at about ten thousand livres; and the balloon was constructed by M. Letourneur. Roberts, of gosses of silk, varnished with a solution of elastic gum. Its form was spherical, and it measured 2 $\frac{1}{2}$ feet in diameter. The upper hemisphere was covered by a net, which was fastened to the hoop enclosing its middle, and called its equator. To this equator was suspended by ropes a car or boat, covered with painted linen and beautifully ornamented, which swung a few feet below the balloon. In order to prevent the bursting of the machine by the expansion of the inflammable air in a rarefied medium, it was furnished with a valve, which might be opened by means of a string annexed to it, for the discharge of part of the internal air without admitting the external to enter. To this balloon was likewise annexed a long pipe through which it was filled. The apparatus for filling it consisted of several casks placed round a large tub of water, each of which had a long tin tube, terminating under a veitch or funnel, that was inverted into the water of the tub. A tube proceeding from this funnel, communicated with the balloon, which stood just over it. Iron fillings and diluted vitriolic acid were put into the casks; and the inflammable air, produced from these materials, passed through the tin tubes, through the water of the tub, and through the funnel of the balloon. The car was ballasted with sand-bags; so that by letting some of the air escape through the valve they might descend, and by discharging some of their ballast ascend. The specific gravity of the inflammable air, with which the balloon was filled, was to that of common air nearly as 1 to 53, and the balloon's power of ascent, when filled for the experiment and when actually ascending, was twenty pounds. The weight of the balloon and of its various appendages was 604 $\frac{1}{2}$ pounds, and therefore the weight sustained by the inflammable air was 624 $\frac{1}{2}$ pounds; and if from the weight of the common air displaced, which was found to be 77 pounds, the former be subtracted, there will remain 147 pounds for the weight of the inflammable air contained in the balloon.

The 1st of December was fixed upon for the display of this grand experiment; and every precaution was made for conducting it with advantage. The garden of the Tuilleries was the scene of operation; and it was crowded and encompassed with an innumerable multitude of observers. Signals were given by the firing of cannon, waving of banners, &c. A small Montgolfier was launched for shewing the direction of the wind, and for the amusement of the people, previously to the general display. At three quarters after one o'clock, M. Charles and one of the Roberts, having seated themselves in the boat attached to the balloon, and furnished with proper instruments, provisions, and clothing, left the ground, and ascended with a moderately accelerated velocity to the height of about 600 yards; the surrounding multitude floundering silent with fear and amazement. At this height the aerial navigators made signs of their safety. When they went up, the thermometer, according to Fahrenheit's scale, fell to 50°; and the barometer at 30, 15 inches. At the height to which they ascended, the barometer fell at 27 inches, whence they deduced their elevation to be nearly 600 yards. During the rest of the voyage the quicksilver in the barometer was generally between 27 and 27 1/2 inches, rising and falling as part of the balloon was thrown out or some of the inflammable air escaped from the balloon. The thermometer generally fell between 53 and 57°. Soon after their ascent, they remained stationary for some time; they then moved horizontally in the direction of N. N. W. and having crossed the Seine, and passed over several towns and villages, to the great amazement of the inhabitants, they descended in a field about 27 miles distant from Paris at a quarter past three o'clock; so that they had travelled at the rate of about fifteen miles an hour, without feeling the least inconveniences. The balloon still containing a considerable quantity of inflammable air, M. Charles re-ascended alone. In ten minutes he thought himself at the elevation of about 1500 toises. The globe, being now in a rarefied medium, swelled considerably; but when some of the inflammable air was discharged, it rose still higher. The barometer, which at his departure stood at 28 inches for lines, had now fallen to 18 inches ten lines. The thermometer, from about 47° of Fahrenheit's scale, had sunk to 21°. From these data the elevation of the globe was estimated at 1524 toises, or about 31,100 yards. M. de Meniller supposes that he ascended to the height of at least 3500 yards. He continued in the air about 33 minutes, and by occasionally pulling the string of the upper valve, and thus letting out the gas, he descended about three miles from the place of his ascent. All the inconvenience he experienced in his elevation was a dry sharp cold, with a pain in one of his ears and a part of his face, which he ascribed to the dilatation of the internal air. The small balloon, launched by M. Montgolfier, was found to have moved in a direction opposite to that of the aeronauts; whence it is inferred,
that there were two currents of air at different heights above the earth.

In the month of December of this year, several experiments with balloons were made at Philadelphia, in America, by Meffrs. Rittenhouse and Hopkins. They contrived to connect several small balloons together, and thus they enabled a man to ascend to the height of 100 feet, and to float to a considerable distance. But fear induced him to cut open the balloons, and thus to descend. Small balloons were at this time very common, both in France and England.

In January 1784, Mr. J. Montgolfier, accompanied by six other persons, ascended at Lyons, with a large rarerfed air-balloon, 134 feet high, and 164 feet diameter, to the height of about 1000 yards. This was the largest machine that had hitherto been made. It was formed of a double covering of linen, with three layers of paper between, and strengthened with strings and ribbons. It contained about 540,000 cubic feet of igneous gas; and its weight, including the gallery and passengers, was 1600 pounds. After remaining in the air about fifteen minutes, a rent in the machine occasioned its fall; and when it came within about 600 feet of the ground, it descended with a degree of velocity which very much alarmed the spectators; but the aeronauts all landed without injury.

On the 22d of February an inflammable air-balloon about five feet in diameter, was launched from Sandwich in Kent, which, travelling at the rate of about 30 miles an hour, crossed the English channel, and descended in a field about nine miles from Lille, in French Flanders.

The first person in Italy, who was at the expense of constructing an aerostatic machine for making an aerial voyage, was the chevalier Paul Andreani of Milan: his machine was spherical, about 68 feet in diameter, and formed upon the principle of those of Montgolfier. The chevalier, and two brothers of the name of Cergli, who had assisted in the construction of it, ascended, on the 25th of February, to the height of about 1200 feet; and they remained in the atmosphere about twenty minutes.

From the calculations made respecting the capacity of this machine, it appears, that the included air was not rarified above one-third, or that the included warm air was not less than two-thirds of that which would have filled the machine, when of the same temperature with the external air; and this is the utmost degree of rarification that can be reasonably expected in balloons of this kind.

The next aerial voyage was performed by M. Jean Pierre Blanchard, who had for several years been employed, though without success, in attempts of flying by mechanical contrivances. This voyage was performed in March 1784, with a balloon 27 feet in diameter, to which a boat was fastened, with two wings and a rudder annexed to the boat, and a large umbrella or parachute spread horizontally between the boat and the balloon, designed to check the fall, provided that the balloon should burst. The greatest altitude to which Mr. Blanchard ascended from the Champ de Mars at Paris, is supposed to be 9331 feet; and it appears from his own acknowledgments that the wings and rudder of his boat had little, if any, power in guiding the balloon from the direction of the wind. He was in the air an hour and a quarter, and descended at Billancourt, near Seine, after having experienced heat, cold, hunger, and an exccssive drowsiness.

Aerostatic experiments and aerial voyages became so frequent in the course of the year 1784, that the limits of this article will not allow our particularly recording them. We shall, therefore, merely mention those which were attended with any peculiar circumstances. Meffrs. de Moreau and Bertrand ascended from Dijon in April, to the height of about 15,000 feet, with an inflammable air-balloon; the thermometer was observed to stand at 25 degrees. They were in the air during one hour and 25 minutes, and went to the distance of about 15 miles. Their ears were affected in the manner described by Mr. Charles. The clouds floated beneath them, and excluded them from the earth; and they jointly repeated the motto inscribed on their aerostat:—

"Surgit nume gallus ad aeram."

In May, four ladies and two gentlemen ascended with a Montgolfier at Paris above the highest buildings; the machine was confined by ropes. It was 74 feet high, and 32 in diameter.

In a second voyage performed by Mr. Blanchard from Rouen, in May, it was observed, that his wings and ears could not carry him in any other direction than that of the wind. The mercury in the barometer descended as low as 20.57 inches; but on the earth, before he ascended, it stood at 30.16 inches.

At Lyons, on the 4th of June, M. Fleuran and Madame Thible, the first lady that made an aerial voyage, ascended in the presence of Gustavus king of Sweden to the height of 8500 feet, and floated to the distance of about two miles in 45 minutes.

A balloon, 32 feet in diameter, filled with inflammable air, extracted from zinc, was raised at Nantes on the 14th of June with two persons, viz. M. Courlat de Maffi and M. Mouchet; which ascended to a great height, and in 58 minutes travelled to the distance of 27 miles.

On the 23d of June, a large aerostat, on the principle of rarified air, 41 feet high, and 50 feet in diameter, was elevated by Montgolfier at Vertouilles, in the presence of the royal family and the king of Sweden. M. Pilatre de Rozier and M. Prouat, ascended with it, and continued for 28 minutes at the height of 11732 feet, and observed the clouds below them, that reflected to the region which they occupied the rays of the sun; the temperature of the air being 5° below the freezing point; and in three quarters of an hour, they travelled to the distance of 36 miles. In consequence of this experiment the king granted to M. Rozier a pension of 2000 livres.

On the 15th of July the duke of Chartres, the two brothers Roberts, and another person, ascended with an inflammable air-balloon of an oblong form, 553 feet long and 34 feet in diameter, from the Park of St. Cloud; the machine remained in the atmosphere about 45 minutes. This machine contained an interior small balloon, filled with common air, by which means it was proposed to make it ascend or descend without any loss of inflammable air or ballast. The boat was furnished with a helm and oars, intended for guiding it. At the place of departure the barometer stood at 30.12 inches. Three minutes after ascending, an agitation of the air, resembling a whirlwind, alarmed the aerial voyagers, and occasioned several shocks, which prevented their using any of the instruments and contrivances prepared for the direction of the balloon. Other circumstances concurred to increase their danger; and, when the mercury in the barometer at 24,36 inches, indicated their height to be about 5100 feet, they found it necessary to make holes in the bottom for discharging the inflammable air: and having made a rent of between seven and eight feet, they descended very rapidly, and at last came safely to the ground.

On the 18th of July M. Blanchard, accompanied by a Mr.
AEROSTATION.

Mr. Baby, made his third aerial voyage with the same inflammable air-balloon, at Rouen; and ascended so high as to make the mercury in the barometer fall 4 76 inches, and the thermometer 40°. In two hours and a quarter they floated 45 miles, or at the rate of twenty miles an hour. In this voyage Mr. Blanchard conceived, that by agitating the wings of his boat he could not only ascend and descend, but move sideways against the wind; but subsequent trials do not seem to have established this fact. The machine retained its air during the night, and several ladies amnified themselves the next day, by ascending with it to the height of 60 feet, the length of the ropes to which it was attached.

In the course of this summer two perfrns, one in Spain, and another in America, were in danger of losing their lives by ascending with rarefied air-machines. The former was struck by the machine's taking fire, and so hurt by his fall, that his life was long despaired of; and the latter was wafted against the wall of a house, and so entangled, that he fell from the height of about twenty feet, and the machine took fire, and was consumed.

In the month of August, the Abbé Caruss, professor of philosophy, and M. Louchet, professor of belles lettres, ascended at Rodez, a town of Guaine in France, with an aerostatic machine of 57 feet in diameter. The air was calm, and the machine did not travel farther than about 14,000 yards in 45 minutes; and the height to which it ascended was 3620 yards above the level of the town. The thermometer was 34 degrees lower than it was at the earth when they ascended. On examining the air in one of two bottles, which they had filled at their highest elevation, they found that it contained a quarter less air than if it had been filled at about the level of the sea; and the air, tried by the test of nitrous air, was found more pure than that near the surface of the earth.

The first aerial voyage in England was performed in London, on the 10th of September, by Vincent Lunardi, a native of Italy. His balloon was made of oild silk, painted in alternate stripes of blue and red. Its diameter was 33 feet. From a net which went over about two-thirds of the balloon, descended 45 cords to a hoop hanging below the balloon, and to which the gallery was attached. The balloon had no valve, and its neck, which terminatet in the form of a pear, was the aperture through which the inflammable air was introduced, and through which it might be let out. The air for filling the balloon was produced from zinc by means of diluted vitriolic acid. Mr. Lunardi departed from the Artillery-ground at two o'clock; and with him were a dog, a cat, and a pigeon. After throwing out some sand to clear the horses, he ascended to a great height. The direction of his motion at first was north-west by west; but as the balloon rose higher, it fell into another current of air, which carried it nearly north. About half after three he descended very near the ground, and landed the cat, which was almost dead with cold: then rising, he prosecuted his voyage. He ascribes his descent to the action of an ear; but as he was under the necessity of throwing out ballast in order to reascend, his descent was more probably occasioned by the loss of inflammable air. At ten minutes past four he descended on a meadow near Ware in Hertfordshire. The only philosophical instrument which he carried with him was a thermometer, which in the course of his voyage stood as low as 59°, and he observed that the drops of water which collected round the balloon were frozen.

The longest and the most interring voyage, which was performed about this time, was that of M'Clirns, Roberts and M. Collin Hullin at Paris, on the 19th of September. Their aerostat was filled with inflammable air. Its diameter was 273 feet, and its length 46 1/2 feet, and it was made to float with its longest part parallel to the horizon, with a boat of nearly 17 feet long attached to a net that went over it as far as its middle. To the boat were annexed wings or ears, in the form of an umbrella. At 12 o'clock they ascended with 470 pounds of ballast, and after various manœuvres descended at 40 minutes past six o'clock near Arras, in Artois, having filled 200 pounds of their ballast remaining in the boat. Hill and other about 14 other which they perceived floomy clouds in which they endeavoured to avoid; but the current of air was uniform from the height of 600 to 4200 feet. The barometer on the coast of the sea was 29 51 inches, and sunk to 23 34 inches. They found that by working with their oars, they accelerated their course. In the prosecution of their voyage, which was 150 miles, they heard two claps of thunder; and the cold occasioned by the approach of floomy clouds made the thermometer fall from 77° to 59°, and condensed the inflammable air in the balloon, so as to make it descend very low. From some experiments they concluded, that they were able by the use of two oars to deviate from the direction of the wind about 22°. But this experiment requires repetition, in order to ascertain with accuracy the effect here ascribed to oars.

The second aerial voyage in England was performed by Mr. Blanchard and M. Sheldon, professor of anatomy to the Royal Academy, the first Englishman who ascended with an aerostatic machine. This experiment was performed at Chelsea on the 15th of October. The wings of a new boat seemed to have produced no deviation in the machine's tracks from the direction of the wind. Mr. Blanchard, having landed his friend about the distance of 1 1/2 miles from Chelsea, proceeded alone with different currents; and ascended so high as to experience great difficulty of breathing; a pigeon also, which flew away from the boat, being for some time with its wings, in order to fill itself in the rarefied air, and after wandering for a good while returned and rolled on one side of the boat. Mr. Blanchard perceiving the sea before him descended near Runley, about 7 5 miles from London, having travelled at the rate of nearly 20 miles an hour.

On the 15th of October, Mr. Sadler, of Oxford, made a voyage of 14 miles from that place in 17 minutes, with an inflammable air-balloon of his own contrivance and construction.

Mr. Blanchard's fifth aerial voyage was performed from London on the 30th of November, in company with Dr. J. Jeffries, a native of America. This voyage was about twenty-one miles. It does not appear that they derived any advantage from their ears in directing the course of the balloon.

On the 4th of January 1787, Mr. Harper ascended with an inflammable air-balloon from Birmingham: he went to the distance of 50 miles in about an hour and a quarter, and found no inconveniences besides such as might be expected from the changes of wet and cold, and a temporary deafness. The thermometer descended from 40° to 28°.

On the 7th of January Mr. Blanchard, accompanied by Dr. Jeffries, departed with the balloon, which had carried him five times through the air, from Dover castle towards the French coast. In their passage they were under a necessity of throwing away every thing which they had with them in the boat, and to part even with their clothes, in order to prevent the balloon from falling into the sea; but

as
AEROSTATION.

as they approached the land, it began to rise: and in two hours they reached the high grounds near Calais, and the balloon rising still higher over the land, they descended late in the forest of Guines. In consequence of this voyage the king of France presented Mr. Blanchard with a gift of 12000 livres, and granted him a pension of 1200 livres a year. A bottle which was thrown out of the boat in the time of their danger, struck the water with such force, that the shock was heard at a considerable elevation, and feebly felt on the ear and balloon.

On the 19th of January Mr. Crofbie ascended at Dublin with an inflammable air balloon to a great height, and rose so rapidly as to be out of sight in 3½ minutes. By opening the valve he descended suddenly as he approached very near the sea. On the 23d of March Count Zanbeccari and Admiral Sir Edward Vernon ascended at London, and failed to Horfham in Suffex, at the distance of 35 miles, in less than an hour. At the height of about two miles, the barometer having fallen from 30.4 inches to 20.8 inches, an accident endangered them, and obliged them to descend. In their descent they passed through a dense cloud, which covered them with snow. They observed that the balloon revolved perpetually round its vertical axis, with such rapidity as to perform each revolution in four or five seconds; they also mention a kind of rushing noise, which they heard among the clouds, and that the balloon was greatly agitated in its descent. On the 5th of May, Mr. Sadler and Mr. Windham ascended at Moufley Hurst; and were driven by a current of air towards the sea. They fortunately descended at the confluence of the Thames and Medway; but the cords of their machine being released, it instantly ascended and floated to a considerable distance, and was taken up by a trading veslel at sea, where it fell. On the 12th of May, Mr. Crofbie ascended at Dublin, but soon came down again with a velocity, which alarmed the spectators. Upon his descent, Mr. McGuire, a college youth, sprang into the machine, and was carried off by the ascending balloon towards the Channel; he at length fell into the sea, and was taken up by a boat dispatched for his relief, just when his strength was exhausted with swimming, and thus his life was saved.

The fate of M. P. de Roziere, the first aerial navigator, and of his companion M. Romain, has been much lamented. They ascended at Boulogne on the 15th of June, with an intention of crossing the Channel to England. Their machine consisted of a spherical balloon 37 feet in diameter, filled with inflammable air; and under this balloon was suspended a small Montgolfier, or fire-balloon, 100 feet in diameter. This Montgolfier was designed for rarefying the atmospheric air, and thus diminishing the specific gravity of the whole apparatus. For the first twenty minutes they seemed to pursue the proper course; but the balloon seemed to be much inflated, and the aeronauts appeared anxious to descend. Soon however, when they were at the height of about three quarters of a mile, the whole apparatus was in flames, and the unfortunate adventurers fell to the ground, and were killed on the spot.

On the 19th of July Mr. Crofbie ascended at Dublin with a view of crossing the Channel to England. To a wicker basket of a circular form, which he had sublimated for the boat, he had affixed a number of bladders, for the purpose of rendering his gallery buoyant, in case of a disaster at sea. The height to which he ascended at one time was such, that by the intense cold his ink was frozen, and the mercury funk into the ball of the thermometer. He himself was sick, and he felt a strong impression on the tympanum of his ears. At his utmost elevation he thought himself stationary; but on discharging some gas, he descended to a very rough current of air blowing to the north. He then entered a dense cloud, and experienced strong blasts of winds, with thunder and lightning, which brought him with rapidity towards the surface of the water. The water soon entered his car; the force of the wind plunged him into the ocean; and it was with difficulty that he put on his cork jacket. The bladders which he had prepared were now found of great use. The water, added to his own weight, served as ballast; and the balloon maintaining its position, answered the purpose of a sail, by means of which, and a flatch-block to his car, he moved before the wind as regularly as a sailing vessel. He was at length overtaken by some vessels that were crowding fail after him, and conveyed to Dunleary, with the balloon towed after them. On the 22d of July, Major Money, who ascended at Norwich, was driven out to sea, and after having been blown about for about two hours, he dropped into the water. After much exertion for preserving his life, and when he was almost despairing of relief, he was taken up by a revenue cutter in a state of extreme weakness; having been struggling to keep himself above water for about seven hours. The longest voyage that had been hitherto made was performed by Mr. Blanchard towards the end of August. He ascended at Lille, accompanied by the chevalier de L'Epinard, and traversed a distance of 300 miles before they descended. On this, as well as on other occasions, Mr. Blanchard made trial of a parachute, in the form of a large umbrella, which he contrived for breaking the fall in case of any accident. With this machine he let down a dog, which came to the ground gently and unhurt.

On the 8th of September Mr. Baldwin ascended from the city of Chelten, and performed an aerial voyage of 25 miles in two hours and a quarter. His greatest elevation was about a mile and a half, and he supposes that the velocity of his motion was sometimes at the rate of 30 miles an hour. He has published a circumstantial account of his voyage, described the appearances of the clouds as he passed through them, and annexed a variety of observations relating to aerolisation, which render his treatise valuable and interesting to those who wish to acquaint themselves with this subject. It would be tedious to recount the aerial expeditions that were performed in various parts of our own country, as well as on the continent, in the whole course of the year 1783; more especially as they have afforded us no experiment or discovery of any peculiar importance. The most persevering aerial navigator has been Mr. Blanchard. In August 1788, he ascended at Brunswick for the thirty-second time. Within two years from the first discovery of this art of navigating the atmosphere, more than forty different perfons performed the experiment without any material injury; and it may be justly questioned, says Mr. Cavallo, whether the first forty persons, who trusted themselves to the sea in boats, escaped so safely. The catarhrophe that befel Roziere, and the unpleasant circumstances that have happened to some of the aeronauts in our own country, have been owing not so much to the principle of the art, as to want of judgment, or imprudent management in the conduct of it.

We shall close this abstract of the history of aerolisation with the observations of a very competent judge on the respective advantages and disadvantages of balloons made with inflammable air, and of those that are raised by means of hot air, to the former of which he gives the preference. The principal comparative advantages of the rarefied air-balloons are, their being filled with little or no expense; their not requiring to be made of so expensive materials; and the com-
AEROSTATION.

Bubbles necessary to fill them being found almost every where, so that when the provision of fuel is exhausted, the aerostat may descend and recruit his fuel, in order to proceed on his voyage. But they must be larger than balloons of the other sort, in order to take up the same weight; and the presence of fire is a continual trouble and a continual danger. Experience has, in many instances, evinced the disastrous consequenees that have attended them. On the other hand, the inflammable air balloon must be made of a substance impermeable to the fugitive gases; the gas itself cannot be produced without a considerable expense; and it is not easy to find the materials and apparatus necessary for the production of it in every place. Improvements, however, daily occur in the preparation of the coverings of these balloons, so as to render them nearly impermeable to the inflammable air: and it has been found that an inflammable air-balloon, 30 feet in diameter, may be so made as to sustain two persons and a considerable quantity of ballast in the air for more than 24 hours, when properly managed; and one man might possibly be supported by the same machine for three days.

AEROSTATION, practice of. The shape of the balloon is one of the first objects of consideration in the construction of this machine. As a sphere admits the greatest capacity under the least surface, the spherical figure, or that which approaches nearest to it, has been generally preferred. However, since bodies of this form oppose a greater surface to the air, and consequently a greater obstruction to the action of the air or wings than those of some other form, and therefore cannot so well be guided in a calm, or in a course different from the direction of the wind, it has been proposed to construct balloons of a conical or oblong figure, and to make them proceed with their narrow ends forward.

Mr. Hoole, an ingenious writer, who is now publishing a translation of the works of Leeuwenhoek, in his Thoughts on the farther Improvement of Aerostation, fuggles the shape of a fish as the most proper: the sharp head, under such a form, will serve to divide the resisting fluid, and open a passage, and the tail will serve as a rudder to steer its course. He also proposes to fix a seat for the traveller in the lower part of the body of the fish, or in the centre of gravity of the whole mass, so that the machine may be always horizontal, and that the impulse of any force used there may actuate the whole body. And he further fuggles, that the traveller should be furnished with instruments of sufficient surface to take hold of the air, and of sufficient strength to bear the whole exertion of his muscular force, analogous in their form and situation to the fins of fishes. But by adopting the oblong shape, the surface, and consequently the weight of the cover, must be augmented, in order to obtain the same lifting power with that of a sphere, both because its capacity will be less under the same surface, and because its capacity must be made greater in order to compensate for the augmentation of weight. Besides, an oblong machine cannot easily be kept with the smallest part forward in the atmosphere: and if it should turn sidewise, as it probably might, the proposed advantage would thereby be lost: not to add, that accidental circumstances might occur which would endanger its overturning.

In order to expedite the calculations that relate to the construction of a balloon of a spherical form, it should be remembered, that the circumferences of spheres are as their diameters; their surfaces as the squares; and their solid contents as the cubes of the diameters. The proportion of the diameter to the circumference of a circle, i.e. 7 to 22, or 1 to 3.14159,..., should be recollected; so that if the diameter of a balloon be 35 feet, its circumference will be 110 feet. If the diameter be multiplied by the circumference, the product will be the surface of the sphere; i.e. $\pi \times 35 \times 35 = 3850$ square feet. If this surface be divided by the breadth (in feet) of the stuff of which the balloon is made, the quotient will be the number of feet in length necessary for constructing the balloon; thus if the stuff be 3 feet wide, $\frac{3850}{3} = 1283$ feet, or 428 yards, nearly, which is the quantity for a balloon of 35 feet in diameter. By knowing the weight of a given piece of this stuff, as of a square yard or square foot, it is easy to find the weight of the whole bag, by multiplying the surface in square feet or yards by the weight of a square foot or yard; e.g. if each square yard weigh 16 ounces, or one pound, the whole bag will weigh 4.8 pounds. Again, the capacity, or solid content of the sphere, may be found by multiplying $\frac{4}{3}$ of the surface by the diameter, or by taking $\frac{4}{3}$ of the cube of the diameter; thus, in the present instance, we shall have $22458$ cubic feet for the capacity of the balloon, or the number of cubic feet of air which it will displace. From the content and surface of the balloon, we may deduce its power of ascent or levity in the following manner:---a cubic foot of air weighs, at an average, about $1\frac{1}{4}$ ounce, and adding to the number 22458, its fifth part, we shall have 26950 ounces, or 1064 pounds, for the weight of the common air displaced by the balloon. From this weight, deducting the weight of the bag, or 428 pounds, there will remain 1236 pounds expressing the levity of the balloon, independently of the contained air. If this be inflammable air, its weight varies from $\frac{3}{5}$ to $\frac{4}{5}$ of the weight of common air, if it be taken at $\frac{4}{5}$ of the weight of common air, then $1236 \times \frac{4}{5} = 288$ pounds will denote the weight of the air filling the balloon; and taking this from 1236, i.e. 1236 - 288, will leave 948 pounds, the power of ascent of the balloon, or the weight which it will carry up, containing the car, ropes, passengers, balloon, and other necessaries. If heated air be used, the density of this is diminished about one-third; and therefore, taking from 1236 one-third of itself, there will remain 1123 for the weight of the contained warm air, and this subtracted from 1236, leaves 1133 pounds for the levity of the balloon; but as this is not sufficient for carrying up the car, passengers, &c. it is evident that a larger balloon, on Montgolfier's principle, is necessary for the same purpose that may be effected by a smaller one of inflammable air. To estimate the power of ascent corresponding to any given weight, e.g. 1000 pounds; since the levisies are nearly as the cubes of the diameters, and consequently the diameters as the cube roots of the levisies; and the levisies being as $1233$ to $1200$, i.e. nearly as 1 to 8, the cube-roots are as $1$ to $2$; consequently $1 : 2 : : 35 : 70$ feet, the diameter of a Montgolfier, made of the same thickness of stuff as the former, and capable of lifting 1000 pounds. Purifying the same kind of calculation, it is easy to estimate the size of a balloon, made of stuff of a given thickness, and filled with air of a given density, that will just float in air. From the weight of a cubic foot of common air, subtract that of a cubic foot of the lighter or contained air; then divide 6 times the weight of a square foot of the stuff by the remainder, and the quotient will be the diameter, in feet, of the balloon that will just float at the surface of the earth. Suppose the stuff to be 1 pound to the square yard, or $\frac{4}{5}$ ounces to the square foot, and this multiplied by 6 gives $\frac{24}{5}$; then the cubic foot of common air weighing $\frac{5}{4}$ ounce, and of heated air $\frac{4}{5}$ of the same, the difference being $\frac{16}{5}$.
AEROSTATION.

Consequently $\frac{22}{3}$ divided by $\frac{2}{3}$ gives $2\frac{1}{2}$ feet, which is the diameter of a Montgolfier that will just float: but if inflammable air, $\frac{1}{2}$ the weight of common air, be used, the difference between $1\frac{1}{2}$ and $\frac{1}{2}$ of it is one; by which dividing $\frac{22}{3}$ or $10\frac{2}{3}$, the quotient $10\frac{1}{3}$ feet will be the diameter of an inflammable air-balloon that will just float. If the diameter in either of these cases be increased, the respective balloons will ascend in the atmosphere.

In order to determine the height to which a given balloon will rise, when the diameter of the balloon, and the weight that exactly balances it are given, proceed in the following manner:—compute the contents of the globe in cubic feet, and divide its restraining weight in ounces by this content, and the quotient will be the difference in density or specific gravity of the atmosphere at the surface of the earth, and that at the height to which the balloon will rise; subtract this difference or quotient from $1\frac{1}{2}$ or $1.2$, the density at the earth, and the remainder will be the density at that height; then the height corresponding to that density will be found with sufficient exactitude in the annexed Table.

c. e. Let the diameter of the balloon be 35 feet, its capacity 22,458, and the weight of the first 976 pounds, or 15016 ounces; the quotient of the latter number divided by the former, $\frac{15016}{22458}$, is the density at the utmost height, and to which in the Table corresponds somewhat less than 1.1 miles, that is, the height to which the balloon will ascend. When the same balloon was filled with heated air, its capacity was equal to 133 pounds, or 2128 ounces, which divided by 22,458, the capacity, gives the quotient, .095; and this subtracted from 1.200, leaves 1.105 for the density; to which, in the table corresponds half a mile, or more nearly $\frac{1}{2}$ of a mile. Such are the heights to which these balloons would nearly ascend, if they retained their figure, and lost none of the contained air: or more precisely, these are the heights at which they would settle; for their acquired velocity would at first carry them above these heights, till their motion would be destroyed; and then they would descend below these heights, though not so much as they had gone above them: after which they would reascend, and pass these heights again; but not so far as they had gone below them: thus vibrating alternately above and below these heights, but every time less and left. These calculations for finding the height to which the balloon will ascend, are formed independently of the different states of the thermometer at the highest point and at the surface of the earth; but the allowances to be made on this account will appear from what is delivered under the article Atmosphere.

Next to the figure, it is necessary to consider the stuff that is most proper for forming the envelope of the inflammable or rarefied air. Silk stuff, especially that which is called lustre-fine, properly varnished, has been most commonly used for inflammable air-balloons: and common linen, lined within and without with paper, varnished, for those of rarefied air. Varnished paper, or gold beater's skin, will answer the purpose for making small inflammable air-bal-}

loons; and the small rarefied air-balloons may be made of paper without any varnish or other preparation.

The stuff for large balloons of both kinds requires some previous preparation. The best mode of preparing the cloth for a machine upon Montgolffer's principle, is first to soak it in a solution of sal ammoniac and lime, using one pound of each to every gallon of water; and when the cloth is quite dry, to paint it over with some earthy colour, and strong lye or glue. It may be also varnished over, when perfectly dry, with some flat oily varnish or simple drying linseed oil; which would dry before it penetrates quite through the cloth. In France much has been said of the elastic gum varnish; but the composition of it is kept a secret. This gum is known to be soluble in divers essentiel oils, and also by vitriolic ether. The former solution forms a varnish which never perfectly dries; the latter dries readily, but the solution is too dear for common use. The following varnish has been recommended. To one pint of linseed oil, add two ounces of litharge, two ounces of white vitriol, and two ounces of gum sandarach; boil the whole for about an hour over a low fire; then let it cool; separate it from the sediment, and strain it through a sieve, and dilute it with a sufficient quantity of spirits of turpentine. But the best varnish for an inflammable air-balloon is made with bird-lime. Mr. Cavallo directs to prepare it in the following manner, which, in his opinion, is preferable to that of M. Faujas de Saint Fond. In order to render linseed oil drying, boil it with two ounces of fuccharum faminor and three ounces of litharge, for every pint of oil, till the oil hath dissolved them; then add one pound of dry lime and half a pint of the drying oil into a pot of iron or copper, holding about a gallon full, let it boil gently over a slow charcoal fire till the bird-lime ceases to crackle; then pour upon it two pints and a half of drying oil, and boil it for about an hour longer, stirring it often with an iron or wooden spatula. As the varnish in boiling swells much, the pot should be removed from the fire and replaced when the varnish sublides. Whilst it is boiling, it should be occasionally examined, in order to determine whether it has boiled enough. For this purpose, take some of it upon the blade of a large knife, and after rubbing the blade of another knife upon it, separate the varnish, and when on its separation the varnish begins to form threads between the two knives, it has boiled enough, and should be removed from the fire. When it is almost cold, add about an equal quantity of spirits of turpentine, mix both well together; and let the mass rest till the next day; then having warmed it a little, strain and bottle it. If it is too thick, add more spirits of turpentine. This varnish should be laid upon the stuff, when perfectly dry, in a lukewarm state; a thin coat at first on each side, and about twelve hours after two other coats should be laid on, one on each side, and in twenty-four hours the stuff may be used.

Mr. Blanchard's method of making elastic gum varnish for the stuff of a balloon is as follows. Dillate elastic gum, cut small, in five times its weight of spirits of turpentine, by keeping them some days together; then boil one ounce of this solution in eight ounces of drying linseed oil for a few minutes, and strain it. Use it warm.

The pieces of which an inflammable air-balloon is to be formed, must be cut of a proper size, according to the proposed dimensions of it, when the varnish is sufficiently dry. The pieces that compose the surface of the balloon are like the following:
The boat may be made of wicker-work, and covered with leather, well painted or varnished over. The best method of suspending it is by means of ropes, proceeding from the net which goes over the balloon. This net should be formed to the shape of the balloon, and fall down to the middle of it, and have various cords proceeding from it to the circumference of a circle, about two feet below the balloon; and from that circle other ropes should go to the edge of the boat. This circle may be made of wood, or of several pieces of slender cane bound together. The meshes of the net may be small at top, against which part of the balloon the inflammable air exerts the greatest force, and increase in size as they recede from the top. A hoop has been sometimes put round the middle of the balloon for fastening the net. This is not absolutely necessary; but when used, it is best made of pieces of cane bound together, and covered with leather. When the balloon and its appendages are constructed, the next object of importance is to procure proper materials for filling it. With respect to those inflated by heated air, nothing need be said till the method of filling them is described.

Inflammable air for balloons of the other kind may be obtained in several ways; but the best methods are by applying acids to certain metals; by exposing animal, vegetable, and some mineral substancesses, in a close vessel, to a strong fire; or by transmitting the vapour of certain fluids through red-hot tubes.

In the skill of these methods, iron, zinc, and vitriolic acid, are the materials most commonly used. The vitriolic acid must be diluted with five or six parts of water. Iron may be expected to yield in the common way about 1700 times its own bulk of gas; or 4½ ounces of iron, the like weight of oil of vitriol, and 22½ ounces of water will produce one cubic foot of inflammable air; six ounces of zinc, an equal weight of oil of vitriol, and 30 ounces of water, are necessary for producing the same quantity. It is more proper to use the turnings or chippings of great pieces of iron, as of cannon, &c. than the filings of that metal; because the heat attending the effervescence will be diminished, and the diluted acid will pass more readily through the interfaces of the turnings, when they are heaped together, than through the filings which stick closer to one another. The weight of the inflammable air, thus obtained by means of acid of vitriol, is, in the common way of procuring it, generally one-seventh part of the weight of common air; and with the necessary precautions for philosophical experiments, less than one-tenth of the weight of common air. The other effervescing fluids, which are generated with the inflammable air, may be separated from it by pulling the inflammable air through water, in which quick-lime has been dissolved; the water will absorb these fluids, cool the inflammable air, and prevent its overheating the balloon, when it is introduced into it. As white vitriol is sold much dearer than the vitriol of iron, it will be a saving to make the inflammable air by means of zinc and vitriolic acid, rather than of this acid and iron: because the fale of the white vitriol arising from the former will, in a degree, be a compensation for the expense of the materials.

Inflammable air may also be obtained at a much cheaper rate by the action of fire on various substancesses; but the gas thus obtained is not so light as that produced by the effervescence of acids and metals. The substancesses proper to be used for this purpose are pit-coal, asphaltum, amber, rock-oil, and other minerals; wood, and especially oak, camphor oil, spirits of wine, ether, and animal substancesses, which yield air of different degrees and of various specific gravity. But pit-coal is the substancess most proper to be used. A pound of

the gores that form the superficies of a globe: and the best method of cutting them is to describe a pattern of wood or thin card-paper, and to cut the filk or stuff upon it. One of these pieces, that may serve as a pattern for others, is represented in Plate 1. Pneumatics, fig. 2. In this figure, suppose A E and B C to be two right lines perpendicular to each other. Then find the circumference answering to the given diameter of the balloon in feet and decimals of a foot; and make A D and D E each equal to a quarter of the circumference, so that A E may be equal to half the circumference. Divide A D into 18 equal parts, and to the points of division apply the lines f g, h; k, &c. parallel to each other, and perpendicular to A D. Divide the whole circumference into twice the given number of pieces, and make D C and D B each equal to the quotient of this division; so that B C will be equal to the greatest breadth of one of those pieces. Multiply this quotient or D C by the decimals annexed to f g, viz. 0.96, 619, and the product expresses the length of f g; and multiply D C by the decimals annexed to h k, and the product expresses the length of h k, &c. Having thus found the lengths of all these lines, draw by hand a curve line, passing through their extremities, and this will be the edge of one quarter of the pattern. The other quarters ABD, EBD, EDC, may be easily defiered by applying to each of them a piece of paper equal to A D C. Suppose the diameter of the balloon to be 20 feet, and that it is to be made of 12 pieces. In order to draw the pattern, find the circumference of the balloon, which is 62.83 feet, and dividing it by 4, the quotient is 15.7 feet: consequently A D and D E will be each equal to 15.7 feet. Divide the circumference 62.83 by 24, or double the number of pieces that arc to form the balloon: and the quotient 2.618 feet will be the length of D C or D B; therefore B C is equal to 5.236 feet. Then dividing A D into 18 equal parts, and drawing the parallel lines from the points of division, find the length of these lines by multiplying 2.618 by the decimals annexed to that line; thus, 2.618 multiplied by 0.96,619 gives 2.608 feet for the length of f g; and multiplying 2.618 by 0.98,541, we shall have 2.578 feet for the length of h k, &c. The pieces cut after such a pattern should be left about one half or three quarters of an inch all round larger than the pattern, in order to allow for the seams. They may be joined by laying about half an inch of the edge of one piece over the edge of the other, and sewing them with a double flitching. Mr. Blanchard joins them very expeditiously in the following manner. He lays about half an inch of the edge of one piece flat over the edge of the other, and polishes a hot iron over it; in doing which, a piece of paper ought to be laid both under and over the filk. The joining may be rendered more secure, by running it with a silk thread, and flocking a ribband over it. The ribbands laid over filks may be fluck with common glue, provided the varnish of the filk is properly dried. When the glue is quite dry, the ribbands should be varnished over, to prevent their being unglued by the rain.

To the upper part of the balloon there must be adapted a valve, opening inward, to which is annexed a fling pullling through a hole made in a small round piece of wood which is fastened to the lowest part of the balloon oppolite to the valve, to the boat below it; so that the aeronaut may open it as occasion requires, and let the inflammable air out of the balloon. To the lower part of the balloon are fixed two pipes of the same fluff with the covering, six inches in diameter for a balloon of thirty feet, and much larger for balloons of greater size, and long enough to reach the boat. These pipes are the apertures through which the inflammable air is introduced into the balloon.
of pit-coal exposed to a red heat, yields about three cubic feet of inflammable air, which, whether it be passed through water or not, weighs about one-fourth of the weight of an equal bulk of common air.

Dr. Priestley observes, that animal or vegetable sublimations will yield fix and even ten times more inflammable air, when the fire is suddenly increased, than when it is gently raised, though it be afterwards made very strong. And Mr. Cavallo informs us, that the various sublimations above enumerated generally yield all the inflammable air in about an hour's time. The usual method is to inclose the sublimated in earthen or iron vessels, and thus to expose them to a strong fire sufficient to make the vessels red-hot; the inflammable air proceeding from the aperture of the vessel, is received into a tube or refrigeratory, and passing through the tube or vessel, at last collected in a balloon or other vessel. A gun-barrel has been often used for effays of this kind. The manner of conducting this process is particularly described by Mr. Cavallo, ubi infra.

The last method of obtaining inflammable air was lately discovered by Mr. Lavolier, and also by Dr. Priestley. Mr. Lavolier made the helmet of boiling water pass through the barrel of a gun, kept red-hot by burning coals. Dr. Priestley uses, instead of the gun-barrel, a tube of red-hot brass, upon which the helmet of water has no effect, and which he fills with pieces of iron which are separated in the boiling of cannon. By this method he obtains an inflammable air, the specific gravity of which is to that of common air as 1 to 1 3/4. In this method a tube about three quarters of an inch in diameter, and about three feet long, is filled with iron turnings; and then the neck of a retort or ether boiler is luted to one of its ends, and the worm of a refrigeratory is adapted to its other extremity. The middle part of the tube is then surrounded with burning coals, so as to keep about one foot in length of it red-hot, and a fire is always made under the retort or boiler sufficient to make the water boil with vehemence. In this process a considerable quantity of inflammable air comes out of the worm of the refrigeratory. It is said that iron yields one-half more air by this means, than by the action of vitriolic acid. See Hydrogen.

Balloons of the smaller size, such as those of two or three feet in diameter, and also bladders, may be filled with inflammable air, after passing it through water, by means of the following simple apparatus. See Plate I. Pneumatics, fig. 3. A is the bottle that contains the ingredients which produce the gas; BCD is a tube in form of a trumpet, fashioned by one extremity into the neck of this bottle, and passing through a hole of the stopper of another bottle E, it extends so far as almost to touch the bottom of this bottle, which is nearly full of water. Into another hole made in the cork of the bottle E, is adapted another tube, to the outward extremity of which a bladder, or the aperture of the balloon is tied. The inflammable air, coming out of the aperture D of the tube, passes through the water of the bottle E, and then enters into the bladder or balloon. Two small calcis might be used instead of the bottles A and E.

Another apparatus for producing hydrogen and conveying it into a balloon is exhibited in fig. 4. ABC is a vessel made of clay, or of iron, in the form of a Florence flask; and the sublimation yielding gas is introduced into it so as to occupy about 3ths, or less, of its cavity. If the sublimation swell much by the action of the fire applied to it, a tube of brass, or fit a brass and then a leaden tube must be luted to the neck C of the vessel, and the extremity D of the tube is made to pass through the water of a tub H I, and to terminate under an inverted vessel EF, to the upper aperture of which the balloon, or a tube going to the balloon is adapted. When the part, AB, of the vessel is put into the fire, and made red-hot, the inflammable air that is generated will come out of the tube CD, and passing through the water of the tube, it will at last enter into the balloon G. As a considerable quantity of inflammable air remains in the inverted vessel EIF, before the operation is begun, it should have a stop-cock, K, through which it may be drawn out by suction, and then the water will ascend as high as the stop-cock. The aperture of the vessel, EF, should be at least one foot below the surface of the water in H I; and the fire should be at a sufficient distance from the tube HI, that the inflammable air, if any of it should escape, may not take fire and do injury.

The method of filling large aerostatic machines with rarefied air is as follows. A scaffold A BCD (Plate 11, fig. 5) the breadth of which is at least two-thirds of the diameter of the machine, is elevated about six or eight feet above the ground. From the middle of it descends a well EF, rising about two or three feet above it, and reaching to the ground, furnished with a door or two, through which the fire in the well is supplied with fuel. The well should be constructed of brick or of plaited wood; and its diameter should be somewhat less than that of the machine. On each side of the scaffold are erected two masts HI, KL, each of which has a pulley at the top, and rendered firm by means of ropes KG, KP, HP, HG. The machine to be filled is placed on the scaffold, with its neck round the aperture of the well. The rope passing over the pulleys of the two masts, serves, by pulling its two ends, to lift the balloon about fifteen feet or more above the scaffold: and the rest of the machine is represented by the dotted lines in the figure MNO. The machine is kept steady and held down, whilst filling, by ropes passing through loops or holes about its equator; and these ropes may be easily disengaged from the machine, by slipping them through the loops, when it is able to sustain itself. The proper combustibles to be lighted in the well are those which burn quick and clear, rather than such as produce much smoke; because it is hot air, and not smoke, that is required to be introduced into the machine. Small wood and straw have been found to be very fit for this purpose. Mr. Cavallo observes, as the result of many experiments with small machines, that spirits of wine are upon the whole the best combustible; but its price may prevent its being used for large machines. As the current of hot air ascends, the machine will soon dilate, and lift itself above the scaffold and gallery, which was covered by it. The passagiers, fuel, instruments, &c. are then placed in the gallery. When the machine makes efforts to ascend, its aperture must be brought, by means of the ropes annexed to it, towards the side of the well, a little above the scaffold. The fire place is then suspended in it; the fire lighted in the grate; and the lateral ropes being slipped off, the machine is abandoned to the air. It will appear in the atmosphere as it is represented in fig. 6. It has been determined by accurate experiments, that only one-third of the common air can be expelled from these large machines; and therefore, the ascending power of the rarefied air in them can be estimated as only equal to half an ounce avoidance per foot. The apparatus for filling an inflammable air balloon is represented in fig. 7. A, A, are two tubes, each three feet in diameter, and nearly two feet deep, inverted in larger tubs B B, full of water. At the bottom of each of the inverted tubs there is a hole, to which is adapted a tin tube E, about seven inches in diameter, and seven or eight inches long. To these tubes the filken tubes of the balloon
AEROSTATION.

Balloon are tied. Each of the tubes, B, is surrounded by several strong cables, so regulated in number and capacity, as to be less than half full, when the materials are equally distributed. In the top of each of these cables are two holes; and to one of the holes is adapted a tin tube, formed so as to pass over the edge of the tube B, and through the water, and to terminate with its aperture under the inverted tub A. The other hole, which serves for supplying the cables with materials, is filled with a wooden plug. These tin tubes may be about three inches and a half in diameter, and the other holes may be smaller. Two mats, with a rope, &c. are used for this machine, as well as for the former, although they are not absolutely necessary; because the balloon, by means of a narrow scaffold, or other contrivance, may be elevated five or six feet above the level of the tubes A A. When the balloon is to be filled, the net is put over it and suspended, as exhibited in CDF; and having expelled all the common air from it, its fill tubes are fastened round the tin tubes EE, and the materials in the cables are properly proportioned; the iron being first put in, then the water, and lastly the vitriolic acid. The balloon will soon be inflated by this inflammable air, and support itself without the aid of the rope GH. As the filling advances, the net is adjusted round it, the cords, proceeding from the net, are fastened to the hoop MN; the boat IK is fastened from the hoop MN, and every thing necessary for the voyage is deposited in the boat. When the balloon is a little more than three quarters full, the fillen tubes are separated from the tin tubes, and their extremities being tied, they are placed in the boat. Finally, when the aeronauts are seated in the boat, the lateral ropes are flapped off, and the machine ascends in the air, appearing as in fig. 8.

In order to produce such a bulk of inflammable air as is necessary for a balloon of 30 feet in diameter, whose capacity is 14,137 cubic feet, there will be required about 3,900 pounds of iron turnings, 3,900 pounds of vitriolic acid, and 1,950 pounds of water. The balloon will not be above three quarters full.

These proportions, stated by Mr. Cavallo, are too great with respect to the metal and acid, and too small with regard to the water. Mr. Lunardi, who had considerable experience in the practice of aerostation, filled his balloons at Edinburgh and Glasgow, with about 2,000 pounds of the chippings of cannon procured from Carron, the same quantity of vitriolic acid, and 12,000 pounds of water. The iron was placed in layers in his vessels, with straw between them, in order to enlarge the surface exposed to the action of the acid. He used only two large cans, which were sunk in the ground, and conveyed the gas into the balloon without passing through water; and he contrived to fill his balloon to less than half an hour, which operation had on former occasions required at least two hours.

The inflammable air with which they fill their balloons at the Aerostatic Institute, not long since established in France, is obtained by the following method, which is simple and not very expensive. Six cylinders, or tubes of iron, are fixed by masonry in a furnace of eady and expeditious construction, in such a manner that the two ends of each cylinder project out of the furnace; and these are furnished with strong covers or lids of iron. Into these cylinders are introduced tubes of metal, one of which serves to convey warm water into the red-hot cylinder, and the other to convey the air which is produced through a refer- voir filled with caustic lye, into the balloon. The cylinders are partly filled with the chippings or turnings of iron that are procured from the boring of cannon. The exciuse heat of the furnace, which is maintained by a supply of char-

coal during the operation, is communicated to the cylinders and their contents. In this rate, boiling water is conveyed by one of the tubes to each cylinder; and as soon as it communicates with the inflamed iron, the water is decomposed: the one part, called the oxygen, attaches itself to the iron and calciues it; but the other part, or the hydro-

gue, is combined with a quantity of the igneous substance, called caloric, and becomes hydrogenous gas, or inflammable air, which remains in a permanent rate of challic fluidity, and weighs seven or eight times less than the atmospheric air. As the water contains a small quantity of carbon or fixed air, which would add weight to the air of the balloon, it is made to pass through water in which caustic alkali has been dissolved. This fluid attaches the carbon to itself, and thus the pure inflammable air is conveyed into the balloon. The cylinders in this operation, are sometimes fused: for preventing which accident, a pyrometer is annexed to the extremity of the cylinder which projects from the furnace; and the fire is regulated by a scale connected with the pyrometer. The operation of filling a balloon, 30 feet diameter, in this way will occupy about four hours.

In eliminating the ascending power of these machines, that of the inflammable air should be considered as equal to one ounce avoirdupois for every cubic foot, which is one fith of the weight of common air; and therefore, if the capacity of a balloon is 12,000 cubic feet, and three-fourths of it are filled with inflammable air, obtained from iron and dilute vitriolic acid, the ascending power of that gas may be estimated at 9,000 ounces, or 56½ pounds; from which the weight of the covering, boat, and other appendages, must be subtracted.

The conduct of balloons, when constructed, filled, and actually ascending in the atmosphere, is an object of great importance in the practice of aerostation. The method generally used for elevating or lowering the balloons with rarefied air, has been the increase or diminution of the fire; and this is entirely at the command of the aeronaut, as long as he has any fuel in the gallery. The inflammable air-

balloons have been generally raised or lowered by diminishing the weight in the boat, or by letting out some of the gas through the valve. But the alternate escape of the air in descending, and discharge of the ballast for ascending, will by degrees render the machine incapable of floating; for in the air it is impossible to supply the losts of ballast, and very difficult to supply that of inflammable air. These balloons will also rise or fall by means of the rarefaction or condensation of the inclosed air, occasioned by heat and cold. It has been proposed to aid a balloon in its alternate motion of ascent and descent, by annexing to it a vessel of common air, which might be condensed by lowering the machine, and rarefied again, by expelling part of it, for raising the machine. But a vessel adapted to this purpose must be very strong, and, after all, the allowance afforded by it would not be very considerable. M. Meunier, in order to attain this end, proposes to incloze one balloon filled with common air, in another filled with inflammable air: as the balloon ascends, the inflammable air is dilated, and of course compresses the internal balloon containing common air; and by diminishing its quantity, lessens its weight. If it should be necessary to supply this loss, he says it may be easily done by a pair of bellows fixed in the gallery. Others have proposed to annex a small machine with rarefied air to an inflammable air-balloon by ropes, at such a distance that the fire of the former might not affect the inflammable air of the latter: the whole apparatus, thus combined, of balloons formed on the two principles of heated and inflammable air, might
might be raised or lowered by merely increasing or diminishing the fire in the lower balloon. Wings or oars seem to have contributed little to the effect of either raising or lowering balloons.

Many schemes have been proposed for directing the horizontal motion of balloons. Some have thought of annexing sails to a balloon, in order to give it the advantage of the wind; but to this proposal it has been objected, that as the aerostatic machines are at rest with respect to the air that surrounds them, they feel no wind, and consequently can derive no benefit from the sails. An ingenious writer observes, that the cafe of vessels at sea is quite different from that of balloons; because the former move with a velocity incomparably less than that of the wind impelling them, on account of the resistance of the water; and therefore, the difference between the velocity of the wind, and that of ships, occasions that dream of air which acts upon the sails. But a balloon finding no resistance acquires the same velocity with the surrounding air, and therefore can feel no wind. The same author adds, that the most rational projects for directing an aerostatic machine are those which propose to exert a force against the ambient air on one side of the machine, so as to move it in the opposite direction. Oars and wings are the only instruments that have been used for this purpose with any measure of success; but farther experiments are necessary to ascertain their effect. If wings or oars be used, the best method of moving them is by the immediate application of human power, as in the case of the oars of boats on the water. However they should be as large and light as possible; and they may be made of silk stretched between wires, tubes, or sticks. If they are flat they must be turned edgeways when they are moved in the direction of the balloon’s course, and flat in the opposite direction. One of the wings, used by Mr. Blanchard, is represented in fig. 9. That used by Mr. Lunnardi consists of many silk shutters or valves ABC D, DE CF, &c. (fig. 10.) each of which opens only on one side viz. A D B C upon the line A B, D E C F upon the line D C, &c.; and by this construction, it becomes unnecessary to turn these oars edgeways. One of the wings, constructed by Zamboncini is exhibited in fig. 11, that is, thing more than a piece of silk stretched between two tin tubes set at an angle; and so contrived as to turn edgeways of themselves, when they go in one direction. Fig. 12. represents one of the wings used by Meffirs. Roberts, in the voyage of September 19th, 1784. The greatest effect produced by the wings of an aerostatic machine was that which occurred in this voyage. It is not difficult to determine what force is necessary to move a given machine in the air with any proposed velocity. Dr. Hutton found, from accurate experiments, that a globe of 52 inches in diameter, and moving with the velocity of 20 feet in a second, sustains a resistance from the air, which is equal to the weight or preassure of one ounce avoirdupois; and that with different surfaces and the same velocity, the resistances are directly proportional to the surfaces nearly; and also that, with different velocities, the resistances are proportional to the squares of the velocities nearly. By these data the resistance to move a given balloon with any velocity may be ascertained. Let the balloon be 35 feet in diameter, then if it moved with the velocity of 20 feet per second, or almost 1.4 miles per hour, it would counteract a resistance equal to 271 pounds; with a motion of seven miles an hour, the resistance would be 63 pounds; and at three miles and a half an hour, the resistance would be 17 pounds, and such is the force with which the aeronauts must act upon the air in a contrary direction, in order to communicate such a degree of motion to the machine. If the balloon move through a rarer part of the atmosphere than that at the surface of the earth, as at the 4th or 4th, &c. higher, the resistance will be less in the same proportion; yet the force of the oars will be diminished as much; and therefore the same difficulty remains. It may be observed in general, that the aeronaut must strike the air by means of his oars, with a force just equal to the resistance of the air or the balloon, and therefore he must strike that air with a velocity which must be greater as the surface of the oar is less than the reflected surface of the globe, but not in the same proportion, because the force is as the square of the velocity. Suppose that the aeronaut acts with an oar equal to 100 square feet of surface to move the balloon above-mentioned at the rate of 20 feet per second, or 14 miles an hour, then he must move this oar with the great velocity of 62 feet per second, or nearly 43 miles an hour; and so in proportion for other velocities of the balloon. Hence it is highly probable, that it will never be in the power of man to guide such machines with any tolerable degree of success, especially when any considerable wind blows, which is generally the case. A helm seems to have no particular power in directing the course of a balloon, for the same reason that has been adduced to evince the inefficiency of sails. We have not in air, as in water, says count de Mirabeau, in his Considerations on the Order of Cincinnati, the resource of a fixed point of action upon a fluid, which has also much greater resistance than air. He adds, that as there are different currents of air, sometimes in opposite directions, and balloons are capable of ascending and descending in search of these currents, this circumstance may favour the hope of directing aerostatic machines. Perhaps, an attention to the means by which birds fly against the wind, added to observations of comparative anatomy upon fishes and birds, which furnish the currents of the two fluids that are common to us and them, may also suggest new ideas with respect to the direction of balloons. Time alone, and numerous experiments, can bring these reflections to maturity, and realize the expectations suggested by them.

Several of the foreign journals have lately announced an invention of professor Danzel for directing an air-balloon through the atmosphere. With this view he has constructed two cylinders, or axles, to the ends of which are fixed, in the form of a cross, four fails, or oars, movable at the point of their insertion in the cylinder, in such a manner, that when made to move round by means of a handle, the eight oars, like the cogs of a water-mill wheel, press successively to the air sometimes their flat side and sometimes their edge. To cause each oar to turn back on itself about the fourth part of a circle, M. Danzel has not only left sufficient play at the point where the flock of each oar is inserted in the cylinder, but has placed the flock in such a manner that the air itself makes the oar fall back, at each turn, with the necessary velocity and precision. Each of the two cylinders, armed with its four oars or fails, is designed to occupy one side of the balloon, with its four oars on each side. For a farther account of this apparatus and of its effect, see Philosophical Magazine, vol. iv. p. 108.

As parachutes, in the form of umbrellas, have been proposed in order to guard against accidents, and to break the fall in cases of sudden defeat, we shall here annex a method of estimating the power of such defensive machines. A person, moving uniformly at the rate of ten feet per second, may descend with safety. For this uniform defeat the resistance of the air must be equal to the whole descending weight. Suppose then that the weight of the aeronaut is 150 pounds, and that the parachute is flat and circular, and made
made of such materials as that every square foot of it weighs two ounces, and that the weight increases in the proportion of the increase of the surface. In this case, the diameter of the parachute, which would descend at the rate of ten feet per second, must be upwards of 75 feet; but if the parachute be con cave on the lower side, its power will be rather greater, and its diameter may be less. In order to estimate the power of a flat circular parachute, or of the resistance it meets with from air of a mean density, when descending with a given velocity, say as the number 800 is to the square of the velocity in feet, so is the square of the diameter in feet to a fourth number, which will be the resistance in pounds. And if it be required to know, with what velocity a parachute will descend with a given weight, say as the given diameter is to the square root of the weight, so is the number 28\(\frac{1}{2}\) to a fourth, which will be the velocity in air of a mean density. Thus, if the diameter of a balloon be 50, and its weight, together with that of a man, be 530 pounds, the square root of which is 23 very nearly; then 50 : 23 : 28\(\frac{1}{2}\) : 13; and therefore the man and parachute will descend with the velocity of 23 feet per second, which, as it is equal to that acquired by leaping freely from a height of two feet, two inches, may be very safely sustained.

**Aerostation, nuf isf.** The advantages of an art, so lately discovered, have not yet been sufficiently ascertained; but we may reasonably expect, considering the progress it has made in so short a space of time, that many benefits may result from the farther prosecution of it. To say the least, it is unphilosophical to discourage future trials and improvements, because the uses of this art do not immediately appear. With regard to philosophical observations, derived from aerostation, it is acknowledged that very few have yet been made. The novelty of the discovery, and of the principle, says Mr. Cavallo, has generally detracted the attention; and besides, most of the aerial voyages have been made by persons who had pecuniary profit alone in view, or who were stimulated to ascend in the atmosphere for the sake of the prospect, or by the vanity of adding their names to the list of aerial adventurers. Aerial navigation, considered as a mode of travelling between distant places, independently of its furnishing means of conveyance to places otherwise inaccessible, is attended with many advantages and conveniences. The aerostat has much less trouble with this machine than a sailor with a ship in the most favourable circumstances. With a moderate wind, aerial navigators have often gone at the rate of forty or fifty miles an hour, and very commonly at the rate of thirty miles without any agitation, or even feeling the wind, and without the danger of losing time by being often becalmed. Aerostatic machines may serve the purposes of escaping from ships that cannot safely land, from besieged places, and from other circumstances of danger. A small balloon six or seven feet in diameter, says an anonymous author in his proposal of various means for saving the crews of vessels shipwrecked near the coast, would answer this purpose, by carrying to the shore a firing capable of drawing a cord, with which several ropes might be afterwards conveyed to the vessel. They also expedite the communication of important events by signals, and serve for exploring, from a great elevation, adjacent coasts or regions, fleets and armies.

To the latter of these purposes they have been actually applied by the French, in the course of the last war; and to the elevation of a balloon, and the information obtained in consequence of thus reconnoitering the army of the enemy, they ascribe the signal victory obtained in the battle of Flurys in 1794. The balloon employed on this occasion, was called the Entreprenant, and it was under the direction of M. Coutel, the captain of the aerostats at Meudon, accompanied by an adjutant and a general. He ascended twice in the same day, to the height of 220 fathoms, for the purpose of observing the position and manoeuvres of the enemy. He continued each time four hours in the air, and corresponded with General Jourdan, who commanded the French army, by means of preconcerted signals. The enterprise was discovered by the enemy, and a battery opened its fire against the ascending aerostats; but they soon gained an elevation which was beyond the reach of their fire. This balloon was prepared under the direction of the Aerostatic Institute, for the use of the army of the north; and as were also another called C editable, for the army of the Sambre and Meuse, and the Hercule and Intrepid, for the army of the Rhine and Mofelle. Another, thirty feet in circumference, and weighing 160 pounds, was designed for the army of Italy. A new machine, invented by M. Contes, the director of the Aerostatic Institute, was designed to aid the aerostats in communicating intelligence, and was designated the Aerostatic Telegraph. Balloons may likewise serve to explore the state of the atmosphere at different heights, and to furnish observations, which shall illustrate a variety of phenomena, depending on the density, temperature, and other qualities of the air. From one experiment that has been already made we learn, that the air of a high region, preferred and examined by means of nitrous air, was found to be purer than the air below. The application of these machines to electrical experiments, is a very obvious use of which they are capable. The first person who employed them in this way seems to have been the Abbé Berthelon, at Montpellier. He raised several air balloons, furnished with long and slender wires, having their lower ends fastened to a glass flock, or other inflating substance; and thereby obtained from the wires electric fluid sufficient to show the attraction, repulsion, and even the sparks of electricity. The existence of a continual electricity, of the positive kind, in a clear atmosphere, known indeed before, has been farther ascertained by strings fastened to balloons floating in the atmosphere. Some have apprehended danger from the electricity of the atmosphere; and have thought that a stroke of lightning, or the smallest electrical spark, happening near a balloon, might set fire to the inflammable air, and destroy both the machine and the adventurers. Mr. Cavallo has sugggested several considerations for diminishing apprehensions of this kind. Balloons have been already raised in every season of the year, and even when thunder has been heard, without injury. In case of danger the aerostats may either descend to the earth, or ascend above the region of the clouds and thunder storms. Besides, as balloons are formed of materials that are not conductors of electricity, they are not likely to receive strokes, especially as by being encompassed with air they stand insulated. Moreover, inflammable air by itself, or unmixed with a certain quantity of common air, will not burn; so that if an electric spark should happen to pass through the balloon, it would not set fire to the inflammable air, unless a hole was made in the covering.

For a variety of other important and useful particulars relating to the subject of aerostation, we must refer to Mr. Cavallo's curious and comprehensive work, entitled, the History and Practice of Aerostation, 8vo. 1785; which will afford the reader ample information concerning the principles of this art, and the history of its progress, the method of constructing and managing balloons, the nature and preparation of the materials of which they are adapted,
adapted, and rules for estimating the heights to which they ascend.

AERSCHOT, or Aeschat, in Geography, a town of the Austrian Netherlands in the duchy of Brabant, and capital of the district of the same name, which was raised to a marquisate in 1597, and to a duchy in 1593. The town is small, but fortified and well inhabited, seated on the river Demer, about ten miles east of Mechlin, and eight miles north of Louvain, and contains a collegiate church, two manufactories, and three nunneries. It belongs to the House of Aremberg, N. lat. 51°. E. long. 5° 44'.

AERTSEN, in Biography. See AERENS.

ÆRVA, in Botany, a genus of the mandragora decem-dria class and order. The characters of which are, that the flowers are polyanthous; the calyx is five-lobed and patent; the flamina are five, and barbed; the pistillum is a globulous ovary, having a filiform style terminated by a bifid stigma; the fruit is a capsule, which is oblong, single-seeded and encompassed by the calyx. There is one species, viz. A. egyptiacus, or somnifera, which grows on sandy calcareous soil in Arabia. La Marche thinks it bears affinity to the Amanthus.

ÆRUGINOSUS, in Ornithology. See Moor Buzzard.

ÆRUGINOUS, something partaking of, or like to, the ruit of copper.

Authors do not seem perfectly agreed about the colour to be expressed by this word, some expressing by it green, others brown.

ÆRUGO denotes rust, especially that of copper.

Naturalists speak of two kinds of ærugo, one native, and the other fictitious; the native is only the superficial particles of the metal dissolved; and intimately mixed with acid salt; in which form it is ordinarily found in copper-mines, and other moist places; and the artificial, commonly called verdigris, or copper, converted into a green alkali by vinous acid.

One species of natural ærugo is a greenish marasmite, like the drops of iron; it is found in copper-mines, but is of no use. Dioecides (lib. v. c. 91, 92.) and Pliny (lib. xxxiv. c. 11, 12.) say expressly that a substance of the nature of these rosets, which yielded copper when melted, was scraped off in the mines of Cyprus, much in the manner now practised in Hungary, where the outer coat of the copper ore is thus collected, and afterwards purified by being washed in water. Another species, according to the account of Dioecides, was procured from the water of a grotto in the same island; and the most facile natural verdigris is still obtained in the same way in Hungary. The clear water which runs from old copper works is put into large vesseis, and after some time the green earth falls to the bottom as a sediment. There is also, on some mountains in Moravia, a sort of green graine, like lead, that is of a grays green, when used in painting. It is called the Hungarian mountain, or sea verdigris. See mountain green.

Ærugo rufus, or æ viridis, is a rust formed on copper, by hanging a plate of it over the stronger vinegar for some time, without suffering the one to touch the other. It was only used externally by Dioecides and the ancient physicians for cleansing ulcers, and destroying excrecences; but it has been more lately employed externally with efeence of myrrh and honey of roses in fifeuso and aphidish, and also internally for malignant ulcers that have corrupted the bones, and either with or without turkith mineral as a remedy for men or beals that have been bitten by mad dogs or wolves. The dose has been from three to six grains. Pils, formed of the ærugo, in a manner however that has been concealed, have been recommended for a cancer of the breasts; but their beneficial effect has been disputed. Omen-lin's App. Med. vol. i. p. 346.

ÆRUGO fulis, in Natural History, a name given by Pliny, and several other ancient authors, to a reddish fiery matter, separated from the Egyptian salt, called natrum, in purifying it. We find this matter remain in the filter, on dissolving and filtering the Egyptian nitre, at this time; it seems to be a mixture of bituminous matter, and a red earth, which had mixed themselves among the cakes of the salt, during the time of their concreting from the water.

ÆRUSCATORES, formed from ærusca, to beig, mmp, &c. in Antiquity, a kind of sharping fliroes, who got their living by tricks, telling fortunes, and the like, much like modern gypilces. The term is also applied to oppriev te- gaters.

The Cauli, or priests of Cybele, were called ærusca macros nocius, on account of their begging, or collecting alms in the streets. To which end they had little bells whereby to draw people's attention to them, much like some orders of mendicants abroad.

ÆRY, or AIRY, in speaking of hawks, eagles, or the like, answers to the nest of other birds.

ÆS, in Antiquity, has various significations; but it properly denotes brevs or copper. It was for a long time applied indiscriminately to either of these metals; and it was not till a late period that metalurgists, in order to distinguish them, gave the name cuprum to copper; æs copier was the first metal used in coinage by the Romans, the word æs was used in their language to signify money in general. It likewise denoted a particular coin made of that metal.

Æs calidum, or æs brevis, otherwise called æs olimum, or æs breve, is a species of brevis mentioned by Pliny, which was not capable of being hammered. This is likewise a term used by the German Georgius, for a substance which sometimes occurs to those who work upon copper, and is used for making the fine blue colour called small.

Æs candidum, among the Ancients, was different from that which we call white brass: it is a purer and whiter kind of metal found, it is said, under the veins of silver, somewhat analogous to Venetian glass. They had probably a method of making copper cuphe as well as yellow, equal, if not superior, to that now in use. The phrases of orichalcum album in Virgil (Æn. xii. v. 87.), are æs cæsum among the Greeks, literally signify white brass.

Æs corinthusium, a precious metallic composition, of a much finer colour than common brass, and for its beauty little inferior to gold. Pliny says (Hist. tom. ii. p. 628. Ed. Hard.), that this was an accidental mixture of metals at the back and conflagration of Corinth by J. Mummus, 146 years before Christ; when the gold, silver, and brass flats, and all metallic substances, melting and mingling together, formed this metal. He says, that there were three forts of Corinthian brass, viz. the red, the white, and that which was of the colour of money, according to the different proportions of gold and silver that were in it. But some refinrs, who have strictly examined this metal, find no gold in it; a circumstance which, if true, suggests one reason, among others, for concluding, that this account is fabulous. However, the falle has been interpreted by some to signify, that the art of making copper into brass was first
first discovered by the Corinthians, who found the calamine stone on the plains of Peloponnese, or at least that they brought this art to perfection.

*Æs corundum* is used by Pliny (H. N. tom. ii. p. 679), to denote brass wrought into thin plates, and which, he says, flamed with the gall of bullf, furnished a sort of gold for the crowns of players. This was called *æs ductile*, in contradistinction to the *æs fusible*, or *æs calidarium*. They were both brought from Cyprus.

*Æs Cyprium* was a kind of copper produced in the island of Cyprus. This denomination was first given to copper in general; whence it was called *cyprium*, and at length *cuprum*. The superiority of the Cyprian copper gave occasion to this appellation.

*Æs flammum*, yellow copper. All the Roman authors have mentioned the method of making brass with calamine and copper; but their first kind, which they called *oriabilum*, or *auriabilum*, they distinguished from the inferior sorts, which had only the name of *æs flammum*.

*Æs gravis* denoted money among the Romans which was paid by weight, and not by tale. In this sense it is used by Budezus and Scaliger.

But others by *æs grave* understand large pieces of copper coined, containing, for instance, an *æs*, or pound of that metal, such as we find current in Sweden. These they affirm bore the title *æs grave* till the time in which they were reduced to a smaller standard.—Gronovius, on the contrary, maintains, that the *æs*, or pound weight, did not acquire the appellation *æs grave*, till after their reduction. Philos. Trans. No. 19.

Kutter rejects all these opinions, and affirms, that the expression is used to denote any kind of copper-money compared with gold or silver; which, with regard to the bulk, and size of the pieces, was much lighter, though of greater value.

But this system, however plausible, is rejected by several learned men, particularly Perizonius and Mr. Ward. The former has a dissertation on the subject, wherein the opinion of Gronovius is farther examined and defended.

*Æs heptagonum* was of a silverish colour, and probably what the moderns call *bronce*; though some confound it with the *æs Corintium*.

*Æs parvum* is a name given to *æs oreus*, divided of its silver, when it contains any.

*Æs rude*, that unshaped, or not fashioned for any particular purpose.—Some will have this to be the same with *æs grave*.—The money, during the first ages of Rome, was all of this kind.

Others, by *æs rude*, understand metal unlimed; in opposition to *æs sigillatum*, that flamed, or coined.

*Æs umium* called also *æs Venetius*,—*æs ceramum*,—*æs Venetia*, and *æs etrusc*, is a term which, like many others among the old chemists, has been applied to two or three different substances; it is, therefore, on this account defectively rejected from the reformed nomenclature. Kinkel (Lab. Chym. p. iii. c. 39) employs it as a general denomination for a perfect oxyd of copper prepared by heat; the expression is, however, more commonly employed to denote a pharmaceutical preparation once much in vogue as an emetic, but now fallen into disuse. This *æs umium* essentially contains of copper and sulphur; and the different varieties originate from the relative proportions of the ingredients, and the different dates of oxidation of the copper. It is usually prepared by distilling in a crucible copper clippings and powdered sulphur, and heating the crucible by degrees till it ceases to emit any vapours; it must then be raised to a dull red heat for an hour; there results a brittle mass which when pulverized and washed is the substance in question. Barchulfen's method is still more simple, consisting merely in heating a flake of copper to whiteness, and rubbing it with a roll of brimstone; as soon as it is taken out of the fire, the copper combines eagerly with the sulphur, and the compound runs down in drops, and is received in a basin of water: this is then pulverized and washed. In both these cases the compound is a slightly oxidated copper, saturated with sulphur; of an iron brown colour. In addition to these processes Lenery goes on to heat the sulphurated oxyd in a reverberatory nine times successively, quenching it in a basin of cold water: he thus obtains a copper of a high red colour, which in fact is a simple oxyd of copper, the sulphur being burnt out. Some recommend a mixture of niter or common salt with the sulphur, and the substance resulting from this, if not washed, is certainly a very powerful emetic on account of the sulphurated alkali which is thus combined with the oxyd of copper. As to the sal ammoniac and vinegar, in which some formerly steeped the copper, it is wholly useless, all its effects being destroyed by the subsequent oxidating. Dist. Method. Art. *Æs umium*—New Difpensatory, 1763, p. 498.—Beaume's Chymic. Experiment. vol. ii. p. 451.—Green's Chemistry, vol. ii. p. 259.

*Æs umium* is very drying and destructive, and has been, on that account, mixed with plasters and unguents, for drying up flatulent ulcers, and imbibing acrimonious humors, or fumes. It is also commended for disorders of the eyes; and joined with cardomons and honey-water, it has been prescribed internally to epileptics, with whom, according to Dioscorides, it operates as an emetic, and according to Artaeus, as a laxative. See Gmelin's App. Med. vol. i. p. 344. It is likewise used for colouring gluts.

*Æs usorium*, in Antiquity, a tax paid, by pupils, as a penalty for living single to old age.

This tax for not marrying seems to have been first imposed in the year of Rome 359, under the censure of M. Furius Camillus, and M. Pollutnus.

At the census, or review of the people, each person was asked, *Et tu es anima usorium?* He who had no wife, was hereupon fined after a certain rate, called *æs usorium*.

*Æs flos*, called by the Greeks, *χαλεκτόν* or *αλαίη* (sometimes confounded by moderns with *chalcanthum*), is prepared of copper melted, and removed into other furnaces, wherein being exposed to a farther and greater heat, and vehemently agitated by bellows, it deposits an infinite number of small flakes, like millet grains, which being separated by lotion, make the *flos eris*. The cold water is poured on the copper, as it runs out of the furnace into the receiver.

*Æs*; *squama* *Æs* properly denotes flakes of that metal struck off by the hammer, in the operations of the forge, &c. These, from the Cyprian copper-works, are called *Hodite*.

*Æs*; *per* *Æs et librum* was a formula in the Roman law, whereby purchases and sales were ratified.

Originally the phrase seems to have been only used in speaking of things sold by weight, or by the scales; but it afterwards was used on other occasions. Hence even in adoptions, as there was a kind of imaginary purchase, the formula thereof expressed, that the person adopted was bought per *Æs* et *librum*.

*Æsalon*, in Ornithology, a species of *facon*, called in English the Merlin. *Æsalon carolinensis* is the name given
given by Briffon to the acceptor minor of Catesby, and the Falco sparrowius of Linnaeus, which has a yellow cere, brown head, red vertex and abdomen, and bluish wings. The head of the female is encompased by seven blackish spots.

ÆSAPIS, in Ancient Geography, a town of Phrygia Major, according to Ptolemy.

ÆSAPUS, a river of Mytilo, in Asia Minor, according to Strabo, which rises south-west of Scopitis, and discharged itself into the Propontis, west of Cyzicus.

ÆSAR, Eflara, a river of Etruria, in Italy, which, says Strabo, joined the Arno at Pisa, but its mouth is said to be ten miles north of that of this river.

ÆSAR, in Mythology, a deity of the Etruscans. It is said that the letter C occasioned in the word Cesar, annexed to a statue of Augustus, the auxiliaries derived from this accident on the part of the flatuary, a sorrowful preface. As C was a numeral letter, denoting 100, they concluded that he had not 100 days to live: but as the word Ælar was the name of a deity, they thence inferred that he would be deified after his death.

ÆSARONISI, in Ancient Geography, a people of the northern part of Sardina.

ÆSARUS, Eflara, a small river of Bruttium, which was near the town of Croton. Ovid (Met. 1.15. v. 23.) calls it Ælaris.

ÆSCH, in Ichthyology, a name by which some have called the Grayling, or tumbler, a fish of the truttaceous kind, called in Latin taimalus.

ÆSCHINES, in Biography, an Athenian philosopher of low extraction, said to be the son of Charinus, a saufage-maker, and by others, the son of Lyfanius. He discovered an early desire of knowledge, and, though oppressed by poverty, was affiduous and persevering in the pursuit of it. With this view he placed himself under the tuition of Socrates, who was gratified by the respect which was paid to him by this young and illustrious, though mean disciple. Upon first offering himself to the notice of Socrates, he told the philosopher that the only thing which it interested him in his power to prevent him, in return for his kindness, in giving him instruction, was himself. Socrates replied, that he accepted and esteemed the present, and hoped to render it more valuable by culture. He adhered to his master with unalterable fidelity and constancy, and enjoyed his particular friendship. Impelled by poverty, he determined to quit Athens; and after the example of Plato and others, to visit the court of Dionysus, the tyrant of Sicily, who was, at this time, either through vanity or jealouisy, a general patron of philosophers. Upon his arrival in Syracuse, he was offered by Plato on account of his poverty; but Arisippus introduced him to the prince, by whom he was liberally rewarded for his Socratic Dialogues. Plutarch, however, vindicates Plato from this charge, and says that when he was neglected at Syracuse, the philosopher recommended him to Dionysus, and engaged for him the protection and favour of the sovereign. See Plut. Comment. de Adultoribus et Amicis, p. 47. ed. Xylander. Æschines remained in Sicily till the expulsion of the tyrant, and then returned to Athens. But fearing to become a rival of Plato or Arisippus, who were in high esteem, by any public exhibition, he taught philosophy in private, and maintained himself by the pecuniary recompence which he received for his instructions. Afterwards, in order to gain a more ample satisfaction, he appeared as a public orator. Lactantius says, that he wrote judicial orations for the vindication of the innocent. Besides orations and griffles, Æschines wrote seven Socratic Dialogues in the true spirit of his master, on temperance, moderation, humanity, integrity, and other virtues: of which only three are extant, viz. one concerning Virtue, whether it can be taught; a second concerning Riches, whether they are good; and a third, concerning Death, whether it is to be feared; a fragment of a fourth, on the Duties of a State under Marriage, may be found in Cicero de Invenzione Rhetorica, I. c. 31. They are published by Le Clerc, with notes and several dissertations, in the "Silvae Philologicae." Amstelod. 1711. Fabriacus (Bibl. Graec. tom. i. p. 529.) Suidas (in Astv.) and Lucian (de Pastificio Op. tom. ii. p. 860. Ed. Reitzii) have given an account of them. Some have charged him with purloining the works of Antiphenes, and with publishing dialogues of Socrates, confided with him by XANTIPPE, as his own. This Æschines, who is a different person from Æschines the orator, is said by Diodorus Siculus (Hist. tom. ii. p. 62. Ed. Weinh.) to have flourished about the 150th Olympiad.

Æschines, the Orator, was the son of Atromocus, a grammarian and schoolmaster, and Glauce-thea, who is said to have been a timbrel-player. See Lucian (in Somn. tom. i. p. 17.) and Fabricius (De Vit. Soph. ap. Oper. p. 566. Ed. Olcvart.) He was distinguished as Plutarch says (de X Orat. Vit. ap. Oper. tom. ii. p. 820.) neither by his birth nor riches. In his youth, Æschines being a robust constitution, devoted himself to the exercises of the gymnasiaium, and having a clear voice he performed a part in the exhibition of tragedies. Some say that he attended the lectures of Plato and Socrates; but according to others, he received instruction from Alcidas, the preceptor of Gorgias. His progress, however, was considerable, and he became a competitor with Democritus; and by his public conduct incurred his displeasure. When the Athenians negotiated a peace with Philip of Macedon, Æschines and Democritus were two of the ten ambassadors employed for this purpose. On this occasion, it is said that Æschines was bribed by Philip, and perjured the Athenians, in opposition to the remonstrances of Democritus, to confide in the promises of the sovereign of Macedon. Thus seduced, they gave this prince an opportunity to poiffess himself of Thessaly, and to enter the territory of Æschines, aspiring to be a generalissimo of the Greeks, was anxious to be appointed to this office by the council of the Amphyictyes. With this view, he contrived, by intrigue and corruption, to engage the support of Æschines; who, in a studied oration, prevailed with the deputies of the Greek cities, assembled in the council of the Amphyictyes, to elect him for their general, and to invest him with full power to act as he should think proper. By this artifice Philip got possession of Eteena, the chief city of Phocis, and thus established himself in a situation the most favourable for the execution of his further designs. Democritus exerted all his powers of eloquence to refute the Athenians, and to induce them to unite with the Thebans in disconcerting the machinations of Philip. His eloquence was effectual, and the two hostile armies encamped near Cheronea, a city of Boeotia. The wisdom and force of Philip prevailed; and Democritus, being left a warrior than a statesman, and being more capable of giving counsel in his hardships than of enforcing and supporting it by intrepid courage, threw down his arms, and fled with the other discomfited troops. The shock which Athens received at this time, the effect of which it was never able to recover, was ascribed to Democritus; and Æschines took the lead in condemning his rival: and he, accordingly, drew up an accusation against Ctesiphan, or rather against Democritus.
The conflict between these two orators excited very general attention, and the two orations that were delivered by them have been always considered as the master-pieces of oratory, especially that of Demosthenes, which is more powerful and impressive than that of Aeschines. The latter left his orate, and was sentenced to banishment for his rash accusation, and Christ. 330. Upon this, he settled at Rhodes, where he opened a school of eloquence, the reputation of which subsisted for many ages. He is said to have commenced his lectures with the two orations that had occasioned his banishment. That of Aeschines himself was received with applause; but when the auditors heard that of Demosthenes, their plaudits were redoubled. On this occasion, Aeschines declared, with a caudour and liberality highly honorable to him as an enemy and rival, What do you mean by public apology? Thucydides, who supra. When Aeschines left Athens, in order to embark for Rhodes, Demosthenes ran after him and obliged him to accept a purse of money; upon which Aeschines exclaimed, How will I be able to defend a country in which I have an enemy more generous than I can hope to find friends in any other part of the world? From Rhodes, Aeschines removed to Samos, and there he died, at the age of 75 years. Some have said, that Aeschines was the first who delivered extemporaneous orations, a practice which others have ascribed to Gorgias. Philoctates extols him for luminous perspicacity, decorous gravity, and distinguished energy; and he is denominated by Demosthenes μεγαλομέγας. Quintilian, comparing him with Demosthenes, says of him, (Inst. Orat. 1. c. 1. tom. ii. p. 92.) Ed. Burnan.) Plinius Aeschines, et magis jussus, et grandiori fortunis, quos minus satis effus: cornis tamen plus habet, lecturae minor. Phœbus lives ascribes nine epistles (according to the number of the muses) to Aeschines; but there are twelve, which were addressed to the Athenians when he was an exile at Rhodes, in Wolf's edition of Demosthenes and Aeschines, p. 205; and Taylor has added them to his edition. The ancients acknowledge only three genuine orations, viz. 1. Adversus Timarchum (Wolf. Ed. p. 258.) Timarchus was his accuser, and it is said that in consequence of the reproaches of Aeschines he laid violent hands on himself. 2. De falso Legatione, (Lb. p. 395.) This is an apology for himself against Demosthenes, who had accused him of perfidy in an embassy to Philip. 3. Adversus Cleobonium, (Lb. p. 425.) who decreed the golden crown to Demosthenes. Fabricius compares these orations to the three graces. Another oration, intitled Ἀλλος τινα ἀπὸ τῶν Ἀσκήνων, was formerly ascribed with the name of Aeschines; but the ancients ascribe it to another perion of the same name. See Plutarch and Philoctates, uti supra. Demochlen. et Aeschin. Opera, by Wofius Francof. 1664. Fabricius Bibl. Græc. tom. i. p. 412—928, &c. Laertius (tom. i. p. 118. tom. ii. p. 107. Ed. Melb.) mentions several other orations called Aeschines; and this identity of name has occasioned no small confusion in the history of the orations, and particularly with regard to the Socratie philosopher and Athenian orator, who are the subjects of these articles.

Aeschna, in Entomology, the name of a species of water-fly, of an ash-colour, with four wings, and a long body, hairy near the tail.

Aeschrich, in Biography, a fellow-citizen, and one of the masters of Galen, by whom he is mentioned with respect. He had great faith in a medicine he invented against the effects of the bite of a mad dog. The following is the prescription, and it is, without doubt, as efficacious as the famous composition recommended by Dr. Mead. Take of the ashes of lobbies, burnt alive in a copper vessel, ten parts; of gentian, in powder, five parts; of juniper, one part; mix them, and let the patient take a spoonful in a glass of water every day, for forty days. There are some idle ceremonies directed to be observed in making the powder, which are here omitted.

Aeschylus, in Geography, a town of Switzerland, in the canton of Bern; two leagues south-east of Spiez.

Aeschylus, in Biography, the famous tragic poet, was born at Athens, in the last year of the 63d Olympiad, or in the 577th year before Christ, according to the Armenian marbles, on which Stanley, in his notes on the life of this poet, relies. He was the son of Euphorion, and distinguished by his military valour as well as by the exercise of those signal talents, which intitle him to the appellation of the father of tragedy.

At the battle of Marathon, his brother, Cynegythus, signallized himself; and, as Herodotus informs us (l. ii. p. 391. Ed. Woffel.) he held of the prow of one of the Per- fians' ships with his hands, which were cut off by an axe, so that he died of his wounds; and his youngest brother Amphines, says Diochorus Siculus (l. xx. p. 556. Ed. Woffel.) who had the command of a squadron of ships, conducted himself with such skill and bravery, that he sunk the admiral of the Persian fleet, and gained distinguished honour. In these battles, as we learn from Pausanias (l. i. p. 35. Ed. Kuban.) as well as in those of Platrea and Artemision, he was present; and we are assured that he acquitted himself with honour. But his principal attention was directed to the composition of tragedies and the improvement of the stage. Pausanias informs us (l. i. p. 49.) that he was admi- nistered by Bacchus, when a boy, and asleep in the field, to write tragedies; and that when he awoke he made a trial and succeeded.

His mind was naturally strong and ardent; and the austerity of his character was manifested by his silence and gravity. From his youth he had been accustomed to the lessons of those poets, who, living near to the heroic times, conceived ideas corresponding in sublimity to the illustrious deeds that were then achieved. In the history of these remote ages he beheld every where the impress of grandeur, and frequently that of ferocity. In order to bring scenes of this kind to view, and to exhibit, as it were, before the eyes of the spectator the time and place, and various circumstances of events, Aeschiylus employed all the resources of theatrical representation; and thus the illusion became a reality. Sufarian and Thespis, and Phrynichus, the disciple of the latter, had proceeded but a little way. Thespis indeed had introduced a single actor, and Phrynichus selecled that kind of verse which is most suitable to the drama, and made some other changes; nevertheless tragedy was in its infancy before the time of Aeschiylus. In his first tragedies he introduced a second actor; and, afterwards, copying the example of Sophocles, who had just entered on his theatrical career, he admitted a third, and sometimes even a fourth. By thus multiplying persons, one of his actors became the hero of the piece, and poifled the principal intereft; and as the chorus now held only a subaltern station, Aeschiylus abridged its part. He is confirmed for having admitted mute characters into his drama; but it has been suggested that the veil which covered them and the silent grief which they manifested, produced a more sensible effect than any lamentations and tears. What he has said of his hero Hippomedeon (Sept. contr. Theb. v. 506.) may be applied to himself:

**" Before him frires**

Gigantic terror, tow'ring to the skies."
Aschylus paid particular attention to the performance of the actors, regulating their steps, and directing them to give additional force to the action, by appropriate and expressive gestures. He also instructed them more effectually by his example, as he performed with them in his pieces. Besides, he employed a person, called Teleclus, who had brought the art of gesture to such perfection, that in the representation of the seven chiefs before Thebes, he performed with so much truth and expression, that his action might have supplied the place of words. See Athen. Deip. p. 22, Ed. Cafaub.

Aschylus also applied to tragedy the lofty modulations and impetuous rhythms of certain airs calculated to excite without adopting those innovations which began to disguise the ancient music. His choral chant is full of grandeur and decorum, and constantly in the diatonic genus, which is the most simple and natural of all.

Quinellianus (Infl. Orat. I. c. 1. tom. ii. p. 897) gives the following character of Aschylus, as a writer: "Trageldae primus in locum Aschylus putatis, sublimis et gravis, & grandissimae soppe etque ad vitium, sed rudis in perficu & incompositus, &c." Longinus (Ed. Pearson, p. 99) says, that he had a noble boldness of expression, and that his imagination was elevated and heroic. Some have affected that he never composed but when he had drank freely; and by others he has been compared to Shakespeare for energy of sentiment and style, as well as for the expression of character and passion by the happy use of trivial circumstances. Horace describes the character of Aschylus in his Ars Poet. v. 252, &c.

"Poet nunc perflone, pallaque repetor nobile,
Aschylus, ut modestis inlavit pulpitae signis,
Et docuit magnamque loquere mitique cothurno."

Aschylus, says a modern author, exhibits both the beauties and the defects of an early original writer. He is bold, nervous, and animated; but very obscure and difficult to be understood; partly by reason of the incorrect metre in which his works have been transmitted to us, and partly on account of the nature of his style, which is crowded with metaphors, often harsh and tumult. He abounds with martial ideas and descriptions. He has much fire and elevation; less of tenderness than force. He delights in the marvellous. The glee of Darius in the Perse, the inspiration of Xerxes in Agamemnon, and the songs of the Furies in the Eumenides, are beautiful in their kind, and strongly expressive of his genius. Blair's Lect. vol. iii. p. 346.

Aelian informs us (Var. Hist. l. v. c. xviii. tom. i. p. 433, Ed. Gronov.), that Aschylus was charged with impity by the Athenians, and condemned to be floned to death.

The
The ground of the charge is not that which Herodotus and
Pausanias have supposed, viz. AESchylius's adopting the
theogony of the Egyptians rather than that of the Greeks,
and pretending to say that Diana was the daughter of Ceres
and not of Latona; but more probably that which Clements
Alex. has stated (Strom. i. ii. oper. tom. i. p. 407. Ed.
Potter,) that AESchylius, being himself uninitiated, professed
the mysteries by exposing them in one of his dramas on the
stage. However this be, the Athenians were preparing to
execute the sentence that was pronounced against AESchylius,
when his brother Aminius drew aside his cloak and pre-
pared him without a hand, which he had left at the battle of
Salamis, in defence of his country. This fight interred the compa-
ッション and honour of his judges, and induced
them to revoke their decree and to pardon AESchylius.

Plutarch (in Cimon op. tom. i. p. 483.) says, that AES-
chylius, being disguised with the preference given to Sopho-

colunte in the contest for the prize of poetic merit, abandoned
his country and went to reside in Sicily. There Hiero
distinguished him with benefactions and honours: but he soon
died at the age of 69 years, ante Christ. 456. Pliny informs
us, (H. N. l. x. c. iii. tom. i. p. 357.) that while he was
walking in the field, in order to avoid a danger of which he
was forewarned, with respect to the mode of his death, an
eagle, hovering over him in the air, let fall a tortoise upon
his head, for the purpose of breaking the shell, which
instantly killed him. The following epitaph, composed by
himself (for the original of which see Pausanias, p. 35. Ed.
Kuhnii.) was engraved on his tomb: — " Here lies AES-
chylius, the son of Euphorion, born in Attica. He died
in the fertile country of Gela. The Persians and the woods
of Marathon will for ever attune his name. " At the time
when he wrote these lines, he was unquestionably disguised
with literary fame, and knew no glory more illusory than
that of arms.

The Athenians decreed honours to his memory; and
authors who have intended to dedicate their talents to the
theatre, have gone to offer libations, and to recite their
works at his tomb. There are seven of his tragedies ex-
tant at which the best edition is the folio of Thomas Stan-
ley, published in 1663, with a Latin translation and learned
Commentary. There have been many other editions, and
also translations (See Fabric. Bib. Graec. tom. i. l. ii. c. xvi.
p. 600—618.) of these tragedies: Potter's translation, pub-
lished in 4to. at London, 1777; and afterwards in 2 volumes,
8vo, deserves to be particularly mentioned. Stanley, in his
Life of AESchylius, has mentioned several other perfections
of the same name.

AESCHYNOMENE, formed of αίσχυμον, to be ashamed,
because it retreats from the touch; by far less frequent plant, in
Botany, a genus of the dactylis decandrae chis and order;
and of the natural order of papilionaceae or leguminosae: the
characters of which are, that the calyx is one-lobed, bell-
shaped, subfusiforme with equal lips, upper broad, and lower
three-toothed perianthium; the corolla papilionaceous, with
sub-cordate, laceately gaping, large banner, fimbriate, obtuse
wings, shorter than the banner, and lanceate, acuminate keel
of the length of wings: the lamina have 10 filaments, fimbriate and non-clasped, and small anthers; the pistil is
an oblong, villous, columnar ofmentum, the stamens with
stigma sessile, rather obtuse; the pericar-
pium is a long, flat, jointed, rough, one-celled legume, open-
ing at the truncate joints; the seeds are follicular, between
the joints, and kidney-shaped. Martyn enumerates twelve
species, viz. the grandiflora, arborea, tinctura, affinis, americana, indica, febran or Egyptian, pumila or dwarf, sphenia, be-
teropollia, ingenina, and cannabina.

The first is a shrub, from 10 to 15 feet in height, a native
of the East Indies, cultivated in Jamaica, and in England
by Miller, in 1768. The seeds are agreeable to domestic
birds. — The second grows to the height of fix or seven feet,
with a single stem, and bears large and copper-coloured flowers. — The 3d is a native of the East Indies, and of the
islands Ophir and Haheine in the South Seas. — The 4th is a native of the East Indies. — The 5th is somewhat
scentuous: during the night, and at the approach of rain,
the leaves fold together. It is a native of Jamaica, and
was cultivated in 1739 by Miller. — The 6th is a native of the
East Indies. — The 7th is a native of Egypt, was cul-
vatined in 1680, in the botanical garden of Oxford, and flowers
in July and August. — The 8th is a native of the East Indies. — The 9th is a native of the East Indies, which may be treated as hemp and
used for the same purposes. The first fort is with difficulty pre-
ferred through the winter in this country. The 10th, 11th,
and 12th, may, like the first, be preferred through the win-
ter in a warm house, will flower early in the following
summer, and their seeds will ripen in the autumn; they must
be kept dry in winter, or else they are subject to rot. The
14th, 15th, and 16th species are annual, and must be
brought forward early in the year, otherwise their seeds
will not be perfected. All the forts are propagated by
seeds, which should be sown on a hot-bed early in the
spring; and when the plants are strong enough to be re-
moved, they should be put each into a separate small pot,
with light earth, and plunged into a fresh hot-bed; and as they advance in growth, they should be shifted into
larger pots; but care should be taken that the pots be not too
large, which will prevent their thriving.

AESCHYNOMOUS Plants among Botanists, are
those properly called Sevestous plants.

AESCULANUS, Ares, or Αέτ, in Antiquity, are
different names given to the divinity who preceded over the coin-
age of copper money. This AESculanus, it is said, was the
father of Argus, because copper was employed before silver;
and Argus, the father of Aacus, because gold
money succeeded silver; and thus they had three divinities
predominating over the coinage of the three principal metals. On
some medals of the emperors there are found three goddesses,
reprented with balances, a cornucopia, and near them a piece of the different metals.

AESCULAPIUS, in Astronomy, the ancient name for the
constellation Ophiucus.

AESCUPLUS, Eacles, and as Pausanias calls him
Aolecplus, in Mythology, the god of medicine, was the son of
Apollo, by the nymph Coronis, born at Epidaurus, and
ceducated by Chiron, the preceptor of Achilles, who taught
him to cure diseases of the most dangerous and desperate
kind, and even to raise the dead. The history of AEScula-
plus, like that of other deified heroes of antiquity, is
involved in great obscurity, and many absurd and incredible
stories are related concerning him. If we regard the reports
of the people of Epidaurus, which is said to be the
place of his nativity, as Pausanias has represented them,
left
loft his dog, and one of his she-goats, found them on a neighbouring mountain, near a child who shone with an extraordinary presence, and whom the goat suckled, and the dog guarded. This child was Æsculapius. As he advanced in age and wisdom, he dedicated his days to the relief of the unhappy. The most dangerous wounds and maladies yielded to his operations, his remedies, his harmonious songs, and the magical words which he employed. The gods, it is said, pardoned him his sacrileges; but as he dared to call the dead to life, Pluto complained, and Jupiter smote him dead with a thunder-bolt. See Pindar. Pyth. i. iii. v. 16. 92. p. 179. 201. Ed. Wetl. and Wetl. Diod. Sicil. i. iv. tom. i. p. 315. Ed. Wef-fer. Flin. H. N. i. 29. tom. ii. p. 403.

It is added, that Æsculapius was the disciple of Chiron, and having been entrusted with the secrets of his master, he communicated them to his sons Machaon and Podalius, who, after his death, reigned over a small city in Thessaly. During the siege of Troy, they signalized themselves by their courage in the field of battle, and by their skill in the treatment of wounds (Homer ii. v. 726. 1. iv. v. 219. 1. iv. x. 833.), the only part of the medical art that was much known in those remote ages. The children of Machaon, who was killed under the walls of Troy, followed the profession of their father, and settled in the country. They raised altars to their grandfather, and merited the fame honours themselves by the services which they rendered to the human race. See Phaulus. lib. ii. c. 11. p. 136. c. 23. p. 163. c. 26. p. 171. and 172. Ed. Kuhnii.

The founder of Æsculapius, a family soon became the object of public veneration, though his advancement to the rank of gods must have been posterior to the time of Homer, who only speaks of him as a simple individual. In process of time divine honours were everywhere paid to him. At Epidaurus he had a famous temple, in which his statue, made of gold and ivory, by Thrasymedes of Paros, was placed on a throne of the same materials. It was crowned with rays with a knotty flock in one hand, and stretching out the other arm over a serpent, which seemed to raise itself up in order to reach it; and a dog lay at his feet. The Epidaurians instituted festivals and games, which were at first annual (Plat. in Ion. tom. i. p. 530. Ed. Serrani.) and afterwards once in five years celebrated in honour of him. From Epidaurus his worship passed to the other cities of Greece, and even to distant countries. In all his temples votive tablets were hung up, on which were recorded the diseases cured by his assistance. This god was brought to Rome, by order of Apollo, when a pestilence raged in that city, in the times of the republic, under the confule of Polibithus Megellus and C. Junius Brutus. About the year of Rome 452, the Sibylline books were consulted, and an embassy was appointed to bring the god from Epidaurus to Rome, who is said to have stolen away from his old worshippers under the form of a serpent; and on his arrival, to the great joy of the people, the plague soon ceased. On this occasion altars were erected along the banks of the Tiber, and numerous sacrifices were offered to the new deity. The Romans designed to erect a temple in honour of him, within the walls of the city; but the god who reposed in the vicinity of Epidaurus, and not within the city, is said to have chosen his abode in the midst of the Tiber, on an island formed in the infancy of the republic by the stream of trees, and, and the rubbish of the city. Thither the serpent retired, and from that time the island was called the island of Æsculapius, and a temple was erected in the form of a slip, to which, as to the temple of the god of health, the common people frequently repaired. The sick were referred to health, and in token of gratitude offered a cock to Æsculapius. Of this temple there were some remains in the 16th century, near the church of St. Bartholomew, in the island of the Tiber. From this time Æsculapius was honoured at Rome as one of the chief of their made gods. On coins, &c. he is crowned with laurel, in token of his defect from Apollo, and he is represented with a mild aspect, and with hair and beard not unlike those of the mild Jupiter: his right arm is bare, in order to denote his readiness for any operation; his left holds a cock, with a serpent twisted round it. He is sometimes seen accompanied by his wife Hygeia or health, with their son Telesphorus, or convalescence, between them. The dog and cock have been reputed sacred to this deity on account of their vigilance; and the raven for his foresight. Status, lib. iii. Sylv. iv. v. 25. Ovid. Met. ix. tom. i. p. 1057. Ed. Burman. Sueton. in Claud. tom. i. p. 686. Ed. Plinie. —Liv. Epitom. lib. xi. tom. iii. p. 197. Ed. Burman. — Plut. Quaest. Rom. tom. ii. p. 236. Paufan. Corinth. l. ii. p. 171. Achaic. l. vii. p. 592. &c. Ed. Kuhnii. —Cicero. (de Nat. Deor. Liii. c. 22. tom. ii. p. 615. Ed. Olivet.) mentions three deities called Æsculapius; the first the son of Apollo, worshipped in Arcadia, who invented the probe and bandages for wounds; the second, the brother of the second Mercury, killed by lightning; and the third, the son of Arhippos and Arsinoe, who first discovered the art of tooth-drawing and purging.

Those who trace the origin of medicine, as well as the other arts and sciences, to the Egyptians, ascribe the invention of it to Toforthor or Selothor, a king of Memphis, and the second of the third dynasty of Manetho, who was called Æsculapius on account of his great skill in that art. This prince was much more ancient than the Grecian Æsculapius; and though Africanus places him some years after Athothis, the faucerr of Mene, supposed to be the same with Thoth, or the first Hermes, yet others make them contemporaries, as they must have been if this Æsculapius was the same with the son of Sydyce and the brother of the Cabiri. —Anc. Un. Hist. i. p. 246. Svo.

Æsculalus, Horae-Chefliity, in Botany, a genus of the heptandria monogyxa class and order, of the natural order of tribulata, and the acer of Jussifin. It is the hippocastanum of Tournefort, and the passia of Boerhaave. The name æsculalus is derived from esca, food; and the old names of hippocastanum and castanea equina, from the similitude of the fruit to that of the chestnut, and from its being given to horses. Its characters are, that the calyx is a one-leaved, ventricose, small, and five-toothed perianthium; the corolla consists of five roundish petals, parted and waving about the edge, flat, spreading, with narrow claws inserted into the calyx, and irregularly colored; the stamens have florulate, declining filaments, of the length much of the corolla, and ascending stamens; the pistillum is a roundish germ, ending in a subulate style; the stigma acuminate; the fructicum is a leathery, roundish, three-celled, three-valved capsule; the seeds are two and sub-globular. Van Royen de Necker and Miller observed both hermaphrodite and male flowers in this genus. There are three species, viz. the AE. hippocastanum, or common horae-chestnut; the leaves of which are digitate, with seven entire leaves, and prickly capsules; the AE. flava or yellow-flowered horae-chestnut, with leaves digitate with five leaves, the laminas of the corolla cordinate roundish, and the claws twice the length of the calyx; and the AE. passia, or scarlet horae-chestnut, which has flowers with eight flamina, digitate leaves with five or six ferrate leaves, smooth capsules,
The horse-chestnut has been employed in France and Switzerland for the purpose of blanching yarn; and it is recommended in the Mem. of the Society of Berne, vol. ii. part 2, as capable of extensive use in whitening not only flax and hemp, but silk and wool. It contains an astringent saponaceous juice, which is obtained by peeling the nuts, and grinding or rasping them. They are then mixed with hot rain or running water, in the proportion of 20 nuts to 10 or 12 quarts of water. Wove caps and flockings were made in this water, and took the dye extremely well; and successful trials were made of it in fulling stuffs and cloths. Linen washed in this water takes a pleasing light sky-blue colour; and the flamentous hemp, steeped in it some days, were easily separated. The author of the memoir above referred to, imagines, that if the meal of the chestnuts could be made into cakes or balls, it would answer the purposes of soap, in washing and fulling. The sediment, after infusion, loses its bitter taste, and becomes good food for fowls when mixed with bran. The Edinburgh College have admitted the horse-chestnut into their Pharmacopoeia of 1793, on the recommendation of Dr. Gardiner, who says, that three or four grains of the powder suffused up the nozils in the evening, operates next morning as an excellent intermittent, and thereby proves very beneficial in obliterating inflammations of the eyes. A patent was granted in 1766, to Lord W. Murray, for his discovery of a method of extracting flakes from horse-chestnuts. See Starch.

The 2d species, or yellow flowered horse-chestnut, is a native of North Carolina, was cultivated with us in 1764, and flowers in May and June.

The 3d species, or scarlet horse-chestnut, rises to the height of 20 feet, without much extending its branches; its bark is smooth, and the leaves, which are opposite, on long red petioles, are of a light green. The flowers, which are produced from the ends of the branches upon long naked peduncles, are much smaller than the common chestnut and wholly red; they appear in June, and are sometimes succeeded by fruit in England; but the seeds rarely ripen here. It grows naturally in Brazil, Carolina, Florida, Japan, and several parts of the east; and was cultivated with us in 1712. This tree may be propagated by the nuts, which must be procured from the countries where it grows naturally. They must be sown in pots early in the spring, and the pots should be plunged into a moderate hot-bed, and towards the end of May into the ground in a south-east border; and in dry weather the plants should be watered, and secured from early frosts. In the following spring they should be planted at the distance of a foot from each other, in a sheltered situation, and in the succeeding winter sheltered from cold by some light covering. The common method practiced by the nurserymen, who propagate this tree for sale, is to graft or bud it upon stocks of the common horse-chestnut; but as the stocks greatly outgrow the bud or graft, the trees make a bad appearance, nor do they last long.

ÆSEPUS, in Ancient Geography, a river of Mycia, which Strabo (l. 12. t. ii. b. 847) on the authority of Homer, makes the boundary between Mycia and Troba. See ÆSEPUS.

ÆSERNA, in Ancient Geography, Iserna, a town of the Samnites, which was a Roman colony belonging to the Caraceni between Aquilenna north, and Boianiun south. It was not far from the river Volturno. Silius Italicus (l. viii. v. 56.) refers to it; and the appellation Iserni for Phly (l. iii. c. 12.) is derived from it.

ÆSHNA, in Entomology, a sub-division of the Unogata, or fifth class of insects, by Fabricius, comprehending several species of the Libellula of Linnaeus, characterized by equal
equal lacinia or fringes of the lip. The species are, 1. _L. or _L. minut a_ with a yellow abdomen, two black lines, hinder wings yellow, and two black spots, found in China. 2. _L. elongata_ with a elevated abdomen, gibbous base, and body variegated with brown and green, found in China. 3. _L. maculata or variegata_ with two yellow lines on each side of the thorax, and a black spot at the base of the wings, found in Terra del Fuego. 4. _L. grandis_, with four yellow lines on the thorax and variegated body, found near the waters of Europe, and in the Sandwich islands. 5. _L. forei pata_, with a black thorax, various yellowish marks, and unguiculated tail, found in Europe.

AESICA, in *Ancient Geography*, is supposed to have been the present village of Netterby in Cumberland.

ÆSIS, _Efes_, *Flaminia_, a small river of Italy, which separated the Samnites from Picenum, and emptied itself into the Adriatic sea, near Ancona. See *Sil. Ital*. lib. viii. v. 446.

ÆSISIUM, a town of Italy, belonging to the Umbrians.

ÆSTÆ, a people of Arabia Deserta, placed by Plutarch below the Cauchabeni.

ÆSTIUM, called also Æsis, a town of Umbria in Italy, situate upon the western bank of the *Æsis*, which was the common boundary of Umbria and Picenum. In after-ages it received a Roman colony.

ÆSCNEY, in *Laece*, denotes priority of age among coparceners.

AESOLA, or _Æsula_, in *Ancient Geography*, a town of Italy, near the Tiber, and not far from Picenum. It was situate upon a hill between the Tiber and Prasclle; and according to Livy, who speaks of *Arcus Efuliani* (l. xxi. e. ix. t. iii. p. 1069. Ed. Burman.) it was a fortified place. It is mentioned by Horace (I. iii. od. 29.) and by Paterculus (I. i. c. 14.) as a colony; and Pliny also (I. iii. c. 9.) speaks of the *Ebulani* in his time, though no vestige of them now remains.

ÆSON, a town of Thessaly, founded by Æson, the father of Jason; and also a river of Thessaly towards Magnesia, near this town.

ÆSONA, or _Isena_, a town of Spain, between the rivers Siceris and Nuceria.

ÆSOP, in *Biography*, a native of Phrygia, who lived in the time of Solon, about the 518 or 520 Olympiad, the first year of which coincides with the 572d before Christ, and during the reign of Cesar as the first king of Lydia. His condition was that of a slave, and his person was so deformed, that one of his masters found great difficulty in dispossing of him, as every one who saw him was shocked at the ugliness of his figure. He is also said to have been for a considerable time without the use of speech. His mental talents, however, compensated for his bodily defects, and commanded attention and respect, notwithstanding the meanness of his condition. His first master was Demarchus, an Athenian, in whose service he is supposed to have acquired his purity in the Greek tongue. From him he was transferred to Xanthus, a Samian philosopher; and he was sold by Xanthus to Iadon, who was likewise a Samian, and who granted him his freedom on account of his extraordinary abilities; others say that he became free by the favour of Rhodope, a celebrated courtezan. Having obtained his liberty, Æsop acquired great reputation, and was much esteemed by Cesarus, although in the first interview his deformity made an unfavourable impression on the mind of the king, who found the observation of Æsop, on another occasion, signally verified in his own cafe, viz. that we ought not to consider the form of the vessel, but the quality of the liquor which it contains. Phedrus (l. i. fab. 2.) informs us that he made several voyages into Greece, either for his own pleasure, or upon the affairs of Cesarus; and being at Athens soon after Cephalus had ushered the sovereignty and abolished the popular government, and observing the impatience of the Athenians under this new yoke, he repeated to them the fable of the frogs who demanded a king from Jupiter. In order to account for the miracles of human life, Æsop used to say, that when Prometheus formed man of clay, he tempered the materials with tears. As to the time of Æsop's death, Censorinus and Suidas refer it to the 54th Olympiad; but this date is not conformable with the occasion to which Phedrus refers the fable of the frogs; for Cesarus assured the sovereignty of Athens in the firt year of the 55th Olympiad. In Blair's *Tables*, his death is fixed to about the year before Christ 501. The manner of his death is thus related by Plutarch, in his *Treatise de bis qui feri a nomine panuntur*, (apud Oper. tom. ii. p. 556. Ed. Xylander.) Having gone to Delphi, by order of Cesarus, with a large quantity of gold and silver, to offer a collyb sacrifice to Apollo, and to distribute a considerable sum amongst the inhabitants, a quarrel arose between him and the Delphians, which induced him to return the money, and to inform the king that the people were unworthy of the liberal benefaction which he intended for them. The inhabitants of Delphi, thus incensed, charged him with sacrilege, and having procured his condemnation, precipitated him from a rock and occasioned his death. Apollo punished him for this act of violence with pestilence and famine; and in order to avert these evils, it was proclaimed in all the cities of Greece, that if any one for the honour of Æsop, would claim vengeance for his death, they would give him satisfaction. A relation of Iadon, a former master of Æsop, presented himself, says Herodotus (l. ii. p. 168. Ed. Wesseling,) and obtained satisfaction; and thus the Delphians were rescued from the pestilence and famine by which they were distafest. The Athenians afterwards erected a noble statue, executed by Lyippus, to the honour of this ingenious and learned fable, in order to let all the people know, as Phedrus (l. ii. i.) observes, that the path of honour was alike accessible to all mankind; and that it was not to birth, but merit, they rendered this distinguishing honour.

Æsop ingentem statum puosure Attici, Servumque solcomar uterna in bali Fra honoris feerent ut cunctis viam, Nc genere tribui, fed virtuti gloriar.

Æsop, it is said, composed his fabes, in order to elevate the hardships of servitude; and it has been generally supposed that he was the first author or inventor of this species of composition: and thus Phedrus (Pro. ad lib. i.) represents him:

"Æsopus anfuer quam materiam repert, Hanc ego polivi veribus farnaris.
If any thoughts in these fables shine,
Th' invention's Æsop's, and the verfe is mine."

But Quinctilian (Inf. Orat. i. v. c. 11. tom. i. p. 441.) affirms the honour of the invention to Hesiod, who is known to have lived more than 750 years before the time of Æsop: and he speaks of them as admirably adapted to delight and captivate the minds, particularly, of the vulgar and uninformed. Æsop, however, improved this kind of writing, and adapted a variety of images, which combine the agreeable with the instructive, and communicate practical precepts in a familiar and impressive manner. To this purpose...
Aulus Gellius (Nep. Att. I. ii. c. 29.) observes, that Aesop, the fabulist, was deliberately esteemed wise, since he did not, after the manner of the philosophers, rigidly and imperiously dictate such things as were proper subjects of counsel and delusion, but by forming amiable and agreeable apologues he charms and commands attention, and thus infuses into the minds subjects that deserve consideration. Many of Aesop's Fables have been ascribed to Plaudeus, who lived in the 13th century, and wrote a book of him, which abounds with anachronisms and incredible relations.

Plato (in Phileb. Oper. tom. i. p. 62.) says, that there is an ancient tradition, that the people of Egypt first began to make music by the time of Aesop, and thence it spread to other parts. The name of Aesop is also mentioned by Suidas in Syriac, and others, inform us, that Socrates, a little before his death, translated some of Aesop's Fables into verse; and Plato (in l. de Republica, tom. i. p. 578.) recommends it to nurses to instruct children in them, in order to form their manners, and to inspire them at an early age with the love of wisdom. Among many editions of Aesop's Fables, by Aldus, Rob. Stephens, Plantin, &c. we may mention Hulson's, Oxon. 1718, Svo. which has been the foundation of several others.

Fabricius (Bibl. Greek, tom. i. p. 391.) has enumerated nine other persons under the name of Aesop. Of these, one was a Greek historian, who wrote a romantic history of Alexander the Great; but it is not known at what time he lived.

Another of them was

AESOR (Clodius), a celebrated tragic actor, who lived about the 67th year of Rome (B.C. 79), and amassed great wealth by the exercise of his profession. Plutarch (in Ciceron. Op. tom. i. p. 862.) informs us, that Cicero had written action under the direction of Aesop, as well as that of Raffius, and in speaking of this performer, he says, that he entered into his part to such a degree as to be sometimes transported beyond the power of self-government. Accordingly, whilst he was representing the deliberation of Atticus, who wished to revenge himself on Thylaeus, he smote one of the servants that happened to cross the stage, with his truncheon, and laid him dead at his feet. Aesop lived in the most luxurious and extravagant manner; and Pliny (N. H. i. x. c. 51 tom. i. p. 571.) Ed. Hardt.) says, that at one entertainment he had a dith, which cost 160 fees, and about 872 pounds in silver, and the dith confined of finging and specking birds, some of which cost 60 fees, or about 53L each. At the dedication of Pompey's theatre, U. C. 698, Aesop, when he was attempting to amuse the spectators in his usual manner, was obliged to flit from a fence on account of the failure of his voice, so that he was, probably, in the decline of life. The son of this Aesop was more luxurious than his father; for he is said, on a particular occasion, to have diffused pearls for his guests to swallow. See Val. Max. l. i. x. c. 2. Pliny N. H. l. i. x. c. 534. Ed. Hard. Horace (Sat. iii. lib. ii. v. 279.) speaks only of one pearl of great value, which he diffused in vinegar and drank:

"Filius Aesopi detraeatum ex aure Metalla, Scilicet ut deces folidum abhorret, acto Dilatat infignem baccan, qui fami, ac si Ilud idem in rapidum flumen, lacertoe cloacam?"

Aesop, notwithstanding his profusion, is said to have died worth above a hundred and sixty thousand pounds. Macrobi. Saturn. i. ii. c. x.

AESOPUS, in Entomology, a species of Papilio, with the wings brown on the upper part, a white spot, and underneath white and unspotted; the Papilio Thysa of Drury; found in India.

AESPING, in Zoology, the caluber chersii of Linneus, a species of viper, found in Sweden, resembling the Aspic, but smaller than that species. Linneus questions whether it may not be the same. Its bite is venomous, and in some cases has proved fatal. Count de la Cepede, in the second volume of his Histoire Naturelle des Serpens, &c. recommends the juice expressed from the leaves of the asf as a specific against it.

ÆSTH, in Ancient Geography, a people of Germany, near the borders of Prufia and Poland. They are represented by Tacitus (De Mor. German, apud Op. t. ii. p. 652.) Ed. Gronov.) as possessing the Suevi in their customs and manners, and the Britons in their language.

ÆSTIMATIO Capius, in our ancient law-books. See Whet, and Werelade.

King Athelstan, in a great assembly held at Exeter, declared what multitudes were to be paid pro animatione capitis, for offence committed against several personls according to their degrees: the estimation of the king's head to be 1000 thrymera; of an archbishop, or fatrapa, or prince, 15000; of a bishop, or a senator, 8000; of a priest, or a thane, 3000, &c.

ÆSTIVAL, or Estival, of or belonging to summer. Thus, we say, the aestival solstitial, &c. in opposition to brumal.

ÆSTIVAL point is that whereby the sun's ascent above the equator is determined.

ÆSTIVAL signs are those extended from the summer foUotlal point, i.e. the sun's greatest declination northward, to the intercession of the ecliptic and equinoctial southward, including Cancer, Leo, Virgo.

ÆSTIVATION, in Botany, a term expressing the state of the bud in summer, and used by Linnaeus to denote one of those circumstances which constitute the habitat of plants.

ÆSTRIANS, in Ancient Geography, the inhabitants of a district of Macedonia, the chief city of which was formerly called Æstirium.

ÆSTUARIUM, a town of Spain, between Noega and Salis.

ÆSTUARY, Æstuarium, in Geography, an arm of the sea, running up a good way into the land. Such is Bristol channel, many of the friths of Scotland, &c. See Bay.

ÆSTUARY is sometimes also used in Pharmacy, for a vapour bath, balneum vaporosum.

ÆSTUARY, in the Ancient Baths, was applied to the occult passages, or openings from the hypocaustum, or flue, penetrating into the chambers. Petriæ. Lex. Ant.

To such a passage is the house of Pompeia, Statius refers (Sylv. lib. i. § 5, v. 58.)

------: Ubi languidus ignis inerat

ÆTHUS, et tenetum volunt hypocastum vaporem."

ÆSYMNETIC monarchy, among Ancient Writers on Government, denotes a limited elective monarchy. Arist. Pol. c. 10. The word is formed from Æsymnus, regina, I govern.—An Æsymnetic state Flans opposite to a barbaric, or corporal one.

ÆSYNUMN, in Antiquity, a monument erected to the memory of the deceased heroes, by Æmminus the Megarens. Upon consulting the oracle at Delphi, how the country might prosper and enjoy the most auspicious government, he received for answer, that it would be most likely to prosper if it followed the counsel of the most numerous: and understanding the oracle to refer to the dead, he built this monument, and encompassed it with a council-house; and thus the Megarens hoped to obtain wise and salutary counsel. See Pausanias Attic. i. p. 134. Kuhnii.
ÆTHÆ, in Ancient Geography, a people, according to Ptolemy, of Arabia Felix.

ÆTARA, a town of Africa, placed by Ptolemy between the town of Tzabra and the river Ampiasga.

ÆTATE probanda, in Lewe, a writ that lay to inquire whether the king's tenant, holding in chief by chivalry, were of full age to receive his lands into his own hands. It was directed to the efcheator of the county; but is now disfrûd, since wards and liveries are taken away by the statute Car. II. Reg. Orig. 294.

ÆTH, or AT, in Geography, a strong little town of the county of Haamult, in the Austrian Netherland, situate on the river Dender, about 20 miles south-west of Brussels. It had formerly an abbey of nuns, and some good linen manufactures.

ÆTHRA, in Ancient Geography, a town of Laconis.

ÆTHALIDE, a people of Attica in the tribe of Leontides.

ÆTHALOEIS, a town of Mylia, Earl of mount Ida, and seat of Scopfa.

ÆTHELING, in Britia History. See Atheling.

ÆTHER, in Phytology, is usually understood of a thin, subtle matter, or medium, much finer and rarer than air; which, commencing from the limits of our atmosphere, poises the whole heavenly space.

The word is supposed to be formed from the verb αἰθέρ, to burn, to flame: some of the ancients, particularly Anaxagoras, supposing it of the nature of fire.

The philosophers cannot conceive that the largest part of the creation should be perfectly void; and therefore fill it with a species of matter under the denomination of æther.

But they vary extremely as to the nature and character of this æther. Some conceive it to be a body sui generis, appointed only to fill up the vacancies between the heavenly bodies; and therefore confined to the regions above our atmosphere. Others suppose it of so subtle and penetrating a nature, as to pervade the air, and other bodies; and poises the pores and intervals thereof. Others deny the existence of any such specious matter; and think the air itself, by that immense tenuity and expansion of which it is found capable, may diffuse itself through the interstices and interstices, and be the only matter found in them.

In effect, æther being no object of our sense, and the mere product of imagination, introduced only for the sake of hypothecis, or to solve some phenomenon, real or imaginary; authors take the liberty to modify it how they please. Some suppose it of an elementary nature, like other bodies, and only distinguished by its tenuity, and the other affections resulting from it; which is the philosophical æther. Others will have it of another species, and not elementary; but rather a sort of fifth element, of a pure, more refined, and spirituous nature than the sublimations about our earth; and void of the common properties of matter, as gravity, &c. Such is the ancient idea of æther or ætherial matter.

The term æther being thus embarrassed with a variety of ideas, and arbitrarily applied to so many different things, the later philosophers choose to set it aside; and accordingly, the Cartesians use the term materia fubtilis, which is their æther; and Sir Isaac Newton sometimes a fubtile ætherius, as in the close of his Principia; (apud Oper. tom. iii. p. 174, Ed. 11th.) and sometimes a fubtile or ætherial medium; as in his Optics. Querius tis 18—24, apud Oper. tom. iv. p. 225—246. See also his letter to Mr. Boyle, apud Oper. tom. iv. p. 383, &c.

The truth is, there are numerous considerations, which seem to evince the existence of some matter in the air much finer than the air itself. There is an unknown something which remains behind when the air is taken away; which appears from certain effects which we see produced in vacuo. —

Hence, Sir Isaac Newton observes, is communicated through a vacuum, almost as readily as through air; but such communication cannot be without some interjacent body, to act as a medium. And such body must be subtle enough to penetrate the pores of glass; and may be very well concluded to penetrate the pores of all other bodies, and consequently be diffused through all the parts of space; which answers to the full character of an æther. He supposes that it is rarer in the pores of bodies than in open spaces, and even rarer in small pores and dense bodies than in large pores and rare bodies; and also, that its density increases in receding from gross matter, so as to be greater, &c. at the 28th of an inch from the surface of any body than at its surface; and so on.

The existence of such an ætherial medium being settled, that author proceeds to its properties; inferring it to be not only rarer and more fluid than air, but exceedingly more elastic and active: in virtue of which properties, he thinks, that a great part of the phenomena of nature may be produced by it. The elastic force of this medium, in proportion to its density, according to his mode of estimating it, must be above 2800000 x 700000 times greater than the elastic force of the air in proportion to its density. If, he says, any one should suppose that æther, like our air, may contain particles which endeavour to recede from one another, and that its particles are exceedingly smaller than those of air, or even than those of light; the exceeding smallness of its particles would contribute to the greatness of the force, by which these particles may recede from one another, and thereby make that medium exceedingly more rare and elastic than air, and by consequence exceedingly less able to reflect the motions of projectiles, and exceedingly more able to press upon gross bodies by endeavouring to expand itself. The resistance of this medium, he supposes, to be very inconsiderable. If this æther should be supposed 700000 times more elastic than our air, and above 700000 times more rare, its resistance would be above 6300000 times less than that of water; and a resistance so small would scarcely make any sensible alteration in the motions of the planets in 10,000 years.

To the action of this medium he ascribes the attractions of gravitation and cohesion, the attractions and repulsions of electrical bodies, the elastic force of the air, and of nervous fibres, and the emission, reflection, refraction, and other phenomena of light, the effects and communication of heat; as also sensation, muscular motion, &c. In fine, this same matter seems the primum mobile, the first source or spring, of physical action in the modern fytem.

The Cartesian æther is supposed not only to pervade, but adequately to fill all the vacuities of bodies; and thus to make an absolute plenum in the universe. See Materia fubtilis.

But Sir Isaac Newton overturns this opinion, from divers considerations; by shewing that the celestial spaces are void of all sensible resistance; for, hence it follows, that
The matter contained in them must be immenely rare, because the resilience of bodies is chiefly as their density; so that if the heavens were thus adequately filled with a medium or matter, how stillful ever, they would rend the motion of the planets and comets much more than quicksilver or gold.

The existence of such a subtle fluid as æther has been almost universally allowed: and its importance and utility, in the general system of nature, have been very generally acknowledged. Dr. Reid, indeed, seems to have entertained doubts on this subject. He observes, that although Sir Isaac Newton had formed conjectures about this æther near 50 years before he died, and had it in contemplation as a subject of inquiry, during that long space; yet it does not appear that he ever found any convincing proof of its existence, but considered it to the last as a question, whether there be such an æther or not. Regarding, therefore, the authority of Newton himself, he is of opinion that we ought to hold the existence of such an æther as a matter not established by proof, but to be examined into by experiments; and he adds, "I have never heard that, since his time, any new evidence has been found of its existence."

Dr. Hartley, however, whose system of the mind and its operations is founded on the reality of this æther, alludes, that if we suppose the existence of such a subtle medium, and of its properties, to be destitute of all direct evidence, yet, if it seems to account for a great variety of phenomena, it will have an indirect evidence in its favour by this means. To which mode of reasoning Dr. Reid replies, that there never was a hypothesis invented by an ingenious man which has not this evidence in its favour. The vortices of Des Cartes, the sylphs and gnomes of Mr. Pope, serve to account for a great variety of phenomena. Hartley's Observations on Man, p. 748. Reid's Essay on the Intellectual Powers of Man, p. 87.

Some late writers have ascribed the phenomena of electricity and magnetism to a fluid of this kind, under the denominations of the electrical and magnetic fluid; and they have referred to its operation in different circumstances, many of those effects, which are inexplicable without such a fluid, diffused through every part of the material universe. See Electricity, cause of Gravity, Heat, Light, Magnetism, Reflection, Refraction, Sensation, Sound, Vibration, &c.

Æther, in Chemistry. See Æther.

Ætheria, in Ancient Geography, is a name formerly given to Ethiopia, under which appellation, it is mentioned both by Pliny (i. vi. c. 50.) and Strabo, I. ii. p. 52.

Ætheria, Herba, is a name given to fringilla.

Ætherial, Ætherius, something that belongs to or partakes of the nature of æther.

Thus, we say, the ætherial space, ætherial regions, &c. Some of the ancients divided the universe, with respect to the matter contained in it, into elementary and ætherial. Under æther, or the ætherial world, was included all that space above the uppermost element, viz. fire. —This they supposed to be perfectly homogeneous, incorruptible, unchangeable, &c. See Corruption.

The ancient Platonists and Pythagoreans suppose different bodies united with the human soul, viz. the grofs, or material one; a finer aerial one; and, thirdly, the finest of all, which they call ætherial, celestial, lucifer, &c.

This kind of body they conceived peculiarly belonging to such souls after death, as are purged and cleansed from corporeal affections, lusts, and passions. That this direction of two interior vehicles, or tunicles of the soul, besides the outer veliment of the terrestrial body, was not a mere figment of the latter Platonists since christianity was introduced, appears plainly from Virgil's description of the pure ætherial and fiery body, which he distinguishes from the spirituous or airy body, in which unpurged souls receive punishment after death. After describing this punishment, he proceeds in this manner:

"Donec longa dies, perfecto temporis orbe, 
Concretam exumit labem, purissumque reliquit
Ætherium fenfum, atque aurum simplicis ignem."

Ed. Burman.

The ground of this opinion seems to have been the notion which these philosophers entertained concerning the pre-existence of the human soul, which, according to their imagination, was invested with a lucid and ætherial body, ethereal from eternity, or else from the first commencement of the habitable world; and which, being coeval with the soul itself, and also incorruptible, inseparably adhered to it, in its subfrequent lapses and defects, first into an aerial, and then into a terrestrial body: this being, as it were, the bond of union betwixt the soul and them. The Pythagoreans and Platonists, however, were not all of this opinion; for some of them supposed, that, according to the real disposition of the soul, it always finds or forms a suitable body, correspondently pure or impure; and consequently that, by moral virtue and philosophy, it might again recover that celestial body, which was lost by its fall and defect into the groser body. See Cudworth's Intell. Syst. b. i. c. 5. vol. ii. p. 788—793. Ed. Birch.

The Chaldees placed an ætherial world between the empyreum and the region of the fixed stars. Befide which, they sometimes also speak of a second ætherial world, meaning by it the flarry orb: and a third ætherial world, by which is meant the planetary region. Stanley Hist. Phil. 1840.

Ætherial phthisis, is a name generally given, by Bernouilli, to that otherwise called mercurial, or barometrical phthisis.

Ætherial oil, is a fine, subtle, essential oil, approaching nearly to the nature of a spirit. Thus, the pure liquor rising next after the spirit, in the distillation of turpentine, is called the ætherial oil of turpentine.

Some chemists distinnguished two principles in urine; the one a volatile umberous tinct, resembling spirit of niter; the other, an ætherial oil, or sulphur, partaking of the nature of spirit of wine.

Ætherial Heaven. See Heaven.

Ætherius, in Biography, an architect, who lived in the beginning of the 6th century, during the reign of Amalarius I. emperor of the east, who made him a privy-councilor. He built an edifice, named Chalch, in the palace of Conidantepe, and he is supposed to have constructed the strong wall which extends from the sea to Scylia, for preventing the incursions of the Bulgarians and Scythians.

Æthicia, in Ancient Geography, a country, according to Strabo, adjacent to Macedonia, Thrace, and Pindus, inhabited by the æthèisci.

Æthipoa, a name formerly given to the island of Lesbos.

Æthiopia, in Geography. See Ethiopia.

Æthiopian crown, in Natural History, the name of a shell-fish, of the genus of the doliuse, or concha globoidea. It is of a brown colour, but differs from the common shells of this genus in having the top or head dentated, so as to represent a crown.

Æthiops, signifies Ethiopian clary. See Salvia.
ÆTHIOPS, in Pharmacy, a name given to certain metallic preparations of a dark colour; and though the term is at present superfluous, it is yet too familiar to chemist to be wholly omitted. There are four pharmaceutical articles of this name, æthiops antimonialis, æthiops martialis, æthiops mercurii per fo, and æthiops minerals.

Æthiops antimonialis, is a combination of the fulpures of antimony and mercury; the old way of preparing it is, to mix together equal parts of common salt and crude antimony, and flux the mass in a crucible; when cold there will be found a dusky fcria, retting upon a metallic looking subsance, which is the crude antimony nearly in the same state as at first. The fcria being separated, the antimony is to be ground with an equal weight of mercury till they are well united. The first part of this process seems wholly unnecessary, and accordingly the antimonial æthiops is generally made by triturating of crude antimony with an equal weight of mercury. A still more expeditious and equally efficacious way of preparing this medicine, is to fuse some crude antimony in an earthenware crucible, and when it is upon the point of fixing, to add to it an equal weight of hot mercury; the mixture immediately becomes more fluid, and after a while becomes solid: when cold it must be levigated in a mortar, and wafted. Sometimes, instead of crude antimony, the golden fulphur of this metal is made use of.

The medical effects of antimonial æthiops are chiefly as a sudorific in small doses, and as a purgative and emetic in larger ones. It has been exhibited with effect in old invertebrate cafes of lues, scrofula, and glandular obstructions; but on account of the irregularity of its action, it is nowfallen much into disufe. The phialæ æthiopics of the late Edinburgh Pharmacopœia, were composed chiefly of mercury and a golden fulphur of antimony, but in the last edition of this as well as of the London Pharmacopœia the æthiops antimonialis is wholly omitted. New Dispensatory, 1765. p. 545.—Lewis's Mat. Med. vol. i. p. 101.

Æthiops muriaticus, fofran de Mars de Lerny, is a pure magnetic oxyd of iron, and was first introduced into the materia medica by the younger Lerny; he directs it to be prepared in the following manner. Into a large glass bafon put a few pounds of clean unrufted crofletting, then add a fufficient quantity of water to cover them to the depth of five or fix inches; this mixture is to be türred up with an iron spatula, two or three times a day, and fresh water to be supplied in proportion to the evaporation; at the end of five or fix months almost the whole of the iron will be converted into a black fine powder which remains fipated in the water for fome fcoras after agitation. The water thus rendered turbid is to be decanted into a cucubit or retort, and allowed to repofe till the whole of the iron is depofited; the supernatant clear liquor must then be poured off, and the remaining moifteur evaporated by the heat of a sand-bath, care being taken to prevent the acces of air to the powder while drying; if the procfs has been well conducted, the folut is a pure black pulverulente magnetic oxyd of iron; as however by moifteur and contact with the atmosphere, it soon falfes into the iron of yellow oxyd, it is necfary to keep it in a dry well closed vessel. M. Lerny, the inventor of this preparation, as is usual in fimilar cafes, strongly maintained its superiority over all the other medicinal forms of iron; the tecloufens of the procfs, however, has prevented its use from being very general; it certainly polifhes in a high degree the tonic properties which characterize the salts and other preparations of iron, but is superceded in both the British pharmacopoeias by the rubigo ferri. Beaumé Chymie. Experim. vol. ii. p. 547. Beaumé Elements de Pharmacie. p. 137. Macquer's Chem. Dictionary. Art. Ethiops Martial.

Æthiops mercurii per fo; æthiops album; by this name is distinguished in the German pharmacopoeias an imperfect oxyd of mercury prepared by triturating the metal with gum arabic, or any other fimple mucilage, or by long continued agitation in contact with atmospheric air. Even when all possible care has been taken, this is a very imperfect mercurial oxyd, and in common the metal is merely reduced to a fine state of division. Loesecke recommends it in a dose from half a fruple to half a dram, either alone or united with jalap, in buboec, gonorrhœa and other cutaneous affections of a venereal kind, and also in inflamations of the liver; and it has been successfully administered in intermittent fevers. Gmelin's App. Med. vol. ii. p. 145. vol. iii. p. 124.

Æthiops minerals.—Æthiops mineral. —Hydroargyrum sulphuratum niger.—Edin. Pharmacie. Hydroargyrum cum fulphure.—Lond. Pharmacie. This is directed by the London and Edinburgh Dispensatories to be prepared by triturating in a glass or marble mortar equal parts of sulphur and mercury, or one part of the former, and two of the latter, till they have united into an uniform black powder. Notwithstanding, however, the directions of the college, the æthiops is in fact generally made by fhirring mercury into melted sulphur, and then pulverizing the mass; by which manipulation much time is saved: a method equally expeditious, and perhaps upon the whole preferable to this, is to mix a solution of sulphurate of alkali with mercury and sulphur, in which cafe the two combine very readily by simple triturating, and by subsequent washing, the alkali is easily got rid of. Æthiops mineral is, therefore, mercury at its minimum of oxydation, fatured with sulphur; it is one of the leat active of the mercurial medicines, and is used in conjunction with tis flings as a vermifuge, and in fome cutaneous difeases. If the combination of the mercury and sulphur is perfect, it will not whiten the surface of gold when rubbed upon it. Lond. and Edin. Pharmacoep.—Lewis's Mat. Med. vol. i. p. 148.—Beaumé Chymie. Experim. vol. ii. p. 457.

Authors are not all agreed as to the merits of æthiops mineral. Cheyne, and many more, commend it highly. It has been prescribed for the worms, and for crudities and acrimony of the humours; and by some perons it has been reputed infallible against the itch and other cutaneous difeases. Gmelin's App. Med. vol. ii. p. 129. Boerhaave, on the contrary, and some others, reject it as useless. He fays that it cannot enter the aborbtent vesfels, the la£teals, or lymphatics, but paffes directly through the intestinal tube, where it may happen to defroy worms, if it operates luckily. Thofe are deceived who expeft any other effects from it. He adds, that it is unwarily given, in large quantities, to children and perons of tender conftutions, as being a foreign mas, unconquerable by the body, and the more to be fpafmed, as it continues there for a long time fluggish and inactive.

The æthiops, as it is now prepared, with a double proportion of mercury, is more likely to produce effect than the inactive preparation formerly used.

Æthiops vegetabilis, is formed by burning the seawreck, or sea-ock, the fucus desedtsus of Linnaeus, in the open air, and then reducing it into a black powder. It is sometimes used to remove leprousfulings.

Dr. Ruffell recommends it as an useful a lient to seawater in the cure of disorders of the glands, when taken in
the quantity of a dram; and he says, that, as an internal medicine, it is much superior to the official burnt sponge; that, used as a dentifrice, it is beneficial for correcting lassities of the gums; and that its detergent virtue appeared by its effect in cleansing the teeth. See Murray's App. Med. vol. v. p. 549.

**Æthiops foetidus**, formed of equal parts of mercury, tin, and sulphur, is recommended in an occasional dose of half a dram, as an antidote to the tannia. Gmelin's App. Med. vol. ii. p. 172.

**Æthiops**, is also a name given to several compositions, which are distinguished by epithets founded on the uses to which they are applied; as *Æ. antiphlebitic*, formed of mercury extinguished by balsam of Peru, of Canada, or of Copaiva, and which is laid by Arab. to afford relief in several species of phthisis: *Æ. antirheumaticus*, confining of mercury ground and uniformly mixed with gum guaicum, which is recommended in the rheumatism and gout: *Æ. diureticus*, composed of quicksilver well mixed with juniper gum or sal ammoniac, which promotes the excretion of urine as well as the indigestible perforation: and *Æ. purgans* formed with manna or japa into an uniform powder, and recommended as a laxative, and for destroying intestine worms. Gmelin's App. Med. vol. i. p. 115.

**Æthiops**, in Entomology, a species of the carabinx, black, with a spinose thorax, and with the two bands of the elytra, and the point of the apex yellow, and middle-sized antennae, found at the Cape of Good Hope. *Æthiops* is also a species of the carabus, wholly black, found at Berlin, and a species of the cymex, black, with a ridge on the middle of the thorax, and black spinose tibia, found at Cayenne. *Æthiops* is also a species of papilio, with black wings; the primores marked with three white bands, and carulean spots on the upper part, and the posterior with two longitudinal pale furrows at the base, and a transverse ridge, with five carulean points; found out of Europe. *Æthiops* is also a species of apis, or the black bee, with the margin of the segments of the abdomen white, found in America. *Æthiops* is also the hairy black musca, with black wings, white at the apex; two points, and a silvery anus; found in Italy.

**Æthiops**, in Natural History, a species of the turbo, with the shell transversely furrowed and black; the bitt windings are nearly divided; the succeeding ones are of a silvery brightness, with the lip and limb brown; the aperture is dilated.

**Æthiops fulica**, in Ornithology, is the wholly black fulica or coot of Sparrman.

**Æthiops Simia**, in Zoology, the white eye-lid ape of Penman, and Mandeville of Buffoon.

**Ætholices**, in Physi, derived from âbol, to inflame, is a name given to superficial pustules, or boils in the skin, occasioned by heat.

**Æthon**, in Mythology, formed of âbol, to burn, one of the four horses of the sun, which caused the fall of Phaeton, according to Ovid. Claudian calls one of the horses of Pluto's chariot by the fam. name, from âbol, black.

**Æthra**, in Geography, a river of Sweden, called also Falkenberg.

**Æthria**, a name formerly given to the island of Rhodes.

**Æthusa**, Adonis, beggarly, in Botany, a genus of the pentandra dugnia ets and order; and belonging to the natural order of umbellate or umbellifera: the characters are, that the calyx is an universal spreading umbel, with the rays gradually shortening towards the middle, and the par-
ÆTHYSSEIS, a people of Libya near Marmarica.

ÆTIANS, AEULIUS, in Church History, a sect or branch of Ariana, so called from their leader AEULIUS, in the fourth century.

The Arians were of the stricter kind of Arians, who hold that the Son and Holy Ghost are in every respect different from the Father. Whence also they are called Anatomists and Heterodoxians; sometimes pure Arians.

The proscription of this doctrine was contrary to an established law of the emperor Constantius, who had decreated, "that no man should say, that the Son of God was of the same substance with God, or of a different substance, but that he was in all things like to him that begat him."

By such nice distinctions were the confessions of mankind directed and guided; and the freedom of religious inquiry restricted; and the slightest deviation from the preferred rule exposed them to exile and other similar penalties.

ÆTINUM, in Ancient Geography, a town placed by Ptolemy, in Macedonia, and which, he says, belonged to the Eletes, but as they inhabited Thessaly, its situation is not well ascertained.

ÆTIOLOGICAL, something that assigns the cause of an effect or appearance.

ÆTIOLOGY, in Medicine, a rationale, or discourse of the cause of a disease, or it is that part of Pathology, which is employed in exploring the causes of diseases. The word is composed of aeus, cause, and logos, discourse.

In this sense, we say, the etiology of the small pox, of the hydrophobia, of the gout, the dropsy, &c.

Ætiology is used for a figure in Rhetoric, whereby, in relating an event, we assign also the cause of it. In which sense, etiology differs from color, as the former assigns the true cause, the latter only a feigned or fancied one.

The sceptics were professed opponents of all etiology, or argumentation from causes.

ÆTION in Biography, an eminent painter, whose picture of Roxana and Alexander was exhibited at the Olympic games. It represents a magnificent chamber, in which Roxana is seated on a bed, with a modest and confident aspect, whilst Alexander is standing before her. Several Cupids are fluttering about her; some of whom hold up the curtain, others uncloths the lady, and others again present Alexander to his mistress, at whose feet he lays his crown, being accompanied by a phalanx with a torch in his hand, and leaning upon a youth who represents Hyman. Other Cupids appear in different attitudes and situations.

The picture gained AEtion such a degree of reputation, that the president of the games gave him his daughter in marriage. AEtion is mentioned with distinguished respect by Cicero, De Claris Orat. ap. Op. tom. I. p. 395. ed. Olivet.

ÆTITES, or eagle flint, in Natural History, a flinty or eroded flint, hollow within, and containing a nucleus, which, on flaking, rattles within. It was formerly in reputation for several extraordinary magical, as well as medical powers; such as preventing abortion, discovering thieves, and other ridiculous properties.

The word is formed from ætites, eagle; and by the Italians this flint is called pietra d’aquila; the popular tradition being, that it is found in the eagle’s nest, whether it is supposed to be carried while the female sits, to prevent her eggs from being rotten. Matins says, that birds of prey could never hatch their young without it; and that they go in search of it as far as the East Indies. Taufch has written a Latin treatise on the subject.

The ætites is found in several parts: near Trevoux in France, one can scarce dig a few feet, without finding considerable flints or beds, of the coarse or scraggroous kind.—They are originally soft, and of the colour of yellow ochre.

ÆTIIUS, in Biography, one of the followers of Arius, was born at Antioch in Syria, and flourished, according to Cave (Hist. Lit. tom. i. p. 218), about the year 350, and died in, or soon after, the year 366. Having contended with difficulties in early life on account of the reduced condition of his parents, he applied with diligence and success to
to the acquisition of literature at Alexandria in his mature years; and in this city he learned the art of physic, which he honourably practiced for the benefit of those who needed his advice. From Alexandria he returned to Antioch, where he was ordained deacon, as some say, by Leontius, bishop of that city; or, according to Epiphanius, by George the Arian, bishop of Alexandria. He seems to have been a man of sound understanding and considerable knowledge, though his acquaintance with the more ancient Christian writers was partial and imperfect. As he had adopted the sentiments of Arius, and had acquired the talents of an able and irresistible disputant; whom, says Gibbon, (Hist. vol. iii. p. 340.) it was impossible either to silence or to convince, he was banished by Constantius, whose timid confidence, says the historian (Id. p. 354.), was alarmed by the imperity of Aetius, into a remote part of Phrygia, i.e. says Gibbon, citing Philostorgius (ubi supra p. 376) to Ambala, a district inhabited by savages, and infested by war and pelfulence; but he was restored by Julian, who honoured him with his patronage, and gave him an estate near Mytilene in Lesbos, where he sometimes resided, though he probably died at Constantinople, and was there buried by Eunomius and his other friends in a very respectful manner. The displeasure of the Catholics against Aetius was so great, that theyigmatized him with the odious appellation of Aytheil. Epiphanius has preferred a small book of Aetius concerning the faith, containing of 47 propositions or short chapters, which he has answered; and he also says, from report, that Aetius had composed 300 such chapters. He is said to have held a public disputation with Apthoines, the Manichean, of Alexandria, and to have obtained to complete a victory over him, that he died of grief seven days after. He was the founder of a sect called Aetians. Lardner's Works, vol. iii. p. 356. vol. iv. p. 122.

Aetius, called Amidenus, from Amida, in Mesopotamia, the place of his birth, flourished at Alexandria, about the end of the fifth century, as Friend clearly demonstrates from several passages in his works, in which reference is made to St. Cyril, who died in 444, and to Petrus Archi-ator, who was physician to Theodoric. He left sixteen books divided into four tetrabiblia, on the practice of physic and surgery, principally collected from Galen and other earlier writers, but with some original observations. "We find many passages (Friend observes) in this author, to convince us how much the actual and potential cauty were then in use; particularly in a palsy. He says from Archigenes, that he should not at all hesitate to make an ecfaur either way, and this in several places; one in the nape, where the spinal marrow takes its rise; two on each side of it, &c. and if the ulcers continue running a good while, he should not doubt of a perfect recovery." The late Mr. Pott revived this practice in the palsy of the lower limbs, applying his cauteries in those cases on each side of the spine, a little above the frac, induced to it, we have no doubt, from reading this passage; and the practice is now general, and is frequently attended with complete success, so that it seems wonderful physicians do not use them in hemiplegia, and in other similar untractable diseases. Aetius is the earliest writer who ascribed medical efficacy to the external use of the magnet. But this he does upon report, and not from his own experience. "Tradunt (says he) magneto-tem daturum manu ebragravorum ac podagrigoram dolores etorum felarum. Res eumque spectabilis. It is reported that those who are afflicted with the gout, or have it in their hands or feet, or with convulsions, are relieved by holding a magnet in their hands." The works of Aetius were translated into Latin by Janus Cornarius, a physician of Frankfort, and published, accompanied with the Greek at Basel, 1542, in folio. Henry Stephens has inserted them in his edition of Medici principes, printed at Geneva, 1597. The latter and best edition is that of Franz at Leipzig, in 1777.

Aetius, whose father was Gaudentius, an illustrious citizen of the province of Scythia, and master-general of the cavalry, and mother a rich and noble Italian, was one of the generals of Placidia, the mother of Valentinian III. who reigned 25 years in the name of her son. Aetius served at Brit among the troops of the emperor's household, and after the battle of Poletia in 403, he was delivered as an hostage to Alaric, and afterwards to the Huns with whose chiefs he became intimately acquainted. His stature, which was tall and majestic, and his constitution, which was robust, fitted him for the duties and toils of a military life. He is also commended by the ancients for his prudence and address in the conduct of political business, as well as for his intrepidity and experience in war. His regard to justice was so strict, that no temptation could induce him to deviate from the exercise of it. On his return from the country of the Huns he married the daughter of Carpo, the captain of the guards; and was employed in offices of high trust in the empire. When Marcellus was attacked by Atanaphus, Aetius and Count Boniface were united in its defence; and these two great commanders are said to have deferred the distinguishing appellation of the last Romans. They were unhappy rivals, and their mutual jealousy and discord terminated in the loss of Africa and the death of Boniface. After the death of Honorius, the empire was usurped by John his chief secretary, and Aetius connected himself with the usurper, and was employed to procure the assistance of the Huns. John, however, was soon cut off; and Aetius with-in three days entered Italy with 60,000 Huns, who served to secure to him a reconciliation with Placidia, and who, by a grant of the province of Pannonia, were prevailed upon to return into their own country. Having induced Placidia to recall Boniface from his government of Africa, and at the same time advised him not to comply, he was the cause of the revolt of his rival, and the loss of Africa; and the discovery of this fraud produced a civil war between these two commanders, which terminated in the death of Boni-face, and in the exile of Aetius to the court of Rugilas, king of the Huns, in Pannonia. He soon returned, how- ever, to his own country; and he was indebted to their alliance for his safety and reformation. Instead of the suppliant language of a guilty exile, he solicited his pardon at the head of a large army of barbarians; and the em- pire Placidia was under a necessity of forgetting his rebellion and his treachery, and of delivering herself, her son Va- lentian, and the Western Empire, into the hands of an insolent subject. The fortunate Aetius, who was immediately promoted to the rank of patrician, and thence invested with the honours of the consulship, assumed, with the title of Master of the cavalry and infantry, the whole military power of the state; and he is sometimes styled, by contemporary writers, the duke or general of the Romans of the West. The Gothic historian, Jordanes, ingeniously confesses, that Aetius was born for the salvation of the Roman republic; and in the eulogy which a con- temporary historian bestows upon him, he says that his mind and body were alike capable of the most laborious efforts; that he possessed the genuine courage, that can defile not only dangers but injuries, and that it was im- possible either to corrupt, or deceive, or intimidate the firm integrity of his soul. But these laudable praises are not very
very confident with his conduct towards Boniface. Ætius at last cultivated the alliance of the Huns. Whilst he refused in their tents, as an hostage or an exile, he had formerly converted with Attila himself, and the two antagonists were connected by a personal and military friendship, which was afterwards confirmed by gifts and embassies. Thus a numerous army of Huns and Alani, whom Ætius had attached to his person, was employed in the defence of Gaul. He established a treaty with Genéricus, which averted the Vandals from the plunder of Italy. He restored the authority of the empire in Spain and Gaul, and compelled the Franks and Suevi, after vanquishing them in the field, to become useful allies. He afterwards concluded a peace with Theodoric, king of the Visigoths, who inhabited the southern provinces of Gaul; after a signal defeat, in which 800 Goths fell near the walls of Narbonne; and Ætius and Theodoric, in mutual alliance, gave battle to the innumerable host of Attila, encamped before Orleans, and compelled them to raise the siege. On the plains of Chalons, where the valiant Theodore fell, Ætius, aided by the intrepid Torismond, obtained a victory over the Huns, and forced Attila to retreat. When Attila invaded Italy, his prudence and courage served to harass and retard the march of the invader; nor did he ever appear more truly great, than at the time when his conduct was suspected by a timid and distrustful sovereign, and blamed by an ignorant and ungrateful people. At length the emperor jealous of his merit, and fearing his wealth, power, and popularity, put him to death in 494, with his own hand, under a pretence, encouraged by the malicious insinuations of Herclus the eunuch, that he had permitted the invasion of the Huns, after Attila's defeat, and that he was aspiring to the empire; and thus plunged his sword in the breast of a general who had saved his empire. Thus fell the last general of his age, the terror of Attila, and the bulwark of the western provinces, says Sidonius, by the hand of the greatest coward in the whole empire. By this act he converted the public contempt into deep and universal abhorrence. Such sentiments, says Gibbon (Hist. vol vi. p. 139.), seldom pervade the walls of a palace; yet the emperor was confounded by the honest reply of a Roman, whose exposed Attila's error; 18 I am, ignorant, Sir, of your motives or provocations, I only know, that you have acted like a man who cuts off his right hand with his left." The memorable letter, entitled the groans of the Britons, was addressed to Ætius, A.D. 449., who was then confid the third time. "We know not, say they, even which way to flee: charged by the barbarians to the sea, and forced back by the sea upon the barbarians, we have only left us the choice of two deaths, either to perish by the fword, or to be swallowed up by the waves." Rome was then threatened by Attila, and the Britons received no assistance. Anc. Un. Hist. v. xiv. p. 417. Gibbon's Hist. vol vi. ÆTNA, in Geography, the highest mountain in Sicily. In the Itineraries it is called Æthana, and supposed to be derived from Ætho, to burn. Bochart (Geog. Sac. i. c. xxviii. apud oper. tom. i. p. 526. Ed. Villem.) deduces the name from ÆTHN, Æthana, signifying either a furnace, or darkness, and he cites several authorities from the poets that burn both the one and the other of these etymologies. The inhabitants of the island call it Monte Gabello, or by contraction Mangibello, i.e. Mount of Mounts. This mountain, which has been famous for both its bulk and volcanic eruptions for many ages, is situated in the eastern part of Sicily, called Vol di Demoni, or Demonia, from a notion that the numerous caverns of Ætna are inhabited by demons, and other wicked and miserable beings. N. lat. 37° 40'. E' long. 15°.

The fire, which is continually burning in the bowels of this mountain, fed the poets to place here the forges of the Cyclops, under the direction of Vulcan, and the prison of the giants who rebelled against Jupiter. Upon this supplication they created a temple to Vulcan upon the hill, in which was kept, as we are informed by Ælian (de Animal. l. xi. c. iii. tom. ii. p. 608.), a perpetual fire, as in the temple of Vesta; this emblem being a symbol of that deity.

The figure of this mountain is a kind of oblique, truncated cone, extended at the base, and terminating in a bifurcated vertex, which consists of two eminences at a considerable distance from each other.

With regard to the formation of Ætna, M. De Buffon is of opinion that, on account of its height and immense bulk, it ought to be considered as one of the primitive mountains, coeval with the earth itself; and that it emitted flames soon after the creation; but that, on the subsiding of the waters which covered the face of the earth, it ceased to burn, because there was not a sufficient quantity of fluid for producing an effusiveness with its mineral contents. After a long lapse of ages, the Straits of Gibraltar were burst open, and the ocean mixed with the Mediterranean Sea; and a similar rupture of the Bosphorus furnished an additional supply of water, and thus it deluged the land between Sicily and Italy, and approached the basis of Ætna. In consequence of this event, the mountain began to emit flames anew, which at different intervals, and with various degrees of force, it has continued to do until the present time. From Homer's silence with respect to the eruption of this mountain, we may justly infer, that it did not burn in his days; and therefore the first known eruptions of Ætna must be dated after his age. Other writers, who have not adopted the whole of Buffon's hypothesis, maintain, that Ætna existed as a mountain before it became a volcano. Dolomieu, cited by Mr. Kirwan (Irish Trans. vol. vi. p. 326.), found immense heaps of sea-shells in the north-eastern fanks of this mountain, at the height of near 2000 feet above the surface of the sea. Hence he concludes, that the mountain existed as a mountain before it was uncovered by the sea. He adds, that at the height of about 2400 feet, there are regular strata of grey clay filled with marly shales; and these strata must have been deposited while the mountain was progressively formed under the sea. He further affirms, that in some parts of this mountain, the calcareous strata exist under the lava. Count Borch also, in his Letters on Sicily and Malta, informs us, that the original stone of which Ætna consists, is granite mixed with jasper, neither of which is lava; and he says, that it abounds in mines of lead and copper, which are never found entire in lava. This geologist pretends, that Ætna is at least 8000 years old; and this high antiquity he infers from the layers of vegetable earth, which he discovered between different beds of lava. Canon Recupero, who had been employed in writing the history of Mount Ætna, has also discovered a stratum of lava, which, in his opinion, flowed from the mountain in the time of the second Punic war, or about 1800 years ago. This stratum, he says, is not yet covered with soil sufficient for producing either corn or vines. It requires, then, about 1800 years to convert a stratum of lava into a fertile field. But in digging a pit near Jachi, in the neighbourhood of Ætna, he discovered seven distinct layers of lava, most of which were covered with a thick bed of rich earth; and as the eruption which formed the lowest of these lavas, flowed from the mountain at least 1000 years.
years ago, he deduces from this circumstance a corresponding era for the formation of the mountain. Mr. Brydone, (See his Tour through Sicily and Malta, vol. i. p. 115) informs us, that Recupero was much embarrassed by this discovery and the inference it afforded, because they contradicted the history of Moses. For the refutation of the canon and the satisfaction of the traveller, we might allege, that the Mosaic history contains nothing that is repugnant to the notions here suggested concerning the antiquity of the earth. Although man has not existed longer on the earth than the period allowed in this history, the earth itself might have existed, and probably did exist, in some other form and for other purposes, for ages before this period. Besides, we might ask, is the lava to which the canon directs our attention, the same which flowed from Etna in the second Carthaginian war; and is not the time required for converting lavas into fertile fields very different, according to the different facility of the lavas and their different situations with respect to elevation or depression, and to their being exposed to wind, rain, &c. jut as the time, in which heaps of iron flag which resembles lava, are covered with verdure, is very different at different furnaces, according to the nature of the flag, and the situation of the furnace? But there is an argument deducible from fact, which invalidates and totally overthrows the canon's objection.

Etna and Vesuvius resemble each other with regard to the various circumstances that pertain to this subject; but the eruption of Vesuvius, which destroyed Herculaneum, happened A. D. 79, or about 1700 years ago. The matter which overlaid this ancient town, is covered by the produce of six other subaqueous eruptions; and these several strata of lava are separated by veins of good foil. See Phil. Trans, vol. lxi. p. 7, and Bishop Watson's Apology for Christianity, in sermons and tracts, p. 593, &c.

Further, Dolomieu (Poncet, 473.) informs us, that vegetable earth does not exist between beds of lava; and he observes, that if this were the case, no conclusion relative to their age could fairly be deduced from this circumstance, as some lavas became fertile much sooner than others. To this purpose, Chevalier Giorni, in 1757, found lavas, that were projected in 1766, in a state of vegetation, while other lavas, much more ancient, remained barren. It is also well known, that beds of volcanic ashes and pumice vegetate sooner than any other. Mr. Dolomieu adds, that canal Recupero denied his ever having expressed any doubt with regard to the Mosaic history; and could not conceive why a late celebrated traveller should endeavour to render suspicious the orthodoxy of his belief. So far from having been perplexed on that account, he had a ponson from the court of Naples to his death, with many testimonies of esteem. The abbé Spallanzani (See Travels into the two Sicilies, vol. i. p. 205, &c.) has stated and examined the argument of Count Borgh, deduced from the decomposition and vegetation of different strata of lava, in proof of the antiquity of the world. A lava, says the Count, that was produced by an eruption in 1137, had a coating of earth in December, 1776, that was 12 inches thick; another which had flowed in 1329, had one of 6 inches; on that of 1659, was found more than one inch; whilst the most recent, that of 1766, was entirely destitute of such earth. The abbé allows that lavas, after a series of years, are invaded with a stratum of earth proper for vegetation; and that the earth is originally produced by the decomposition of the lava and that of the plants which have taken root upon it. But lavas are very different in their consistency and other qualities; and these differences must render the argument of Count Borgh and such reasoners very inconclusive. The lava, which flowed in 1329, and which was examined by the Count 447 years after its eruption, was covered with eight inches of earth; and yet the lava of the Arbo in Tuscum, which rushed into the sea in 1302, appeared in 1785 to have preserved its hardness and fertility. Another current of lava, near Catania, which has been employed for 2000 years for the purpose of building, retains such a degree of hardness, that where the art and labour of cultivation have not been applied to it, it still continues altogether fertile. He concludes upon the whole, that all calculations on the greater or less quantity of earth which may cover lavas are very uncertain and fallacious.

But to return from this digression, with regard to the antiquity of Etna, we observe, that naturalists have generally maintained, that Etna, like other inflated mountains, is the gradual production of volcanic eruptions. It is certain, that every great eruption produces a new mountain; and that Etna consists of a number of hills and declivities, nearly or more remotely connected, which have been occasioned by the commotions and changes, to which it has been subjected in the course of many past centuries. Etna may therefore be regarded, not as a single volcano, but as an assemblage of volcanos, many of which are extinguished or burnt with a gentle fire, and of some few are still acting imperceptibly or visibly, with violence.

Mr. Houël, one of the latest and most accurate inspectors of this mountain, observes, (in his Voyage Pittoreque,) that Etna is entirely composed of substances that have been discharged from the volcano in its various eruptions. From the quantities of marine bodies that are deposited over its lower part, he infers, as others have done, that it must have been once covered by the sea, to at least one half of its present height; and he supposes that, in this state, the currents of the ocean would gradually accumulate upon it large masses, not only of its own productions, such as shells and bones of fishes, but of several other substances intermixed with the matter discharged from the focus of the burning mountain. These masses, he conceives, would, in process of time, so increase as to form those various mountains which now surround the volcano. The currents of the ocean would likewise convey some part of the discharged matter of the volcano to a greater distance; and thus form those mountains that are separated from it, and that are found farther removed. The base of this mountain, according to this ingenious author's observations, consists of alternate layers of lava and marine substances, successively deposited upon one another, and reaching to a considerable, but unknown depth. These muscles delved to the level of the stratum of lava, which was discharged by the volcano at its first origin. The last layer, deposited by the sea, is a range of calcareous eminences of considerable height, placed on a basis of lava. Beneath this, there is another stratum of pebbles, rounded by their mutual attrition in the conflict of the waves. This, again, lies upon a yellowish rock, consisting of a species of indurated sand. The river Simeto flows over this rock; and the base of the river is much higher than that of the sea; and the lava on both sides is covered with the sea; but the primary base of the volcano is unknown.

From the mountains of calcareous matter that are scattered over the lower part of Etna, the inhabitants provide themselves with lime-dough, and they apply fragments of lava, instead of stones, of which they have none, to the purposes of building. The mountains that surround Etna, and that are observed to great advantage from its summit, evidently indicate, by their conical figure and the cavity at their top, their
their being the productions of fire. They bear unequivocal marks of the effects of this destructive agent in an accumulation of lava, scoria, and volcanic sand. Whether the origin of these mountains is to be traced to the expansive effort of the ignited matter contained within the great abyss of Ætna, and which, incapable of ascending to the upper crater, bursts forth at the fides; or whether they are to be ascribed to particular conflagrations and eruptions, which have no communication with the immense furnace within the crater, has been a subject of inquiry and discussion. The former alternative has been generally allowed; and it must be acknowledged that this is frequently the fact. Instances, however, may be cited, which afford strong reasons for believing that the production of the lateral mountains is owing to partial eruptions, which have no communication with the principal crater.

Of this kind is Monte Ruso, of which an account will be given in the sequel of this article. Sir W. Hamilton reckons 44 mountains of this kind on the side of Catania, with their distinct craters, most of which are now in a state of fertility.

From the consideration of the constituent parts of Ætna, and the mode of its formation, we shall proceed to state its dimensions. These have not yet been satisfactorily ascertained. Its stupendous height and bulk were noticed so long ago as the time of Pindar, more than 435 years before Christ, in a passage which we shall cite in the progress of our account. He represents it not only as the eternal abode of snows, but as the pall of heaven. The ancients, in general, as well as the moderns, have been accustomed to consider Ætna as one of the highest mountains on the globe. There are many passages in their writings, says Mr. Blydone, that shew this; though, perhaps, none more strongly than their making Deucalion and Pyrrha take refuge on the top of this mountain, in order to save themselves from the universal deluge. These ideas, however, appear to be very erroneous; for Sir George Shackburgh observes, (Phil. Trans. vol. lxvii. p. 558.) that Vespasian, placed upon Mount Ætna, would not be equal to the height of Mont Blanc. The accounts of those who have visited Ætna in later times have been very various. The following measures have been given by different authors:

| Height above the surface of the sea, 10,936 feet. |
| Circumference at the base, 180 miles. |
| Height, 4000 French toises. |
| ——— 3 miles 264 paces. |
| ——— 1200 feet ——— |
| ——— 2500 toises; circumference 183 miles. |
| ——— 1950 toises; diameter 30 miles. |
| ——— 2000 fathoms; circumference 60 leagues; and superficies 300 square leagues. |
| ——— summit above the Mediterranean 10954 feet. |
| ——— circumference of the visible horizon on the top of Mount Ætna, 6 being allowed for refraction, is 1093 English miles. |

M. Houll (nul supr) states the circumference of the base at 30 miles; and though he had no opportunity of measuring the altitude, he observes, that it had been done by M. de Saullaire, who found it to be 10,936 feet, or, as we learn from Sennacher, 10,952 English feet. This was ascertained on the 5th of June, 1773, at 29' after seven in the morning. The height of the barometer, on the most elevated part, at the brink of the crater, was 18 inches 11 3/4 lines; which, by the necessary corrections, is reduced to 18 inches 10 1/8 lines. At the same time, the mercury at Catania, placed only one foot above the level of the sea, stood at 28 inches 2 1/2 lines, which much be reduced to 28 inches 1 1/2 line, on account of the requisite corrections for the thermometer.

Some have supposed, that volcanic mountains always increase in height by the products of successive eruptions, till they are extinguished. However, it is generally conceived that the height and bulk of Ætna are much the fame now as they were in former times. The dilapidations, occasioned by the falling in, and absorption of the summit, have produced, for time immemorial, no sensible diminution; as the loaves resulting from some eruptions are repaired by others which succeed. In proof of this, it is alleged, that if any considerable decrease of the mountain had taken place, ice and snow would not have continued, in a climate so mild, to envelope the top of the mountain, as they now do, even during the greatest heats of summer. On the contrary, it is a very old opinion (vide Seneca, Epist. 175, and Albin Var. Hilli. lib. xi. c. xii. tom. i. p. 548.) and adopted by M. Houll, that Ætna is in a state of decay and diminution, so that it cannot be observed at so great a distance as formerly. It is full of excavations; and he considers the torrents of lava, which overpass its sides from time to time, as insufficient for repairing the walls occasioned by rains, rivulets, and torrents flowing down from the summit. Hence he concludes that, unless the eruptions become more frequent than they have been for some time past, the height of the mountain will be gradually reduced to that of the surrounding beds of lava. Over the sides of Ætna there are fea-

Tt 2
tered no fewer than 57 cities, towns, and villages; and allowing 1200 or 1500 persons to each of these, the whole number of the inhabitants of Mount Ætna, will be 92,400 or 115,500.

In our farther description of this mountain, and of its volcanic productions and appearances, we shall avail ourselves of the accounts that have been given by those who have visited it; selecting from each of those circumstances that are most defying of notice, and combining them together so as to form a connected and continued narrative. The writers to whose observations we shall principally refer are Borelli, Hist. Incend. Ætna, An. 1669; M. Jac. d'Orville's Sicula, Mr. Brydone's Tour through Sicily, vol. i. Sir William Hamilton's Campi phlegrei, and Phil. Trans. Kiedelev's Travels in Sicily, Swanburne's Travels in the Two Sicilies, vol. iv. Abbé Spallanzani's Travels in the Two Sicilies, &c. vol. i. M. Dolomieu, and M. Houël, Voyage Pittoresque.

The ascent of Mount Ætna is tedious, difficult, and perilous: and few have had resolution to undertake it. From Catania, where the journey usually commences, to the summit, the distance is about 30 miles; and the traveller, in the progress of his journey, passes through three distinct climates, which might be justly denominated, on account of the variety of their temperature, the torrid, the temperate, and the frigid zones. Accordingly the whole mountain is divided into three distinct regions, called La Regione Calda, or Pâmsonte, the fertile region; II Regione Selvosa, or Nemososa, the woody region; and II Regione Deferta, or Scoperta, the barren region. Count Borch has added a fourth, which he calls the region of snow; and he has subdivided the four regions into several districts.

The first or lowest region, extends through an interval of ascent from 12 to 18 miles, according to the statements of different writers. Its whole circumference is estimated by Recuperato at 183 miles, and its surface is suppos'd by Buffon to exceed 220 square leagues. It is bounded by the sea to the south and south-east, and on all other sides by the rivers Scetemus and Alcantara, which almost run round it. The city of Catania, and several villages are situated in this first zone; and it abounds in pastures, orchards, and various kinds of fruit trees. The fertility of this region has been recorded by Strabo, Fazello, Peter Dembo, and most of the travellers who have visited Ætna; and it is justly ascribed to the decomposition of the lava, and of those vegetables, which have been introduced by the arts of agriculture, and the exertions of human industry. In some parts, however, the lava appears in craggy eminences above the soil. Where the earth is shallow, the roots of trees, unable to penetrate the hard lava, extend themselves horizontally near the surface; but where there is a greater depth of earth, the soil is more fertile and productive.

The first station in the ascent of the mountain is Nicolosi, (see Pl. 1. Nat. Hist. fig. 2. let. II.) which, according to Brydone's statement, is 12 miles up the mountain, and by Houël's account 2456 feet above the level of the sea. The road from Catania to this station lies over old lavas and the mouths of extinguished volcanos, which are now converted into corn fields, vineyards, and orchards. The figs of this region, and the fruit in general, are reckoned the finest in Sicily. When the harvest was finished at Catania and the heat extreme, Mr. Brydone found the corn green at Nicolosi, and the heat moderate. The lava of this region flows from a number of small mountains, which are dispersed over the immense declivity of Ætna. These mountains, which are of a conical or hemispherical figure, are formed by eruptions; and they are generally about two or three miles in circuit, and about 300 or 400 feet high. They are covered with a rich verdure, and beautiful trees. Not far from Nicolosi is Monte Raffa, which was formerly a plain; but in 1669 a new vertex was opened in it, and discharged a dreadful torrent of lava, which flowed as far as the sea, and formed a kind of promontory (as Y.) It is surrounded to the extent of two miles with a black sand, which was thrown out in that eruption, and which then covered a space of 15 miles, to such a depth that the vines and shrubs that were scattered over the soil. Some of the finer particles of it were wafted by the wind as far as Calabria. The sand is very deep as you approach the mountain; and the mountain is forked at the vertex. By Borelli's account its circumference at the base does not exceed two miles, and its perpendicular height is not more than 150 paces; whereas, Sir William Hamilton estimates its height at a mile, and its circuit at three miles. Spallanzani prefers the former estimate. Amongst 100 or more mountains, which rear their heads on the sides of Mount Ætna, this is the only one with the history of the formation of which we are acquainted. The bate of the lava of this mountain is horn-lime, of a grey colour, rough to the touch, and of a moderately fine grain. It gives sparks with red, and sounds when it is struck. It forms a matrix to a great number of felt-spathoë or chondrocalcous crystallizations. The scoriæ, of which the mountain is principally composed, have the fame kind of base, containing foehers and felt-spars; but they are more light and friable than the lava, and have a kind of vitreous appearance. These and other differences are produced by the mutual collision and pulverization of these scoriæ. The number of detached foehers that are found on and near Monte Raffa is very great. Dolomieu thought, that they first entered into the body of the lava, and that they were separated from it by means of the sulphur, which had功效d the lava, but had not produced the same effect on the foehers, because of the small quantity of iron which they contain; and consequently they remained free and detached. Spallanzani rejected the hypothesis; as upon experiments with the magnetic needle he found that the mutual principle was more abundant in the foehers than in their base; and he therefore accounts for their separation from the lava in another way. The volcanic fire, which melted the lava, was incapable of melting these foehers, which are not only refractory to the fire, but of a different specific gravity from the lava. When this was melted, elevated to a great height, and separated into small particles in the progress of the eruption, a number of foehers were detached from it, and fell, isolated, partly within the crater, and partly around it. Accordingly he found, that the foehers detached from the lava are insensible in the furnace; but those which are incorporated with the lava sustain a perfect fusion. These foehers are not peculiar to the lava of Monte Raffa; but they are found in many other mountains of Ætna. Spallanzani analysed them, and from 100 docimalous pounds, he obtained the following result: viz.

The mountain derives its name Monte Raffa, or red mountain, from the tinge of this colour which some parts of
of it exhibit; though other parts are white, and others yellow, blue, and green, with different shades and mixtures. All these parts, says the Abbé, are found in a flate more or less decomposed; and in general, they are only scoria; the colours are produced by iron, changed or modified by acids. Of these scoria, some have not been affected by acids; and they are covered with a thin pellicul coat of glafs, just as if a sheet of water had been thrown over them, and suddenly frozen. This phenomenon is remarkable at Ætna, because we there meet with no vitrifications.

M. Houël went down into one of the openings of this mountain with torches, but could not reach the bottom, and was obliged soon to return on account of the extreme cold. The crater is of an oval form, and the opening through which he descended was in one extremity; but he inclined to think that the crater which rises above it had been formed of matter discharged by another mouth; or perhaps it might have had a more ceniral opening, through which the flånes, fand, &c. that form the crater, were discharged. This mountain is one of the mouths of Ætna. It is now covered with all the greater quantities of lava, fandy, ashes, &c. The sides of the craters are not all of the fame height; those to the east and west are considerably higher than the intermediate summits, because the currents of the ashes pass'd alternately from east to weft, and fell upon these fides in greater quantities than upon the others; which circumstance has given to this volcano the appearance of two summits.

St. Niccolo dell'Arena, in the neighbourhood of this mountain, is an agreeable resting-place for travellers who visit Ætna. This is an ancient edifice, founded on the lava, and was formerly the habitation of a number of Benedictine monks, who, about 200 years ago were obliged, on account of the devastations occasioned by the lava to abandon it, and retire to Catania. Here are many inscriptions, which record the miraculous earthquakes, torrents of lava, and flowers of fand and ashes by which it has been damaged and even destroyed, together with the dates of their different repairs. The black fand, thrown up in 1669, is more easily changed into vegetable earth than the lava; and has for many years been inhabited with extensive vineyards: whilst there are many beds of ancient lava that remain in an unproductive flat, and deftitute of every kind of vegetable.

At a small distance there is another mountain, called Montpelier, or Monpelleri (see letter G.). This is of a spherical form, and its perpendicular height does not exceed 300 feet, and its circuit is about a mile. It is perfectly regular on every side, and richly overgrown with fruits and flowers. Its crater is large in proportion to the mountain itself, and is as exactly hollowed out as the bell moulded. This mountain was formed by the first eruption that destroyed the ancient Hybla, which was celebrated for its fertility, and particularly for its honey, and thence called Mel Päfis; thus, in consequence of being reduced by several eruptions, and more particularly by that of 1669, to a flate of wretched fertility, it obtained the contemptuous appellation of Mel Päfis. The lava, however, in its course over this beautiful country, has left several little islands or hillocks, which exhibit a singular appearance, with the bloom of the most luxuriant vegetation, encompassed and retained almost inaccessible by large fields of black and rugged lava.

About three miles above San Nicolo dell'Arena, the lower region of Ætna terminates, and the middle region begins. This is called the Regione Sylvis, the woody region, or the temperate zone; and extends from eight to ten miles in a direct line towards the top of the mountain. Its circumference is estimated by Recupero at 70 or 80 miles; and it comprehends a surface of about 40 or 45 square leagues. It forms a zone of the brightest green all around the mountain; which exhibits a pleasing contrast to the white and hoary head of this venerable mountain, and it is called the woody region, because it abounds with oaks, beeches, firs, and pines. The soil is a vegetable earth, generated by the decomposition of the lava, and similar to that in the lower region. "As soon as we entered these delightful forests," says Mr. Brydone, "we seemed to have got into another world. The air, which was before sultry and hot, was now cool and refreshing; and every breeze was loaded with a thousand perfumes; the whole ground being covered over with the richest aromatic plants. Many parts of this region are really the most heavenly spots upon earth; and if Ætna resembles hell within, it may with equal justice be said to resemble Paradise without. Here," he says, "you gather the most delicious fruit, rising from what was lately a black and barren rock. Here the ground is covered with every flower, and scented with every herb of the earth. The clover and the flowers produce the luxury of the earth, and the trees afford the shade and the coolness of the air." These advantages they owe to the soil on which they grow, which is peculiarly favourable to luxuriant vegetation. The hawthorn trees are of an immense size. The beeches appear like so many ramified pillars, and the tufted branches of the oak, like clove bushes, impenetrable to the rays of the sun. The appearance of the woods in general is exceedingly picturesque, not only on account of the number and variety of the trees, but from the inequality of the ground, which exhibits them like the ranges of an amphitheatre one above another. The east side of the woody region abounds with chestnut trees of an extraordinary size. These are cultivated by the inhabitants with particular attention; and as they are brought into bearing after 20 years, they yield a profitable article of trade. But the most remarkable of these trees is the Calloegna di cento Cavalli, or the chestnut tree of an hundred horses; so called, because it is supposed to be capable of sheltering an hundred horses under the canopy of its boughs. Fabulous report deduces its name from the following circumstance. Jean of Arragon, during her stay in Sicily, whilst she was travelling from Spain to Naples, visited Mount Ætna, and was attended by her principal nobility; but being overtaken by a storm, all of them found shelter under this tree. It stands upon a rising ground, and is surrounded by an open pasture, which is bounded by woods and vineyards. Its height has of late been much diminished by lopping its branches, partly under a notion of increasing its fruitfulness, but principally, perhaps, for obtaining a supply of fuel. Some have supposed that it was merely a built or clump of several trees united. But Recupero, and Swinburne inform us, that upon digging round it they found all the limbs united in one root, or body, at a very small depth under ground. Of this trunk five divisions are formed, each of which sends four to five twigs, which rise from the branches. The superior surface of these divisions is covered with bark, but on the inside there is none; the subtilence and verdure of the tree depending upon the external bark. The intervals are of different extent: one of them is wide enough for two coaches to drive abreast. In the middle cavity, or the part that is denominated the hollow of the tree, a hut is built for the habitation and use of those who collect and preserve its fruit; and who dry the nuts in an oven, and prepare
AE TNA.

prepare confers of them for sale. Mr. Swinburne says, that his whole caravan, men and animals, were accommodated at their cave in this extraordinary incloufe: and that after three accurate measurements, he found the outer circumference at one inch above the ground, to be 196 English feet. This tree formerly belonged to St. Agatha, but has lately been declared the property of the crown. There are other trees of a similar kind at a small distance, which are more worthy of admiration than this, as their trunk is entire. One of them, which was clear of branches to the height of 15 feet, and perfectly found, measured, in the girth, at three feet above the ground, 57 feet. The forest of pines, as it is called, is almost inaccessibe, on account of the rocks and precipices that surround it. It is chiefly worthy of notice, as it leads the traveller to the *fseau grotto*. This cavity has been lately formed by the action of the waters under the beds of lava, and removing the stratum of pozzolda below them. It is situated on a mount named *Fimocchio*. This grotto has been repaired at the expense of the Knights of Malta, who have hired this and other caves in the mountain for the purpose of holding snow, which is more wanted in their island than in Sicily, and which forms a very considerable article of commerce. The snow is thrown in at two openings above; and they have access to these as well as to the internal parts by flights of steps. A considerable extent of ground is enclosed by high walls above the grotto; so that when the wind drives down the snow from the higher parts of the mountain, it is flopped by the walls of this incloufe. It is then thrown into the grotto, where the thickness of the beds of lava, which cover it, prevents any injury from the summer heat.

At the leafl of exportation, it is pressed clofe in large bags, and lumps of it are wrapped up in leaves, and conveyed to the shore on mules. Pieces of snow, preferred in this manner, have appeared like the most transparent crystal.

Spallanzani deteacts from the commencement which had been given by other writers to the luxuriance of vegetation in this region. The oaks, he says, are low and finted in their growth; and the beeches which grow only in the upper extremity of the zone, would appear mere pignies, if they were placed beside those which rear their lofty heads on the Apennines and the Alps. This he attributes to the little depth of earth proper for vegetation.

The woods and verdure of the regions, now described, viz. the inferior and the middle, have been recorded by most of the ancient writers; and therefore the commencement of this vegetation must be left in the obscurity of time. What is still more remarkable with respect to this woody region, is the circumstance, that the surface of it is so unequal, that it every where presents hills, or rather mountains; all of which have been produced by different eruptions from the summit of Etna, and other craters below the summit, several of which have formerly lain wide this zone, which is now converted into luxuriant forests. Most of the travellers in this region have sought shelter on the night preceding their further ascent, in the cave called *La Stazione del Capriccio*, or *La Grotta delle Capre*, or the grotto of the goats, because these animals take refuge here in bad weather. This cave has been formed, from time immemorial, by the lava, when in a fluid state, and seems to have been enlarged by the torrents of water that have passed through it, and carried away some of the sand and loaves of which it consists. The lava is of a horn-stone bafe; and though its texture is earthy and porous, it possesses a considerable degree of hardness. It contains some florets, and two kinds of felt-spars, some of which are of a flat figure, and brilliant appearance, and others irregular in their form, with little lustre, and manifesting a degree of calcination without any fusion. There are some other pines interfeerfed, which are thought, from their hardnefs and green colour, to be chryfites. This grotto is situated about 5854 feet above the level of the sea, according to the calculations of M. de Sauffuye. It is surrounded by flately and majeffic oaks, the dry leaves of which supply the travellers who shelter in it with beds, as the wood does with fuel. In the neighbourhood of this cave there are two beautiful mountains, the craters of which are larger than that of Vefuvius. They are now filled with oaks, and covered to a great depth with the richcft foil.

The upper region of Etna, called its *figid zone*, or the *Regione Deserta*, is marked out by a circle of snow and ice, extending, as some flate, to the distance of about eight miles; but according to Fazello, nearly twelve, and having the great crater in its centre. The surface of this zone is for the most part flat and even; and the approach to it is indicated by the decline of vegetation, by uncovered rocks of lava, and heaps of sand, by near views of an expanse of snow and ice, and of the torrents of smoke issuing from the crater of the mountain, and by the difficulty and danger of advancing amid streams of melted snow, sheets of ice, and gulfs of chilling wind. The curious traveller, however, thinks himself amply recompenced, upon gaining the summit, for the perils with which he has encountered. His fatigue is alleviated by the magnificent scene that the emperor Adrian, and the philofopher Plato, underwent in their time; for the purpose of exploring the summit of the mountain, and of gratifying themselves with a view of the rising sun from this eminence. Most of the travellers who have visited Etna, have been anxious to reach its summit at the dawn of the morning, before the vapours that are raised by the sun obscure surrounding objects; and they all agree in describing the extent and beauty of the prospect. When Mr. Brydone and his companions ascended this eminence, elevated above the common region of vapour, in the night, they observed that the number of the firfs seemed to be much in creafe, and that their light appeared brighter than usual. The baffle of the milky way was like a pure flame, that shot across the heavens; and with the naked eye they could observe clusters of firfs which were totally invisible in the lower regions. Below them on the mountain they perceived a moving light among the forefts, which might probably have been the ignis fatuis, and they took notice of several of those meteors that are called falling firfs, which appeared to be as much above them, as when they were seen from the plain; and from this circumstance Mr. Brydone infers, that these meteors move in regions much more remote than the bounds which some philosophers have ascribed to our atmosphere. Before dawn they arrived at the ruins of an ancient structure, called *Il Torre del Filosofo*, which some fooppose to have been built by Empedocles, for his convenience in observing the conflagrations, and studying the nature of Mount Etna. By others it is supposed to be the ruins of a temple of Vulcan. Others again imagine it to be a watch-tower, built by the Normans, for the purpose of observing the motions of their enemies, and giving notice of them by signals, to the different bodies of troops scattered over the island. M. Houël thinks it is not very ancient; neither the materials of which it consists, nor the mode of architecture, bearing any resemblance to those of the Greeks or Romans. Some have asserted, that they have found in this ruin, fragments of brick and marble; but no such fragments now exist. The materials were examined by Spallanzani, who discovered that they consisted of a cement of lime, which by length of time is become carbo
bonate of lime, and two kinds of lava, which exhaled an argillaceous odour in their fractures, and whose base was the horn-flone. These materials were collected upon the spot, and rendered compact and united by a cement of lime.

The prospect from the summit of Ætna has been described in very animated and glowing colours, by many writers. The gradations of the morning dawn appear with singular advantage from this elevated station. At the rising of the sun, says M. Houël, the horizon was serene, without a single cloud. The coast of Calabria could not be disinguished from the adjoining sea; but a fiery radiance soon began to appear behind the Italian hills, which bounded the prospect to the east. The fleecy clouds, which usually appear in the morning, were tinged with purple; the atmosphere became strongly illuminated; and, reflecting the rays of the rising sun, glowed with a bright effulgence of fame. The immense elevation of the summit of Ætna caught the first rays of light, and yielded a dazzling, but animating splendour. The sea still retained its dark hue, nor did the fields and forests yet reflect the solar rays. As the sun gradually advanced above the horizon, his light was diffused over the hills which lie below the peak of Ætna. This huge mountain flood like an island in the midst of the ocean, presenting to view a multitude of luminous points, the number and lustre of which rapidly increased. The scene, says this author, was as if the universe had been observed suddenly springing from the night of non-existence. The tall forests, the lofty hills, and extensive plains of Ætna, now presented themselves to view. The base, the vast tracts of adjacent level ground, the cities of Sicily, its parched shores, with the dashing waves and wide expanse of the ocean gradually appeared, whilst some fleeting vapours, driven by the wind, occasionally interrupted part of this grand and magnificent prospect. In a little while the display was so distinct, that places before known were easily recognized. On the south were seen the hills of Camerata and Trapani; on the north, the mounts Pelegrino and Therrini, with the celebrated Enna, once crowned with the temples of Ceres and Proserpine. Among these mountains appeared many rivers, like lines of glittering silver, winding their course through rich and fertile fields, and washing the walls of twenty cities, while their banks were crowded with villages, hamlets, &c. that roamed among the ruins of the most illustrious republics of antiquity. On the south and north were observed the rivers whose course bounds the immense base of Ætna; and at a much greater distance were seen the isles of Lipari, Alicudi, Telecidee, Panarea, and Stromboli.

On the sun's first rising, says Mr. Bredon, the shadow of the mountain extends across the whole island, and makes a large tract visible even in the sea and in the air. This shadow is gradually shortened, and, in a little time, is confined only to the neighbourhood of Ætna. Between the body of the sun, as it is seen rising from the ocean, and the spectator, immense tracts of sea and land intervene; the islets of Lipari, Panarea, Alicudi, Stromboli, and Volcano, with their smoky summits appear under your feet; and you look down on the whole of Sicily as on a map, and can trace every river through all its windings from its source to its mouth. The extent of the horizon is no less than 800 miles in diameter; and Malta, a Sicilian author, observes, that the African coast, as well as that of Naples, with many of its islets, have often been discovered from the top of Ætna. But the most beautiful parts of the scene, in the judgment of Mr. Bredon, are the mountain itself, the island of Sicily, and the numerous islands lying around it; all which seem as if they were brought close round the skirts of Ætna, the distances appearing reduced to nothing. The same scene is described in similar language by Spallanzani. No elevated region in the whole globe, says this author, offers at one view a more sublime scene than the summit of Ætna. The first of the sublime objects which it presents is the immense mass of its own colossal body. The first part, and that which is nearest the observer, is the upper region, commonly covered with snow and ice, and occasionally exhibiting rough and raggy cliffs, either piled on each other or separate, and rising perpendicularly, towards the middle of this zone; an assemblage of foggy clouds, irradiated by the sun, and all in motion, increased the wild variety of the scene. Lower down appeared the middle region, with its numerous woods and multitude of mountains, originating from furious eruptions; and beyond this the eye discerner, with admiration, the lower region, the most spacious of the three, adorned with elegant villas and castles, verdant hills and flowery fields, and terminated by the extensive coast, where, to the south, stands the beautiful city of Catania, to which the neighbouring sea serves as a mirror. The observer, at this elevation, discovers not only the entire massy body of Ætna itself, but the whole of the island of Sicily, with all its noble cities, lofty hills, extensive plains, and meandering rivers. Malta is also perceived at an indistinct distance; the eye commands the environs of Messina, and the greater part of Calabria; while Lipari and the Æolian islands appear so near as to be under the feet of the observer, and as if by floating down he might touch them with his finger. The far stretching surface of the adjacent and surrounding sea presented an object so lovely and majestic, and led the eye to an immense distance, bounded only by the heavens. "Seated," says Spallanzani, "in the midst of this theatre of the wonders of nature, I felt an indefinable pleasure from the multiplicity and beauty of the objects I surveyed; and a kind of internal satisfaction and exultation of heart. The sun was advancing to the meridian, unobscured by the smallest cloud, and Resenur's thermometer flood at the 10th degree above the freezing point; I was therefore in that temperature which is most friendly to man, and the refined air I breathed, as if it had been entirely vital, communicated a vigour and agility to my limbs, and an activity and life to my ideas, which appeared to be of a celestial nature."

The access to the principal crater of Ætna is rendered both inconvenient and perilous, for a distance of near four miles, by a variety of circumstances which different travelers have described. The summit of the mountain is at first covered with foamy, ashes, and sand, which have been thrown out of the volcano at its successive eruptions, and which are so loose as to endanger the traveller's being swallowed up at every step of his progress. It is also covered with snow and ice, and obscured with clouds, excepting at times when these clouds are low and range along the sides of the mountain, so as to present an object of terror. The winds, likewise, blow with such violence that persons can scarce stand securely, nor endure the cold which benumbs their limbs. The south wind is, on the top of Ætna, the most prevalent, and the cold is so intense, that travelers have often found their clothes insufficient to protect them. But the most formidable impediments to the progress of the adventurers in this perilous journey, are the streams of mephitic vapour which rise on the sides, and the thick clouds of sulphureous smoke which burst from the mouth of the volcano, even when it is not in a state of agitation. The fumes that issue from the crater are also singularly terrifying and have discouraged some persons from approaching the spot whence they proceed. M. Houël compares them
a discharge of cannon in the wide abyss, which being reflected from the various caverns, produces reverberations of the most alarming kind. By means of these, founds, which in the open air would be considered as flight exploins, become more tremendous than the loudest thunder.

When Spallanzani visited this mountain, he observed, when he was at the distance of two miles and a half from the limit of his journey, two white columns of smoke, which arose from its summit; one, towards the north-east side of the mountain, and another towards the north-west; several other streams of smoke, which arose from inferior parts towards the west, pursued the direction of these two larger columns. As he proceeded, he met with a torrent of lava, which he was obliged to cross in order to arrive at the smoking summit. This torrent was covered with scoria, which projected in some places in a variety of prominent points, and in others sunk in hollows, rendered his passage extremely difficult; and the lava itself, though the interval from its discharge was 11 months, was in many parts of it red-hot. Its difficulties increased as he passed that tract, which may properly be called the cone of Aetna, and which, in a right line, is about a mile in length. Having arrived, after much labour and fatigue, within 150 paces from the vertex of the cone, he found himself enveloped by the vapours of the several streams of smoke that issued from the top and sides of the mountain; and his progress was rendered extremely hazardous by the effect which these noxious vapours produced on his respiration. He soon, however, recovered his strength and resolution, and arrived at the utmost summit of the mountain, where he began to discover the edges of the crater. Here he viewed with astonishment the configuration of the borders, the internal sides, the form of the immense cavern, its bottom, and an aperture which appeared in it, the molten matter which boiled within, and the smoke which ascended from it; and he has minutely described the several appearances from his own attentive and accurate observation. The upper edges of the crater, which are broken and indented in several places, are, as he judged by the eye, about a mile and a half in circuit, and form an oval, the longest diameter of which extends from east to west. Its internal sides, which are inclined at different angles in its several parts, form a kind of funnel of a conical figure, and abound with concretions, which he found to be the muriate of ammoniac. The bottom was nearly an horizontal plane, about two-thirds of a mile in circumference; in which plane was visible a circular aperture, about five poles in diameter, from which proceeded the largest of the two columns of smoke, observed before he arrived at the summit of Aetna. This column appeared at its origin to be about 20 feet in diameter, and whilst it remained within the crater, ascended in a perpendicular direction; but when it arose above the edge, it was made to incline towards the west by a light wind; and afterwards it dilated into an extended and rare volume. The smoke was of a white colour. Within the crater Spallanzani observed a liquid and ignited matter, which continually undulated and boiled, alternately rising and falling, without spreading over the bottom. This, he says, was the melted lava, which had arisen to that aperture from the bottom of the Aetnaean gulf. Several large stones were thrown into the crater, some of which struck the liquid lava and produced a sound similar to that which would have been occasioned by their falling into a thick tenacious paste; but the stones which fell on the bottom rebounded, and their found was different from that of the others. Hence our author infers, that the bottom must be thick and solid, which, if this were not the case, would have been broken by heavy stones falling from so great a height.

The summit of Aetna, surrounded with large masses of lava, is exhibited in Plate I. Nat. Hist. fig. 2. A. A. A. represents one edge of the lava of 1787, which issued from the upper crater. B. B. is the circumference of the crater, with its level, C. C. through which the internal part is discernible. D. is the flat bottom of the crater; and E. the aperture in the bottom, from which the larger column of smoke F. F. arose; which aperture, though it was at one side of the bottom, is, for the greater distinctness of view, represented in the middle. G. G. is that part of the edge of the crater from which its internal part is best seen, and where the design of it might be most conveniently taken. H. H. is the smaller column of smoke to the north-east.

Spallanzani informs us, that besides the eminence on which he stood, there is another to the north, a quarter of a mile higher, which renders the summit of Aetna properly bifurcated. The crater on this second pre-eminence, and from which the smaller column of smoke ascends, is about one half smaller than the other, and is separated from it by a partition of scoriae and accumulated lava, which lies in a direction from east to west. The Abbé has compared his own observations with those of others who have described the crater of Aetna in the course of 20 years, or from the time when it was visited by Baron Riedeckel in 1767, to that of his own journey in 1788. At the time of the Baron's observation, the crater was enlarged towards the east with an aperture which does not now exist; and as the stones which were then thrown in did not return the smallest found, the bottom of the crater could not be formed with the hard and flat surface which the Abbé has described. Within the gulf itself was heard a noise similar to that of the waves of the sea, when agitated by a tempest; and this may possibly have proceeded from the lava within the bounds of the mountain, in a liquified and perturbed state. Sir William Hamilton arrived at the summit of Aetna on the 20th of October, 1769; but was prevented from distinctly viewing the lower parts of the crater by the smoke that issued from it. From what he was able to observe he concludes, that its figure resembled that of a funnel diminishing till it ended in a point, and that this funnel was crusted over with fall and sulphur. The crater was then two miles and a half in circumference; and must have undergone great changes in the interval that elapsed between these observations and those of Riedeckel, in whose time there must have been an abyss as well as a funnel; nor does the point in which the funnel terminated admit of the flat bottom described by Spallanzani. The dimensions of the crater, stated by Sir William Hamilton, the Abbé accounts for by supposing, that the partition which now separates the great crater into two parts has been produced since the time of his observation; for the sum of the two circumstances which the Abbé has noticed would not much differ from the other measures. Mr. Brydone, who observed the crater on the 9th of May 1770, says, that it was then a circle of about three miles and a half in circumference, that it shewed down on each side, and that it formed a regular hollow, like a vall amphitheathe, and that a great mouth opened near the centre. Count Borch arrived at the mountain on the 16th of October 1776, and merely observes, that the crater is formed like a funnel, and that the summit is bifurcated; a circumstance unnoticed by Sir W. Hamilton, who affirms, on the contrary, that the summit is single; and the Abbé therefore concludes, that one of these summits has been produced since the journey of Brydone in 1770. M. D'Orville,
D’Orville, who ascended Etna in 1727, remarked two craters, one larger than the other, and in circumference somewhat more than four miles, from which issued clouds of smoke and reddish flames. On looking into this crater, he and his companions were unable to discern the bottom on account of the flames and smoke. They only observed that a conical hill, formed of lava, rose in the middle of the crater, the top of which they estimated to be 60 feet below them; and as they were probably able to see about 60 feet lower, they conjectured that the circuit of this hill might be from 600 to 800 feet.

M. Houel, whose account of this mountain was published in 1782, and who made a drawing of the crater, represents its environs as consisting of three eminences, forming an equilateral triangle, though, when viewed at a distance, only two of them can be seen; for which reason the Sicilians have denominated the mountain birore, or double-horned. The situation of the principal mouth is in the midst of these three eminences. Its diameter was only about 60 feet; but it was so filled with smoke that nothing remarkable could be discovered. This author observes, that the cone is not exactly in the middle of the plain, but that it lies somewhat more to the north than to the south. Every observation, therefore, tends to evince the inconstancy of the internal configuration and dimensions of this volcano. Besides the changes which have taken place on the summit of Etna, with respect to the number, form and size of its craters, Fazello and Borelli describe another alteration occasioned by the falling in and absorption of the extreme summit of the mountain within its crater. The former author relates, that in his time there arose in the mouth of the crater a little hill, isolated on every side, which formed the vertex of the mountain, and which, in a terrible eruption, fell into the gulf, and thus enlarged the crater and diminished the height of the mountain. The hill itself had been produced by a former eruption in 1444. Borelli likewise informs us, that in the configuration of 1669 the summit of Etna, which rose like a tower to a great height above the part which is level, was swallowed up in the deep gulf. Strabo (tom. i. p. 430, &c.) relying on the account of those who had visited Etna in his time, describes the summit as a level plain, about 20 itadia in circumference, surrounded by a brow, or ridge, of the height of a wall; and he adds, that in the middle of the plain arose a smoky hill, the smoke of which proceeded in a direct line towards the height of 20 feet. Solinus (cap. 11) informs us, that there were two craters, from which the vapours issued. Cardinal Bembo likewise found two craters, one higher than the other, and about as far distant as a stone might be thrown from a sling. The extreme violence of the wind and the exhaled fumes prevented his approaching the upper crater; but he describes it from the information of others, as situated on the highest part of the summit of Etna, about three miles in circumference, formed like a funnel, and having in its middle a spacious cavity. In the time of Fazello, who visited Etna after Bembo, there was only one crater about four miles in circumference. Its form was that of a funnel; it emitted fire and thick smoke; and a subterraneous noise was heard, which resembled the boiling of an immense caldron on a very fierce fire.

As for the difference that occurred with regard to the appearance of the smoke, noticed by different writers, some of whom represent it as rolling down the sides of the mountain, and others, as ascending perpendicularly to a great height, and afterwards falling, like white flowers on the top of the mountain; it was owing, without doubt, not only to the different density of the air on Etna at different times, but also to the diversity of the smoke, which would sometimes be lighter and sometimes heavier than the air itself, according to the qualities of the substances from which it is produced.

The effects of the air at the summit of Etna, recited by different writers, have also been very different. Some have complained of the difficulty of respiration which they experienced, whilst others felt no such difficulty, and assure that respiration is performed with equal ease on the top of the mountain, as in the country below. It appears from the observations of M. Sauflure in his travels on the Alps, that although at the height of Mont Blanc, about 2450 feet above the level of the sea, a considerable difficulty of respiration was occasioned by the rarefaction of the air, no such inconvenience was experienced at the less elevation of 1900 feet. The height of Etna being less than the latter measure, it is natural to infer that the respiration of many persons would not be incommode, whilst the contrary happens to others, according to the different strength and habit of body of different individuals. The observed difference of the barometer indicated in these various circumstances a considerable difference in the weight and rarity of the air.

Spallanzani observes, that Etna has at all times been very deficient in springs, and when he visited this mountain, water was so extremely scarce, that a single drop of rain had not fallen for nine months. As the rain water which the peasants, who inhabit different parts of it, had collected in cisterns was exhausted, they were obliged to go in search of it to those parts of the mountain at considerable distances, where a scanty spring might still be found. This author has observed a similar scarcity of springs in the Eolian or Lipari islands; and he apprehends, that other volcanic countries are subject to the same inconvenience. The rains, he says, which descend on mountains of this kind, fall on tufas or scoriae, in which they sink deep and do not again appear, because they meet with no argillaceous or stony strata capable of detaining them; whereas such strata are frequent in other mountains, and produce numerous springs, as we find to be the case in the Alps and Apenines. When the rains fall on compact and solid lavas, they do not sink into them, but run down their declivities, forming rivers and torrents in the rainy season, and not true springs. In several parts of Etna, and especially near the Grande delle Erpere, he observed large furrows hollowed in the lavas, by the action of the rain water. Other writers, however, have given a very different account. They state, that Etna abounds with fountains and with rivers of considerable magnitude. See Acis and Alcantara. Mr. Brydone informs us, that there are several periodical springs on Etna, that flow during the day and stop at night, which attributes to the alternate melting and freezing of the snow. There are also poisonous springs, which emit a very noxious vapour; and others which afford fine salt; and others again, whose water serves for drying particular colours. On the north side of the snowy region, there are several small lakes which never freeze. M. Houel estimates the quantity of water which flows down the sides of the mountain to be such, that if it were collected it would fill the channel of a river 36 feet broad and six feet deep; and he adds, that dreams of water are seen to issue at all different degrees of height from the base to the summit of the mountain; and that these continue to flow even during the drought of summer. The supply of these dreams, he thinks, cannot be accounted for by the water deposited by the clouds, nor by the melting of the snow; but the source of it must be more regular and permanent. This he conceives to be the evaporation of those aqueous particles that arise from the confluent exhalation at the bottom of the volcanic focus, and which, in his opinion, are necessary to the subsistence of volcanoes. These vapours, issuing from the U
AETNA.

great crater, and from innumerable fissures in the sides of the mountain, are condensed by the cold of that elevated region of the atmosphere, and percolating through the earth, furnish the numerous streams of Aetna with water.

The numerous cavens that are met with in different parts of Aetna deserve notice. The groote of the goats, the snow grotto, and those of mount Rosio, have been already mentioned. Kircher speaks of one, which he saw, capable of containing 30,000 persons. One of these cavens still retains the name of Proserpina, from its being supposed by the ancients, that it was by this entry Pluto conveyed her into his dominions; on which occasion Ovid describes Ceres as searching for her daughter with two trees, which he had picked from the mountain, for serving the purpose of torches. These trees he calls Teda; and they produce great quantities of a kind of snow, called Catalana, and esteemed a cure for fevers. Ovid. Fast. l. iv. tom. iii. p. 274, Ed. Burm. Diod. Sic. tom. i. p. 317. Ed. Weideling.

Aetna produces a great variety of plants and flowers, as well as trees of a larger size; such as the chesnut, oak, and cork tree, &c. Mr. Brydone enumerates the cinnamon, farfapanilla, fafsafras, rhubarb, and palma Christi; and he adds, that it was celebrated by the ancients for its admissible productions. See Diod. Sic. tom. i. p. 342. Plutarch and Aristotle intimate that the soil of the plants was so strong on many parts of the mountain, that it was impossible to hunt. There was formerly a great variety of wild beasts in the woody region of Aetna; but the number of them is now much reduced. There are still wild bears, roebucks, wild goats; but the race of flags is thought to be extinct. The hares and cattle of mount Aetna were once ensconced the best in Sicily. The cattle are full of a large size, but the horses are degenerated. Spallanzani informs us, that partridges (Tetrau rauses, Linn.) were shot at the upper extremity of the middle region, and in this region he met with several birds of the titmous species (Perus corneus, Linn.) a kite (Falco milurus), three jays (corvus glanduligerus), two thrushes (Turdus sferovorus), and several ravens and crows (corvus corax; corvus corone). But in the middle of the higher region he saw no other animals, except some lion-ants (Myrmelon formicarium, Linn.) which made their pittals in the dust of the lavas.

We shall close this article, already extended to a considerable length, and comprising every kind of information which we have met with concerning Aetna, with an account of its principal eruptions. The first symptom of the approaching eruption is an increase of the smoke, in fair weather; and after some time, a puff of black smoke is seen to shoot up to a considerable height in the midst of the white. These puffs are attended with considerable explosions; and the ascending column of black smoke is followed by a red-dish flame. The smoke appears black in the day, and in the night resembles flame. Showers of ashes precede; earthquakes frequently accompany them; and red hot stones are projected to a great height in the air. The crater and smoke, at the time of an eruption, are so highly electrical, that they throw off spontaneous flashes into the air; and the smoke has sometimes extended, says Mr. Brydone, for upwards of 100 miles, and produced dreadful effects, killing shepherds and flocks on the mountains, blustering trees, and setting fire to houses which occupied an elevated situation. From the column of ascending smoke continual flashes of forked or zig-zag lightning proceed, and this is sometimes attended with thunder. When these appearances have continued for three or four months, the lava, or stream of melted mineral matter, boils over the top of the crater, or bursts through some weak place in the side. Upon the appearance of the lava, the violent eruptions of the mountain generally, though not always, cease; but without a vent for the lava, the commotion is very much increased. In the night the lava appears like a stream of fire, and flows to a great distance; but in the day its progress is marked by a white smoke. It has been a subject of discussion among philosophers, whether the eruptions of volcanoes are now less frequent than they were formerly. This is probably the case, as the matter in the volcanic focus was then greater in quantity than it is at present; and the castings being smaller were sooner filled with vapour, and the centre of the focus was nearer the surface than it is now, in consequence of repeated eruptions and disbeliefs. The whole number of the eruptions of this mountain, of which we have any record, says Spallanzani, before and after the Christian era, is 31; and 10 only, according to Giomi, have issued immediately from the highest crater; but it is not easy to make an exact estimate, as the same eruption has continued with or without interruptions, for some time; and has been taken singly by some writers, whilst others have reckoned every renewal of it separately. The eruptions of Aetna have been reported and described by several of the ancient poets. The hill of these, by whom they are mentioned, is Mount, in the following passage, the fifth decade of an ode which was composed in the 78th olympiad, about four or five years after the second eruption mentioned by Theocydides.

... Kers,  
Aeporini cinis;  
Nebulos . Aetna, frar.  
Nesos . Etna, frar.  
Pythia. Od. i. v. 36. &c. p. 168.  
Ed. Weideling.

Now under sulph'rous Cuma's sea-bound coast,  
And vast Sicilia lies his shaggy breast;  
By snowed Aetna, nurt'ry of endless froth,  
The pilar'd prop of Heav'n, for ever pre'sd:  
Forth from whole nitrous caverns issuing rife  
Pure liquid fountains of tempellious fire,  
And vein in mudy mists the noon-day skies,  
While wreath in smoke the eddying flames aspire  
Or gleaming thro' the night with hideous roar.  
Far o'er the redning main huge rocky fragments pour.  
1580. &c.

They are also described by Virgil, in consequence of the eruption which happened, according to Mr. Oldenburg (fol. infra) at the time of the expedition of Ence, who, being terrified with the fire of this burning mountain, left Sicily.

---- Horrificis juxta tonat . Aetna ruinis,  
Interdumque atram prouumpt ad Aethera nubem,  
Turbinum fumantem piceo et caudente favilla;  
Adolitique globos flammarum, et Sidera lambit;  
Interdum foculos volatique vilcera montis  
Erigit etiamnum, liquefacta faxa sub auras  
Cum gemitu gloriam, fundaque exultat imo.  
Aeneid. i. ii. v. 571, &c. tom. ii. p. 433, &c.  
Ed. Burman.

The philosophical poet, Lucertus, has also mentioned the eruptions of Aetna.

---- Per fumes montis ut Aetna  
Expirent ignes interdum turbine tanto,  
 Expediam: neque enim mediocri clade co'orta  
Flammae tempellae, Siculhum dominata per agros  
Finitumis ad fe convertit gentibus ora;  
Fumida queo cach fcinillare omnia templo  
Cerente,
Catana. This is mentioned by Livy (l. xi. c. 47. tom. vi. p. 11.) An eighth eruption happened in the 43rd year before Christ, not long before the death of Caesar, and was afterwards regarded as an omen of this event. The ninth eruption was mentioned by Suetonius in his Life of Caligula (tom. vi. p. 668. Ed. Petrii.) It happened A.D. 408, and invited the emperor so as to make him fly precipitately from Messina. This is reckoned the 13th eruption by Cluverius in his Sicil. 1. 8. § 2. Carrara mentions two eruptions, one in the year 274, and another in 420. The eruption which happened in the reign of Charlemagne, A.D. 812, is recorded by Geoffroy de Viterbo in his chronicle. In 1166, Sicily was disturbed by a violent earthquake, which extended to Reggio on the opposite side of the island. Catania was destroyed by it, and 15,000 persons perished. On this occasion old rivers disappeared, and new ones broke out; and the ridge of Etna fell on the side near Taormina. The spewing of Arethusa became muddy and blackish; and the fountain of Ajo ceased to flow for two hours, and then gushed forth more abundantly than before. The sea at Messina retired far within its natural limits, and then overflowed its ordinary banks, and swallowed up a number of persons, who had fled to the floor for safety. Corn and trees of all sorts were destroyed, and the fields were covered with stones so as to become unfit for cultivation. From the year 1169, or as some say 1157, to 1169, Sicily repeatedly suffered from earthquakes and eruptions. This was followed by another eruption in 1181 or 1183, when streams of fire ran down the declivity of the mountain; and in 1259 the inhabitants of the mountain and of the whole island were alarmed by the convulsions and noises of Etna, and by the flames and stones, and other attendants of an eruption, which succeeded them. On this occasion a new crater was opened, and the flaming materials that were discharged from it overlaid the adjacent fields, destroyed their buildings, and occasioned the death of birds and quadrupeds, and of the fishes of the rivers and contiguous parts of the sea. A spectator says, that he could not think Babylon or Sodom was destroyed with such awful severity. The ashes were carried by the wind as far as Malta, and many persons are said to have died of terror. In 1383, Etna made another fearful explosion, which was succeeded by that of 1581, which extended its ravages to the confines of Catania, and burnt up the olive-yards in the neighbourhood of the city, and again by another in 1444, when the mountain shook and discharged a quantity of lava, and large rocks were broken off from its summit, and precipitated into the sea. Slight eruptions occurred in 1446 and 1447; but the eruption of 1556, after a cessation of near 100 years, was very dreadful in its appearance and effects, and lasted for a considerable time. A thick cloud, tinged with red in the middle, hovered over the summit of the mountain, which was attended by a strong west wind, and succeeded by the discharge of a large quantity of burning materials, that rained with the noise and rapidity of a torrent down the eastern side of the island, and destroyed buildings and animals that lay in its way. A thick stream of liquid fire held its course towards the sea, and did great damage. Several chains were opened on the sides of the mountain, from which streams of heated matter were thrown up to a great height into the air, and a learned physician, who curiosity led him to examine the eruption, was burnt to ashes by a volley of burning stones. This continued with little interruption for a whole year, and terminated by causing the river Simitus suddenly to overflow its banks, and carry off those who lived near it with their cattle and other property. The country near Patavium
frowned much; and the neighbouring castles, and more than 500 houses were destroyed by the ravages of the river, and trees were torn up by violent blasts of wind. Aetna was convulsed and rent in several places, and poured forth torrents of lava, which destroyed the vineyards and gardens at the monastery of St. Nicholas of Aetna, and proceeded onwards to Nicolò, burned Monpelleri and Fallica, and did great injury wherever it spread. The emissions of Aetna were so great, that the summit fell in with a tremendous noise, and the shocks of the earthquake that attended them were felt through the whole island. The inhabitants were so much alarmed and disdiered, that they appeared in mourning, and continued in this state for a considerable part of the year. In 1657 and 1679, the ravages of Aetna were renewed; and from 1603 to 1636 its eruptions were occasionally repeated, and torrents of lava flowed from it, which destroyed the woods and vineyards in those parts to which they reached. In 1630, as Oldenburg informs us, from Kirch’s Mandus Subterraneus, the mountain burnt on the north side, and produced great devastation. Carrera was witness of a dreadful conflagration in 1664, which lasted till the end of May 1678. But the eruption of 1669 was the most formidable and most destructive. Borelli, who was an eye-witness of this catastrophe, and some English merchants who were also upon the spot and who examined its effects, of whose report we have a detailed account, in the Philos. Trans. No. 51. (1st vol. ii. p. 539.) have minutely described the ascent, and progress, and ruinous consequences of this eruption. It was preceded, for eighteen days, with a dark sky, thunder, and lightning, and frequent concussions of the earth, which destroyed many houses in the village of Nicolò, and dispersed its inhabitants. The old crater on the summit of Aetna raged for two or three months before this event, in an unusual manner; and this was also the case with Etna and Stromboli, two burning islands to the west of it. In the evening of the 11th of March, at the distance of about twenty miles from the old mouth, and ten miles from Catania, a chimney was opened in the east side of the mountain; which is said to have been several miles (Borelli says twelve) in length, and five or six feet wide. This was not far from the place where Monte Raffa afterwards arose, and extended in the direction of the great crater of Aetna. See Pl. i. Nat. Hist. pg. 2. V. V. V. On the night following, in the place where this mountain now stands, another large cleft opened, and several other clefts were formed in different parts of the mountain; and there issued from all of them huge volumes of smoke, accompanied with the usual phenomena of thunder and earthquake. From the principal chimney there issued the famous night a stream of lava, which directed its course to a lake, called la Hordie, about six miles from Monpelleri, and in its way destroyed many dwelling-houses and other buildings in the adjacent villages. The next day it moved towards a tract of country called Mai Pepe, inhabited by about 500 people, which, in the space of twenty hours, was entirely depopulated and laid waste; the lava then changed its direction, and destroyed some other villages. Monpelleri, and its inhabitants, were also destroyed. On the 23d of March the stream of lava was in some places two miles broad, and extended itself to the village of Maranata. On this day a new gulf was opened, from which were discharged sand and ashes, which formed a hill with two summits, two miles in circumference, and 150 paces high; these composed of flows of different colours. The new mountain of Nicolò continued to discharge ashes for three months, in such quantity as to cover the adjoining tract of country for 15 miles. Some of these ashes were conveyed by the winds as far as Messina and Calabria; and others spread over the southern country, about Agosta, Lenti, and remoter parts. On the 25th of March the whole mountain, even to its highest summit, was agitated by a very violent earthquake. The highest crater, or its loftiest eminence, then sunk into the volcanic focus, and the spot which it had occupied became a deep gulf, more than a mile in extent, from which were thrown up enormous mounds of smoke, ashes, and volcanic. At this time it is said, the famous block of lava on mount Fruenstein was discharged from the volcanic focus. The torrent of lava, which still continued to flow, directed its course towards Catania; it first passed under its walls for a considerable distance into the sea, but afterwards accumulated and passed over them in several places. The gardens and grounds belonging to the convent of the Benedictines were overwhelmed by it; and by its taking this direction many buildings in the town escaped. From hence it divided into separate channels or streams, and flowed chiefly into the sea. The English merchants say, that it had overwhelmed in the updland country, 14 towns and villages, some of which contained 3 or 4000 inhabitants, and flooded in a fruitful country, where the fire had not before this time made any devastation; and they add, “there is not now so much as any sign where those towns flood, except the church and fleecle of one of them, which was situated on an eminence.” The Earl of Winchelsea, who at this time happened to be there on his way home from an embassy to Constantinople, in his account of this tremendous catastrophe, informs us, that the inundation of fire, cinders, and burning stones, advanced into the sea 600 yards, and a mile in breadth; that it destroyed in 40 days the habitations of 27,000 persons; and of 20,000 persons, who inhabited Catania, 3000 only remained. He adds, that the fiery deluge, in its progress, met with a lake four miles in compass, and not only filled it up, though it was five fathoms deep, but raised it into a mountain. He observes, according to an extract, cited by Sir William Hamilton, that he could see at ten miles distance the fire begin to run from the mountain in a direct line, and the flame to ascend in bulk and height equal to those of the loftiest fleecle in this kingdom, and to throw up large stones into the air. He discerned also the river of fire descending the mountain, exhibiting a terrible fiery or red colour, and bearing stones, which swam upon it, as big as an ordinary table. This fire was observed to move in several other places, emitting flames and smoke resembling those of a furnace of melted iron, and occasioning a loud noise especially by means of the great pieces that fell into the sea. He added, upon the information of a cavalier of Malta, that the river was as liquid, when it issued from the mountain, as water, and came out like a torrent with great violence; and that it was five or six fathoms both in depth and breadth, and that no stones could sink in it. Borelli observes, that when they threw stones into the chimney of the mountain, they could not hear them strike the bottom. Burning rocks, he says, 50 palms in length, were thrown to the distance of a mile, and stones of a lefser size were carried upwards of three miles, and the thunder and lightning from the smoke were not less terrible than the noise of the mountain. After the most violent struggles, and shaking of the whole island, when the lava got vent it spread up into the air to the height of 60 palms; and in this form, for many weeks, did not appear, and the day seemed to be changed into night; and it was not till four months from the time when it began to discharge its contents, that these dreadful symptoms abated. This deluge of fire, after destroying the finest country in Sicily, and sweeping away churches, villages, and convents...
convents before it, built over the lofty walls of Catania, and covered five of its balconies, with the intervening curtains; and from thence pouring down on the city, it laid waste every object it met with, overwhelming and burying all in one promiscuous ruin. He regrets the destruction of many remains of antiquity; particularly an amphitheatre, which he calls Collisen, the Circus Maximus, the Nannarchia, and several temples. Borelli has calculated, that the matter discharged at this eruption was sufficient to fill a space of 93,183,750 cubic paces.

The English merchants, to whose account we have already referred, describe the lava as a mass consisting of metals and minerals, which being rendered liquid by the fierce heat of the fire in the bowels of the earth, boiled up and gushed forth as the water does at the head of some great river; and having run in a full body for a stone's cast or more, the extremity of it became crusted, and formed those hard floes which the people call sitinni, and which resembled huge cakes of sea-coal strongly ignited. The lava thus proceeded to the sea, when the conflict between the two elements occasioned a noise more dreadful than the loudest thunder, which was heard to a great distance; the water retired before it, the fish on the coast were destroyed, the transparency of the waters was lost for several months; and the clouds or vapours that ascended from it darkened the sun. The fire, say these gentlemen, spread about three miles in breadth, and 17 miles in length. When they attempted to go up to the mouth, wherein the lava issued, they could not advance nearer to it than a furlong; long they should be overwhelmed by a pillar of ashes which seemed to them to exceed twice the bulk of the fleaep of St. Paul's church in London, and to ascend into the air to a much greater height. From the mouth proceeded a loud noise, like the beating of billows against rocks, or distant thunder, which was at intervals so violent as to be heard 60 or even 100 miles off; and so far were the ashes carried. The hole wherein the lava issued was about ten feet in diameter. Sir William Hamilton informs us, that the lava, on which there were no signs of vegetation in 1769, is 14 miles in length, and in many parts six in breadth, and that after destroying many hundred monasteries in Catania it ran far into the sea, forming a safe harbour, which was soon after filled up by a fresh torrent of the fame inflamed matter.

The eruption of 1682 produced a burning gulf on the top of the mountain, and its lava was diffused over the hill of Mazzara. In 1696 a quantity of this ignited matter was thrown off from the summit of the mountain, and after confining woods, vineyards, and crops of grain through the extent of four leagues, its course was stopped in a valley near the castle of Massaia. Several people, whose curiosity led them to watch the progress of the lava on a hill between the wood of Catania and the confines of Ciretus, were buried under the hill which suddenly sunk inwards.

After a long interval of rest, the eruptions of Etna were renewed in 1755, when a prodigious torrent of boiling water issued from the great crater. The discharge of water was preceded by smoke and flames, terrific thunder, and concussions of the earth, the usual signs of an approaching eruption; at length the torrent burst forth, and formed tremendous castes descending from one chain of rocks to another, till it reached the cultivated plains, which it overspread for many miles, and after separating into several deep and rapid rivers, it discharged itself into the sea. The ravages of this inundation, on account of both the quantity and the heat of the water, were very extensively injurious; and though the mountain continued to throw up water only for half an hour, it produced not only alarm but very considerable damage wherever it flowed. When the discharge of water ceased, the noise, smoke, and commotions were continued; and there appeared two new chasms, from which two torrents of lava issued, and poured their course through the sea, which covered the summit of the mountain. The discharge of water was followed in five days by an explosion of small stones and sand, some of which were carried as far as the hills of Messina; and the black sand was driven to Messina, and even over the strait to Reggio in Calabria. Some of the sand was conveyed by the shifting of the wind, to the plains of Agosta. In two days the mountain opened again, and discharged a torrent of lava which moved towards the plain, at the rate of a mile a day, and continued for six days.

Recupero examined the course of the torrent of water above mentioned. He found that it proceeded from the bowels of the mountain, and pursuivg a channel which it formed from the summit to the sea, it gained access to the melted snow; and in its progress destroyed a large forest of trees, which were torn up by the violence of the current, though some of them were not less than two and two and a half feet in diameter. The main torrent divided into four principal streams, and these again separated into smaller currents; but afterwards reuniting, they formed islands, and larger rivers, about 300 feet wide, and of a depth which could not be easily ascertained. The channel of the waters, in their farther descent, was alternately contracted and dilated; and in some places it was not less than 1500 feet. Fragments of lava, and huge rocks, were removed by the current, and valleys were filled up by the sand which the waters deposited. When Recupero visited the mountain, after an interval of ten years from the eruption, the whole side of the hill bore the marks of the deluge. In 1763 there was an eruption, which continued with intermissions for three months. From the crater, opened on this occasion, a pyramid of fire issued; which ascended to a great height in the air, and exhibited an artificial firework, attended with the explosion of a formidable battery, which shook the earth under those who were spectators of the scene. The lava that flowed from the crater yielded a very brilliant light, retained its heat, and exhaled its smoke for two years; nor did any snow appear on the summit of Etna for five years. In 1764 a new crater was opened at a considerable distance from Etna; and in 1766 another was opened at the groto of Paterno, which formed a mountain that after an interval of four years discharged great quantities of smoke, with loud explosions. In this interval the lava was not cooled, nor was the fire extinguished. Its fury was spent on a beautiful forest, which it laid waste, to the extent of many miles. In 1778, the convulsions of the mountain were often renewed, and several new craters were formed: and from these flowed streams of lava, which moved with different velocities, and in various directions. The most considerable of these flowed from a crater on Mount Frumento on the summit of Etna; and flowing in a stream about 200 paces in breadth, at the rate of about a mile a day, spread through the valley of Landunza. From another crater hot flames were projected, and a current of lava was discharged, which flowed over a tract of country two miles in extent.

The next eruption of Etna happened in July, 1787, and has been accurately described by Gomi, in an account of it printed at Catania in the same year, of which we have a French translation, by M. Dolomieu, at the close of his Catalogue Raisonné. It was preceded by the usual signs of an approaching eruption for several davs, i.e., from the 1st to
to the 17th of July, when the lava flowed from the hinder part of one of the two mountains that form the double head of Etna. On the next day, after renewed shocks and the appearance of a thick smoke, a shower of fine black brilliant ash descended on the cult field there was a fall of black ashen charges; and at the foot of the mountain a deluge of ashes of fire, foam, and lava. In the evening conical flames appeared alternately to rise and fall from the volcano; at times the next morning the mountain seemed to be covered, and the sun it was a burning mass. Of the conical flames, one on the north and another on the south, were of an immense extent; where these separated, another cone of flame, composed of many smaller ones, appeared to ascend above the mountain over a space of about a mile and a half in diameter to a height supposed to be about two miles. This cone was covered with a thick smoke, in which were seen very brilliant flashes of lightning; a phenomenon which had not been observed in other eruptions. Sounds resembling the explosions of a large cannon were also occasionally heard. From the cone, as from a fountain, there was perceived a jet of many shining volcanic matters, which were thrown to the distance of six or seven miles; and from the base of the cone there issued a thick smoke, which darkened parts of the heavens, at the time when the rivers of lava were discharged. This beautiful appearance continued for three hours of an hour. It began the next night with greater force, but lasted only for half an hour. In the intervals Etna continued to throw out flames, smoke, ignited stones, and showers of sand. From the 22d to the 23d, the appearances gradually ceased. The stream of lava flowed towards Bronte and the plain of Lago. After the eruption, the western side of the top of the mountain was covered with hardened lava, foveo-, and flows. The travellers were annoyed by smoke, showers of sand, mephitic vapours, and exhalations of heat. The lava that proceeded from the western point was observed to separate into two branches, one of which was directed towards Libecchio, and the other, already mentioned, towards the plain of Lago.

The lava on the western head of the mountain had been evidently in a state of fusion; and from one of the fountains, the snow was that of laver of sulphur. The thermometer in the evening was at 52° of Fahrenheit's scale; but near the lava, on the plain of Lago, it was 40°. The lava extended two miles; its breadth was from 1/3 to 1/4 foot, and its depth 1/3 foot. There was another eruption in October, 1808, but the effects of which were described by the Abbé Spallanzani. The stream of lava that issued on this occasion, from the great crater, was three miles in length; its breadth was in some places about a quarter of a mile, and in others one-third, and in other parts full greater; its greatest depth was about 18 feet, and the least six. Its course was along the west side of the mountain, and the effervescence which produced it was, like that of July, extremely violent. The foveo- were like that of the torrent in July of a black colour; but differed from them in their adhesion to the lava, in their external vitiates appearance, their greater weight, and their hardness, which was such as to yield sparks with red, almost as plentifully as flakes. These differences are ascribed to accidental combinations of the same substance; the constituent principles of both these foveo- being the same. Both contained the same foveo- imbecile. For other particulars, relating to the causes and effects of volcanic eruptions, see Basaltes, Lava, Pozzolano, and Volcano. For the places adjacent to Etna, see Catania, Cyclops, Hybla, and Trinza.

Ætna, a name given to a city of Sicily, founded by Hiero of Syracuse, in the 1st year of the 5th Olympiad, on the ruins of Catana; which was dispossessed of its primitive inhabitants. After the death of Hiero, the Catanians returned, expelled the new occupiers, and destroyed the sepulchre of the Syracusan monarch. The Ætlns retired to Tindari, or Enwifia, which was the name given to mount Ætna, and which was diffused about the 8th century B.C. from Catana, called it Ætna, and announced Hiero to be its founder. Diodorus says, that Donnyilis of Syracusa persuaded the inhabitants of Catana to remove to Ætna, because it was a fortified town. An inferred name is also applied to the formation of Ætna: Strabo, tom. i. p. 434; Johnson, Dict. Sicily, c. 76. tom. i. p. 431; Livy, p. 644, 86. Temple, Anon., s. p. 31; Ed. Wellcome.

Ætna fall, fall Étna, a name given by some authors to the fall announce, which is found on the surface and sides of the openings of Ætna, and other burning mountains after their eruptions; and sometimes on the surface of the rugged masses which they throw out. This fall makes a very various appearance in many cases; it is sometimes found in large and thick cakes, sometimes only in form of a thin powder, scattered over the surface of the earth and stones. Some of this fall is yellow, some white, and some greenish.

This fall is a concrete of nitre, sulphur, and vitriol, burnt and sublimed together. Borda found once a vast quantity of this fall on mount Ætna, and tried many experiments on it; from whence he concluded, that this fall is to be seen from the explosions of the mountain, as some have supposed, that it does not exist in it, but is formed during the burning. Phil. Trans., N.S. 2nd. 

Ætolia, in Ancient Geography, a province of Greece, which formerly comprehended the country now called the Despotat, or little Greece, was parted on the eights by the river Evros, now the Itharini, from the Locrienes Ocole, and on the west by Acarnania by the Achelous; on the north it bordered upon the country of the Dorians and part of Epirus, and on the south extending to the bay of Corinth. Its utmost extent from north to south was about 350 miles; and from east to west its greatest breadth was somewhat above 60 miles. According to Strabo (l. ii. tom. ii. p. 67) it was customary to divide Ætolia into two districts, the one called the ancient Ætolia, which lay between the rivers Achelous and Lyconnus on the Evros, and which was a level and fruitful country, and the other denominated Ætolia, or the acquired, which was contiguous to the Locrians, towards Naupactus and Epaphus, and extending northwards towards the mountain Ætna, and which was more craggy and barren. He also informs us (tom. i. p. 542, tom. ii. p. 714) that it derived its name from Ætolus, the son of Linus, who being compelled to leave Elis, removed to this country, and founded several cities in it; of which the principal were Thermus, Calamon, and Pieton. Their only sea-port was Oeniad on the Corinthian bay. Of their kings, who succeeded Ætolus, little more is known than their names. It does not appear by whom it was inhabited before Ætolus took possession of it; and its subsequent history for several ages is very obscure and doubtful. Thucydides (i. 1. p. 5, Ed. Ducker.) Plutarch (in Thlic), Strabo, and other ancient writers represent the Ætolians, as the greatest robbers in Greece, and as continuing such for many centuries, after Heracles, Theseus, and other heroes, had extirpated those banditti everywhere else; to them Strabo ascribes the invention of the ship. Livy (i. xxxv. tom. iv. p. 1030.) describes them as a proud, arrogant, and ungrateful people, but as good warriors; and they are said to have fought with one foot, whence the epithet monstrosus has been
been applied to them. Polybius (Megal. Hist. i. iv. p. 270, &c. Ed. Calaboson.) speaks of them as a turbulent people, always engaged in quarrels, and generally at war with their neighbours; utter strangers to all sense of friendship, or principles of honour; ready to betray their friends whenever they had the least prospect of deriving any advantage from their treachery; and, in short, as persons who were regarded by the other states of Greece as outlaws and public robbers. In war, however, they were bold and enterprising; inured to hardship and labour; and jealous of their liberties, in defence of which they were ready to sacrifice their lives.

The constitution of the Aetolian republic was formed in imitation of that of the Acheans, and with a view of counteracting their growing power. It was governed by a general assembly, a prætor, and other magistrates of inferior rank and authority. The general assembly usually met once a year, and on extraordinary occasions it was summoned by the prætor more frequently; and this national council professed the whole power of enacting laws, declaring war, making peace, and concluding alliances with other states. Each city of the Aetolian alliance deputed members, composing a council which was called the Apo- cleti, and which consisted of the most eminent men of the nation, whose office resembled that of the demingari among the Acheans. Their chief magistrates, in subordination to the prætor, were the general of the horse, the public secretary, and the ephori. The republic of Aetolia, thus formed and governed, distinguished itself above all the other nations of Greece, in opposing the ambitious designs of the Macedonian princes. Having kindled the Cleonic war, and that of the allies, called the Social war, in the heart of Peloponnæus, with a view of humbling their antagonists the Acheans, they reigned for three years, with the assistance of the Eleans and Lacedæmonians, the united forces of Achaia and Macedon; but they were at last obliged to purchase a peace by surrendering to Philip the whole of Acræmania. But as they gave it up with reluctance, they were anxious to seize the first favourable opportunity that occurred for regaining it. With this view they concluded an alliance with the Romans, Ante Chr. 211, which was ratified two years after it was formed, by both nations. The articles of which it consisted were ordered by the senate to be deposited in the capitol, as a lauding monument of their firſt alliance with the Greek nation. Husbands, however, immediately commenced, as soon as the treaty was concluded. Whilst the forces of Philip were employed in Macedon, the Aetolians entered Acræmania; where they found a very determined and vigorous opposition. Notwithstanding the alliance which they were likely to derive from Lævinas, the Roman General, who had presided over the alliance with them, they were intimidated by the resolution of the Acræmantians, and returned home without attempting to provoke a people who had declared their purpose either to conquer or die. Diverted from prosecuteing their first design, they turned their arms against Anticyra, a city of the Locri, and aided by the Romans, compelled it to surrender. This success encouraged them to march into Achea, and to oppose the forces of Philip. The hostile armies met near Lamia, a city of Phthiotis, where the Aetolians were twice defeated. After this victory Philip was prevailed upon by an embassy from Philopater, king of Egypt, and by deputies from the islands of Chios and Rhodes, and the city of Athens, to grant the Aetolians a truce of thirty days, and to enter into a negotiation for peace. Polybius has preferred (i. xi. c. 4. p. 626.) one of the speeches which was delivered on this occasion, and which may be considered as a master-piece of that kind. The negotiation, however, proved unsuccessful; and the war was renewed with considerable, though temporary, advantage on the part of the Aetolians and their confederates. During the absence of Philip, they plundered themselves of several cities: but upon his return, being abandoned by the Romans, they were under a necessity of concluding a peace on very unfavourable terms, Ante Chr. 204. This peace was of short duration. An extraordinary diet was held at Naupactus, in which the friendship and alliance of the Aetolians were solicited by Philip, and also by the two powerful republics of Athens and Rome. The Romans, however, prevailed (Ante Chr. 201.), and the Aetolians, after some previous engagements, entered Thebais, where they were met by Philip, and, after a considerable slaughter, totally routed. Next year they rallied again, and renewed the late battle. The Aetolians maintained their attachment to the Romans during the course of the war, and were favoured by the Roman commanders above the other nations of Greece; but after the battle of Cyrusphâle, in which Philip was entirely defeated, their mutual affection abated. The Aetolians arrogated to themselves the glory of this victory; and Flaminius, the Roman general, mortified their vanity and exalted their resentment, by granting a truce to the deputies of Philip without consulting them. When a negotiation for peace between Philip and the Romans commenced, the Aetolians obstructed it; and it was concluded Ante Chr. 195., without their concurrence. Dissatisfied with the conduct of the Romans on this occasion, they meditated revenge, and exerted themselves in raising new enemies against their former allies. They made their first attempt in the assembly of the Amphyxonts, but failing here, they had recourse to Antiochus king of Syria, Nabûs, tyrant of Lacedæmon, and even to Philip king of Macedon. They were immediately joined by the Nabûs; and having concerted a plan for seizing on three cities, which were reckoned the bulwarks of Greece, viz. Chaleis in Euboea, Demetrias in Thebais, and Lacedæmon in the centre of Peloponnæus, they proceeded to the execution of it. Having succeeded by stratagem in gaining possession of D. and Antiochus, who had declared in their favour, determined to land in this place; and in the year (Ante Chr. 193.) he arrived in Greece; and in a circuit held at Lamia, he was honoured with the title of generalissimo, or commander in chief of all the Greek armies against Rome. The king of Syria having gained possession of Chaleis, was joined by several of the Greek states, who renounced their alliance with Rome; but Chaleis in the event proved to be fatal to Antiochus than Capua had been to Hannibal. During his residence in the city he formed a connexion with the daughter of Cleopatra, one of the chief citizens, and married her. Such was the state of his attachment to the new queen, that he seemed to forget Rome, Greece and Syria. The king spent the winter in fealteties and rejoicing; his enemy infected the officers of his army; the soldiers abandoned themselves to idleness and debauchery; and mutiny and disorder universally prevailed. The Romans availed themselves of these circumstances; and in the year Ante Chr. 191., declared war against him, and dispatched a powerful army into Greece. The Aetolians could afford him little assistance; nor was he able to stop the progress of the Roman army, till they compelled him
to take refuge first in Chalaeis, and afterwards to set sail for Asia and retire to Ephesus. The Ætolians were strongly fortified at Heracle; although their number amounted only to 2,000, they held out forty days against the inceasing attacks of the whole confederate army under the victorious Aelius. The town was at length taken by fraetagen, and delivered up to be pillaged by the soldiers. Lamia, which had been for some time unsuccessfully besieged by Philip, surrendered to the Romans. After the loss of these two cities, the Ætolians sent ambassadors to the Roman confidant, who sued for a peace; but they could merely obtain a truce of 10 days. When this truce was near expiring, the Ætolian ambassadors at Rome were admitted to an audience of the senate; and were told, that they must either submit to the will of the senate, or pay the republic a thousand talents, and make neither war nor peace with any other power, without the consent and approbation of Rome. The ambassadors hesitated in complying with these terms, and were ordered to leave Rome that day, and Italy in a fortnight. The Ætolians upon a second application obtained a truce of six months; and the confederate army was withdrawn from Greece. But during the interval of negotiation they invaded the territories of Philip, and reduced several provinces, which they solicited the permission of the Romans to retain. Their ambassadors enforced their application by a false report, that when the Scipios had been made prisoners by Antochus, and that the Roman army was entirely defeated. The senate, incensed by this artifice, disfranchised the ambassadors, and forced their return without the express consent of the generals whom the republic were about to send for carrying on the war in their country. In the year, Ante Chrifi. 189, the Romans began their hostile operations with the siege of Ambraia, which was successfully succoured by the Ætolians, and which they vigorously defended. The contending armies having formed two mines near the wall of the city, fought for some time under ground, first with pickaxes and spades, and then with swords and spears; and each party secured itself by making a kind of rampart with the loose earth. The Ætolians on this occasion invented a singular kind of machine, in order to drive the enemy out of the mine: this was a hollow vessel, with an iron bottom, bored with holes and armed with spikes for preventing the approach of the enemy. They filled this vessel with feathers, and having brought it to the place where the two mines met, they let the feathers on fire; and by driving with a bellows the smoke on the bottom obliged them to quit the mine; and by this stratagem they gained time for repairing the foundations of the walls. The siege, however, was continued, and Abraia was under a necessity of capitulating. After this event, the Ætolians sent ambassadors to Rome; and their application being enforced by the concurrence of the Rhodians and Athenians, and also of Valerius, who was brother to the consul Fulvius, and the son of Lævinus, who formed the first treaty of alliance between Rome and Ætolia, a peace was concluded on the following terms.—1. The majesty of the Roman people shall be revered in all Ætolia. 2. Ætolia shall not suffer the armies of those who are at war with Rome to pass through her territories, and the enemies of Rome shall likewise be enemies of Ætolia. 3. She shall in 100 days deliver to the magistrates of Corecyra all prisoners and defectors, both of the Romans and their allies, except those who have been taken twice, or during her alliance with Rome. 4. The Ætolians shall pay to the Roman general in Ætolia 200 Euboean talents, of the same value with that of the Athenian talents, and engage to pay 50 talents more within five years. 5. They shall deliver to the confed 40 hostages of his choice, none of whom shall be under 12 or above 40 years of age, the prætor, general of the horse, and those who had been already hostages at Rome, excepted. 6. Ætolia shall renounce all pretensions to the cities and territories which the Romans have conquered since the confabulation of Plancius, though they had formerly belonged to the Ætolians. 7. The city of Orenos and its district, shall continue subject to the Acaenians. 8. Cephalenia shall not be included in this treaty. Severe as these terms were, the Ætolian republic was reduced to a much worse condition after the conquest of Macedon by Paulus Æmilius; for those who had openly declared for Perseus, and who had secretly favouring him, were sent to Rome, and there detained, so that they were never allowed to return to their native country. Five hundred and fifty of the chief persons of the nation were barbarously afflicted by the partisans of Rome under a supplication of willing well to Perseus; and though the Ætolians appeared in mourning habits before Paulus Æmilius, and complained of this inhuman treatment, they obtained no redress. From this time none were advanced to stations of honour or office in Ætolia, but those who were known to prefer the interest of Rome to that of their own country. In this state of humiliating subjection did the Ætolians continue till the destruction of Corinth, and the dissolution of the Achaean league, when Ætolia, with the other free states of Greece, was reduced to a Roman province, commonly called the province of Achaia. Nevertheless, each state and city were governed by their own laws, under the superintendancy of the prætor, who was sent annually from Rome into Achaia. The whole nation was a fluctuating tribe, and the rich were prohibited frompossessing lands any where except in their own country. Livy, l. 26.27.—31.32.—33.—35.—36.—37.—38.—39. tom. iii. iv. v. Ed. Drakenb. Polybius Hist. l. 2. 4.—9.—10.—11.—17. pp. 91.—272.—560.—590.—626.—743. Excerpt. Legat. pp. 788.—796.—820.—826.—825.—828. Ed. Calaub. Pauliniani in Achaic. p. 521. &c. Ed. Kuhni. In this state, with little alteration, Ætolia continued under the emperors, till the reign of Confiantine the Great, who, in his new partition of the provinces of the empire, divided the Western parts of Greece from the rest, calling them new Epirus, and subjoining the whole country to the praefettus praetorio of Illyricum. Under the successors of Confiantine, Greece was divided into several principali- ties, especially after the taking of Confiatnople by the western princes. At that time, Theodorus Angius, a noble Grecian, of the Imperial family, feized on Ætolia and Epirus. The former he left to Michael his son, who maintained it against Michael Palaeologus, the first emperor of the Greeks, after the expulsion of the Latins. Charles, the last prince of his family, dying in 1430, without lawful issue, bequeathed Ætolia to his brother's son, named also Charles, and Acaenania to his natural sons, Memnon, Turnus, and Hercules. But great disputes arising about this division, Amurath II. after the reduction of Thessaloni- ca, feized it favourable an opportunity, and expelled them all in 1432. The Mahometans were afterwards dispossessed of this country by the famous prince of Epirus, George Cai- friot, commonly called Scanderbag, who, with a small army, opposed the whole power of the Ottoman empire, having defeated those barbarians in 22 pitched battles. This hero, at his death, left great part of Ætolia to the Venetians; but they not being able to opprise such a formidable power, the whole country was soon reduced by Mahommed II. whose successors still possess it. Anc. Un. Hist. vol. vi. 155.—205. 8vo. 

Ætolia,
A FF

ÆTOLIA, an ancient town of the Peloponnesus, placed by Steph. Byzant. in Lacoa. ÆTORCHÆCUM, a promontory of Bithynia. ÆTUATES, a people of Helvetia, upon the frontiers of Rhétia, towards the sources of the Rhine. ÆTÜLANA, a country of Armenia Minor. ÆTYMANDRI, a people of Asia. ÆVSKAIA, in Geography, a town of Siberia, situated on the Irriltri; 20 leagues north-west of Yara. ÆX, the name of one of the murs of Jupiter, who was placed among the stars. ÆXONIA, a borough of Attica, dependent upon the tribe of Cecropides. The inhabitants were so much addicted to calumny, that exoneros was used proverbially for speaking evil of another. ÆXONIA, was also the name of a city of Magnesia in Thebaly. Stephan. Byz. ÆZALA, a town of the greater Armenia in Asia. ÆZANIS, a town of the greater Phrygia in Asia. ÆZARI, an ancient people of Africa, who gave name to a canton of Marmarœ. ÆZICA, a country of Thrace. AFDELLES, in Ichthyology, a name given by the Cretans to the fish called at Rome, denizzella, sa zigrella. See Julius. A FER, Constantinus, in Biography. See Constantius.

A FER, Dometius, a celebrated orator, was born at Niphæ, in Gaul, in the year before Christ 15 or 16, and lived under Tiberius, and the three succeeding emperors. After his advancement to the office of prætor, his ambition led him to aspire after higher honours; and with this view, preferring fame to virtue, he exercised his talents as an orator. Claudia Pulchra, the cousin of Agrippina, was the first object of his attack; and by charging her with adultery, witchcraft, and magical operations against the emperor, he recommended himself to Tiberius, who had conceived an invincible detestation of Agrippina. Agrippina, however, boasting as much as the law had retailed his conduct, treated him with the contempt he deserved; for when the accidently met with him after the imprisonment of Claudia, and he was endeavouring to avoid her, she pertinently applied to him the passage in Homer (I. a. 35.) - "It is not of you, it is of Agamemnon I complain!"

Thus intimating her dislike of him, who was the mere minister of an injustice that proceeded from a higher power. After next year directed his accusation against Quintilius Varus, the son of Claudia; in which he was aided by P. Dolabella, who was a man of birth and the relation of Varus. Finding this practice to be a source of wealth and honours, at the degenerate period in which he lived, he adhered to it through life, and incurred the contempt even of his admirers, by perfiling in it when his faculties were impaired by age, and the decay of his powers eclipsed the fame of his former eloquence. His advancement at this period depended on his talents for flattery, as well as on those by which he was distinguished as a public speaker. Having erected a statue to Caligula, he introduced into the inscription a record, which he undoubtedly designed as an expression of felicity, that the emperor was a second time consul at the age of 27 years. Caligula interpreted the compliment as a cen% uire upon him for violating the law, and as a reproach of his youth; and pronounced a vehement oration against him in the senate. After, instead of making any reply in his own vindication, professed the highest admiration of the emperor's eloquence, and re-

ATTOMATIA, in Ancient Law, a kind of donation made by thurning a wand into the person's bosom, to whom it was made. Du-Change.

AFFECtED, in Algebra. See AFFECTED.

AFFECTIO lovina, is a disease incident to cattle, occasioned by a little worm, bred between the flesh and the skin; which works its way over all parts of the body.

AFFECTION, in a general sense, denotes an attribute peculiar to some subject, and arising from the very idea or essence of it.

The word is formed from affectr, to affect; the subject being here supposed in some measure affected, or acted on, by the thing attributed to it.

In this sense, affection is synonymous with property, or with what the schoolmen call pr~prium quarto modo. Philosophers are divided as to the doctrine and division of affections: according to Aristotle, they are either subdivided, or subordinated; under the first of which come only modes; and under the second, finitentes, place, and time. The generality of Peripatetics divide affections into internal, as motion and finitentes; and external, as place and time. According to Sperlingius, affections are better divided into simples or united, and joined or separate; under the first he comprehends
AFFECTIONS are also distinguished into those of body, and those of mind.

AFFECTIONS of body are certain modifications of it; occasioned or induced by motion; in virtue of which, a body comes to be fo and fo disposed.

The affections of body are sometimes subdivided into primary and secondary.

AFFECTIONS, primary, are those which arise either from the idea of matter, as quantity and figure; or from that of form, as quality and power; or both together, as motion, place, and time.

AFFECTIONS, secondary, or derivative, are those which arise from some of the primary; e.g. from quantity, as divisibility, continuity, contingency, finity, impenetrability; from figure, as regularity and irregularity; from quality, as health, strength, &c.

The epithet mechanical is applied to those affections that are properties of matter, resulting from its figure, bulk or motion.

AFFECTIONS of mind, are what we more usually call passions.

Dr. Cogan, in his Philosophical Treatise on the Passions, very properly distinguishes between affection and passion; and he accurately discriminates between both these terms, and that feeling, which is usually denominated emotion. The term affection, he says, has a different signification from either of the other two, and represents a less violent, and generally a more durable influence, which things have upon the mind. It is applicable to the manner in which we are affected by them for a continuance, and supposes a more deliberate predilection and aversion, in consequence of the permanent influence of some prevailing quality. This distinguishes it from the transient impulse of passion; nor is it so intimately connected with any external signs, which distinguishes it from emotions. The affections sometimes succeed to passions and emotions, because these may have been excited by something that becomes permanently interesting; or they may be gradually inspired, by a deliberate attention to the good or bad qualities of their objects. In this philosophical sense of the word, affection is applicable to an unpleasing as well as a pleasent state of the mind, when impressed by any object or quality; it may be produced by any thing that torments or corrodes the heart, as well as by that which charms and delights it. Cullum, however, chiefly appropriates the term to the kindly and benevolent affections.

In the same manner Dr. Reid (Essays, p. 143. 167.) has applied the general name of affection to those various principles of action in man, which have pieces for their immediate object, and which imply, in their very nature, our being well or ill-affect to some person, or at least, to some animated being: and whether they dispose us to do good or hurt to others. He observes, however, that the word affection signifies, by custom, to be limited to good affections. Accordingly, when we speak of having affection for any person, it is always understood to be a benevolent affection. In the extensive sense above stated, our affections are very naturally divided into benevolent and malignant, as they respectively imply our being well or ill-affect towards their object. The characters of love and hatred, resulting from the infinitely various situations and circumstances upon which their development and operations depend, entitle them to the denomination of primary or cardinal affections.

Our benevolent affections, whilst they differ in the feeling, or sensation, which is a common ingredient in all of them, and in the objects to which they are directed, agree in these two respects, viz. that the feeling which accompanies them is agreeable, and that they imply a desire of happiness to their object. The first of these affections is that of parents and children, and other near relations, commonly called natural affections: the second, is the sentiment of the wife and good: the fifth is friendship: the sixth, is love between the sexes: and the last is patriotism or public spirit; that is, an affection to any community to which we belong.

The malevolent affections, commonly called passions, in the arrangement of Dr. Reid, are evaporation and resentment. For the difference between affection and disposition; see Disposition.

AFFECTION, in Geometry, is synonymous with property.

AFFECTION, in Medicine, denotes a morbid, or preternatural state of the body, or some of its parts. Thus we say, an hypochondriacal or hysterical affection: and, in like manner, such a part of the body is affected, i.e. indisposed, or feizued with a disease.

AFFEERORS, AFFERATORES, in Law, persons appointed in court-quests, and courts baron, upon oath, to settle and moderate the fines of such as have committed faults arbitrarily punishable, or which have no express penalty set down by statute. See Jatt. 25 Ed. III. c. 7.

The word is formed, according to Covel, of the French afferer, to affirm; by reason those appointed to this office do affirm, upon their oaths, what penalty they think, in conscience, the offender hath deserved. Others better derive it from affereur, a word in the customary of Normandy, rendered by the Latin interpreters, taxare, to set the price of a thing; as afferrar, indicare, &c.—Kitchin joins the three words as synonymous; affidati, amerciatori, affereors.

AFFENTHAL, in Geography, a valley of Susa in the Ortenau, near Strauburg, famous for its excellent wines.

AFFERI, in Law. See AVERIA.

AFFETTUOSO, or Con Affetto, in the Italian Music, is used to denote that kind of music, which must be performed in a very tender, moving, and affecting manner; and for that reason rather flow than fast. This term, placed at the beginning of a musical air, implies, in point of time, a movement between adagio and largo; and requires a sweet and affecting expression of the melody.

AFFIANCE, in Law, the plight of troth between a man and woman, upon an agreement in marriage to be had between them.

AFFIDATIO Dominorum, signifies an oath taken by the lords in parliament: thus called in the Rot. Parl. Hen. VI.

AFFIDATUS, or AFFIDATIUS, in our Law Books, denotes a tenant by fealty.

Affidati are not properly vassals, but quasi vassals, or persons who vow fealty to, and put themselves under the protection of, another.

In this sense that, about to the same with what are otherwise called committati, and recomitati.

AFFIDAVIT, an Oath in writing, sworn before some person who hath authority to take such oath; and made use of; and read in court, upon motions: though not allowed upon trials.

In the court of Chancery is an Affidavit-office, under the direction of a Master of Chancery.

AFFILA, in Ancient Geography, a district of Italy belonging to the Hernici.
AFFILIANUS montis, a mountain of Italy, near the Tiber. The colony Aesula was at the foot of this mountain.

AFFILIATION, Adfiliation, in Middle Age Writers, the same with ADOPTION. See also ADIATION. Among the ancient Gauls, affiliation was a sort of adoption only practised among the great.—It was performed with military ceremonies: the father presented a battle-axe to the person he was to adopt for his son, as an intimation that he was to preferre the effects he thus called him to succeed to, by arms.

AFFINAGE is sometimes used, in Ancient Law Books, for the refining of metals.

AFFINITY properly imports a relation contracted between one of two parties married, and the kindred of the other party.

The word is originally Latin, composed of ad, to, and fruits, boundary, limit; by reason, as the lawyers say, that one of the families here approaches to the bounds of the other. Quod due cognitiones per emptas copulatur, & aliter ad alterius cognitiones fuium accedit. Or, as another expresses it, Quod utrique cognitionis sui in unum locum confessus est.

In which sense the word stands contradistinguished from consanguinity, which is a relation by blood.

Affinity does not found any real kinship; it is no more than a kind of fiction, introduced on account of the close relation between husband and wife. It is even said to cease, when the cause of it ceases. Hence a woman who is not capable of being a witness for her husband's brother, during his life-time, is allowed for a witness, when a widow, by reason the affinity is dissolved. Yet, with regard to the contracting marriage, affinity is not dissolved by death, though it be in every thing else.

In the Mosaical law there are several degrees of affinity, wherein marriage is expressly prohibited, which yet seem not at all prohibited by the law of nature.

Thus (see Lev. xviii. 7, &c.) a son could not marry his mother, nor his father's second wife; a brother could not marry his sister, either by the father only or by the mother only, much less if related to him both by father and mother; a grand-father could not marry his grand-daughter; no one could marry the daughter of his father's wife, nor the sister of his father or mother: nor the uncle his niece, nor the aunt her nephew: nor the nephew the wife of his uncle by the father's side: a brother-in-law could not marry his daughter-in-law; nor a brother the wife of his brother, while living, nor after the death of that brother, if he left children; if he left no children, the living brother was to raise up children to his deceased brother, by marrying his widow: it was forbidden to marry a mother and her daughter at one time, or the daughter of the mother's son, or the daughter of her daughter, or two sisters together. The patriarchs, indeed, before the law, sometimes married their half-sisters, as Abraham married Sarah, his father's daughter by another mother; or two sisters together, as Jacob married Rachel and Leah; but these cases are not examples, because they might then plead neceffity or custom, and the prohibitory law as not existing. If other inances occur before or since the law, the Scripture expressly disapproves of them, as Reuben's incest with Bilhah, his father's concubine, and the connection of Amnon with his sister Tamar; and that of Herod Antipas with Herodias, his sister-in-law, or his brother Philip's wife; while her husband was living, and that which St. Paul reproves among the Corinthians, 2 Cor. vi. Calmet.

The Romanists distinguish three species of affinity.—The first, that contracted between the husband and the relations by blood of his wife; and between the wife and the relations by blood of her husband.

The second, between the husband and those related to his wife by marriage; and the wife, and those so related to her husband.

The third, between the husband and the relations of his wife's relations; and the wife, and the relations of her husband's relations.

By the fourth council of Lateran, held in 1215, it was decreed, that none but the first kind was any real affinity; the rest being mere refinements, which ought to be set aside.

The degrees are reckoned after the same manner in affinity as in consanguinity; and therefore differently in the Canon Law from what they are in the Civil Law.

Whatever line or degree of consanguinity the kindred of one of the parties married are in, they are in the same line and degree of affinity to the other. And again, in whatever line or degree of affinity persons are, in the first kind, they are in the same in the second and third kinds of affinity. Hence arise what we may call a direct and collateral, an ascending and a descending line of affinity.

The Romanists talk of a spiritual affinity, contrasted by the sacrament of baptism and confirmation. In that church, a god-father may not marry with his god-daughter, without a dispensation.

The degrees and terms of affinity are chiefly, father-in-law, i.e. husband's or wife's father, in Latin, filus; step-father, i.e. mother's husband, vitriceus; mother-in-law, i.e. husband's or wife's mother, soror; step-mother, i.e. father's wife, nomen; son-in-law, gener; daughter-in-law, nurus; step-daughter, i.e. husband's or wife's daughter by another marriage, privigina; step-son, i.e. husband's or wife's son by a former marriage, privigina; those which last, considered in relation to each other, are called compriprivigina; son-in-law, i.e. daughter's husband; brother-in-law, i.e. husband's brother, or sister's husband, levis; wife's brother, brother's wife; filter-in-law, i.e. husband's or wife's filter. Calv. Lex. Jur.

Affinity, in the Civil Law, is divided into civil, that between free persons; and servile, that between slaves.

Affinity, legitimate, is that contracted by a proper and legal marriage; or, between slaves, by contemporium.

Affinity, illegitimate, that contracted out of legal marriage.

Affinity may be contracted by an unlawful commerce; thus a person who has impregnated two filters, is prohibited marrying either of them; thus an affinity may commence between husband and wife, by his lying with her filter.

Affinity, true, is that subsisting while the marriage between the two parties subsists.

Affinity, quivi, that subsisting either after the dissolution of the marriage, as between a husband and his wife's daughter, begot by another after her being divorced from him; or before the marriage is solemnized, as that between a father and a daughter, only espoused, or betrothed to his son.

Affinity is also used figuratively, for a conformity, or agreement, between one thing and another.

In which sense the word stands opposed to diversity, variety, opposition, &c.

Bishop Wilkins gives tables, wherein things are clasped according to their affinities. Vide Real Chiarct. p. ii. p. 22.

Hencekllus has a treatise on the affinity between vegetables and minerals.

X X 2 Affinity
AFFINITY.

Affinity is more particularly used in speaking of the relation or similitude between languages, occasioned by their being derived from the same source. We use also of words, sounds, &c.

This term, which in its proper and original sense signifies a proximity of relationship, has been adopted by modern philosophers as the expression of a force purely chemical, by which substances of different nature are made to combine with each other. This particular metaphysical use of the word is not, however, of very old standing. Barchusen is probably the first who introduced it; speaking of the difficulty of obtaining chemical elements perfectly pure, he accounts for it in the following way, "Arctam enim atque reciprocam inter fid habent atfinitatem." Boerhave, however, contributed more than any other to bring the word into common use; thus we find in his Elementa Chymiae; "Particula solventes et soluta: fe affinate fis nature, colligunt in corpora homogenea." Bergman has preferred the term attraction, as more conformable to the precision of scientific language; since, however, all bodies in nature attract each other, while chemical affinity exists only between particular substances, it seems upon the whole more convenient to appropriate a term to the expression of this particular force, without, however, rigorously excluding the synonymous phrase elective attraction, which the high authority of Bergman has introduced into the chemical nomenclature.

In treating of so important a subject as chemical affinity, it will be necessary, for the sake of clearness, to divide it into fix sections:

The first will contain a sketch of the progress of discoveries in affinity.

In the second the cause of affinity will be discussed.

The third will treat of single and compound affinity, and the construction of tables and schemes.

In the fourth the several methods of estimating numerically the force of affinity will be considered.

The fifth will contain the laws of affinity.

The sixth will be appropriated to the consideration of certain anomalies.

§ I. History of Affinity.

The general fact that all substances have not the same relative degree of affinity for each other, must have been observed as soon as the smallest attention began to be paid to chemical phenomena, and in the first rude attempts to explain the cause of this difference of force, recourse was had to the maxim of Hippocrates, Omne quoddam visus, quod est in corpore, simile est ad simile. This doctrine of the old school we still find in Béccher, who supposed that there was a hidden principle of similitude in all substances capable of mutual chemical combination. Another fact, at the head of whom was Lémery, endeavored to explain chemical agency by considering solvents as composed of a multitude of fine points, and thus mechanically predisposed to enter the pores and separate the particles of substances exposed to their action.

Stahl, however, rejecting the hypothesis of mere mechanical forces, attributed the power of menimina to the attraction of contact or intimate cohesion; for, to use his own language, "combinationes qualitumque non aliter fieri quam per arctam appositionem."—"Non per modum cuncli, neque per modum incursus in unam particulam separata, sed per modum apprehensionis in unam arctae ap-
Bergman are expunged on the authority of later investigations, and the number of columns is increased to 62.

It is not, however, to the construction of tables, important as they are, that the researches of chemists on the subject of affinity have been confined. Since the discovery of the great law of attraction, by Newton, it has been the uniform endeavour of the able philosophers to sift that the cause of chemical phenomena is only a branch or modification of this universal property of matter, and the names of Buffon, Macquer, Lihmbour and Moreau, stand conspicuous for their endeavours in this department: it is to Kirwan that we owe the able attempt to reduce the force of contending affinities to numerical calculation; and the sagacious Berthollet, in his "Recherches sur les lois de l'affinité," has just now opened a new field of enquiry on this most important subject.

§ II. Cause of Chemical Affinity.

There have been only two ways of accounting for chemical affinity: the one is by having recourse to a gratuitous and inexplicable principle of sympathy, and which therefore is merely the abstraction of one metaphor for another; and the other is an endeavour, by the help of experiment and calculation, to show the identity of affinity and the Newtonian attraction. The first of these, as it does not profess to be supported by any external evidence, may be passed by; the other requires a particular examination.

It was the opinion of Newton, and a very natural one in his situation, that the force of attraction which he had demonstrated to be the efficient cause of the planetary motions, of the alternation of the tides, of the motion of heavy bodies, and of the oscillation of the pendulum, was an essential property of matter, and, as such, the cause of chemical phenomena: perceiving acids to be some of the most powerful agents in the production of these effects, he hence defined them as bodies that attract strongly, and are strongly attracted ("acidum dicianum quod multum attrabat et attrabatur.") This however is to be considered merely as a conjecture of that great man, since no attempt was made by him to submit to calculation any cases of affinity, or even to obviate the weighty objections that might be brought against the theory. The essential foundations of the Newtonian attraction are, that the force of gravitation is in a direct ratio to the mass or quantity of ponderable matter; and that the increase of the force is in an inverse ratio to the square of the distance, or, to make this plainer by an example: If the lead of a plumb-line is suspended two yards from the side of a mountain, the attractive force exercised upon it will be four times less than if the distance between the lead and the mountain was only one yard; for

\[2 \times 2 : 1 \times 1 :: 4 : 1.\]

Although, however, the justness of this law be rigorously demonstrated in all cases where the distance is capable of being measured, how does it apply to those influences in which bodies are supposed to touch each other? How can the apparent uniformity of attraction be made to explain the infinite variety of chemical affinity? To this fundamental and obvious objection Buffon has given the following reply. The distances between the several heavenly bodies are so considerable, that they may be looked upon with regard to their action on each other as so many gravitating points, the slight differences in their figure being of little or no account. If the moon and the earth, instead of being spherical, were each in the form of a short cylinder, whose transverse axis should be equal to their prefront diameters, the law of their reciprocal action would not be materially altered by such a change, because the relative distance of each particle of the moon from the earth would, notwithstanding, be nearly the same as before; but if these globes were drawn out into very long cylinders, and brought within a short distance of each other, the law of their reciprocal action would seem very different, on account of the prodigious change in the situation of their particles relatively to each other, and to the whole; thus in proportion as the figure enters as an element into the calculation of distance, the law would appear to vary, though remaining fundamentally the same.

Whatsoever slight be laid upon this proposition (which appears to have been acquiesced in by Bergman and Macquer), that in attractions between bodies that are nearly in contact with each other, the force is modified by the figure of the molecule, it must be confessed that not a single case of affinity has yet been resolved by the application of the laws of the square of the distance, modified by the figure; and several eminent mathematicians, at the same time that they admit chemical affinity to be only an effect of attraction, maintain to follow in these cases a different law from that which Newton demonstrated, which yet remains to be investigated.

Moreau, in his elaborate treatise of affinity in the "Dictionnaire Méthodique," has endeavoured to support the theory of Buffon, by certain analogical arguments, the scope of which is, that in the attractions of adhesion and cohesion, in capillary attraction and crystallization, all of which are generally admitted to depend upon the same law as the attraction of gravitation, there are cases equally difficult to be reconciled with the rule of the square of the distance, as those in chemical affinity: he also brings to his aid an ingenious argument of Macquer, to this effect: Since we are ignorant of the density of the elementary particles of bodies, it is impossible to ascertain the density of the aggregates formed by their union; it may therefore happen, that a body, whose primitive particles have little density, should, notwithstanding, be an aggregate of great density, provided these particles are of such a figure as to adhere intimately to each other by all their surfaces: for the same reason, a compound may have but little density, though its constituent particles have individually a great deal, if their figure is such as to allow of but few points of contact. Thus, although copper in mass has less density than silver, it is possible that its ultimate particles should be superior in this respect to that of silver; or, allowing it to be of inferior density, it may still be capable, on account of the figure of its component particles, to enter into such intimate contact with those of a third body, as shall make more than make up for its inferior density: hence the superior affinity which copper has for nitric acid, over that which silver possesses, may be owing to a superior attraction, on account of the greater density of its primitive particles, or their better aptitude for contact.

It is obvious, however, that all these arguments are merely hypothetical, and at best, only enable us to conceive the possibility of the phenomena of chemical attraction being equally reconcilable to the laws of general attraction as those cases of adhesion, capillary attraction, etc., which have not yet, by the ablest mathematicians, been reduced to calculation.

If a single case of affinity had been demonstrated by the rule of the square of the distance, modified by even the supposed figure of the molecule, it might be admitted as a strong presumption, that affinity depended on the same laws as gravitation; but as long as this remains a desideratum,
we must be content to acquiesce in our total ignorance of the primary cause of chemical phenomena.

§ III. Of different kinds of Affinity, and the Constitution of Tables and Schemes.

Whether the attractions of gravitation, of adhesion, of cohesion, and of composition, be or be not considered as essentially the same, there is yet difference enough between them to allow of a very accurate definition of each, and this is the more necessary to be done, as there are certain complicated cases of chemical affinity, in which the agency of all these forces may be distinctly perceived.

Gravitation then is an attraction between two bodies at an ascertainable distance from each other, whose force is directly as the mass, and inversely as the square of the distance.

Adhesion is an attraction that takes place at the plane of contact, whose force is peculiar for each substance in nature, and in a direct ratio to the surface of contact.

Cohesion, or aggregation, is an attraction between molecules of the same nature, whose force is peculiar for each substance, and in an inverse ratio to the quantity of caloric, interpolated between the particles.

Affinity, or the attraction of composition, is that which, uniting together different homogeneous substances, whether simple or compound, produces an uniform whole, incapable of being resolved by mechanical force, and whose characteristic properties are often different, and sometimes contrary to those of its constituent parts. Thus, if running mercury is added to melted sulphur, a compound is produced, which has neither the colour, the splendour, the inflammability, the volatilitv, nor the specific gravity, of either of its constituent parts.

It is this affinity of composition which is the greatest agent in all the operations of nature and art, that are referable to the science of chemistry; not only as an instrument of synthesis, as might be supposed from the primary meaning of the term, but also as the sole means of analysis; there being no way of resolving a chemical compound, but by exposing its elements to the action of stronger affinities than those which retain them in union.

All the known infinities of affinity may be arranged under three classes, according to the number of elementary substances, acting on each other at the same time, and the number of new compounds thus produced. Where only two are concerned, it may be called a case of concurrent affinity, or affinity of composition, in which, if the force of their mutual affinity is ever so little superior to the sum of their respective degrees of cohesion, combination will take place. Thus, if a piece of quicklime is put into muriatic acid, the sum of their cohesive being less than the force of their mutual affinity, the two substances will unite together, and there will result a homogeneous compound, uniting at once, potash and the properties neither of the earth nor of the acid. Thse infinities also, in which more than two bodies unite together into one compound, come equally under this rule; as, when sulphuric acid, aluminate, and potash are mixed together; the result is common alum, a salt potassiiig peculiar properties, which could never have been inferred from those of its elements. All the cases belonging to this fifth class are those of concurrent affinities, where two or more substances by virtue of their attraction for each other, unite into one homogeneous body. Hence it appears, that though every substance has different degrees of affinity for other substances, yet the stronger does not necessarily act to the exclusion of the rest.

It is not, however, always, nor indeed generally, the case, where more than two substances are concerned, that their respective affinities concur to produce one new substance; for it usually happens that their difference of force produces one binary compound, to the exclusion of the third. In the productions of the affinity of composition account of the weakness of its attraction for the new compound. Thus, if muriatic and sulphuric acid are mixed together, and an aqueous solution of pure barytes is then added, an infallible combination will take place between the sulphuric acid and the barytes, to the exclusion of the muriatic acid; and this last, having also no affinity with the sulphat of barytes thus formed, or at least not sufficiently strong to overcome the sum of their several forces of cohesion, remains permanently excluded. In this instance, therefore, we see how two bodies, whose mutual affinity is very considerable, may unite together to the total exclusion of a third substance. To make this clearer, let A, B, be two substances, whose affinity for C, is equal respectively to a and $7 = a$; it is is obvious then, that B will unite to C, with a force $7 - a = 3$; the first effect, therefore, of mixing the two substances will be the production of BC, to the exclusion of A; and if the affinity of A for BC should be superior to the cohesive attraction of the several particles of BC, to each other, it is clear that A must be permanently excluded, notwithstanding its original affinity for C. This exclusion of the weaker of the stronger affinity takes place, not only when the two forces commence their action at the same time, but even when the weaker affinity has been previously allowed to exert its whole action on the base; thus, if muriatic acid and barytes are brought into contact, they combine and form muriat of barytes, which compound is held together by the force of affinity between the two; but when to this compound we present sulphuric acid, whose affinity for the earthy base is stronger than that of muriatic acid, an immediate change takes place, the whole of the muriatic acid is dislodged, and the sulphuric acid combines with the barytes in a force equal to their mutual affinity, minus that of the muriatic acid; or, to recur to our former illustration; if A, C, are held together by a force $= 4$, upon the addition of B, whose force is $= 7$, the attraction of A, to C, will be counterbalanced by $\frac{1}{2}$ of C's affinity for A, and the remainder of B's force will produce the combination $BC = \frac{1}{2}$ of the original attraction between B, and C.

This, and similar cases, are naturally illustrated by supposing C, to have a disposition to unite with A and B, A, by itself, only one present; the combination A C, is produced; afterwards, when B, offers itself, C, having a preferable attachment to B, rushes A, and forms the combination or partnership B, C. It is this metaphorical explanation which induced Bergman to call all those infinities where a compound already formed is separated by the action of superior affinities, cases of elective attraction; and because in the above example only three substances are concerned, one new compound being formed, and the element of weakest affinity being excluded, it is properly distinguished as a case of single elective affinity, which forms the second class, ranking immediately after that of concurrent affinity.

From the consideration of single elective affinity the progress is easy to that of double, or, more properly speaking, compound elective affinity. Suppose the affinity between sulphuric acid and potash, the constituent parts of sulphat of potash, to be $= 12$, and the affinity of nitric acid for potash $= 9$, and that of oxygen of mercury for sulphuric acid $= 8$, it is evidently impossible to decompose sulphat...
If, however, their action be combined, so as that the metallic oxides shall exert its affinity on the sulphuric acid, while the nitrous acid is doing the same with respect to the potash, then, as $9 + 8$ is greater than 12, so will the affinities of nitrat or potash and sulphat of mercury be superior to that of sulphat of potash; but nitrous acid and mercury, the two agents in this decomposition, have also a strong attraction for each other, tending to unite them into the compound salt nitrat of mercury, let this force be $= 4$; it is evident then, that, upon the addition of nitrat of mercury to sulphat of potash, there are four distinct affinities acting two by two against each other. The quiescent affinities, or those which resist decomposition, are the attraction between sulphuric acid and potash $= 12$, and that between nitrous acid and mercury $= 4$, the sum of which is $= 16$. The divellent affinities, or those which tend to break the original combinations, are those of nitrous acid and potash $= 9$, and of sulphuric acid and mercury $= 8$, which together are $= 17$. Now as 17 is to 16, so is the sum of the divellent to that of the quiescent affinities. On the addition, therefore, of nitrat of mercury to sulphat of potash, there will be a decomposition of both salts, and the formation of two new ones, nitrat of potash and sulphat of mercury. This is an example of compound elective affinity; which may therefore be defined as the resolution of a compound by means of the united affinities of its elements for those of another compound. It is obviously impossible, by means of double elective attraction, to obtain either of the elementary parts of a body in a separate uncombined state; but although in this respect it is inferior to single elective affinity, it is nevertheless infinitely superior in the vast variety of its application, and in its rendering not merely possible but even easy, a number of decompositions, which are absolutely impracticable by single elective attraction. Almost all the substances in nature are compounds, and the changes that we see continually operating around us, are brought about by very complicated affinities; for it is in nearly every process of art in which chemistry is concerned; a thorough knowledge, therefore, of the general principles of compound affinity is absolutely necessary to be acquired at the very threshold of the science.

From what has been already said, it is obvious that every chemical fact arranges itself under one or other of the three species of chemical affinity; and hence may be conceived the obligation that science is under to Geoffroy, for his ingenious method of arranging cases of single elective attraction, so as to enable the enquirer to discover in an instant any particular fact that he is looking for, or to compare, at a single glance, the results of numerous and complicated experiments.

</table>

Of these Tables, the first is a transcript of the original one, published by Geoffroy, and which merits preservation as an historical memorial of an important era in chemical science. The second and third are, with a few alterations, copies of Dr. Pearson's enlarged edition of Bergman's tables.

Table II. contains the elective affinities, as far as they have been ascertained, of sixty of the most important chemical substances. All these take place through the medium of water, in which one or both the substances are dissolved, and in which the temperature is always the same. All the cates here mentioned, cannot exceed 180° Fahrenheit. At the head of each column, in larger characters than the rest, and divided from them by a horizontal line, is the name of the substance whose affinities are the subject of the rest of the column; and these are arranged in the order of their intensity, so that the substance of strongest affinity with that which is at the head of the column, stands nearest to it. Thus in the column of lime, N° 8, the substances from oxalic acid downwards, present a decreasing series of the affinities of lime; hence the combination of lime with any substance in the column, may be decomposed by any of the bodies that precede this substance, but is not broken by those which succeed it. The use and application of this table are obvious. If, for example, it is required to decompose an aqueous solution of muriatic acid of soda (common salt) by fickle affinity; the first inquiry is, which of the two component parts is to be left at liberty? Suppose it to be the acid, I am then to find a substance whose affinity with soda is greater than that of muriatic acid; for this purpose I turn to the column of soda N° 11, and find that by the addition of either sulphuric or nitric acid, I shall be able to decompose the salt in question, so as to obtain its acid in a diflagged state: if, on the other hand, the alkaline base is wanted, I find, upon inspecting the column of muriatic acid, N° 18, that the affinity of potash for muriatic acid is greater than that of soda; and therefore, by this means, I obtain muriatic acid and free soda. Again, if citrate of lime is to be decomposed, I find, by referring to citric acid, column N° 30, that it is impossible to do so as to let lime at liberty, because this flanks the first in the column of citric acid; but from the column of lime N° 8, it appears that no less than thirteen acids will each of them separate the lime, so as to leave the citric acid diflagged. If the decomposition of sulphur of Barytes is required, it is plain from the column of Barytes, N° 6, that it cannot be decomposed so as to let the sulphuric acid at liberty; it is also equally obvious from the column of sulphuric acid, N° 14, that the Barytes cannot be separated, sulphur of Barytes therefore is undecomposable in water by single affinity.

In Table III. the affinities of forty-three substances, without the medium of water, and at a temperature equal to the fusion of at least one of the substances in each instance, are registered: the application and construction of this table is precisely the same as the former; to enlarge more upon it is therefore unnecessary: it is curious, however, to observe how the order of affinities is modified by temperature; for we find that sulphur of Barytes, which is undecomposable by single affinity in water, may at a high heat be decomposed with separation of the Barytes, by potash or soda; and with separation of the acid by the phlogphoric, boracic, or arsienic acids.

The construction of Geoffroy's tables, although admirably well suited to express the general results of single affinity, is deficient as a method of registering the conclusions from single and unconnected experiments; on which account the schema of Bergman, either invented or at least first brought into general use by him, have been universally adopted for this purpose. The register of an experiment in affinity ought not to be considered as complete, except it expresses clearly, i. the result, i.e. whether or not any change is effected; 2d, the medium, whether water, alcohol, &c. is the fluid in which the substances are dissolved; 3dly, the temperature of the substances at the time of experiment; 4thly, the rate of the new substances, whether they are precipitated from the medium, or remain dissolved, or are sublimed. Now all these circumstances are expressed clearly and concisely in the following schemes. Suppose the experiment is made to decompose muriatic acid of potash in water at the common temperature, by soda, it will be found that no change.
change takes place, this is expressed by the following diagram, or scheme.

\[
\begin{align*}
\text{Muriat} & \begin{cases} 
\text{Muriatic acid} & \text{Soda} \\
\text{of } & \text{water } 60^\circ \\
\text{Potash} & \text{Potash}
\end{cases} \\
\text{Muriat} & \begin{cases} 
\text{Soda} \\
\text{of } & \text{water } 213^\circ \\
\text{Potash}
\end{cases}
\end{align*}
\]

The substance to be decomposed is placed on the left hand, and is immediately followed by a bracket whose point is turned towards the compound; within the bracket are the names of the two simple substances of which the compound is formed, and parallel to one of them is the substance by whose affinity a decomposition was expected; no change however taking place the scheme is left thus imperfect; in the centre is the name of the menstruum and the temperature in degrees of Fahrenheit's thermometer.

\[
\text{Muriat of Potash} \\
\text{Muriat} \begin{cases} 
\text{Mur. a.} & \text{Potash} \\
\text{of } & \text{water } 60^\circ \\
\text{Potash}
\end{cases} \\
\text{Muriat} \begin{cases} 
\text{Soda} \\
\text{of } & \text{water } 213^\circ \\
\text{Potash}
\end{cases}
\]

This scheme expresses, that if to a boiling hot solution of muriat of soda in water, potash be added, a decomposition takes place; muriat of potash being formed, and the soda being set at liberty; the straight line under the soda, and the pointless bracket under muriat of potash, express that both substances remain in solution.

\[
\text{Sulphat of Strontian.} \\
\text{Sulphat} \begin{cases} 
\text{Sulph. a. Strontian.} & \text{Magnesia} \\
\text{of } & \text{water } 60^\circ \\
\text{Magnesia}
\end{cases}
\]

\[
\text{Nitrat of Potash.} \\
\text{Carbonat} \begin{cases} 
\text{Potash. Nitric acid.} & \text{Carb. a.} \\
\text{of } & \text{water } 60^\circ \\
\text{Potash}
\end{cases} \\
\text{Sulphat of Soda.} \\
\text{Sulphat} \begin{cases} 
\text{Sulph. a. Soda.} & \text{Magnesia} \\
\text{of } & \text{water } 60^\circ \\
\text{Magnesia}
\end{cases}
\]

\[
\text{Muriat of Lime.} \\
\text{Muriat} \begin{cases} 
\text{Mur. a. Lime.} & \text{Ammonia.} \\
\text{of } & \text{Fire.} \\
\text{Ammonia}
\end{cases}
\]

\[
\text{Proof Spirit.} \\
\text{Solution} \begin{cases} 
\text{Water Alcohol.} & \text{Sulphated Soda.}
\end{cases}
\]

The above five schemes illustrate all the remaining cases of simple affinity: in the first we see that strontian added to sulphated magnesia dissolved in water, at the ordinary temperature, decomposes it, and produces sulphat of strontian, and magnesia, both of which are precipitated. In the second, the addition of nitric acid, to a solution of carbonated potash, produces nitrat of potash remaining in solution, while the carbonic acid is volatilized. In the third, sulphated magnesia with soda, produces sulphat of soda remaining in solution, and the magnesia is precipitated. In the fourth, dry muriat of ammonia and lime, heated together, produce ammonia which is volatilized in the form of gas, and muriat of lime remains behind. In the fifth, a solution of sulphated soda being added to alcohol, the water and alcohol unite together, while the sulphat of soda is precipitated.

It is impossible to arrange the results of experiments in compound affinity in a tabular form; accordingly schemes framed on the same principles as those for single affinity, have been adopted for the convenient registering of all the known facts on this subject. For example, the facts that sulphat of lime and muriat of potash do not decompose each other; and that muriat of strontian, and sulphat of ammonia do decompose each other, together with the circumstances of such experiments, are expressed in the following schemes.

\[
\begin{align*}
\text{Sulphat} & \begin{cases} 
\text{Sulph. a. Potash} & \text{Muriat} \\
\text{of } & \text{water } 60^\circ \\
\text{Lime} \\
\text{Lime} & \text{Muriat} \\
\text{of } & \text{water } 60^\circ \\
\text{Potash}
\end{cases}
\end{align*}
\]

\[
\begin{align*}
\text{Muriat of Ammonia.} \\
\text{Muriat} \begin{cases} 
\text{Mur. a. Ammonia.} & \text{Sulphat} \\
\text{of } & \text{water } 60^\circ \\
\text{Strontian.} \\
\text{Strontian. Sulph. a.} & \text{Ammonia.}
\end{cases}
\]

\[
\text{Sulphat of Strontian.}
\]

§ IV. Methods of estimating numerically the force of elective Affinities.

Notwithstanding the vast importance of Geoffroy's tables, and of all later ones constructed on the same plan, it is obvious that we can only learn from them the greater or less degree of affinity which different substances have for the same body, according to the order in which they are arranged; and though this is sufficient for foretelling the result in cases of single elective affinity, yet in more complicated cases, where the mutual attractions of four or more substances are concerned, the want of a numerical expression for the force of affinity, in order to infer with any probability the result of an untried experiment, must have forcibly impressed the mind of every chemist. Thus, if the result of a mixture of nitrat of potash with acetic acid be required, all that can be learnt from the inspection of the tables is, that the affinity of nitric acid for potash is stronger than for lime, and that the affinity of lime for acetic acid is weaker than that for potash; or, to express it in a tabular form,

\[
\text{Nitrat} \begin{cases} 
\text{Nit. a. } & \text{Lime.} \\
\text{of } & \text{Acetite} \\
\text{Potash} \begin{cases} 
\text{Potash.} & \text{Acet. a.} \\
\text{of } & \text{Lime}
\end{cases}
\end{cases}
\]

hence we have,

Quiescent affinities = \( r + w \).

Divalent affinities = \( r + w \).

And
AFFINITY.

And it is impossible hence to conclude whether or not any chemical change will take place; but if we find the affinity of nitrous acid for potash = 12, of the same for lime = 7; of acetic acid for potash = 14, of the same for lime = 6,

\[
\begin{align*}
\text{Nitrate} & \quad \text{Lime,} & \quad \text{Acetic} \\
& \quad 6 & = 14 \\
& \quad 7 & = 12
\end{align*}
\]

we shall then have

Quiescent affinities = 12 + 7 = 19

Divalent affinities = 6 + 14 = 20

and hence we may with certainty infer that a double decomposition will take place, with a force equal to the excess of 20 over 19.

Chemical philosophers have not, however, by any means agreed on the method to be followed for the attainment of this definable object; for, with M. Wenzel, consider the time requisite for effecting solution as the expression of the force of the affinity between a sub stance and its menstrum; others, with Fourcroy, believe the intensity of this to be more accurately measured by its resistance to decomposition, than by its rapidity in uniting bodies; according to Macquer the force of affinity is expressed by the facility with which bodies unite, compounded with the force by which they continue united. Kirwan, on the other hand, has estimated the affinity of acids for their bases by the different proportions of them that they require for saturation. And from this very diversity of opinions may be inferred the great difficulty of the subject.

According to M. Wenzel, the disposition to chemical union between bodies varies with the figure of their constitutive parts; and, regarding the action of menstrum upon them as a mere mechanical impulse, subject to calculation upon the principles of statics, he concludes, that the rapidity of solution is an exponent of the force of affinity; and therefore, that the affinity of different bodies with any common menstrum, is in an inverse ratio of the time required for their solution. To prove this, he procured equal cylinders of silver, copper, lead, and other metals in a state of purity, having weighed them, he covered them with wax with so as to leave only one end exposed to the action of the solvent; they were then separately suspended in equal quantities of nitric acid, and left to its action for an hour; being then taken out and freed from their varnish, they were weighed, and the quantity dissolved of each was found to correspond with the order of their respective affinities for the acid.

This large conclusion of M. Wenzel’s from his partial experiment, is, however, most strikingly contradicted by facts: the cylinders of silver and lead will be scarce perceptibly acted on in muriatic and sulphuric acids, whereas there will precipitate a nitrous solution of either metal with the greatest ease; a multitude of similar obvious contradictions to the rule might be mentioned, if need were, besides that M. Wenzel’s method, in so far as accurate, is capable only of being applied in cases where one of the substances is a solid.

The resistance which the parts of a compound offer to any force that is employed to separate them, offers a probable method of estimating the degree of their mutual affinity; since, however, the union is chemical, it is plain that mechanical means of separation cannot be used for this purpose, and there are very few chemical agents that can be made the subject of calculation. The only method proposed by Fourcroy, and one that he himself allows is applicable to the greatest number of cases, is to ascertain the thermometrical temperature necessary to effect a separation.

It is certain that the application of high degrees of heat in many cases opposes the action of chemical affinity; the force of affinity for caloric (heat) is also probably different in every natural substance, we know in many cases, as in the burning of lime, the reduction of mercurial oxides, &c. that mere caloric is capable of separating carbonic acid from lime, oxygen from mercury, &c. it is not therefore a priori improbable, that the affinity of any acid for the different alkaline, earthy, and metallic bases should be truly expressed by the various quantities of caloric, as indicated by the degree of the thermometer and pyrometer, required for the decomposition of the different salts. But although this rule certainly holds good in some cases, yet the greater number of compounds are incapable of being decomposed by the greatest quantity of mere caloric that we are able to apply, and almost all the cases of chemical affinity through the medium of water, are also incommensurate with the scale proposed.

In consequence of these difficulties both Fourcroy and Morveau have agreed in proposing an arbitrary number as the basis of their respective numerical series, all the other terms of which are brought by approximation and comparison with the results of known experiments, to bear certain proportions to the standard term, and to each other.

It is plain, therefore, that a table, constructed on these principles, can never be any thing more than an approach towards the truth; and even this can only be effect ed by repeated corrections according to the results of a vast multitude of experiments; and in all untried cases it is reduced merely to an argument from analogy. In order to verify the numbers in the following short table of Morveau, no less than 250 experiments would be necessary, and probably more than half these would require separate adjustments of all the numbers in the table; it may be conceived therefore how many centuries of incessant labour would be required totabulate in this manner with any accuracy even the binary combinations of the present chemical substances.

How far this Table, which has already undergone repeated corrections by its able author, is to be depended upon, a few examples will show.

If acetic of barytes is added to sulphate of soda, a decomposition will take place, and there will be produced sulphate of barytes and acetate of soda: now according to the Table, the sum of the

mutually decompose each other, forming nitrate of lime and acetate of potash, but by the Table.

Quiescent affinities = \(58 + 19 = 77\)
Divellent affinities = \(44 + 26 = 70\)

The Table, therefore, in this instance, is erroneous.

Nitrate of soda and muriat of ammonia mutually decompose each other; but by the Table,

Quiescent affinities = \(50 + 21 = 71\)
Divellent affinities = \(38 + 31 = 69\)

Nitrate of potash and sulphate of ammonia mutually decompose each other; but by the Table,

Quiescent affinities = \(58 + 16 = 74\)
Divellent affinities = \(38 + 62 = 100\)

Hence is obvious the great probability of error in all calculations and reasonings founded on this Table.

Mr. Kirwan's numerical system of affinities is founded on the proportion of base necessary to saturate a given quantity of acid; and as no one has treated this important subject with such unwasted ability and profound investigation as the learned president of the Royal Irish Academy, it will be necessary to enter somewhat minutely into an examination of the fundamental parts of his system.

The first object with Mr. Kirwan was to ascertain exactly the quantity of real acid in each of the three mineral acids, at a determinate specific gravity (by real acid is to be understood acid free from all water, except such as is necessary to its very constitution). For this purpose, assuming that muriatic acid, in the form of gas, is free from all mixture with water, he procured 100 cubic inches of this acid gas, and found its weight to be \(65\) grains, the barometer standing at \(29.74\) inches and the thermometer at \(57.1\). The barometrical pressure remaining the same, and the temperature being \(59\), he found that \(10\) grains of water absorbed an equal weight of muriatic acid gas, and the liquid acid thus formed occupied the space of \(13.3\) grains of water; hence the specific gravity of this acid was equal to about \(1.5\), and that of a muriatic acid equal in purity to the acid gas, and of the same degree of condensation as the real acid contained in the above-mentioned liquid acid, would be equal to \(3.03\).

Taking this, therefore, as the specific gravity of real muriatic acid, he next established the proportion of this contained in muriatic acids of different specific gravity. Not being able to obtain nitric or sulphuric acids in a state of gas, he calculated the proportion of real acid contained in these liquors, upon the supposition that equal quantities of the three acids, reduced to the state of real acid, required equal weights of potash for their saturation: the results of these calculations being found to accord with the actual specific gravities of these acids, diluted with different known quantities of water, he hence inferred the truth of the principle that he had assumed. Proceeding from these data he next ascertained the quantity of real acid, and real base in all the salts formed by the three acids, with alkaline and earthy bases, and comparing these results with the known order of affinity of the bases for the acids, he drew the general conclusions, “That the quantity of real acid necessary to saturate a given weight of any of the bases, is in an inverse ratio to the affinity of the bases with the acid; and that the quantity of any of the bases necessary to saturate a given quantity of any acid, is in the direct ratio of the affinity of the same acid with the base.” Or in other words, that, of two bases, which has the strongest affinity for any given acid, requires the least quantity of acid for its saturation; and a given quantity of acid will take up a greater quantity of one base than of another, in proportion to the force of its affinity for the base.

If these deductions are legitimate, the following Table, containing the quantities of base required to saturate 100 parts of real acid, is also a true expression of their respective forces of chemical affinity.

Mr. Kirwan's method has, however, been examined with much care, by two of the ablest chemical philosophers that the age can boast of, M. M. Moreau and Berthollet; and a number of very serious objections have been brought against it. These may be divided into those which call in question the essential principle of the force of affinity being in direct ratio to the quantity of base, and those which only relate to the accuracy of particular experiments.

The essential objections are contained in the following experiments of Moreau. A quantity of sulphuric acid containing, according the table of Kirwan, 100 grains of real acid, required, for saturation, 201 grains of crystallized carbonate of potash. A quantity of nitric acid, containing also, according to Kirwan, 100 grains of real acid, required 905 grains of the same salt. A quantity of muriatic acid, containing 100 grains of real acid, required 907 grains of the same salt. Hence it appears either that Mr. Kirwan's fundamental calculations are erroneous, or that the very principle of his whole system is false; for not only do equal quantities of real acids require for their saturation different quantities of the potash, but the quantity of base required is in an inverse ratio to the force of affinity, being exactly the reverse of the principle that Kirwan lays down.

Again, according to Kirwan's corrected tables,

- Sulphate of potash consists of Acid 100
- Sulphate of lime - - Acid 100
- Nitrate of potash - - Acid 100
- Nitrate of lime - - Acid 100

Now, if a solution be made in water of such a quantity of sulphate of potash as contains 100 grains of real acid, and to this a sufficient quantity of nitrate of lime be added to convert the whole of the sulphuric acid into sulphate of lime, it is evident that 80.6 grains of lime will be required, and 234.4 grains of nitric acid will be left at liberty; but this quantity of nitric acid would require for saturation 105.32 grains of potash, whereas the decomposed sulphate of potash will furnish only 108.7 grains; there should remain therefore 64.87 grains of nitric acid in excess, or uncombined with
with any base. If, however, we put this calculation to the test of experiment, we shall find whether the liquor be diluted, or concentrated, or even brought to crystallization, that there is not the smallest trace to be found of any disengaged acid.

Besides the above, there are several other important objections to Mr. Kirwan's theory, especially to that part of it in which he supposes equal quantities of real sulphuric, nitric, and muriatic acids, to require for their saturation the same proportion of potash. The force of these objections has been acknowledged by Mr. Kirwan in his treatise "on the strength of acids and the composition of neutral salts;" he has, in consequence, deduced the proportion of real acid, in nitrous and sulphuric acids, from other less exceptional data; so that his numerical table of the strength of affinities is now by far the most correct of any that has yet been constructed; and his fundamental principle, that the quantity of base required to saturate a given quantity of real acid, is a true expression of the force of affinity between the acid and the base, seems to receive additional confirmation in proportion to the advance of chemical knowledge.

The following corrected table of the quantity of base taken up by 100 parts of sulphuric, nitric, muriatic, and carbonic acids, is copied from Mr. Kirwan's essay on the analysis of mineral waters.

§ V. Laws of Affinity.

Before the subject of affinity was far well understood as it is at present, or rather while chemists were not yet aware of the extreme difficulty and uncertainty of their researches, all the known facts were collected and claffified, and from them was deduced a number of general laws of affinity, most of which have been since overturned, or essentially modified by later more accurate investigations. The enumeration of these laws, with such restrictions as have been induced by modern discoveries, will form the subject of this section.

1. Chemical affinity takes place only between bodies of different natures.

This necessarily follows from the definition given in the third section, by which chemical affinity was distinguished from the attraction of aggregation or cohesion, by this very circumstance.

2. Affinity takes place only between the ultimate particles of bodies.

Where two simple substances enter into combination, this may be allowed to be the case, but certainly does not happen when compound bodies unite with each other: thus when oxygen and hydrogen combine together into water, and oxygen and sulphur into sulphuric acid, there is probably an affinity between the ultimate particles of oxygen with those of hydrogen in one case, and those of sulphur in the other; but when water and sulphuric acid combine together, the affinity takes place between particles of water and of acid, each of which is reducible into its chemical elements, and is, therefore, not in a state of ultimate division.

3. The affinity which any one body has for a series of others, is not equal in force towards each individual of that series.

It is probable that no two substances can be found, whose separate affinity for a third is perfectly equal in similar circumstances; that such instances, if they ever occur, are at least very rare, is obvious from all that has been said concerning simple and compound elective affinity; the whole of which essentially depends upon this law, and is at the same time a demonstration of its truth.

4. Chemical affinity may act upon more than two substances at the same time, and unite them into one compound.

A considerable number of triple salts has lately been discovered which seem to countenance this law; perhaps, Vol. I.

however, it is scarcely yet established beyond the reach of controversy. In one sense, indeed, almost all the facts may be said to be compounds of more than two substances, thus, sulphat of iron consists of sulphur, iron, and oxygen; carbonat of ammonia, of carbon, hydrogen, azot, and oxygen: but in these and similar cases, it is universally allowed that the affinity of a binary compound is totally different from that of its elements: so, the neutral salt, carbonat of ammonia, is not held together by the concurrent affinities of its four primary elements, but by those of its two immediate compound parts, carbonate and ammonia. Common alum is usually considered as a proper triple salt, in which the separate affinities of sulphuric, alumine, and potash, are acting on each other at the same time; of this, however, there appears not the least evidence, for though the salt in question may be made by adding together sulphuric acid, alumine, and potash, yet the same result is obtained by combining acidulous sulphat of alumine with sulphat of potash. Similar observations may be made on the ammoniacomagnesian and other triple salts, as they are called.

5. Chemical action will not take place between two bodies except one of them, at least, is in a fluid state.

This, though more accurate than the ancient maxim, "corpora non agunt nisi fluida," is obviously borrowed from it. There are two kinds of fluidity, the active and non-active, and these require to be carefully distinguished from each other: the first, or the gaseous, is for the most part very unfavourable to chemical combination, while the second, or the liquid, (including both fusion and solution) is one of the most indispensable circumstances in all cases of affinity.

6. Chemical affinity is in an inverse ratio to the attraction of aggregation.

This would seem to be a necessary deduction from the preceding law; it is not, however, to be admitted without many limitations. The aggregation of bodies may be destroyed by mere mechanical means to a certain degree; such is the effect of the operations of cutting, rasping, pounding, &c. Now, in all these, and similar cases, the above law holds strictly true: the case of rapidity with which bodies are decomposed, or enter into new combinations being directly as the quantity of surface that they present, or inversely as their masses. Thus, the surface of lime, of other salts, in entire crystals, is wholly unaffected by sulphuric acid, but in Z proportion
proportion as its surfaces are multiplied by grinding it down to power, so is its attraction of aggregation diminished; and the action of the sulphuric acid on the lime, to the exclusion of the fluoric acid, becomes more energetic. It would be more correct to say, that the affinity of chemical affinity is inversely as the attraction of aggregation; because its absolute force remains constantly the same, and it only appears to increase on account of the diminution of its antagonistic attraction. Thus, let the chemical affinity of lime and calcite be = 10, and the force of its cohesive attraction, when crystallized = 6, the sum of its quiescent affinities will be = 16. Let the affinity of sulphuric acid for lime, or the divalent affinity be = 1; it is obvious that no decomposition can take place, although the chemical divalent affinity is superior to the quiescent one; but, these continuing the same, let the attraction of aggregation be reduced by mechanical triture to be only = 2, then the strongest chemical affinity will become efficacious, and a decomposition will take place.

The aggregation of bodies is, however, more frequently overcome by the action of solution by water, or fusion by fire, and these methods are so commonly made use of that the habit is insensibly acquired of considering solutions of substances in water or fire, as equally simple with the same bodies when ia a concrete state. It is from this oversight that all the apparent exceptions to this law have originated.

If, says Morveau, "we apply heat to a mixture of acid and water, or of alcohol and water, which are real chemical combinations, we only augment the degree of their "rarefaction;" but instead of thus promoting their union we "separate them;" the name is the case with those metallic "oxides that are decomposable by mere heat, and of all "those compound salts, one of the principles of which is "more fixed than the other." If, however, caloric is capable of being exhibited in an uncombined state, and of being distinguished from all other substances by peculiar sensible properties, if these are modified and changed by combination with different bodies, if caloric may be transferred from one body to another, according to an ascertained order of chemical affinity; and finally, if it may be separated from its combination, and again exhibited with all the original properties that were at first characteristic of it, what reason is there to deny that it is so far a material substance, as to be capable of chemical combination? To recur, therefore, to the examples adduced by Morveau: if to the compound of alcohol and water a certain quantity of caloric be added, it will be divided between the two ingredients, according to their respective affinities, and in proportion to the addition of this new substance will the original affinities of the water and alcohol be weakened: the alcohol being the sooner saturated with caloric, will assume a gaseous form, and being afflled by the attraction of gravitation, will separate from the water. In all this there is nothing inconsistent with the general order of chemical agency; whereas the reasoning of Morveau involves a contradiction in terms: for if the force of chemical affinity is capable of being overcome by rarefaction, and if rarefaction is nothing but the greatest possible resolution of an aggregate, it follows that the absolute force of chemical affinity may be overcome by the negation of the attraction of aggregation.

7. When two or more substances unite to form a chemical compound, they lose their own peculiar properties, and those of the new compound are not to be inferred from the properties of its elements.

It is not meant by this that the properties of a compound are always, and in every particular, different from those of its constituent parts, only that they are by no means intermediate between them. The reverse of this was maintained by the earlier chemists, and accordingly Stahl taught that salts were composed of earth and water, because he fancied their properties to be a medium between those of the two substances. It will probably be thought at present that the very inference which Stahl has selected to prove his maxim is rather conclusive on the contrary side; but numerous other unexceptionable examples occur in every department of chemistry. Tin and iron are both of them very ductile, but if equal parts of the two are melted together, the result is a brittle alloy. Magnesia is tasteless, sulphuric acid is intensely sour, combine them, and we obtain a bitter salt. Alkali is colourless, syrup of violets is purple, the product upon mixture is green; carbo- nite acid and ammonia, when separate, are gaseous, mix them, and they become solid. Alum and lead, or bismuth are solid, by combination they form a liquid.

8. The capacity for caloric is always changed by chemical combination.

This law is, in fact, only an offset from the preceding; and for the explanation of it, see caloric.

§ VI. Anomalies.

All those cases of chemical affinity, which either really or apparently contradict the general laws that have just been cited, may be reduced to two classes; viz. those depending on the variable force of affinity itself, and those occasioned by the action of other antagonistic attractions.

1. The whole system of Bergman depends on the absolute uniformity of elective attraction, on its being a constant force, so that if (the temperature and mensurium remaining the same) the combination A B is decomposed by C, to the exclusion of B, the new substance A C, cannot be again separated by B, so as to reproduce A B, and leave C at liberty. With still more rigour does this apply to all the methods of estimating numerically the excess of one affinity over another, independently of the relative quantities of the substances employed. It appears, nevertheless, from Berthollet's treatise on this subject, that in almost all cases of change produced by elective affinity, there is not a total transfer of the base, but a partition of it between the two opposite attracting substances in a compound ratio of the relative force of affinity and quantity of each. That in many cases the excess of quantity may supply the deficiency of force, and therefore that the mafs must be carefully taken into consideration, together with the specific force in the construction of tables of affinity. Barytes is properly placed by Bergman at the head of the column of the affinities of sulphuric acid, in water; not, however, because it is impossible for sulphuric acid, to be decomposed by any other substance, but because, if equal quantities are taken of all the substances that combine with sulphuric acid, barytes will be found to decompose the greatest proportion of any other sulphate; and of the sulphate of barytes the largest part will remain undecomposed by a quantity of any body equal in weight to the barytic part of the salt in question. Thus, if equal parts of pure potash and sulphate of barytes are boiled together to dryness in a small quantity of water, it will be found that the sulphuric acid has been divided between the two bases in the compound ratio of their mafs and their force of affinity; the greater part of the barytic sulphate will be found undecomposed, a small quantity of barytes will be found at liberty, most of the potash...
potaath will also be uncombined, but a certain proportion will be united with the sulphuric acid which the barites has loft, in the form of sulphat of potaath. To make this matter plain, let us examine the reffults of the decompo- 
sition of sulphat of barites by potaath, and of sulphat of pota-
ath by barites, as calculated from Mr. Kirwan's data. Sul-
phat of barites contains 3.73 parts of sulphuric acid and
6.66 of barites: if therefore we take ten parts of this falt
and an equal quantity of potaath we have,

3.73 Sulph. a.
6.66 Barites
10.43 Sulph. a.

and the affinity of equal parts of barites and potaath for
sulphuric acid being 2:1.21 the acid, if shared between
them in the compound ratio of their mafs and their affinity,
will be 13.33 to barites, and 12.1 to potaath: now the
composition of sulphat of barites being as already flated,
and that of sulphat of potaath being 54 of alkali to 45 of
acid, there will remain undecomposed 5.22 parts of baritc
sulphat; 5.18 of barites will be fet at liberty; and 3.47 of
fulphated potaath will be produced, and 8.11 of potaath will con-
tinue uncombined. If, on the other hand, we mix equal
parts of sulphat of potaath and barites we fhall have

5.48 Sulph. a.
4.32 Sulph. a.
10 Barites

and the acid being divided between the bases in the com-
pound ratio of their mafs and force of affinity, will give
6.63 parts to the potaath and 20 to the barites: there will then be 2.48 parts sulphat of potaath remaining unde-
composed, and 3.24 barites uncombined; 4.12 parts potaath will be
felt at liberty, and 10.14 sulphat of barites will be produced.

It is not merely in a few infallacies that this partition of
one body between two others, according to their respective
masses and affinities, takes place, there being feearcly any
example to the contrary. Lime has a weaker affinity than
potaath for sulphuric acid; yet lime, when acting on an equal
weight of sulphat of potaath, is capable of partly decompo-
ing it; the fame happens with phosphat of lime and potaath,
with sulphat of potaath and foda, &c.

From these and fimilar experiments it follows, that when
a compound of two fubfiances is acted on by any third
body, that part of the compound which is the fubject of
combination, is shared between the two remaining elements,
not only in the proportion of their respective degrees of
affinity, but also according to their quantity; these two
fubfiances therefore must be confidered as opposite forces,
dividing between them the fubject of combination, according
to the ratio of their intensity, and this intensity depends, not
only on the energy of affinity, but also on the quantity, fo
that by varying this in either, the effect produced will be
proportionably modified.

Another consequence is, that the action of a fubfance in
opposition to any particular combination decreases, as it
advances towards saturation; and as the force of this is
continually diminishing, fo the power of the fubfance eli-
minated is enlarging according to its increased quantity, and
this effect takes place till the antagonist forces exactly coun-
terpoife each other.

A third inference is, that in cafes of precipitation the pre-
cipitate necessarily retains a portion of the fubfance with
which it had before been combined; for during the infalt
of this action, a partition is made of the fubject of combina-
tion in proportion to the affinities and mafs of the fub-
stances employed.

2. The variable ratio of the force of affinity between
the two elements of particular compounds, is another ano-
maly and occasional source of error. Thus the black oxyl
of manganese readily parts with a portion of its oxygen,
by the action of such a portion of calorie as will just raise
it to ignition; but after it has parted with this excess of
oxygen, the affinity which unites it to the remainder, fol-
ows a much higher ratio, fo that the utmost possible ac-
cumulation of calorie is unable to produce any further de-
composition: hence the affinity of metallic manganeze for
oxygen is very high, and the affinity of the white oxyl
of manganese for oxygen is much lower than it ought to be;
provided the affinity of these two fubfances was in an un-
iform ratio, according to their relative proportions. So
again, the acidulous sulphat of barites is decomposed by
an equal quantity of water into the common baritc sulphat
and sulphuric acid, yet the addition of water can produce any
further decomposition of this earth, only; the general fact,
therefore, of mafs compensating for inferiority of attractive
force does not here hold good. Another flinking example of
the fame is the decomposition of tartrite of potaath by ace-
ous acid, into acidulous tartrite of potaath and acetite of po-
taath; and the refiftance made by the acidulous tartrite to all
further decomposition by any quantity of acetic acid. The
fame may be faid of the affinity of muriatic acid to oxygen,
and of its base for the fame fubfance.

3. The order of chemical affinities is often modified by
the attraction of faine vegetation, a power belonging to all
but the deliquecent salts, which causes them to separate
from the water that holds them in solution, and rife in
the form of vegetations up the fides of the vefsel in which they
are contained; the effcacefiant falts are more particularly
fubject to this attraction, and consequently their affinities
are the most frequently disturbed by this force. Muriat
of foda is fearcey, if at all, decomposed by carbonated lime
in water; but if, according to Scheele's proccfs, lime and muri-
at of foda are mixed with only fo much water as will make
the mafs into a paste, and this is exposed to carbonic acid
gas, a faine effcacefence will shortly make its appearance,
poffeffing all the properties of carbonated foda, and the
muriat of lime in a deliquecent flate will be found at the bot-
tom of the vefsel; but if the carbonat of foda is dissolvcd and
added to the muriat of lime, an immediate decomposition
will take place, and carbonated lime and muriat of foda
will be produced. A fimilar effcct happens when iron is
moiltened with muriat of foda and exposed to carbonic acid
gas.

4. The laft caufe of anomaly that need be mentioned,
aries from the affinity of water with fubfance. Dissolvcd in
it, and this is a very important circumstance to be aware of,
as it accounts for the otherwife inexplicable phenomenon of
what are called incompatible falts in certain mineral waters.
Bergman, Kirwan, Cavendish, and other eminent chemists,
have discovered in mineral waters the co-exiftence of small
quantities of various falts, which, in common circumstances,
decompose each other; thus the waters of Raithbone-place,
according to Cavendish, contain in the pint 0.9 of a grancarbonated ammonia, and 1.2 grain of sulphat of lime.
A gallon of Harrowgate water contains 13 grains muriated lime,
and 5 grains sulphated magnesia. But in both these
cases, on account of the small quantity of salt compared to
that of the water, the affinity of this laft, aided by its mafs,
is capable of overcoming the excess of the divellent, over the
quieft affinities of the falts that it holds in solution; and
is obviously the true reafon of the fact, for, by evapora-
tion, a considerable proportion of the water is taken away,
the divellent affinities of the twofalts become efficacious, and
decomposition takes place.

For other fubjects in fome measure connected with the
important
AFF

important subject of chemical affinity, see Adhesion, Crystallization, Saturation, Solution.

AFFION, is a name given by the Arabsians to opium; and also to an elecary, in which opium is an ingredient.

AFFIRMATION, in Logick, a positive proposition, alluding the truth or reality of something.

Affirmation is defined, by the Logicians, an act whereby we attribute one idea to another; as imputing it to belong, or agree to it.—As when, conceiving perfection to agree to the Deity, we say, God is perfect.

This, on other occasions, is called Enunciation, Proposition, Composition, and Judging.

Affirmation, in Law, signifies the ratifying or confirming a former law, or judgment.

We say, to affirm a judgment: the house of lords, on an appeal, affirmed the decree of the Lord Chancellor, or of the lords of judicature of Scotland.

Affirmance is used in the same sense, 8 Hen. vi. c. 12.

Affirmation is also used in Grammar, by some refining upon that art, for what is usually called a verb; because the office of that part of speech is to express what we affirm or attribute to any subject.

Affirmation is also used for a solemn form of stating the truth, allowed to be used by the Quakers, instead of an oath, which they hold absolutely unlawful to take. See the form of the affirmation, &c. under the article Quaker.

Affirmation is of divers kinds, tacit, by words, by a nod, or gesture, &c.

In a civil law sense, affirmation may be divided into simple, which is that from which no obligation arises; and qualified, which infers an obligation.

The requisites of this latter are, that it be, 1. deliberate and free; 2. sincere; 3. certain and specific; 4. clear and periphrastic.

AFFIRMATIVE, in Logick. See Affirmation.

There are universal affirmative propositions; and such, usually, are the first of syllogisms.

In Algebra we have also affirmative or positive quantities, which have their appropriate characters. The term affirmative was introduced by Vieta.

Affirmative, &c., or character. See Character.

Affirmative, in Grammar. Authors differinlinist affirmative particles; such as, is, xia.

The term affirmative is also sometimes used substantively. Thus we say, the affirmative is the more probable side of the question: there were so many votes, or voices, for the affirmative.

Affirmative is particularly applied, in the Roman inquisition, to such heretics as own the errors and opinions with which they are charged; and maintain them in their examination with firmness and resolution.

Affix, affix, compounded of ad and fix, I fix, in Grammar, a particle added at the close of a word, either to diversify its form, or alter its signification. In which sense, affix is the name with suffix; though affix is sometimes, but less properly, applied more generally so as to include prefix particles.

We meet with affixes in the Saxon, the German, and other northern languages; but more especially in the Hebrew and other oriental tongues.

The Hebrew affixes are single syllables, frequently single letters, subjoined to nouns and verbs; and contribute not a little to the brevity of that language. The affixes of nouns may be called affirmative affixes, as they denote the positive pronouns; and those of verbs, verbal affixes. In feminine nouns, ending in נ, the נ is changed into נ, before the affixes, and נ is affected after the plural feminine termination נ, probably for softening the sound: e. g. נִנְיָא, my law, and נִנְיָ֑יָךְ, our laws. The נב of the plural masculine termination is expelled by the affixes, and when נ is affixed to the plural, after נ is expelled, the נ of the plural coalesces with the affix; and they are distinguishable only by the tense, or by other words in the sentence: e. g. נִנְיָא מְנַנְטָת, my books, נִנְיָא, our books.

Plural affixes are not unfrequently subjoined to singular nouns, and vice versa; e. g. נַנְיָא (I Kings viii. 26) for נַנְיָא thy word; and נַנְיָא (Exod. iv. 5) for נַנְיָא, their fathers. As the positive pronouns are subjoined to nouns, the personal pronouns are subjoined to verbs in the same manner. In this case the נ of the third person singular feminine is changed into נ, and the נ of the second person singular feminine affixes נ, before the affixes.

In the second person plural, masculine and feminine of Kal, the נ and נ final are ejected, and their place is supplied by נ, inflected before the affixes; e. g. יַנְיָא for יַנְיָא, ינ, ינ, ינ, and ינ delivered him. Sometimes the נ is wanting, and thus this person is not easily distinguishable from the third, second and first person singular; as יַנְיָא ( Ezek. xvi. 10), for יַנְיָא, and thou gavest him. In the second person plural, masculine and feminine of Kal, the נ and נ final are ejected, and their place is supplied by נ, inflected before the affixes; e. g. יַנְיָא for יַנְיָא, ינ, ינ, ינ, and ינ delivered him. Sometimes the נ is wanting, and thus this person is not easily distinguishable from the third, second and first person singular; as יַנְיָא ( Ezek. xvi. 10), for יַנְיָא, and thou gavest him.

Affixes are sometimes subjoined to the infinitives of passive verbs, in which case these infinitives assume the rank of subfinitive nouns; as יַנְיָא (Gen. v. 2). In the day when they were created, or of their creation. When affixes are thus joined to infinitives, they may be taken either actively or passively, or expressed by the nominative or accusative case, according to the sense of the sentence; e. g. יַנְיָא מְנַנְטָת, may be rendered to signify in the day in which he himself delivered, or in which he delivered him. Some adverbs, and all prepositions, assume affixes; but as the affixes of verbs are generally rendered by the accusative, and those of nouns by the preposition governed. Wilken's Elements of Heb. Gram. p. 108. 174. Maseleaf, Heb. Gr. vol. i. p. 65, 171, 189.

The oriental languages are much the same as to the radicals; and differ chiefly from each other as to affixes and prefixes. Mem. Acad. Inscript. tom. ix. p. 334.

Affluence, formed from ad and fluere, to flow, literally denotes a blast of wind, breath, or vapour, striking with force against another body.

Naturalists sometimes speak of the affluence of serpents. Tully uses the word figuratively, for a divine inspiration. In which sense, he ascribes all great and eminent accomplishments to a divine affluence. See Pythia.

Afflent, in Geography, a town of Stiria, in Germany; two leagues north of Prueck.

Affliction is not itself, in propriety of medical speech, a disease, but it produces many; for whatever excites envy, anger, or hatred, produces diseases from tender fibres; as whatever excites fear, grief, joy, or delight, begits diseases from relaxation.

Many
Many chronicled dikes, particularly the pikes, spring from affliation. For a very remarkable history of the effect of affliation, see Hill de l'Acad. Roy. des Sciences, an. 1752.

AFFLUX, in Electricity, is opposed to efflux; and both terms were used by the Abbé Nollet, and also by Dr. Watson, previously to the discovery of positive and negative elecories. They apprehended that in all electrical operations, there was both an influx of electrical matter to the globe and the conductor, and likewise an efflux of the same matter from them. Dr. Watson soon corrected this mistaken opinion; but the Abbé Nollet was more tenacious; and he was confirmed in his attachment to this favourite theory by observing, that bodies not infiltrated, plunged in electric atmospheres, shewed signs of electricity; not perceiving, that the electricity of such bodies was in its nature and effects different from, and directly opposite to that of the electrified body, in the atmosphere of which they were involved. See Electricity.

AFFORAGE, in the French Custom of a duty paid to the lord of a district, for permission to fell wood, or other liquors within his territory.

Afforage is also used for the rate or price of provisions laid and fixed by the provost, or sheriffs, of Paris.

AFFORARE, to affaire, in Law, is to set a value on any thing; and afforato denotes appraised or valued, as things vendible in a fair or market. Du-Cange. See Affereors.

AFFOREEMENT, afforcicument, derived from the barbarous Latin afforcicare, to strengthen, confirm, in some ancient charters, denotes a fortefl, or work of fortification and defense.

AFForesting, affostatio, the turning ground into forest. In this sense, the word stands opposite to deforestation.

The Conqueror, and his successors, continued afforeling the lands of the subject for many reigns; till the grievance became so notorious, that the people of all degrees and denominations were brought to sue for relief; which was at length obtained, and commissions were granted to survey and perambulate the forest, and separate the new afforeling lands, and re-convert them to the use of their proprietors, under the name and quality of purfuel, or feu ville land.

AFFRANCISEMENT. See Manumission.

AFFRAY, in Law, is derived from the French word affraie, to affright, and it formerly meant no more; as where persons appeared with armour or weapons, not usually worn, to the terror of others. Stat. 2 Edw. III. cap. 3. But it now implies a skirmish or fighting between two or more, in some public place, to the terror of his majesty's subjects; and there must be a stroke given or offered, or a weapon drawn, otherwise it is not an affray; but if the fighting be in private it is no affray, but an assault. 3 Hohn. 178. It is iniquitous in the court leet, and punishable by justices of peace in their fiefs, by fine and imprisonment; and it differs from assault, in that it is a wrong to the public; whereas assault is of a private nature. Lamb. lib. ii. Affrays may be fuppressed by any private person present, who is justifiable in endeavouring to part the combatants, whatever conseqences may ensue. But a contable, or other familiar officer, may break open doors to suppress an affray, or apprehend the affrayed; and he may either take them before a justice, or imprison them by his own authority for a convenient time, till the heat is over; and may then, perhaps, also make them find sureties for the peace. 3 Hohn. 138. Hawkins P. c. 134, 136, 138. The offence of affray admits of several degrees of aggravation. This is the case when two persons deliberately engage in a duel, though no mischief has actually ensued. Another aggravation is, when the officers of justice are disturbed by an affray, in the due execution of their office, or where it occurs in the king's court and such places. All affrays in a church or church-yard are deemed heinous offences; and therefore it is enacted, by Stat. 2 and 6 Edw. VI. c. 4, that if any person shall, by words only, quarrel, chide, or brawl, in a church or church-yard, the ordinary shall suspend him, if a layman, ab ingredio ecclesie; and, if a clerk in orders, from the ministration of his office, during pleasure. And, if any person in such church or church-yard proceeds to feite or lay violent hands upon another, he shall be excommunicated, infra facto; or if he strikes him with a weapon, or draws any weapon with intent to strike, he shall, besides excommunication (being convicted by a jury), have one of his ears cut off; or, having no ears, be branded with the letter F in his cheek. Blackf. Com. vol. iv. p. 146.

AFFREIGHTMENT, or AFFRETTAMENT, AFFRETTMENT, in Law, signifies the freight of a ship.

The word is formed from the French freit, which expresses the same thing.

AFFRONTÉ, French, compounded of ad, to, and front, forehead, in Heraldry, is understood of animals born in an escutcheon as facing, or with their heads turned towards each other. This is otherwise called confront; and stands opposed to adoff. When a savage's head is full-faced, it is said to be affronté. The word often occurs in the same sense with gandant.

AFFUERA, in Geography, one of the islands of Juan Fernandez, on the south-east coast, in the kingdom of Chili. Its longitude, from the meridian of Callao, is 30° 20', and it is about 400 leagues to the north of Cape Horn. This coast swarms with seals and wolves.

AFFUJAGE, infra ignum, derived from affu, q. d. afforc, to make a fire, of ad and focus, in Ancient Cyprians, a right of cutting fuel-wood in a forset, or the like, for maintaining family-fire. Du-Cange.

AFFUSION, the act of pouring some fluid substance on another body. Dr. Grew gives several experiments of the luftation arising from the infusion of divers metals on all sorts of bodies. Divines and church historians speak of baptism by affusion; which amounts to much the same with what we now call sprinkling.

AFGHANS, in Geography and History, comprehend generally the several tribes of Mahometans, who inhabit the northern parts of India; some of whom are spread over the whole of India, and known by the name of Pathans: they are esteemed the best soldiers in the country. In a more restricted sense, they are the indigenous possessors of a tract of country, which stretches from the mountains of Tartary to certain parts of the gulf of Cambay and Persia, and from the Indus to the confines of Persia; and their principal settlements have been the mountainous districts bordering on Candahar, Cabul, Chitzen, Peshawur or Peishor, and Hazarist, &c. The Afghans are represented as a rude untutored people, without a written character, says Mr. Fordier (Journey from Bengal to England, through the northern parts of India, &c.), and speaking a language, called Pushto, peculiar to themselves. They are a robust Hardy race of men, and being generally addicted to a state of predatory warfare, their manners largely partake of a barbarous insolence, and they avow a fixed contempt for the occupations of civilized life. The territory which they chiefly inhabit is denominated by Mr. Fordier Afghanist, and he observes that, though the natives are denominated Tartars in some histories of Asia, they bear no resemblance to those people,
people, in their persons, manners, or language. They have been sometimes subject to the Moguls, and sometimes to the Persians, but more frequently independent. During the weak reign of Shah Sultan Hoffein, and the tyranny of the emirs, by whom he was governed, they suffered many severe oppressions; and under the direction of Mir, i.e. Amir, Weis, or Vaez, one of their chiefs, a man of a bold and enterprising spirit, they determined to revolt, and to throw off the Persian yoke. Having intellectually petitioned for redress, and their deputies to the Persian court being dismissed, as the agents of fictions and turbulent people, their leader, Mir Weis, was fetized and sent as a prisoner to Isphahan. He contrived, however, by his presents and his eloquence, to ingratiate himself with the king's ministers, and with the king himself, that he was not only releaved, but acquitted and favoured with the royal protection. This visit afforded him an opportunity of obliterating the weaknesses of the Persian monarchy, and of concerted measures for the success of the enterprise which he had projected. With a view of uniting the Afghans in his interest, he obtained leave to make the pilgrimage to Mecca; and here he obtained a dispensation for effecting the revolt which he had meditated. After the successful execution of several preparatory measures, and the murder of the Khan of Kandahar, and his Persian and Georgian adherents, he marched forward to the city which he surprised and took, and then joined the Afghans, who, after several alternate defeats and victories, obtained peaceable possession of the whole kingdom of Kandahar, A.D. 1713. Mir Weis, however, who had for some time assumed the title of king, with other enigmas of sovereignty, died in his new kingdom in the year 1715, and was succeeded on the throne by his brother, Mir Abdollah. This prince was delituité of talents, ambition, and courage; and therefore formed a design of restoring Kandahar to the crown of Persia. Whilist he was negotiating the surrender, he was killed by his nephew Mir Mahmud, a prince of the age of 18, who was proclaimed king of Kandahar, within six months after the death of his father.

In 1717, the Abdollas, another tribe of Afghans, who resided in the province of Herat, and who had submitted to Persia, on condition of not being subject to foreign governors, resolved to follow the example of the Afghans of Kandahar, and to emancipate themselves from the Persian yoke. They succeeded in their attempt, and Herat became an independent republic. Mir Mahmud, availing himself of the revolt of the Abdollas, and of other concurrent circumstances, which contributed to enslave the Persian government, proceeded to the execution of the design which his father had conceived of subduing the whole of Persia, and engaged the Afghans, the Abdollas, and the other inhabitants of adjacent states, to co-operate with him. Accordingly he began his march in January 1723; and having advanced within three leagues of Isphahan, the capital, he pitched his camp and prepared for battle. The Persian army, after suffering a great slaughter, whilst the losses of the Afghans was very inconsiderable, was betrayed by one of its own generals, and reduced to the greatest distress. Mahmud having gained the subsurbs, invaded the city; but several unfavourable circumstances occurred during the siege, and the Afghans must have withdrawn if Shah Hoffein had not been deterrcd and betrayed by those in whom he placed his chief confidence. After enduring the horrors of famine for two months to such a degree that the besieged were under the necessity of consuming every kind of brute animal they could find, and of appeasing their hunger by eating the bodies of those who died, and even murdering their fellow-citizens and children, the city capitulated on condition of Hoffein's resigning the empire, together with his person and principal officers of the court, into the hands of the conqueror. "Such," said the vanquished and dilligent monarch, addressing the Afghan prince, "is the infallibility of human grandeur: God dispenses of empires as he pleases, and takes them from one nation to give them to another; but I promise to consider you always as my own father; and I will undertake nothing for the future without your advice." As soon as these words were uttered, four thousand Afghans were ordered to take possession of the royal palace, and the gates of the city. Thus, when Hoffein had reigned 28 years, the dynasty of the Saffi, or Safis, ended in the person of this prince, the 10th successor of Ismail, its founder, after having lived 233 years. For the manner in which Mahmud closed his life and reign, see the article MAHMUD. He was succeeded by Ahruff, the son of Abdollah, whom the Afghans raised to the throne of Persia, A.D. 1725. The Afghans at this juncture were masters of Khorasan, Kerman, and Persia; and under the conduct of Ahruff, they obtained some successe against the Turks; but in 1727, they concluded a peace with them, and Ahruff acknowledged the Ottoman emperor lawful sovereign of Persia. About this time, especially in 1729, Nadir Shah, otherwise called Kuli Khan, began to distinguish himself. Having totally routed the Abdollee Afghans, of whom 5000 were made prisoners, and near 15,000 killed and wounded, and having taken possession of Herat, he proceeded to meet Ahruff, who was marching towards Khorasan at the head of an army of 50,000. The Afghans were terrified by the prospect of encountering the victorious general of the Persians, and wished to avoid an action. They were, however, compelled to engage, and the event was a complete victory on the part of the Persians. The losses sustained by the Afghans was about 12,000 men; and that of the Persians amounted to the number of 4000. Ahruff retreated towards Isphahan, and was pursued by Kuli Khan. On his approach the Afghans quitted their several garrisons and fled towards the capital, where they deposited ample stores of provisions, with the purpose of defending themselves to the last extremity. But Ahruff determined to try the event of a battle before he submitted to a siege. Accordingly he marched out to a convenient situation about 30 miles from the city, and waited Kuli Khan's arrival. In the mean time he exercised the most wanton cruelty on the Persians, ordering all the principal men to be cut off, and afterwards all they could find in the streets; so that, for the space of twenty days, there was not a Persian to be seen abroad, none appearing but women, who came out to buy the common necessaries of life. At last Kuli Khan arrived and obtained a complete victory. Ahruff having loft 7000 men, retired to Isphahan, and inflicted an order, that all the inhabitants should be slaughtered, and the palace and other houses set on fire. As they were about to execute this barbarous order, the Persian army approached the city; upon which Ahruff and his men, having loaded their beasts with money, hastened to save themselves by flight; and in a few hours there was scarce an Afghan to be seen in the city. The Afghans took up their winter-quarters at Shiras; but they were pursued by Kuli Khan, Jan. 1730; and after an obstinate resistance, compelled to fly, and to leave behind them a great part of their treasure, and most of their women and children. Ahruff, with about 1500 of his men, marched directly towards Kandahar; but most of them defeated him; and the rest were surprized by a body of the Balluchis, and after a gallant defence, he and most of his party were cut to pieces. Thus ended the usurpation of the Afghans in Persia.

After Nadir Shah was proclaimed emperor of Persia in 1736,
1736, he proceeded with his army towards Cabdahar, in order to reduce to subjection the Afghans, who were the only enemies of the Persian empire whom he had not subdued. Having secured Cabdahar and Cabul, and advancing in his march towards Peshaw, he was much incommode by the hardy mountaineers, and in several skirmishes with them lost many men, who were either killed or wounded. The Afghans had fortified themselves so strongly on the tops of the hills, that this victorious general found it impossible to force their pales without much bloodshed; and he therefore sent them offers of accommodation, which they accepted the more readily, as they had not received for four or five years the usual allowance from court for their services in defending the pales of the mountains. Nadir Shah, upon paying them a certain sum of money, was allowed to march forward without molestation; several of the Afghans enlisted in his army; and others joined him in his further progress. The mountainous residences of the Afghans were included in the territories to the westward of the river Attok, formerly ceded to Nadir Shah by Ma- hommed Shah, in the year 1739. A body of Afghans, in the service of Nadir Shah, was commanded by Ahmed Khan, who, after the affiance of this barbarous conqueror in 1747, took possession of Cabul, and with the resources furnished by the tribute which he thus obtained, laid the foundations of an independent government, including Afghan, Goor, Multan, Sind, and Casmir. Ahmed was succeeded in 1753, by his son Timur Shah, who, besides his Afghan and Indian dominions, possessed a large division of Khorasan. His successor, who now fills the throne, carried his arms in 1765 as far as Labor, when he was recalled by intellel commotions. Hanway's Hist. Acc. of the British Trade, &c. vol. iii. p. 25, &c. &c. Hanway's Trav. vol. iii. p. 148, &c. Fraser's Hist. Nadir Shah, p. 91. Raynal's Revol. vol. ii. p. 68.

In the 2d volume of the Asiatic Researches, we have some curious particulars relating to the Afghans: they call themselves the povertiers of Melic Talut, or king Saul. In a war, they say, which raged between the children of Israel and the Amalekites, the latter being victorious, plundered the Jews, and obtained possession of the ark of the covenant. Considering this as the God of the Jews, they threw it into the fire, which did not injure it, and having effectually endeavoured by other methods to destroy it, they placed it in their temple, and all the idols bowed to it. At length they fastened it upon a cow, which they turned loose in the wilderness. They are said to have applied to Samuel, after their defeat by the Amalekites, for a king: and at this time the angel Gabriel defenced it, and delivered a wound, with instruction, that the perfon, whose stature corresponded with that wound, should be king of Israel. Melic Talut was then a herdman of inferior condition: and having lost a cow, he applied to Samuel for assistance to satisfy the owner. Samuel, perceiving his lofty stature, asked his name: He answered Talut. Upon which, having measured him with the wound, he said to the children of Israel, "God has raised Talut to be your king." How shall we know, say they, that he shall be our king? Samuel replied, they should know, that God had constituted Talut their king, by his resting the ark of the covenant. He accordingly rested it, and they acknowledged him their sovereign. After Talut obtained the kingdom, he feized part of the territories of Jabul, or Goliat, who assembed a large army, but was killed by David. Talut afterwards died a martyr in the war against the infidels; and God constituted David king of the Jews. Melic Talut, they say, had two sons, one called Berka, and the other Irmia, who served David and were beloved by him. The son of Berka was called Afghan, and the son of Irmia was named Ulbec. The latter was eminent for his learning; and the former for his corporeal strength, which struck terror into Demons and Genii. Afghan made frequent excursions to the mountains; where his progeny, after his death, established themselves, lived in a state of independence, built forts, and exterminated the infidels. The late Henry Van- fittart, Esq. informs us, that a very particular account of the Afghans has been written by the late Hope Rohmat Khan, a chief of the Rohilas, from which the curious reader may derive much information. They are Musulmans, partly of the Sorsite, and partly of the Shiite persuasion. They boast much of the antiquity of their origin, and the reputation of their tribe; but other Musulmans reject their claim, and consider them of modern, and even base extraction. From history however, we learn, that they have distinguished themselves by their courage, both singly and unitedly, as principals and auxiliaries. They have conquered for their own princes and for foreigners, and have always been regarded as the chief strength of the army, in which they have served. As they have been applauded for their virtues, they have also been reproached for vices; having sometimes been guilty of treachery, and even acted the base part of assassins. They were divided into four classes, viz. pure Afghans, whose fathers and mothers were Afghans; those whose fathers were Afghans, but their mothers of another nation; such as bad Afghan mothers, and fathers of another nation; and the children of women, whose mothers were Afghans, and fathers or husband of a different nation.

The above account is extracted from the Persian Abridgment of a book, called The Secrets of the Afghans, written in the Pushto language, a specimen of which is added. The work was communicated by Henry Vanfittart, Esq. to the late Sir William Jones, who was then president of the Asiatic society. Although their claim to a descent from Saul seems to relieve some of the fictions borrowed by Malomet from the later Jewish Rabins, Sir William Jones has no doubt that the Afghans are descendants of Israel. "We learn," says he, "from Esdras, that the ten tribes, after a wandering journey, came to a country called Arafat, where, we may suppose, they fell into the hands of the Afghans. Now the Afghans are said to have been written by the Persian historian the. Hebrews could be defended from the Jews; they have among themselves traditions of such a defect; and it is even asserted, that their families are distinguished by the names of Jewish tribes; although, since their conversion to the Islam, they studiously conceal their origin: the Pushto language, of which I have seen a dictionary, has a manifest resemblance to the Chaldaic; and a considerable district under their dominion is called Hazarb, or Hazaret, which might easily have been changed into the word used by Esdras. I strongly recommend an inquiry into the literature and history of the Afghans."

AFLOAT, in Sea language, denotes the rate of a ship when she is buoyed up by the water from the ground.

AFROBA, in Botany, a name given by the natives of G'ina, to a kind of plant, of the genus of the phaeolus, or kidney bean. They use it pounded and mixed with oil, to cure the itch, and other external sores. It is more hairy than the common kinds, and its leaves are very small. Phil. Trans. N. 232.

AFORE, signifies that part of a ship which lies forward, or near the stem. It also means further forward, as the manger stands afore the fore-mast, or nearer to the stem.

AFRA,
AFRA, in Geography, a strong cable on the frontiers of Quara in Africa, built by Cherif Mahommed, king of Sur, N. lat. 28° 20'. E. long. 23° 10'.

AFRA, in Entomology, a species of Papilio, with brown wings, fix ochel, and the hinder wings marked with cinerous veins; found in the southern deferts of Russia.

AFRANUSI, L., in Biography, a Latin comic poet, who flourished about the year U. C. 6641, or a century before Chrill. Cicero (de Clar. Orat. apud. Oper. t. i. p. 474; Ed. Olivet.) says, that he imitated C. Titius, and commends him for the acuteness of his genius and the fluency of his style. Horace (Eniill. 1. ii. ep. i. v. 57) represents him as refencing Memander, Quintilian (i. x. c. i. ii. p. 913) whilst he celebrates his talents for comedy, expresses a wish that he had not fulfilled his performances by impure and unnatural love-adventures, which were declaratory of his own manners. Suetonius in his life of Nero, (apud. Oper. t. i. p. 743; Ed. Pufic.) mentions a comedy of Afraniius, intitled Incendium or Confagracion, on the exhibitions of which the house that was burned was devoted to be pillaged by the attors. Some fragments of this poet's works are preferred in Maittaire's Corpus Poetarum, Lond. 1775, f. 103. AFRICA, in Geography and History, was anciently one of the three parts of the known world which was divided into Europe, Asia, and Africa, and called by the Greeks 

Africa, continent; and is now one of the four quarters of the globe. Bochart (Geog. Sac. apud. op. tom. i. col. 488.) after enumerating several etymologies of the name Africa, which he disapproves, deduces it from a Punic word seris, signifying an ear of corn, and referring to the fertility of this country. Dr. Hyde supposes it to be derived from the Phenician or Punic Haurorca, or Horace; i.e. the Barca, or country of Barca, which was one of the most remarkable parts of this continent. Servius in Virgil (Aen. v. v. 128. tom. ii. p. 618. Ed. Burm.) deduces it from ara frigoris, fine frigores, and the appellation expresses the heat of the climate. Africa, called by the ancient Liby, was divided by them it into Africa propria, and Africa interior. Africa propria, or the territory of Carthage, has had various limits assigned to it by the ancient geographers. Mela (l. i. c. 7.) and Ptolemy (l. iv. c. 3.) comprehended under this appellation all the countries situated between the river Ampagia and the borders of Cyrenaica, which, according to Pliny (H. N. 1. v. c. 4.) were inhabited by twenty-six different nations; and thus they would include Numidia and the Regio Syrta, which are countries distinct from the proper territory of Carthage. Its true limits seem to have been (See Cellar. Ant. Geog. tom. ii. p. 857.) the river Tufca, or boundary of Numidia, on the west; the Mediterranean or African Sea on the north; the frontiers of the Garamantes and deferts of Libya interior on the south; and the Mediterranean, with the Leifer Syrta, on the e aft. It comprehended two provinces, viz. the Regio Zeugitana and Byzacium, with which the kingdom of Tunis, as it is divided by Dr. Shaw (Travels, p. 73.) into the summer and winter circuits, nearly correspond. The chief lakes of this region, noticed by the ancients, are Hippopotamis, the Pala Sjfira, the Pala Triense, the Pala Palaia, and the Pala Libya; the most famous river was the Bagaza; and the principal islands on the coast of Africa propria were the Cossea, the Taricia, Lopadusa, Agusa, the Larinse, Draconta, Galata, and Segimus.

Africa was first peopled, principally by Ham and his descendants. Mizraim peopled Egypt. (See Gen. x. 6. 13.) The Pharaohs, the Naphthalim, the Cudshim, and the Ludim took possession of other parts; though their respective situations are not precisely known. Some have supposed that the Lehabim settled in Libya, and Phut between Numidia and Libya, along the Mediterranean, and that many of the Canaanites, when they were driven out of their country by Jotham, retired into Africa. At a later period, the inhabitants of this country were the Aifa, whose chief city was Arousa, the Maxvse and Machlye both Libyan nations, the Zanaces, and the Zygantes, who cultivated bees, and made honey. All these were, probably, a mixture of old Libyans and Phoenicians, and in several respects resembled both these nations.

Africa interior comprehended those remoter and more southern countries of Africa, most of which were little known to the Greeks and Romans otherwise than by uncertain and fabulous reports. The western part of this division was called Libya interior, and it was chiefly inhabited by the Gafala, Garamantes, Nigrites, and Heptarian Ethiopians. The eastern part was denominated by Ptolemy Ethiopia sub Aegypto. See Abyssinia, Egypt, and Ethiopia. The Romans do not seem to have extended their conquests and intercourse beyond the tropic of Cancer. The kingdoms with which they were more immediately connected were Numidia, Mauritania, and Gathul. As for the inhabitants of the more retiered and southern parts, they were considered as the most and greatest of their kind and more of their character and manners. Some accounts will be given of the notions that prevailed respecting them in their proper places, under the real or fabulous appellations by which they were distinguished, as Aflacures, Blennymas, Cadupi, Delopen, Elephantopbagi, Ichthyophagi, Latophagi, &c. &c.

The ignorance of the ancients, concerning the extent of Africa, appears from their disagreement in ascertaining its just limits; whilst some, as Salvid, (Jugurth. Bell. c. 20. tom. i. p. 26. Ed. Haverc.) Mela, (l. i. c. 8.) Pliny (l. iii. c. 1. tom. i. p. 135. Ed. Harvid.) Dionylius, (Perig. v. 18.) Curtius, (De Alex. Bell. c. 14.) Polybius, (Hift. i. p. 191. Ed. Calau.) and Solinus, have preferred for this purpose the western branch of the Nile, or even the great Catabathmus or desert; which last would afford to Asia, not only Egypt, but part of Libya: others, as Ptolemy, (l. iv. c. 5.) and Strabo, (l. i. tom. i. p. 67.) with the modern geographers, fix the limitus of Suez, and the Arabian Gulf, as the boundaries of Asia and Africa. This, says Strabo, is a more natural limit than the Nile; and thus, says Ptolemy, the whole of Egypt is included in Africa. But the knowledge both of Ptolemy and Strabo comprehended only a small part of Africa. Strabo was only acquainted with that part of it which the Romans had reduced under their power, and this was fearedly a tenth part of it, and he seemed not to have known anything with certainty concerning the form and state of the southern parts of Africa (l. xvi. i. p. 1180.) and though Ptolemy was acquainted with some other parts, which were not known to the Romans, yet by the division which he hath made of it into twelve regions, we may conceive that nearly one half of it was unknown to him. This inquisitive and learned geographer appears to have been unacquainted with any part of Africa, situated a few degrees beyond the equinoctial line; for he supposes that this part continent was not surrounded by the sea, but that it stretched without interruption, and increasing in its breadth, towards the south. Geog. l. 4. c. 9. Leo Africanus, who was an eminent African geographer, after all his studies, travels, and researches, appears to have been imperfectly acquainted with this country; for by dividing it merely into four parts, viz. Barbary, Numidia or Bilegulgerd, Libya, and Nigrisia or Negrolaud, he excludes it from the whole kingdom of Egypt.
AFRICA.

Egypt, and the two Ethiopias. It was not known for many ages that Africa was a peninsula, every where surrounded by the sea, excepting at the illusius of Suez, which joins it to Asin. The knowledge of the Romans was restricted to those provinces which stretch along the Mediterranean sea, from Egypt westward to the straits of Gades. The Phoenicians, however, at an earlier period, seem to have been acquainted with both the south- and west-coasts of Africa. A Phoenician fleet, as Herodotus informs us, (l. iv. c. 22. p. 298. Ed. Walfading.) fitted out by Necbo, king of Egypt, took its departure about 604 years before the Christian era, from a port in the Red sea, doubled the southern promontory of Africa, and, after a voyage of three years, returned by the straits of Gades, to the mouth of the Nile. Endoxus of Cyzicus is said to have held the fame course, and to have accomplished the same arduous undertaking. Plin. H. N. i. ii. c. 67. tom. i. p. 106. Strabo (i. ii. tom. i. p. 155.) mentions this voyage of Endoxus, and treats it as a fabulous tale. Dr. Vincent, in his Periplus of the Erythrean sea, published in 1800, argues with great ingenuity against the possibility of an African circumnavigation previously to that of the Portuguese; and he affists, that there is no evidence of a farther progress to the south, on the western coast of Africa, than that of Hanno; nor on the eastern than that of the Periplus. An anonymous writer is disposed to credit the voyage, related by Herodotus, till it can be proved that the circumnavigation, in such vessels as the Phoenicians then possessed, was physically impossible; and in support of this opinion, he alludes the simplicity of the narrative, unblended with miraculous adventures—the discovery of two important truths, viz. the falling of the shadow to the south, and the penin- sular form of the African continent; one of which could be ascertained by no other means, and the former of which was disbelieved by the writer who relates it; and the consider- ation, that the navigators only put to sea when circum- stances were favourable; and though the attempt was hazardous, and success improbable, still no insurmountable impediment to its completion exists. Monthly Rev. New Series, vol. xxxiv, p. 122. The Carthaginians also, imbibing the spirit, and following the example of the Phoenicians, ex- tended their intercourse with this country. Whilt they made considerable progresses, by land, into the interior provinces of Africa; trading with some of them, and suffer- ing others to their empire; they sailed along the western coast of this great continent, almost to the tropic of Can- cer, and planted several colonies, in order to civilize the natives, and accustom them to commerce. In the prospers age of the Carthaginian republic, Hanno, with a fleet equipped by authority of the senate, and at the public ex- pense, was directed to steer towards the south, and seems to have advanced much nearer the equinoctial line than any former navigator. Major Rennell supposes his navigation to have terminated at Sherbro' river, or sound, which was also the limit of the knowledge of Ptolemy. Plin. H. N. l. v. c. i. t. i. p. 241. Hannonis Periplus apud Geograph. minores ed. Hudson, vol. i. p. 1. The authenticity of this work has been questioned by Mr. Dodwell (ubi supra,) and vindicated by M. de Montefequien (Sp. of Laws, b. xx. c. 3. v. ii. p. 44.) and M. de Bouganville, in a Diléctation published in tom. xxxvi. of the Mem. de l'Acad. des Inscript. c. 5. The voyage, it is said, was performed in small vessels, which kept near the coast; and the observations made on the appearance and state of the countries on the coast of Africa have been confirmed by the relations of modern navigators. Nevertheless, Polybius, (Hist. i. iii. p. 192. Ed. Cafaub, long after the period alluded to Vol. i. these voyages, affirms, that it was not known in his time, whether Africa was a continued continent, stretching to the south, or whether it was encompassed by the sea; and Pluy (H. N. i. ii. c. 68. t. i. p. 107.) afferts, that there can be no communication between the southern and northern temperate zones. In order to obviate these difficulties, Dr. Robertson observes, (Hist. Amer. vol. i. p. 15. 580.) that the Phoenicians and Carthaginians concealed any know- ledge they acquired concerning the remote regions of the earth, with a mercantile jealousy. Many of their disco- veries seem to have been scarcely known beyond the precincts of their own states. The navigation round Africa is recorded by the Greek and Roman writers, rather as a strange amusing tale, than as a real transaction. As neither the progress of the Phoenician and Carthaginian discoverers, nor the extent of their navigation, were communicated to the rest of mankind, all memorials of their skill in naval affairs seem, in a great measure, to have perished, when the maritime power of the former was annihilated by Alexander's conquest of Tyre, and the empire of the latter was overturned by the Roman arms. It was not till a century after the invention of the mariner's compass in 1502, that navigation began to advance beyond the limits to which it had attained before the downfall of the Roman empire. The first regular plan for discovering unknown countries was formed in Portugal by John I. furnished the bafal, after he had obtained secure possession of the crown, by the peace concluded with Caibide, A. D. 1411. Whilt an armament was equipping, in order to attack the Moors who were settled on the coast of Barbary, a fleet, consisting of a few vessels, was delined in 1412 to sail along the westem shore of Africa, and to discover the countries that were situated on that coast. This fleet doubled Cape Non, which had been the formidable boundary of the Portuguese navigation before this period, and proceeded 160 miles beyond it to Cape Bojador. The rocky cliffs, adjacent to this cape, de- terred any farther progress. In 1418, a new attempt was made for doubling this cape, but though the attempt proved unsuccessful, it terminated in the discovery of Porto Santo; and another expedition, in 1419, was recompensed by the discovery of Madeira. The Portuguese, by their voyage to this island, were accustomed to quit the coast, and venture into the open sea. By pursing this course they succeeded, A. D. 1431, in doubling cape Bo- jador, and in advancing within the tropics; so that in a few years they discovered the river Senegal, and the whole coast extending from Cape Blanco to Cape de Verd. As far as the river Senegal they found the African coast inhabited by people resembling the Moors of Barbary; but to the south of that river, they beheld men with skins black as ebony, with short curled hair, flat noses, thick lips, and all those peculiar features which are now known to distinguish the race of negroes. The search for unknown countries became now an object of general attention; and it was encouraged first by the discovery of the Cape de Verd islands; and soon after, viz. in 1449, by that of the Azores. So slow and gradual, however, was the progres- s of discovery, that the Portuguefe, during the life of prince Henry, who had projected and patronised undertakings of this kind, and who died in 1493, did not advance nearer to the equinoctial line than five degrees; and after their continued expeditions for half a century, they had not dis- covered more than 1500 miles of the African coast. From Cape Non to the Senegal, the country along the coast was found to be a sandy, barren tract, thinly inhabited by a wretched people, professing the Mahometan religion, and subject to the extensive empire of Morocco. But to the
of that river, the power and religion of the Mahometans were unknown; the country was divided into small independent principalities, the population was considerable, the soil fertile; and the Portuguese soon discovered that it produced ivory, rich gums, gold, and other valuable commodities, which afforded the prospect of a lucrative commerce, as well as the gratification of curiosity. Having ventured to cross the line in 1471, they found that region of the torrid zone, which was supposed to be encompassed with intolerable heat, to be not only habitable, but populous and fertile. In 1484, a powerful fleet was fitted out, which, after discovering the kingdoms of Benin and Congo, advanced above 1500 miles beyond the line; and in order to secure the possession of the countries which they discovered, and to derive commercial advantages from them, forts were erected on the coast of Guinea, colonies were settled on, and by various measures of policy, the Portuguese power and commerce in Africa were established on a solid foundation. By constant intercourse with the Africans, the Portuguese gained increasing knowledge of the country; they found, that contrary to the doctrine of Ptolemy, the continent inclined towards the east; and they began to indulge a hope, founded on the report of the ancient Phoenician voyages round Africa, of proceeding by the same route to the East Indies, and of engrossing that commerce, which has been the source of wealth and power to every nation by which it has been possessed. In 1486, a voyage of discovery was projected, and the conduct of it was committed to Bartholomeu Diaz, an experienced and brave officer, who stretch'd farther towards the south than any of his predecessors, and discovered near 1000 miles of a new country. After encountering many difficulties and hazards, in an unknown and tempestuous ocean, he at length descried that lofty promontory which bounds Africa to the south; but having made the discovery, he was compelled, by the shattered state of his ships, and the turbulent disposition of his crew, to return home. This promontory he called Cabo Tormentoso, or the Stormy cape; but the king, his master, extending his views by this course to India, gave it a name of better omen, which it has ever since retained,—the Cape of Good Hope. In 1497, a squadron was equipped for prosecuting the scheme of opening a passage to the East Indies by this cape; and the command of it was entrusted with Vasco de Gama, a man of noble birth, and poiseft of talents adapted to the enterprise. Ignorant of the course of the winds in the Atlantic ocean, he set sail in July, an improper season of the year; and bearing towards the south, he struggled with contrary winds for four months, before he reached the cape. During an interval of calm weather, he doubled this formidable promontory, and pursued his voyage towards the north, along the African coast. After touching at several ports, and various adventures, he came to anchor before the city of Melinda. From hence he proceeded to Calcuta, where he arrived May 22, 1498; but as he had neither force sufficient to attempt a settlement, nor commodities proper for carrying on any commerce, he hastened back to Portugal, with an account of his successes in performing a voyage the longest, as well as the most difficult, that had ever been made since the first invention of navigation. He landed at Lisbon, Sept. 14, 1499, two years, two months, and five days from the time he left that port. To this voyage we are indebted for the discovery of the southern and western boundaries of the African continent; and from the Portuguese we also derive our earliest knowledge of many of its interior parts, and of the most confiderable kingdoms and empires of which it consists, particularly those of Habich or Abyssinia, Monomotapa, Monomug; the califer kingdoms of Congo, Angola, Matabia, Lango, and others on the western side; those of Sofala, Mozambique, Quiloa, Mombaza, and Melinda, on the eastern coast. Their missionaries collected and recorded many particulars with respect to their various religions, governments, laws, customs, products, and commerce, at a time when the means of information concerning the interior of Africa were very feantry and imperfect.

Africa, at a former distant period, contained several kingdoms and states, eminent for the liberal arts, for wealth and power, and for the most extensive commerce. Almost all the northern parts of this continent were full of people, from the Red Sea to the Atlantic Ocean. The kingdoms of Egypt and Ethiopia were much celebrated, and the rich and powerful state of Carthage extended its commerce to every region of the then known world; and even the British isles were visited by her fleets. At length the Romans, after a contest which lasted for more than 100 years, totally subdued this famous republic and destroyed their city, and then reduced under their power other kingdoms and states of Africa. See Numidia, Mauritania, Gathulia, &c. The Roman empire retained its possessions in this country for several ages, and found them an ample source of revenue as well as necessary supply.

The 10,000 Euboic or Phoenician talents, amounting to about four millions sterling, which vanquished Carthage was condemned to pay within the term of fifty years, as Polybius informs us, (Hist. l. xv. c. 2. p. 707.) were a flight acknowledgment of the superiority of Rome, and bear a very small proportion to the taxes afterwards raised both on the lands and on the persons of the inhabitants, after the fertile coasts of Africa was reduced into a province. It would be tedious to recite the oppressions which the Africans suffered from the rapacity of the Roman governors, and the disfractions which were the consequences of their religious disputes, after the introduction of Christianity, and which were rather augmented than appeased under the unfeamly interference of the civil power. Of the latter, some account will be given under the articles circumcisiones and donatists; and with respect to the former it will be sufficient to select a single instance.

About the year of our Lord 366, Count Romanus poisefted the military command of Africa. At this time the three flourishing cities of Oea, Leptis, and Sabrata, which, under the name of Tripoli, had long constituted a federal union, were invaded and pillaged by the barbarians of Gathulia; and several of the most honorable citizens were surprised and massacred. In this state of distress they applied to Romanus for succour; but the price of his assistance was so enormous, that they were incapable of purchasing it. Their application by two deputies to the emperor Valentinian was equally unavailing; for though he deputed Palladius to examine the state of Africa, and the conduct of Romanus, he behaved in such a manner that, for concealing his own guilt, he was under a necessity of attesting the innocence and merit of the Count. The charge of the Tripolitans was declared to be false and frivolous; the citizens of Leptis were compelled to contradict the truth of their own decrees, and to confine the behaviour of their own deputies; the president of Tripoli, who had presumed to pity the distress of the province, was publicly executed at Utica; four distinguished citizens were put to death, as accomplices of the imaginary fraud, and the tongues of two others were cut out, by the express order of the age of the Count. Romanus was continued in the command, till the Africans were provoked, by his avarice, to join the rebellious standard
of Firmus the Moor, A.D. 372. Firmus was the son of one of the richest and most powerful of the Moorish princes, who acknowledged the prepotency of Rome; and having slain his brother in a domestic quarrel, he became obnoxious to the displeasure of Romanus. Unable to conciliate him, he appealed against the tyrant, who was an object of universal contempt and hatred, to the sword and to the people. Having established his power in the province of Mauritania and Numidia, and whilst he was hesitating whether he should assume the diadem of a Moorish king, or the purple of a Roman emperor, Theodosius, the famous Roman general, with a small band of veterans, unexpectedly arrived on the African coast, and quelled the rebellion by his prudence and activity; and Firmus, deprived of all hopes of escape, dis-appointed the insulting triumph of the Romans, by strangling himself in the night. Romanus, who was the original cause of this rebellion, escaped with impunity, by fraud and forgery; and Theodosius, the restorer of Britain and of Africa, on a vague suspicion that his name and services were superior to the rank of a subject, was ignominiously beheaded at Carthage. Gibbon's Hist. vol. iv. 391—398. 8vo.

The Romans, however, did not long retain their dominion in Africa. It was lost in consequence of a quarrel between Boniface and Atius, two Roman generals, who were rivals in reputation and power. The former was supreme governor of the Roman territories in this country; but in the year 427, he was induced to revolt, by the treachery of the latter: and in order to avenge his quarrel and maintain his authority, in opposition to his rival, he sought the assistance of Genéric, a warlike prince of the Vandals, who left the kingdom of Gælica, where he had succeeded his brother Gonderic, and sailing over the straits of Gades, landed on the coast of Barbary, A.D. 429. The army, which he commanded, amounted at first only to 50,000 effective men: but his own dexterity, and the discontents of Africa, soon fortified the Vandal powers, by the accession of numerous and active allies. The wandering Moors of Mauritania precipitated themselves into an alliance with the enemies of Rome; and a crowd of naked savages rushed from the woods and vallies of Mount Atlas, to fatten the Vandal's rapine on the pillaged tyrants, who, in injudiciously expelled them, had given away the heritage of the land. The perfections of the Donatists favoured the designs of Genéric, who avowed himself an enemy of the orthodox communion, and who led them to expect a repeal of the odious and oppressive edicts of the Roman emperors. The conquest of Africa was facilitated by the active zeal, or the secret favour, of a domestic faction; and the intolerant spirit, which disgraced the triumph of Chilperic, contributed to the loss of the most important province of the west.

Boniface having vindicated his innocence at the imperial court, and regained the favour of the emperors Placidia, repealed the application which he had made to Genéric, and attempted, by various conciliatory means, to induce him and his adventurers to return to Spain. But all his efforts for this purpose were ineffectual. Although Carthage, and the Roman garrisons, returned with their general to the allegiance of Valentinian, the revolt of Africa was distracted with war and faction; and the invincible king of the Vandals disdained all terms of accommodation. Boniface and his veterans, with the hafty levies of provincial troops, were defeated with considerable loss; the victorious barbarians insulted the open country; and Carthage, Cirta, and Hippo Regius were the only cities that still adhered to the declining interest of Rome. The long and narrow tract of the African coast to which the Roman power extended was fertile and populous; and besides the supply which it afforded to the inhabitants, the annual exportation, particularly of wheat, was so regular and plentiful that Africa deferred the name of the common granary of Rome and of mankind; and it was called by an ancient writer the soul of the commonwealth. On a sudden, the seven provinces, from Tangier to Tripoli, were overwhelmed by the invasion of the Vandals; and where they found resistance, such were their depredations and habits, they seldom gave quarter. Boniface disapproved beyond measure by the view of the ruin which he had occasioned, and by his inability to stay its progress, retired into Hippo Regius, which was immediately besieged. By the skill of this distinguished commander, the siege was protracted above fourteen months; and thus Boniface was recruited by a powerful armament from Constantiopole. As soon as he obtained this help he marched out against the Vandals; and the loss of a second battle irretrievably decided the fate of Africa; upon which he embarked for Italy with the precipitation of despair, and soon after, A.D. 432, fell in a rencounter with his rival Atius. In the year 439 Carthage was reduced, 585 years after the destruction of the city and republic by the younger Scipio; the licentious troops of the victor were permitted to ravage, and violence, and all persons were enjoined by an edict, and under the threatened penalty of death and torture, to deliver their gold, silver, jewels, and valuable furniture or apparel, to the royal officers. The lands that formed the immediate district of Carthage were divided among the barbarians; and Genéric, received for his own domain the fertile territory of Byzacium and the adjacent parts of Numidia and Getulia. Genéric was no less arbitrary and intolerant in the government of the church than of the state. He would not allow the Africans, who fled before him in the field, to dispute his will in synods and churches; and therefore, as he himself had renounced the orthodox communion, he oppressed his catholic subjects by severe laws and punishments. His son Huneric, who succeeded him, A.D. 477, inherited his vices, and tormented the catholicks with the same unrelenting fury. The throne of Africa was successively filled by the two nephews of Huneric, Hilderic and Damaud, A.D. 484, and by Thraevenus, A.D. 486; both of whom emulated the cruelty of their uncle, and the laity of whom even exceeded it; for the hour of death he exacted from his successor a solemn oath, that he would never tolerate the fectors of Athanarus. Hilderic, the gentle son of the savage Huneric, ascended the throne A.D. 513, and his accension was distinguished by the restitution of peace and universal freedom. In 519, the government was wrested from him by his cousin Gelimer; but the Vandal kingdom, before he could enjoy or abuse his power, was subverted by the arms of Belisarius; and the orthodox party retaliated the injuries which they had suffered. The recovery of Africa was intrusted to Jutinian with Belisarius; and in 533 he landed on the coast with an army, well chosen and properly equipped for the important service to which they were destined. As the Romans approached Carthage, the mind of Gelimer was filled with anxiety and terror. The battle that ensued terminated in the defeat of the Vandals, who, accoutered only to a Moorish enemy, were incapable of withholding the arms and discipline of the Romans. Gelimer fled toward the defects of Numidia, and Belisarius pitched his camp on the field of victory at the distance of ten miles from Carthage. When he drew near the city, he found it blazing with torches, as signals of the public joy; the gates were thrown open; and the inhabitants, with acclamations of gratitude, hailed and welcomed their Roman deliverers.
The battle, feared while joined, decided Africa. The victors were triumphantly admitted to the city, and the Vandals, claiming the cities which Gelimer had assigned to the victorious troops. The dissatisfaction and mutiny increased; and they were aggravated by soldiers, who had imbibed the doctrines, and were inflamed by the clergy of the Arian sect. A conspiracy was formed at Carthage, against the life of Solomon, the successor of Gelimer; and a furious sedition was kindled in the Circus which defoliated Africa above ten years. The head of the insurgents was a private soldier, whose name was Stzoa. When he fell, another person, called Gonthar, promised to divide Africa with the Moors, and aspire to the throne of Carthage. His reign, however, lasted only 30 days. The rebellion of the Moors continued for some time; but their insurrection was checked by a battle, in which 17 of their princes were slain, and the submission of their tribes was celebrated with laviith applause by the people of Constantinople. Such irritation, as it has been observed, was the defolation of Africa in the reign of Julian, that, in many parts, a stranger might wander whole days without seeing the face of either a friend or an enemy. The nation of the Vandals, amounting to 150,000 warriors, exclusively of children, women, and slaves, had disappeared. Their number was much exceeded by that of the Moorish families, extirpated in a relentless war; and the fame destruction was retaliated on the Romans and their allies, who perished by the climate, their mutual quarrels, and the rage of the barbarians. Proporcius confidently affirms, that five millions of Africans were consumed by the wars and government of the emperor Julian. The conquest of Africa, by the Saracens, was first attempted by the arms of the caliph Othman, A. D. 647; and the conduct of the war was entrusted to Abdullah, his younger-brother. After some partial successes and very considerable losses, in a campaign of 15 months, the Saracens retreated to the confines of Egypt, with their captives and the wealth of their African expedition. Their western conquests were suspended near 20 years. At length the fearless Akaah plunged into the heart of the country, traversed the wilderness, in which his successors erected the splendid capitals of Fez and Morocco, and penetrated farther to the verge of the Atlantic and the Great Desert. The career of Akaah was restrained by the prospect of a boundless ocean. Spurring his horse into the waves, and raising his eyes to heaven, he exclaimed with the tone of a fanatic—"Great God! if my course were not stopped by this sea, I would still go on, to the unknown kingdoms of the west, preaching the unity of thy holy name, and putting to the sword the rebellious nations who worship any other god than thee." But this ardent conqueror was recalled from the shores of the Atlantic by the defection of the Africans; and overpowered by a multitude of infidets, he had only the respite of an honourable death. His fate was avenged by his successor Zuheir, who vanquished the natives in many battles, and was himself overcome by a powerful army, sent from Constantinople to the relief of Carthage. The conquest of Africa was resumed by the caliph Abdalmalek; and after some progress, his farther advances were obstructed by the forces of the eastern empire, under the prefect and patrician John, a general of experience and renown. But in the ensuing spring, he was compelled to evacuate the fortifications of Carthage; and after a second battle in the neighbourhood of Utica, the Greeks and Goths were again defeated, and
and compelled to embark, and make their escape. The conquest of Africa was finally completed between the years 699 and 709. To the progress and establishment of the Saracens, we may ascribe the decline and extinction of Christiainity, on the northern coast of Africa, Gibbon's Hill, of the Decline and Fall of the Roman Empire, vol. iv. 501. vol. vii. 169. 1386. 349. vol. ix. 449. &c.

When the Saracens empire was divided into seven kingdoms in 936, the African states retained their independence long after the others were subdued by the Turks; but in the beginning of the 16th century, being afraid of falling under the yoke of Spain, they invited the Turks to their assistance; who first protected, and then enslaved them. They are still dependent on the Ottoman empire; not as subjects of the Grand Seignior, but as acknowledging his protection by an annual tribute. On the coast piracy prevails to such a degree, that some of the chief princes in Europe have been glad to procure liberty to trade in the Mediterranean without molestation, by a pecuniary compensation.

Africa, as it is described by modern geographers, is a large peninsula, connected with Asia by the isthmus of Suez; bounded on the north by the Mediterranean, which separates it from Europe; on the east by the above-named isthmus, the Red Sea, and the Indian Ocean, which divides it from Asia; on the south by the Southern Ocean; and on the west by the Atlantic, which separates it from America; and extending from Cape Bona in the Mediterranean, 37° 10' N. lat. to the Cape of Good Hope, 34° 25' S. lat. or about 4900 miles, and from Cape Verd 17° 33' W. long. to Cape Guardafui, near the straits of Babelmandel, 53° 20' E. long. or about 4700 miles. Its figure is that of a triangle or pyramid, whose base is the northern part, reaching along the Mediterranean from the mouth of the Nile to the straits of Gibraltar, and vertex the Cape of Good Hope; but the sides, extending along the Atlantic to the west, and the Red Sea or Indian Ocean to the east, are very irregular. As the equator passes nearly through the middle of the country, the greatest part of it lies within the tropics; and therefore the heat, augmented by the reflection of the sandy soil of the interior parts, is hardly tolerable to any besides the natives. Those parts, however, that lie near the coasts or in valleys, and on the banks of the rivers, are very fertile and productive; and the country in general is capable of great improvement by cultivation. Its situation for commerce is preferable to that of any other quarter of the globe; as it has a more easy communication with Europe, Asia and America, than either of these has with the rest. Its coast is opposite to that of Europe, for almost 1000 miles from east to west, and the distance of one from the other is no where 100 leagues, and in some places not more than 20 leagues. It is separated from Asia only by the Red Sea for a considerable interval from north to south, and their distance is from 5 leagues to 50: it also forms the southern coast of Asia, though at a greater distance, and it is adapted for commerce by the interposition of islands from Madagascar to Malabar, and by the alteration of the trade winds. Its coast for 2000 miles lies opposite to America, and the western islands, at a distance of 500 to 700 leagues. Besides, it has many large and navigable rivers, which intersect the country in various directions, and form a communication between the internal parts and the surrounding ocean; and its harbours are very numerous and commodious, and capable of being rendered secure by fortifications. The principal rivers of Africa which we shall more particularly describe under their several names, are the Nile, Niger, Morocco, Gambia, Senegal, Sierra Leone, Benin, Congo, Zaire, Wanzu, Bravahu, Rio del Spirito Santo, Kuneki, Macunhu, Lorenzo, Sarla, Kuanu or Zambeze, Coavo, Zebby, and Magadona. There are many other rivers which will be mentioned in the detail of the several countries to which they belong. On the banks of several of these rivers there are villages and towns, which carry on a considerable traffic, and exchange their valuable commodities, as gums, elephant's teeth, slaves, civet, bezar, and gold dust for European trinkets, glafs beads, bugles, or, at best, some brazs or iron tools, and frequently for brandy and other spiritous liquors, of which the inhabitants are too fond that they will part even with their children in order to obtain them. Another source of commerce is found in the mines with which the mountains abound. The mountains of Africa are the Atlas, the mountains of the Moon, the mountains of Sierra Leone; the mountains of Crystol near the like of Zañan, so called from their mines of that beautiful mineral, and those of falt-petre, stretching eastward from the kingdom of Congo, the Pico-franco running through the middle of Caffaria, and part of the country of the Hottentots, the Table mountain at the Cape of Good Hope, so called from its square figure, and other mountains of Abyssinia. From the discoveries of Mr. Park, a late traveller in Africa, we learn, that a belt of mountains, extending from west to east, occupies the parallels between 10 and 11 degrees of N. lat. This great ridge of mountains is very productive in gold, and more particularly in the parts opposite to Mandingo and Bambouron, on the west, and to Wangara on the east. See Tomburro.—Most of the countries bordering on the mountains share in their wealth by means of the rivulets that flow from them. There is no country in the world, fays Gibbon, richer in gold and silver than some kingdoms in Africa; as those of Mandingo, Ethiopia, Congo, Angola, Batna, Quincti, Monomotapa, Calcut and Moenemugi. Father Labat also minutely specifies a great variety of rich mines, of which the negroes have not been able to avail themselves sufficiently, on account of their ignorance of the operations of mining. Copper is a valuable ore found in this part of the globe; and in such abundance, that an opinion prevails, that the mountains called Atlas are all copper. On the northern coasts, the fields, though imperfectly cultivated, produce very large crops of grain: and it is very reasonably supposed, from the quality of the soil and climate in different parts of the country, that the richest articles of the East and West-India commerce might be obtained from Africa. The spices of Banda, Ternate and Ambonova, might be produced on the rich and fruitful shores of Melinda on the east side, or on those of the slave coast on the west side of the country. The cinnamon of Ceylon, the tea of China and Japan, and the coffee of Mocha, might be produced on the same coast; and it has been affirmed, that the sugars of Barbadoes and Jamaica, and also the ginger, cotton, rice, pepper or pimento, the cocoa, the indigo, and every other plant which is now obtained from these islands, would be as easily produced in Africa, and that the crops would be equally profitable, if they were cultivated with the same skill and industry as in Africa. Notwithstanding the capability of cultivation, and the advantages for commerce which Africa possesses, it is lamentable to reflect, that a country which has near 10,000 miles of sea-coast, many large rivers and good harbours, a productive soil and extensive population, should remain destitute of the benefits which arts and industry, and commerce, might afford them. It is a reproach to neighbouring nations, that such a country should be so long neglected;
and reflected; and that the principal advantage derived from it should be of that kind, which entails war and wretchedness on the Africans themselves, which perpetuates the degradation and misery of so great a part of the human species, and which reflects indelible disgrace on those enlightened and Christian empires of the globe, that, amid all the improvements of modern times and various laudable attempts for ameliorating the condition of mankind, have not, at the commencement of the nineteenth century of the Christian era, abolished a traffic, long known and long lamented, under the denomination of the Slave-trade. Of the nature of this trade, and of the efforts that have been made for regulating, prohibiting and abolishing it, an account will be given under the present article. The principal branches of the African trade are slaves, gold, and ivory, which is carried on with the Guinea or western coast, by the exchange of woollen and linen manufactures, hard-ware, and spirituous liquors. The Dutch and French, as well as the English, have their different settlements for this purpose. See African Company—Gold, Grain, Ivory and Slave coasts, and Sierra Leone. The Portuguese are in possession of the coast and west coasts of Africa, from the tropic of Capricorn to the Equator; which immense tract they became masters of by their successive voyages and fortunate discovery of the Cape of Good Hope. From the coast of Zanguebar, on the eastern side, they trade not only for the articles above-mentioned, but likewise for several others, as sene, aloes, civet, ambergris and frankincense. The Dutch have also had settlements towards the southern parts of the continent, in the country called Caffaria, or the land of the Hottentots; and they were long in possession of the Cape Town, which is well settled and fortified, till it was captured by the English in 1797, but retaken and made a free port by the peace of 1801; and here their ships bound for India were accustomed to put in, and trade with the natives for their cattle, in exchange for which they gave them spirituous liquors. Some laudable attempts have been lately made for establishing colonies on the western coast of Africa, with a view of civilizing the inhabitants, introducing commerce among them, and gradually abolishing the slave-trade. Mr. Wadliff in his Essay on Colonization, published in two parts in 1794 and 1795, has given a particular account of these attempts; but we are forry to observe that their permanent utility is very doubtful and precarious. See Aquasim, Bulam, Sierra Leone, and Slave-trade. — With respect to the inland parts of Africa, they form in all ages of the world to have been in the same barbarous and uncivilized state in which we find them at present. To account for this fact, many ingenious writers have observed, that there are in Africa none of those great inlets, such as the Baltic and Adriatic seas in Europe, the Mediterranean and Enixine seas in both Europe and Asia, and the Gulphs of Arabia, Períma, India, Bengal, and Siam, in Asia, for carrying maritime commerce into the interior parts of that great continent; and the great rivers of Africa are at too great a distance from one another to give occasion to any considerable inland navigation. Béneath the commerce which any nation can carry on by means of a river, which does not break itself into any great number of branches or canals, and which runs into another territory before it reaches the sea, can never be very considerable; because it is always in the power of the nation who possesses that other territory to obstruct the communication between the upper country and the sea. Smith's Wealth of Nations, vol. i. p. 32. The chief capes on the African coast are Bon, Blanco, Cantin, Geer, Non, Borjador, Barbé, Veré, Monte, Palmas, Three Points, Coast, For-

African Company.
lefted in the Desert. Hence he infers, that there must be a large hollow in the interior of Africa, between the high land of Nubia on the east, and Manding on the west, and of which the mountains and desert form the other two sides; similar to the cavity in Asia, to whose waters the Capfian and Aral serve as recipients. The third part of North Africa, in the distribution of Mr. Rennell, is the Great Desert or Sahara, and its members, consisting of the latter deserts of Bornou, Bilma, Barea, Sort, &c. For the description of this part, see Sahara.

Many laudable attempts have been lately made, under the encouragement afforded by the African Association, for discovering the interior, and hitherto very much unknown, parts of Africa. Mr. Park, a very intelligent and intrepid, and it may justly be added, a very successful adventurer in this minion, has made several important discoveries. Having left Pisania, N. lat. 12° 35' about 300 miles from the mouth of the Gambia, Dec. 2, 1795, he returned thither after an absence of eighteen months. In this long interval of time, he explored the interior of Africa to the distance of 1100 miles in a direct line from Cape Verdi; proceeding in a tract bounded by the 15th and returning by the 12th parallel of latitude. His first station was Medina, the capital of the kingdom of Woolli, where he pursued his journey by Kolor, to Kooja, the frontier towns of this country. Here he refreshed himself with a liqueur made from corn previously malted, with bitter roots instead of hops. After pursuing a wilderness of two days journey, he reached Taliika, the frontier town of Bondou, and at Battecondja, the capital, he was introduced to the king Almami. From Bondou Mr. Park proceeded to the kingdom of Kajaga, and having been ill treated at Joag, the frontier town, he proceeded his journey to the kingdom of Kasson, and passing Tesse, the frontier town, arrived at Koninarka, the capital. Here he was treated kindly by the king; and having remained here for some time, he resumed his journey, and arrived at Kemmo, the capital of Kaarta. Following the route which Daft, the king of this country, prescribed, through the kingdom of Ludamar to that of Bambarra, he passed Marina, on his way to Simbing, the frontier town of Ludamar.

Having left Jarrak, the frontier town of this country, he pursued his journey and reached Sampaka. He was afterwards seized by a party of Moors, and conducted back to Benown, the residence of Ali, king of Ludamar, where he was treated with great severity by the bigoted and malicious Moors, and escaped death only by a pillar's being missing fire. At length he fortunately escaped, and reached a negro town called Wakra, belonging to Manfong, king of Bambarra; and passing through several towns of this kingdom, he arrived at Sango, on the banks of the Niger, which he found to be as broad as the Thames at Westminster, and flowing slowly to the southward. Pursuing his course in this direction along the banks of the river, he passed through the town of Kabba, Modibo, and Ken, and reached Moorzan. Here he crossed the Niger to Silla, which was the termination of his journey to the east. In his return westward on the northern bank of the river, he arrived at Bamako, the frontier of the kingdom of Bambara, and quitting the Niger at this place, he proceeded to Simbogolo, the frontier town of the kingdom of Manding. Hence he pursued his journey to Kamalia, where he remained seven months. In his progress from Kamalia he traversed the Jalonko wilderness, by an interval of 1100 miles, and having crossed the Black River, a principal branch of the Senegal, he arrived at Malecotta; and after a journey of 500 miles reached Medina, the capital of the kingdom of Woolli's dominions, on the 4th of June 1797, which he had left in December 1795. From hence he proceeded to Pisania, and afterwards returned to England.

All the inhabitants of the African continent, though distinguished under a variety of denominations, according to their different situations, origin, tribes, and governments, are commonly included under the twofold distinction of Africans and Arabs, or Whites and Blacks. The white Africans, according to Leo Africanus, (l. i. c. 9.) and Marmol, (l. i. c. 24.) are divided into five nations or tribes, viz. the Zambians, Musmurnan; Zemite, Gomeranian, and Hosses; and to these were added families of Bythians, and the most considerable ones in Africa, owe their origin. They first settled in Barbary, and from thence gradually dispersed themselves over the greatest part of Africa. For an account of the black Africans, see Blacks and Negroes.

The Ancients and Moderns have concurred in giving a very unfavourable representation of the disposition and character of the native Africans. Lucan (l. iv.) Virgil (Aen. viii. cum not. Servii) and many others, describe them as proud, indolent, thievish, revengeful, addicted to all kinds of lust, cruel, inconstant, superstitious, and cowardly. So general has been the unfavourable opinion entertained concerning these people, that it has given occasion to a common proverb, that all the inhabitants of the globe have some good as well as ill qualities, except the Africans. But this degeneracy of character is owing more to their bad education, their tyrannical governments, and their unfelted state, than to their country; for this has produced several distinguished persons, among whom we might enumerate St. Cyprian, Angulim, and Tertullian, in the class of divines; Hannibal and Afridual, in the list of heroes; Terence among the poets, and many others. We might also appeal to the industry with which they have formerly cultivated their lands, and applied to commerce and the useful arts. If they are now, too generally, ignorant and depraved, idle, diabolical, or superstitious, we are to seek the cause of the evil in the nature of their governments, and the inattention and neglect with which they have been treated. The religion of the native Africans has been the grossest kind of idolatry, blended with the magical and superstitious rites of the ancient Egyptians. Nevertheless we discover many relics of Judaism not only in Abyssinia, but in many other parts of Africa; where many Jews, driven there at a very early period, or by the dispersion after the destruction of Jerusalem, by the perfections of later times, have settled and maintained their religious worship and ceremonies. Christianity was also introduced at an early age of the Christian era into this country, and has fulfilled, under one form or other, and amidst great disturbances and corruptions, in various districts of Africa to the present day. The interior parts of Africa remain still in the darkenss of Paganism, as they have been in a great degree inaccessible to the most adventurous of the Europeans. Indeed, in the maritime provinces of this great peninsula, and especially where the Portuguese have their settlements, there are several districts in which the religion of Rome has prevailed over the savage superstitions of that barbarous region. But the ingenious historians, even of the Roman Catholic persuasion, who have given accounts of the African colonies, acknowledge that of the probity made to the faith of the gospel few deserve the denomination of Christians; as most of them retain the abominable superstitions of their ancestors, and the belief among them in their own profession by various practices of a most vicious and corrupt nature. The missions in Africa have been much neglected by the Portuguese; and the few
millenaries that were sent thither were men void of learning, and delirious almost of every qualification that was necessary towards carrying on such an important undertaking. What may be the result of Protestant millions, more lately undertaken and prosecuted with a considerable degree of zeal, time alone must discover. Those who liberally patronize and encourage them, anger from circumstances that have already occurred incalculable. But the most prevalent religion in Africa (if we except Paganism) is that of Mahomet, which is blended and intermixed with tenets and practices, that are more or less of Pagan, Jewish, and Christian original. See Marabout. Of the habits and manners of the Africans, an account will occur under the appellation of Africa, under the different denominations by which they are distinguished, as Moors, Negroes, &c. and in the description of the different countries in which they reside.

The interior parts of Africa are inhabited, according to Mr. Park’s report, by three distinct races of men: viz., the Mandingoos or proper negroes, native children of Niger; the Foulahs, or white Ethiopians of Tolaemy and Pliny, who have neither the crisp hair, the thick lips, nor jetty blackness of the Mandingoos; and the Moors, natives of Arabia, who, in their persons and complexions, exactly resemble the Mulattoes of our West Indies, and who are devoted followers of Mahomet, and the most intolerant, perfidious, and fanguinary of the human race. Though these three nations are frequently intermixed, yet the negroes, whether Mandingoos or Foulahs, generally inhabit to the south of the moors. The negroes are for the most part husbandmen; the moors, like their Arabian ancestors, are roving shepherds, or wandering merchants, who, from the earliest times, to have overspread the habitable parts of the great African desert, and the Oases or fertile isles, thinly scattered through that sandy ocean. Hence they extended their arms southwards, and made themselves masters of the several negro kingdoms on the Niger; so that their dominions form a narrow belt running from west to east on the skirts of the Desert, from the Atlantic coast to the mountains of Abyssinia. The common boundary of the moors and negroes forms a striking feature in the moral, as well as in the political and physical geography of Africa. Herodotus (compare En-tant, p. 32, and Melpomene, p. 197—pp. 117 and 368. Ed. Wilks) fixed the boundary of the Libyans and Ethiopians, i.e. of the moors and negroes, near the banks of the Niger; and in this respect circumstances do not seem to have been materially altered since his time.

Mr. Park observes, that the population in the countries which he visited was not very great, considering the extent and fertility of the soil, and the climate with which lands were obtained. He found many extensive and beautiful districts entirely delitute of inhabitants; and, in general, the borders of the different kingdoms were either very thinly peopled, or entirely deserted. Many places, such as the banks of the Gambia, the Senegal, and other rivers towards the coast, were unhealthful, and on this account unfavourable to population. To this circumstance, it is chiefly owing, that the interior countries abound more with inhabitants than the maritime districts; for the negro nations, observed by this traveller, though divided into a number of petty independent states, inhabited chiefly by the same means, live nearly in the same temperature, and possess a wonderful sameness of disposition. Perhaps the circumstance of the slave trade may suggest another cause of the poverty of native inhabitants towards the sea-coast. Our traveller concurs with others in representing the disposition of the women as uniformly benevolent; in proof of this the following incident is related. When Mr. Park was prohibited by the king of Bamburra from crossing the Niger, and ordered to pass the night in a distant village, none of the inhabitants would receive him into their houses, and he was preparing to lodge in the branches of a tree. In this state, exhausted with hunger and fatigue, and unprotected from a storm, he was relieved by a woman who was returning from the labours of the field. To her he was kindly invited; and his distress was alleviated by the tender attention which he experienced. The female part of the family, says Mr. Park, lightened their labour by fongs, one of which was composed extempore; for I was myself the subject of it. It was sung by one of the young women, the veil joining in a fort of chorus. The air was sweet and plaintive; and the words, literally translated, were these: ‘The winds roared, and the rains fell. —The poor white man, faint and weary, came and sat under our tree. He has no mother to bring him milk; no wife to grind his corn.—Chorus. Let us pity the white man; no mother has he, &c. &c.’ These words have since formed into verse by the Dukes of Devonshire, and set to music by Ferrari; and the song is as follows:

I.

The loud wind roared, the rain fell fast;
The white man yielded to the blast:
He sat down, beneath our tree;
For weary, sad, and faint was he:
And ah! no wife or mother’s care,
For him, the milk or corn prepare.

Chorus.

The white man’s dwelling is so drear;
Alas! no wife, or mother’s care,
For him, the milk or corn prepare.

II.

The storm is o’er; the tempest past:
And mercy’s voice has hushed the blast:
The wind is heard in whispers low,
The white man far away must go:
But ever in his heart will bear
Remembrance of the negro’s care.

Chorus.

Go, white man, go— but with thee bear
The negro’s wife, the negro’s prayer:
Remembrance of the negro’s care.

From Mr. Park we further learn, that with respect to the property in the soil, the lands in native woods were considered as belonging to the king, or, where the government was not monarchical, to the state. When any individual of free condition had the means of cultivating more land than he actually possessed, he applied to the chief of the district, who allowed him an extension of territory, on condition of forfeiture, if the lands were not brought into cultivation by a given period. The condition being fulfilled, the soil became vested in the possessor; and, for aught he knew, descended to the heirs. The Africans appear to have no astronomical knowledge; and the little geography to which they pretend is erroneous; for they suppose, that the earth is an extended plain beyond which is the sea, or river of salt-water; and on the farther shores of which are situated two countries, called Tobano doo, and Jang fang dao, ‘the land of the white people!’ and ‘the land where slaves are sold.’ Park’s Travels in the interior districts of Africa in 1795, 1796, 1797. "African; or, the name of a sea port of Tunis on the coast of Barbary."
Barbary, 30 leagues south-east from Tunis, N. lat. 32° 60'. E. long. 11° 10'. The fortifications were demolished by Charles V.

AFRICA, in Antiquity, is represented on medals by the head of a woman, dressed in the skin of an elephant, with the trunk projecting forward in front. This kind of attire is peculiar to some queens of Egypt. Near the figure of Africa we frequently see a scorpion, serpent, or lion, animals belonging to this part of the world, and mountains alluding to the seven mountains of Mauritania Tingitana.

AFRICAN Affidation was formed in 1788, with a view of promoting the discovery of the interior parts of Africa. Out of 57 members, of which this society appears to have confided, a committee of five gentlemen was elected, for directing its funds, conducting its correspondence, and the choice of the persons to whom the geographic millions was to be assigned. These gentlemen were Lord Rawdon, the Bishop of Landaff, (Dr. Watfon) Sir Joseph Banks, H. Beaufoy, Esq., and Mr. Stuart. The two first persons that were appointed for accomplishing the laudable object of the society were Mr. Ledyard and Mr. Lucas. The former undertook, at his own expense, the perilous task of traveling from caft to west in the latitude attributed to the Niger, the widest part of the continent of Africa. With this view he arrived at Cairo in Augulf 1788; but death disappointed the hopes that were formed from his projected journey. For a short account of the singular adventures of this extraordinary man, see LEDYARD. Mr. LUcas embarked for Tripoli in October 1788, with instructions to proceed over the desert of Zaara to Fezzan, to collect, and to transmit by way of Tripoli, whatever intelligence he could obtain respecting the interior of the continent, and to return by way of Gambia, or the coast of Guinea. The peregrinations of this traveller terminated at Mefurata, in Feb. 7, 1789; and he was able to transmit to the society only the refult of his conferences with perrons who were travelling with him to Fezzan. See FEZZAN, BORNOU, and CASINA. The object of Mr. Park's million was to ascertain the course, and, if possible, the rise and termination of the Niger, and to use his utmost exertions for visiting the principal towns in its neighbourhood, particularly TOMBOCTOO and Houssa; and of the refult of it some account is given in the preceding article, and will be farther found under the several heads to which we have referred.

AFRICAN Company. See Company.

AFRICAN Islands are distributed into those which lie in the Eafern or Indian Ocean, and those of the Western or Atlantic Ocean. The former are SUCHUR and SOCOOTRA, BABELMANDEL, COMORAS, lands, MAURITIUS, MADAGASCAR, and BOURBON. The latter are ST. HELENA, ASCENSION, ST. MATTHEW, ST. THOMAS, ST. ANNA, ANDREAS, PRINCE'S island, Fernando Po, Goree, Cape Verde Islands, ARGUIN island, CANARY islands, MADEIRA, PORTO SANTO, and the AZORES.

AFRICANUS, JULIUS, in Biography, an eminent Christian writer and chronologer, who flourished in the beginning of the third century. It is not certain, whether he was a native of Palestine, or of Africa; but as he was employed in an embassy to the emperor Heliogabalus, between the years 215 and 222, for the reformation of Emmaus, which was afterwards called Nicopolis, and as he attended the lectures of Heraclus, at Alexandria, some time before the year 231, there can be no doubt concerning the time in which he lived. Some says he was of Africa; but his more confirm refidence seems to have been in Palestine, where he was probably born.

The works ascribed to this author by Eusebius and Photius are "the Celi," a collection of passages from various authors, chiefly on physical topics, of which only a few fragments remain; "Chronology," in five books, containing a recital of events from the creation to the year of Christ 221; and two letters, "one to Origen," concerning the history of Sufanna, annexed to the book of Daniel, which he considers to be a forgery, and "another to Ariades," for reconciling the disaffairment between Matthew and Luke, on the genealogy of Christ. The Celi is ascribed by Eusebius to Phoebus, as concise and yet comprehending every thing necessary to be related. Some fragments of it are preserved; and have been freely used both by Eusebius in his chronicle and by other historians.

Of the letter to Ariades, there is a large fragment in Eusebius's Ecclesiastical History, and the entire letter to Origen is extant, which is learned and critical, and does great honour to its author. Africanus affords a valuable attestation to the two Gospels of St. Matthew and St. Luke; and we have sufficient reason to believe, that this great and learned man received as scripture the books generally received by Christians in his time. "We may glory," says the excellent Dr. Lardner, "in Africanus as a christian. For it cannot but be a pleasure to observe, that in those early days there were some within the inclosure of the church of Christ, whole fluiling abilities rendered them the ornament of the age in which they lived; when they appear also to have been men of unfotted characters, and give evident proofs of honesty and integrity." Lardner's works, vol. ii. p. 431.

AFRICANUS, Leo. See Leo Africanus.

AFRICANUS, Scipio. See Scipio.

AFRICERONES, a people, according to Ptolemy, of Libya, a province of Africa.

AFRICTA denotes a kind of wafers, which the ancients ufed in their facrifices. Arnob. lib. vii.

AFRIQUE, in Geography, a small town of France, in the department of Aveyron, six miles east of Valbres.

AFRIQUE, a mountain of France in Burgundy, extending between Dijon and the small town of Chagni about ten leagues. At the foot of these mountains the vines are found which yield the Burgundy wine.

AFSHAR, the denomination of a Turcoman tribe, which is divided into two or three classes, one of which the father of Kuli Khan was chief.

AFSLAGERS, persons appointed by the burgo-masters of Amsterdam, to preside over the public foles made in that city. They muft always have a clerk of the secretary's office with them, to take an account of the fale. They correspond to our brokers, or auctioneers.

AFT, the hinder part of the ship, or that nearest the stern. See AftafT.

AFTER, is a term applied to any object in the hinder part of the ship, as after-hatchways, after-fails, &c.

AFTER-BIRTH, in Midwifery. See Placenta.

AFTER-GRASS, or After-math, in Agriculture, denotes the second crop, or grass which springs up after mowing; or grass-math that is cut after some kinds of corn.

AFTER-MOON, the latter half of the artificial day, or that space between noon and night.

The ancient Romans dedicated their afternoons to diversion,
After-falls usually comprehend all those which are extended on the mizen-mast, and on the stays, between the mizen and main masts.

After-threes, or pangs, eninus posteri, dolores post partum, in Midwifery, are pains resembling labour pains, though ordinarily less violent, which occur after the expulsion of the fetus and placenta. They are occasioned by the contraction of the uterus to expel congealed blood, parts of the membranes, or other foreign bodies from its cavity, as well as to reduce the capacity of the blood vessels, which during pregnancy acquire a considerable magnitude, to the size they had prior to conception. They are more or less frequent in different women, but are found very rarely to occur after first labours. They are more frequent, severe, and lasting, after the birth of large, than of small or middling sized children, or after labours that have terminated in an unusually quick and rapid manner, particularly if the placenta has been extracted almost immediately after the birth of the child. Mr. White, of Manchester, to whom we are indebted for many valuable practical observations, on the manner of conducting labour, is of opinion, that after-pains are almost entirely occasioned by extracting the shoulder and body of the child, immediately after the birth of the head, instead of waiting and suffering them to be expelled by the pains; and says, that by pursuing a different course, and leaving the whole of the process to nature, in ordinary cases, he had been fortunate, that, in the course of several years, he had neither been under the necessity of introducing his hand into the uterus to extract the placenta, nor to give opiates or other medicines to quiet after-pains, except in a single instance, “the after-pains having been so tolerable, under his management, both with regard to violence and duration, as not to deserve notice.” Treatment on the management of pregnant and lying-in-women, p. 111. See more on this subject, under the word Labour. After-pains, even when most severe, are still unattended with danger. They are best relieved by the application of warm cloths, with gentle friction, to the abdomen, by giving internally twenty-five or thirty drops of the tincture of opium, or by assiduously rubbing upon the region of the uterus, a mixture composed of four parts volatile liniment, and one of the tincture of opium, by administering frequent draughts of warm gruel, and giving caltor oil, or some other gentle purge on the following day. See Labour.

After-swarms, in speaking of bees, are secondary or posterior swarms, frequently found to quit the hives within a fortnight after the first.

Boutier tells us, that the after-swarms differ from the prime, in that the latter are directed by the vulgar, or crowd of bees, whose only rule is the fulness of the hive; whereas the former are appointed by the ruling bees, and indicated by a noise or call, which makes for the space of two or three days, as it were to give warning to the common herd to prepare for a march. Within eight or ten days after the prime swarm is gone, if the princefs next in order find a competent number fledged and ready, he begins to tune her treble voice, in a mournful and begging note, as if he prayed the queen-mother to let them go; to which voice, if she condescends a reply, by turning her back to the other's treble, it marks her consent: in consequence of which, within a day or two after, if the weather allow, the new swarm appears. If the prime swarm be broken, the after will both call and swarm the sooner, perhaps the next day; in which a third, sometimes a fourth, succeeds in the same season: but all usually within a fortnight after the prime swarm. See Swarm.

AFTO, in Botany, a name given by the natives of Guinea, to a plant of the caryophyllus kind, which they grind to powder, and take as a medicine, to cure the head ache. Pettiver has called this plant the woolly and woolly opium, or hedge-muffard, of the coasts of Guinea. Phil. Trans. N. 232.

AFUERA, in Geography. See AFUERA.

AFWESTAD, a large copper-work, belonging to the crown of Sweden, situate on the river Dal-elbe, in the province of Thalland or Dalecarlia. It resemblas a town in its extent, and has its own church. Copper-plates are manufactured, and the small copper money is coined in this place; which has also a royal poll-house.

AFZELIA, in Botany, a genus of the diaphragma angiospermin clafs and order; the characters of which are, that the calyx is quinque-partite, the corolla campanulatet, and the capsule rotundated, acuminate, double-celled, gaping at the apex and polysemous; with hemispheric receptacles. There is one species, viz. the Afzelia Caffia. This is the Afzelia of Gmelin, which Dr. Smith says is too uncertain to be honoured by such a name, after that of Adam Afzelius, professor of botany in the academy of Upsal; and therefore he has appropriated it to a new species of the decandria monoeygia clafs and order, near the Hymenaea, and of the natural order of leguminosae: the essential characters of which are, that the calyx is tubulose with a limb quadrifid, decussate; the petals are four, unguiculate, with a very large head; the laminae are two, superior, feree; the legumen many-celled; the seeds arillated at the base. It is found in Africa, near the equinoitlal. Linnaen Trans. vol. 4. p. 221.

AGA, in the language of the Moguls, &c. signifies a great man, lord, or commander.

In this last sense, the term is also used among the Turks; thus, the Aga of the Janizaries is their colonel; and is the only person who is allowed to appear before the Grand Seignior, without his arms across his breast, in the posture of a slave. The capi aga is the captain of the gate of the feraglio.

The title aga is also given, by way of courtesy, to several persons of distinction, though not in any office, or command, to entitle them to it; as to the eunuchs of the seraglio.

The chief officers under the Khan of Tartary are called by this name. And among the Algerines, we read of agas chosen from among the boltek beyfars (the first rank of military officers), and sent to govern in chief the towns and garrisons of that state. See Alger.

On some occasions, in lieu of aga, they say agathi, or agaffi. Thus the aga, or governor of the pases, is called capi agathi, and the aga or general of the horde, agathi aga.

AGA, or ADJA, in Geography, a village about half a mile from Anamoba, on the gold coast of Africa, where the Dutch formerly had a fort; and where, it is said, they have now one factor. Its situation is by no means favourable to commerce, as the landing is difficult and dangerous, but the adjacent country produces several valuable commodities, and among others a very fine cotton.

AGA Cretensium, in Botany, signifies the Spanish milk-thistle.
AGA. See AGAR.

AGAAZI, or AGACI, in Geography, a denomination given in Abyssinia to a class of those shepherds who are said to have been employed by the inhabitants of Cush, the first inhabitants of the country, in dispersing the produce of Arabia and the eastern coast of Africa over the Continent, and who thus acquired wealth and influence. The hobbit and most wailde of all the shephers were those that inhabited the mountains of Habab, a considerable ridge reaching along the Red Sea, from the neighbourhood of Mafiah to Suezam, and who by degrees extended themselves through the whole province of Tigré. Aga, says Mr. Bruce, denoted the nobles and chiefs of the armed shepheards, whence came their title, King of Kings; and the plural of this is Agaci, or, as it is written in the Ethiopic, Agaezi. The king of Amalek, mentioned in Samuel, ch. xv. and sixth by Samuel, was, according to this writer, an Arab shepheard. Bruce's Trav. vi. 387. Of this appellation, Ludolf (Hist. Ethiop. b. i. c. i.) gives a different etymology: The Agaezi affirmed this denomination, and called their country Gerea, either on account of the liberty they enjoyed, or because they transported themselves from one place to another: the radical word Gerea admitting both these significations. Their language is Gere; they have always had letters among them; and they are all circumcised, both men and women. This right they professed to have derived from the family of Ishmael and his descendants, with whom they were connected at an early period in their trading voyages.

AGABENI. See AGABENI.

AGABUS, in Scripture History, a prophet, and as the Greeks say, one of the 70 disciples of our Saviour (Acts xii. 28.) A. D. 43. He predicted a great famine, which, as St. Luke informs us, occurred in the 4th year of Claudius, A. D. 44. It is also mentioned by profane historians, Sucton, in Claud. c. xvii. t. i. p. 608. ed. Ptitte. Josephus, ant. l. xx. c. i. i. Oper. t. i. p. 960. ed. Haver. On this occasion, the Churlians at Antioch lent their contribution by Paul and Barnabas to Jerusalem, for the relief of their distress'd brethren. Helena, queen of Arabiae, also assisted the Jews with corn and other provisions from Egypt and Cyprus, as Josephus (ubi supra) informs us. Several years after this period (viz. A. D. 50) Agabus had an interview with St. Paul, at Cæsarea, and foretold the sufferings that awaited him at Jerusalem, whether he was determined to proceed, Acts xxii. 10. From the Greeks we learn, that Agabus suffered martyrdom at Antioch, and they observe his festival, March 8. The Latins, since the 5th century, have kept it. Feb. 9.

AGABRA, or AGAERA, in Ancient Geography, a town of Boetica, in Spain.

AGADEK, one of the Fox islands in the Northern Pacific Ocean.

AGADEZ, in Geography, a kingdom of Africa, placed by Leo Africanus and Marmol, directly east of Yguida, and by De Lille, south and south-east of it. On the coast it has the kingdom of Bornou; on the north-north-east, the defert of Lempita and Yguida; on the south, Cano; and on the west, the provinces Zapara and Guber, and a lake north of the Niger. This province is divided into two districts, the northern, called on account of its fertility the Defert, and the southern, called in graces, corn, and cattle. De Lille mentions three considerable towns in the latter division, viz. Agad, the capital of the whole province, Deyhur and Scemama, little inferior in wealth and population to the metropolis. He adds, that flax is produced here in great abundance, and that the principal trade of the natives consists in this article and manna. The southern inhabitants feed cattle, live in the open country, and resemble in their manners the wandering Arabs. Agad, the capital, called alo by the Arabs Andegaft, is situated in a valley between two high mountains, and at the spring of a considerable river that waters the southern country and discharges itself into the Niger. According to La Croix's account, the inhabitants are chiefly merchants, and strangers, who have fettle there, encloze the town with walls, and built their houses in the Meroitic fashion. The sovereignty is said to descend by the king of Tombucto, and yet to prefer the title of a powerful, independent, and delphic prince. Mod. Un. Hist. vol. xiv. p. 265. 8vo. The province of Agad. z. placed by Major Kennell, in his map of North Africa, in the eastern division of the Great Desert, or Sahara, and the capital in N. lat. 20° 15'. E. long. 13° 14'. In the proceedings of the African association, Agadex is made a province of the Calitha empire, and the inhabitants are said to load their immense caravans with the salt of Bornou, and to engrave the profits of this invaluable trade. The only acknowledgment they make for it is the trifling price which they pay in brass and copper (the currency of Bornou) to the neighbouring peacans.

AGADNA, a small town in the island of Guam.

AGAG, or AGGA, a kingdom of Africa, which depends on the empire of Monomotapa. It is bounded on the east by the country of the Negroes, and on the north by the kingdom of Tchaca. The capital is of the same name.

AGAGEER, a name given in Abyssinia to those whose business it is to hunt and kill elephants. Their appellation is formed from the word Agar, which signifies to hough or dress-lining with a sharp weapon. They perfons dwell constantly in the woods, and live entirely upon the flesh of the beasts which they kill, chiefly on that of the elephant and rhinoceros. They are light and agile, both on horse-back and on foot; of a swarthy complexion; and have European features. None of them are woolly-headed. The manner in which they kill the elephant is as follows: two men, altogether naked, mount the same horse; the foremost manages the horse, and the hindmost has a broad sword, such as the Schavonians use, and procured from Trierie; the handle of which he grasps with his left hand, whilst with his right he takes hold of a part of the blade, round which whip-cord is twilled. The edges of the sword are as sharp as a razor, and yet he thus carries it without a sheath. When the elephant is found feeding, the horfeman runs before him, and when he flies, crofles him in all directions, using at the same time a variety of expressions and exclamations, which he is foolish enough to believe the elephant understands. The animal incensed by this noise, attempts to seize the horse and rider with his trunk, or proboscis; and for this purpose he turns himself about in every direction, instead of making his escape. The horfeman after some evolutions of this kind, rides up to the side of the elephant and drops his companion on the off-side; and whilst the rider engages the attention of the animal, the other person gives him a stroke above the heel, in that part which in the human subject is called the tendon of Achilles. At this moment the horfeman turns round and takes up his companion; and runs with full speed after the rest of the herd; and sometimes an expert Agageer will kill three out of one herd. The blow commonly separates the tendon, or at least wonds it to such a degree that the weight of the animal breaks it. In this state the horfeman, and his companions, speedily dispatch the animal with their javelins and lances; when he is slain, the flesh is cut off the bones into firings; and these are hung on the branches of trees to dry, without salt; and are then laid by for their flock of provision in the season of the rains.

3 B 2
The elephant sometimes reaches the most dextrous riders with his proboscis; and having dashed the horse to the ground, sets his feet upon him, and soon tears him limb from limb. Bruce's Travels, vol. iv. 297. See Ele-
phant.

AGAI. See ACH.

AGAI, in History, a small port of Provence, about two leagues from Fréjus.

AGALACTIA, in Physic, signifies a deficiency of milk, in a mother, who is therefore called by Hippocrates of A-

AGALLEG. See CALLAG.

AGALLOCHUM, a medicinal wood imported from the East Indies, usually in small bits, of a very fragrant scent. The word is derived from the verb ἀγαλλόομαι, I角落, in allusion to the excellency of its odour. This wood is otherwise called lignum aloes, and xyloconia, q. d. aloes-wood, not that it is produced from the common aloe-plant, which yields the infradified juice of that name. It is the produce of a tree of a very different kind, growing in the East Indies, particularly Sumatra and Cochinchina, or the Excoecaria Agallocha of Linnaeus. Some call it likewise lignum paradys. It yields a concrete oil. See its chemical history in Neumann's Works, p. 420.

It is of a bluish purple colour, marked with veins and spots, very heavy and bitter; when burnt it yields drops of an allrangent liquor, and a sweet aromatic fume. It is hot and drying, and esteemed a great strengthenr of the nerves in general, but particularly of the head and stomach.

The various names and accounts given of the agallochum are so very different, as well as the specimens of it common in our shops, that it does not seem to be properly known amongst us.

Bashin and the Moderns distinguish three sorts of agallo-
chum, which differ either as to the excellence of their quality, or to the country that produces them; accordingly they call the first CALAMAC, which is the most excellent agallochum, denominated also calambae Indorum, kenam Cochinchinensis, and fokio. The second is the agallochum of the shops, denominated lignum aloes. The third is also called calambac, agallochum sylvestre, and lignum aloes Mexicanum.

M. de Loueiro, whose long residence in Cochinchina, whence the real and most esteemed agallochum is exported to all the Aryan markets, led him to an acquaintance with this substance, has described the tree which produces it, and gives a history of its formation. To the genus of plants, of which this is a species, he gives the name of aloesylum, and the particular species he calls aloesylum vertum. The reinos concretion which is found in tistle trees, when in a decayed state, is the true agallochum, the history of which is satisfactorily detailed in a Memoir, on its true nature and origin, in vol. i. of the Memoirs of the Royal Academy of Sciences, at Lisbon.

AGALMATA, in Antiquity, originally denoted the or-
caments of temples and statues; but came afterwards to be popularly used for the statues and temples themselves, and for the impositions and images on a seal.

AGAMA, in Zoology, a species of LACERTA, with a long round tail, the upper part of the neck and under part of the head aculeated, with reverse scales. There is a variety of this called iguana jamaicensis, with the tail imbricated by large scales, as the former is denominated iguana cordylina. It is found in America.

AGAMASKA, or VINERS, in Geography, an island in James's bay, in North America.

AGAMEDA, in Ancient Geography, a place in the isle of Lefbos, near Pyrrha. Here was a fountain of the same name, which had been also that of a woman, who was distinguished by her skill in preparing poisons.

AGAMEMNON, in Classical Biography, one of the heroes engaged in the Trojan war; was the son according to Homer, and according to Herodotus, the grandson of Atreus, whom he succeeded in the government of Argos and Mycenae. Homer calls him and his brother Menelaus Atrides, the sons of Atreus; but Hesiod and others say, they were the sons of Phthithenes, the brother of Atreus. Agamemnon, having engaged the fuscour of Tyndarbus, king of Sparta, drove Thyestes, his uncle, from Argos; killed his son Tantalus, and married Clytemnestra, his wife, to whom he had four daughters, but according to Euripides only two, viz. Iphigenia and Electra, and one son, the fa-
mous Orestes. To him was entrusted the command of the confederate army against Troy, which expedition commenced, according to the chronology of Bion, 1103 years before Christ. At Aulis, where the fleet was detained by contrary winds, Calchas, the foothlayer, enjoined the fa-
crifice of Iphigenia, the daughter of Agamemnon, as a prop-
itiatory offering to Diana; but his compliance with this superlitions and cruel order produced a fatal hatred between him and his wife Clytemnestra. In the Trojan war he dis-
tinguished himself as a prince and general; through his unjust treatment of Achilles, from whom he took Briseis, occa-
sioned many evils to the Greeks. Upon his return he brought him, as a concubine, Caffandra, the daughter of Priam, and was indignedly received by Clytemnestra, who had formed a criminal connection with Egithus, and who afflictcd that prince in afflating him. His son Orestes after-
ds took revenge on the murderers, and the calamitous events that marked the history of this family have been fa-
vourite subjects of the tragic muse of ancient Greece, and of its imitators in modern times. The death of Agamem-
non is the subject of a tragedy of Alcbylus and of Seneca.

AGAMEMNON, in Entomology, a species of Papilio, with black wings, spotted with green, and the hinder ones having on the under part a lunated ocellus and red spots. It is found in Asia.

AGAMEMNON's fountains were situated in Ionia, about 5000 paces from Smyrna.

AGAMENTIALIS, in Geography, a high mountain of America, in the districl of Maine, distant about six miles from Bald-head and eight from York harbour, which is a noted mark for scamen, particularly in the entry of Pafca-
taqu harbour. It is covered with wood and thurbs, and affords pasture to its summit, whence the prospect is en-
chanting. N. lat. 43° 16'. W. long. 70° 30'.

AGAMENTS, is also a river in the centre of York county, and district of Maine. It receives its waters from the ocean through the bay of Pafcatqua, and has only a scanty supply from streams of fresh water. Its mouth is about four miles south from Cape Neddie river, and admits small vessels.

AGAMI, in Ornithology, a name given by the French at Cayenne, and applied by Buffon to the Psophia crepitans of Linnaeus, the grus psophia of Pallus, the Phasania Antillarum of Brisson, and the gold-breasted trumpeter of Latham; the specific character of which is, that its head and breast are smooth and shining green. This bird is 22 inches long, with a short tail concealed by the upper covert and not pro-
jecting beyond the wings, and legs five inches high, covered with small scales, reaching two inches above the knees, which are not feathered. Its head, throat, and superior half of the neck, are covered with a short, close, and soft down; the
AGA

fore-part of the lower surface of the neck and breast are covered with a beautiful gorge of brilliant colours, varying between green, gold, green, blue, and violet; the upper part of its back and adjacent portion of the neck black, and the plumage of the hinder part of the back changes into a tawny-rufous; but the under-side of the body, and also the wings and tail are black, the great feathers which extend on the rump and tail are light ash-coloured; and the legs are greenish. The most characteristic property of these birds is the singular noise, called trumpeting, which they make, as some have commonly supposed, by the anus, but as others have ascertained, by means of their lungs and the capacity of their membranous cells. The wind-pipe, before its entrance into the breast, is about the thickness of a swan’s quill, bony and cylindrical. In the breast it is more slender and cartilaginous, and divides into two semicircular canals, formed of membranes, and capable of extension. The air-bag on the right side descends to the pelvis, and within the breast is divided into three or four cells by transverse membranous diaphragms. That on the left side is much narrower, and terminates in the loins. The common food of these birds is grain; but they also eat small fish, fleshes, and bread. In their natural state, they inhabit the forests in the warm climates of America, and associate in large flocks on the mountains; and they escape, when surprised in their haunts, by the swiftness of their feet rather than by the use of their wings, as they never rise higher than a few feet. They form a bed for their eggs, of which they lay from 10 to 16, by scattering the earth at the roots of large trees, but construct no nest. In their domestic state, they manifest a wonderful attachment to their benefactors, and are no less fond and faithful than dogs. By their intercourse with men, their iniquities are moulded like those of dogs; and it is said that they may be trained to tend a flock of sheep. They are jealous of rivals; fight with dogs, cats and birds of prey, and keep the poultry in great subjection. They follow perfoms through the streets and out of town, and it is difficult to get rid of them. Of all the feathered tribes the agami is the most attached to the society of man, and indeed is the only bird that has a social turn. In this respect it is as eminently distinguished above other birds, as the dog is above quadrupeds.

AGAMI is also a species of Ardea, in the Linnean system by Gmelin, found in Cayenne, about 31 inches long, and having long feathers in the tail. These feathers are of a deep blue; the under side of the body is rufous; the neck is of the same colour before, but bluish below, and dark blue above. The head is black, the occiput bluish and crested, the temples and the portion above the eyes white.

AGAMIA, in Ancient Geography, a promontory and port of Asia Minor, near Troy. Steph. Byz.

AGAMINA, or AGAMANA, Kebem, a borough of Meopotamia, situate, according to Ptolemy, on the Euphrates, towards 33° 57° lat.

AGAMIAM, a borough of Italy, belonging to the Infubres.

AGAMUS, a town of Asia Minor, near Heraclea.

AGAN, in Geography, one of the Ladrone islands. Here Magellan, the famous navigator, was assassinated in 1521.

AGANAGRA, in Ancient Geography, a town of India beyond the Ganges, according to Ptolemy.

AGANGINE, a people of Ethiopia.

AGANIPPE, a fountain of Helicon, sacred to the Muses, whence they derived the appellation of Aganippe.

Ovid (Fast. l. v. l. 7.) makes Hippocrene and Aganippe the same; but Solinus, and others, distinguish them and ascribe their being united to poetic licence. The water of this fountain was, to those who drank it, the test of the futor poeticus.

AGANLY river, a branch of Kuban river, which falls into the sea of Azof from the south.

AGANZAVA, a branch of Alina, in the interior part of Media, situate, according to Ptolemy, in long. 80° and lat. 39° 30′.

AGAPE, or AGAPES, formed of the Greek agon, love, in Church History, a kind of religious festival, celebrated, in the ancient church, to keep up a harmony and concord among its members. To these agapae we have a reference by St. Jude, v. 12., and also by St. Peter (2d Epistle c. ii. v. 13.) if with the Alexandrian copy, vulgar Latin, and Arabic versions, we read agazn; for apsana. Tertullian is the first author who has particularly described these feasts. Apolog. c. xxxix. Oper. p. 37. Ed. Rigalt. Having taken notice of some luxurious feasts among the Heathens, he adds, “the nature of our supper is indicated by its name; it is called by a word, which, in the Greek language, signifies love. We are not anxious about the expense of the entertainment; since we regard that as gain which is expended with a pious purpose, in the relief and refreshment of all among us that are indigent.—The occasion of our entertainment being so honourable, you may judge of the manner of its being conducted; it confines in the discharge of religious duties; it admits nothing vile, nothing immaterial. Before we sit down, prayer is made to God. The hungry eat as much as they desire, and every one drinks as much as can be useful to other men. We feast, as men, who have their minds impressed with the idea of spending the night in the worship of God; we converse, as men, who are conscious that the Lord observes them.—Prayer also concludes the feast; and every one departs to his own concerns, &c.” Pliny also (Ep. xcviii. cited by Tertullian, Apolog. c. ii. xii. supra p. 3.) evidently refers to these feasts, when he informs Trajan, that the whole fault or error of the Christians was this, that it was their custom, on a flated day, to hold their assemblies before the morning-light, and to bind themselves by a solemn (or oath) to do no wickedness, &c.; which things being performed they departed, and came again to partake of a common and innocent meal; from which however they defisted, after I published my edict against clubs or assemblies. Lucan (de Morte Peregriini &c. vii. Oper. t. iii. p. 335. Ed. Retzius) says, that when Peregrius, a Christian, was in prison, various fuppers were brought in, and their sacred discourses were delivered. These feasts seem to have been the agape of the ancient Christians. It appears, therefore, that they were of early origin, and had been long in use: yet they were not considered as an innovation of the Gospel, or observed in obedience to a divine command. If this had been the case, they would not have been discontinued in consequence of the edict of a Heathen magistrate, or diluted in future times. They were conducted with decorum, and afforded opportunities for the exercise of devotion and charity; and therefore do not warrant the reproach imputed to a celebrated historian, who, in his usual sarcastic manner, says (Gibb. Hist. vol. ii. p. 346. Svo.) that “the feasts of love or agape, constituted a very pleasing part of the public worship.” The ingenious Mr. Hallett in his discourse on the agape (Notes on several texts of scripture, &c. vol. iii. p. 235. &c.) maintains, in opposition to some other writers, that these agape, being suppers, were not concomitants, or appendages of the eucharist. They were entirely distinct and independent things, celebrated about twelve hours after the eucharist, which was celebrated in the morning. To which may be added the testimony of Justin Martyr, who, in his account of the public worship of the church, and particularly;
A garland of the eucharist, does not lay one word of the agape, or love-feast, as connected with it either before or after. They continued in the church during the four first centuries; but the council of Laodicea, about the middle of the fourth century, banished them from the churches, and still allowed them in private houses. The third council of Carthage, A. D. 397, ordains by a canon, which is repeated by the African council, in the beginning of the fifth century, that they should not be held in churches, except in cases of peculiar necessity; with which the decree of the council of Ancyra, in the beginning of the seventh century, agrees. Photius, about the middle of the ninth century, and Arsenius, in the middle of the thirteenth century, represent the matter accordingly; or that the agape were prohibited in churches, but allowed and encouraged in private houses. When they were totally abolished, we have no account. When they were occasionally charged with impurity by the Heathens, they were restrained and regulated.

The kiss of charity, with which the ceremony used to end, was no longer given between different sexes; and it was expressly forbidden to have any beds, or couches for the convenience of those who should be dispensed to eat more at their ease. Notwithstanding these precautions, it was found necessary to discontinue them; for as they were introduced when Christians had all things common, or with the community of goods, which under wise restrictions their first circumstances required, they lasted long after the diftinct of thecustom, which was the original occasion of them. See Arbyssin.

Some authors imagine the agape to have been, not a commemoration of our Saviour, but a custom borrowed from the Heathens: Miss vero ille, at referendum, says Sedulius, on the sixth chapter of the Epitome of the Corinth. de genti ad haec superfliliones venirebat. And Faustus, the Manichee, is represented by St. Augustin, as reproaching the Christians with converting the Heathen facicles into agape: to which he replies, we do not borrow our love-feasts from the facicles of the Gentiles; our love-feats feed the poor. Cont. Faust. Manich. I. xx. c. 20. Some have thought that St. Paul speaks of the agape, when he reproves the Corinthians for their disorderly practice. 1 Cor. xi. 17, &c. These agape, as Chrysostom, Theophylact, Pelagius, Occatianus, &c., imagined, immediately succeeded the eucharist, and at these feasts the disorders happened. Mr. Hallott (ubi supra) contends, that they occurred in celebrating the eucharist itself. It may be observed, that the Christians did not consider the agape as religious or divine institutions, like the Lord's supper. If they had, their councils would no more have banished them out of the churches than the eucharist itself.

AGAPANTHUS, (αγαπανθος, agapantos, pleasant flower) in Botany, a genus of the Caudex monogynus clas and order, of the natural order of Liliaceae, the Spathaceae of Linnaeus, and the Nartici of Jussieu. Its characters are, that the calyx is a flat common gaging at the side; the corolla is one-petalled, funnel-shaped and regular; tube cornered, as if composed of six claws, the border six-parted, with the parts oblong and spreading; the flaminia are six filaments inserted into the throat, shorter than the corolla, declinate; the anthers kidney-shaped and incumbent; the pistillum is a superior germ, oblong, three-cornered: the style filiform, of the length of the flaminia and declinate; the stigma simple or trifid; the pericarpium is an oblong capsule, three-fidged, three-celled, three-valved: valves navicular, with contrary disposition; the seeds numerous, oblong, compressed, and enlarged with a membrane. There is one species, viz. agapanthus umbellatus, the crinum africanum of Linnaeus, or African blue lily. This is the African tuberose hyacinth, with a blue umbellated flower.

The root of this plant is composed of thick fleshy fibres; from the same head arises a cluster of leaves, which are thick and succulent, and of a dark green colour. Between these flume the flower flanks, supporting an umbel of blue flowers in a sheath, and each flower hanging on a pedicle, about an inch long. The umbel being large, the flowers numerous, and of a light blue colour, make a fine appearance. They come out at the end of August or beginning of September, and frequently continue in beauty till spring. The flowers are those of the kaveraeallis, but this genus is different from it in its saphke. It is a native of the Cape of Good Hope, from whence it was brought to Holland, and in 1692 it was cultivated at Hampton Court.

This plant is propagated by offsets, taken off at the latter end of June, planted in separate pots, with light kitchen-garden earth, and placed in a shady situation. In five weeks the offsets will put off new roots; and the pots should then be removed to a more sunny situation, and have more water. In September they will put out their flower flanks, and toward the end of the month the flowers will begin to open, and should be removed under shelter in bad weather, but in good weather exposed to the free air. Toward the end of October they should be removed to the green-house and have the benefit of free air, and be occasionally watered during winter in mild weather, but in frost they should be kept dry. It requires only protection from frost and moisture; and should not therefore have any artificial warmth in winter, and in summer it should be placed in the open air. Martyn's Miller's Dicit.

AGAPE, in Antiquity, signifies an afternoon, or evening's meal.

AGAPETÆ, in Ecclesiastical History, a name given to certain virgins and widows, who, in the ancient church, associated themselves with, and attended on ecclesiastics, out of a motive of piety and charity.

In the primitive days there were women instituted deaconesses; who, devoting themselves to the service of the church, took up their abode with the ministers, and affixed them in their functions.

In the fervour of the primitive piety, there was nothing scandalous in these societies; but they afterwards degenerated into libertinism: insomuch, that St. Jerom afflicted, with indignation, unde agapetarum peflia in ecclesiao introit?. This gave occasion to councils to suppress them. St. Athanasius mentions a priest, named Leontius, who, to remove all occasion of suspicion, offered to mutinate himself to prefer his beloved companion.

AGAPETUS, in Biography, a deacon of the church of Constantinople in the 6th century, who addressed a letter called σημείο ταξιδική, Scheda Ritis, to the emperor Julianus, on the duties of a prince, and thus obtained rank among the most judicious writers of the century. This letter was printed at Balf by Frobenius in 1521, vto, and at Cologne in 1604. It is included in the Bibliotheca patrom. Molheim, Eccl. Hist. v. vi. p. 120. Fabric. Bibl. Græc. i. vi. p. 527.

AGAPETUS, Pope, was a native Roman, and raised to the papal see by the interced of Theodotus, king of Italy, in 535. This pope refuted the interference of the emperor Julianus in ecclesiastical concerns, asserted the supremacy of the papal authority in the church, and maintained its independence on the civil power. He was firm and resolute, notwithstanding the threats of the emperor in opposing a measure which he disapproved, and boldly said, "when I came to Julianus, I hoped to meet a Christian prince, but I have found a Diosclesian." He died at Constantinople in 536, and
and was enrolled among the saints; and the Roman fee was at this time so poor, that in order to defray the expenses of his journey thither, he was obliged to pawn the sacred vessels of the church of St. Peter. Bowes and Dupin.

Agapetus II. Pope, a Roman by birth, obtained the papacy in 946, and held it till the year 956. He exerted himself in terminating the diffensions of Italy, and sent for the emperor Otho to oppose Berenger II. who allumed the regal power in this country. He was reputed a man of extraordinary sanctity. Dupin. Fabr. Bibl. Græc. t. vi. p. 570.

AGAPHONOVA, in Geography, a river of Sicilia, which runs into the Frozen Ocean.

AGAPIS lapis, in Natural History, a name given by ancient writers, to a stone of a dully yellow, or the colour of a lion's skin; it was held in great esteem in many nations, on account of its supposed virtues, as an anodyne and vulnerary.

AGAPIUS, in Biography, a Manichean writer, mentioned by Photius, who is supposed to have lived about the middle of the fourth century. Some say, that he was a disciple of Manes towards the close of the third century, that he opposed the sentiments of Eunomius concerning the Trinity, and that he wrote three books in defence of the Manichean principles; one a work of twenty-three books, another consisting of 102 chapters, inscribed to a woman of the same sect, named Urania; and a third, entitled Heptalogus, preferred in the Anathemas against the Manichæans, or form of abjuring Manicheism, by Fabricius, Cotelerius, and Tollius. His works, says Photius, was so absurd and impious, that it could only flame and confound those who followed him and the Manichean doctrines; and he is denominated by the same writer a detestable and impious man, and distingjuished as one of the twelve disciples of Manes. Gen. Dict. Lardner's Works, vol. ii. p. 366. Fabricius (Bibl. Græc. t. x. p. 383.) has mentioned several other persons of this name; such as a monk of mount Athos, who lived about the year 1040, and published a book entitled ιμμανις σπε- τσις, the salvation of sinners; Agapius, a bishop of Cæsarea, the predecessor of Eufebius; Agapius, an Athenian philosopher, a disciple of Proclus, and supposed to be the fame with the eminent philæsian and historian of Alexandria and Constantinople, whose distingjuished talents are noticed by Suidas.

Agar, in Ancient Geography, a town of Byzacium, described by Hirtius, a few miles westward of Lempta or Leptis parva, and sixteen miles from Thaphis. It was one of Cæsar's flations; the village which now occupies the rocky situation in which it stood is called by the Arabs Boo-Hadjar, i.e. the father of a stone, or the stone city. Shaw's Trav. p. 159.

Agara, a town of the Phylliates, in India, on this side of the Ganges, according to Ptolomy.

Agaraffo, or Acharaffe, a small, pleasant, and fertile country of Andalucia, in Spain. Its principal town is San-Lucar la-Mejor, erected into a duchy by Philip IV. in favour of count d'Olivarez.

Agard, Arthur, in Biography, a learned antiquary of this country, was born at Tolton, in Derbyshire, A.D. 1540; and having been educated for the law, was appointed deputy-chamberlain of the Exchequer in 1570, which office he held 45 years. By means of this office he was enabled to pursue those curious researches, of which he produced several valuable publications. Having directed his particular attention to the Dooms-day book, he wrote a learned treatise on the use and true meaning of the obscure words that occur in it; he also compiled a book, containing a catalogue of the records preferred in his Majesty's four treasuries, and an account of all leagues, treaties of peace, intercourses and marriages with foreign nations. This work, with eleven other treatises in MS. relating to matters of the Exchequer, he ordered by his will to be delivered to the office. His other collections, amounting to twenty volumes, were bequeathed to Sir Robert Cotton, and deposited in his library. His essays read to the Antiquarian Society, were published by Mr. Hearne, in his "collection of curious discourses by eminent antiquaries," and are as follow, viz. "Opinion touching the Antiquity, &c. of Parliament," the genuine of which is doubted:—"The Antiquity of English Shires?"—"On the Dimensions of the Land of England?"—"Of the Authority, &c. of Heralds in England?"—"Of the Antiquity and Privileges of the Inns of Court and of Chancery."—"Of the Diversity of Names of this Island." By his established reputation for the knowledge of antiquities he was one of the most conspicuous members of a Society of Antiquaries, which subsisted from 1572 to 1604. He died in 1615, and was buried in the cloister of Westminster Abbey. Mr. Camden denominates him a most excellent antiquary. Biog. Brit.

Agari, Agaric, Agaricus, called Amantia, by Dillenius, in Botany, a genus of the order of fungi, and class of cryptogamia; the characters of which are, that the pileus or cap has gills underneath; that the gills differ in substance from the rest of the plant, being composed of two laminæ; and that the seeds are in the gills. Gilpin, in the 13th edition of the Linnean sytem, 1759, enumerates 350 different species; and Dr. Withering, in the third edition of his arrangement of British plants, 1766, (vol. i. p. 145, &c.) ascertains and describes 282 British species, besides several varieties. He distributes them into three general classes, comprehending those which have central stems, those with lateral stems, and those which have no stems; and he again subdivides the two former classes into such as have solid, and such as have hollow stems, with decurrent, fixed, and loose gills respectively. Under these heads he ranges the species, by the colour of the gills, into those whole gills are white, brown, red, buff, yellow, grey, green, and purple. As this ingenious author has formed a system, that serves to facilitate the investigation and description of the several species of agarics, we shall here give a brief sketch of the principles upon which it is founded. Agarics are composed of a cap, or pileus, with gills underneath, and are either with or without stems. The stems are either central or lateral. They have also a root, which is more or less apparent, and some of them, in their unfolded state, wholly enclosed in a membraneous or leather-like cafe, called a wrapper. Some of them have also a stem or thin membrane, extending from the stem to the edge of the pileus, which is rent as the pileus expands, and soon vanishes, but the part attached to the stem often remains, and forms round it a ring, which is more or less permanent, as its substance is more or less tender. These parts are seen in Plate V. Botany, fig. F, which exhibits the vertical section of an agaric in its egg-state. The wrapper is seen at m, m, m, m; the pileus at n, n; the gill at o, o; p is the stem before it flows up; and q, q, the curtain. On the section of a stem at B, may be seen the remains of an
curtain, then called a ring. The curtain, ring, and wrapper are of little use in the determination of the species. The two former are common to all the secondary subdivisions of agarics with central stems; but the latter is confined to plants with solid stems, nor does it pertain to those whole gills are decurrent. The item of an agaric is either solid or hollow; the former is represented at A; the latter at B. In examining an agaric, it will immediately appear whether the item be solid or hollow, by cutting it across the middle with a sharp knife. Next to the gills, the item of an agaric is the part least liable to variation. The gills are the flat, thin sublimations of agaric, attached to it, and are of a different texture from that of the item or pileus. They assume different colours in different species, and vary much in their respective lengths. Each gill consists of two membranes, between which the seeds are formed. The gills are always attached to the pileus, and sometimes to that only, as at fig. E. c. c. They often stand upright against the item, and are fixed to it, as at fig. A. b.; and they are also extended along it downwards, as at a. This is called a decurrent gill. The fixed and decurrent gills are attached to the item only by their ends, which are next to the centre of the pileus, and not by their edges, as is sometimes the case in agarics, whose pileus are nearly cylindrical. The gills, as they contain the fructification of these plants, are peculiarly important. They vary in length, always extending to the edge of the pileus, but seldom reaching to the item; and they are sometimes forked or divided, and sometimes connected or anastomosing with one another. These circumstances are illustrated by fig. C. and fig. G. The gills are uniform at d; and below it they are connected at the edge of the pileus; at e they appear in pairs, at f there are four, and at g eight in a set; at h they are seen irregular, or without any determinate number; at i they are branching; and at k branching and anastomosing. Fig. C exhibits the gills loose from the item, with the inner end fixed to a collar which surrounds the top of the item, though not in contact with it. These several circumstances are subject to such variations, that they do not serve to distinguish the different species.

The colour of the gills, however, is obvious and permanent; and as the colour is principally, if not solely, caused by that of the seeds within them, this affords the most fixed and certain characteristic, on which to found the distinctions of the species; and together with the structure, the colour, particularly of the flat sides of the gills, will be at all times sufficient to furnish permanent specific distinctions. The item is a less variable part than the pileus; its shape, the proportions of its length to its breadth, and of both to the pileus, afford tolerable distinctive marks; and its colours, though more changeable than those of the gills, are perhaps rather more fixed than those of the pileus. The pileus, or cap, is the part of an agaric, that is least certain. Its shape is either conical (as at E), convex (as at D), flat, or hollowed at the top like a funnel, and is constantly varying in the same plant, though it is much the same in the same species, when the plant is in perfection, or when it is fully matured; fully expanded. Its colour is uncertain; and so also the variability or clamminess on the surface of the pileus and item, which has sometimes characterized agarics. The lactificence of some agarics, or their property of yielding a milky juice, which in some species is mild, and in others acrid, is very precarious and inconsistent. Such as we have briefly recited, are the principles upon which Dr. Withering's system is founded; and it seems well adapted for extending our acquaintance with the various species of agaric that occur, and rendering the knowledge already acquired more accurate. Withering's Arrangement, vol. i. pp. 375—380. See CRYPTOAGARIC, Fungus, and Musciboro.

Of all the species of agaric, one only has been selected for cultivation in our gardens, viz. the A. campestris, or common mushroom, or champignon. The gills of this species are loofe, pinky red, changing to a liver-colour, in contact with the item, but not united to it; very thick set, irregularly disposed, some forked next the item, some next the edge of the pileus, some at both ends, and in that case generally excluding the intermediate smaller gills. The pileus is white, changing to brown when old, and becoming fuscous; regularly convex, fleshy, flatter with age, from two to three inches, and sometimes nine inches in diameter, and liquefying in decay; the flesh white. The item is solid, white, cylindrical, from two to three inches high, half an inch in diameter; the curtain white and delicate. When this mushroom first makes its appearance, it is smooth and almost globular; and in this state it is called a button. This species is esteemed the belt and most favourable of the genus, and is much in request for the table in England. It is eaten fresh, either floured or boiled, and preferred either as a pickle or in powder; and it furnishes the sauce called ketchup. The field plants are better for eating than those raised on artificial beds, their flesh being more tender; and those who are accustomed to them can distinguish them by their smell. But the cultivated ones are more tightly, may be more easily collected in the proper stage for eating, and are firmer and better for pickling. The wild mushrooms are found in parks and other pastures, where the turf has not been ploughed up for many years; and the belt time for gathering them is August and September. Dr. Withering mentions four varieties. The A. Georgii of Lineeus resembles the former, but is much inferior to it in flavour. Its gills are yellowish white; the pileus yellow, convex, hollow in the centre; the item yellow, thickish, and smooth; the juice yellow, which flows plentifully from it when wounded. It is gathered in September in woods and pastures. A variety of this is found on the sea-coast of Cornwall, of a large size, with the button as big as a potato; the expanded pileus 18 inches over, the item as thick as a man's wrist, the gills very pale, the curtain tough, and thick as leather, and the juice yellow. A plant of this kind, as Dr. Withering informs us, was gathered on an old hot-bed in a garden in Birmingham, which weighed 14 pounds. The A. procinus, or tall mushroom, is not uncommon on hedge banks and dry pastures, and is sometimes exposed to sale in Covent-garden market. It may be distinguished from the genuine frit by the pognincts of its flesh, and from others by its fine and large horizontal ring. The gills are white, uniform, and fixed to a collar; the pileus is a broad cone, bifid, white brown, and fleshy; the item is fragile, and the ring loose. This plant, when preferred in pickle, is very apt to run into the vinous fermentation. Dr. Withering enumerates four varieties of this species, one of which is the A. exsanguis of Schoenher and Hay, which is a beautiful plant, approaching in structure to the former, but of a smaller size. It is gathered in September. A. xerampelius is the most splendid of all the agarics. Its gills are fixed, bright golden yellow, and nearly orange under the edge of the pileus, regularly disposed four in a set; fleshy, brittle, and serrated at the edge with a paler cottony matter: the pileus is a fine lake red, changing with age to a rich orange and buff, and every intermediate shade of
of these colours, which render it very beautiful; convex, even; tuft; brellae, edge turned down, three to four inches in diameter; slightly to the touch; flesh pale buff; stem solid, nearly cylindrical, but gradually tapering upwards, rich buff, shaded with fine rose red, three to five inches high, half inch in diameter; flesh pale, buffy, spongy and elastic. This is common in Italy, and brought to the markets for sale. The ancient Romans esteemed it one of the greatest luxuries for the table. It was made the vehicle for poison to Claudius Caesar by his wife Agrippina, and has since been celebrated by Juvenal and Martial. Scheaffer and Chirius have recorded several curious circumstances respecting it. Dr. Withering apprehends that these authors have mistaken the species, and that their account should be transferred to the A. delicatus. The A. scabrum is notable, but its table is not at all agreeable. It is the A. cinnamomeus of Schaeffer, and first found by Dr. Withering's daughter, on the red rock plantations at Edgbaston, July 6th 1791; and afterwards in Sept. 1792; and in July 1792, amongst moss in the fir plantations at Tettenhall, Staffordshire. Dr. W. enumerates five varieties.

A. delicatus has gills decurrent, flame coloured, narrow, regularly branched; pileus rich red brown; flesh nearly flat, but somewhat hollowed at the centre and the edge turned in, from one and a half to three inches over; orange-colour; stem orange, folid, tapering downwards, from one to two inches high, and a quarter to three-eighths inch diameter; hollow with age. The juice is rich yellow, which soon turns green. It is found in the fir plantations of Scotland, and in those of the barren hills at Bar, in Staffordshire; Dr. Smith also found it at Hillingdon, Middlesex, under some fir-trees, and it also grows near Guildford. It is much esteemed in Italy, and exported in the markets, and supposed to have been the A. cinnamomeus mentioned by the authors cited under the preceding article. Dr. Withering enumerates three varieties, one of which affords, from every part of it when wounded, a copious discharge of yellow acid juice. They are gathered in woods and dry pastures in Sept. and Oct.

A. cinnamomeus has gills, four in a set, broad about the middle, deep tawny red, and fixed by claws; pileus convex, but brellae, of a rich cinnamon colour, from one and a half to three and a half inches diameter; the stem hollow, cylindrical, flobby, flaming, two inches high, thick as a goose quill, of a fine full yellow colour. This is 'a species that is readily distinguished by its cinnamon-colour.' It is found in woods in September and October; and has a good flavour. It is the A. cinnamomeus of Bolton. The A. cinnamomeus of Schaeffer is a variety of this.

A. bulbosus has white, loofe, irregular gills; pileus convex, white, smooth, sometimes fringed at the edge, four or five inches over, flesh white, spongy and very thick; stem solid, cylindrical, smooth, white, four inches high, and half inch or more in diameter; ring permanent, broad, and white. This species poulfes all the parts belonging to the genus, and is well adapted to instruct the learner in understanding them. It is found from spring to the end of autumn in rich soil, and also in gardens, on the fides and at the base of hot-beds. Dr. Withering enumerates four varieties, found in woods about the roots of trees, and in pastures: and he refers the A. bulbosus of the Fl. angl. to the A. glaucopus of Schaeffer, with brown gills, from four to eight in a set, chef-nut and semi-globular pileus, thick stem of a white or pinky colour, and curtain refibring a cobweb, white flesh with a pinky tinge, solid whitifh stem, and very large bulbous root. The A. bulbosus of Hudson, and Ray is referred to by this author to A. velutinus of Linneus; which has fixed purple gills, numerous, eight in a set; long gills sometimes cleft, and a few of them decurrent; purple pileus, soft, smooth, firm, convex, but centrally depressed with age, and cracking at the edge, which is somewhat turned down, from half inch to five inches over; stem solid, cylindrical, purple, bulbous at the base from one to four inches high, and from a quarter to one inch in diameter; and curatos like a cow-web. In maturity, it plentifully emits a powder of the colour of Spanish faust. It is not uncommon from October to December, in Edgbaston and Bare plantations, in the woods near Bath, and at Powick near Worcester. With much broiling and sunbathing, it is esteemed delicious as an oyster. A. candidus of Linneus is small and white, with an hemispherical pileus having its margin turned inwards and flexile gills, and stem cylindrical and flexuous. Dr. Withering refers the A. candidus of Hudson to the Mannatus unbellicatus. A. visci has gills decurrent, white, few, short and in pairs; pileus white, bals yellowish, with frst conical, then flat, and lastly inverted, two inches in diameter; stem solid, whitish buff, bending, three inches high, and a quarter of an inch in diameter. The whole plant is very vilified, but dries when gathered. Dr. W. suspects it to be an unusually large plant of the A. cinnamomeus. It is found in autumn in Packington Park, Warwickshire. A. mutabilis of Schaeffer has loose, yellow brown gills, four in a set; brown orange pileus, convex and brellae; stem hollow, cylindrical, red brown and sealy below, and white above the ring; curtain thready; ring permanent and imperfect. It is common in August, on decaying and rotten wood. The A. mutabilis of Hudson, Ray, Sc. is referred by Dr. W. to the A. velutinus of Curtis, with pale yellow gills, eight in a set; pileus brown orange, nearly flat; stem yellow below, velvety and dark brown below. It is not uncommon in April and October, grows in clutters, and is generally attached to rotten wood. A. crassipes has gills white, brownish at the edges, fleshy, diaphant, four in a set; pileus reddish brown, bellowd and cracking; stem tapering downwards and ribbed. It grows in clutters, at the base of decaying trees. The A. crassipes of Schaeffer is made by Dr. W. a variety of the A. elasticus with white gills, four in a set; pileus chef-mut and semi-globular; stem buffy, white and tapering. This agaric is tough and strong, with a considerable staleness, and found under oak trees in August, September and October. A. varius has white gills, not numerous, two or four in a set; pileus conical and droorded; stem cylindrical, glossy, riff, and about the size of a crow-quill. Of this species Dr. W. has enumerated eight varieties, most of which are found at the roots of fiebered trees. The A. varius of Schaeffer is in Dr. W.'s arrangement a variety of the A. glaucopus, and that of Bolton a variety of the A. fan-purit of Bulliard, which has gills dark brown to black, four or eight in a set; pileus pale brown, conical, blunt, with polished apex, and white stem. It is found in October, in gardens. A variety of it, with four gills in a set, and a pileus grey to black, is found among rotten leaves in grafs-land. Another variety, which is the A. varius of Bolton, is found on grafs-plats and new mown fields in July. It has chocolate gills from brown to black, mottled, and in pairs; pileus mecke-colour, conic and pointed; stem of the same colour, cylindrical and firm. This, though a common, is a very beautiful species. In a finner morning it is covered with a blarem like that of a plamb, having often a glittering fnaped appearance; its form is regular, and the fringe of the curtain peculiarly delicate. Another variety, with the stem of a dark mulberry colour, is found in wet gravel where no grafs grows, and sometimes on cow-dung, in which case the stem, under the shelter of long -wings, is covered with a white hominefs, which is easily rubbed off.
A. integer of Linnæus has gills white, mostly uniform; piles of various tints, crimson, pink, lila, or tawny brown, changing to dirty yellow or to lead colour; stem solid, cylindrical and white. It is very common and beautiful; found in woods and pastures, under trees, and initials are very fond of it. Dr. Withering enumerates nine varieties. A. oreades has loose gills, with the part attached to the pileus jutting up very close to the stem, so as to give them almost the appearance of being fixed, waxy brownish white, two or four in a set, the small ones very minute, and the large ones sometimes splitting at the outer end; not numerous, rather broad for the size of the plant; frequently connected to the pileus by ligaments; pileus pale brownly convex, irregular, with a sudden depression of the border at some distance from the centre, often giving the appearance of a large rounded boil in the middle; central colour generally deeper; from one to one and three quarters inch over; and the edge turning up with age; stem solid, white, changing to waxy brown, cylindrical, but thicker and flattened just under the pileus, very tough, mottly crooked, twisted when dry, rarely central, one and a half inch high and thick as a crow-guilt. This is the 27th fungus of Ray's synopsia, ed. p. 6. A. praeterita of Hudson, and conicus of Lightfoot. There are two varieties; one with cream-coloured gills, buff pileus, and mealy stem, and another with yellow brown, more flechy and more regularly convex pileus, found in groves. Mr. Woodward says, that this species has a much higher flavour than the common mushroom, but he fuggels, that from its leathery nature it is indigestible, except in the form of powder, in which it is admirable. Dr. Withering, however, observes, that he has seen the pileus and gills of this agaric very brittle and tender, when fully saturated with moisture in rainy seasons, and in that state it is sufficiently digestible. Professor Martyn informs us, that he has eaten these mushrooms for 45 years without injury, and without perceiving that tough chefs like leather, of which others have complained; except in very dry weather, or when they are in too advanced a state. They should be gathered young and early in a morning, and properly dressed. They are found in hedge banks, upland pastures, and sheep common, particularly in those patches called Fairy rings. Those that are found in woods and hedges are of inferior flavour to such as are gathered in dry pastures, which have a very pleasant smell and lucious flavour, either when fried alone, or in ragouts, &c. This sort makes excellent ketchup, and is much valued in the form of powder. It is in season during September and October, but may be dried so as to be in use for table all the winter. Mr. Lightfoot supposes that this species is the muscoron of the French, who use it in ragouts, instead of that, and acknowledge it to be equal in flavour, but more tough. The muscoron, however, has a very thick and flechy pileus, its gills are very narrow and numerous, and fixed to the stem, and the stem is thick and short. Dr. Withering has carefully distinguished several other species from this fairy-ring agaric, or Scotch bonnets, as it is called by Mr. Ray. A. chantarculus of Linnaeus, is the merulius chantarculus of Dr. Withering, and may be eaten with safety; but it is more tough and less highly flavoured than either the A. oreades or A. campyris. Allone enumerates the following species as edible, viz. A. candidus—bulbopus—chantarculus—nitens—dulcius—mutabilis—brunneus—exomires—georgii—cratipes—varius—olivaceus—fribriae. But he has omitted A. campyris. In many parts of Europe several other forts are eaten, which are thought with us to be poisonous. Of this number we may reckon the A. piperatus, which, though it be the most acid and fulphricous of all the agarics, is eaten in great quantity by the Russians. They fill large vessels with these mushrooms in the autumn, freeze or pickle them with salt, and eat them in the ensuing Lent. The A. piperatus of Linnæus has gills, pale pinky red, numerous, in pairs; pileus dirty yellow whitish, woody, depressed in the centre; and stem pale yellow. This is the A. muscoron of Schaeffer. The A. piparius of Bolton, and A. liebifus of Bulliard is referred to Dr. W. to the A. Liebleri, which has gills white, numerous and narrow; pileus smooth, irregular, flatfitted, depressed in the centre; stem white, eccentric; and juice like milk. Lieber first found it in England. This plant, with its varieties, is met with in plantations of wood. It is much eaten by insects and snails. A. erythropus is described by Dr. W. as having gills fixed slightly to the stem, greyish wavy brown, four or eight in a set; pileus brown, convex, bossed, border feared, very viscid, so that flies lighting upon it cannot cleave; paler in colour when covered with this viscid matter, one to one inch and half over; stem hollow, white, viscid, tender,Unity broken, flitting, three or four inches high, and thick as a crow-guilt. This species is found in woodland pastures in September. Dr. Percival, in the last vol. of his Essays, p. 267., relates the case of a man, who was poisoned by eating a mushroom, which Mr. Hudson thinks was one of this species. A. muscorus, or reddish mushroom, has a large pileus, varying much in colour, white, red or crimmon, convex, sprinkled with downy warts, which are raised, compact and angular, or thin, flat, and ragged, turning up with age, from two to seven inches over; flesh white, reddish in decay: gills fixed, white, yellowish with age, mostly uniform, but a shorter one sometimes intervening; the shorter gill varying much in length, but rarely less than one-third the length of the long ones: the stem solid and cylindrical, but the internal subsidence thriving with age, leaves irregular hollows; scaly, bullos at the base, from three to five inches high, and from three quarters to one and a half inch in diameter; ring broad, permanent, and turned down upon the stem. This plant rises out of the ground inclosed within its brown floddled wrapper. It is found in pastures. The juice rubbed on the walls and bed-posts destroys bugs; and in the north of Europe the inhabitants infuse it in milk, and let it in their windows, in order to poison the flies who take it. This is the moucho-more of the Russians, Kamtschadales, and Koriars, who use it for intoxication. They sometimes eat it dry, and sometimes immerse it in a liquor made with the epilobium; and when they drink this liquor, they are seized with convulsions in all their limbs, followed with that kind of raving which attends a burning fever. They perfonify this mushroom; and it they are urged by its effects to suicide, or any dreadful crime, they pretend to obey its commands. To fit themselves for premeditated assassination, they recur to the use of the moucho-more. A powder of the root, or of that part of the item which is covered by the earth, is recommended in epileptic cafes, and externally applied for dissipating hard globular swellings, and for healing ulcers. The deco is from half a dram to one, taken thrice a day in water; and a dram admiistered once a day in vinegar, has been thought more efficacious. Murray, App. Med. vol. v. p. 560. Dr. Withering enumerates ten varieties of this species.

The agarics, with lateral items, and those without items, are chiefly found on rotten wood, or stumps and fragments of decayed trees. Of the latter fort we shall mention only the A. quercinum, or agaric of the oak: the gills are brown, very much branched and anamolising, thick, forming ob-long angular, and nearly circular cavities, especially towards the edges; the pileus brown, woody, nearly flemicircular, or
or of no regular shape, marked with circular tiled ridges, as well as with different shades of colour, soft to the touch like buff leather or fine cork, from one to five inches over, or more. This species, of which Dr. W. enumerates two varieties, seems to connect the agars with the boleti. For a further account of the dietetical and medical qualities of agars, and for the method of cultivating and propagating those which are chiefly used, see MUSHROOM.

Agaric, in *Phoronomy*, a kind of fungus excrecence, growing on the trunks and large branches of several trees; but chiefly on the larch-tree and on some kinds of oak, when old and decayed. Three-fourths of it consists of a firm substance, and the remainder is a finely mucilaginous earthy matter, so tenacious, as scarcely, by any method, to be dissolved by water. It comes forth on the tree in the beginning of the spring, and continues to increase till autumn. The belt is easily cut with a knife, friable between the fingers, and has no hard, or gritty, or coloured veins. It has no pedicle, and is internally of a simple uniform structure throughout its whole substance. Agaric is brought from different places; the belt comes from the Levant; that which comes from Savoy and Dauphiny being less esteemed. Holland also supplies some, but that is reckoned the worst; because it is grated, and whitened at top with chalk. By a chemical solution it grizes almost wholly into oil; it yields no volatile salt, but abounds with a sort of flinty earth, and acid phlegm, as to texture, it seems much to resemble COLOCYTHEUM. Agaric is an ingredient in the *thuringia Andrenodactyla*, where it is admitted in quality of a cordial; though its cardiac virtue is exerted to as much as its purgative. Agaric was a purge in much esteem among the ancients, but has deservedly fallen into disrepute of later years, as it occasions unsupportable nausea; and as no preparations of it appear to be equal to the more common and experienced cathartics. The druggists consider only that which grows upon the larch-tree to be the right sort. For its chemical history, see Newmann's Works, p. 349. The *Agaric* of the oak, so denominated, because the belt is supposed to be produced on the oak, sometimes also called falle or bauert Agaric, is the *Boletus Igniarius* of Linnaeus. This fungus has been specifically named Igniarius, and also touch-wood or spunk, from its readily catching fire, and from its being used in some places as tinder. For this purpose the Germans boil it in flaming ley, dry it, and boil it again in a solution of salt-petre. It is externally of an ash-colour, and internally dullly coloured, soft and tough. In France, pieces of the inner substance are beaten to a film to resemble leather, and sewed together for making garments: this agaric has been much used by surgeons as an external flyptic. The mode of preparing this substance is as follows: Take a piece of a fresh agaric, which has been removed from the oak or larch-tree in autumn, and pare off its exterior rind; the coat underneath, being of a compact texture, is then to be separated from the porous part, and well beaten with a hammer until it becomes extremely pliable. The outer hard part, and the inner liquor surface, are of very little use; but the middle portion, thus prepared, must be kept dry in slices of a convenient size. A small piece is to be laid exactly over the bleeding artery, and over that a fiscoid, or even a third, somewhat larger; and lastly a compres, to retain the whole in its place. Its application to this purpose was derived from the French, and it was successively recommended, first by Brodfard in 1750, afterwards by Morand, Bouquet, Faget, Rochard, and De Mey, who employed it not only to restrain the bleeding of wounds, but to prevent haemorrhages after amputations, which it is reported to have done as effectually as the ligature. Several English surgeons have also published cases in which the agaric was successfully used, as Sharp, Warner, Gooch, and others. Some have remarked that, where it seemed to succeed, the subjects were brought to low before the operation, that little danger was to be apprehended from the haemorrhage, though no other application had been made than that of dry lint and flour. Neale's Obs. on the use of agars, &c. It has now lost its reputation both in France and England; nor does it appear, from its fitful qualities, to be possessed of any truly flyptic power, at least to any considerable degree. This fungus probably acts no otherwise than as a phlegm, adhering to the orifices of the wounds, till they have contracted spontaneously. Some other fungi have been employed with the same intention; such as the hydroporon, or dusty mushroom, and the fungus vinus, found on the oaks and walls of wine-vaults. Lewis's Mat. Med. Woodville Med. Bot. vol. iv. p. 162. Since it possesses no efficacy without a firm compres, we believe the ligature will be generally preferred, as more secure, and less troublesome to the patient. See HEMORRHAGE.

Agaric, Female. See Boletus.

Agaric Mineral. Bergmilch, Bergmilch. Germ. *Crata farinae*.—This mineral substance is always found in a loose or semi-indurated state in the figures of rocks or at the bottom of lakes; it almost floats on water, is entirely soluble in nitric acid with effervescence, and probably consists wholly of carbonat of lime: it is not applied to any particular uses. There are two varieties of this species, of which the following are the essential characters.

Var. I. Bergmilch of Werner.

Dusty—colour white, red or yellow; very friable; of a dry feel. It does not adhere to the tongue, and gives no gloss to the skin when rubbed on it.

Var. II. Colour white, composed of scaly particles, very friable; of a greasy feel, and communicates a gloss to the skin; falls to pieces in water, and adheres to the tongue. Mr. Kirwan (Elem. Miner. vol. i. p. 76) mentions a third variety, of a silvery white colour, resembling mica in its structure, of a soft feel and somewhat unsuitable like tale, almost entirely soluble in nitric acid; and the solution has all the properties of a solution of calcareous earth. This substance was formerly used internally against hemorrhages, stranguary, gravel, and especially in dysenteries; and externally to dry and heal old ulcers, stop defluxions of the eyes. See SIMUM, CVALE.

Agaricites, in *Natural History*, a species of *Mastopora*, flemets, and furrows, with carinated furrows and concenctrated hairs. It is found in the sea, between the islands of America.

Agaricum, a species of *Alcyonium*, with a siliform stem, and a kidney-shaped case. This is the kidney-shaped purple Sea-Pen of Ellis, found in the sea that washes the coast of South Carolina. Its body is about an inch long, and half an inch across the narrowest part, with a small roundish tail, an inch in length, proceeding from the middle of the body, full of rings from one end to the other, like an earth-worm, with a small groove running along the middle of the upper and under part, from one end to the other. The upper part of the body is convex, and near a quarter of an inch thick; the whole surface is covered with minute yellow flary openings, through which are protruded little suckers, like polypes, each furnished with six tentacles or filaments, which form to the proper mouths of the animal. The under part of the body is flat, and the surface is full of the ramifications of fleshy fibres, which proceed from the insertion of the tail, as their common centre, branch out so as to communicate with the flary opunges on the exterior edge and upper surface of the animal. See Plate 3 C 2
AGARICUS Sires, in Ancient Geography, a gulf of
India, on this side the Ganges, according to Ptolemy.
AGARON, in Natural History, a name given by Adan-
son to a species of voluta; the Cyphulca of Gmelin's edi-
tion of the Linnean System.
AGARRA, in Ancient Geography, a town of Suliana, in
Asia; placed by Ptolemy in long. 83° 58' and lat. 35° 28'.
AGARUM, a promontory of Attic Sarmatia, near the
river Aganur, which ran from north to south, and
discharged itself into the Euxine Ocean. According to Ptolemy,
it was situated in long. 62° and lat. 35° 40'. Ovid. (Pont.
iv. 103) calls the river, Sagiris; and it is now Sorgre.
AGASUS, a port mentioned by Pliny, situated between
the promontory of Garganus and the river Corbasus; and
supposed to be the same with Portus Greco. Agafus, or Agallia,
was also a town of Macedonia in Europe.
AGASULLIS, in the Materia Medica, a name given
by some of the ancient Greek writers to gum ammoniac,
and by Dioscorides, to the tree which produces that gum.
By their description of this medicine, it appears not to have
been the same which we know by this name.
AGATA, in Ancient Geography, a small town and bishop's
see of Naples, in the Principato Ultra.
AGATE, Agata; Abatea, of Theophrastus and Pliny;
Achates, Fr. Achat, Germ. Agate, Swed. This
word is used by modern mineralogists not as denoting any
particular species of stone, but a felicitous mixture of quartz,
hematite, flint, calcereous, amethyst, jasper, carnelian, or
hebetrope, aggregated into binary or more complex com-
bixations. It has nevertheless several peculiar characteristics
by which it may readily be distinguished from other minerals.
Although it consists of parts differing in colour and trans-
parency, yet these posse a certain uniformity of arrange-
ment, and glide into each other by such nice gradations as
show them to have been all of simultaneous formation; and
hence it differs from felsen Breccia, in which angular
fragments of felsic pebbles are cemented by a felsic
pale: for in all this the cement, whether quartz, calcere-
yous, or flint, is wholly distinct from the fragments that
insects, and the arrangement of the whole is merely casual.
As it differs in the colour of its constituent parts, so it does
in their transparency; it is never wholly opaque like jasper,
or transparent like jaspe or crystal. It takes a very high
polish when polished parts usually present the appearance
of dots, eyes, veins, zones, bands, or ramifications. Its
colours are yellowish, reddish, bluish, or milk white, honey-
orange, or ochre yellow, flesh blood, or brick red, reddish
brown, violet blue, and brownish green. Specific gravity
from 2.55 to 2.7. It gives fire with flint very plentifully.
It is found in the form of irregular rounded nodules,
from the size of a pin's head, to more than a foot in diam-
eter; or in strata, and sometimes, though rarely, flatalatic.
Several varieties of agate are distinguished by the lapidaries:
the finer semi-transparent kinds, confining principally of
calcereous, are called orientals; in the banded agates the col-
ours are disposed in straight parallel lines or bands; while in
the fortification agate, the most beautiful of all the vari-
ties, they are arranged in waved and angular concentric
zones; the landscape agate, by the name dale, sufficiently
declares its irregular appearance; the moss agate, or Mochoa
flava, is filled with dendritic crystallizations of iron ore,
so nearly resembling some kinds of moss, as to have been
actually mistaken for real vegetables by Daubenton.
Agates are found, for the most part, in argillaceous por-
phyry, occasionally in gypsum, near the river Wolga they
occur between the strata of secondary limestone, and certain
rocky tracts in Siberia consist almost entirely of a pudding-
stone, of which agates and calcereous form an essential con-
finitant part. The argillaceous porphyry being a rock
that is easily disintegrated by the action of the air and mois-
ture, the agates and other felsic pebbles that it contains
fall out and are washed by the rains into the beds of rivers;
here, by friction upon each other, the asperities on their sur-
face are worn off, and in this state they are generally found
on the beach and in gravel beds. The most beautiful
agates that this tilled produces, are commonly known by
the name of Scotch pebbles; these are met with in various
parts of Scotland, but principally in the vicinity of Dumbra.
The agates of Germany are the largest, especially those
from Kummerfeld in Saxony. The Dutchies of Deux-ponts,
the Bashme, Heffe, Thuringia, Wurtzberg, Bavaria,
Bolonia, and Sicilia also furnish them in great abundance.
The river Achates in Sicily was of old celebrated for these
pebbles, and hence they have acquired their name: the
other parts of Europe, where they are found, are principally
Tuscany, Candia, and Iceland. Some exquisitely fine spec-
cimens have been brought from Siberia, and the island of
Ceylon; and they have lately been discovered in great
plenty in the bed of a river at the eastern extremity of the
settlement at the Cape of Good Hope.
The uses of agate are principally for ornamental works;
the engraved gems, those precious remains of ancient art
are principally agate, and much ingenuity has been shewn in
the accommodation of the natural veins and markings to the
figures engraved upon them; it is also much esteemed by
modern lapidaries for seals. Small mortars are made of
agate, and are used by the enameller, and in the laboratory
for grinding substances that are too hard to be triturated
any other way.
A dark film approaching to red, or red purple, may be
communicated to agate, by heating it in warm ashes, and
then moistening its surface with nitro-murrit of gold, or
nitrate of silver; when the stone is become dry, it must be
laid for a day or two in a dark moist place, and then exposed
to the full sun: by this method the most delicate zones
and ramifications, which are not visible in the natural state
of the stone, are made to appear in a very beautiful manner;
this tinge is, however, destroyed by nitrous acid, or a mod-
erate heat; and thus artificial stains may be distinguished
from the native colours. A deep black is given to agate
by soaking it when heated in a boiling nitrate of copper, and
then heating it nearly to redness in a covered crucible.
Mochoa stones are imitated by spreading a solution of nit-
rate of copper over the surface of a plain agate, and then
etching a small iron nail on its head in the middle; the ni-
trous acid unites with the iron, and deposits the copper in
beautiful arborescent radiations from the centre; the nail
mutil is then removed, and the surface carefully washed, by
dipping the stone in warm water; afterwards on the appli-
cation of a moderate heat, the copper becomes black.
This deposition, however, being merely superficial, requires
to be covered with a plate of polished crystal, in the man-
ner of a doublet. If the ramifications are required to be
very fine, the agate should be moistened with a dilute nitrat-
e of silver supernituated with the metal, or a solution of
lunar caustic in water, a small piece of zinc is to be placed
in the middle till the ramifications are sufficiently far ad-
nanced; the stone must then be washed carefully in warm
water, and afterwards exposed to sulphurated by hydrogen
gas, till the silver is become black.
Agate is said to be imitated very successfully in glads;
and Nerii, in his "Art de la Verrierie," gives three different
receipts for this purpose: of these the following is recom-
}
AGA

A composition for splendour and vividness of colour often superior to real agate. Take seven ounces of granulated silver, and five ounces of mercury, four drams of minimum, one ounce of verdigris, and flakes of copper, crude antimony, and black manganese, of each half an ounce; dissolve the silver by itself in nitric acid, and having ground the cell of the materials together, add first two parts of acetic acid, and then the nitrous acid, both liquors evenly and intimately with the other substances; then dissolve two drams of gold in nitro-muriatic acid, and grind together the following ingredients: viz. cinnabar, twelve drams; sulphurated oxide of copper, twenty drams; sulphurated oxide of iron, four drams; and white oxide of tin, five ounces of iron, scales, zaffre, orpiment, and white arfæ, of each half an ounce; mix the solution of gold with this compound, and powder, and then add thrice its weight of nitro-muriatic acid: digest in separate glasses vessels for twenty-four hours in a sand-bath the above nitrous and nitro-muriatic mixtures, then add them together, and distil to dryness; there will remain a powder of a reddish green colour. Also take twenty pounds of clear flint glass, and reduce it to a fine powder, in a clean flint mortar, add to this two ounces of the above compound, and mix them together; when the whole is in clear fusion, stir it up from the bottom and let it continue melted for twenty-four hours, then stir it again, and allow it to cool very gradually; its colour will then be a middle tint between yellow and blue. Place the crucible again in the furnace, and when the glass is melted, add, at five or six different times, the following mixture: calcined tartar, eight ounces, vitriol wood foot, two ounces, and half an ounce of perfect oxide of iron: this will make the glass swell considerably, and therefore requires much care to prevent it from flowing over; when all is quiet, heat it well for twenty-four hours longer without touching it, and it will then be fit for use. Kirwan Minn.-ed. — Kirwan Geol. Eds. — Lamethere Theorinde de La Terre.—Lewis's Commerce of Arts.

Some writers have distributed agates, with regard to the objects that are represented upon them, into arborescent, dendrochates and dendrites; horned or cerachates; aphrodisian, a term given by Velchius to an agate in his collodion, of a flesh colour with a half moon on one side represented by a milky femicircle, and on the other, the phases of Venus, or the evening-star; corded, with human air; arithmetic, with the numbers 4194, 191 (Settala. Muf. 81.) astronomical, with the hemisphere and its several orbs, and the earth in the middle: anthropomorphous, with the figures of men or women, one of which, mentioned by Kircher, represents a heroine armed: and another, in the library of Francfort, exhibiting the heart, lungs, and part of the vena of a man; but the most celebrated of this kind is that of Pyrrhus, representing the nine Muses with their attributes, and Apollo in the middle, playing upon the harp (see Pinn. l. xxxvii. c. 3. Hard. Not.); leucothalmous, bearing the figures of eyes, as of birds, fishes, and wolves, called by Cordan and others lycothalmous; of grains denominated aeguspathilus, of oxen boophthalmi, &c.; the Tiberian agate in the treasury of the French king's chapel representing the apotheosis of Augustus, and the series and portraits of the family of Tiberius and Julia, with divers foreign nations subdued in war, concerning which, many different conjectures and explanations have been advanced by the learned; and the Iadic agate, a curious antique at Rome, so called, because it represents the head of Isis, and distinguished by the epithet annularis, as being set in a ring. However, in this kind of distribution, and in the denominations to which it has given occasion, the imagination has often muddled the judgment.

AGA

Becaria observes, that the electric sparks will not be conducted by the surface of polished agates; and M. Boile has shown, that the agate was very early known to polish electrical powers.

AGATE, among Antiquaries, denotes a stone of this kind, engraved by art; so that agates make a species of antique gems, in which we find eminent proofs of the great skill and dexterity of the ancient sculptors. Several agates of exquisite beauty are preferred in the cabinets of the curious. Many of the facts, or histories, represented in antique agates, however well conducted, are become, at this distance of time, obscure and dubious, and in explaining them divers mistakes have been committed, and numerous conjectures and disputes raised. Hist. Acad. R. Inser. tom. i.

AGATE, is also the name of an instrument used by gold-wire drawers; so called from the agate in the middle of it, which forms its principal part.

AGATHA. See ACHATES.

AGATHA, St. in Geography, a small town of Naples, in the farther principality, on the confines of Terra di Lavora, between Capua and Beneventum, eight leagues N. E. of Naples, N. lat. 43° 34′ 1″, long. 14° 22′ 6″. A city called Agatha, in Ancient Geography, a city of Gallia Narbonensis, built by the Massilians, mentioned by Pliny (lib. iii. c. 4.) and by Strabo, (tom. i. p. 272. 276.) See AGDE.

AGATHA, in Entomology, a species of the Papilio Nympheus, with dentated wings, the upper part yellow, the under grey; and the posterior wings have one black spot above, and three spots beneath. It is found in India.

AGATHARCHIDES, or AGATHARDOUS of Cnidus, in Biography, a Greek historian, grammarian, and rhetorician, mentioned by Josephus, (antiq. l. xii. c. 1. tom. i. p. 385. Cont. Appon. l. ii. tom. ii. p. 457. Ed. Hard.) Diodorus Siculus, (Bib'. Hist. tom. i. p. 530. 531. Ed. Weitl.) Strabo, (tom. ii. p. 460. p. 1125. Ed. Canab.) Lucian, (tom. iii. p. 222. Ed. Reitz.) and other ancient writers, was contemporary with Eratothenes, and flourished under Ptolemy Philometer, about 177 years B. C. He was reader to Heracleides, and president of the Alexandrian Library, and wrote several historical treatises of which Phoebus mentions 49 books, concerning the affairs of Europe, of Asia, of the Red Sea, and an epitome of what had been written on this subject in one book. Some fragments of his writings may be found in Josephus (ubi supra), and Photius in his Bibliotheca. 213. 250. Fabric. Bib. Grœc. tom. ii. p. 207. The testimony of Agatharchides is alleged to prove, that in the reign of Ptolemy Philometer, 145 years after the death of Alexander, the Greek sovereigns of Egypt had not yet traded directly to India, but imported the commodities of India, from Saba, the capital of Yemen. This ancient writer's description of the western coast of the Red Sea eludes at Ptolemæus, as if there were no regular commerce beyond that point. See Vincent's Periplus of the Euxine Sea, part i. p. 31.

AGATHARDOUS, E., painter of the isle of Samos, about the year 450 B. C. said to have been instructed by Archelaus in the art of introducing perspective into the decorations of theatres, and to have first written on this subject. He communicated the art to Democritus and Anaxagoras. Vitruvius, lib. ix.

AGATHEMER, Orthobas, a geographer, who lived, as some fay, near the time of Septimius Severus, and according to others, in the 15th century. He wrote in Greek two books of a compendium of Geography for the use of his pupil Philo, which is commended by J. Vofius, L. Hollin- meus and G. Wendelius, and which was first published in 1800, with a translation and notes, by Tenenius, at Amsterdam, in 1671; afterwards by Gronovius, in 1754. at Leyden, 1697; and
A G A

AGATHIIAS, one of the Byzantine historians, was born at Myrina, a city of Aiolis; and having studied the law at Alexandria, exercised the profession of an advocate at Smyrna, and acquired the appellation of Scholasticus, from the schools in which lawyers were instructed. Although in the introduction to his history, he speaks favourably of the Christians, it does not appear that he himself was of this number: Vellius and others believe that he was a Pagan; Pagani and Fabricius maintain, that he was a Christian. It is certain that no invectives against Chalcedony have escaped either him or Procopius. He was undoubtedly a man of candour and moderation. In speaking of the Germans, who had a multitude of duties, and offered cruel sacrifices, he says, they who are in error are rather objects of commiseration than of contempt and hatred; for all men aim at truth: if they are in error, it is not the fault of their will but of their judgment, as they are attached to opinions once embraced by them. He also laments, in the introduction to his history, that wars and battles are no more the subjects of poems and histories; which, as he says, he cannot ascribe to the wars, nor to fate, as some did: for if the world were governed by fate, there would be an end of choice; and there would be no longer virtue among men, nor any room for instruction or improvement in arts and sciences. Nor, with wars and even counsels, he adds, agreeable to the mind of God, who is supremely good: they must therefore be ascribed to the avarice and ambition of men. His history was written after the year 559, when Julianus died, and published after the year 592. It was undertaken at the desire of Eutychianus, secretary of flate, who is supposed to have furnished materials; commences with the 26th year of the emperor's reign, A. D. 553, where Procopius ends, and closes with the death of the Huns in 559. He investigates the causes of the events which he records, and often gives his opinion of them without difficulty. His style is easy and florid, though Sigionus has represented him as a low and unpolished writer. He also wrote 80 Epigrams, which are preferred in the Anthologia; and, as Suidas informs us, other pieces, partly in prose and partly in verse, intitled, "Daphniaca." Agathias's history was published by Vulcanius, with a translation and notes, at Leyden, in 410. A. D. 1594: and elegantly reprinted at Paris in fol. in 1660. Fabric. Bib. Graec. tom. iii. p. 260. Lardner's Works, vol. ix. p. 85.

AGATHIAS, a very famous Grecian satyrum, born at Ephesus. According to some accounts, this was the sculptor who executed the celebrated Apollo Belvedere; and the Gladiator Repellens; but other accounts, more to be relied upon, state, that the artists who produced these works are unknown.

AGATHO, the Athenian, a tragic and comic poet, was the disciple of Prodicus and Socrates, applauded by Plato, in his Protagoras. (Oep. tom. i. p. 315. Ed. Ser- rani) for his beauty and virtue, and described by Ariosto in his comedy of the Frogs, (p. 123. Ed. Kalteri) as a good poet and the darling of his friends; but severely cenured for his morals in the comedy, intitled Theophobravus. (p. 483.) He is represented as the favourite of Euripides, and also of Paulinus the Cerman, whom he accompanied, as Eilian informs us. (Var. Hist. ii. c. 21. tom. i. p. 120. Ed. Grnonov.) to the court of Archelaus, king of Macedon, where he continued till his death. Eilian says, that he often quarrelled with Paulinas for the sake of enjoying the exquisite pleasure which a reconciliation afforded him. His first tragedy obtained the prize; and he was crowned in the presence of 30,000 persons, in the 4th year of the 39th olympiad, B. C. 417. There is nothing now extant of Agatho, except a few quotations preferred by Ariosto, Athenaeus, Eelian, and others. His compositions abounded so much with anathemas, as to give him occasion for saying to a person, who wished him to expunge them, "you do not consider that you would rend Agatho from him!" See Athenaeus (Var. Hist. i. c. 17. tom. ii. p. 947) Athenaeus (Deipnosoph. l. v. p. 211. Ed. Ca- rius) on the following anathema: "If I tell you the truth, I shall not plague you; and if I plague you, I shall not tell you the truth." The anathemas recorded by Ariosto, (Eudemio- ram. l. v. c. 2. and c. 4. tom. ii. p. 243, 244, and Rhetor. l. p. c. 24. tom. ii. p. 581. Ed. Du Val.) are the three following: "The only thing impossible to God, is to caufe that not to be made that has been made; "fortune loves art, and art loves fortune;" "it is probable, that a great many improbable things may happen to mortals."

AGATHO, Pope, a native of Palermo, who was advanced from a monastery to the papal see, in 679. At this time the controversy occasioned by the Monothelites agitated the Chalcedian church, and the first exarch of Agatho's pontifical authority was that of convening synods in the western provinces, to decide concerning their doctrine. These synods having declared the Monothelite doctrine to be heretical, Agatho sent lectures on behalf of the western church to the bishops of the east. At this council the Monothelites were solemnly condemned. Thus Agatho, by his legates, renounced a doctrine which had been confirmed by the edict of a former council, and sanctioned by the approbation of his predecessor, Pope Honorius; and he concurred in the condemnation of Honorius, and enforced by penal laws the sentence of the council. In this instance the infallibility of Honorius, and that of Agatho and the sixth council, are in direct opposition. It is observed, likewise, as a fact worthy of notice in the history of the papal power, that this council was summoned by the emperor; that no appeal was made to the decision of former popes; and that no peculiar reverence was manifested to the authority of the bishop of Rome. After the dissolution of this council, Agatho directed his attention to the temporal interest of his see, and particularly to the remission of the fine paid to the emperors on the election of a new pope. He died, A. D. 682. Eulogius was held in such veneration that, if we credit the account of Plutina, his kins was an infant cure for the leprosy. His letters against the Monothelites, addressed to the emperors Constantine, Eiracius, and Tiberus, Gr. and Lat.; and to Ethelred, king of the Mercians, and Theodore, archbishop of Canterbury, Lat.; and the abbot Sexuplus, which last is said to be supplicated and written by some English monk, are preferred in the records of the third council, A. D. 682. Hardin's Concilia, tom. iii. Another letter granting peculiar privileges to the monastery of Weremouth, may be seen in Dugdale's Monasticon Anglicanum. Dupin's Hist. Seventh Century, vol. iii. p. 37. Bower.

AGATHOCLES, king or tyrant of Sicily, was the son of Carinus, a potter of Rhegium, and born at Thermae in Sicily. In consequence of strange dreams of his mother, whilst she was pregnant, to which the father paid a superstitious regard, the infant was exposed in the fields, as soon as it was born, and committed to the care of a person who was to watch it till it died. The mother, hearing of his condition, took the child and entrusted it with her brother Heraclides, and called it, after her father's name, Agathocles. At the age of seven years, he was introduced to the father, and the secret of his preservation was communicated to him by the mother. The diviners occasioned by self-reproach in the recollection of his conduct, was soon succeeded by
by the joy of having a son, who was singularly beautiful, restored to him. Soon after the discovery, Carinus, with his family, removed to Syracuse, and brought up his son to his own trade. Having joined Timoleon, who had routed the Carthaginians, both the father and son were enrolled among the Syracusan citizens. Upon the death of Carinus, Agathocles was recommended to Demas, a rich citizen, by whose favour and interest he was liberally supplied, and, in due time, advanced to the dignity of a chieftain, an office which gave him the command of a thousand men. Agathocles, having distinguished himself by his military talents, married the widow of his patron, Demas, and thus became the most wealthy citizen of Syracuse. When the supreme power in this city was usurped by Sophilatus, Agathocles retired to Italy; but aspiring to the sovereignty, first of Crotona, and afterwards of Tarentum, he became an object of general hatred and terror; and being expelled from these cities, and finding no admission into any other, he assembled a band of exiles and robbers, and plundered the country. At Rhegium, he unexpectedly attacked Sophilatus, and compelled him to abandon his enterprise. When this usurper was forced to abdicate the sovereignty of Syracuse, and to quit the city, he and the exiles who accompanied him, had recourse to the Carthaginians, who espoused their cause. The Syracusans recalled Agathocles, and appointed him to the chief command of the forces that were raised for repelling the attack of Sophilatus and the Carthaginians. Having successfully discharged the trust that was reposed in him, he assumed a sovereign power, and by the measure he pursued convinced his fellow-citizens that he was aspiring to the monarchy. The Syracusans, in these circumstances of alarm and danger, applied to the Corinthians for a commander; and they deputed Accoreides to this office. Agathocles faved his life by a stratagem; and having made his escape, he proceeded to raise troops in different parts of Sicily, and was soon in a condition to approach the city at the head of a considerable army. The Syracusans, dreading a civil war, sent ambassadors to treat with Agathocles, who disbanded his forces; and being conducted by the citizens to the temple of Ceres, took a solemn oath, according to the established custom, that he would do nothing to the prejudice of the democracy. Being again refuted to the chief command of the army, he indulged his ambitious views without regarding his oath, courted the favour of the populace, and massacred the nobles and chief citizens, so that in a few hours, more than 4000 of them were killed, and the streets were covered with dead bodies. Although he pretended to resign the command and to retire, he conducted his army with so much skill and success, that he was unanimously proclaimed king, and appointed to govern with an absolute and uncontrollable power. In order to render himself popular, the first law he enacted was, that all former debts should be cancelled, and the lands equally divided among the rich and the poor; and such was his behaviour that he acquired the attachment and confidence of his subjects. With their cordial concurrence he reduced, in two years, the whole island; a few cities held by the Carthaginians excepted. His progress alarmed the Carthaginians, and they deputed Hamilcar, with a powerful fleet and army, to restrain it. The first encounter, near the river Himera, terminated in favour of Agathocles; but the loss which Hamilcar had sustained by a storm in his voyage, and by the first engagement, being repaired by a powerful reinforcement, the attack on the part of the Carthaginians was renewed, and Agathocles was compelled to save himself, first in Gela, and afterwards within the walls of his metropolis, to which they laid close siege; propping by the reduction of this city to gain possession of the whole island. Thus profuced by the Carthaginians, and abandoned, on account of his former cruelties, by all his allies in Sicily, Agathocles formed the bold design of transferring the war into Africa, and besieging Carthage, when he himself was besieged in the metropolis, which was the only city of Sicily in his possession. Without communicating his design to any confidential person, he informed the Syracusans in general terms, that he had conceived a plan which would be effectual for their revenge; and collecting together the most intrepid of the soldiers and citizens, and incorporating the slaves, whom he emancipated, among his troops, he embarked all his forces on board 60 galleys, sailed directly for Africa, and landed on the coast, in the third year of the 117th olympiad, B.C. 310. Here he displayed his views to the army, and animated them to vigorous efforts by assurances of success. The soldiers received his address with loud acclamations. He then determined to burn all his ships, except one or two, which he reserved for carrying dispatches. When he communicated this daring resolution to the army, he told them, that when they left Syracuse and were pursued by the enemy, he applied in the moment of danger to Ceres and Proserpine, the tutelary goddesses of Sicily, and promised to burn all the vellets of his fleet, if they were delivered from the enemy, and enabled them to land safe in Africa. "Aid me, therefore, O fellow soldiers," said he, "to discharge this vow; for the goddesses can easily make us amends for this sacrifice." When these words were uttered, he allowed no time for deliberation; but taking a torch in his hand, he set fire to his own ship; the officers imitated his example, and were cheerfully followed by the soldiers. He then led them against an important place, called the Great City, that was subject to Carthage, which they took by storm; they then proceeded to Tunis and took it. Having enriched themselves with the plunder, he cau ed both cities to be levelled with the ground, that there might be no place of retreat, and no hope of safety but in victory; and encamped in the open fields. He next proceeded towards Carthage; and charging the Carthaginian army with incredible vigour, killed Hanno, one of their chief generals; and at last, by the treachery of Bomilcar, another general, obtained a complete victory. When the news of this victory was conveyed to Syracuse, Hamilcar raised the siege, and was afterwards taken by the Syracusans, who made an unexpected sally and routed his army, confining 120,000 men, and put to a cruel death. His head was sent to Africa, as an acceptable present to Agathocles. Whilst Agathocles was preparing for the siege of Carthage, he was joined by Ophellas, prince of the Cyrenians, who had been one of Alexander's captains; but the deluded prince was perfidiously murdered. The savage tyrant, being now at the head of a numerous army, assumed the title of the king of Africa; and invaded Carthage, with a view of reducing it by famine. During this interval, he passed over into Sicily with a detachment of 2000 men, in order to reduce those inhabitants of the cities, who had taken up arms and associated in defence of their liberties. His purpose was speedily accomplished; and he hastened his return to Africa. He found his army in great distress; and in an attempt for obtaining relief, he was defeated, and then defeated by the Africans, so that he was under a necessity of leaving the country. Upon his return to Sicily, he perpetrated the most horrid acts of cruelty. He first marched against the Egestines, who had revolted in his absence; and having taken their town by storm, he put all the inhabitants to death, without distinction of age or sex, and with circumstances of the most savage barbarity. He also ordered all those to be massacred who were related to the Syracusans, who attended him in the Carthaginian expedition,
AGATHODEMON, in Geography, a town of Sicily, built, according to Diodorus, (tom. i. p. 337.) by Agathonys, the son of Eolus, in the time of the Trojan war. It is supposed to have stood near the place now called San-Marcos, at a small distance from the promontory, called by the Sicilians Capo d'Orlando.

AGATHYSIANS, in Ancient History, the inhabitants of a district of Scythia, or European Sarmatia, mentioned by Herodotus (iv. c. 104., p. 328. Ed. Weil). They were rich, and who had their women in common, for the sake of binding the men more intimately to one another, and preventing jealousies and other ill effects of matrimony. In other respects they conformed to the customs of the Thracians. From Virgil (Aen. iv. v. 146.) who calls them "—pieni Agathyrh," it appears, that they had the common practice of painting their bodies. They also are said to have used gold in their ornaments. They pretended to be descended from Agathyrus, the son of Hercules the Libyan.

AGATTON, in Geography, a town of the kingdom of Benin, in Africa, situate on a small eminence, forming an island, at the entrance of the river Formosa, near the sea. It is more healthy than any other part of the country, and surrounded with fruit trees. It has several circumjacent villages, whose inhabitants resort to it at every principal market, which is held for five days. It was formerly very considerable, but has suffered much from wars. N. lat. 6° 30'. E. long. 5° 44'.

AGATU, one of the Fox islands, in the northern Pacific Ocean.

AGATY, the name of a Malabar tree, bearing a fruit in taste and shape like the kidney-bean. Ray's Hist.

AGAI, or AGAW, in Geography, a small kingdom of Africa, dependent upon Abyssinia. It lies between the lake Dymba and the Nile.

AGAVA, in Ancient Geography, a town of Africa, placed by Ptolemy in the Pentapolis, or Syrtis.

AGAVE, formed from agawy, admirable, in Botany, a genus of the becardia monyoxia class and order, of the natural order of coronaria, and of the boronelie of Jaffier. Its characters are, that it has no calyx; that the corolla is one-petalled, and funnel-shaped, with a fix-parted equal border, and lanceolate erect parts; the stigma is filiform, erect filaments, longer than the corolla; the anthers linear, shorter than the filaments, and versatile; the pillillum is an oblong germin, growing thinner towards both ends, inferior; the ily filiform, of the length of the flamina, and three-cornered; the stigma headed and three-cornered; the pericarp is an oblong, three-cornered, three-celled, three-valved capsule; and the seeds are numerous. The species enumerated

AGATHODEMION, in Biography, an artist of Alexandria, prepared a series of maps for the illustration of Ptolemy's Geography, in which the position of all the places mentioned by this eminent geographer, with their latitude and longitude, is laid down precisely according to his ideas. Fabr. Bib. Græc. tom. ii. p. 412.
A g a v e, but Portugal air, painting thus caiia, the leaves grows this fort Karratto. The firs, of fresh. Aloe, and which of American Spain, only to refembled. The flowers are enumerated to Botanical, and which of Martyn \((1755)\). A. tuberoza, or tuberous-rooted agave, has the leaves indented at their edges, and each indenture terminates in a spine; the root is thick, and swells close above the surface of the ground; in other respects it agrees with the leaf spikes; it has two varieties, viz. the single-tubered and double-tubered agave. It grows in the Antilles, and has been cultivated at Paris under the name of A. nymphyflora. 6. A. fuscita has long, narrow, stiff leaves, of a pale green colour, waved on their edges, those on the side spread open, and those in the centre closely folded over each other, and encompassing the bud. The juice of the leaves has a bad smell. It is seldom more than 3 feet high, but the flower stems rise to 20, and branch out in the manner of the frill, but more horizontally, and the flowers are smaller and of a greener colour. This species grows in the woods of St. Domingo. A plant of this species, which flowered in 1755, and then died, was cultivated in 1762 in the Royal garden at Hampton Court. Of the leaves are formed ropes and various kinds of cloth, which serve for garments and other purposes.

A. cubenbo has ciliato-pinnate leaves and an hexapetalous corolla. M. La Marck makes this a variety of the A. mexicana, the Metl, or Mayet of the Mexican; it grows in Mexico and the island of Cuba. The mucilaginous juice is used as soap for washing, and the leaves are formed into a thread, which serves them for ropes, cloth, and other uses.

The first and third species are hardy. Those of the former fort will bear the open air in mild seasons; but require being sheltered in the winter. They are propagated by off-frets. The third species generally puts out suckers enough for propagation. They should be planted in pots filled with light sandy earth, housed in winter, and have little wet. In the summer they may be exposed to the open air, and remain thus till October. The Vera-Cruz agave should be longer in the house, as it is more tender. The second, fourth, and sixth, never produce off-frets or suckers from the root; but when they flower, there will be abundance of them; but they may be propagated by taking off some of the larger roots, when the plants are shifted. The second, fifth, and sixth, with the Karatto and rigid agaves, are more tender than the others, and cannot be preserved in winter, unless they are placed in a warm frame, nor will they thrive if set abroad in the summer. They require a light sandy earth, and should have little wet in winter; but in summer they may be gently watered twice a week. They must be shifted every winter into fresh pots; but the pots should be small that their roots may be confined; otherwise the plants will not thrive. Linnæus has separated this genus from the Aloe, because the lamina and style are extended much longer than the corolla, and the corolla falls upon the germ. Besides, all the agaves have their central leaves, closely folding over each other, and embracing the flower-fret in the centre; so that these never flower till all the leaves are expanded, and when the flower is past, the plants die. Whereas the flower-fret of the aloe is produced on one side of the centre, annually from the same plant, and the leaves are more expanded than in this genus. Martyn's Dicotyledon.

**A g a v e**, in Mythology, the name of one of the 50 Nereids. A g a v e, in Natural History, a species of Papilio Danae, with roundish yellow wings; the anterior black above and brown below. It is found in Cayenne.
AGAVI, in Ancient Geography, a people of Media, or of Thrace.

AGAUNA, now St. Maurice, a burg of the Vallais, in the valley of Pened, celebrated on account of the martyr of the Thbean legion, who suffered decimation rather than renounce Christiantiy. Sigignon, king of Burgundy, erected a monastery here in 515.

AGAUPÉ, in Botany, a name used by some authors for the common white water-lily.

AGAZZIRI, in Geography, an ancient people near the mouth of the Vibata.

AGBIENSIUM municipium, Beijon, a municipal town of Africa, built upon a hill, about half a league from Thucca. Here are found the ruins of ancient temples.

AGDAM, a town of Arabia Felix, placed by Ptolemy in long. 73°30', and lat. 21°20'.

AGDE, anciently Agatha, a small but populous city in the department of Herault, and late province of Languedoc in France, in a diocese of the name, situate on the river Herault, at the distance of about half a league from the sea. The diocese is one of the richest districts of the country; it is within the province of Narbonne, and contains 18 parishes. The ancient Agatha was a small island: but the accumulation of sand at the mouth of the Herault has now joined it to the continent. It produces fine wool, wine, oil, corn, and silk. The town has a harbour for small vessels, defended by a little fort at the mouth of the river. Most of the inhabitants are traders or farmers. The buildings are mean, the cathedral small, and the bishop's palace an old building. The bishop is lord of the city, and styled Count of Agde. The chapel of Notre Dame de Grace, in the vicinity of the town, attracts a great number of pilgrims and devotes. The Capuchin convent is also much resorted to on account of the image of the Virgin Mary, which is placed in a distinct chapel adjoining it: the convent has apartments for the accommodation of the pilgrims, who repair hither to perform their nine days' devotion. The vicinity of Agde abounds with extinct volcanoes. Cap d'Agde is one of them; and the rock of Agde is nothing but a hard lava, so that the town is built and paved with this lava, which is very black. Buffon's 'Nat. Hist. by Smellie,' vol. ix. p. 201. N. lat. 43° 18' 57", E. long. 5° 28' 11'.

AGDENAS Bay, is a part of that of Drontheim, in Norway; in the neighbourhood the soil produces plenty of grain.

AGDENITES, a name given to a people of Carmania.

AGDERUINE, a small town in the island of Minorca, situate near a mountain south-west of Cape Bajoies. N. lat. 46° 15'. E. long. 4° 14'.

AGDISTIS, a mountain of Asia Minor, near the town of Pellinus.

AGDUS, a rock on the frontiers of Asia Minor, famous in ancient mythology.

AGE, in Antiquity, a word which was proclaimed by a public crier whilst the Roman magistrates were taking the auspices, or whilst they were fabricating, in order to command the attention of the people. The word was also an order to the priest or other person, for immolating a victim, as age, or hoc age, in reply to his question, agon, or agoen? shall I slAY? Thus Ovid Fast. 1. 321. tom. iii. p. 323. Ed. Burtm.

"Qui calido fliriios tincturus fanguine culturos
Semper agone? rogas; nec nisi julius agas."—See Agon.

AGE, in the most general sense of the term, denotes the duration of any subsistance, animate or inanimate; and is applied either to the whole period of its existence, or to that portion of it which precedes the time to which the description of it refers. In this sense it is used to dignify either the whole natural duration of the life of man, or any interval of it that has elapsed before the period to which we refer. The ordinary age of mankind has been observed to vary in such a manner as to afford an instructive and pleasing display of the wisdom of Divine Providence. When age is understood of a certain portion of the life of man, its whole duration is divided into four different ages, viz. infancy, youth, manhood, and old age: the first extending to the 14th year; the second, denominated youth, adolescence, or the age of puberty, commencing at 14, and terminating at about 25; manhood, or the virile age, concluding at 50; and the last ending at the close of life. Some divide the first period into infancy and childhood, and the last likewise into two stages, calling that which succeeds the age of 75, decrepit old age. Shakespeare has admirably described these different stages in his comedy of "As you like it."

———"His acts being seven ages. At first, the infant, Mewing and puking in the nurse's arms:
And then, the whining school-boy, with his fitches.
And shining morning face, creeping like snail
Unwillingly to school:
And then, the lover
Sighing like furnace, with a woof ballad
Made to his Mithrel's eyebrow:
Then, a soldier:
Full of strange oaths, and bearded like the pard,
Jealous in honour, huddled and quick in quarrel,
Seeking the bubble reputation
Even in the cannon's mouth:
And then, the justice:
In fair round belly, with good capon lin'd,
With eyes severe, and beard of formal cut,
Full of wise saws and modern instances,
And so he plays his part: The sixth age shifts
Into the lean and slipper'd pantaloon;
With spectacles on nose, and pouch on side;
His youthful hope well fav'd, a world too wide
For his shrunk shank; and his big manly voice,
Turning again toward childish treble, pipes
And whistles in his head: Last scene of all,
That ends this strange eventful history,
Is second childishness, and mere oblivion;
Sans teeth, sans eyes, sans taste, sans style, sans everything.
See Longevity.

Age is applicable to the duration of things inanimate or fictitious: and in this use of the term we speak of the age of a house, of a country, of a state or kingdom, &c. It is likewise used in reference to vegetable subsistences, as roots, leaves, corn, wine, &c. Trees are said, after a certain age, to wane and decay. An oak, at 100 years old, ceases to grow. The usual rule for judging the age of wood, is by the number of circles which appear in the subsistence of a trunk or flock cut perpendicularly, each circle being supposed to be the growth of a year; though some reject this method as precarious, alleging, that a fumple circle is sometimes the produce of several years: besides that, after a certain age, no new circles are formed. Phil. Trans. No. 43. Age, in Chronology, is used for a century, or a period of 100 years: in which sense it is the same with sedulum, and differs from Generation. It is also used in speaking of the time past since the creation of the world.

The several ages of the world may be reduced to three grand epochs, viz. the age of the law of nature, called by the Jews the void age, from Adam to Moses.—The age of the
the Jewish law, from Moses to Christ, called by the Jews the present age.—And the age of grace, from Christ to the present year. The Jews call the third age, the age to come, or future age; denoting by it the time from the advent of the Messiah to the end of the world. See Incarnation and Epoch.

The Romans distinguished the time that preceded them into three ages: the obscure or uncertain age, which reached down as low as Ogyges king of Attica; in whose reign the deluge happened in Greece.—The fabulous or heroic age, which ended at the first Olympiad; and the historical age, which commenced at the building of Rome. Varro calls the period preceding the deluge, an age entirely unknown. The second he calls fabulous, on account of the numerous fables, with which the accounts of it, that have been transmitted to posterity, are interwoven. Diodorus Siculus, (tom. i. p. S.) extends the fabulous age no farther than the Trojan war; from which time the myth which had overcast the preceding periods begins to clear up, and some rays of truth to break out. The commencement of the historical age is usually referred to the first Olympiad, in the year of the world 3228, and still continues. This division, it is to be observed, only holds good with regard to the Greeks and Romans, who had no histories earlier than the first Olympiad. The Jews, Egyptians, Phcenicians, and Chaldsees, not to add the Indians and Chinefs, pretend to much higher antiquity.

Among the poets, the four ages of the world are, the golden, the silver, the brazen, and the iron age. See the Metamorphos of Ovid, lib. i. or rather Hesiod, in his poem, Epyrinx opus suum, Opera et Difœ, ver. 108, &c. He is the first that has described these four ages.

During the golden age Saturn reigned, and universal harmony and plenty prevailed. See Saturn. The silver age commenced when men began to deviate from the paths of virtue, and their lives became less happy. The brazen and iron ages denote periods of greater degeneracy. A late author, however, inverts the order of the poets; and thinks the first, which was a period of ignorance and barbarism, might be more properly denominated an iron than a golden age; when cities and states were founded, the silver age commenced; and since arts and sciences, navigation and commerce, have been cultivated, the golden age has taken place.

Bochart (Geog. Sac. Lib. c. 12. i. i. col. 226. Ed. Villen.) has described these four ages of the poets in the following manner. The first or golden age, lasted under the government of Saturn, or Noah, 100 years from the flood to Phæleg, in which period there was no division of the land. Thus Tubal represents it (lib. i. eleg. iii.)

“Non fixus in agris, Qui reget certis finibus arva, lapis.”

And Virgil (Georg. l. v. 126.)

“Nee figura quidem aut partitri limite campum Pas erat.”

In the silver age, the lands were divided and cultivated, houles were built, and the tower of Babylon was erected.

“Tum primum fubierit domos, &c.”

The third, or brazen age, was marked by the insurrection of Nimrod, the Baccus of the ancients, first a hunter and afterwards a warrior, who transferred his power from wild beasts to men, and established a tyrannical government. Thus described by Virgil (ubi subirop, l. v. 139.)

“Agrum laqueus captare feras, et fallere vico, Inuentum: et magnos caebus circundare fallus.”

And by Ovid : Metam. lib. i. v. 125.

“Tertia polli illis succefft æneæ prose, Sevior ingenius, et ad horrida promtior arma.”

And also by Hefiod, (Op. and Dices. l. 143. p. 134. Ed. Robin.) thus translated:

“Tertia deinde atas famini Jovis edita nutu, Vivor argentio, de duro conßitit ere. Fraxinæa et vehementes robustaæque, Martis amore In pugnas et bella ruens.”

This was succeeded by the iron age in which we live. On some ancient northern monuments we find the rocky or stony age, which corresponds to the bræzen age of Hefiod, and the Greeks; being called rocky, on account of Noah’s ark, which reigned on Mount Ararat. The northern poets also denominate the fourth age the iron age, from a Gothic king, Medæris or Mannus, who, on account of his great strength, was said to be made of iron: because in his time people began to make use of weapons made of that wood. Phil. Tranf. No. 301.

Age is sometimes used among the ancient poets in the same sense with generation, for a period of 30 years. Thus Nefior is said to have lived three ages, when he was 50 years old.

The East Indians also reckon four ages since the beginning.—The first, which they represent as a sort of golden age, lasted according to them, 17280000 years; in this the god Brahma was born, and the men were all giants; their manners were innocent: they were exempt from diseases, and lived 400 years. In the second age, which lasted 10960000 years, their rajas were born; vice now crept into the world; men lives were fallen to 300 years, and their size retrenched proportionally.—Under the third age, which lasted 8064000 years, vice being more increased, men only attained to 200 years.—The last age is that wherein we now live, of which 402713 years are already gone; and the life of man funk to one fourth of its original duration.

The period preceding the birth of Jesus Christ has been generally divided into six ages. The first extends from the creation to the deluge, and comprehends 1650 years. The second age, from the deluge to Abraham’s entering the land of Promise, A.M. 2082, comprehends 425 years. The third age, from Abraham’s entrance into the promised land to the Exodus A.M. 2512, includes 430 years. The fourth age, from the Exodus to the building of the temple by Solomon, A.M. 2992, contains 480 years. The fifth age, from the foundation of Solomon’s temple to the Babylonish captivity, A.M. 3416, comprehends 424 years. The sixth age, from the Babylonish captivity to the birth of Jesus Christ, A.M. 4000, the fourth year before the vulgar era, includes 584 years. Those who follow the Septuagint, or Greek version, divide this period into seven ages, viz. 1. From the creation to the deluge, 2562 years. 2. From the deluge to the confusion of tongues, 738 years. 3. From this confusion to the calling of Abraham, 460 years. 4. From this period to Jacob’s descent into Egypt, 215 years; and from this event to the Exodus, 430 years, making the whole 645 years. 5. From the Exodus to Saul, 774 years. 6. From Saul to Cyrus, 583 years. 7. From Cyrus to the vulgar era of Christifians, 1538 years; the whole period from the creation to this period, containing 6200 years. See Chronology.

The Sibylline oracles divide the duration of the world into

3 11 2 10
The age of Augustus was appropriated by the senators in a peculiar manner to the time in which this emperor lived.

Other historians reckon from the creation to the taking of Troy, 2830 years; and to the foundation of Rome, 3250; from the conquest of Carthage, by Scipio, to Jesus Christ, 200; from Jesus Christ to Conantiple, 312; and to the re-establishment of the empire of the West, 503 years.

The denomination of middle age is applied by some to the space of time, which commenced from Constantine, and ended with the taking of Constantinople by the Turks, in the 15th century; or, to the interval that elapsed between the fall of the western or Latin empire, near the close of the fourth century, and that of the eastern or Grecian about the middle of the fifteenth, comprehending near 1000 years. Others date the middle age from the division of the empire by Theodosius, at the close of the fourth century, and extend it to the time of the emperor Maximilian I. at the beginning of the 16th century, when the empire was first divided into circles. This seems more accommodated to the state of Germany in particular, than to that of Europe in general. The middle is by some denominated the barbarous age, and the latter part of it the lowly age. Some divide it into the non-academical and academical. The former comprehends the interval from the 6th to the 9th century, during which schools or academies were lost in Europe. The latter denotes the period from the 9th century, when schools were restored, and universities established, chiefly by the care of Charlemagne.

Age, in the History of Literature and the Arts, is applied to a period peculiarly distinguished by the cultivation of learning, and the extraordinary productions of genius. Accordingly learned men have marked out four of these happy ages. The first is the Grecian age, which commenced near the time of the Peloponnesian war, and extended till the time of Alexander the Great; within which period we have Herodotus, Thucydides, Xenophon, Sophocles, Plato, Aristotle, Demosthenes, Herodes, Thucydides, Pindar, Isias, Menander, Anacreon, Theocritus, Lycurgus, Apelles, Phidias, Praxiteles. The second is the Roman age, included nearly within the days of Julius Cæsar and Augustus; affirming us, Catullus, Lucretius, Terence, Virgil, Horace, Tibullus, Propertius, Ovid, Pedrus, Cæsar, Cicero, Livy, Sallust, Strabo, Dionysius of Halicarnassius, Varro, and Vitruvius. This period, or at least a considerable portion of it, has been denominated by way of eminence the Augustan age, or the age of Augustus, which has been regarded as the age of genius, elegance, and politeness. The third is that in which followed the taking of Constantinople by Mahomet II., or that of the reformation of learning, under the popes Julius II. and Leo X., which produced the following eminent characters, viz. Ariosto, Tasso, Sannazarius, Vida, Machiavel, Guicciardini, Davila, Erasmus, Paul Jovius, Michael Angelo, Raphael, Titian. The fourth age comprehends that of Louis XIV. and Queen Anne, when France was distinguished by Corenne, Racine, De Retz, Moliero, Boileau, Fontaine, Roulleau, Bossuet, Fenelon, Bonnardoube, Pafcal, Malbranche, Mafillon, Bruyere, Bayle, Fontenelle, Vertot; and when England exhibited Dryden, Pope, Addison, Prior, Swift, Parnell, Arbuthnot, Congreve, Otway, Young, Rowe, Atterbury, Shaftsbury, Dohngbrooke, Tillet, Temple, Boyle, Locke, Newton, Clarke. Those who lived in the two first of these periods are generally distinguished by the appellation of the ancients, when a comparison is instituted between the ancients and the moderns, including also under the first class one or two who lived in a more early age, as Homer in particular; and the moderns comprehend those who flourished in the two last of the ages mentioned, including also the eminent writers down to our own times. Voltaire’s Age of Louis XIV. vol. i. p. 1, &c. Blair’s Lectures on Rhetoric and Belles Lettres, vol. iii. p. 4.

There are other periods, which, on account of the extreme ignorance that prevailed, have been denominated ages of ignorance. Such are the 9th, 12th, and 11th centuries, in the modern history of Europe; when few kings and nobles, much less the common people, were able to write or read. These were ages of slavery, civil and religious, as well as ignorance.

Age of Medals. See Medal.

Age in Horsemanship, forms a very important branch of knowledge, and confers in being enabled to judge of the habits and age of a horse, and the value of his parts. This becomes necessary, as there are but few whose knowledge is sufficiently extensive to enable them to judge of the age by any other means; but where it can be done it is more useful than by this ordinary mode; for in this country, where horses are ridden very hard, and consequently early ruined, it is not uncommon to find a horse at six years old, feeble, debilitated, and exhibiting all the marks of old age, except in his mouth; on the contrary, when the animal falls into other hands, at 10 or 12 he has all the vigour of youth, and his teeth are the only parts that present an indication of age: it is therefore more useful to examine the general appearance of the animal, than to be guided altogether by the marks in the teeth; for, provided the horse has not been too early worked, nor too hard rode, and has no natural nor accidental defects, his nominal age should be but a secondary consideration. It is the custom of some excellent horsemen never to hunt their horses, till they are eight or nine years old, a period at which other horses are usually refused as aged, and unfit for fatigue.—Horses, when aged, usually become hollow above the eyes, the hoofs become rugged, the under lip falls, and if grey, they become white. La Fosse, the younger, recapitulates the appearances of the teeth nearly in the following manner. The horse is foaled with fixed molar or grinding teeth in each jaw; the tenth or twelfth day after the two front nippers appear above and below, and in fourteen or fifteen days from this, the two intermediums are put out; the corner ones are not cut till three months after. At ten months the incisive or nippers are on a level with each other, the front lefts than the middle, and these again less than the corners; they at this time have a very fenital cavity. At twelve months this cavity becomes smaller, and the animal appears with four molar teeth on each side, above and below, three of the temperaneous or colts, and one permanent or horse tooth; at eighteen the cavity in the nippers is filled up, and there are five grinders, two of the horse, and three temperans; at two years, the first of the colts molar teeth in each jaw, above and below, are displaced. At two years and a half, or three years, the front nippers fall and give place to the permanent ones; at three and a half the middle nippers are likewise removed, at which period the second molar falls; at four years the horse is found with fixed molar teeth, five of his new set, and one of his last; at four years and a half the corner nippers of the colt fall and give place.
place to the permanent ft, and the half temporary grinder disappears. At five years old the tubes in the horse usually appear; at five and a half they are completely out, and the internal wall of the corner nippers, which before was incompletely formed, is now on a level with the rest; at this period the incisive or nippers have all of them a cavity formed in the substance between the inner and outer walls, and it is the disappearance of this that marks the age. At six years those in the front nippers below are filled up, the tubes are likewise slightly blunted; at seven years the mark or cavity in the middle nippers is filled up, and the tubes a little more worn. At eight years old the corner nippers are likewise plain, and the tubules are round and shortened. At this period the horse is said to be aged, and to have lost his mark, but among good judges the teeth still exhibit sufficient indications. At nine the groove in the tubules is worn away nearly, and the nippers become rather rounded; at ten these appearances are still stronger; at twelve the tubules only exhibit a rounded bump, the nippers push forward, become yellow, and as the age advances, appear triangular and usually uneven.

Mr. Dent, the late professor of the English Veterinary College, used to assert, that after eight years the cavities in the anterior or upper incisive teeth filled up with equal regularity; thus from eight to ten the front ones were filled up; from ten to twelve the two middle, and from twelve to fourteen those of the corner; but though some palms have been taken to ascertain this, it does not appear that the disappearance of the cavities in these teeth is attended with sufficient regularity to warrant confidence. It is a custom with diamond-darters to draw the colts nippers, particularly the corner ones, by which means the permanent set which are underneath, immediately appear, and the horse is considered much older than he is; but if the other appearances detailed here are attended to, this may be readily detected. See Plate where the age from the appearance of the teeth is accurately represented. See also Teeth, and Anatomy of the Horse.

Age, in Hunting, is an article of conformation.—Deer, and other beasts of game, have different denominations according to their age.

The age of a hart, &c. is chiefly judged of by the furniture of his head, which is annually enlarged both in height and thickness, from the second to the eighth year, and then continues nearly in equal beauty during the vigour of life. But, when he grows older, i. e. from eight years forward, his horns decline.

The first head, called, in sallow deer, branches, and, in red deer, pricks, does not come till the second year of their age; the next year, they bear four or fix small branches; the fourth year, eight or ten; the fifth, ten or twelve; the sixth, fourteen or sixteen; the seventh year they bear their heads beamed, branched, and fumed, as much as ever they will be. The number of antlers or palms is by no means constant, when the animal is in the highest degree of vigour and perfection; for it varies according to the quantity of nourishment and repose the animal has enjoyed, and the size of the horns depends upon the fame caesal. The huntsmen have several other marks, whereby to know an old hart without seeing him, as the flat, entries, abatures, foils, fewmets, gate, and fraying pofts. See Slot, &c.

The age of other beasts that are chafed, is estimated by their appearance: as a fox and a hare by their colour. In birds of the game kind, it is usually distinguished by the colour of the legs and wing-feathers.

Age of new cattle, viz: the ox•cow, and bull, is known by their teeth and horns: but from long habit and the greater convenience, the horns are more usually judged; but in that breed without horns, the teeth must be nearly the sole criterion. The ox has no upper incisive teeth, but a few days after calving eight nippers appear in the lower jaw, which remain till ten months, when the second denition commences by the displacement of the two front teeth, to which succeeded two permanent ones, larger but not fo white.—At 12 months, the grinders are some of them changed; at 15 or 16 months, the incisive on each side next the front is changed; at two years the third incisive on each side: and at three years the corners are replaced by the permanent, which complete the ft. These are for the first years of the animal's live, even, long, and white; but in advanced age become yellow, or black, and uneven; between these periods all the grinders are changed.

The horns are likewise a permanent and a temporary pair. The temporary pair are changed at the end of three years, and the permanent pair appear small, smooth, and terminated at the end with a small tubercle or button. In the following year this button grows from the head, and the line of growth is marked by a horny circle; the horns continue growing through life, and every succeeding year adds a circle, so that the age may be readily gained by counting three years for the first button, and an additional one for every remaining circle.

Age of Sheep, is learned likewise from the horns in those which have them, in others from the teeth. M. Buffon says they have, in the third year, four broad teeth before, in the fourth year fix broad teeth, and in their fifth year eight of the same kind: but our farmers reckon, that when a sheep is one year, or year, it has two broad teeth before, when two, it will have four; when three, will; and when four, or years, it will have eight. The age of the horned sheep is most conveniently learned by the horns, which flew themselves in the first year, soon after birth, and are not changed, but continue to protrude a ring or circle annually, as long as they live, so that as many circles as their horns poffeft, so many years are they old. In goats, the teeth and horns follow the same laws; and therefore their age may be learned in the same way.

Age of the Moon, in Astronomy, is understood of the number of days elapsed since the last conjunction, or new moon; called also her quarter. The method for discovering her age is mentioned under the article Moon.

Age, in Law, is particularly understood of a certain rate or time in life, wherein a person is qualified for certain offices of civil society, of which before, for want of years and duration, he was incapable.

By the Roman law we find different ages ascertained for different purposes; as, confider age, or that wherein a person might regularly hold the consulship, which was the 43d year, so that he might sue for it in the 42d. Where it is to be observed, that it was not necessary either of those years—should be expired, but only begun; besides, that men of extraordinary merit towards the republic, were in this matter exempt from the ordinary laws. Hence Corvinus was conful at 25 years. Scipio Africannus at 36, and Pompey at 35: others broke through the laws by violence, as Cn. Maruus the younger, and Octavius Caesar, who procured themselves to be made consuls, before 20 years of age. Machiv. Difc. in Liv. lib. i. c. 60. p. 210.

Judiciary age, or that wherein a person was capable of sitting as judge, was not always the same; for by the Lex
AGE

Lex Servilia Glauce, none were allowed to be chosen under 30 years of age, or above 60. By some other laws that age seems to have been limited to 30, but reduced afterwards by Augustus to 30; though Pitiusa supposes a mistake here in the text; and that, instead of 35 and 30, it ought to be read 25 and 30. Lex Ant. tom. 1. Military age, or that wherein the Romans were obliged to enter themselves in the army, was at 17 years; at 45 they might demand their discharge. Aquin. Lex. Milit. tom. 1. This age was subject to considerable variation. The ancient practice, as Vegetius informs us, was to arm young men when they attained the age of puberty: and this fulfilled before and under the first kings. Servius Tuilius (about the year of Rome 178) fixed the period of military service from 17 to 46 years: those who had not reached this half term were called juvenes, and those who had passed it veteres. Manlius, however, who saved the capitol, had served from the age of 16 years. Adrian commenced his military service at the age of 15 years; and influences occur, in the Roman history, of persons who were called forth to military service within the age of 50 years. But the age established by Servius Tuilius was confirmed by Caius Graecus, A. U. C. 632. The Gauls and Germans served from the age of puberty to extreme old age. The Persians fixed the period of military service from 20 to 50 years. The Scythians and Lacedaemonians extended it from the age of puberty to 60 years. The Athenians commenced at 18 years to guard the city and frontiers, and at 20 they engaged in foreign service, and continued to the age of 40 years. Aristotle fixed the military age at 17 years (Polit. lib. viii.); and Plato, in his Republic, determines it from 20 to 60 years. Among the Lombards, the age of entry was between 18 and 19; among the Saxons at 13.

The age for holding office in the city, as quaestor, exilid, tribune of the people, &c. is not determined by the annual laws of Villius, but appears to have been the 27th year. For it was necessary that the person who claimed any urban employment, had first served ten years without interruption in the army, commencing from the 17th year. Though some think the quaestorship might have been held at 15 years. Polyb. lib. vi. cap. 17. The praetorian age, or that wherein a person might solicit for the praetorship, was at 40; two years earlier than the age required for consul. But M. Brutus was praetor with Caius, two years before his death; i.e. at the age of 35 years; and Dion (lii. p. 477.) fixes this age at 30 years. Legitimate age denotes the age of 25; so called, as some imagine, because youth were then by law allowed to take the direction of their affairs into their own hands. Briff. Sedct. Ant. ex Jur. Civ. lib. iii. c. 2. Dispensation of age, statutum vieni, is a right which a person obtained from the prince, or sovereign, of setting aside a tutor or curator, and taking the administration of his affairs into his own hands, before the legitimate age. Calv. Lex. Jur. The adoptive age requires the adopter to be eighteen years older than the person adopted, that there may appear a probability of his being a natural child. Pitic. Lex. Ant. See Adoption.

By the common law, there are two principal ages in a man: at 14, he is at the age of discretion; at 21 years, at full age.

With respect to a woman, there were anciently six ages observable: at seven years, her father might distrain the tenants of his manor for aid to marry her; for at those years she may consent to marriage. At nine years old the is

GRADE

dozable; for then, or within half a year after, she is said to be able promoveri domi. & virum subjicere. At twelve years, she is liable finally to ratify and confirm, or annul her former consent to marriage; and, if proved to have sufficient discretion, may bequeath her personal estate. At 14, she may take her lands into her own hands; and should be out of ward, if she were at this age at her ancestor's death; at this period the is at years of legal discretion, and may choose a guardian. At 16, she should be out of ward, though at the death of her ancestor she was under 14: the reason is, that then she might take a husband and able to perform knight's service: she may be executrix at 17. At 21 years, she may dispose of herself and alienate lands and tenements.

As for a man: the age of 12 years binds to appearance before the sheriff and coroner for inquiry after robberies, and impowers taking the oath of allegiance: 52 Hen. III. 14. At the age of 14, he may chuse his own guardian, and claim his lands held in foage; though Bracton limits this to 15 years, with whom Glanville agrees. At 14, a man may consent or disafford to marriage. At that age, likewise, he may dispose of personal estate by will, if his discretion be actually proved, though not of lands until 21; at 14 also, perons may be witness, though in some cases they have been admitted much younger. 2 Hawk. 434. Persons under 14 are not, in general, punishable for crimes: but they must answer for any trepas, p. 1. Int. 247. At 15, he ought to be sworn to the peace, an. 24 Edw. I. flat. 3. At 17, he may be an executor. At the age of 21, a man was obliged to be a knight, if he had 20 pounds land per annum fee, or for term of life, anno 1 Ed. II. flat. 1. But this statute is repealed, 16 Car. I. cap. 20. The same age also enables him to make contracts and manage his own estate; which, till that time, he cannot do with security to those who deal with him; so that at this age he is at his own disposal, and may claim his lands, goods, and chattels. Full age, in male or female, is 21 years; and this age is completed on the day preceding the anniversary of a person's birth (Salk. 44. 625. Lord Raym. 486.) who, till that time, is an infant, and is fled in law. Among the ancient Greeks and Romans women were never of age, but subject to perpetual guardianship, unless when married; and when that perpetual tutelage were away in processes of time, we find, that in females as well as males, full age was not till 25 years. By the constitution of different kingdoms, this period is fixed at different times. Scotland agrees with England in this point; but in Naples they are of full age at 18; in Holland at 25; and formerly in France, with regard to marriage, not till 30.

With regard to capital crimes, the age of 12 years was estaishned, by the ancient Saxon law, for the age of possible discretion; and from thence till the offender was 14, it was anutubertia pronsima, in which he might, or might not be guilty of a crime, according to his natural capacity or incapacity. Under 12 it was held, that he could not be guilty in will, neither after 14 could he be fupposed innocent of any capital crime which he committed. But by the law, as it now stands, and has stood, at least ever since the time of Edw. III., the capacity of doing ill, or contracting guilt, is not so much estimated by age, as by the delinquent's maturity of understanding, so that malitia supposita statem. Under seven years of age, an infant cannot be guilty of felony; but at eight years old he may be guilty. Under 14, though an infant shall be prima facie adjudged to be doli incapax, yet, if it appear to the court and jury, that
that he was doli capre, and could discern between good and evil, he may be convicted and suffer death. Thus, a girl of 13 has been burnt for killing her mistress; and one boy of ten, and another of nine years of age, who had killed their companions, have been sentenced to death, and the boy of ten years of age was actually hanged; because it appeared upon their trial, that the one hid himself, and the other hid the body of the person he had killed. An inquest occurred in the 17th century of a boy eighteen years old, who was tried for firing two bars: and it appearing that he had malice and cunning, he was found guilty, condemned and hanged. In later times a boy, ten years old, was convicted on his own confession of murdering his bed-fellow, and by the unanimous opinion of all the judges capitaly punished. In such cases, however, the evidence of that malice, which is to supply age, ought to be clear and strong beyond all doubt and contradiction.

The age of 24 years enabled a man to enter into an order of religion, without consent of parents, anno 4 Hen. IV. cap. 17. At 24, he may be ordained a priest; and at 30, he may be a bishop. No person can be a member of parliament under the age of 21 years. Though the age of 21 is the full age of either man or woman, yet they may under that age contract for necessaries suitable to their quality and proper instruction, and the contract shall bind them. An infant, who has an advowson, may prentent to the benefit when it becomes void. He may also purchase lands, though the purchase be incomplete; and when he is of age, he may agree or disagree to it, without alligning any reason; and so may his heirs after him, if he should die before the completion of the agreement. In some cases, he may bind himself apprentice, by indenture, for seven years. 5 Eliz. c. 4.—43 Eliz. c. 2. and he may, by deed or will, appoint a guardian to his children, if he has any. 12 Car. II. c. 24. If either man or woman do any act before the time precribed by law, they may retract it when they come to the proper age; but if they do not, they are supposed to ratify it, and it shall be deemed valid. Thus, if a man marry before fourteen, or a woman before twelve, they may either agree or disagree to the marriage, when they attain their respective ages. See Marriage. But the age of marriage has undergone divers modifications: in princes, it is allowed earlier than in private persons; in some countries than in others. In Peru, girls are married at nine, boys only at thirteen; in Holland, males are not allowed to marry without consent of parents or curators, before twenty-five; girls not before twenty: the Romans chose to marry their wives young, for the advantage of having them innocent and tractable. Others declaim against premature marriages. Some have pretended to limit the other extreme of marriageable age to forty-five; but this too will be variable in different constitutions. We meet with instances of generation from 60 to 104, or even 121 years of age. Plott. Nat. Hist. Staff. chap. viii. § 2.

Various methods have been in use for determining this age. One fact of ancient Roman lawyers, called Calliann, fixed it by the stature of the body, which Juliusin and others after him, suppose to have been done by search, or inspection of the genital parts, at least in the male sex; for as to the female, it is pretended the twelfth year was the only guide, though others allege that the eruption of the mones served instead of it. The Proculiani, on the contrary, determined the puberty of males by the expiration of the fourteenth year. Javolenus took a middle course, and made use of both methods.

The Canon or Ecclesiastical Law also denotes divers ages, viz. of baptism; or ordination to priesthood, and confirmation to episcopacy.

The Civil Law distinguished the age of minors, or those under 25 years old, into three sages: infantes from birth till seven years of age; puellae, from seven to 14; and puellae, from fourteen years up.

The period of puberty was again divided into infinita proxima, from seven years to 15, and etas post pubertas proxima, from 16 to 14 years. During the first stage of infancy, and the next half stage of childhood, infantum proxima, they were not punishable for any crime. During the other half stage of childhood, approaching to puberty, from 15 to 14, they were indeed punishable, if found to be doli capres, or capable of mischief; but with many mitigations, and not with the utmost rigour of the law. During the last stage (at the age of puberty, and upward) minors were liable to be punished, as well capitally, as otherwise. Blackst. Com. vol. i. 453.

AGE PRIOR, etatem precari, a petition, or motion made in court, by one in his minority, having an action brought against him for lands coming to him by descent; requiring that the action may rest till he come to full age.—This the court, in most cases, ought to grant. But minors, as purchasers, shall not have it: nor intent of affile, dower, or partition; though, they may in debt. Hob. 341. D. Aile. 257.

It is otherwise in the Civil Law, which obliges children in their minority to answer to their TUTORS OR CURATORS. See PAROL DEMURRER.

AGEA, in Geography, a town of Ithak, in Periis, 35 leagues east of Ispahan.

AGED OF THE MOUNTAIN, is a title, or denomination, given to the chief, or prince, of the people called ASSASSINS.

AGEDA, in Geography, the name of a plain about 30 leagues from Budia in Hungary, on which was held a general assembly of the Jewish Rabbies, A.D. 1750, in order to examine and debate the question, whether the Mefhiah was come. Three hundred Rabbies, with a great multitude of other Jews, from different nations, were collected together on this occasion; and R. Zachariah, of the tribe of Levi, was chosen their president and speaker. The negative of the question was carried by a majority of voices, and it was agreed that the advent of the Mefhiah was delayed on account of their sins and impenitence. They also agreed, after some debate, in the circumstances that would attend his appearance: and they were of opinion, that he would appear as a great conqueror, and deliver them from every foreign yoke—that he would alter nothing in the Mosian religion—and that he was to be born a virgin; and that his miraculous birth was to be a characteristic, by which he should be known to those who were strangers to the covenent. Some ecclesiastics, deputed from Rome, attended this meeting; and when they began to extol the worship, ceremonies and authority of their church, they excited a tumultuous outcry of "no Christ! no God-man! no intercession of Saints! no worship of images! no prayers to the Virgin!" accompanied with loud clamours, rending of clothes, &c. and thus the conference of that day terminated. On the 8th day, they agreed to hold another council, three years after this, in Syria. Some of the Jewish doctors are said to have hesitated in their opinion, and expressed a desire of conversing with protestant divines; but the interference of too many monks deterred them, and made them fear some tragical conclusion to their assembly. BRENTI's Narrative in the Phoenix, tom. ii. p. 554.

AGEDAMA, a small island on the coast of Carmania.

AGEDINCUM, Sams, a town of Gaul, the capital of the Sienes. See AGENDICUM.
AGEEG, a small island on the coast of the Red Sea. N. lat. 18° 5', E. long. 38° 30', which gives name to a nation inhabiting the adjoining district of the country.

AGELASTA, in Antiquity, formed of a præx. and 70x2, to laugh, and denoting forceful, a famous one in Attica, near the well called Callichoras, upon which Ceres rolled, when she was fatigued in the search for her daughter. Here, according to Paulinus, (Attic. p. 93) they commenced the Eleusinian feasts.

AGEDNOUTH, or EGELNOUTH, Abbot, in Biography, succeeded Lindivus, in the see of Canterbury, in the reign of Canute the Great, A. D. 1028; he was the son of earl Agilmer, and obtained the appellation of good. for his acts of piety and benevolence. By his interest and influence with Canute, he restrained some of his exceses, and induced him to bestow large sums of money for the support of the foreign churches. In his way to Rome, for receiving his pall from pope Benedict VIII. he purchased at Pavia, with a large sum, a relic, which was the arm of St. Augustin, and transmitted it to England as a present to Leofric, earl of Coventry. By other more important services he is laid to have given luftre to the archiepiscopal see. Upon Canute's death, he refused to crown his son Harold; alledging a promise which he made to the late king, that he would place the crown only upon one of the issue of queen Emma. Neither threats nor promises could prevail with him to violate his engagement; and he laid the crown upon the altar, with an imprecation against those bishops who should dare to perform the ceremony. He died in the year 1038. His writings were "A Panegyric on the Blessed Virgin Mary,"—"A Letter to earl Leofric, concerning St. Augustin,"— and "Letters to several person." Biog. Brit.

AGEM, in Botany, is a name given to the Persian Lilac.

AGEMA, in the Ancient Military Art, a kind of foildier, chiefly in the Macedonian armies.

The word is Greek, and literally denotes vehemence; to express the strength and energies of this corps; or it may be derived from σεβη, to lead; because it consisted of elephants, horse, and foot, which preceded the king, and formed, as it were, the royal guard.

Some will rather have agema to have denoted a certain number of picked men, answering to a legion among the Romans, which is authorized by a passage in Livy, (l. xxiii. c. 51. v. 58. tom. i. p. 67.) Drakenb. Not.; Arrian (De Exped. Alex. l. vii. p. 287. Ed. Gronov.) on the contrary, speaks of the agema as a wing of horse; but the term is also applied to foot. This body of troops is also mentioned by Q. Curtius, (l. iv. c. 13. tom. i. p. 271.) Ed. Drakenb.) and by Polybius, (l. v. p. 372. 408. Ed. Cafaub.) vid. Suidas in voc.

AGEMOGLAN, or AZAMOGLAN, children of tribute, raised every third year by the Grand Signior, among the Chirilians whom he tolerates in his dominions.

The word, in its original, signifies a barbarian's child; that is, a child not a Turk.—It is compounded of two Arabic words, 1. DNN. agem, which among the Turks signifies as much as barbarous among the Greeks; the former people dividing the Arabs or Turks, and agem; as the latter divided it into Grecians and barbarians.

2. Enu, child.

The commoners appointed for this levy take them by force even out of the houses of Chirilians; always claiming one in three, and pitching upon such as seem the handsomest, and promise to be the most servicable.

These are immediately conveyed to Gallipoli, or Conflan
tine; where they are first circumcised, then intrusted in the Mahometan faith, taught the Turkish language, and the exercises of war, till such time as they become of age to bear arms; and out of these the order of Januaryes is formed.

Such as are not judged proper for the army, they employ in the lowest and most servile offices of the feraglio; as in the kitchen, flables, &c.

The agemogans only differ from the ichglans, as the former are bred up for the lower, and the latter referred for the higher offices of the empire. Their pay does not amount to more than seven after, and a half, or threeperpence halfpenny, a day.

AGEN, in Geography, an ancient large and well inhabited, but ill built, city of France, the capital of Agenois, in the late province of Guienne, and new department of the Lot and Garonne, and the episcopal see of the department of Aveyron. Its situation in a fertile country on the banks of the Garonne, is favourable for trade; but the indolence of its inhabitants deprives them in a degree of the advantage of it. Prunes are a considerable article of commerce; and the hemp which grows in the neighbourhood is manufactured into linens, and sent from hence to Cadiz, and afterwards exported to the Spanish islands. Here are also manufactories of camlets, farges, and failcloth. The gates and old walls, which remain, mark the antiquity and extent of this town. The palace, which was formerly the castle of Montval, and where the fessions is held, is situate without the walls of the old city; and there is another castle, called La Sagne, of which the ruins only exist. Agen is 108 miles south-east of Bourdeaux. N. lat. 44° 12' 50". E. long. 0° 35' 49'.
AGE

The word is also written agefnrlica, and agensfric. It is derived from the Saxon ages, own, and frees, lord.

AGENHINE, in our Old Writers, signifies a guest that has lodged at an inn for three nights, after which time he is accounted one of the family; and if he offended the king's peace, his host was answerable for him. It is also written hogenbine and hogenbyne.

AGENOLS, in Geography, a country of France, in the late province of Guienne, (now department of the Lot and Garonne) comprehending about 120 square leagues. It is a very fertile and healthy country, and was formerly inhabited by the Nitribriges, mentioned by Caesar. It formed a part of the kingdom of Aquitania, and was afterwards plighted by the counts of Toulouse, and succeffively by the English and French. See AGES.

AGENOR, in Fabulous History, was the son of Neptune and Lybia, and the father of Cadmus. He reigned in Phoenicia and married Thelaephas, by whom he had three sons, Cadmus, Phoenix, and Crix, and a daughter called Europa. Jupiter carried away the daughter, and Agenor ordered his three sons to seek for her, forbidding them to return to his court without her. Their search was fruitless, and they were banished, and settled in different countries.

AGENOR, in Natural History, a species of papilio Eques, with black wings, sanguineous at their base; the posterior having a white disc with black spots. It is found in China.

AGENORIA, formed of agens, strong, in Mythology, the goddess of industry and courage, as Vesta was of indolence.

AGENT, Agents, in Physics, that whereby a thing is done, or effected; or that which has a power whereby it acts on another; or by its action induces some change in it. The word agent is used promiscuously with efficient, and in contradistinction to patient.

The schools divide agents into natural and free.

Agents, natural, or physical, are those immediately determined by the Author of nature, to produce one sort of effect; with an incapacity to produce the contrary.

Agents, natural, or again subdivided into universal, which are such as produce effects of the same kind and denomination with the agents themselves; and equivocal, whose effects are of a different kind, &c. from the agents.

The schoolmen reckon the following circumstances necessary to the being of an agent; viz., that it be contiguous to the object, distinct from it, have a power over it, a sphere of activity, and a proportion or rate of acting.

Agent, free or voluntary, is that which may equally do any thing, or its opposite; as acting not from any predetermination, but from choice. Such is the mind supposed to be, which has a spontaneous power of choosing or refusing.

It is a celebrated question among philosophers and divines, whether man be a free, or a necessary agent? It may be thus flated: man is a necessary agent, if all his actions are so determined by the cause preceding each action, that no one part of it could possibly have come to pass, or have been otherwise than it was; nor one future action can possibly not come to pass, or be otherwise than it shall be. On the contrary, man is a free agent, if he be able at any time, in certain circumstances, to do different things; or, in other words, if he is not ever unavoidably determined in every point of time, by the circumstances he is in, to do that one thing he does, and not possibly to do any other.

Which of these two definitions agrees to man, is a question of fact to be determined by what we experience in ourselves, with regard to the operations of our own minds. See Liberty; Necessity; and Will.

Vol. I.

The term agent evidently implies a power of self-determination; and the epithet necessary, applied to agent, forms a folemnium both in sense and language. Price's Review, &c. p. 315, &c.

Agent is more particularly used for the minister of a prince, or flate, at another court.

In which sense, agents are commonly reputed a species of public ministers, or ambassadors: but they differ essentially, as agents are not invested with any representative character, although entrusted with the affairs and interests of their princes. See Envoy.

Agent is also used for a person intrusted with the management of affairs, either of a corporation, or private perfon. In which sense the word coincides with deputy, procurator, families, factor, &c.

Among the officers in the exchequer, there are four agents for taxes.

Agents of bank and exchange, are public officers, chartered in the trading cities of France, to negotiate matters between merchants relating to bills of exchange, and the buying and selling of goods; the same with those who, among us, are called exchange-brokers.

Agents of the exchequer, are officers under the commissioners, appointed to buy and contract for provisions, &c. Some of these are settled in the ports, where they have much the same office and authority as the commissioners in London.

Agent-nilculator, is used in the same sense.

Agent and patient, in Common Law, is where a person does, or gives, something to himself; so that he is at the same time both the doer and giver, and the receiver or party it is done to. — Such is a woman, when she endows herself with part of her husband's inheritance.

Agent, in Chemistry. According to the ancient chemists, substances were composed of active and passive principles; the latter of which received impressions from and were modified by the former, without exerting any reciprocal action. Spirit, oil, and salt, were considered as the active, and earth and water, as the passive principles. This distinction evidently arose from the phenomena of solution, and the apparent energy which acids and other fluids exhibit in their combination with metals and solids in general. It is now however universally allowed, and indeed necessarily follows from the doctrine of affinity, that whenever two substances combine together, it is in consequence of a mutual attraction, which belongs as much to one element as to the other of a compound; this definition therefore of chemical agent is no longer adhered to, and though we still continue to use the expression of one body having a powerful action on another, it is by no means intended to deny the equal reciprocity of chemical attraction.

The general term agent signifies, therefore, in Brienne, any substance capable of producing chemical action; and when, in explaining a process, the quality of agent is attributed to a body, it is only used as a designation of the substance whose presence determines the combination or decomposition. In which sense it is sometimes attributed to menstrua, or such bodies as in mixture have the greatest share of activity and motion: and it is sometimes also used for what we more usually call a solvent. Thus fire, water, air, earth, and menstrua, are chemical agents.

That internal agent in man, whereby all the vital moti ons necessary to the preservation and restoration of the body are managed, is by some called nature; by others archev, calidum innam, animal soul, vital spirit, or principle, &c.

AGENTS, in Mijves, a term which, in the infancy of counterpoint, was given, by the Italians, to the note of percussion;
AGE

that occasions and accompanies a prepared discord upon a
binding note; which note was termed the *patiense*.

In the preceding example, C is the *patient*, E prepares the
discord, D is the moving note or agent, and B its resolu-
tion.

*Agentes in rebus*, one of the ranks of officers, in the
court of the Constantinopolitan emperors, whose business was
to collect and convey the corn, both for the army and house-
hold; carry letters and melfages from court to all parts of
the empire; regulate couriers, and their vehicles; to make
frequent journeys and expeditions through the prov-
ces; inspect any motions, disturbances, machinations
rending that way, and give early notice thereof to the
Calv. Lex. Jor.

The agents in rebus, are some made synonymous with
our post-masters, but their function was of great extent.
They correspond to what the Greeks call τετάρτης, and the
Latin *vulcanarii*.

There were divers orders or degrees of agents in rebus,
as *tribuni, primiterii, senatorii, ducentarii, bicretii, circitores,*
equites, tyrones, &c. through all which they rose gradatim.
Their chief was denominated *princeps*, which was a poit
of great dignity, being reckoned on a level with that of pro-
contul.

The *princeps agentium in rebus* resided at Constantinople,
others of them were settled in every part of the empire; and
are also said to have served as interpreters.

*Ageometria*, a defect in point of *Geometry*, or a
deviation from the strict principles and conclusions of that
science.

This is otherwise called *ageometria*.

Some have complained of the *ageometria* of the Scrip-
tures in respect of the proportions of the *brazen sea, ark,*
&c.

*Agter* *vulgaris privatus*, in Roman Antiquity, that whose
property was granted to private persons on the reveare of a
certain rent, or tribute.

*Agter* *vulgaris publicus*, that whose property was refered
to the public, and being left out to farm, the rents or profits
accrued to the public treasury.

*Agter* is also used for a certain portion or measure of
land, artificently allowed in the division of grounds to each
citizen.

In the early days of the Roman state, the ager was only
two *jugera*, amounting to 1 1/2 English acre. After the ex-
pulsion of the kings, seven *jugera* were allowed a plebeian.
—Under the tribunes of C. Licinius Stolo, in the year of Rome
379, a law was made to limit cultes to 500 *jugera*, or
350 English acres, and to decree the distribution of the fur-
pius in the possession of any individual amongst those who
had no land. Under Julius Cæsar another *Agrarian law*
was published, by which those who enlarged their pittance
of land were to pay 50 *aurei* to the public.

*Agter* is also used in *Middle Age Writers*, for what we
now call an ACRE.

*Ager*, or *Aguer*, in Geography, a small town of Cat-
talia, in Spain near the river Segura, north of Lerida,
and 25 leagues west of Barcelona. N. lat. 41° 55'. E.
long. 6° 34'.

*Ager*, a river of Austria, which runs into the Traun,
about a league north from Schwannafflatt.

*Ager* is also a district in a sie of Agerhus, in
Norway, called Ager-Haard.

*Ager Picenum*. See *Picenum*.

*Ageratum*, compounded of the privative *a* and
*agera*, old age, and denoting *never-old* or *ever-green*, in
*Botany*, a genus of plants, of the *Ageratnidae equilib* elas
and order, of the natural order of *composfts daisiose*, and *com-
biere* of Jullieu; the characters of which are, that the com-
mon *calyx* is oblong, with many, lanceolate, sub-equal scales :
the compound corolla is uniform, corollis hemisphroido, tu-
bulous, numerous, equal, scarce longer than the calyx;
proper monopetalous, funnel-shaped, border quadrifid and
spreading; the flamina are capillary filaments, very short,
the anther cylindric and tubular; the pistillum is an oblong
*gram*, *filelliform*, of the length of the flamina, the *fflagms*
are two, very tender and erect; no pericarpium, calyx un-
changed; the seed solitary, oblong, angular, crowned with
a chaffy, five-leaved, upright awned calyle; the receptacle
naked, convex, and very small. It differs from *Eupatorium*
in the crown of the feeds; and from *Bides* in the naked-
ness of the receptacle. Martyn enumerates two species, viz.
1. A. *conyoides*, hairy ageratum, with ovate leaves
and hairy stem, which flowers in July and August, and is
a native of Africa, the islands of America, and the isle of
Tenera, in the South Seas. This species is propagated by
sowing the seeds on a hot-bed in the Spring; and when the
plants are strong enough to bear removing, transplanting
them into another moderate hot-bed; where they should
be watched, and shaded till they have taken root. In June they
should be removed to the open air, and transplanted towards
the middle of the month into the open ground, where they
will continue flowering from July till the frosts in Autumn
destroy them. The seeds ripen in September and October.
2. *A. thorei*, with leaves ovate, crepitate, obtuse, and smooth,
and flowers in July. This species is cultivated for its
*brazen sea, ark,* &c.

*Agter* is also used in *Middle Age Writers*, for what we
now call an ACRE.

*Ager*, or *Aguer*, in Geography, a small town of Cat-
talia, in Spain near the river Segua, north of Lerida,
and 25 leagues west of Barcelona. N. lat. 41° 55'. E.
long. 6° 34'.

*Ager*, a river of Austria, which runs into the Traun,
about a league north from Schwannafflatt.

*Ager* is also a district in a sie of Agerhus, in
Norway, called Ager-Haard.

*Ager Picenum*. See *Picenum*.

*Ageratum*, compounded of the privative *a* and
*agera*, old age, and denoting *never-old* or *ever-green*, in
*Botany*, a genus of plants, of the *Ageratnidae equilib* elas
and order, of the natural order of *composfts daisiose*, and *com-
biere* of Jullieu; the characters of which are, that the com-
mon *calyx* is oblong, with many, lanceolate, sub-equal scales :
the compound corolla is uniform, corollis hemisphroido, tu-
bulous, numerous, equal, scarce longer than the calyx;
proper monopetalous, funnel-shaped, border quadrifid and
spreading; the flamina are capillary filaments, very short,
the anther cylindric and tubular; the pistillum is an oblong
*gram*, *filelliform*, of the length of the flamina, the *fflagms*
are two, very tender and erect; no pericarpium, calyx un-
changed; the seed solitary, oblong, angular, crowned with
a chaffy, five-leaved, upright awned calyle; the receptacle
naked, convex, and very small. It differs from *Eupatorium*
in the crown of the feeds; and from *Bides* in the naked-
ness of the receptacle. Martyn enumerates two species, viz.
1. A. *conyoides*, hairy ageratum, with ovate leaves
and hairy stem, which flowers in July and August, and is
a native of Africa, the islands of America, and the isle of
Tenera, in the South Seas. This species is propagated by
sowing the seeds on a hot-bed in the Spring; and when the
plants are strong enough to bear removing, transplanting
them into another moderate hot-bed; where they should
be watched, and shaded till they have taken root. In June they
should be removed to the open air, and transplanted towards
the middle of the month into the open ground, where they
will continue flowering from July till the frosts in Autumn
destroy them. The seeds ripen in September and October.
2. *A. thorei*, with leaves ovate, crepitate, obtuse, and smooth,
and flowers in July. This species is cultivated for its
*brazen sea, ark,* &c.

*Agter* is also used in *Middle Age Writers*, for what we
now call an ACRE.

*Ager*, or *Aguer*, in Geography, a small town of Cat-
talia, in Spain near the river Segura, north of Lerida,
and 25 leagues west of Barcelona. N. lat. 41° 55'. E.
long. 6° 34'.

*Ager*, a river of Austria, which runs into the Traun,
about a league north from Schwannafflatt.
AGE

cents, the name of a flone mentioned by Galen and other writers; and said to be of the nature of the Phrygian flone, but more astringent; and as that was used in dying, this was in dressing of leather. We have no account of its external appearance, but probably it contained vitriol, and perhaps alum.

The great use of vitriol or copperas in the management of leather is well known; and the stones which contain it, or pyrites, are everywhere common. The method used also in the preparation of the Phrygian Lapis, which was the wetting and slightly calcining it, must be very proper to make the vitriol contained in this appear, and exert itself in the working with it. This stone is used by shoemakers to polish women’s shoes.

AGERIUM. See AGRIMENT.

AGERSEO, in Geography, a small island of Denmark, in the Greater Belt; it two leagues south of Corfoer.

AGES, signifies the palm or hollow of the hand.

AGESANDER, in Biography, one of the three sculptors, who jointly executed the famous antique group of Lacocon, was born at Rhodes, and flourished about the 5th olympiad. His name ranks first upon the plinth of the group.

AGESILAUS, in Ancient History, one of the most ill-natured kings of Sparta, succeeded his brother Agis against the competition of his nephew Leotychides, to whom by the laws the crown would have regularly descended. As he was a younger son of Archidamus II. he could have no view to the kingdom; and he was therefore educated in all the rigour of the Spartan discipline, and in the habits of fer- denial, labour, and obedience, from which those who were heirs to the throne were exempted. He thus acquired a degree of popularity, which, notwithstanding his low stature, and his being lame in one leg, secured his succession; more especially as he was patronized and supported by Lyfander, whose influence in the state was very considerable, and his rival was suspected of being the son of Aleibiades, who was said to have corrupted the queen of Agis, by a present of a thousand drachmas. His disposition and manners, which combined resolution and activity with condescension and gentleness, more than counterbalanced his natural defects; and though the oracle had warned the Spartans against a home reign, Lyfander contrived to interpret the warning as a caution against the illegitimacy of Leotychides, and thus to facilitate the establishment of Agesilaus. By his subsequent conduct he ingratiated himself with persons of all ranks and parties to such a degree that the Ephori are said to have clespected his ambition by imposing a fine upon him, because he attached the affections of the citizens to himself alone, and thus alienated them from the republic to which they rightfully belonged. Such, however, were the attention and deference which he manifested towards the Ephori and the senate, that he obtained their entire confidence; and his authority was superior to that of any other king of Sparta. Soon after he ascended the throne, ante Christ. 396, the king of Persia fitted out a powerful fleet, in order to deprive the Lacedemonians of their empire at sea. Agesilaus, at the instigation of Lyfander, was appointed general of the forces that were destined to an expedition against Arabs; and he accepted the office on condition, that a council of 30 Spartan commanders should accompany him, and that Ly- fander should be the chief of this council. During his delay at Aulis, he had a quarrel with the Boeotians about a facri- fice, which occasioned a war, that terminated in the sub- version of the Spartan dominion. When he arrived at Ephesus, a message was addressed to him by Tifaphernes, the lieutenant of the Persian king, demanding his reason for coming into Asia with an armed force; to which he replied, that his purpose was to aid the Greeks, who inhabited there, in recovering their ancient liberty. Tifaphernes, in order to gain time, promised in behalf of his master to grant liberty to the Greek cities of Asia. Agesilaus acquiesced, and a truce was settled between them. In the mean while the Persian general, regardless of his oath, took advantage of the delay, assembled troops and prepared for war. Agesilaus, though apprized of his treachery, adhered to his engagement; and this religious observation of a solemn treaty gained him, as Xenophon informs us, the universal clemency of the cities, whilst Tifaphernes, by a different conduct, entirely lost their favour. This interval afforded the Laced-emonian general an opportunity for acquiring an accurate knowledge of the state of the country and of the disposition of the inhabitants. In the course of his inquiry he found that Lyfander arrogated a degree of power, which encroached on his authority and obstructed his influence. Agesilaus did not dissemble his disaffection. Having given the most considerable commands and belt governments to private officers, he appointed Lyfander commissary of the stores and distributor of provisions, and for the purpose of further mortifying him and deriding the Ionians, he directed them "to consult their master-butcher." Lyfander, afterwards returning to Greece, projected a variety of schemes for overturning the constitution of Sparta, but his death prevented their accomplishment.

When Tifaphernes had collected his forces, he com- manded Agesilaus to retire from Asia, and upon his refusal declared war against him. The subordinate officers of the Spartan general were alarmed, but Agesilaus himself was composed and cheerful; and having transmitted his thanks to Tifaphernes "for having made the Gods, by his per- jury, the enemies of Peria, and the friends of Greece," he made a feint of marching his army into Caisia, the residence of the Persian lieutenant, but actually overran Phrygia, where he took many towns and amassed immense treasure, which he distributed among his officers and soldiers. Having wintered at Ephesus, he devoted the ensuing spring to the exercise and discipline of his army, which he encouraged by the distribution of prizes; and at the same time he inspired his soldiers with a contempt of their enemies, by intriguing the prisoners and exploiting them and their garments to sale. The latter were eagerly purchased; but the prisoners themselves were so delicate and feeble, that they were deemed of no service or value; "for," says Agesilaus to his fol- diers, "the persons against whom you fight, are richer than to their rich spoils, "behold there for what you fight." As the Achaen advanced, the Lacedemonian army marched into Lydia, defeated the Persians near Sardis, and ravaged the whole country. This success terminated in the death of Tifaphernes; his command devolved on Tithraustes, who attempted to conciliate Agesilaus by rich presents, and to induce him to withdraw his troops and to return into Greece by the promise of liberty to the cities of Asia, upon their payment of the customary tribute. The Spartan king, however, deferred the proposed accommodation till he had submitted it to the consideration of the state, and received orders for this purpose. In the mean while he marched into Phrygia, which was the province of Pharnabazus, and the expence of his expedition thither was defrayed by Tifaphernes. During his progress he received new powers from home, by which he was constituted sole commander both by sea and land; an honour which Sparta had never before conferred on any of its generals. From Phrygia, where he amassed large sums of money, he advanced as far as Paphlaogon, and formed an alliance with Cotys, the prince of that country.
country. Thryest was at this time laid waste by Spithridates
who had revolted from Pharnabazus and joined Agefilius.
In these circumstances Pharnabazus demanded an interview
with the Spartan king, whom he found sitting upon the
grafs; whilst the Persians spread rich carpets of various
colours and magnificent cushions for the accommodation of
their master. Overcome by the simplicity and modesty of
Agefilius, Pharnabazus sat down by his side upon the grafs.
At the close of this conference, they parted with mutual
tokens of friendship and respect; to the expoliations of
Pharnabazus, which the Spartans heard with downcast eyes
and profound silence, Agefilius replied, that war often arms
the bell friends against each other for the defence of their
country. "But," says he, "if you prefer the appellation of
the friend and ally of the Greeks to that of the king of
Peria's slave, you may reckon that all the troops you see
before you, our arms, our ships, our perfons, to the last man
of us, are only here to defend your possessions, and secure
your liberty, which of all blessings is the most precious and
defirable." Pharnabazus pledged himself not to depart from
the faith he had sworn to him, nor to quit his service; and
Agefilius taking him by the hand, and riding with him, re-
piled, "that it was the pleasure of the Gods, that with such
noble sentiments you should be rather our friend than our
enemy;" and he promised to withdraw from his government,
and never to return to it, whilst he could subsist any where
else.

During the two years of Agefilius's command in Asia, he
exhibited all the talents of a warrior and statesman, and
all the virtues of a Lacedaemonian. The remotest provinces
trembled at his name, and reounded with the fame of his
wealth, diluteffence, moderation, intrepid valour in the
most perilous dangers, and invincible patience and ferreus
in enduring toil and fatigue. Such was the respect which
his conduct and character commanded, that deputies were sent
from all parts in order to form alliances with him; and his
army increased continually by the accession of barbarians
that enlisted under his standard. Whilst he allowed his
soldiers the advantage of pillage, he himself was not charge-
able with any act of cruelty or injustice. His prudence and
authority were so much esteemed, that he restored order and
tranquility to all the cities of Asia, and reinstated them in
the possession of their liberty, not only without shedding of
blood, but without even banishing a single perfon. Ambitious
of extending the glory of his country, and of grace in
general, he had formed the design of attacking the king of
Peria in the heart of his dominions, and of occupying his
time and attention, that he might have no leisure for
directing his hostile views and schemes to distant provinces.
But before he could execute his purpofe, he was recalled by
the Ephors to the defence of his own country. As soon as
he received the order for returning, he impatient obeyed;
alluding, that he received the command not for himself, but
for his country and its allies. "I knew," says he, "that a
general does not deferve, or possess, that name really, but
as he submits to the laws and the Ephori, and obeys the
magiftrate." On his departure, however, he said, "that 30,000
of the king's archers drove him out of Asia," alluding in these words to a species of Perian coin, which
had on one side the figure of an archer, 30,000 of which
pieces of money had been dispersed in Greece to corrupt the
enemies and perfons of greater power in the cities.

Agefilius, when he quitted Asia, was accompanied by
Xenophon; and at Ephesus he committed half the gold he
had brought with him from his expedition into Peria with
Cyclus to the custody of Megabyzus, the guardian of Dla-
na's temple, with an order, in case of his death, to confe-
crate it to the goddes. On his return through Thrace
he only demanded, "whether he should pass as a friend or an
enemy,? and when the king of Macedon replied, "that he
would confider of it," "Let him confider," says Agefilius,
"in the mean time we will march." Before he arrived at
Sparta, he received an order from the Ephori to invade
Boetia, with which he complied, though the menace was
not such as he approved. On the plains of Cheromen, a
very severe engagement took place, in which Agefilius
received several wounds, and his life was exposed to great
danger. Some of the enemy had taken refuge in a temple
of Minerva, near the field of battle; and these Agefilius
ordered to be difmissed, and appointed a guard to escort
them in safety wherever they chose to go. After this the
he returned to Sparta, and was received with admiration
and joy. Uncorrupted by the customs and manners of
foreign countries, as other generals had been, he made no
alteration in his diet, furniture, or equipage. His enter-
prise against Corinth did not succeed; but his expedition
against the Acsaniabians compelled them to flee for pence.
In the year before Christ, 387, the sovereignty of Greece
was guaranteed to Sparta by the peace with the Perian
king, negotiated by Antalcidas, on the dishonourable con-
dition of abandoning the Greek cities of Asia to the Peri-
ians. After this event, the Spartans treated some of the
smaller states in a tyrannical manner, and unjustly seized
the citadel of Thebes, in which act Agefilius disgracefully
concurfed. Sparta was thus involved in a new war with Athens,
in which the Thebans, under the illustrious Epaminondas,
became formidable to their oppressors; and it was alleged
against Agefilius, that he had taught them the art of war,
by his expoliations against them, fo that they were able to
encounter the Lacedaemonians in the field, as was the case
in the battle of Leuctra, when Archidamus, the son of
Agefilius, and Cleombrotus, the other Spartan king, were
defeated with great loss, and Cleombrotus left dead on the
spot. In confequence of this difafter, Agefilius was in-
vited with a dictatorial power, for the purpose of faving
the fugitives from the severity of the Spartan laws, without
prejudice to the state; and on this occasion he decreed; —
"let the laws scep to-day, but to-morrow let them resume
their full vigour." After this battle, Agefilius exerted
himself in levying a new army, in defending Sparta from
the hostile attacks of Epaminondas, and in suppreffing a
conspiracy which took place among the Spartans them-
selves. In the year before Christ, 386, some new com-
moners broke out in Peloponnesus; and Agefilius was de-
feated at the head of the Spartan army and their allies, in
the battle of Mantinea, by Epaminondas, who died in the
moment of victory. When a general peace was established,
the Lacedaemonians were excepted, by the culpable obli-
gation of Agefilius, who refused to concur, because the Me-
ffeans were comprehended in it as a separate state.

Agefilius, in the decline of life, accepted the command of
a band of mercenary troops in the service of Tachos, who
aspired to the throne of Egypt. This commiffion reflected
no great honour on the character of this illustrious Spartan,
who, at the age of 80 years, degraded himself by receiving
the pay of an Egyptian, and serving a barbarian, who had
revolted against his master. The Egyptians reported in great
multitudes to see a man, whose name and character had been
for a long time and generally applauded: but connecting splen-
dour and magnificence with their ideas, they were disap-
pointed at the situation of an old man, of a mean aspect and
downfigure: they applied to him the fable of the mountain
in labour, and could scarce refrain from laughter and ri-
der. His conduct, however, soon produced a change of
opinion.
opinion. When he found that Tachos did not assign him the command of the whole army, but restricted his authority merely to the foreign troops, he was surprised and mortified; and he was the more incensed by the contempt with which his counsel was received, and by various instances of neglect which he experienced. Thus provoked, he joined those Egyptians who took part with Néctanebus, the other competitor for the crown, and affiliated them in establishing the rival of Tachos on the throne. Ageclus pleaded public utility as an apology for his vertuful conduct in this instance: Xenophon attempts to palliate it; but Plutarch charges it with the infamy of perfidy and treachery. The following winter, in the year before Christ 261, he embarked to return to Lacedæmon; but was driven by a storm upon the coast of Africa, into a place called the Port of Menelaus; where he fell sick and died, at the age of 84 years, after a reign of 41 years, during 30 of which he maintained the most distinguished reputation. His latter years, after the battle of Leuctra, were lefs honourable: and Xenophon, in his eulogy of this prince, has been thought too much to exaggerate his virtues, and to extenuate his faults. His body was carried to Sparta, and embalmed with was instead of honey, which was usually employed for this purpose. His son Archidamus succeeded to the throne, which continued in his house to Agis, who was the fifth king of the line of Ageclus. His life and actions have been recorded, not only by Xenophon, his intimate friend and paregryt, but by Diodorus Siculus, Plutarch, and Nepos. Many anecdotes are related concerning him, which sufficiently mark his character, and evince the high estimation in which he was held by his contemporaries. Having the great king, an appellation assumed by the kings of Persia, spoken of in terms of extraordinary commendation; he is reported to have said—"I cannot conceive wherein he is greater than I, unless he be more just." His regard to justice, however, was sometimes sacrificed to his attachment to his country, and to the bias of private friendship and affection. In recommending a friend to a judge, he said—"If Nicias be not guilty, acquit him for his innocence; if he be, acquit him for my sake; but, however it be, acquit him." His contempt of unmerited praise, and his superiority to ostentation and vain-glory were prominent features in his character. Accordingly, he would never permit, during his life, that his picture should be drawn; and at his death, he expressly forbid any image to be made of him, either in colours or relief. "Let my actions," he would say, "if deserving, be my monument." The following anecdote furnishes a pleasing evidence of his domestic affections. When a friend found him riding upon a flock with his children, "Tell nobody what you have seen (fay Ageclus) till you are yourself a father." XenophonHist. Græc. Plutarch in Agæli. Corn. Nepos in Agæli. Univ. Hist. vol. v. p. 463. Diodorus Siculus. Rollin's Ant. Hist. vol. iii. p. 369—400. vol. iv. p. 137—196.

Ageclus, in Mythology, the surname of Pluto, which was given to him, because he conducted all mankind into his empire: παρά τού κράτος της λαοῦ.

Ageinates, in Ancient Geography, a people of Gaul, placed by M. d'Anville in the territory of the Frétons or Belgian.

Agegus, a town of Thrace, called by Pliny (l. iii. c. 11.) Argaca, and by Livy, (l. xiv. c. 7.) Argaca, but alligned to Macedonia in the confines of Thrace. Steph. Byz. Hardoun mentions imperial Greek medals belonging to this city.

Agetoria, in Antiquity, fæals mentioned by Hefy-
the defence and attack of towns, camps, &c. In which sense it is the same with what is otherwise called *tumulus*, and in later times *aggireum*, and among the moderns *linum*; sometimes *cavalera*, *ittrica*, &c.

The agger was usually a bank, or elevation of earth, or other matter, bound and supported with timber; having sometimes turrets on the top, wherein the watchmen, engineers, and gildery were placed. It was also accompanied with a ditch, which served as its chief defence.

The usual materials of which it was made, were earth, boughs, fagades, lakes, and even trunks of trees, ropes, &c. variously crooked, and interwoven somewhat in the figure of flans; whence they were called *flaliari* axes. See *Lucan* iii. 456, 501. *Silius* luid. xiii. 197. Where these were wanting, bones, bricks, tiles, furnished the office: on some occasions, arms, utensils, pack-faddles, were thrown in to fill up. What is more, we read of agger formed of the carcases of the slain; sometimes of dead bones mixed with lime, and even with the heads of slaughtered citizens. For want of that binding, or solid materials, aggers have sometimes tumbled down, with infinite mischief to the men.

The besiegers used to carry on a work of this kind nearer and nearer towards the wall, till at length they even reached the wall. The methods taken, on the other side, to defeat them, were by fire, especially if the agger were of wood; by fapping and undermining, if of earth; and, in fore cases, by erecting a counter agger. Thus the inhabitants of Gaza defended themselves against Alexander. Q. *Curtius* iv. b. xxi.

The height of the agger was frequently equal to that of the wall of the place. *Cæsar* tells us of one he made, which was 30 feet high, and 330 feet broad. Besides the use of aggers before towns, the generals used to fortify their camps with such works; for want of this precaution divers armies have been surprised and ruined.

There were tall aggers made in towns and places on the sea-side, fortified with towers, cailles, &c. Those made by *Cæsar* and *Pompey* at *Brundusium* are famous. Sometimes aggers were even built across arms of the sea, lakes, and rivers; as was done by *Alexander* before *Tyre*, and by M. *Antony* and *Caesar*.

The wall of *Scythia* in the north of England, may be considered as a grand agger, to which belong several lesser ones. Besides the principal agger or *wallum*, on the brink of the ditch, Mr. *Horace* describes another agger on the south side of the former, about five paces distant from it, which he calls the fourth agger; and another larger agger on the north side of the ditch, called the north agger. This latter he conjectures to have served as a military way; the former, probably, was made for an inner defence, in case the enemy should best them from any part of the principal *wallum*, or to protect the soldiers against any sudden attack from the provincial Britons.

*Agger Tarquinii*. *Tarracini’s agger*, was a famous fenc built by *Tarquinius Superbus*, on the east side of Rome, to stop the incursions of the Latins, and other enemies, whereby the city might be infall. See *Pliny* iii. 5. *Carminals* were thrown down from the top of this rampart. *Juv. Sat. vi. 283.* *Suetonius* in *Ca. c. 27.* n. 2.

*Agger* is also used for the earth dug out of a trench and thrown up on the brink of it.

In which sense, the chevalier *Poland* thinks the word to be understood, when used in the plural number, fince we can hardly suppose they would raise a number of cavaliers, or terricks.

*Agger* is also used for a bank, or wall, erected against the sea, or some great river, to confine or keep it within bounds.

In which sense, agger amounts to the same with the ancients call *tumulus and malet*; the Dutch, *dyke*; we, *dam*, *sea-wall*.

*Agger* also denotes a heap of earth, raised over the graves of the ancients.

In which sense, it amounts to the same with *tumulus*; and is sometimes also called *aggireum*.

*Agger*, in *Geography*, a river of the circle of *Wadphalos*, which waters the country of *Marck* and the duchy of *Borg*, and falls into the Rhen.

*AGGERHUS*, or *CHRISTIANIA*, the largest diocese or general government in the south part of Norway; and the richest, as well as most considerable, in the whole kingdom. It was formerly called *Hammerfest*, and afterwards known by the name of *Obelae*. *Aggerhus* is also the name of a fortress in this diocese, on the west side of the bay, near which lies the city of *Christiania*. It is not known when it was built. It has been repeatedly besieged by the Swedes, *viz.* in 1510, in 1557, and in 1717, by *Charles* XII. without success. The governor of *Aggerhus* is the chief of government of Norway; he resides in the high court of justice, called *Overhuflet*, which judges in the last resort, all civil causes above a certain value. In all causes passing that value, an appeal lies to the supreme court at *Copenhagen*. N. lat. 59° 8'. E. long. 10° 20'. The eldest church in this diocese, said to have been built about 700 years ago, and called *Agger*, is situated about a quarter of a Norway mile north of the castle. The population of this diocese is estimated at 215,923 persons.

*AGGERS-HERRED*. A field of *Aggerhus*, which comprises three diocets, with as many courts of judicature, *viz.* *Aはじer*, *East* and *West Barum*, and *Ager* *Christiana* is situated in this district.

*AGGEROUT*, or *AGGEROUD*, supposed to be the ancient *Arinsinde*, is situated at the extremity of the Red Sea, about two leagues from the port of *Suez*. Here terminated the famous canal, begun by *Necos* and finished by *Ptolemy* *Philadephiz*, for joining the Nile to the Red Sea. Between the time of *Ptolemy* and our days, the Red Sea has retired two leagues, which is the distance of *Aggerroud* from *Suez*.

*AGI*, a river of *Periie*, which runs into the *Ares*, near *Chambre*, in the province of *Aiderbeizian*.

*AGGILE*, a town of *Prussia*; 13 leagues east-north-east of *Konigberg*.

*AGGLESTONE*, otherwise called *Stone-Barrow*, and vulgarly the *Devil’s Night Cap*, is a remarkable monument of antiquity situated in the north-east extremity of the *isle of Purbeck*. Its dimensions are 60 feet in circumference at the bottom, in the middle 82; and at or near the top 90; and it is computed to contain 307 tons of stone. The name seems to have been derived from the *Saxon* *baligs*, or *baligs*, *ballis*, and *flans*, *flame*, which expresses its ancient use; as it was probably a rock idol in the Britih age.

*AGGLUTINANTS*, in *Pharmacy*, a species of strengthening medicines, whose office and effect are to adhere to the solid parts of the body, and thus recruit and supply the place of what is worn off, and wasted, in the animal actions.

*Agglutinants* are most of them of the glutinous kind, or such as easily form themselves into jellies, and gummy confections; whence the name *agglutinant*, which is formed of *ad. to*, and *gluten, glue*.

For the operation and use of *agglutinants*, see *Strengtheners*.

The principal simples which come under this class, found in the *shops*, are, *flings*, *olibanum*, *gum arabic*, *dragon’s blood*, *...
AGGREGATE, is formed of ad, to, and grex, gregis, a flock, the sum, or result of several things, aggregated, or added together.

Natural bodies are aggregates, or assemblages of particles, or corpuses, bound together by the principles of attraction. Bodies politic are likewise said to be aggregate; such as mayor and commonality, dean and chapter, &c. in contradistinction to corporation sole; such as the king, a bishop, &c.

AGGREGATE, in general, signifies a body resulting from the union of others of the same kind which are smaller, the whole sum of which is called the aggregate. The minute parts into which an aggregate can be imagined to be divided without decomposition, are called integral parts; but the parts into which it is divided by decomposition are called component parts or principles. It is particularly used by some chemists and naturalists, for a numerous collection of atoms, or minute corpuses, whether homogeneous or heterogeneous, joined together by contiguity, without regard to the quality of such atoms. In which sense aggregate differs from mixt, as the former supposes no particular situation, or position of the corpuses, other than what arises from their proportion, and the relation they bear to the ambient bodies, among which the cohesion is formed.

Aggregate also differs from mixt, as the latter is formed immediately out of the principles of matter, so firmly united, as that it was very difficult, if not impossible, to separate them.

Aggregate again differs from compound, as the latter is formed out of mixts, and is easily dissolvable.

Aggregates, then, are the ultimate compounds, or the last effects of composition; they resolve into compounds as their next ingredients, these into mixts, and mixts into simples, or principles; though in its natural state aggregates may resolve also into mixts, and mixts into simples, inasmuch as they consist of heterogeneous parts.

This doctrine and distinction of aggregates, mixts, and compounds, is the foundation of the chemical theory of Beyer and Stahl; the bulk of whom has traced it with great exactness. Hence has arisen a new doctrine of earths, metals, &c., which has since been illustrated and extended by the best modern chemists.

AGGREGATE, in botany, is a term used to express those flowers which are composed of parts or florrets, so united or incorporated by means either of the receptacle or calyx, that no one of them can be taken away without destroying the form of the whole. They are opposed to simple flowers, which have no such common part, which is either the receptacle or the calyx, and are usually divided into seven kinds, viz. the aggregate, properly so called, whose receptacle is dilated, and whose florrets are supported by foot-flalks; such as the blue daisy, thistle, or sea-pink, &c.; the compound, which consists of several florrets, that are placed, without partial peduncles, on a common dilated receptacle, and within a common perianthium; and where each florret has its proper calyx; it is also a perianthium: Umbellate, when the flower consists of many florrets placed on fastigate peduncles, proceeding from the same stem or receptacle; and which, though of different lengths, rise to such a height as to form a regular head or umbel, flat, convex, or concave: Cymose, when several fastigate peduncles proceed from the same centre, like the umbel, and rise to nearly an even height; but unlike the umbel, the secondary...
ary or partial peduncles proceed without any regular order, as in fumariae, viburnum, &c.: Amelanchier, which have a long common receptacle, along which are disposed flowers, which form that fort of calyx called the amেntum: Glomera, which proceed from a common husky calyx belonging to gracies, called Calum, many of which flowers are placed on a common receptacle called roach, collecting the florets into spikes, as triticum, lardicicum, lollum, &c.: and Spadicus, which have a common receptacle, protruded from within a common calyx, called Spatha, along which are disposed several florets. Such a receptacle is called a spadiх, and is either branched, as in phoenice; or simple, as in marciuus, &c. In this last case, the florets may be disposed all around it, as in calla, dracunculn, &c.; on the lower part of it, as in arum, &c.; or on one side, as in zöntter, &c. Thesё flowers have generally no partial calyx.

Aggregatе, in the Linnaean System of Botany, is one of the natural methods of classing plants, and comprehending those which have aggregatе flowers.

Aggregatе fund. See Fund.

Aggregatе corporation. See Corporation.

AGGREGATION, in Physic, a species of union, whereby several things, which have no natural dependence or connection with one another, are collected together, &c. 23 in some sense to constitute one. Thus, a heap of sand, or a mass of ruins, are bodies by aggregation.

Aggregation, in Chemistry, denotes the adhesion of parts of the same kind. Thus, a number of pieces of brickstone united by fusion, form an aggregate. For the difference between aggregation, mixture, and combination, or composition, see those articles.

Aggregation is also used figuratively, for association.

We say, to be of a company, or community, by aggregation.—An aggregation of several doctors to the faculty of laws.—In Italy, aggregations are frequently made of houses, or families; by virtue whereof, they all bear the same name and arms.

Aggressor, in Law, is the person of two contending parties, who makes the assault or attack; or who began the quarrel, encounter, or difference.

In criminal matters, it is always first inquired who was the aggressor.

AGGSPACH, in Geography, a market town in the circle above the Manhartsberg, in Austria, seated on the Danube; 12 leagues west of Vienna.

AGGIA, in Ancient Geography, a town of Africa, mentioned by St. Augustin.

AGHADOE, a village of Ireland, antiently a bishop's see, now united with Ardlem.

AGHENISH, an island of Ireland, in the river Shannon; 96 miles below Limerick.

AGHER, or AEGHER, a town of Ireland, in the south of Ullter, not far from Clougher.

AGHEUSTIA, in Medicine. See AGUSTIA.

AGHRIM, in Geography, a town of Ireland, in the county of Wicklow and province of Leinster, about 31 miles south-west of Wicklow.

AGHRIM, a village in the county of Galway, worthy of being recorded on account of a decisive battle fought there and at Kilcommonan hill, July 12th, 1691, between general Ginkel and M. St. Ruth, the two commanders under William III. and James II. when St. Ruth, with 7000 of his men, were slain, and of the English only 600.

AGHIRIS Points, a cape on the west coast of Ireland, and north coast of the county of Sligo; 11 miles west of Sligo. N. lat. 53° 17'. W. long. 9° 22'.
Toodpur, Rantampur, Ioinagur, Bankwali, Nagore, and Bickancer. The capital of this fubah, of the fame name, probably the Gagafmiria of Ptolemy, is fituated in a pleafant valley, and on all fides furrounded by mountains. Its circumference is fix miles, and it is guarded by walls, towers, and a strong fortrefs; about 250 miles by the road W.S.W. from Agra, and 75 W.S.W. from Delhi. N.lat. 26° 24', E. long. 75° 20'.

AGIMTHA, a town of Aina in India, on the other side the Ganges. According to Ptolemy, it was fituated in long. 17° 40', and lat. 18° 40'.

Agincourt, in Geography and History, a village of the French Netherlands, fituated in the county of St. Pol, ex-department of the Straits of Calais; N.lat. 50° 47', and E. long. 2° 10'; remarkable for a glorious victory which the English, commanded by king Henry V., obtained over the French, Oct. 25th, in 1415. The army of Henry was reduced by sickness and various accidents to 10,000 men; and the French had collected a force confifting of 100,000 or, as some fay, of 140,000 men, to intercept the march of the English from Harfleir towards Calais. The king had recourse to all the means in his power for encouraging the progres of his small army, amidst the difficulties and inconveniences of their route; and on the evening of October 24, they arrived at Agincourt, within fight of the French, and prepared for a battle, which it was impossible to avoid. Whilst the English folders were exhorting one another to fight bravely in the approaching action, the king over-hearing fome of his nobles exprifing a wish, that the many brave men who were idle in England were prefent to affift them, exclaimed—No! I would not have one man more, if we were defeated, we are too many if it shall please God to give us the victory, as I hurl he will, the smaller our number, the greater our glory? Henry, with the advantage of moon-light, reconnoitered the ground, and pitched upon a field of battle, admirably adapted for preferring a small army from being furrounded by a great one. It was a gentle declivity, from the village of Agincourt, of sufficient extent for his small army, defended on each fide by hedges, trees, and brush-wood. Having determined upon the place of action, the king and his army betook themselves to reit; except thofe who, confidering this as the laft night of their lives, spent it in devotion. The French, exulting in their numbers, confident of victory, and supplied with abundance of provifions, fpent the night in riotous felicity, and in forming fchemes for the difpoft of their prisoners and booty. It was, in general, refolved to put all the English to the fword, except the king and the chief nobility, who were to be made prisoners for the fake of their rafon. On the next morning the hostile armies were ranged in order of battle; each of them forming three lines, with bodies of cavalry on each wing. The couiable d'Albert, who commanded the French army, loft the advantage of his superior number by drawing up his troops in a narrow plain, between two woods; and this was observed to be the chief caufe of all the difabilities that followed. The king of England employed various arts to supply his defect of numbers. His firft line confifted wholly of archers, four in fife; each of whom, besides his bow and arrows, had a battle-axe, a fword, and a flake pointed with iron at both ends, which he fixed before him in the ground, with the point inclining outwards to proteft him from the cavalry. This was a new invention, and had a happy effect. He difmissed all his prisoners on their word of honour to surrender themselves at Calais, if he gained the victory; and lodged all his baggage in the village of Agincourt, in his rear, under a flender guard. The firft line was commanded by Edward duke of York; the fecond by the king himfelf; and the third by the duke of Exeter, the king's uncle. When the lines were formed, the king, in shining armour, with a crown of gold, adorned with precious ftones, on his helmet, mounted on a fine white horse, rode along them, and adreffed each corps with a cheerful countenance and animating speeches. To inflame their r迸ment againft their enemies, he told them that the French had determined to cut off three fingers of the right hand of every prisoner; and to ruffle their love of honour, he declared, that every foldier who behaved well, should from that time be deemed a gentleman, and entitled to bear coat-armour. The English thus incited to exertion, flipped themselves almost naked, that they might deal their blows with the greater rapidity and vigour. The French, however, fearing that the English would difcover the danger of their fition, and decline a battle, commanded the charge to be founded. Upon this the English kneaded down and killed the ground, and then rising suddenly difcharged a flight of arrows, which did great execution among the crowded ranks of the French. This onfet was fucceeded by the attack of a body of archers, who had been placed in ambush, and who difcharged their arrows on the flank of the French line, and threw it into disorder. The battle now became general, and raged with uncommon fury. When the English archers had expended all their arrows, they threw away their bows, and, rushing forward, made dreadful havoc with their swords and battle-axes; the firft line of the enemy was thus defeated; and its leaders either killed or taken prisoners. The fecond line, commanded by the duke d'Alençon, who had vowed either to kill the king or take him prisoner, or to perifh in the attempt, advanced to the charge, and was encountered by the fecond line of the English, conducted by the king. The conflict was very furious. The duke d'Alençon forced his way to the king, and affaulted him with great violence; but the king brought him to the ground, and he was infantly difpatched. Discouraged by this difafter, the fecond line made no farther resistance; and the third fled without firing a blow; and thus the English, after a violent struggle of three hours, obtained a complete and signal victory. Although the king did not permit his men to pursuie the fugitives to any great distance, the number of his captives exceeded that of his folders; and many of these prisoners were persons of rank and fortune, who, encumbered with their heavy armour, could not make their escape. The French left dead on the field of battle, the couiable d'Albert, three dukes, the archbishop of Sens, one marfhal, 13 earls, 52 barons, 1500 knights, and a far greater number of gentlemen, besides several thousands of common folders. The French historians acknowledge, that the los of the English was incomparably greater than that of their enemies; and that of the English below 100; and that the duke of York and the earl of Suffolk were the only great men who fell on that fide in this memorable action. To the grofs error committed by the couiable d'Albert, as much as to the wife meafures of Henry, and the heroic valour of the English, the disgrace and ruin of the French army may be imputed. Henry, after this battle, pursuied his march to Calais, with his spoils and prisoners; embarked for England, Nov. 16, and arrived that evening at Dover, where he was received with transports of joy, many of the people plunging into the sea to meet his barge. At his triumphant entry into London, Nov. 25, the fhow and pageants exhibited by the citizens were fo numerous that it would have required a volume to decribe them. Henry's Hall. vol. ix. p. 46-54. Svo.

AGINNA, a burch or village of Aina in Susiana, situate on the eft bank of the Tigris, towards lat. 50° 15'.

3 F
AGINNA, one of the towns of Iberia, mentioned by Ptol. civ. at the boundary of Galatia, and placed in long. 75° and lat. 46° 30'.
AGINNATIE, a people of India, on the other side of the Ganges.
AGINNUM, a city of the Nitobriges, in Gallia Aquitanica, now Angoulême, or Agen.
AGINSKA, a river of Siberia, which runs into the Uda. N. lat. 52° 32'; E. long. 95° 44'.
AGIO, in Commercio, an Italian word, signifying aid, is a term used chiefly in Holland, and at Venice, for the difference between the value of bank money, and current money. So that if a merchant who sells his merchandise, stipulated to be paid either 100 livres bank money, or 105 caf. on current money, in such case the agio is said to be 5 per cent.

The bank agio varies in almost every place, and is greater or smaller, according as the currency is supposed to be more or less degraded below the standard of the state. At Amsterdam it is said to be generally about 5 per cent.; and by a resolution adopted not long before the late period of confusion, the bank fold bank-money for currency, at 5 per cent. agio, and bought it again at 4 per cent. agio. In consequence of this resolution, the agio could neither rise above 5, or sink below 4 per cent.; and the proportion between the market-price of bank, and that of current money, was kept at all times very near to the proportion between their intrinsic values: One part of the profit of the bank accrued from selling bank-money at 5 per cent. agio, and buying it in at four. At Venice, the agio was 20 per cent. fixed: at Genoa, from 15 to 16 per cent. The agio of the bank of Hamburg, which is said to be commonly about 14 per cent. is the supposed difference between the good standard money of the state, and the elipt, worn, and diminished currency poured into it from all the neighbouring states. See BANK and EXCHANGE.

Agio is also used for the profit arising from discounting a note, bill, or the like.

Agio is also used, though with some impropriety, for the rate of exchange of a sum negotiated, whether to profit or loss. It is also sometimes called agai.

Agio of assurance is used, by some, for what we more usually call policy of assurance.

AGIOI Saranta, in Geography, a town of the island of Candy; 16 miles south from Scitia.

AGIOSYMANDRUM, compounded of AGIO, holy, and mandro, a wooden instrument used by the Greek and other churches, under the dominion of the Turks, to call together assemblies of the people.

The agiosymandrum was introduced in the place of bells, which the Turks prohibited their Christian subjects the use of, lest they should make them subservient to fideition.

AGIRIA, in Ancient Geography, a district of Spain, south-east of Bibilis, belonging to the Celtiberians.

AGIRIUM. See ACQUIRUM.

AGIRU, in Geography, the western part of the island of Corfu, comprehending 20 villages, and about 5000 inhabitants: the only remarkable place in it is Cattle St. Angelo, which lies on the south cape called Palamara; and beneath it stands a lately catted called Paleo Caltraza.

AGIS IV. in Ancient History, a king of Sparta, was the son of Endamidas, and the 16th descendant from Aggeus, who made an expedition into Persia. This prince was eminently distinguished by his virtue in a corrupt period of the Spartan state, and by his laudable efforts for the reformation of his country. Sparta was sunk by the influx of wealth into luxury and indolence; and the discipline esta

blished by the wisdom of Lycurgus, was neglected and contemned. Agis, though brought up in influence and indulgence by his mother Agelaia, and his grandmother Archidamia, who, as Plutarch informs us, possessed more gold and silver than all the other Lacedaemonians, lamented the degeneracy of his country; and at the age of 20 years, exhibited a signal example of self-denial and abstinence in his own conduct, and nobly attempted to restore the ancient discipline of Sparta. With this view he aspired to the royal power, and explicitly declared, 'that he should not value being king, if it were not for the hopes of rekindling the ancient laws and discipline of Sparta.' A new law had been introduced, at the instigation of Epitades, one of the Ephori, in order to avenge himself on one of his foes, who had displeased him, for the altercation of hereditary estates. The consequence of this law was, that all patrimonial possessions were soon engrossed by a few perfolns; general poverty, and indolence prevailed; the inferior classes of the people envied their superiors; and those who were delitute of revenues, and excluded from a participation of honour and wealth, were indifferent and reluctant in their efforts against a common enemy, and constantly waiting for an opportunity to ameliorate their abject and depressed condition. In these circumstances of aggrievedness, on the one hand, and oppression and dissatisfaction on the other, Agis determined upon reformation. By the influence of Agefas, his maternal uncle, who with similar views embarked in the design, he engaged the co-operation of his mother and grandmother. The young men generally concurred; but those in more advanced life, and also the women of rank and wealth, trembled at the name of Lycurgus, and reformation; and induced Leonidas, the other king, to oppose the projects of Agis. Agis, however, succeeded in obtaining a decree for cancelling all debts, and for the equal division of all the lands. For this purpose, he made an offer to the community of his own large estate, with 600 talents in money; and he procured, by the interposition and assistance of Lyfander, the deposition and banishment of Leonidas, and the concurrence of Cleombratus, his successor. The first measure that was adopted was the cancelling of debts; and in the execution of this, Agefas, who being much in debt, was likely to be greatly benefited by it, was very active. Accordingly, all bonds were brought to the market-place, and burned in one pile, which Agefas called 'a glorious flame.' But he contrived to defer the accomplishment of the other part of the equalizing plan; and, as Agis was under a necessity of marching to the succour of the Achaeans, Agefas, by his tyrannical conduct, induced a conspiracy for restoring Leonidas, which proved successful, and Cleombratus was sent into exile. Agis, upon his return, was obliged to recur for sanctuary to a temple; and being betrayed by some false friends, who were bribed for this purpose, he was arrested in the name of the Ephori, and hurried to prison. Leonidas with a band of mercenaries, surrounded the prison, and the Ephori, and members of the senate who were in his interest, went in to interrogate Agis concerning the motives of his proceedings. The king averred, that it was his purpose to restore the institutions of Lycurgus; and that he would adhere to this purpose, even in the prospect of an immature death. His enemies then proceeded to pass sentence of death upon him, and the officers were ordered to remove him into a room where malefactors were strangled. But they, and even the mercenary soldiers, were restrained by their respect for his character from doing him any injury. When it was known that he was in custody, his mother and grandmother, and a multitude of people, assembled round the prison, and requested that he might have a fair trial. This applica
tion in his favour, merely served to hasten his fate. As he was led to execution, he said to an officer who offered in turn—"Weep not for me, my friend, for as I am thus suffering contrary to all law and justice, I am much happier, and more to be envied, than those who have condemned me." He then offered his neck to the executioner, without the least sign of reluctance. The grandmother of Agis was next seized and executed; and last of all his mother was ordered to enter the dismal dungeon, where she beheld her son lying dead on the ground, and her aged parent at a little distance, with the fatal cord about her neck. Having laid the corpse by that of his son, and decently covered it with linen, the curf himself on the body of Agis, and tenderly faluting his cold lips, exclaimed—"O my son, the excels of thy humanity and moderation has been fatal both to us and thee." Upon which, Amphareus, one of the senators, whose cruelty had been signally exhibited in this tragic scene, addressed her with a savage aspect—"Since you knew and approved the designs of your son, you shall share his recompense." She infantly rote, and rushed to the fatal cord, crying out—"May this, at least, be useful to Sparta!"

Leonidas completed this tragedy, by forcing Agisitis, the comfort of Agis, who was very rich, and distinguished by her wisdom and virtue, as well as her beauty, to marry his son Cleomenes, to whom she conducted herself with as much attention as was consistent with the tender regard she entertained for the memory of Agis, and who is said to have profited by the account the gave him of the designs which the murdered sovereign had formed for the regulation of the government. Phut. in Agid. apud Oper. tom. i. p. 795. Rollin's Anc. Hist. vol. v. p. 425—442.

AGISTOR, in Law, signifies to take in and feed the cattle of strangers in the king's forest, and to gather up the money due for the same. Chart. de Forc. 9 Henry III. cap. 9. The officers appointed for this purpose are called agistors, or gishlers, and are made by the king's letters patent: there are four of them in every forest, wherein the king hath any pannage. Manw. For. Laws, 8vo.

The time for this is fifteen days before Michaelmas, and as many after, when the running of the cattle cannot prejudice the game.

AGISTMENT, is supposed to be formed of the French gisier, a bed, or lying place; though Kennet excepts to this etymology, and chooses rather to derive it from agir, the field, or feeding-place for cattle; imagining agitation to have originally been the same with agrarium, agerium, or agroticum, the profit of feeding cattle on such a piece of ground. The term is applied to taking other men's cattle into any ground, at a certain rate per week. It is so called, because the cattle are suffered agist, that is, to be levant and couchant there; and many great farms are employed to this purpose. 2 Inst. 647. Our graziers call cattle which they thus take in to keep gisements; and to gisir, or juris, the ground, is when the occupier thereof need not feed it nor with his herd, but takes in the cattle of others, to gisir or pasture it. Agistment is likewise the profit of such feeding in a ground or field; and extends to the deputaring of barren castle of the owner, for which tythes shall be paid to the parson.

Agistment is also used metaphorically for a charge, or burden, on anything.

In this sense we meet with Terra agistamentum maris agitatur, i.e. charged with a tribute to keep out the sea. —So terra agitata, are lands whose owners are bound to keep up the sea-banks.

Agistment denotes likewise the duty or levy for repairing the banks and walls in Romney-marsh, which was particularly called agistamentum; and the act of laying such a portion of this duty on the several estates, was called agistate. Spelman.

AGISTOR, or Agistator. See Agist and Agistment.

AGISYMEA, in Ancient Geography, now Zanguebar, a district of Libya interior, situated, according to Agathemerus, to the south and east of the AEthiopes Anthropophagi. The parallel passing through this country 10° south of the equator, bounded the knowledge of the ancients to the south.

AGISYMEA, in Modern Geography, a town of Africa, in the kingdom of Congo.

AGITA, or Aguti, in Ancient Geography, a small island between Sicily and Africa.

AGITATION, agitation, properly signifies shaking; or reciprocal motion of a body.

The propeats, quakers, Pythian priests, etc. were subjects to violent agitations of body. See Inspiration.

Among physiologists, the term is sometimes appropriated to that species of earthquake, called temur, or aridita.

Among the philosophers, it is chiefly used for an intense commotion of the parts of any natural body.

Thus, fire is said to agitate the minute particles of bodies.

—Fermentation and effervescence are attended with a brisk agitation of the particles.

Hcat is suppos'd by some to confit in the agitation of the parts of the hot body; and found is produced by a tumultuous agitation, excited first in the honeyous body, and communicated thence to the ambient air.

Agitation is likewise used for a violent hurry or perturbation of spirits, occasioned by some predominant passion.

Agitation is also used, in Medicine, for a species of exercese, popularly called fawing; and, in general, for any exercise which makes the body strong.

Bartholein mentions fits of the tooth-ach, deafnes, etc. removed by vehement agitations of the body; and they have been found of especial use for preventing and dissolving concretions.

Dr. Sydenham attributes the great benefits of riding to agitation, which is very efficacious in removing obstructions of the vesica. See Ænora.

Sanguification is in great measure effected by the agitation of the parts of the blood and chyle, in their continual circulation. Digestion itself is only suppos'd by some to be an insensible kind of agitation.

Agitation of beasts in the forest, anciently signified the drift of beasts in the forest.

AGITATIVE, something having power to agitate or shake another.

Agitative force of a pendulum, is that which produces motion in it.

The agitative force of the pendulum arises from three things: 1. The power of gravity. 2. The weight, or weight, and wight, at the end of the rod. 3. The distance of that weight from the point of suspension; or, which amounts to the same thing, the length of the rod, or pendulum. Hist. Acad. Scien. 1714.

AGITATO, in Æneid, a term which implies not only a quick movement, but a character of expression arising from passion and perturbation. Piccin's air, "Si d e ciel mi divide," in the Alessandro di Metafido, furnishes an admirable example of this kind of movement.

AGITATOR, in Antiquity, a charioteer; or he who drove or directed a chariot, or horses, in a race.

1. In which sense agitator amounts to the name with what the Romans called euripsis; and we, a coachman, driver, etc.

2. Agitator was more peculiarly used for him who drove in the public curule games in the circus.

The agitators were distinguished by their habits, into...
AGLA

**AGLA**

**ruffii, allati, profuus, and uncius,** which gave rise to denomination to so many factions. Besides which, they had other marks or enigmas of their family, corresponding to what we call arms. The conquerors, besides the ordinary rewards, **bravus,** as crowns, &c. had statues erected to them in the circus; on the bafes whereof, their titles, achievements, &c. were inscribed; several of which are still found among ancient inscriptions, drawn in the following formule: 

*Vicit* 

**set** *set* *set* *set* 

*trigius,* trigius, trigius, uno annuo, aliquo principio, duobus 

*trigius,* &c. 

It has been disputed, whether the agitators were on the footing of mimes and pantomimes, and by law held infamous? Briffon. *Select. ex. Jur. Civ. Ant. lib. i. cap. 10.*

**Agitators, in English History,** were certain officers, created by the army in 1647, to take care of its interests. Each troop or company furnished two private men or inferior officers under this title, who represented the army whilst a council of the principal officers was appointed after the model of the house of peers; and thus a military parliament was formed in opposition to the parliament at Westminster. Cromwell engaged himself with the agitators, whom he found to have greater interest than the council of war; and who undertook to make proposals relating to the reformation of religion and the state. The agitators as well as the council of officers were altogether moved by his direction, and conveyed his wishes to the whole army. By means of these instruments he overawed the parliament, and reduced it to submission and having gained possession of the king's person, to whom for some time he and his officers paid attention and respect, he at last resolved to try himself by the presence of the agitators, and thus induced him to make his escape from Hampton court, and to take refuge at Carli broke castle, in the Isle of Wight. Cromwell being entirely master of the parliament, and freed from all anxiety with regard to the custody of the king's person, applied himself seriously to quell those disorders in the army, which he himself had artfully raised and successfully employed, against both king and parliament. With this view, besides other measures which he adopted, he issued orders for discontinuing the meetings of the agitators; and he pretended to pay entire obedience to the parliament, whom, being now fully reduced to subjection, he proposed to make, for the future, the instruments of his authority. But the Levellers, for so that party was called, because they wished to abolish royalty and nobility, to level all ranks of men, to introduce an universal equality both of property and of power, and who maintained that the meanest fethchel, if enlightened by the spirit, was entitled to equal regard with the greatest commands, having tided the sweets of dominion, would not easily be deprived of it. They secretly continued their meetings; they affected, that their officers, as much as any part of the church or state, needed reformation; and several regiments joined in seditional remonstrances and petitions. Separate rendezvous were concerted; and every thing tended to anarchy and confusion. But this discontent was soon cured by the rough, but dexterous hand of Cromwell. He chose the opportunity of a review, that he might display the greater boldness, and spread the terror more widely. He seized the ring-leaders before their companions; held in the field a council of war; shot one mutineer instantly, and struck such dread into the rest, that they presently threw down the symbols of faction, which they had displayed, and thenforth returned to their discipline and obedience. *Hume's Hist.* vol. vii. p. 109, 8vo.

**AGLA,** formed of the initial letters of the four following Hebrew words דב רכיב וְנַעֲרָיָהּ וָנָּעָרָיָהּ, g. d. *theu art strong in the eternal God,* was a name given by the superlative Jews in the Middle Ages, to the Deity; and which they disposed of in the three angles, and in the middle of two triangles laid one over the other. This figure they called the shield of David, and pretended, that it was a security against wounds, would extinguish fire, and was able to perform other wonders. *Fab. Cod. Apocry. V. T. tom. ii. p. 1006. tom. iii. p. 143.*

**AGLA, or AGLA, in Geography,** a town of Africa, in the kingdom of Mem, near the river Guara.

**AGLA Minor,** a district of Spain, alligned by Pliny to the Baetitan.

**AGLABITES, in History,** one of the Arabian independent dynasties, which subsisted in Africa in the ninth century, and which derived its name and power from Ibrahim, son of Aglab, the lieutenant of the famous Harun al Rashid, and governor in Africa, *Heg. 184. A. D. 800.* This dynasty lasted till the year of the Hegira 206. A. D. 918; and possessed the country which extended from Egypt to Tunis.

**AGLAIA, in Mythology,** the name of the youngest of the three Graces, espoused to Vulcan.

**AGLAIA, in Natural History,** a species of *Papilio* 

*Nymphalis,* with dented yellow wings, tipped with black; the under part having livid spots. It is found on the violet in Europe. The larva is solitary, fpinal, and black, with ferruginous spots disposed on the sides of a square; the pupa is brown.

**AGLAOPHAME, one of the Sirens.**

**AGLAOPHOTIS, in Botany,** a name used, by some, for *fiony.*

**AGLASOUN, in Geography,** a town of Asiatic Turkey, eight miles south-west from Ibarbeh.

**AGLAURA, or AGRALLA, in Mythology,** the daughter of Cccrops, founder and king of Athens. She had two sisters, Hera and Pandrofa. Minerva having conceded Erechthonius, after his birth, in a basket, committed him to the custody of these three princesses, forbidding them to open the basket. Hera and Pandrofa observed the order; but Aglaura, unable to restrain her curiosity, opened the basket and found the infant with feet like serpents. Minerva punished her by means of Envy, who made her jealous of Hera, the favourite of Mercury. When the attempted to prevent the access of this deity to his mistress, he struck her with his caduceus, and converted her into a rock. Nevertheles she was honoured after her death in a temple at Salamina, with a yearly sacrifice of a human victim, which Deiphilus, king of Cyprus, in the time of Seleucus, changed into an ox. See *Agraulia.*

**AGLETS, AGLEETS, or AGLEEDS, among Florists,** the apices, or pendents hanging on the tip-ends of chives, or Stains; as in tulips, roses, spike-grafs, &c.

**AGLIA, in Geography,** a small town of Italy, in the marquique of Jvrca, and principality of Piedmont, in which belonged a district and earldom; seven miles south from Jvrca.

**AGLIA, among Ancient Surgeons,** a whitic cicatrix, or spot in the eye, formed by a conglomeration of humours.

**AGLIDOLUS.** The Palmynres worshipped the sun under this title.

**AGLIONBY, John, in Biography,** an English divine, was born in Cumberland, and admitted a scholar at Oxford in 1553. He was distinguished as a poet and learned preacher. After his return from his travels, he was made chaplain in ordinary to queen Elizabeth, to which office he was also appointed by king James 1. and he is said to have had a concern in the translation of the New Testament, ordered by that king in 1604. He died at Ilip near Oxford, where he was rector, Feb. 6th, 1609-10, at the age of 43. He was eminently accomplished in various kinds of learning, well
well acquainted with the fathers and school divinity, and a
great critic in the languages. Gen. Dict.
AGLONE, in Geography, a river of Pruflia, which runs
into the Minuce, near Proculis.
AGMANISPE or ATMANSPE, in Ancient Geo-
graphy, a village of Arabia Felix, assigned by Ptolomy to
the Homeritics.
AGME, in Surgery, signifies a fracture.
AGMEN, in Antiquity, properly denotes a Roman army
in march. In some cases, it stands contrariwise unhoned
from actes, which denoted the army in battle array; though,
on some occasions, we find the two words used indifferently
for each other.
The Roman armies, in their marches, were divided into
primaq agmen, anfwering to our vanguard; medium agmen,
our main-battle; and posterior ammen, the rear-guard.
The order of their march was this: after the first signal
with the trumpets, &c. the tents were taken down, and
the baggage packed up; at the second signal, the baggage
was to be loaded on the horses and carriages; and at the third
signal, they were to begin their march. First came the ex-
traordinary; then the auxiliaries of the first wing with
their baggage; these were followed by the legionaries. The cavalry
marched either on each side, or behind.
AGMEN pilatun, that disposed in a narrow oblong form,
or column; being alto close and compact; thus called,
as resembling the figure of a pila, or pier. Vegetius compares
it to that of a broach, or spilt. This form was chiefly used
in marching without their baggage, through bad ways and
close countries.
AGMEN quadratum, that ranged somewhat in a square
form, being the method ordinarily observed in the Roman
armies. This was also called agmen gracc, by the Greeks
τετραγώνος πάξος. The three lines, or columns, in which the
army usually marched, were considerably more in length or
breadth, than in depth; but as the baggage marched some-
what in the same order, the whole approached to the figure
of a square.
AGMEN is also used for any number of persons, or even
animals, moving or advancing in some regular order.
AGMET, or AGNAT, in Geography, was formerly the
capital of Morocco, in Africa, situated on a declivity of
a hill, which is part of Mount Atlas, and near a river of the
same name; six leagues south of Morocco. It is at present
reduced, and inhabited by poor people. N. lat. 30° 50'. W.
long. 5° 15'.
AGMONGEMEHAM, or AMERSHAM, an ancient town
of Buckinghamshire, situated betwixt hills that are covered
with woods; about 26 miles north-west from London. It
has a town-hall and free-school, fends two members to parlia-
mament, and has a market on Tuesday. The manufacture
of this town is black lace; and a cotton manufactory was
lately established in it, which employs many of the lower
crafts, though the business is performed by machinery. The
number of houses in this borough is 267; but the right of
voting is restricted to about a fourth part of this number,
which consists of those who pay taxes and rates. This parish,
which is adjacent to Holywell, contains 453 houses, 859 male
and 1171 female inhabitants. The manor of T. D. T. Drake,
Esq. called Shadecroes, to which family the borough belongs, is situated about 1/2 mile from the
town.
AGNA, in Ancient Geography, a river of Mauritania.
AGNACAT, Stalutus pyri species. A country of Amer-
ica, beyond the Terra de Labrador, toward the island of
Darien, there is a tree of the figure and size of a pear-tree,
always covered with leaves, and of an extraordinary green-
ness and luster. It bears a fruit also like a pear; but green
even when it is ripe; the pulp is of the same colour, sweet,
fat, and tastes like butter. It is a powerful promoter of
venereal vigour. Ray's Hist.
AGNADELLO, in Geography, a small town of Italy, on
a canal between the rivers Adda and Serio, in the duchy of
Milan and territory of Cremona. It is famous for a victory
gained here by the French over the Venetians in 1599, and
for a battle fought between prince Eugene and the duke of
Vendome in 1705. See CASSANO. N. lat. 45° 25'. E. long.
11° 12'.
AGNAN, St. a town of the late province of Berry, and
depot of Loire and Cher, in France, situate on the river Cher.
Three leagues with one college church and two convents.
N. lat. 46° 27'. E. long. 1° 25'.
AGNANIA, or ANAGNI, a small ancient town of
Italy, in the Campagna of Rome. It is situated upon a
mountain; and has a cathedral and five convents. N. lat.
41° 41'. E. long. 12° 55'.
AGNANO, lake of, a circular lake, nearly two miles in
circumference, in the vicinity of Naples, near Pozzuolo,
which has all the appearances of a volcanic crater. Its
shape is that of an inverted funnel; and its sides and bottom
are formed of tufta, interfused with fragments of lava and
puccione-flone. Numerous flocks of ducks swim on its surface,
and its waters contain great quantities of tenches and frogs.
The frogs in their tadpole state, having tails resembling the
hinder part of a fish with a round body and legs like a frog,
firmly occasion for the vulgar to conclude that they were
monstrous animals, half fish and half frogs. Vallisneri dis-
covered the cause of this vulgar error. The tenches and eels
of this lake arc, in winter, of a very good flavour; but in
summer they are not estable, on account of the great quan-
tities of flax and hemp which are brought hither from all the
neighbouring parts to be mellowed in the water. The water
sometimes boils up to the height of two inches, but without
any fenible heat. Keyser's Trav. vol. iii. p. 113. Sal-
planzani's Trav. vol. i. p. 125.
AGNANTUS, formed of ayos, amant, a
flower, in Botany, the name given by Vailant to a genus of
plants, called afterwards cornealia by Plummer and Lin-
nan.
AGNATI, in the Roman Law, the male descendents
from the same father; and in the Scots law, agnates are un-
derstood to be those who are nearest related by the father,
though females intervene.
AGNATION, from ad, to, and nasat, to be born,
in the Civil Law, the kinship, or relation between the de-
scendants of the same father, being males, and illused only
from males.
Agnation differs from cognation, as the latter is an univer-
sal name, under which the whole family, and even the cognati
themselves are contained; and agnation, a particular branch
of cognation, which only includes the descendants in the male
line. Again, agnation is properly only a civil name, as that
of genus, or family; cognation, a natural name, or derived
from blood.
By the law of the Twelve Tables, males and females suc-
ceded one another, according to the order of proximity, and
without any regard to the sex: but the laws were afterwards
changed in this respect, by the Lex Viscidia; and women
were excluded from the privileges of agnation, excepting
such as were within the degree of consanguinity; i.e. ex-
cepting the fathers of him who died intestate; and it was
hence that the difference between agnati and cognati first took
its rife.
But this difference was again abolished by Justinian (Inf.
3. 10.), and the females were reinstated in the right of ag-
nation; and all the descendants on the father's side, whether
males
Agnel, an ancient French gold coin, first struck under the reign of St. Louis, worth about twelve fols five deniers. The agnel is also called sometimes monton d'or, and agnel d'or. The denomination is supposed to have arisen from the figure of a lamb, or sheep, struck on one side. After the reign of St. Louis, they bore on the reverse the words, "Christus rex, victor, imperator."

AGNEL, an ancient French silver coin, first struck under Philip le Bel, worth about twenty fols.

AGNELI, FREDEVIC, in Biography, was an engraver of Milan, in the beginning of the 17th century. His chief employment seems to have been portraits, though he sometimes engraved architecture and emblematical subjects. The dome of Milan was engraved by him. Strutt.

AGNERIES, in Geography, a small place, which was once the residence of a Castellan, in the former principality of Dombes, and present department of Ain, in France.

AGNES, in Natural History, a name given by Gramer to a species of Papilio Danae, the Zangis of Gmelin's edition of the Linnaean System.

AGNES, Sr., in Geography, one of the Scilly islands which, though of small extent, is well cultivated, and fertile in corn and grasses. The inhabitants, who are poor, form about 50 households, and yield the proprietor 40l. a year. The church is small and neat, and was built by the Goldolphin family in South A. their patron, and support of this island is the light-house, whence St. Agnes is called the Light-house Island. This stands on the most elevated ground, and is built with stone from the foundation to the lantern, which is 51 feet high; the gallery 4, the shaft lights 11 1/4 feet high, 3 feet 2 inches wide, and 16 in number. The floor of the lantern is brick, upon which is placed a square iron grate, barred on every side, with one great chimney in the canopy roof, and several ladders, to let out the smoke; and a large pair of smiths' bellows is so fixed as to be used with ease when it is wanted. This noble structure is plastered white, and serves as a day-mark to ships coming from the South. The keeper of this light-house has a salary of 40l. a year from the Trinity-house, with a dwelling-house and garden for a salary. His assistant is allowed 21l. a year. The light-house is annually fumigated with coal, and the carriage of there from the sea-side to the building is a benefit to the poor inhabitants. The true latitude of the light-house is N. 53° 37' 56" W. long. 4° 40' 36".

AGNES, Sr., is also the name of a Cape on the coast of Patagonia. See PATAGONIA. N. lat. 52° 50'. W. long. 67° 35'.

AGNESSA, Agneta, in Geography. See GETANA.

AGNETI, or AGNETIN, two contiguous towns of Tranilvania, on the river Hopefch, four leagues north of Hermannstadt. N. lat. 44° 45'. E. long. 25° 26'.

AGNI-CORNUS. Acceseua, a promontory of Egypt, to the north-coast of the Boaistone gulf.

AGNIERS, the denomination of a tribe or canton of Iroquois Indians, who vigorously and repeatedly resisted the French in their attempts to settle in Canada. They appeared for a long time among the most determined enemies to the popish missionaries, who made various efforts for their conversion; however, in 1665, many of them were converted to the Catholic faith, more perhaps from a regard to convenience and interest than by conviction. These converts among whom were some distinguished females, removed to the Huron settlement of Loretto, where they were encouraged to reside, in hopes of their forming a barrier against the incursions of their savage countrymen. But no influence or address was sufficient to keep them steady in their attachment to the French nation. Frontenac, who, in 1665, was declared governor of Canada, though his previous conduct had been extremely offensive and irritating, planned an expedition against the Agniers, and resolved utterly to extirpate them. For this purpose he employed a large army of regulars, and of such Canadians and Indians as were attached to his interest; which entered into the country of the Agniers, destroyed three villages, and massacred most of the inhabitants. See CANADA AND IROQUOIS.

AGNIFER, an amputation applied, by some Ethnological Writers, to John the Baptist, and used in the same sense with precursur, or forerunner.

AGNINA membrana, in Anatomy, the same as the AMNIS.

AGNINA lactea, see LACTUCA.

AGNO, in Geography, a district of Luania, in Switzerland, containing 41 parishes or villages, and bordering on a part of the Lugano lake, which is called the lago d'Agno, and receives into it a river of the same name.

AGNO, a river of Naples, which rises in the mountainous parts of Terra d'Uova, washes the town of Acerba, and, passing between Capua and Avera, falls into the Mediterranean, about seven miles north of Pozzuoli.

AGNODICE, in Biography, an Athenian lady, who in the disguise of a man, attended the labours of Herophilus, and acquired so much knowledge of the treatment of dif- eases, as to be in great request among her own sex, to whom she discovered her countenance. She was particularly expert in the practice of midwifery. At length the physicians, jealous of her success, in Eion, accused her of herfelf to the women under the pretence of afflicting them in their labours and complaints; but in reality from views of incontinence. Being cited to the areopagus, she made herself known; and her judges were so well satisfied with her conduct, and perhaps with the women for patronizing her, that they repealed a law then existing, prohibiting women to practice any branch of medicine, and decreed that women of the rank of citizens might be allowed that liberty. A physician, M. Hecque, Eloy faus, published a volume in the year 1747, entitled, "De L'indie- cence aux Hommes, d'accouder des Femmes," written with much ingenuity; in which he attributes the looefens in the morals of the present age, to the custom of admitting men to the general practice of midwifery; for in particular cases he acknowledges their assistance to be necessary. His book has givenbirth to others in this country, written with the same view of endeavouring to excite a prejudice in the women against employing men, particularly by the late Mr. Philip Thickners. But the virulence, and the indiscretion of his writings on the subject, must have defeated his end; as it would argue a greater degree of indelicacy to have been suppos'd capable of reading his book, than to permit the practice he pretends to censure. The strongest argument against admitting men into the general practice is, that in all ordinary cases, women are perfectly competent; but as cafes do, and must for ever occur, in which a kind of affluence is required that women are incapable of giving, if the men were not to attend in ordinary cases, they would not acquire the expertness that is necessary to enable them to deliver in difficult and extraordinary cases.

AGNOLETI, de aEow, to be ignorant of, in Church History, a fact of Eutychians, whose founder is said to have been Theophilus, a deacon of Alexandria, in the 6th century, who maintained that Christ, considered as to his human nature,
was ignorant of certain things, and particularly of the time of the day of judgment.

Eulogius, patriarch of Alexandria, affirms this doctrine to certain solitaries in the neighbourhood of Jerusalem, who, in defence thereof, alleged divers texts of the New Testament, and, among others, this of St. Mark, chap. xiii. ver. 32: "Of that day and hour knoweth no man; no not the angels who are in heaven, neither the Son, but the Father only."

The ancient Arians, and the modern Unitarians, urge this and similar passages as arguments against the deity of Christ. To which it has been replied, by means of a distinction to which the other object, that of Christ, as a man, did not know the day of judgment; or, that he was not commissioned to gratify the curiosity of his disciples in this respect, by revealing it to them. Accordingly Dr. Macknight (Harmony, p. 550.) observes, that the word οὐκ (Mark xiii. 32.) has the force of the Hebrew conjugation Hiphil; and also, in the sense of this conjugation, signifies to make another to know, or to declare. And he reads the text, "But of that day, and hour, none maketh you to know," i.e. none hath power to make you to know it. Neither man, nor angel, nor even the Son himself can reveal the day and hour the destruction of Jerusalem to you; because the Father hath determined that it should not be revealed.

AGNOIA, a word used by Physicians, when a person in a fever does not know his acquaintance. When a rigor accompanies this symptom, Hippocrates says it is dangerous.

AGNOMEN, in Antiquity, an epithet given to a person either by way of praise, or displeasure, or from some remarkable event, which became, as it were, an additional name, but peculiar to the person, and not defendable to his issue. Thus, one of the Scipios was named Africarurus, and the other Afriaticus; from the brave achievements which the one performed in Africa, and the other in Africa. The agnomen was the third in order of the three Roman names—Thus in Marcus Tullius Cicero, Marcus is the praenomen, Tullius the nomen, and Cicero the agnomen.

Others think the agnomen to have been the fourth or honorary name, superadded on account of some extraordinary action or virtue. Thus, in the case of Lucius Cornelius Scipio Africanus, Lucius was the praenomen, Cornelius the nomen, Scipio the surname or cognomen, and Africanus the agnomen. But many of the ancient authors, as Livy, Cicero, and Valerius Maximus, call the fourth name cognomen. Some imagine agnomen and cognomen to have been the same, as they generally are, except in cases of adoption.

It was a custom among the Romans, for a person, when adopted into another family to lay aside all his other names, and only retain his family-name, to which he added the praenomen, nomen, and cognomen of the adopter. Thus P. Cornelius Scipio, being adopted by Q. Cezelius Metellus, laid aside his praenomen Publius, and nomen Cornutius, and was called Q. Cezelius Metellus Scipio.

AGNON, in Ancient Geography, a fountain of Greece, in Arcadia, which derived its name from the nymph Agno, who had been the nurse of Jupiter. It is said that the water of this fountain rose in a cloud and then descended in rain.

AGNONE, or ANGKON, in Geography, a town of Naples, in the Abruzzo citra; nine miles south south-east of Civita Borella.

AGNONIA, a town of Thrace, near Amphipolis, founded by Agnon the Athenian, who conducted hither a colony. Steph. Byz.

AGNOS, a borough of Attica, belonging, says Steph. Byz. to the tribe of Demetriades, but according to Suidas to the tribe of Acamantides, and aligned by others to the tribe of Attalides.

AGNOS, in Ichthyology, a name given by Athenæus, and many of the other Greek writers, to that fish called calophycius or uranocarpus.

AGNOTES, in Ancient Geography, a people of Gaul, whose situation is not precisely known. M. d'Anville places them in Brittany, north-west of the Obélim; and he says that the western part of the diocese of Leon has still preserved in one of the districts of the diocese the name of Ark.

AGNUS Cadaver, the chalybe tree, in Botany, a species of Vitis. This is a native of Sicily, where it affords a humid and shady places; but has been introduced into the gardens of this country, where it bears the cold of winter in the open ground. This plant was famous among the ancients as a specific for the preservation of chastity, and the preventing of all venereal diseases, pollutions, &c.

The Greeks call it αίγιος, chalybe; to which has since been added the reduplicative καθαρός, v. d. chalybe, chalybe.

The Athenian ladies, who made profession of chastity, lay upon leaves of agnus cadaver, during the feast of Ceres. Piny Hist. N. h. xxiv. c. 9. See CEREALES. The seeds, which have long been medicinally used, and were formerly admitted as an article of the Materia Medica, are of a round figure and about the size of pepper; they have a pungent air, and an unpleasant aromatic smell; from the days of Dioscorides they have been much celebrated for their efficacy in rubbing the inclination natural between the sexes; and from their utility to those that lead a monastic life, they have been called monastik piper. The seeds, so far from poising an antiapertic virtue, have had an opposite quality ascribed to them by modern writers. Their aromatic pungency favours this opinion, which is confirmed by the statement of Berger, who says that they are carminative and emmenagogic. In this island they do not produce much medical advantage.

The shrub is also called agnos, vites, sometimes declacn, lygon, and byzon.

AGNUS Dei, in the Romish Church, denotes a cake of wax flanked with the figure of a lamb, supporting the banner of the cross, consecrated in the due form by the pope, to be distributed in presents among the people, and supposed to have great virtues annexed to it.

The name literally signifies Lamb of God; this being supposed an image or representation of the Lamb of God, who took away the sins of the world.

They cover it up with a piece of fluff, cut in form of a heart, and carry it very devoutly in their processions. The Romish priests, and religious, derive considerable penitential advantage from keeping the Agnus Dei's to home, and presenting them to others. The pope provides a regular supply, by consecrating once in seven years; they are distributed by the master of the wardrobe; and received by the cardinals, and other prelates, with great reverence, in their caps and mitres. This ceremony they pretend to derive from an ancient custom of the church, wherein part of the pashal taper, consecrated on Holy Thursday, was distributed among the people, to perfume their houses, fields, &c. in order to drive away devils, and to preserve them from storms and tempests.

Some
Some authors also speak of a kind of metalline Agnus Dei's, hung to chaplets, or pater-nosters.

The Agnus Dei is forbidden to be brought into England, under the pain of incurting a præsumption. 13 Eliz. cap. 2.

Agnus Dei is also a name popularly given to that part of the mass, wherein the priest, striking his breast three times, recompenses, with a loud voice, a prayer beginning with the words Agnus Dei. It is said to have been first brought into the mifal by pope Sergius I.

Agnus Scythicus, in Natural History, a kind of zoophyte, or plant-animals, said to grow in Tartary, resembling the figure and structure of a lamb.

The Scythian lamb is also called agnus vegetabilis, agnus Tartaricus, and by the people of the country, borometz, borometz, or borometz.

The usual account given of this extraordinary production is, that the Tartars sow in their ground a feed resembling that of melon, but pefis oblong; from whence arises a plant called by them borometz, i. e. lamb, growing almost to the height of three feet, and having feet, hoofs, ears, and the whole head, excelling horns, resembling that animal. In lieu of horns, it has a peculiar fort of hair, not unlike horns; it is covered with a fine thin skin, which being pulled off, is worn by the natives as a cover for the head. The pulp within resembles that of the gammaretz; and when made into a liquor, ouzes out like blood. It lives as long as there are graves and herbalists about it; but when these are confumed, it withers and dies. They add, that wolves are fond of it, while no other beasts will feed on it.

Dennius seems to have been the first who suspected this account to be fabulous: and Kempter, when in the country, made diligent inquiry concerning it, but could hear of nothing like it.

As to the plants shown under this denomination, in some repositories of rarities, they appear to be originally the roots or flanks of certain vegetables, probably of the capillary or fern kind, and supposed by fome to be the polypodium auratum, covered with a woody mofs, which naturally bearing resemblance to the figure of a lamb, have been helped out and brought near to it by art, and the addition of new parts.

Sir Hans Sloane, and Breynius, give us the figures and descriptions of such borometzes in their collections. It is from these plants that the Indian mofs is gathered, famous for its use in staunching blood. Breynius and Libanius have written expressly on the Agnus Scythicus. Phil. Trans. N.° 287, and No. 392. See Also vol. ii. p. 646. vol. vi. pt. 2. P. 317. See Botany, pl. vi. fig. 7.

AGOAS Bellas, in Geography, a town of Portugal, in the province of Estremadura; three and a half leagues north-east from Thomar.

AGOAS de Moura, a town in the same kingdom and province; four and a half leagues north-east of Setúbal.

AGOAS de Soutar, a town in the same province of Portugal, seven leagues east-north-east from Abrantes.

AGOBARD, in Biography, archbishop of Lyons, was one of the most learned and celebrated prelates of the 9th century. He was born in the year 779, removed from Spain into France in 782, ordained priest in 804, and, having been nine years coadjutor to Leidrade, archbishop of Lyons, was appointed his successor in 816, upon his retiring to a monastery, with the consent of the emperor and the whole fynod of the French bishops. From this fce he was expelled by Lewis the Debonaire, because he owned the party of his son Lotharius, and was one of the chief instruments in deposing him in the assembly of bishops at Compigne in 833. But the sons of Lewis, having made their peace with him, restored Agobard to the favour of the emperor, and also to his fee, in the possession of which he continued till his death in 840. As a scholar and a divine, Agobard was much more distinguished than as a politician. He zealously opposed the worship and use of images in a treatise de Picturis et Imaginibus; and wrote another treatise to prove that Christ was not merely the adopted, but the true and natural Son of God; and a tract on the Priesthood, recommending attention to the character of those who were appointed to this office, affecting their privileges and inculcating their duty. His work concerning hail and thunder, was a direct attack upon superstition, and designed to expel a prevailing error, that it was in the power of forcers to rule tempests. During an epidemic disease, which occasioned large donations to the church, in hopes of preventing the infection, he wrote a tract to expel the avarice of the clergy, who, in a season of public calamity, took advantage of the fears and credulity of the people. He also opposed the practice of duelling, and wrote to the emperor soliciting the repeal of the law of Gondebaud, which allowed the decision of disputes by single combat, or by the ordeal of fire and water. He also wrote several tracts against the Jews. His manner of writing was simple and easy; his reasoning was commonly just; and he manifests an extensive acquaintance with the doctrines of the fathers and the discipline of the church; so that, considering the period in which he lived, he deserves to be regarded as a man of talents and learning. His works, having been long buried in obscurity, were published by Magno, in 1605; and a more correct edition of them by Baluzze at Paris in 1666, in two volumes, 8vo. This edition has been reprinted in tom. xiv. of the Bibliotheca Patrum. Gen. Diet. Dupin. Cave's Hist. Liter. tom. ii. p. 11. Ed. Oxon.

AGOBEL, in Geography, a town of Africa, in the kingdom of Tlemcen; four leagues from Oran. There is another town of the same name in the province of Hca, and empire of Morocco.

AGOCA, airen, ducus, of ayo, duco, I draw, in Natural History, a ditch or drain for carrying off the water from a mine.

AGOCA, in Geography, a town of Africa on the slave coast.

AGOCE, r. c. in the Ancient Muse, a species of modulation wherein the founds or notes proceed by continuous degrees of the scale, both rising and falling. As when we sing re, mi, fa, fol, la; la, fol, fa, mi, re.

Agoge anwers to what the Latins call dutus, and the Italians condusimento, and di grado; it stands contradistinguished from place, pettòia, &c.

Agoge makes the first part of the melopoeia, or art of modulating.

There are three species and cafes of this modulation: first, when the sounds follow each other from grave to acute, i. e. rising as in singing, BCDE. This the Latins call dutus retius, and the Italians condusimento retto.

The second, when they go from acute to grave, i. e. falling, as in the notes E D C B, called by the ancients dutus revertent, and by the modern Italians condusimento retroante.

The third, when they rise by flats and fall by sharps, as in D E F, sharps, G or, vice versa, as in G F, natural, E flat, D. This the ancients call dutus circumcurrens, and the Italians condusimento ciscorrens. See also the Italian work of Morosini, and the English, movement; of which, in compositions of two parts, there are three kinds: viz. moto retto, moto contrario, and moto oblique, i. e. equal, contrary, and oblique.

AGO.
AGOGASTRO, or Aquilastro, in Geography, a small island in the Mediterranean; three miles north from cape Barbarossa, in Sardinia.

AGOL, a town of Africa, in the Upper Ethiopia.

AGONG, an island in James's bay, near its western coast, north-east from Albany fort.

AGOMPHIASIS, or Gomphiasis, a dissipater of the teeth. It confits in their being loose in their sockets.

AGON, in Antiquity, a dispute or content for the mastery, either in some exercice of the body or of the mind.

There were agones on certain days, in most of the ancient feasts, and other ceremonies in honour of the gods, or heroes.

There were also agones established expressly, and not attached to any other solemnity.—Such was the agon gymnasticus, at Athens; the agon Nemear, instituted by the Argians in the 53d Olympiad; the agon Olympius, instituted by Hercules, 450 years before the first Olympiad; the agon Adrianus, instituted at Athens, by the emperor Adrian, called Procession, Paroli, and Olympius Nemeus.

The Romans had also agones instituted after the example of the Greeks: the emperor Aurelian established the agon solis, agon of the sun; and Dioecletian, the agon capitolinus, which was held every fourth year, after the manner of the Olympic games.—Hence the years, instead of leaera, are sometimes numbered by agones. The agon ιεροθειος, instituted at Puzzuoli by the emperor Antoninus Pius, and held every fifth year, was a faced combat, and the victors at it were called hieronices: they were to be received into the city, through a breach in the wall, made on purpose. The agon μνημειος was that wherein either poets, or musicians, disputed for the prize; such was that dedicated by Ptolemy to Apollo and the Muses, with rewards assigned to the writers who gained the victory. Of this kind were also found fome in the Pythian, Nememan, and Ithman games; also in the Olympic games, after Nicer's time, who first introduced a musical agon here: others were founded by the emperor Domitian, and others at Rome, Naples, Alba, &c. The agon Neronianus was a quinquennial combat, called also Neronian, from the name of its institutor, who here bore away the prize for playing on the harp, &cithara.

Agon is also used for a place near the Tiber, otherwise called circus Flamininus, wherein curule games and combats were celebrated.

Agon is also used by Physicin for the struggle of death.

Agos was also a minifter of facrifice, whole bufinefs was to strike the victim: the name is supposed to have been derived hence, that flanding ready to give the stroke, he asked agon, or agon, fublime stroke.

The agon was also called βους, culturarius, and victorius.

Agon, in Geography, an island in the north part of Haligoland, one of the provinces of Sweden, which has a good harbour and skilful mariners. It is in that part of the Baltic, called the Bothnia Gulph. N. lat. 61° 2'. E. long. 18° 10'.

AGONALES, in Antiquity, an epitaph given to the Salii, consecrated by Numa Pomphilius to the god Mars, surnamed Gradivus.

They were also called Quirinales, from the Mons Quirinalis, where they officiated. Robins calls them Agenantes Salii.

AGONIALIS, in Antiquity, feasts celebrated by the Romans in honour of Janus; or, as some would have it, in honour of the god Agonias, whom the Romans used to invoke upon their undertaking any bufinefs of importance.

They appear to have been instituted by Numa, and held twice in the year, viz. on the fifth of the ides of January, on the twelfth of the calends of June, and the third of the ides of December. Strux. Ant. Rom. c. 8.

AGONALIS Circus, now the Piazza Novana, is one of the most magnificent areas in Rome, near 80 common paces in breadth, and about 750 in length, adorned with three feated fountains, which serve to keep the air fresh and cool, and with noble statues, viz. Neptune by Bernini, the Triton and Dolphin by Michael Angelo, the Dumb by Claude, the Ganges by Borelli, the Nile by Fancelli, and Rio de la Plata by Raggi: all of which are of white marble, and alfo the obelisk of Caracalla of Egyptian marble, and covered with hieroglyphics, which was erected here by Innocent X. in 1654. The reason of annexing the epitaph Agonalis to this Circus is not ascertained. Ovid seems to derive it from the Agones, or solemn games, supposed to have been the iulii Apollinari, or Attic, instituted by Augustus, from which circumstance the Circus was called Apollinaris, and it was alfo denominated Alexandrianus, from Alexander Severus, who either incoled or repaired it.

AGONATA, in Entomology, the fourth clas of insects in the fystem of Fabricius; comprehending the cancer, the pagurus, the hippa, the scellaria, the aescus, the squilla, and the gammarus. Linnaeus has included the insects of this clas under the genus of cancer.

AGON. See HENBERNE.

AGONIES, in Ancient Geography, a people who, according to Mela, inhabited that district of the Milanei, now called la vol de Gogna. Polbyus (I. ii. p. 103.) places them in the Celtic Gaul, near Sens. Acumum was their capital.

Agones, an island near the mouth of the Anas.

AGONIUS, in Mythology, a name given to Mercury, because he preceded over the Agonian games, of which he is said by fome to have been the inventor. See Agonalas.

AGONISMA, in Antiquity, the palm or prize given to the victor in a game or combat.

AGONIARCTA, or aor, combat, and aor, chief, seems to have been much the fame with agonathed: though some fuggesit a difference, making it the office of the former to præfide at, and direct the private exercices of the athletes, which they went through by way of practice, before they made their appearance on the public theatres or amphitheatres.

AGONISTIC, agonificus, the science of what relates to the combats or agonis of the ancients.

In which fene, agonificus amounts to much the fame with athleticism, and makes a branch of gymnastics.

AGONISTIC, agonus, is also used among Ancient Physicins, for cold spring-water.

The reason of the denomination is taken from the plentiful afs of that element in the flate of an acute erysipelatous fever, wherein water was suppoled to combat and struggle with the febrile heat.

AGONISTICI, in Eclectic History, a name given by Donatus to thofe of his fect, whom he fent into the neighbouring places, fairs, markets, &c. to preach his doctrine: for which reafon they were also called circumtile, circumtile, circumtile, and, at Rome, montemfes.

They were called agonifici, from aor, combat; because they were fent, as it were, to fight and subdue the people to their opinion.

AGONIUM, in Roman Antiquity, was used for the day wherein the rex sacrarum Sacrificed a victim. The fame name was alfo given to the place wherein the games were ancintly celebrated.
AGONY, in Greek, a kingdom of Africa, on the Gold Coast, extends from the Devil's Mount, which separates it from Ascan, and stretches along the sea coast to the village Aunna, on the borders of Aguanoe, through a space of sixteen miles, bounded on the north by Songyay, and on the south by the ocean. It abounds in towns and villages along the sea, the chief of which are Dajon, Polder, Mango, Winiba, or Simpa, besides several others. It is said to be rich in gold mines, the gold of which the negroes gather in the sand after a heavy fall of rain; but the natives have opposed opening the mines for fear of being dispersed of their territory by the Europeans. Agonna surpasses Ascan in extent and population, and is equal to it in fertility and beauty. It has the advantage of a large fresh-water river, well walled with fish and oysters. The English have built a fort in the middle of Agonna, at a village called Simpa or Winiba, but the fort is not of any great strength. The village is populous, and the inhabitants industrious in fishing and in agriculture; for they breed a great number of cattle, which they sell to their neighbours. At a small distance is Barku, a village once frequented by the French, where the language is uniform along the Gold Coast changes into a different dialect, and a little farther it becomes altogether new.

This, according to Barbot, is the chief town in the kingdom of Agonna; and he says, that the surrounding country is fertile, pleasant, and well adapted for the establishment of a factory. The English had formerly great influence here; but the Dutch have gained advantage, and built a triangular fort at Barku, mounted with 12 pieces of cannon. When Bofman wrote, Agonna was governed by a queen, who was distinguished by extraordinary talents. But though the did not chuse to share her power with a husband, she was no stranger to the foster passages; and contrived means of indulging them, by a succession of falls, and as some say by a number of lovers at a time. N. lat. 5° 6'. W. long. 1º. Mod. Un. Hist. vol. xiii. p. 445.

AGONODRAMA, composed of a'ron, combat, and 3yron, he who disputeth, in Antiquity, a magistrate chosen among the Greeks, to preside, and to be the superintendent of the fared games, or combats; and whose province it was to register the name and country of each champion, to defray the expenses of the games, and to adjudge the prizes to the conquerors.

Among the Romans, the like officer was denominated deiugitor, and numerarius.

Middle-age writers usually confound agonist, the combatants at the games, with the agonistes, or judges of them.

The agonistes had also the immediate charge of the discipline and morals of the athletes. They examined, and admitted them into the society or order, or expelled them from it. During the combats, the agonistes were clothed in purple, and rode in a triumphant manner through the Circus, holding in their hands an ivory sceptre with an eagle on it. Juv. Sat. xi. 193.

Van Dale has an express dissertation on the agonistes.

The name agonistes is still retained in schools and academies, for him who defrays the charge of the prizes distributed. The founders of prizes are perpetual agonistes.

AGONOS, in Physt, a Greek word signifying barren. Hippocrates applies it to women who have no children, though they might have them, if the impediment were removed.

AGONUS, in Ichthyology, a name used by authors, for the fish called by some farzachus, by others elacías, and by others rudilla.

It is in many particulars very like the alamia, or had, called the mother of herrings, but smaller, never arriving at more than a foot in length: and is always lean and lank in spring, and fat in autumn. But the distinctions between it and the alamia, if real, are so very small, that Mr. Ray, and many of the most accurate naturalists, have interspersed it the same fish, only in a different state.

AGONY, Agonna, denotes the extremity of pain, or a disease, when nature makes her last effort, or struggle, to throw off the evil that oppresses her.

The word is formed from the Greek avuth, certamen, combat; this being a kind of strife between life and death.

Much of the terror of death consists in the pangs and convulsions wherewith the agony seems attended; though we have reason to believe that the pain in such cases is, ordinarily, not extremely acute; a course of pain and sickness having usually rupified, and indulged the nerves for any quick facilitations. However, various means have been thought of for mitigating the agony of death. Lord Bacon considers this as part of the province of the physician, and that not only when such a mitigation may tend to a recovery, but also when there being no further hope of a recovery, it can only tend to make the passage out of life more calm and easy. Accordingly, he ranks euthanasia, or the art of dying easily, among the disfederata of science: and does not even seem to disapprove of the course Epicurus took for that end.—"Hine illygias erius hairt aquas." De Augm. Sc. lib. iv. c. 4.

Opium has been applied for this purpose, with the applause of some, but the condemnation of more.

Bagiwi promised a treatise express, De Medicina Agonisztantum, or the method of treating persons in the agonies of death. But perhaps one of the best receipts for this end, is that of Mr. Patin, vis. affinity from all medicines.

Our Saviour's agony in the garden has perplexed several commentators; and some learned persons seem to have avoided the term agony in their translations, as Beza, Le Clerc, and Lefarant; and in the translations of the Syriac version by Tremaellus, Trofius, and others, we have timor, or fear, for agony. Dr. Lardner (vol. xi. p. 86.) suggests that ἀγωνίας εἰς ἀγωνίαν, (Luke, xxii. 44.) might be translated being under great concern. The effect of this agony has been differently explained. Some expound it with M. Le Clerc, that the expression ἀγωνίας εἰς ἀγωνίαν, only implies, that the drops of sweat were large and clammy, like drops of gore. Grotius understands the expression metaphorically, as denoting excessive sweat; but Dr. Whitby (in loc.) obseres, that Arifotle (Hist. Anim. lib. iii. c. 19. Oper.tom.i. p. 809. De part. Anim. lib. iii. c. 5. Oper.tom.i. p. 1088.) and Diodorus Siculus (lib. xvi. Oper.tom.i. p. 230.) mention bloody sweats, as attending some extraordinary agony of mind. Leti also, in his life of pope Sixtus V. p. 208, and Sir John Chardin, in his History of Persia, vol. i. p. 126, mention a similar phenomenon; to which Dr. Jackson (Works, vol. ii. p. 819.) adds another from Thuanus, lib. x. p. 221. See Doddridge's Family Expositor, vol. ii. p. 517.

Bartholinus (de Cruce, p. 184, 193.) produces examples of sweats that have been actually mixed with blood. So does Maldonat in Matt. xxvi. 37. The possibility of this circumstance is ascertained by a fact well known in history, viz. that Charles IX. of France died of a malady, in which his blood gushed out of all the pores of his body. Votataire (Univ. Hist. chap. 142.) describes it thus: "Charles IX. died in
AGORÆUS, formed of *μωρία*, market, in *Antiquity*, an appellation given to those districts that had flatuses in the public market-places, or fora. Mercury, whose flatuse was erected in almost every public place, was distinguished by this appellation.

AGORAH, Malagros, in *Ancient Geography*, a city of the Thracian Chersoneseus, which flourishes on the gulf of Melas. 

AGORA, an ancient money of Egypt and Asia. See GERAMA.

AGORANIS, in *Ancient Geography*, a river of India, mentioned by Arrian, Indic. cap. 4. which flowed into the Ganges.

AGORANOMUS, composed of *μωρία*, market, and *νόμος*, law, in *Antiquity*, a magistrate of Athens, established for the maintenance of good order and policy in the market, settling the prices of provisions, excluding corn, and deciding disputes relating to buying and selling, inspecting the weights, measures, and the like.

The agoranomus, among the Greeks, was much the same with the *curate* *adile* among the Romans.

Aristotle distinguishes two kinds of magistrates, the *agoronomi*, who had the superintendence of the markets; and the *affonomy*, who inspected the building of the *στάδια* cities. The agoranomus, at Athens, were ten in number, five belonging to the city, and as many to the Piraeus; though others make them fifteen in all, of whom they assign ten to the city. To these a certain toll or tribute was paid, by all who brought anything to sell in the market.

AGORITÆ, in *Ancient Geography*, a people of Asiatic Sarmatia.

AGORO, in *Geography*, a town of Italy, situate on the river Cordevol, on the frontiers of the Tyrode; 21 miles west north-west from Belluno.

AGOSTA, a town of Sicily on the east end of the island, to the south of Catania, with an excellent harbour. The greater part of it was destroyed by an earthquake in 1693; but has been since rebuilt. N. lat. 37° 20'. E. long. 15° 15'.

AGOSTA *island*, in the Gulf of Venice, is nearly south of the island Carzola and Lechina islands, and west of Augufina flats and rocks. It affords a good road for ships, in N. lat. 43° 42'. E. long. 35° 57'.

AGOSTINO, PAOLO, DA VALERONA, in *Biography*, an eminent musical composer, was born in 1503, educated in the Roman school of music, under Bernardo Namini, and succeeded Soriano, as master of the pontificial chapel at St. Peter's. He is represented as one of the most scientific and inventive composers of his time in every species of music; and his productions for four, six, or eight choirs or chorusses were the admiration of all Rome. Padre Martini has preferred an agusi del, in eight parts, of this composer, which is a very extraordinary performance. He died in 1629, at the age of 36 years. Burney Hilt. Musie, vol. iii. Hawkins Musie, vol. iv.

AGOSTUS, AD757, in *Anatomy*, signifies the part of the arm from the fingers to the elbow; also the palm or hollow of the hand.

AGOUT, in *Geography*, a river of France, which rises in its course in the Marne, and runs to the Tarn, near Montauban.

AGOUTI, in *Zoology*. See AGOUT.

AGOWS, in *Geography*, the inhabitants of a province of Abyssinia, which is bounded by the mountains of Amid Amil on the east; by Bour and Umbarma, and the country of the Gongas, on the west; by Damot and Gafat on the south; and by Dingleber on the north. Of the Agows there are two nations; the one near the fountain of the Nile; called the Agows of Damot, from their vicinity to that province; the other near the head of the Tezzezâ, in the province of Laifa, called the Thcheratz Agows, from Tcherera, a principal town, tribe and district, near Laifa and Begemder. The country of Agows lies in a very elevated situation, and forms a kind of amphitheatrical of lofty mountains; and the climate of course is temperate and wholesome. In the shade, or in a house, the air is cool, as there is a continual breeze which mitigates the scorching heat of the sun, even at noonday, though the latitude is not much greater than 10°. But notwithstanding the moderate temperature of the climate, the Agows do not live to any great age, which is probably owing to the oppression they suffer. Their country abounds with all the necessaries of life; and yet their taxes, tributes and services are so numerous, and their dependent condition so difficult, that they are only the manufacturers of the commodities they sell, in order to satisfy the exorbitant demands of their oppressors; and are constrained to live in a state of penury and misery, that is scarcely conceivable. Mr. Bruce informs us, that he saw a number of women, wrinkled and sunburnt so as hardly to appear human, wandering about under a burning sun, each of whom had one or sometimes two children upon their back, and gathering the seeds of bent grass to make a kind of bread. The Agows, in whole country the Nile rivers, are one of the most confederate nations, with respect both to power and wealth, in Abyssinia. When their whole force is raised, they can bring into the field 4000 horse, and a great number of foot; but their power has been much reduced by the incursions of the Gallars. Their riches, however, are still greater than their power; for though their province is hardly 60 miles long, and 30 miles broad, yet Gondar and the whole neighbouring country depend for the necessaries of life, cattle, honey, butter, wheat, hides, wax, and a number of such articles, upon the Agows, who frequent the capital to the amount of 1200 and 1500 at a time, in order to dispose of their commodities. The Abyssinian princes have therefore compounded with them for an increase of tribute, in lieu of military service; but when they have deviated from this prudent practice, the Agows have been great sufferers. The butter, which they carry to a great distance in this hot climate, is prevented from putrefaction by a root called moc-moco, resembling a carrot; which they bruise and mix with it, and thus they preserve it fresh for a considerable time. This root answers the purpose more certainly than salt, which could not be conveniently appropriated to this use, as it ferments for money, and is used instead of silver coin as change for gold. Brides paint their feet, the palms of their hands, and their nails, with this drug. Mr. Bruce brought a considerable quantity of the seed, resembling that of coriander, into Europe. The Agows dispose of their commodities, not only at the market of Gondar, but to the neighbouring black Savages, the Galla, head of Shangalla, and receive in exchange the plants' teeth, horns of the rhinoceros, gold, and fine cotton. This trade, which might be materially beneficial, is very much
much interrupted by the barbarity and fraud of both
nations. Besides what they sell, and what they pay to
the governor of Damot, the Agows present a tribute to the king
of 1000 dabra of heavy, each dabra containing about 60lb.
weight; 1500 oxen, and 10000000 ounces of gold. The clothing
of the Agows consists of hides, which they often and manu-
facture in a manner peculiar to themselves. Of these they
form a kind of skirt, which reaches down to their feet, and
is girded with a belt about their middle. The lower part
refembles a large double petticoat, one fold of which they
turn back over their shoulders, fastening it with a floer
across their breast before, and the married women carry their
children in it behind. The younger sort are generally naked.

The women are commonly thin, and, like the men, below the
middle size. Barrenness is unknown among them. They
are marriageable at nine years of age; and at 16 they actually
marry and bear children; and continue child-bearing to the
age of 30, and in some instances beyond that period.

With regard to religion the Agows are grossly idolatrous
and superstitious. The Nile, or the spirit residing in that
river, is the object of their worship; whom they address under
the titles of the everlasting God, light of the world, eye
of the world, God of peace, their Saviour, and Father
of the Universe. To this Deity they present their supplications
for seasonable rain, plenty of grass, and the preservation of
a particular kind of serpents; at the same time depreciating
thunder; and their prayers are pronounced very pathetically
with a kind of tone or long. The flunt or priest of the river,
with whom Mr. Bruce conversed, pretended to have inter-
coursed with a spirit, which occasionally appeared to him, and
revealed to him future events. This spirit, he said, was of
the river, God, the father of mankind. Thunder was
depicted, as the priest informed him, because it was hurtful
to the bees, and their chief revenue was honey and wax.
They prayed for serpents, because they taught the approach
of good or evil. Serpents are kept in some of their houses;
and they are fed with butter and milk before they undertake
a journey, or any affair of consequence; and if they do not
eat, this is considered as a bad omen. Before an invasion of
the Gallas, they say these serpents disappear, and are no
where to be found. Faid, a lagacious governor of the
country, who was addicted to this species of divination,
would never mount his horse, or go from home, if an animal
of this kind, which he had in his custody, refused to eat.
Once a year, on the first appearance of the dog-filar, or, as
others say, 11 days after, their devotion is attended with
circumstances of peculiar solemnity; on which occasion
they sacrifice a black heifer, distribute parts of it to severa
clans, eat the carcase raw, and drink the water of the Nile.
The bones are then burnt to ashes; and the head is carried
into a cavern, which they say reaches below the fountains
of the river, and there they perform their secret worship, which
no one is allowed to divulge. The Agows of Damot worship
the Nile; and those of Lafta pay nearly the same worship to
the Siris or Tseozae. These have a separate language, and
are Troglodytes, who live in caverns. Mr. Bruce ap-
prehends that Agow is a compound of two words, Ag-oia,
g. d. the Shepherds of the river; and that the species of
idolatry introduced by them is a proof that they originally came
from Cauana, where they imbibed materialism instead of the
pure Sibean worship of the shepherds of Agra, which
was, at an early period, the only religion of this part of
Africa. These mountains in all the districts or clans of Agows
are perforated in caves of a very large size, which some sup-
pone were their ancient habitations, when they were Tro-
glodytes, or places of retreat; when they were alarmed by the
approach of their most formidable enemies, the Galars.
Others think it not improbable, that these caverns were used
for religious purposes; that of Geesh, in particular, was
without doubt a place of secret worship paid to the river,
as it is ill appropriated to that use, not only by the
inhabitants of the village, but by the assembly of the clans in
general, who retire for the celebration of those rites, to
which none but the heads of the families in the Agows country
are ever admitted. Bruce's Trav. vol. i. 401, vol. iii. p. 527.

Agra, a kind of sweet-scented wood, found in the
island of Hainan, on the coast of China.

Agra, or Carumba, is another sweet-scented wood, which
allowed comes from the island of Hainan.

Agra, in Ancient Geography, the name of a district of
Attica, near the source of the Liffis, where Diana hunted
for the first time. Paufanias (Attic. lib. i. p. 45) says that
she had a temple in this place, dedicated to Diana Agretils.

Agra was also a town of Susiana—another of Arabia:
—and another, an episcopal see of Numidia in Africa.

Agra, called Agara by Ptolemy (but the Agara of Pto-
lemy is supposed by Rennell to have been Agraron), in Geogra-
phy, the capital of a Subah or province of the same name,
in Hindostan. It stands on the river Jumna, about 50 miles
above its confluence with the Tamba, and 300 miles north-
call of Surat; and from being an inconsiderable town with a
small castle of earth, it became not only the capital of the
province, but the first city in India for magnificence and
commerce, during the long reign of the emperor Akbar,
and of his son; and it even now exhibits more numerous
monuments of former splendour than any city of Hindostan.
Akbar, pleased with its situation, very much enlarged and
adorned it, and in 1566 made it the seat of his court and
city; and the site of it is has been often called Akbarabad,
or Akbar's habitation. The city is very long but not broad,
in the form of a crescent; and surrounded by a wall of red
stone, and a ditch 100 feet wide. The streets, with the
exception of a few, are narrow and ill-arranged; the houses
are generally low and mean buildings; and the space within
the wall is laid out in gardens and palaces, so that it is less
populous than might be imagined, considering its extent.
The castle and palace are structures of astonishing size and
magnificence. The walls of the former consist of stone and
brick, terraced in several places, and 20 cubits high. Be-
tween this and the river is a large space, designed for the
exercise of the troops and other diversions in the emperor's
view.

The palace, which is within the castle, contains
three courts, encompassed with porticos and galleries, all
painted and gilt; and some pieces are said to have been
plated with gold. Under the galleries of the first court are
the lodgings for the imperial guards; those for the officers
are in the second court; and the third contains the flately
apartments of the emperor and his ladies. The completion
of the palace occupied above 1000 labourers for 12 years,
and cost nearly three millions of rupees. The emperor, for
the execution of his plan, collected together, by the promise
of ample rewards, the most skilful architects and the most
celebrated artists in every branch, both of external ornament
and domestic decoration. Besides the royal palace, there are
several others ranged in a line, which belong to the princes
and great lords of the court; and before it there is a very
large square, and there are also 12 other squares in different
parts of the city. The Caravanerais are more than 60 in
number, and some of them have fixed large courts with their
porticos. There are at Agra above 800 public baths, and
a great number of mosques, with very magnificent sepul-
chres. Among the latter is the mausoleum of Akbar him-
self,
self, and another erected by the emperor Shah-jehan for his empress Mahd-Ali, at the expense of 60 lacs of rupees, or 7,370,000/. N. lat. 27° 15' E. long. 78° 29'.

Between this city and Lahore in the Panjub, which are distant from each other 500 miles, there is planted on each side of the road a continued row of shady trees, forming an avenue, to which, whether we consider its extent, its beauty, or its utility in a hot climate, there is nothing similar in any country. Rennell's Memoir, p. 69. Fraser's Hill.

Nadir Shah, p. 25.

The province, or Subah of Agra, is bounded on the north by the province of Delhi, on the east by Oude, on the south by Malwa, and on the west by Agimere; and is about 175 miles long and as many broad. According to the divisions of the emperor Akbar, it contains 13 circars or counties, which are divided into 203 pengurnahs or hundreds. The amount of the revenue is 16,150,257 Sicca rupees; and the number of the forces are 50,000 cavalry, 575,570 infantry, and 221 elephants. It is, after many revolutions, says Mr. Maurice, in vol. i. of his Indian Antiquities, published in 1797, at present possessed by Madajee Sindia, one of the most formidable of the self-created sovereigns of the Hindoostan. The indigo of this province is deemed the most valuable in the East Indies. Its productions are also rice and cotton, oranges and lemons; and its manufactures are white cloth, siken stuffs, silver and gold lace, &c.

Agra, or Egara, is the name given by Pliny (Nat. Hist. tom. i. p. 339. Ed. Hard.) to the town of Henaja, in Arabia Felix, now called Hejir, or Al-Fhegur; situated, in N. lat. 28° 30', amidst a ridge of rocky mountains, denominated 'Al-Athaleb, i. e. the fragments of stones; out of which many houses have been cut, as some say, by the Amalekites, or by their ancestors the Adites, framites, and Thamudites. The Thamynders of the ancients are represented by Pliny as neighbours to this city.

AGRADO Ilhes, a town of Africa, in Lower Guinea.

AGRAE, a city of Arcadia, mentioned by Pliny, tom. i. p. 105.

AGREJA, a country of Greece, which extended itself into Aetolia and Acarnania.

AGREI, a people of Arabia Felix, who, according to Pliny, were good warriors: and also a people of Aetolia in Greece, near the Acheleans.

AGRA, an episcopal city of Spain.

AGRAGAS. See AGRIGENTUM. This was also a river of Sicily, which joined the Hypsa, below Agrigentum.

AGRAI, Agris, and Arieni, a people of Paeonia, between Hacius and Rhodope.

AGRAKOVA, a town of Russia, in the government of Archangel, on the west of the White Sea; 17 German miles west of Archangel.

AGRAM. See ZAGRA.

AGRAMONT, a small town of Catalonia in Spain, between Lerida and Sollona, on the river Segre, but the capital of a jurisdiction. N. lat. 41° 50'. E. long. 58'.

AGRANE, a borough of Babylon, ruined by the Persians.

AGRARIAN SITUATIONS, in the Ancient Military Art, corps of guards posted in the fields, and in the open air.

AGRARIAN LAWS, in the Roman Jurisprudence, a denomination given to such laws as relate to the partition or distribution of lands.

There are 15 or 20 agrarian laws; whereas of the principal are, the Lex Caiffa, in the year of Rome 268, the Lex Licinia, in 361; the Lex Flaminia, in 552; two Sempronian laws, in the year 620; the Lex Apollonia, in the year 635; the Lex Bambia; the Lex Cornelii, in 675; the Lex Servilia, in 690; the Lex Flavia; the Lex Julia, in the year 691; the Lex Flavia Licinia, the Lex Licinia, the Lex Marcia, the Lex Roffitza, made after the taking of Carthage; the Lex Flavia, and the Lex Titia. See AGRAR.

AGRARIAN LAWS, Lex AGRARIA, absolutely, and by way of eminence, so called, was a celebrated law, published by Sporus Caiffius, about the year 268, B. C. 486, for an equal division of the conquered lands among all the citizens, and for limiting the quantity of ground possessed by each person to a certain number of acres. Tho' other two in the Digest, the one published by Caxar, and the other by Nerva, only relate to the limits or boundaries of grounds; and have no relation to that of Sporus Caiffius. The Roman lands were of divers kinds, some conquered from the enemies, and not yet brought to the public account; others brought indeed to the public, but clandestinely usurped by private great men; lastly, others purchased with the public money, in order to be divided. Agrarian laws, either for dividing lands taken from the enemy, or the public lands, or those purchased with the public money, were easily passed without disturbance; but tho' whereby private rich men were to be ousted of their lands, and the common people put in possession of what had been held by the nobility, were never attempted without great disturbances. This is the first time the Agrarian law was mentioned; and the measure originated in the ambitious views of Caiffius, who thus intrigued for gaining the favour of the people, and for attaining absolute power. The law had the appearance of equity, and could not less than be agreeable to the people, whose misery it relieved. But as the lands, which Caiffius wished to have distributed among the poorer citizens had been unjustly usurped by the rich, the proposal alarmed the Senators, partly because they were personally interested in it, and partly because they apprehended its dangerous consequences. The people were at first pleased; but when they understood that the Latins were to partake with them of the advantage, they were disgusted. To conciliate the Latins, and to engage their concurrence in his favour, were the objects which Caiffius had in view; but the jealously and dissatisfaction of the Roman people disappointed his hopes, and terminated in his death. As soon as he was found guilty of aspiring to the sovereignty, and sentence was passed upon him, he was carried by the Quellers to the Tarpeian rock, which fronted the Forum, and thrown down from the top to the bottom in the presence of the people; such was the customary punishment of this crime amongst the Romans. His house was also demolished and his estate sold by auction. With the money arising from it a statue of brass was erected to Ceres. The Plebeians, when they afterwards found that the decree of the Senate for the distribution of lands was not executed, nor any measures adopted for this purpose, reproached themselves with the condemnation of Caiffius, as an act of imprudence, and even of injustice. In the year of Rome 299, the subject of the agrarian laws, which had been suspended for 30 years, was revived by the Tribunes; and the people demanded, that as they shared with the Patricians in the labours and dangers of the commonwealth; they might also share with them in the benefits accruing from them. But a new partition would have been attended with great difficulty, and the attempt seemed impossible to proceed in this business, without manifest injustice to many persons in actual possession of the lands to be distributed, who had really
really bought them, and without occasioning great and univeral commotions in the commonwealth. For these reasons the Senate firmly opposed the establishment of the agrarian laws. About the year 377, C. Licinius Stilo, a rich plebeian, and tribune of the people, attempted to refrain the overgrown power and wealth of the patricians, by proposing a law, which should restrict every Roman citizen to the possession of 500 acres, and oblige him to surrender the overplus, in order to be divided among the poorer citizens. His motion, though enforced by the influence of his colleague in the tribuneship, L. Sextius, was over-ruled; and new commotions occasioned by the approach of the Gauls, having engaged the public attention, the business of the agrarian law was deferred for nine years; and about the end of that time it was again revived, and the law was established: this was called the Licinian law; and the mover of it was soon afterwards condemned by his own law. Having been found to possess more than 1000 acres, 500 of them were distributed among the poor citizens, and he was compelled to pay the fine, which he had annexed to the violation of the law. In consequence of this abuse, the law itself was abandoned. In process of time, however, the great and rich possessed themselves of almost all the lands that belonged originally to the State, either by purchase, or by paying a greater quit-claim, or by violence. Several regulations had been proposed for restraining these usurpations. At length other measures having been found ineffectual, (A. U. C. 620. B. C. 134,) Tiberius Gracchus, urged by his mother Cornelia, proposed the revival of the Licinian law; and that the rich should quit the lands which they held contrary to the laws, after having received from the public the value of them; and that the citizens, whose circumstances required it, should take possession of them. Many objections were urged against this mild and humane regulation, as Plutarch calls it: and the prosecution of it brought the commonwealth to the brink of destruction, and cost the two illustrious brothers, the Gracchi, their lives. Their efforts were of little avail, as the laws they laboured to introduce were gradually abolished after their death. Cicero, in speaking of the partition of lands and the remittance of debts, says (Offic. I. 2. n. 78.) "that to undertake to discharge debtors by the authority of the magistrate, or to put the law to oftenProposed for the distribution of lands, is to sap the two principal foundations of the commonwealth: of which one is peace between the citizens, which could not subsist, if creditors were to lose their fortunes by the discharging of debtors; and the other justice, which is entirely subverted, from the infant no one can aflure himself of ceasing in peacable possession of his right." The agrarian law of the tribune Saturninus, which was carried with violence A. U. C. 652, was of very short duration; and that of Rullus in the year 689, which was more exorbitant than any other; and gave up to a small number of citizens, under the pretext of relieving the poor, almost all the revenues of the commonwealth, afforded Cicero an admirable opportunity of displaying his eloquence in exposing it, and inducing the people to reject it. The exordium of his oration on this occasion has been much admired. Cic. ii. 11. in Rull. The agrarian law of Cesar was presented to the Senate in the beginning of his consulship, A. U. C. 693: and he urged in its favour, that a distribution of lands among the poor citizens was altogether useful, and necessary to deliver the city from a multitude of people with which it was overburdened, and often gave rise to seditions; to repeople and cultivate several parts of Italy, which were abandoned; to recompense theolders who had served the commonwealth, and to give subsistence to many citizens who wanted it. He proposed the execution of it in the mildest and most moderate manner; and that 20 commissioners should preside at the distribution of the lands, excepting himself out of the number. Notwithstanding these specious pleas, Cesar inveighed loudly against the project of Cesar, alleging that he did not to much apprehend the division of the lands, as the wages that would be required of the people by those who fought to inveigle them by this present. Cato was imprisioned for his opposition; and when another senator was asked by Cesar why he departed before the Senate broke up, he replied, "because I had rather be with Cato in a prison, than with you in the Senate." Cesar appealed to the people; and having engaged the concurrence of Pompey and Crassus, the reliance of Bibulus, Cesar's colleague in the confulsip; and the vehement opposition of Cato were ineffectual. The law was authorized by the suffrages of the people. Cicero acquiesced in this measure, by observing a kind of neutrality; and argues to this purpose: "Let us remain neutrals, as if buried in a house in the country. Cesar hopes that I will second him and invites me to it. See the advantages I shall gain by taking this party; the friendship of Pompey, and even that of Cesar, if I defined it; a reconciliation with my enemies; the peace of the multitude; and the assurance of quiet in my old age: but after the conduct I have maintained in my consulship, and the principles which I have maintained in my writings, ought not my rule to be this maxim of Homer (II. M. 441), the bell of all counsel is to defend one's country?" Cicero ad Attic. II. 3. In persuading Cato to give up his reliance to this measure, he conjures him to consider, "that if Cato has no need of Rome, Rome has need of Cato." Cic. pro Sext. p. 61.

Several have pleaded for the necessity of agrarian laws among us. William Spigge, or, as some say, Tr. Ofborne, has written expressly on this subject. See also the Supplement to Dr. Price's Observations on Reversionary Payments, &c. p. 381.

But the author who seems to have entered most deeply into the nature and use of agrarian laws, is Harrington; he shews that the balance of property in a state cannot be fixed but by laws, and the laws whereby such a provision is made are agrarian laws. Now these are necessary to the stability of government, because governments will, according to the diverse balance of property, be of diverse or contrary natures, that is, monarchical or popular. Thus monarchy requires of the standard of property, that it be vast or great; and of agrarian laws, that they hinder recefs or diminution, at least in so much as is thereby entailed upon honour. But popular government requires, that the standard be moderate, and that its agrarian laws prevent accumulation.

This author thinks, that in a territory not exceeding England in revenue, if the balance be in hands than 300, it is declining from monarchy; and if it be in fewer than 5000 hands, it is swerving from a commonwealth.

The same writer defines an equal agrarian, a perpetual law, establishing and preferring the balance of dominion by such a distribution that no one man, or number of men, within the compacts of the few, or aristocracy, can come to overpower the whole people by their possessions in lands.

He also observes, that the people of Rome, by striving for an agrarian, strove to save their liberty: and that commonwealth, through want of such a law, or the non-observance of it, came to ruin.

In the Grecian cities, the defect of an agrarian was supplied by oikakia.
AGRARIUM. See Agrimont.

AGREDA, in Geography, a town of Spain, in Old Castile, at the foot of Mount Cayo, where the ancient Gracchoris flood; three leagues south-west from Tarazona. N. lat. 41° 53'. W. long. 2°.

AGRES, is also the name of a town in the kingdom of Popayan, in South America; forty miles north from Quito.

AGREDa, Mary of, in Biography, a devoted fanatic, or a bold imposer, was born at Agreda, in Spain, in 1602, took the veil in 1620, in a convent founded by her father and mother, was elected superior in 1627, and died in 1663. In 1637, she began to write the life of the Holy Virgin, in consequence, as she pretended, of orders received from God and the Virgin; and when it was finished, she annexed to it an attachment, that its contents had been communicated to her by divine revelation. This fanciful work was translated by Father Crozet, and formally condemned by the dectors of the Sorbonne. The translation, in three volumes, 4to., was published at Brussels, in 1717. Gen. Dict.

AGREMENT, Agreement, in Law, a joining, or putting together, of two or more minds in any thing done or to be done.

Of this there may be three forts.—The firrt, an agreement executed at the beginning, mentioned in the statute of 25 Edw. III. exp. 3, which says, "That the goods " bought by forefellers, being thereof attainted, shall be " forfeited to the king; if the buyer thereof have made "gree with the seller": where the word gree otherwise called "agreement executed", signifies payment for the things, or satisfaction.

The second is an agreement after an act, that is, where one does an act, and another agrees and affents thereto afterwards.—The third is an agreement executory, which is, when both parties at one time are agreed that such a thing shall be done in time to come. It is called executory, because the thing is to be done afterwards.

Agreements are to be in writing, by flat. 29 Car. II. cap. 3., of frauds and perfons.

AGRESSES, or Ugresse, in Heraldry, the same as Pellets.

AGRESTA, in the Materia Medica, an unripe grape; otherwise called ouakas, and woa acoba, by the French varus.

Agrestes are huld cooling, delerive, and alfrinct; they temper the actimony of the bile, and the heart. Eaten plentifully, they have been found to destroy worms. The term is sometimes also applied to the juices of this fruit, more properly called amphacum.

AGRESTI, Livio da Furli, in Biography, was a painter of histry, who died in 1580. He was a disciple of Perino del Vaga, and is commended by Vafari, for the richness of his invention, the goodness of his colouring, and the correctness of his design. Pilkington.

AGREVE, in Geography, a small town of France, in Vivarais, at the foot of the mountains.

AGRI, in Ancient Geography, a people placed by Ptolemy, in European Sarmatia.

AGRIA, a name given to Holly, and also to a malignant puttle, of which there are two forts. The one is small, with a roughness, redness, and flight corosion of the skin; it is of a round figure, its centre is smooth, and it spreads slowly. It is cured by rubbing it with faling spittle. The other fort ulcerates with a violent redness and corosion, so as to make the hair fall off; it is of an unequal form, and turns leprous. It is cured by poultices of Pellytory of the wall.

AGRIA, or Eger, in Geography. See Eracle.

AGRIAMPELOS, formed of aepyos, wild; and aperios, a vine; the wild vine; and, according to Gerard, the black brinck.

AGRIANA, in Ancient Geography, a town of Cappadocia.

AGRIANES, a small river of Thrace, which rose north of Heraclea, and discharged itself into the Hebrus. This was also the name of people near mount Pagaeus, in Thrace.

AGRIANIA. See Agronia.

AGRICOLA, Cnæus Julius, in Biography, an illustrious Roman, was born on the 13th of June, in the second confulship of Caius Cæsar, A. D. 38. Tacitus dates his birth, in the third confulship of Caius; but as he died in his 56th year, by the fame historian's account, he must have been born sooner. He was a descendant of the colony of Forojuli or Frejus, in Provence, the place of his nativity; and his grandfathers, on both fides, were of the equefran rank. His father, Julius Gracchius, was of the order of senators, and distinguished by his wisdom and eloquence. His character is mentioned with respect by Seneca, (de Benef. lib. ii.) and he is cited as a writer by Pliny, tom. i. p. 710. Vid. Index Auctorum, tom. i. p. 61. Ed. Hard. Cæliqula wished him to accufe Silius; and because he refused, caufed him to be put to death. Agricola being thus deprived, at an early age, of the instruction which his father was fo capable of giving him, the care of his education devolved upon Julia Procilius, his mother. By her he was removed, when a child, to Marcellis, which was then deemed the Athens of Gaul; where the politefnes of Greece was happily blended with the provincial simplicity.
attachment to the old religion, though he lived among Lutherans. He died at Chemnitz, November 21, 1556, and was buried at Zeitz; the bigotry of his townsmen not allowing him a grave among them. G. Fabricius, his intimate friend, composed the following epigram on his works:

"Viderat Agricola. Phæbo montaniter, libellos, Jupiter, et tales editis ore fonos. Ex ipso hic terce thefanos crucem orco, Et iritatis pandet tertia regna melter."

His works on mines, published originally in parts, were collected and printed together, at Basil, 1546, in folio. They are chiefly comprehended under the following titles: "De ortu et causis fictorum, De Naturæ corum quæ effinunt ex terra, De Natura Toffilium, De Medici Fossilibus, De Subterraneis Animantibus, De Veteribus et novis Metallis." His great work, "De Re Metallica," was printed at the same place, 1561, also in folio; "De Menfuris et Ponderibus Romanorum et Graecorum," with additions referring to modern times, 1550, folio; "De Pelle Libri tres," Basil, 1554, 8vo.; "Opus de Toffilibus, cum Annotationibus Georgii Fabricii." 1557. He also wrote other treatises on political and theological subjects.

Agricola, John, a Saxon divine, was born at Eisleben, in Germany, April 20th, 1492. Molheim describes him as an eminent doctor of the Lutheran church, though chargeable with vanity, presumption, and artifice. He was minister, and principal of a college in his own country; and attended the elector of Saxony to the diet of Spire, in 1526; and to that of Augsburg, in 1528. Urged by ambition, he quitte his own country in 1526, and went to Wittemberg, where he settled as a professor and minifter. Although he wrote against Melancthon, in 1527, he was not much noticed before the year 1538, when he took occasion, from the doctrine of Luther, concerning the ground of man's acceptance and salvation, to declaim against the law; maintaining, that it was neither fit to be propounded to the people as a rule of manners, nor to be used in the church as a means of instruction; and that the gospel alone was to be inculcated and explained, both in the churches and in the schools of learning: and he thus became the founder of the sect of Antinomians. Luther, who had been before his friend, attacked him with great severity; and his accusations were supported by the divines of Wittemberg. At length, by the interposition of the electors of Saxony and of Brandenburg, Agricola was induced to publish a recantation of his errors, and to retract the injurious reproaches which he had cast upon Luther. Molheim says, this recantation does not seem to have been sincere; as he returned to his errors, when his fears were dispelled by the death of Luther, and gained proficiency to his extravagant doctrine. Agricola was employed by Charles V., in 1548, in conjunction with other persons, and liberally rewarded, in composing the Interim. It is said, that he wanted to restore the use of holy oil in the case of the sick; and that he attributed a supernatural efficacy to it. Some have said, that he was a Papist; and others charge him with being a man of pleafure, and with maintaining all religions to be in themselves really indifferent. When he left Saxony, he was patronized at the court of Brandenburg, by the elector Joachim II., whose favour he enjoyed till his death, which happened at Berlin, in 1566. His "Exposition of German Proverbs," and his "Commentaries upon St. Luke," are the principal of his works, Gen. Dict. Moth. Excl. Hist. vol. iv. p. 321, &c.

Agricola, Martin, a theoretic and practical musician, who was chancellor of Magdeburgh, and flourished about the middle of the 16th century. He died June 1oth, 1556. His works are two treatises on music, written in German verse, and published at Wittemberg, in 1528 and 1529; the latter of which, viz. "Musica Instrumentali," was re-published, with large additions, in 1545; and contains an explanation of the fundamentals of music, together with a description of the instruments used in his time, and the method of playing upon them; and an account of the division of the monochord, and of a temperature for the organ and harpichord: a tract "on Pigurate Music," and a brief treatise "De Proportionibus," a treatise, intitled, "Scola in Musica Planam Wesseni Philomatis ex variis Musico-Philosophis centralis," a larger work, intitled, "Melodie Scholastica sub horarum inter- vals decantanda," published at Magdeburg in 1582; and a posthumous work, intitled " Duo Libri Musicæ continentem Artis, et illustria Exempla, &c." published in 1561. His several treatises were designed for the instruction of beginners in the study of music. Hawkins's Hist. Music, vol. iii. p. 83.

Agricola, Michael, a Lutheran minifter at Abo, in Finland, was the first who translated the New Testament into the language of the country, and thus contributed to the propagation of Lutheranism. It was printed in 1548. He died in 1556. Gen. Dict.

Agricola, Rodolphus, was born in the village of Baffon, near Gromingen, in Friesland, in the year 1442; and distinguished by his love and pursuit of literature. Having finished his education at Louvain, where he maintained an exemplary character for sobriety and application, he declined the professor's chair, which was offered him, and visited France and Italy for further improvement. At Ferrara, he studied Greek, and availed himself of the lectures of philosophy that were read by Theodore Gaza; and at the same time taught Latin, which he was able to write with so much purity and elegance as to rival Guarini, in prose; and the Strozzius, celebrated writers at that period, in verse. After a residence of two years in Ferrara, he returned to the Netherlands, about the year 1477; and, at Davenport, had an interview with Erasmus, whose future celebrity, though he was then a boy of ten years old, he had the sagacity to predict. His love of independence, and his felicitude for securing leisure to indulge his literary taste, induced him to forego several offices of honour and profit, which he might have obtained by the favour of the emperor Maximilian I. At length, in 1482, he settled in the palatinate, residing sometimes at Heidelberg, and sometimes at Worms, and delivering occasional lectures in polite literature. The Elector Palatine was his auditor; and in compliance with his request, Agricola composed, "An Abridgment of Ancient History." He was also much respected by John d' Alburgh, bishop of Worms, whom he had instructed in the Greek language. About the 40th year of his age he directed his thoughts to the study of divinity; and by the assistance of a few, made considerable progress in the Hebrew language; but death put a stop to his literary pursuits, at Heidelberg, in 1485. Although his natural temper, which was characterized by a fondness for ease and leisure, was altogether inconsistent with the active exertions of a reformer, he seems, however, to have deplored the darkens of the church, and to have had some glimpse of the light which illuminated it in the next century. The indulgence of his disposition prevented his entering into the married state, though he professed an attachment to the female sex; and took pleasure in amusing them with elegant verses, and with musical performances, both vocal and instrumental, in which he excelled. To
Agriculture belongs the praise of having restored the Greek learning to Germany; and of having contributed, in an eminent degree, to the revival of literature and classical taste, in an age which required his exertions, and when they were highly useful. Erasmus, in his Adages, calls him "a man truly divine." Bayle says, "that Italy, which at that time treated every thing as barbarous that was on this side the Alps, produced no genius comparable to what Friesland could boast of in her Agricola." A learned Venetian, in an epitaph, ranks Agricola with the most celebrated names of Greece and Rome. His works, of which the principal is his treatise intitled, "De Inventione Dialectica," were collected by Alard, in two volumes, 4to, and printed at Louvain, in 1516; and by Occo, at Cologne, in 1539. Gen. Dict.

AGRICULTURE. The science which explains the art or means of cultivating and improving the earth or soil, so as to render it fertile and productive. The term seems to be formed from the Latin words ager, field, and cultura, culture, or tillage, from cohere, to join.

The art of agriculture, in this view, comprehends the nature of climate and soil, the methods of performing the different operations that are requisite in the cultivation and improvement of arable and grass lands, as including, the making of fences, as hedges, ditches, walls, railings, gates, draining, paring, and burning, watering, harrowing, ploughing, manuring, sowing, harvesting, druing, hoeing, &c.; the growing and preparing of different sorts of field crops, as wheat, rye, barley, oats, beans, peas, potatoes, turnips, carrots, cabbages, hops, hemp, flax, wheat, madder, &c.; and the raising of various kinds of feeds, as rape, mylar, &c.; the rotation of crops, reposing, mowing, flaking, thrashing, &c.; the management of artificial and natural grasses, as clover, lucerne, sainfoins, torets, vetches, &c.; the converting of arable lands to grass, meadows, pastures, hay-making; the cultivating and preserving of fruits, as apples, pears, cherries, filberts, &c.; and the preparation of fruit liquors, as cider, berry, &c.; the forming of orchards; the planting of timber-trees, wood, coppices, plantations, &c.; the inventing and constructing of implements, as ploughs, harrows, rollers, hoes, drills, wagons, carts, mills, kites, &c.; the construction of farm-buildings, as houses, barns, offices, sheds, cottages; the nature of forms, tithe, leaves, &c.

In a more extensive sense it also includes the breeding, rearing, feeding and general management of all sorts of live stock, as cattle, horses, sheep, lambs, hogs, rabbits, poultry, pigeons, bees, &c.; the conducting of the several processes and preparations which have a relation to the different products obtained from them, as milk, butter, cheese, bacon, eggs, honey, &c.; or what are generally termed cow-keeping and dairying; and lastly, as connected with political economy, the construction of roads and canals, the forming of embankments, and the nature of weights and measures. Full accounts and explanations of each of these will be given in the course of the work, under their respective heads.

Gardening may likewise be considered as an improved branch of agriculture.

Among the Ancients the business of husbandry was frequently understood by the term Georgics.

This useful and important art, though less splendid than many others, appears to have attracted the notice of mankind in the earliest periods of the world; and this is not indeed very extraordinary, when it is considered that the existence and prosperity of them at such periods must almost have solely depended upon it. In the earliest stage of society, men, as hunters, must have found, from experience, that the mode of procuring subsistence by the bow or the chase was attended with infinite toil as well as hazard, and precarious in the event; and therefore, not by any means calculated to supply the wants or increase the comforts of social life. In the pastoral state also, which may be regarded as the second step in the advancement of society, men must have discovered, that though more certain of subsistence, and less exposed to danger and hardships, their herds and flocks were liable to innumerable accidents, and that they might at once be reduced to all the miseries of famine.—Under such circumstances and apprehensions, it was therefore natural for them to think of some means by which they might, with more certainty, procure the necessaries of life. For this purpose they would naturally turn their attention towards the earth, and discover that from it might be drawn whatever could render life comfortable. Experience would likewise quickly inform them, that, by due cultivation of the soil, fruits and grain of various kinds, fit for nourishment, might be procured in abundance; but that, by neglecting this art, the natural fertility of the soil, the warmth of the sun, and the regular revolutions of the seasons, would be in a great measure unwrapping.

What may be termed the art of husbandry having commenced in this way, it is easy to perceive that it must have been extremely simple in these early ages, and its advances towards perfection slow and almost imperceptible. By most of the eastern nations agriculture forms, however, to have been particularly attended to and encouraged from the most early periods. That the Japanese were extremely interested in its promotion is evinced by the great care taken in collecting and preserving all sorts of manures; and among the Chinese it has constantly received the distinguished regard and protection of their princes and nobility, and been considered as the most honourable and important of all employments. The use of the drill, which has but lately been introduced and adopted in European countries, is said to have been long known and employed by them.

The Chaldeans are found to have early carried this valuable art to a considerable degree of advancement; as they cultivated their lands with great assiduity, and enjoyed the pleasing satisfaction of receiving from their fields plentiful harvests. The Egyptians also, who, from the fertility of their country, cauned by the annual overflowings of the Nile, reaped prodigious quantities of corn, were so sensible of the blessings resulting from agriculture, that they ascribed the invention of it to Osiris, and even carried their superstitious gratitude so far, as to worship those animals that laboured in tilling the ground. The Pharaohs were also famous for their skill in agriculture; but finding themselves too much confined in their native country, by the conquests of neighbouring nations, they spread themselves through the greater part of the islands of the Mediterranean, and carried with them their knowledge in husbandry. The Carthaginians following the tale of their ancestors, are said to have applied themselves affluently to the study of agriculture. Mago, their famous general, wrote no less than twenty-eight books upon that subject, which Columella, if his book was translated into Latin by an expert deceiver of the Roman senate; and Servius adds, that Virgil used these books as a model when he wrote his Georgics. The art of sowing corn, and the tillage of land, were probably invented in Sicily; as the island was very fruitful in corn, and agriculture was there esteemed honorable an employment, that even their kings did not disdain to practice it with their own hands. The Athenians, who were the first people that received any tincture of polite-ness, taught the use of corn to the rest of the Greeks; they also taught them the manner of cultivating the ground, and preparing it for seed. The Greeks soon perceived that bread was more wholesome, and its taste more delicate than acorns, and accordingly thanked the gods for such an unexpected
AGRICULTURE.

and beneficial present. After this, the Athenian kings thinking it more glorious to govern a small state wisely, than to aggrandize themselves by foreign conquests, withdrew their subjects from war, and employed them solely in cultivating the earth. This constant application to the business of husbandry carried agriculture to a considerable degree of advancement, and reduced it into a more perfect art.

Hesiod, who is generally thought to have been contemporaneous with Homer, was the first among the Greeks who wrote on this subject. He called his poem "Weeks and Days," because agriculture requires an exact observance of times and seasons. The other eminent Greek writers upon agriculture are Democritus of Abdera, Sophocles, Xenophon, Tarentinus, Architas, Aristotle, and Theophrastus, from all of whom the art received considerable improvements, as also from Hieron, Epicharmus, Philometer, and Attalus.

The ancient Romans esteemed agriculture such an honourable employment, that, in the earliest times of the republic, the highest praise that could be given to a man, was to say of him, that he cultivated well his own spot of ground. The most illustrious senators applied themselves to this profession; nor had they either splendour or majesty, but when they appeared in public. And their greatest generals, at their return from the toils of war, from taking of cities, and subduing of nations, were impatient till they were again employed in cultivating their lands; and thought it no disgrace to follow the plough, though they were at the same time prepared to serve the wants of the republic, attend her councils, or put themselves at the head of her armies. It must indeed be allowed, that when the Romans became tainted with the luxury of Asia, they gradually lost the noble simplicity of their ancestors, and employed their slaves in the feverish labours of a country life. But though they did not themselves hold the plough, yet even men of consular dignity looked upon it as a reward for their public services, when they obtained leave to retire into the country; and were equally respected when overlooking their farms, as when seated in the chair of magistracy. M. Cato, the censor, that illustrious Roman general, orator, politician, and lawyer, after having governed provinces, and subdued nations, did not think it below his station to write a large treatise on agriculture.

This work, according to Servius, was dedicated to his own son, and was the first Latin treatise on that subject. It has been handed down to us, it is said, in all its purity, and in the same manner that Cato wrote it. Varro compiled a treatise on the same subject, but on a more regular plan. This work is embellished with all the Greek and Latin erudition of that learned author. Agriculture also received great improvements from the two Safrænsæ, and likewise from Scorfa, Tremellius, and M. Terentius. Virgil has adorned it with the language of the muses, and given it majesty by his verse. He has finely embellished those precepts of husbandry which were left by Hesiod and Mago.

Columella, who flourished in the reign of the emperor Claudius, wrote twelve books on husbandry, which contain a variety of interesting facts and observations. He was a native of Boetica, in Spain, and had devoted much time to the study of rural affairs.

From this period till the reign of Constantine IV. husbandry appears to have been in a declining state, when that wise emperor caused a large collection of the most useful precepts relating to the art to be extracted from the best writers, and published under the title of Geoponics. Some fay he made this collection with his own hand. Nor is this at all improbable, as it is well known that, after he had conquered the Saracens and Arabsians, he not only practised, but studied the arts of peace, fixing his chief attention on the advancement of agriculture. But from the time of Constantine IV. till about the year 1478, it lay in a kind of dormant and neglected state, when Crencenzio, an Italian, revived it by publishing an excellent performance on the subject at Florence. He was soon followed by several of his countrymen, among whom Tatti, Stefano, Augudio Gallo, Santorino, Lauro, and Tarelo, deserve to be particularly noticed.

In the mean time, in our own country, Fitz Herbert, judge of the common pleas, wrote with unrivalled force in the practical parts of husbandry. He published two treatises on this subject the first, which was entitled "The Book of Husbandry," appeared in 1534; and the second, called "The Book of Surveying and Improvements," in 1539. As the observations and instructions contained in these works were the refult of much experience, they excited great attention to the subject, and soon raised a spirit of emulation in his countrymen, in consequence of which many treatises of the same kind successively appeared; but time has deprived us of many of these writings, or at least they are become so very scarce, as only to be found in the libraries of the curiosus.

About the year 1600, France made considerable efforts to retrieve husbandry, as appears from several large works, particularly Les Moyens de devenir riche, and the Colompoite, by Barnard de Palissy, an indigent porter; Le Theatre d' Agriculture, by de Serres; L'Agriculture et Mesnil Racine, by Meffrs. Etienne and Labaudis, and lately Le Cours Complet d'Agriculture, by M. L'Abbe Rofer, &c. —The Flemings, about the same period, were more attentive to the practice of husbandry than the publishing of books on the subject; their attention being doublets to carry on a private lucrative trade, without influencing their neighbours in their modes of cultivation; hence it happened, that whoever was desirous of copying their method of agriculture, was obliged to travel into their country, and make his remarks upon the spot. Their principal idea of husbandry, which was indeed just enough, consisted in making a farm resembling a garden as much as possible. The adoption of such an excellent principle at first setting out, led them of course to undertake the culture of small cultes only, which they kept perfectly free from weeds, by continual hoeing and turning the ground, and rendering it rich and productive, by manuring it plentifully and in the most judicious manner. When by this means they had brought the soil to a proper degree of cleanliness, health, and vigour, they ventured chiefly upon the culture of the more delicate grases, as the surest mode of acquiring wealth in husbandry upon a small estate, without the expense of keeping many draught horses or servants; and the experience of a few years was abundantly sufficient to convince them, that ten acres of the best vegetables for feeding cattle, properly cultivated, would maintain a larger flock of grazing animals than forty acres of common farm grases. They also found that the best vegetables for this purpose were lucern, sainfoin, trefoil of malt denominations, sweet fenugreek, buck, and cow-wheat, field turnips and sowery. The political secret of their husbandry, therefore, consisted in letting farms on improvement. They also discovered eight or ten new sorts of manure. They were the first among the moderns who ploughed in living or green crops, for the purpose of fertilizing the earth, and confined their sheep at night in large sheds built on purpose, whose floors were covered with sand or virgin earth, &c. which the shepherd carted away every morning to the compoit dung-hill. This useful and judicious practice has, since that period, been too little attended to by the practical farmer.
AGRICULTURE.

Our fatal domestic wars, during the reign of Charles I.,
changed the instruments of husbandry into martial weapons;
but after the death of that unfortunate monarch, artful and
avaricious men crept into the confiscated estates of the nobility,
gentry, and clergy; and as many of these new encroachers had
risen from the plough, so they returned with pleasure to their
old profession, being chiefly animated by a love of gain. Platters,
Hardilb, Brythes, and others, feized this favourable dispo-
sition of the common people, and encouraged it by writings,
which have since had few to equal them; nor was Cromwell
willing in lending his assistance in this important business.
Sir Hugh Platt was one of the most ingenious husbandmen
of the age in which he lived; and to great was his modesty,
that all his works, except his Paradise of Flora, seem to be
posthumous. He held a correspondence with all the lovers
and promoters of agriculture and gardening in England;
and such were the justice and honesty of his temper, that he
always named the author of every discovery that was com-
monicated to him. Perhaps no man, in any period in the
history of the art, discovered, or at least brought into use,
so many new sorts of manure, as his account of the compact
and covered dunghill, and his observations on the fertilizing
qualities, contained in silt, freted dirt, and the fillage of
fields in great cities, clay, fuller's-earth, moonriff earth,
dunghills made in layers, fern, hair, burned vegetables,
malt-duft, willow-tree earth, soap boilers ashes, marl, and
broken piecehills, sufficiently demonstrate.

Gabriel Platter may likewise be esteemed an original gen-
ius in promoting the improvement of agriculture. He
began his valuable observations in the time of queen Eliz-
habeth, and continued them through the reigns of James I.,
Charles I. and during the first three or four years of the
commonwealth. But notwithstanding the great merit dis-
played in his writings, the public flaminially suffered him to
starve and perish in the streets of London, not having a shilling
upon his back when he died.

Samuel Hartlib, a celebrated writer on husbandry, was
highly beloved and esteemed by Milton, and other ingenious
men of that time. In his preface to a work commonly
called his Legacy, first published in the year 1650, he
laments that no public director of husbandry was established
in England by authority; and that we had not adopted the
Plemitih method of letting farms upon improvement. These
observations of Hartlib procured him a pension of one hun-
dred pounds a year from Cromwell, who was a great favourer
of agricultural improvements, and the writer afterwards, the
better to fulfill the intentions of his benefactor, procured
Dr. Beati's excellent annotations on the Legacy, with several
other valuable pieces from his numerous correspondents. The
period in which this author flourished appears to have been
an era when English husbandry refe to great perfection;
for the preceding wars had made the country gently poor,
and in consequence, more industrious. They found the
cultivation of their own lands to be the most profitable poll
they could occupy. But a few years afterwards, when the
Reformation took place, all this industry and knowledge became
useless, from the new system that was acted upon, and were
exchanged for needlekeifs and disputation; from which huf-
bandry passed almost entirely into the hands of common farmers.
But the famous work usually attributed to Hartlib, and called
the Legacy, was only drawn up at his request, and, after
passing through his correction and revision, published by him.
The real author of the treatise, which contains one ge-
neral answer to the following question: "What are the
actual defects and omissions, as also the possible improve-
ments, in English husbandry?" was a person of the name of
R. Child, who seems to have been acquainted with many
ingenious improvers of agriculture at that period. Several
other pieces succeeded the publication of the Legacy, which
greatly improved and augmented the means of culti-
vation.

Grew, by the publication of the Anatomy of Plants, and
showing, in some measure, the economy of the vegetable
system, contributed to enlarge the views and extend the in-
quiries concerning the nature of vegetation and the food of
plants. But a principal writer who inspired his countrymen
with a desire of reviving the study of agriculture after the
Restoration, was Evelyn; who being followed by Ducket,
Ray, Dugdale, and several other authors, the art of culti-
vation was greatly recovered, and some new improvements
introduced; and the establishment of the Royal Society,
which took place a few years afterwards, contributed still
more fully to the advancement of it, by serving as a focus
for collecting and recording valuable materials on the nature
of vegetation and the principles of agriculture, as well as
other subjects. About the year 1756, many additions and
improvements were made in this useful art.—Mortimer,
by his explanations of various practical modes of management;
Bradley, by reducing the facts on vegetation into a more
lysematic order; Hales, by his valuable flatical experiments
and investigations; and Miller, by the publication of his
dictionary, and other works, contributed very materially to
its advancement. But agriculture is probably still more in-
debted to the exertions of Till, notwithstanding the evident
futility of many of his positions, as by showing the utility
and importance of draining, and frequent hoeing or flaring
the ground about the roots of plants, and thereby keeping
them clean and free from weeds, farmers have been induced
to adopt more clean and sure methods of cultivating their
arable lands. The introduction of this system of manage-
ment, therefore, in some degree, forms a era in the history of
English husbandry.

In Ireland about the middle of the last century, the
art of husbandry began to make considerable progress; that
country having had very strong prejudices in behalf of a very
wretched method of agriculture, until about that period,
when Blythe opened the eyes of the people by his incom-
parable writings; since which a spirit of improvement has
more or less, been promoted and carried on with zeal and
constancy by the nobility, clergy, and gentry of the king-
dom. In proof of which it may be sufficient to observe,
that a society for the encouragement of agriculture has been
established, the transactions of which are highly respectable
and important. In many respects, however, Irish huf-
bandry is still much behind that of Britain.

At the conclusion of the peace of Aix-la-Chapelle, almost
all the nations of Europe, by a sort of tacit consent, applied
themselves to the study of agriculture; and continued to do
so, more or less, amid the universal confusion that soon
succeeded. The French found, by repeated experience,
that they could never maintain a long war, or procure a
tolerable peace, unless they raised corn enough to support
themselves in such a manner as that they should not be ob-
liged to submit to harsh terms on one hand, or perish by
famine on the other. Their king, therefore, thought proper
to give public encouragement to agriculture, and was even
present at the making of several experiments. The rich and
great, of various ranks and stations, followed this noble
example, and the ladies even put in for their share of fame
in the laudable undertaking. Even during the hurry and
difficulties of the late war, some attention was paid to agri-
culture. Prize questions were then proposed annually in
their rural academies, particularly at the two academies of
Lyons and Bourdeaux, and many alterations were made by the
society.
society for improving agriculture in Brittany; and after the
conclusion of peace, matters were carried on with greater
vigour.

The university of Amiens has made various proposals to
the public for the advancement of husbandry; while the
Marquis de Tourbillly, a writer, proceeding chiefly on expe-
rience, undertook the principal direction of the Geog-ri
cial Society, established at Tours, and the society of Rouen
was also usefully employed on the same subject.

It may be added, that many societies were afterwards
established by royal approbation, for the promoting of ag-
culture, and rendering the knowledge of it more general and
extended.

The convulsive shock of the Revolution, which has over-
turned many useful establishments, and retarded the advance-
ment of many improvements, has not by any means pre-
vented the progress of agriculture, as is evinced by the ap-
pearance of numerous papers on the subject in the trans-
actions of different societies. Indeed, it would seem prob-
able, that from the crippled state of commerce in that
country, unusual attention has been paid to the art of cul-
tivation.

The science of agriculture is publicly taught in the Swe-
dish, Danish, and German universities. Nor has Italy been
inactive. The Neapolitans of the present age have con-
defended to return back to the first rudiments of revived
husbandry, and begun to study afresh the agriculture of Cre-
feczio, hifi published in the year 1748. The people of Ber-
gamo have purveyed the same track, and given the world a
ew edition of the Ricardo d'AgriJcultura de Tarello, which
was originally published at Mantua, in 1777.

The duchy of Tuscany has imbibed the same spirit. A
private gentleman left his whole fortune to endow an academy
of agriculture. Even Ferrara, a small territory in the papal
domains, has contributed its full contingent, and made
some laudable attempts in this art. Animated with a desire
that the people under his government should excel in hu-
bandry, his Sardinian Majesty sent some of his subjects to learn
the practice of foreign countries, and made several attempts
to establish a better method of agriculture among them.

In Poland, where a natural fertility of soil seems in some mea-
Sure to dispense with the necessity of calling in improvements,
Mr. de Bieclwski, formerly grand marshall of the crown, made
many successful attempts to introduce the new or drill
husbandry among his countrymen, and procured the best
instruments from France, England, and other parts of
Europe.

The Hollander seem to have given the least attention to
agriculture, if we except a few collateral instances, such as
the draining of fens and morasses, and the making of canals
and embankments; and even these have probably proceeded
more from the motives of self-preference, than any particu-
lar turn towards husbandry.

In the year 1759, a society established itself at Bern, in
Switzerland, for the advancement of agriculture and rural
economy. That society confided of many ingenious private
persons, and also of some of great weight and influence in the
republic; most of them men of a true taste for the improve-
ment of husbandry, being enabled to join the practice with
the theory. They have published several useful papers on
different matters connected with the subject. We shall not
omit to mention here, that Linnaeus and his disciples per-
formed much in the north of Europe, particularly in dis-
covering new, profitable, and well tasted food for cattle.
At the same time Sweden has bestowed lucrative labours on
a soil, which was before looked upon as cold, barren, and in-
capable of melioration; of this the memoirs published at
Stockholm will be a lasting monument.

Denmark, as we
as many courts in Germany, have followed a similar example.
His Danish Majesty encourages, in particular, the woolen
manufactory; and the late king sent three persons into Arabia
Felix, to make remarks, and bring ever such plants and trees
as might be useful in husbandry, building, &c. Nor has
the duchy of Wintenberg, a country by no means particu-
larly favourable to corn and paitilage, failed to contribute its
assistance towards the improvement of agriculture, having
borne some time ago communicated to the public its economical
labours from the press at Stuttgart. The learned of Leipfie,
and Hanover, have not been inattentive to the art of support-
ing the human kind; for amidst the rage and devastations
of war, the Journel d'Agriculture, printed at Leipfie, and
the Recueil d'Hanevve, printed at that city, have been
brought out.

Even Spain, naturally inactivc on these occasions, in spite
of all the prejudices of a bigoted religion, invited Linneas,
with the offer of a large pension, to superintend a college,
founded for the sake of making new inquiries into the history
of nature, and the art of agriculture.

But it is probably in our own country that agriculture has
been most attended to, and received the greatest improvement;
from his Majesty having long, with a patriotic zeal and personal
attention, worthy of the elevated situation which he holds,
directed his views to the introduction of new and better modes
of cultivation and rural improvement, as well as economy
and convenience in the management of every department of
agricultural businesse, connected with his varied and extensive
farms, an example and encouragement have not only been held
out, but an attention excited to the art, which could not
possibly have been produced by any other kifs distinguished
means; so that there is reason to hope, from the spirit that
now animates a great number of the nobility and gentry, that
this useful art may, in a few years, be carried to a much
greater degree of perfection than it has yet reached in any age or na-

tion. In this view, the respectable society esta-

blished at London, for the encouragement of arts, have
already done much, and there is reason to hope, from their
increased resources, that they may do much more. A vast
variety of different machines for facilitating the practice
of agriculture have been invented and presented to the public,
in consequence of the large premiums and bounties which
have been offered. The institution of societies in many dif-
ferent parts of the kingdom for the improvement of agricul-
ture, and the endowment of a professorship at Edinburgh for
the same laudable purpose, cannot but promote the study,
and enlarge the boundaries of the science.

About the year 1767, Mr. Young commenced his valuable
and well directed labours, which, by attracting the attention
of practical agriculturists to those improved means of cul-
tivation that are made use of in parts of the country very
remote from each other, and shewing the great utility of ex-
perimenue inquiries on the subject, and by promoting and
diffusing a taste for the science, from the easy and popular
language of his writings, have rendered the most essential
advantages to the agriculture of the nation. Doctor George
Fordyce has likewise contributed in no small degree to the
advancement of the science, by the publication of his El-
ments of Agriculture and Vegetation, a work in which the
chemical principles of the various substances that enter into
the composition of soils and manures are well explained.

Mr. Marshall, too, by registering the local customs and
practices of different districts, has afforded considerable ser-
vice to the farmer, by bringing him acquainted with a vari-
ty of modes of rural management, which he could not other-
wise have known.

The
The indefatigable exertions of Dr. Anderdon in promoting the improvement of the more practical branches of the art, by his warous detached writings, have likewise contributed much to its advancement; and Mr. Dakewell, by drawing the attention of the breeder and grazer to the most advantageous modes of breeding, rearing, and feeding, as well as the general management of different kinds of live flocks, has greatly promoted the improvement of that intricate, though important branch of husbandry, which has since been brought still nearer perfection by the vast and well directed exertions of his Grace the Duke of Bedford, and other noblemen, equally zealous in forwarding the advancement of this difficult department of the art. In this view the establishment of annual cattle fairs in different places, with the judicious distribution of prizes for improvements in breeding and fattening them, should not by any means be overlooked.

But neither the distinguished example of the Sovereign, the endeavours of provincial societies, nor the exertions of private individuals, with whatever zeal and attention they may be directed, are probably sufficient to extend the knowledge of husbandry to that degree which is necessary for its complete and radical improvement. This could only be fully accomplished by the powerful influence and expensive exertions of a national establishment instituted for the purpose. Such an institution has at last been brought forward and established by the intelligent and persevering efforts of Sir John Sinclair; to the honour of the country, the age, and the individual who suggested it. The institution of a Board of Agriculture and internal improvement has already contributed materially to the extension and advancement of the knowledge of rural affairs. The state of the art in the greatest part of the kingdom has been of aedicated, a great variety of new and interesting facts and practices have been brought to view, and improvements in the instrumental and other departments suggested. Among these the elucidation of the principles and practice of draining or removing the injurious wetness of land, arising from springs and other causes, as laid down and explained by Mr. Elkington, is of great importance and defering of notice, not only as the basis or foundation of many improvements in the art, but as leading to the convenient and easy application of water for irrigation and various other purposes. See Internal Improvement, Board of.

In addition to this great source of improvement, the science of agriculture has lately derived essential advantages from the judicious application of the principles of other sciences.

In this respect the modern discoveries in chemistry and vegetation have been particularly important, as is evident from the works of Tillet and Hafienfatz, on the Continent, and of Preffley, Anderdon, Kirwan, Duddondald, Darwin, Dickson, and many others in our own country. By these our knowledge of the principles of vegetation, and the operations of different substances upon each other, has been much enlarged; and our acquaintance with the nature, formation, and modes of applying manures, or the food of plants, rendered more clear and satisfactory.

AGRIEL.A.EA. in Botany, the wild olive.
AGRIFOLIUM, orAquifolium. See Ilex and Holly.
AGRICAN, or ile of St. Francis Xavier, in Geography, one of the Ladrongs or Marianne islands, which is mountainous and large, being about 50 miles in circumference, and remarkable for its volcano. N. lat. 19° 4'. E. long. 149°.

AGRIGENTUM, or Agrages, in Ancient Geography, a very famous city on the south coast of Sicily, near the spot which is now occupied by Girgenti. The principal part of the ancient city, as Mr. Sibburne and M. Fouille inform us, lay in the vale; and the present town of Girgenti is situated on the mountain, where was the citadel of Cocalis, and probably the ancient city. Aigrigentum derived its name from Agrages, the original name of the city, and also of a neighbouring stream, both which, according to Polybius, were so called from the country, denominates Agrigenses, agrarius, on account of its fertility. Some authors, inclining to fabulous antiquity, relate, that Dedalus fled to this spot for protection against Minos, and built many wonderful edifices for Cocalis, king of the island. Polybius (lib. ix. p. 502. Ed. Cafaub.) says, that it was founded by a colony of Rhodians; that it was situated on a rock; and guarded by a fortress to which there was only one way of access; and that in the citadel there was a temple of Minerva, and also of Jupiter Arabythus, who was worshipped under this appellation, in the land of Rhodes. Thucydides (Hist. lib. iv. p. 539, and Annal. p. 7.; Ed. Duker.) informs us, that Agrages was founded by a colony from Gela, under the command of Aridinous and Pylus, in the 52nd Olympiad, or 579 years before Christ. It stood between the rivers Agrages and Hypha, the former of which is now called Fiume di Gergenti, and Fiume di San Biagio, and the latter Fiume Drago. The situation of Aigrigentum was admirably adapted to the purposes of defence, commerce, and pleasure. It was guarded by a barrier of rocks, which were strongly fortified; sheltered by pleasant hills; and enjoyed the view of a spacious plain, watered by the Agrages, and a convenient port or emporium at the mouth of the river. Its free government and commercial spirit raised it to a degree of wealth and power, exceeded only by that of Syracuse. Its buildings of every kind were in a singular degree magnificent and splendid. Before the temples already mentioned, that of Jupiter Olympus defends particular notice. According to the account of Diodorus Siculus (lib. xiii. tom. 1. p. 627. Ed. Weelins.) it was 340 feet long, 60 broad, and 110 feet high. This historian extols the beauty of the columns, which supported the building, the admirable structure of the porticoes, and the exquisite tale with which the bas reliefs and paintings were executed; but he adds, that the flately edifice was never finished. On the easterm side was exhibited the battle of the Giants, and on the west the capture of Troy, with the figures of the heroes in their appropriate habits. Cicero, against Verres, speaks of the magnificence of the statues which he carried away. Mr. Sibburne informs us, (Travels, vol. iv. p. 44.) that it has not now remaining one stone upon another; and that it is barely possible, with the liberal aid of conjecture, to discover the traces of its plan and dimensions. He adds, that the cathedral of Rome exceeds this celebrated Aigrigentines temple more than doubly in every dimension; being 215 feet higher, 334 longer, and 437 wider. The other ruins which this writer furnishes, and which he curiously describes, are those of the temple dedicated to Ceres and Proserpine, the peculiar patronesses of Sicily, the temple of Juno, the doric temple of Concord, which has all its columns, entablature, pediments, and walls entire, with part of the roof wanting, and which is now converted into a church, consecrated to St. Gregory, bishop of Girgenti; the temple of Hercules, the tomb of Thero, the temple of Efeulapius, and the temple of Caflor and Pollux. Near this is a large lake or fish pond, described by Diodorus as seven stadia in circuit and 20 cubits deep. It was cut in the solid rock, and water was conveyed to it from the hills; a great quantity of fish was bred in it for the public entertainments; swans and other wild fowl swam along its surface for the amusement of the citizens, and the depth of water prevented an enemy from furnishing the town on that side. It is now dry, and used as a garden.

The inhabitants of Aigrigentum, with all their advantages, were corrupted and enfeebled by their addicted to luxury.
Agrigentum, in consequence of the treachery of Mutines, about the year before Christ, 158. This officer being deprived of his commission by Hannu, because he envied and dreaded his increasing reputation, meditated revenge; and conspiring with the Numidians, who were attached to him, against Hannu, he placed himself at their head, and having seized one of the gates, put the Romans in possession of it. Hannu, and a few officers, made their escape; but the rest of the army were murdered by the guards, which Livius had posted in all the avenues to intercept their flight. The chiefs of the Agrigentines were, by the contiu's order, hurcured with rods, and then beheaded. The common people were made slaves, and sold to the bell bidder. The ipoils of the pillaged city were put up to sale, and the money returned to the public treasury. Livy, lib. xxvi. c. xl. tom. iii. p. 158. Ed. Drakenb. Polybius, lib. i. p. 15-19. After this period, Agrigentum is seldom mentioned in history; nor is it easy to ascertain the precise time of the desolution of the old city, and the building of the new one. See Girgenti.

The Agrigentines had a port to the east of the mouth of the small river, Agragas; called Emporium Agrigentinum.

AGRIGENTINE falls, in Natural History, a kind of eatable fall, famous among the ancients for its not crackling in the fire as common falls do. It might probably owe this quality to the friends of the powder, in form of which it was generally used.

AGRILL, in Ancient Geography, a place of Ethiopia, called by the Greeks Cyanomelo.

AGRILIA, a town of Gaul on the river Liger.

AGRILUM, a town of Achaia Minor, in Euthynia, to the south-east of Nicaea.

AGRIMONY, Agrimony, in Botany, a genus of the dodecaurdis dyanica class and order, of the natural order of Gentianos, and of the Rese of Juliet. Its characters are, that the calyx is a one-leaved, five cleft, acute, small, superior, permanent perianthium, filmed with an outer calyx; the corolla has five, flat, emarinate petals, with the claws narrow, inferted into the calyx; the flaminum are capillary filaments, shorter than the corolla, inferted into the calyx; the anthers small, tuft, and compressed; the pistillum is a gern inferior; the stylos simple, of the length of the flaminum; the stigma obtuse; no pericarpium; the calyx contracted at the neck, and having three, two and roundish. N.B. The number of flaminum is very uncertain, 12, 16, 7. The agrimony is of Tarentum has the outer calyx growing to the inner; two eats; 12 to 20; fruit with fustile. The agrimoniodes T. has the outer calyx detached; one seed; flaminia about seven. Of this genus there are five species; viz. 1. A. caputoria, common agrimony, with flamen-leaves pinnate; the end-lobe petiolate; the fruits hispid. Of this species there are two varieties: A. minor, or white agrimony, and A. colorata, or sweet-scented agrimony. 2. A. reptis, creeping agrimony, with flamen-leaves pinnate or winged; the end-lobe fiddle; the fruits hispid. 3. A. decumbens, with leaves pinnate lirinote; stem procumbent; fruits every way hispid-hooked. 4. A. agrimoniodes, three-leaved agrimony, with flamen-leaves ternet, and fruits smooth. 5. A. preeftorium, small-flowered agrimony, with flamen-leaves pinnate, leaflets many and lanceolate, petals half as long again as the calyx, and fruits hispid. The first species has a cylindrical, roughish, hairy stem, from one to three feet high; hairy leaves, covered with rising dots, and segments ending in small reddish glands,interruptedly pinnate; composed of six or seven pairs of leaflets,
leaves, the small leaf pair being entire, the others deeply ferratet; the fruit flasks are surrounded at the top with a fort of outer calyx, which is cloven into five spear-shaped irregular segments, hairy at the edges and on the outside; within this the fruit-flask is covered with white upright bristles, above which is a circle of numerous green awns hooked at the end, and within these the proper calyx of five leaves, spear-shaped, glandular without, marked within with three green lines, terminating with a reddish point; the petals are egg-shaped, concave, slightly notched at the end, twice as long as the cup: the stamina from 5 to 12; the germen crowned with the calyx, and a yellowish felty receptacle; the flowers yellow in a long thin spike; and one feed is frequently abortive. This grows in the borders of corn-fields, shady places, and hedges in Great Britain and most parts of Europe; it is perennial, and flowers in June and July. The root in spring is sweet-scented; an infusion of it is used by the Canadians with great success, in burning fevers; and Dr. Hill says, that an infusion of six ounces of the crown of the root in a quart of boiling water, sweetened with honey, and drank, to the quantity of half a pint, three times a day, is an effectual cure for the jaundice. He recommends to begin with a strong dose, to keep the bowels freely, and to pervert in the use of the medicine as long as any symptoms of the disease remain. The leaves have a slight bitterish roughish taste, accompanied with an agreeable, though weak, aromatic flavour: the flowers have a stronger and more agreeable smell, resembling, when fresh gathered, that of apricots. They readily give out their virtues to water and rectified spirit: and in distillation with water, the leaves afford a yellowish essential oil, with the odour of the herb. This plant has been principally regarded as a mild astringent and carminative, and many recommend it as a debilitant, especially in hepatic and other vesicle obstructions. Infusions occur of its useful use in cafes wherein the liver was much enlarged and indurated. It has been used with advantage in hemorrhages, and for giving tone to a lax and weak flake of the solids. In cutaneous disorders, particularly the febrile, it is said to have great efficacy: for which purpose it was given infused with liquorice in the form of tea: but, according to Allon, it should be always exhibited in the flake of powder. The country people sometimes apply the leaves by way of castaflam in contusions and fresh wounds. When the plant comes into flower, it will dye wool of a good bright tine unken colour; and if gathered in September, it yields a darker yellow; and for the purposes of the dyers, it deserves further trial. In the Berlin acts, it is recommended for dressing leather. Sheep and goats eat it: Cows, horses and swine, refuse it.

The white agrimony is smaller than the common fort, and grows naturally in Italy. The sweet-scented agrimony grows near four feet high; its leaves have more wings than the former; they are longer and narrower, and have sharper serratures; when handled they emit an agreeable odour. The infusion of the leaves is an agreeable cooling tea to persons in a fever. This is a native of Italy, and was cultivated here in 1640. Martyn's Miller's Dict. Lewis Mat. Med. p. 28. Murray Mat. Med. vol. iii. p. 148. Withering's Bot. Arr. vol. ii. p. 443. Woodville's Med. Bot. vol. iv. p. 125.

Dr. Cullen, (Mat. Med. vol. ii. p. 31.) after observing that agrimony is now omitted by the London and Edinburgh colleges, adds, that it still has more attention given to it than it deserves. It has some astringent powers; but they are very feeble. Dr. Cullen expresses his surprize on finding Dr. Halter and Prof. Murray repeating after an author of so little credit as Chomel, that he had cured a seborrhous liver by means of agrimony; and it seems equally frivolous in Spilemann to tell us, that Forrestus had by agrimony broke down a stone in the bladder, and brought it away in pieces by the urine.

The second species is of humble growth; it has longer and narrower pinnas than the former, and the spikes of flowers are very short and thick. It multiplies faster than the common fort, and the seeds are much larger and rougher. It has been furnished from the botanic garden at Paris, whither it was sent by Mr. Tournefort; and cultivated here by Mr. Miller, in 1739. The third species is a native of the Cape of Good Hope, and is usually mossy and the fourth species is a native of Italy and Carniola, in moist woods and among bulbes; and was cultivated in 1739, by Miller. The fifth species is a native of North America, and cultivated in 1766, by Mr. James Gordon.

These plants are hardy and perennial, and will thrive almost in any soil or situation, and require no other care than keeping them clear from weeds. They may be propagated by parting their roots in autumn, and planting them at a distance of at least two feet; or by seeds sown in autumn.

Agrimonia Melica, is a variety of Bidens pilosa.

AGRIMONIDES, in Botany, a species of Agrimony.

AGRIMONTE, or Agrononte, in Geography, a small ruined town in the Basilicata, in the kingdom of Naples. N. lat. 40° 25′ E. long. 22° 34′.

AGRIMONY, in Botany. See Agrimonia.

AGRIMONY, hemp, in Botany. See Lupinum.

AGRIMONY, bylar. hemp. See Geratum.

AGRIMONY, water-hemp. in Botany. See Bidens.

AGRINAGARA, in Ancient Geography, a town of India, on this side the Ganges; placed by Ptolemy in lat. 22° 30′, and long. 118° 15′.

AGRINIA, a town placed by Polybus in Asia. It was on the left of the river Achelous, and north-east of Thermus.

AGRICARDAMUM. See Cardamine.

AGRIODCASTANUM. See Cardamine.

AGRIODCASTANUM, the same as earth-nut, popularly called dig-nut, and aromat.

AGRICINANA, in Botany, a name used by some authors for that species of wild Artichoc, the root of which is used instead of the coxus niger.

AGROICCIMELA, or prunus fylervirs. See Plum-tree.

AGRIOMELA, a name for the crab apple.

AGRIOMELANZANION, in the Botanical Writers of the Ancients, a word that has perplexed many of the later writers. The Arabian writers Avicenna and Serapion used the word bedelugan for the fruit of the pomum amoris, a kind of eululent night-shade, or solanum, called by the old Greek writers, as Theophrastus, &c. srychnus, and only distinguished from the other srychni, or night-shades, by its being defecred as wholombe, not poifonous. From this Arabic word bedelugan the Italians formed their word melonzana, and the late Greek writers their melonzianon, which they used as the name of the same fruit. This, when the plant was cultivated in gardens, was probably larger and fairer than when it grew wild; but in this latter state it was not used, but was distinguished by the term agriomelinianon. If the Greeks, who use this word, or the melanzianon, would have appropriated it to the pomum amoris, and distinguished it from the other night-shades, they would have done service to the world.

AGRION signifies the peucedanum, called also agriplin.
AGRIOPHAS, compounded of agros, wild, and *pagi I., in Antiquity, a name given to those who fed on wild beasts. Pliny places them in Ethiopia. Ptolemy refers them to India, on this side the Ganges, and ascribes the appellation to the people whom he calls Pulindas.

AGRIORIGANUM, in Botany, wild marjoram.

AGRIOSELIUM, signifies wild parsley.

AGRIPALMA, a name given to mother-wort.

AGRIPENNE, in Ornithology, a name given by Buffon to the Emberiza argyzora, of the Linnaean system.

AGRIPO, in Geography, a peninsula, commonly called Negropont.

AGRIPPA, a name applied among the ancients, to children burned in an unusual or irregular manner; particularly such as come with the feet furcated, instead of the head.

They were called agripes, according to Pliny, on account of their being (aere partis) born with difficulty. Salmasius derives it from the Greek ory, to bend, and ousa, ou, a. d. a hunter of horses.

Daventer has a particular chapter of agripes, or infants coming with their feet foremost, which, according to him, is one of the most convenient and safe ways for a mature birth.

Agrippa gives the denomination to an unguent, described in the Antidotarium Nicolai, and in several other dispensatories, supposed, by some, to have been invented by Agrippa, king of Judea, but as others suspect, by Julius Agrippa, a Roman physician.

Agrippa, in Biography, an astronomer of Bithynia, lived towards the close of the first century. Ptolemy in his Almagest informs us, that Agrippa observed a conjunction of the moon with the Pleiades on the 29th of November, in the fourth year of the 217th Olympiad, or A. D. 92.

AGRIPE, Henry Cornelius, a physician, philosopher and divine, of various and great attainments, but of an eccentric disposition, which exposed him to great vicissitudes of fortune, was born at Cologne, September 14th, A. D. 1485, of a noble family, which had been long in the service of the house of Austria. In early life he was secretary to the emperor Maximilian, and continued his military service in the army for seven years. As a soldier he distinguished himself by his valour, and obtained the honour of knighthood; nor was he less distinguished by his application to literature and science. Of eight languages, which he acquired in his youth, six were so familiar to him, that he could even use them fluently in public discourse. Soon after he forsook the military profession, he obtained the united academic honours of doctor in law and physic. The philosopher's stone as it was called, or the art of transmuting baser metals into gold, engaged his attention; and in the pursuit of it he had no doubt of commanding the admiration of the multitude, and the patronage of princes. With these romantic views he commenced his travels; and in 1577, being then in the 79th year of his age, he visited France, and in the following year spent some time in Spain. Upon his return to France, he resided at the college of Dole in Burgundy, and read public lectures in divinity, in consequence of which he was appointed regent with a salary. Notwithstanding his popularity as a public lecturer, the freedom and novelty of some things which he advanced alarmed the monks, and rendered it necessary for him to remove from his office at Dole. In 1591 he removed from France into England, and during his stay in London, published a treatise on the epistles of St. Paul. His next move was to his native city, where for some short time he read lectures in scholastic theology; he afterwards resumed his military station in the emperor's army in Italy; but he was soon induced by Cardinal de St. Croix to abandon this connexion, and to attend as a theologian at the council of Pisa. After the dissolution of this assembly, he read lectures in divinity, sometimes at Turin and sometimes at Pavia. But he was constrained by the difficulty of procuring decent subsistence for his wife and son, to whom he was affectionately attached, to leave Pavia, and to try what his friends at Cologne could do for him. In 1518, their interference availed in procuring for him the office of synodal advocate, and orator of the city of Munich. Here he provoked the enmity of the monks, partly by maintaining the dangerous error, that St. Anne, the mother of the Virgin Mary, had only one husband, whereas it was the popular opinion that she had three; and partly, by exciting himself in the vindication of a poor woman, who had been accused to the inquisition of witchcraft. In 1620, he left Munich, and returned to Cologne, where he left his wife in 1521. Reliefs in his temper he removed to Geneva; and here, in 1522, married a second wife, whom he supported by the practice of physic, as long as he continued in this city; but in 1523, he exercised his profession at Friburg in Switzerland, and in 1524, settled at Lyons, as physician to the mother of Francis I. This lady, apprehending that he could, by his astrological talents, predict future events, desired to be informed concerning the affairs of France. Agrippa was dissuaded by the application; the prelates, displeased by his declining to satisfy her curiosity, discon- tinued his pension, and this circumstance involved him in new difficulties. His next settlement was at Antwerp, where his figalar talents attracted general notice, and procured for him various offers of distinguished patronage. In 1526, he was honoured with invitations from Henry VIII. of England, the chancellor of the emperor, an Italian marquis, and Margaret of Austria, mistress of the Nether-lands. He accepted the proposal of the latter, and became historiographer to the emperor Charles V. Agrippa's eccentric genius would not allow him to enjoy at once the honour and emolument to which he was invited. In 1528, he published a "Treatise on the vanity of the Sciences," which was a severe satire on the monks, theologians, preach-
AGrippa.

ers, and members of the universities: but Erasmus, in speaking of this work, says, "that on every occasion he lishes vice and commends virtue; but there are persons who can have nothing but praise." On this occasion, the emperor, probably inflamed by his filler, whom the monks had proceeded against Agrippa, withdrew his pention, and suffered him to be imprisoned for debt at Bruxelles, in 1531.

After the death of Margaret, Agrippa was released from prison; but he published another treatise at Antwerp, "on Occult Philosophy," which revived the animosity of his enemies. The design of this work was to explain, on the principles of the emanative sytem, the harmony of the elementary, celestial, and intellectual worlds. But the clergy discovered or suspected error and heresy; and succeeded in delaying the publication of a third edition. But in 1533 it was published at Cologne; and another edition appeared in 1542, which is the most complete, and the most fearless. This publication was accompanied with an "Apology for himself to the Senate of Cologne," which excited violent resentment, and obliged him to withdraw to Bonn; where he is said to have divorced his third wife, whom he had married after the death of his second in 1529, by whom he had five sons. The peculiar situation of his temper, and the narrowness of his circumstances, impelled him once more to try his fortune in France; and accordingly he returned to Lyons in the year 1535. Here his reception was very different from what he expected: he was imprisoned on account of some satirical papers which he had published against the mother of Francis I. Having obtained a release, he retired to Grenoble in the same year, 1535, and there he died, either in the hospital of the city, or in the house of a friend.

As Agrippa was an adept in chemistry, and professed to be an alchemist, he was reputed to be a magician, and supposed to be accompanied by a genius, or devil, in the shape of a black dog. That he was not poffessed of the grand art of alchemy is plain, from the poor circumstances in which he lived and died. He professed wonderful talents for acquiring the knowledge of languages, and a verity of genius, which enabled him to assume and exercise a variety of professions. He was a soldier and a philosopher; a municipal officer and a lecturer; a lawyer and a physician; an astrologer and a divine. Nevertheless, he was always embarrassed and distressed; and though one flattering prospect after another presented itself, he could not so avail himself of them as to procure a permanent competence. Such were the liberality of his mind, and the extent of his knowledge, that he might have been eminently useful in instructing and reforming the age in which he lived, if he had not been sickle and selfish. While he applauded Luther, he continued in the communion of the church of Rome, and obtained the commendation of the pope for his fidelity. "If he had any decided principles, they were those of that mystical sytem of philosophy, which finds a sublime and spiritual meaning in all the operations of nature, and leads the soul, (according to his own language, in his Epistles) to a mysterious intercourse, and an effential and immediate union with God. The most valuable service which he performed to society was that of chastising the follies of ignorance and the vices of priesthood, in his satirical writings, which entitle him, in the scale of letters, to a place, though of inferior distinction, with Erasmus. In fine, Agrippa, though an extraordinary, and on the whole a splendid character, was rather a dazzling meteor than a steady and useful luminary."

His principal writings, besides those we have mentioned, and several other pieces, were, "A Dissertation on Original Sin," designed to prove that the fall of our first parents was the consequence of uncheckt love: "A Declaration on the Excellency of Women," written to gratify Margaret of Aquila; "A Commentary on the Art of Raymond Lully," which is unintelligible and ridiculous as the original. A multifold edition of his works was printed at Lyons, in 1586. These were published in French at Paris, in 1736. His "Vanity of the Sciences" was printed in 4to. at Antwerp, in 1559, 1572, 1591; and the last edition has a head of the author. It was printed at Paris, or Lyons in 1551; and has been translated into Italian and French. Gen. Dict.

AGrippa, surnamed CAStOR, flourished under the Emperor Adrian, about the year 152. Eusebius (Ecc. Hist. lb. iv. c. 7. p. 120. Ed. Valer.) represents him as an excellent writer, who had ably confuted the errors of Bafides; but his works are lost, and no considerable fragment of them remains.

AGrippa I., Herod, was the son of Ariothobus, by Bernice, the daughter of Herod the Great. He was brought up at Rome, with Drusus, the son of Tiberius; but having been reduced to penury by his liberality and magnificence, he was under a necessity, upon the death of Drusus, of retiring to Judea, where he immured himself in a cell of Idumea, and determined, it is said, to give himself to death. His wife, Cyprus, the daughter of Phaaces, and the granddaughter of Herod the Great, diverted his purpose by procuring for him some present relief. He also obtained temporary assistance from Herod, the husband of Herodias, who made him a magistrate of Tiberias; but afterwards upbraiding him at a banquet with his kindness, Agrippa was offended and withdrew to Flaccus, governor of Syria, and afterwards to Rome. Here he attached himself to Caius Caesar; and having incensed Tiberius, by some expressions that signified a will for his death, and which were reported to the emperor, he was thrown into prison and loaded with chains. Upon the death of Tiberius, and the accession of Caius Caligula, he was immediately released and distinguished by tokens of favour. The new emperor arrayed him in purple; exchanged his iron chain for one of gold of the same weight; put a diadem on his head, conferred on him the title of king, and granted him the tetrarchy of his late uncle Philip, and that of Abilene, in Syria; which had formerly belonged to Lyfandis, A.D. 37.

After continuing a year at Rome, he obtained leave to visit his new dominions; and embarking at Puteoli, he failed over to Alexandria, where his magnificent entrance provoked the inhabitants, and exposted him to insult and indignity. The conduct of Flaccus, the Roman governor, who refused him the redrefs which he demanded, and who was a violent persecutor of the Jews in this city, was reported by Agrippa to the emperor; and by him he was ordered to be recalled, stripped of his wealth, and banished into an island of the Archipelago, where, at length, he was put to death. Herod Antipas, who had, on a former occasion, treated Agrippa with contempt, beheld his elevation with jealousy and envy; and accompanied by his wife, Agrippa's sister, he took a journey to Rome, in order to obtain similar honours; but Agrippa, in the mean while, accused Herod to the emperor, as having been concerned in the conspiracies of Sejanus, and thus procured his disfance and banishment to Lyons, in France. Caius conferred the treasures of Herod, and also the tetrarchy which he had possessed 43 years, on Agrippa. A circumstance, however, occurred at this time, A.D. 39, which was a very severe test of Caligula's attachment to Agrippa. The emperor had ordered his statue to be erected and worshipped in the sanctuary.
tuary of the Jewish temple at Jerufalem. The Jews re-

fited the execution of the order; and Petronius, the gov-

ernor, delayed it. Whilist the emperor was reading Petro-

nius's letter, in which he excused his delay, and reques-
ted further instructions, Agrippa presented himself as an in-
ter-

cessor in behalf of the Jews; but so great were his agita-
tion and diftrefs, that he fainted away, and was carried off
to his own palace. As soon as he recovered, he wrote a
pathetic letter to the emperor, preferred in the works of
Philo (tom. ii. p. 586. Ed. Mangey), in which he declares,
that, for his own part, he should not out-live the pro-
tection of the sacred temple, and that it would undoubtedly
complete the ruin of the Jewish nation. Caius retaliated
and after some further artifices on the part of Agrippa, the order
was countermanded. The attempt, however, was afterwards
renewed; but the affillation of the emperor, A.D. 41,
presented the dreadful consequences which the execution of
it must have produced.

Agrippa, who was now at Rome, contributed to the ac-

ception of Claudius; and was remunerated by the confirmation
of all Caligula's grants; by the addition of Judæa,
Samaria, and the southern parts of Idumea; and by seve-
ral edicts in favour of the Jews. He was, likewise, ho-
noured with the consular insignia, and indulged with the
privilege of paying his compliments to the emperor in
Greek; a ceremony which was usually performed in the Latin
language. At his requcst, the Kingdom of Chalcis,
in Syria, was bestowed on his brother and son-in-law, He-
rod. All these grants were engraved on copper, and set up
in the Capitol: and Agrippa was thus pedled of territo-
ries, which extended to the fairest limits of the dominions
of his grandfather, Herod the Great. Agrippa, soon after
the establishment of Claudius, returned to his kingdom,
where he manifested a zealous attachment to the religion
of his country; and caused the golden chain, which Caius had
given him, to be hung up in one of the most conspicuous
parts of the temple, as a monument to pothery of the
inhabitants of human affairs. He deposed and appointed
several high-priests in a short time. His government
was conducted, according to Josephus, with a great degree
of moderation and clemency; but Dion Cassius, (lib. lex.
tom. ii. p. 928. Ed. Reimar) says, that Agrippa was
reckoned one of Caligula's advisers in his cruel and tyran-
nical measures. If he had been less anxious to please the
Jews, he would not probably have disgraced his reign by
the persecution of the Christians, who feemed to have been
very quiet at Jerufalem ever since St. Paul's conversion.
The martyrdom of James the Less, the brother of John,
and the imprisonment of Peter, are justly ascribed to him.
But with his zeal for the Jewish rites and practices, he
blended Heathen observances, which gave offence; and, in
conformity to the Roman taste, he exhibited fows of gla-
diators and public games. At Cæsarea, whether he went
with a splendid and numerous retinue, for the purpose of
celebrating some games in honour of Claudius Cæfar, he
appeared in a brilliant garb on the theatre, and addressed
an elegant speech to the deputies of Tyre and Sidon, who,
appeared before him to make an apology for some offence,
and to solicit his future favour. These ambassadors,
and other attendants on the occasion, expressed their adulation
in the most extravagant terms; exclaiming, that his voice
was that of a god, and not a man, and practising some atti-
uades that approached to those of adoration. The king,
for his part, receivcd their expressions of flattery and ho-
mage, manifested his approbation of them; he was imme-
diately seized with a violent disorder in his bowels, probably
similar to that of Herod, his grandfather, and attended
with the same circumstances, which, after a torture of five
days, terminated in his death, A.D. 44, in the 54th year
of his age, and the 7th of his reign. He left a fon of
the same name, and three daughters, viz. Berenice, who was
married to Herod, her father's brother; and Mariamme
and Drusilla, both unmarried, but contracted; the former to
Julius Archelæus, the son of Chalcis, or Echlias, probably
of the Herodian family; and the latter to Epiphanes,
the son of Antiochus, king of Commagene, but afterwards
married to Azizus, king of Emea. Mariamme abandoned
Archelæus, her husband, to marry Felix, governor of Judea;
by him she had a fon, named Agrippus. Drusilla left
her husband, and renounced the Jewish religion to marry
Felix, governor of Judea: by him she had a fon, called
Agrippa, who purified with his mother, in the confagra-
tion occasioned by mount Vefuvius, under the emperor
Titus. His death was celebrated at Cæsarea with tumultu-
sous rejoicings, and his memory infulted with the vilest
vol. iii. p. 272—279. Svo.)

Agrippa II. Herod, was the fon of Agrippa I.; edu-
cated at Rome, and at the death of his father was 17 years
old; and therefore thought too young for succeeding in
the kingdom. Judea, on this occasion, became a Roman
province, and was committed to the care of Cæsarius Fades,
who received instructions to punish those who had infulted
the memory of the late king. When Herod, the uncle of
Agrippa, died, the superintendence of the temple and sacre-
ted treasury, the privilege of nominating the high-priest, and
the kingdom of Chalcis, were conferred upon him. He
refided chiefly at Jerufalem, where, with his filter Berenice,
he heard Paul's defence before Felix, the Roman governor,
(recorded Acts, xxv. xxxv.) and owned himself as con-
vinced by it. Agrippa displeased the Jews by building a
palace, which overlooked the temple, and exposed their
service to the view of Felix and the Romans; but to pre-
vent this intrusion, they erected a partition wall, which the
king ordered to be demolished. On application to the em-
peror, and by the intercession of Poppaea, the wall was
allowed to remain. At the commencement of that revolt,
which terminated in the destruction of the Jewish nation,
Agrippa, attempting to appease the Jews, was so infulted
by them that he was obliged to secure himself from their
violence, by leaving Jerufalem. He afterwards joined Cæ-
sius, the Roman governor; and when Vefuvian arrived in
the province, he met him with a considerable reinforcement,
and accompanied him to Rome, when he took possession
of the empire. During the reign of Jerufalem, he was very
servile to Titus; and after its reduction, he and Beren-
icc (with whom he was suspected to have had an inecc-
tuous intercourse) retired to Rome. His kingdom is said
to have been enlarged by the influence of Titus, who was
passionately attached to his filter Berenice; and who would
have married her, if the Romans had not refuted his design,
partly because she was a Jewess, and partly because she was
royally defended. He was, therefore, obliged to fend her
away. As for Agrippa, he was the laft of the Herodian
race that bore the royal title, and is supposed to have died at
Rome, as some fay, A.D. 97; according to others, A.D.
94; and as others fay, A.D. 100. (Joseph. Ant. Bell. Jud.

Agrippa, Marcus Vipsanius, was a perfon of obscure
origin, at Rome, educated with Ocelaius, afterwards Au-
rilus, distinguished as his companion and friend, con-

"
mily is not known, he must have riven into early notice, as his first wife was Attica, the daughter of Pomponius Atticus. When the war broke out between Marc Antony and Octavianus, Agrippa refused Salvidemus, the general of the latter, in circumstances of imminent danger; and, concurring with him, drove Lucius, Antony's brother, into the city of Perusia, and invested the place before he had time to reflect on his own perilous situation. Being afterwards appointed commander of the fleet of Octavianus, he took Hiero, one of the Eolian islands, and afterwards obtained, by his skill and valour, a complete victory over the whole fleet of Pompey, for which he was honoured with a standard and a rostral crown. On another occasion, when Antony had assembled his fleet at Actium, Agrippa interrupted his convoys; and having made several delects on the coast of Greece, which harassed the enemy, and dispersed a squadron that was advancing to join Antony, he directed the famous naval engagement that ensued, and by which Octavianus secured the empire. Octavianus, having thus acquired the supreme power, consulted his two friends Agrippa and Lucius Munatius Plancus to assist him in the government of the Roman provinces. Agrippa, however, declined; and, perceiving that his influence would tend to render it to the senate. Agrippa advised the refutation of the Roman liberty; but Marcus Agrippa's bearing that office; and the coalition was renewed in the following year.

Agrippa by marrying Marcella, the emperor's niece, was received into the imperial family; and in their command of the army, Octavianus and Agrippa possessed equal authority and distinction. His munificence was magnifically displayed in the buildings which he erected at Rome; the most remarkable of which were his portico for the use of popular assemblies, and the famous temple called the Pantheon. When Octavianus was dangerously ill in the year before Christ 25, he committed to his ring, which being considered as a preference of Agrippa for his successor, offended Marcellus, and rendered it necessary on the recovery of Augustus, to remove him from court by an honourable exile to the rich government of Syria. Upon the death of Marcellus, Agrippa was recalled to Rome, where he was married to Julia, the daughter of Augustus and Marcellus's widow, and contributed to restore the tranquillity of the city. The next service he performed was to oppose the Germans, who had made an incursion into Gaul, and to drive them back beyond the Rhine. The Cantabrians, who were vigorously combating for liberty, demanded greater exactions; but they were at last completely reduced. A triumph, which he declined, was decreed to him by the senate on this occasion; but in recompense of his service, Augustus associated him with himself in the tribunitian power, which was conferred on him for five years; he was also appointed joint consul, and concurring with Augustus in that reduction of senatorial rights, which was called a Reform of the Order. His two children by Julia were adopted by the emperor in the year before Christ 17. After three years he was sent to appease the discontents that had occurred in the east. As he was passing through Ionia with Herod the Great, the Jews complained to him, that they were hindered in sending their tribute to the temple at Jerusalem; that they were obliged to serve in the army; and had other hardships imposed upon them inconsistent with the privileges granted them by the Romans. Agrippa gave them and their adversaries a solemn hearing, and in court confirmed to them their privileges; and gave orders, that no one should molest them in the observance of their peculiar rites and customs. Having also appealed some troubles which had arisen in the Cimmerian Bosporus, he returned home, and a triumph was again decreed, which he refused. After this period no perfon that was not of the imperial family ever obtained a triumph in Rome. The tribunitian power having been renewed to him for five years more, he was next sent to Paestum, and having quieted the disturbances in that country, he returned to Italy, where he was attacked in Campania, with a fever that soon terminated in his death, A. U. C. 742. B.C. 12, in the 51st year of his age. Augustus, as soon as he heard of his illness, left the sports which were then exhibited by his two grandsons in honour of Minerva, and hastened to visit his dying friend; but he had expired a few minutes before his arrival. The news greatly afflicted him, and he lamented the loss of the greatest general of his age, the wifest minister, and the most faithful and disinterested friend. His body was conveyed to Rome, and buried in Augustus's own mausoleum, near Marcellus; the emperor pronounced his funeral oration, and declared, that he would not be separated, even after his death, from two personages, whom he tenderly loved in his life. By his will he bequeathed to his wife the fine buildings and baths, which were called by his name, to the Roman people; but his principal heir was Augustus. His surviving children were one daughter by his first wife Caecilia Attica, named Agrippina, and married to Tiberius; and three sons and two daughters by his third wife Julia. Two of the sons died in their youth; and the other, Posthumus Agrippa, was sacrificed to the jealousy of Tiberius soon after his accession; one of the daughters, viz. Julia, was married to Lucius Paulus; and the other Agrippina, to the celebrated Germanicus. Agrippa's fame, sufficiently established by his great actions, has derived an accession from the immortal records of poetry. Virgil, in his anticipation of the battle of Actium, gives the following dignified sketch of this commander:

"Parte alia ventis et disp. Agrippa fecundis, Arduos, agmen agens: cui, belli ingens fuperbium, Tempora navalis tumultu rostrata corona."

Ann. viii. 682.

"Agrippa fecundis, Arduos, agmen agens: cui, belli ingens fuperbium, Tempora navalis tumultu rostrata corona."

Dryden.

AGrippa, MENENIUS, was consul of Rome, A. U. C. 257. B. C. 53. He obtained the honours of a triumph for a complete victory, which he and his colleague, P. Posthumus, gained over the Sibines. When the people repulsed the tyranny of the Patricians, in the confusion of Virginia and Veronius, he was deputed to effect a reconciliation; and it is said that, on this occasion, he pronounced the famous apologue of the Romans and members, by which, with promises of a redress of grievances, he gained their purpose. In their demand of magistrates of their own (who were the tribunes) to protect their rights, he acquiesced; and he advised the senate to comply. He died, at an advanced age, with a character highly esteemed for wisdom and integrity; but so poor, that his relations intended to bury him in a private manner. The people, how-
ever, inflicted themselves at two ounces of brass each, in order to procure for him a magnificent funeral; and when the senate, unwilling to fraction this mode of raising money, decreed a sum for the purpose out of the treasury, the people refused to receive back their money, but ordered it to be paid to the children of the deceased. Livy, lib. ii. c. 16. 

AGrippina, in Ancient Geography, a colony of Bithynia in Aias, founded by the Agrippines.

AGrippinae, surnamed by Herodoto Ammon. Agrippina, the elder, in Biography and History, was the daughter of Marcus Agrippa, and wife of Germanicus Caesar. When the German Legions revolted in the beginning of the reign of Tiberius, she attired her husband in the camp; and though she had the charge of an infant son, and was pregnant with a second child, it was with difficulty that she was persuaded to retire from the danger that threatened them; and the commination which she her situation excited induced the revolters to return to their allegiance. On another occasion, when the victorious Germans were on their march to make an irruption into Gaul, and it was proposed to demolish the bridge on the Rhine, near Treves, in order to flay their progres, Agrippina prevented it, and thus secured a retreat for Cecina and his legions. When they arrived, she met them at the head of the bridge, returned them thanks for their valor, and distributed among them clothes and medicines. The jealous spirit of Tiberius took offence at this conduct, which merited commendation, and aggravated the dislike with which she was regarded at court, in consequence of her disagreement with Livia, the mother of the emperor. She afterwards attended her husband in his difficult and perilous expedition to the Eastern provinces of the empire, and was the sorrowful witness of his last conflicts, which happened at Antioch, A. D. 19. The dying prince conjured her by the memory of a husband once dear to her, and by their children, the product of mutual love, to refrain her great spirit, yield to her hallowed fortune, and take care at her return to Rome not to irritate those in power by an ill-judged rivalry. Agrippina gathered the affe:s of her deceased husband, and braving the dangers of the sea in the worst season of the year, hastened home, and landed at Brundusium, carrying the episcopal stump, and accompanied by two of her children. The mournful spectacle produced an universal groan amidst the multitude, who waited her landing; nor were the lamentations of relations to be distinguished, as Tacitus has described the scene, from those of strangers, nor of men from those of women. Agrippina's spirit was unfurnished; after her return to Rome, she forgot the dying charge of her husband, and fell a sacrifice to the wicked arts of Sejanus. By his agents he persuaded her, that it was the intention of the emperor to poison her; and she had the imprudence to disclose her suspicion to the reigning tyrant. This circumstance induced him to determine upon her ruin; and immediately after the death of his mother, Livia, he sent to the senate letters of accusation against her and her son Nero. The senate hesitated; but Sejanus furnished the evidence that was necessary for their condemnation. She was banished to the isle of Pandateria, now Santa Maria, lying off the coast of Terracina; and her son Nero was banished to the neighbouring isle of Pontia, where he soon died. Drusus, her second son, was confined in the lower apartments of the palace, and there famished. Agrippina survived about four years; and her death, which happened through want of food, either voluntarily or by compulsion, A. D. 33, was announced by Tiberius to the senate; and the fayage tyrant accepted the thanks of this body, for not ordering her to be strangled, and her body to be exposed like that of a common malefactor. This pretended clemency was more than counter-balanced by a charge against her of adultery with Afinus Gallus, whose death, he said, had been the cause of hers. Her known character for chastity repelled this infamous charge; and Tacitus turns it up in a few words, by observing, that "impatient of equality and greedy of domination, she had banished female frailties by her masculine ambition." Her remains were brought in great pomp from Pandateria, by her son Caligula, soon after his accession, and deposited in the mausoleum of Augustus, and all sorts of honours were paid to her memory—"an influence, says an excellent biographer, of filial pty, which is one of the best things recorded of that imperial monstret Tact. Annal. lib. i. ii. iii. iv. Crevier's Hist. of the Emperors, vol. ii. 

Agrippina, the younger, was the daughter of Germanicus, by the preceding Agrippina, and the mother of Nero. In the year 28 she was married by Tiberius to Cn. Domitius, belonging to the imperial family, but faithless, ferocious, and debauched; and as Agrippina was no less profligate than her husband, Domitius might well observe, as Suetonius informs us, (in Nero c. 6, tom. ii. p. 374. Ed. Pitte,) when he was congratulated on the birth of a son, that from him and that prince nothing could be born but some monster, fatal to the human species; and his declaration was too exactly verified by the crimes and cruelties of Nero. Agrippina was distinguished with honours by her brother Caligula, at his accession; but left her husband before the end of that reign. Before his death, however, he had an intrigue with M. Lepidus, who was the companion of Caligula in his debaucheries, and who aspired to the empire; and was concerned with him in his conspiracy against her brother. For this crime she and her sister Julia were deprived of the honours, which were conferred upon them at the commencement of this reign; their possessions were forfeited and sold by an auction in Gaul, at which Caligula presided; and they were banished to the isle of Pontus. Agrippina was compelled to carry in her arms the urn that held Lepidus's ashes all the way from Gaul to Rome; and at the same time Tegellinus, under the charge of adultery with her, was exiled. In the reign of Claudius, Agrippina was recalled from banishment, and married to a second husband, whose name was Crispus Paffinus, a celebrated orator, who had been twice conful, and who was very rich; and whom his wife poi soned in order to obtain possession of his wealth, which he had bequeathed to her by his will. After the death of Mefius, the third wife of Claudius, this emperor was induced A. D. 48, by the persuasions of Pallas, to marry her niece Agrippina, who exercised the new powers thus acquired with a degree of haughtiness, injustice and cruelty, that might have been reasonably expected from her well-known character. She did not blith, says Tacitus, to prostitute herself to Pallas, in order to secure her fon's elevation, and to gratify her own insatiable thirst for gold; and because Lollius Paulina had been her rival for the imperial dignity, she was banished and put to death; and Dion Cassius (lib. ix. to. ii. p. 970. Ed. Reimarg,) says, that her head was brought to Agrippina, who opened and examined the teeth, in which there was some particular mark, that she might thus identify her person. She manifested her wisdom, however, in using her influence for recalling Scceea from banishment, and placing her son Nero under his tuition; but regardless of every principle of justice, she engaged the interest of Pallas, and prevailed with the weak emperor to adopt her son Domitian, and as (see A. D. 50.) called Nero Claudius Caesar, though he had a son of his own, Britannicus, to whom he was affectionately
A R

feionately attached, and to give him the prerogative of an elder brother. On this occasion Agrippina herel received an additional honour in the surname of Angilia. But
nicians was deprived of every opportunity of recommending himself to his father, and reduced by the arts of the empress to the most degraded condition. Agrippina ostentatiously exercised her authority in establishing a colony at the capital of the Ubi, where she was born, and in giving it the name of Colonia Agrippina, or Agrippinensis; but it has been for many ages called Cologne, and the name of Agrippina has been suppressed. Her vanity also led her to obtain leave to enter the capital in a car, like those in which the prachts were carried, and on which all forced things were deposited. In order to gratify her avarice, as well as her pride, she caused Statilius Taurus to be accosted, and provoked him by false charges to suicide, that she might get possession of his fine gardens. At length, Claudius began to be sensible of the crimes of Agrippina; and after drinking freely he happened to drop an expression, which alarmed her, viz. that it was his fate first to bear the wretchedness of his wives, and then to punish them. She had also a rival in Domitia Lepida, Nero's aunt, a woman no less unprincipled and debauched than herl and she contrived, by accusing her of sorcery and magic and other crimes, to destroy her. She then defied the efforts of her malice against Narcissus, who was the declared friend of Britannicus and a powerful freedman; and succeeded first in driving him from court, and at length in procuring his death, as well as that of Julius Silanus, who was of high rank, and a descendant of Angulus. In the mean while, having removed Narcissus, the vigilant guardian of Claudius's life, the determinate to sacrifice the emperor himself. His attachment to Britannicus was undiguated; and he resolved upon soon giving him the toga virilis. “I know that Rome, as he said, may at last have a true Caesar.” Agrippina's fears aerated her purpose; and she applied to Lucilla, who had been lately condemned for administering poison after she had been long spared as the useful instrument of tyranny, to prepare the poison by which she designed to get rid of the emperor. The poison was mixed with mushrooms, a favourite dish of Claudius, and very freely produced effect. Having dispatched the cnp mor, A.D. 54, the pretended sorrow on the occasion; and all citing tendernefs for Britannicus, whom she kept in a state of retire ment, she caused Nero, accompanied by Burrhus, to appear before the soldiers and nobles, Nero deprived her of her guards and honours, excluded her from the palace, and obliged her to retire, solitary and neglected, to her own palace. Never theless, she was again restored to favour, which she endeavoured to secure by various artifices; and, as it is said, by some compliances, which are the most odious and reproachable that can be conceived of in the relation of a mother and son.

Poppea's influence over Nero soon became paramount to every other; nor was it restrained even by the guilt of paricide, to which she subjected him. But how to perpetrate this horrid deed, without exposing himself to public detestation, was a subject of serious deliberation. At length a galley was prepared by Anicitus, commander of his fleet, which might easily admit water and founder; and Ag ripina was enticed on board in the Bay of Panay. The fltragem, however, did not succeed; for though Acernia, the companion of Agrippina, left her life, Agrippina herself got safe to shore. The crime could no longer be concealed; and it became necessary to complete what had been begun. According Anicitus, with a body of mariners, surrounded the house where she had taken refuge; and entering her chamber, dispatched her with many wounds, A.D. 59. To the afflictions, it is said, she preferred her wound, and bade them strike that part which had insulted such a monster. She was buried the same night without any ceremony, and had no tomb whilst Nero lived; but after his death some of her surviving servants erected a mean monument over her remains, near the high road from Rome to Milemum. Nero affted contrition after the event; but afterwards wrote a letter to the senate, or rather procured one to be written by Seneca, for which he has been much blamed, accusing her of many crimes, and charging her with a conspiracy, which rendered her death a fortunate event to the Roman people. The senate fervently decreed thanks to the gods for his escape, and the day on which Agrippina was born was marked in the calendar as an insipiduous day. Her crimes were of the most atrocious kind, and her memory has been excerable. Nevertheless she is said to have been a princess of some learning, and to have written memoirs of her life, referred to by Tacitus and the elder Pliny, Suetonius in Calig. Claud. and Nero. Tacit. Annal. lib. xii. 14. Crever's Hist. Rom. Emp. vol. iii. and iv. Volli. de Hlll. Lat.

AGRIS, or Agriss, in Ancient Geography, the name of a town of Carmena, between the mouth of the Sarus and the strait that leads to the Phisian gulf. Long. 56° 30'; and lat. 23°, according to Ptol. my.

AGRUM, in the Motera Medica of the Ancients, a name given to an impurer sort of vitrum. The purer sort of this selt they call holmyrbaga, and the coarser and dirtier kind agrum. The former of these they had from Media, the latter from Thrace.

AGRIUS, in Entomology, a species of the Sphinx Zygnea, which is black, with wings pointed with green; the pronoeas black, and the posterior blue; found in Surinam.

AGRIZALA, a town of Asia Minor, belonging to the Teclofagi of Galatia. Long. 2°. Lat. 41° 36', according to Ptolomy.

AGRO, in Geography, a town of Africa, in the kingdom of Tigré.

AGROCA Road. in Geography, lies to the west of the Baltimons, near Porto Bello, on the Spanish main, and is well secured for eight or nine ships; where they are land-locked.
locked by several islands, which appear at sea like part of the main. Malham's Naval Gazette.

**AGROIRA.** A name which some have given to **Attalea** of Lydia.

**AGROMON, in Medicus,** a disease frequent in Bengal, and other parts of the Indies, wherein the tongue chaps and cleaves in several places, being also extremely rough, and sometimes covered with white spots. The Indians are very fearful of this disease, which they attribute to extreme heat of the stomach.

Their remedy is, to chew the black-seeded babilica, and drink some chalybeated liquor, or the juice of large mint.

**AGROPOLI,** in Geography, a town of the Principato Citra of Naples, on the gulf of Salerno; 26 miles west-south-west of Cangiano; and 22 miles south-south-east of Salerno. N. lat. 40° 22'. E. long. 14° 51'.

**AGROSTEAMMA,** in Ancient Geography, a town of Ethiopia, situate, according to Ptolemy, on the banks of the Nile.

**AGROSTEEMA,** in **AGROIRA,** a genus of the decandria pentagonar class, and order, natural of carrotophyta. Its characters are, that the calyx is a one-leaved, concave, or keath-ridged, tubulous, five-toothed, permanent perianthium; the corolla has five petals, with claws of the length of the tube of the calyx, and border spreading, obtuse and undivided; the flamina are ten awl-shaped filaments, five alternately later than the other five, inserted into each claw of the petals, the anthers simple; the pistilum an ovate germ, with filiform, erect styles, of the length of the flamina, and simple stigmas; the pericarpium an oblong-ovate, covered, one celled, five-valved capsule; the seeds very numerous, kidney-shaped, and dotted; the receptacles free, as many as seeds; the interior ones gradually longer. **A.G.**

The **A. gibbosa** has not a crowned corolla, or bloom, as the others have. Dr. Smith (Flor. Brit. vol. ii. p. 493.) observes, that this genus is scarcely distinct from the **Lychinis.** There are four species, viz. 1. **A. gibbosa,** corn campion or cockle, which is hispate or hairy, with calyx larger than the corolla, petals entire, or slightly emarginate, and naked. 2. **A. coronaria,** rose campion, tomentose, with leaves ovate-lanceolate, petals finely emarginate, crowned and serrate. 3. **A. filis flexo,** umbellate rose campion, tomentose, with emarginate petals and flowers in a corymb or kind of spike. 4. **A. cali rota,** smooth campion, with leaves linear-lanceolate, emarginate petals, crowned. The first species is a common annual weed, in corn-fields, and flowers in June or July; the seeds are black, with a surface like shagreen, and appear in the microscope like a hedge-hog rolled up. The second species is biennial, a native of Italy, the Valais, and Siberia; but so long an inhabitant of English gardens, that it is become a kind of weed. Of this plant there are three varieties, one with deep red, another with red-coloured, and a third with white flowers; but they are not much esteemed, as the double red-campion, which is a fine flower, has excluded the others from most good gardens. The single rose campions are sufficiently propagated by their self-sown seeds. The variety with double-flowers, having no seeds, is propagated by parting the roots in autumn, and planting them in a border of fresh undug earth, at the distance of about six inches; they should be watered gently till they have taken root; afterwards well, as well as dung, is injurious to them. In spring they should be removed into the borders of the flower-garden, where they will be very ornamental, whilst they flower in July and August. The third species grows naturally on the Swiss and Piedmontese mountains, and in the Palatinate, and was cultivated in 1729, by Mr. Miller.

It flowers in July, and the seeds ripen in September. It will thrive best in a moist soil and shady situation. The fourth species is annual. It is a native of Italy, Sicily, and the Levant; but being a plant of little beauty, it is preferred in botanic gardens merely for variety. It was cultivated in 1739, by Mr. Miller.

**AGROSTIS,** formed from **AGROS,** a field, **BENT-GRASS,** in Botany, a genus of the tridentaria digynia class, and order, and of the natural order of graminea or grasses. Its characters are, that the calyx is one-flowered, bivalve, acuminate glume, or husk tapering to a point; the corolla, bivalve and acuminate, with one valve larger than the other; the flamina have three filaments longer than the corolla, with forked anthers; the pistillum is a roundish germ with two reflex villous styles, and stigmas longitudinally bilipid, or as Dr. Smith says, plurid: the pericarpium is a corolla growing to the seed, not gapng to the seed; the seed is roundish, point to each side, with the corolla adhering closely to it. Professor Mattyn enumerates 37 species, and Gmelin 42 species. They are distributed into two classes; the amphiote or those with awns, and the nuixae or naked, without awns. To the first class belong the following. 1. **A. floribunda,** silky bent-grass, with entire petals, the outer petal having a straight, and very long awn, and the panicle spreading. 2. **A. interrump,** interrupted-spike B. with bidental petals, the outer awned, the panicle attenuated, contracted and interrupted. 3. **A. milaceus,** millet B. with the outer petal terminating in a reflex awn, a moderate length. 4. **A. broneoides,** with a simple narrowed panicle, pubescent corolla, an awn straight, longer than the calyx. 5. **A. australis,** southern B. with the panicle approaching to a spike, the seed ovate and pubescent, and awn of the length of the calyx. 6. **A. armacole,** red B. with oblong petal, awned petal, villous at the base, and furnished with a whirted awn, longer than the calyx. 7. **A. calamagrostis,** branching B. with thickened panicle, the whole of the outer petal woolly, awned at the tip, and branching culm. 8. **A. ferroidea,** late B. with oblong mucronate floccules, and culm covered with very short leaves. 9. **A. rubra,** red B. with the flowering part of the panicle very spreading, outer petal smooth, awn terminal, spirally and recurved. 10. **A. spiniformis,** spiky B. with the panicle resembling a spike, two-awned flowers, one awn inserted into the receptacle, jointed and longer than the other, which is straight, and inserted below the tip of the corolla, which is rough. 11. **A. hispata,** hairy B. with the panicle approaching to a spike, culm and leaves hispate, glumes of the corolla awned on the back, and bifid at the tip. 12. **A. matrella,** with the flowers in racemes, outer valve of the calyx bent in, and the tip of the keel only gapng. 13. **A. canina,** brown B. with ovated coloured calyx, naked corolla, an incurred awn on the back of the petal, and prostrate calyx in a branching. To the class of awned agrostis, Gmelin refers the following species, viz. 1 A. vincaulis and A. canina, of Martyn. A. apina, with falcate leaves, compact panicule, rough and coloured calyx, and exterior petal with a jointed awn in its back. A. levis, with elongated calyces, awn of the petals recurved at the back, and prostrate culms with four branches. A. gigantea, with the upper part of the panicle first flowering very wide, rough calyxes, the exterior petal smooth, the back slightly awned above, and an erect culm. A. davis, with equal smooth calyxes, corolla mucronated below the apex, and falcate leaves. A. filiformis, with falcate leaves, spreading panicule, and petals with awn bent in at the base twice as long as the calyxes. A. filiformis, with filiform leaves and culms, approximate panicule, and smooth floccules awned at the base. To the second class of agrostis without awns are referred the
the following species, viz. 14. A. filaminita, creeping B. or black squat, with branches of the panicle spreading, naked, creeping calm, and equal calyces. Dr. Smith describes this species as having a compact panicle, ramose creeping calm, congested flowers, and calyces equal, lanceolate and penicillate. 15. A. capillaris. fine B. with panicule capillary, spreading, flexuose, and calyces equal, pubescent smooth (slightly roughened, Gmel.) colored. 16. A. fominata, wood B. with panicle contracted, calyces equal, those of the lower flowers shorter than the corolla, those of the fertile ones twice as long. 17. A. cf. white B. with panicule-foke, calyces equal, and calum erect. 18. A. plumosa, dwarf B. with panicle on one side, calums erect in battle. 19. A. flavida, leslie B. with panicle-foke, flowers, ciliate, glande and awned, and villous corolla. 20. A. lenis, tough B. with panicle contracted, pilose; flowers linear, and valves parallel. 21. A. virginica, virginian B. with panicle contracted; leaves rolled inward, pubescent, rigid, standing out. 22. A. mexicana, Mexican B. with panicle oblong head; calyces and corolla acuminate and nearly equal. 23. A. paniculata, purple B. with panicle contracted, clasping, branches pseudo cloek, upright, and flowers unequal and acuminate. 24. A. indica, Indian B. with panicule contracted, racemes lateral, erect, alternate. 25. A. Zaluzii, ciliate B. with umurs of the calyx angular and ciliate. 26. A. pinnata, bearded B. with panicle-foke. branches and branchlets fascicled; valves of the calyx and one of the corolla awned, that of the corolla very frot. 27. A. lenta, forked B. with spikes obtuse, umbellate, folicles awned, oblong, acute, calyces valves sub-fid, leaves and theae smooth. 28. A. complanata, flat-foliate B. with spikes umbel- lated, fuscous; outer calyce valves awned; flatted leaves and fuscous theae. 29. A. paniculata, pubescent B. with panicle contracted, leaves involute, fusc, punctate, the upper ones obliquely opposite, and branching stem. 30. A. sinuata, smooth-awned B. with calums adnate, calyx color- ed, awn nearly straight. from below the middle of the back, about as long as the calyx. 31. A. ovata, ovate-panicle B. with outer petiole awned below the tip; panicle ovate, contracted and spikeiform. 32. A. odorata, sweet B. having spikes, with the florets pointing one way, heaped together, awnless. 33. A. plerota, plaited-leaved B. with leaves plaited, and spike linear, awnless. 34. A. cinna, with panicle contracted, awnless, flowers acuminate, with one, two or three flamin, and leaves flat, scabrous. 35. A. diuatra, with panicle elongate, contracted; flowers fooleate, awnless, di- androous or two-flaminiate; and convolute leaves. Gmelin has omitted some of the preceding awnless species, and added the following, viz. A. vesiculata, with sprightly panicle, interrupted by radiated rigid verticil or whorls. A. flosca, with fowl panicle, having rocks, and an erect calyx. A. linearia, with subquartn digtated spikes, and adpressed alternate, unilaterally floesces. A. procera, with the foot-flanks of the panicle, racemose and somewhat erect, and the flowers hairy and lanceolate. A. cornelianiana, with the panicle ovate, patent, the foot-flanks simple; second flower, and equal, acute, glossy calyces. A. ofiica, with contracted panicle; lateral, alternate, stiff racemes, and rough leaves. A. avenacea, with an erect, very flender panicle; and the awns twice longer than the calyx. A. pinnata, with bifid, glomerate, terminal spikes, and clawed plumose bracte. A. latifolia, with bifid, lateral, solitary spikes, and clawed plumose bracte. Dr. Stokes has observed that this is an artificial genus, and that the species which are clothy dis- gusted by the presence or absence of the awn in the corolla, and which is inconspicuous, are not precisely ascertained. He therefore recommends particular attention to the open-celled flat in which the valves of the calyx are found, immediately after the shedding of the polylopodium pinnate of the island likewise to the flowers, whether they are bended or un- bended. The last species, which is annual, is common in sandy cornfields, and flowers in June and July. It is liable to be covered. It has and goats eat it; but sheep refuse it. The second is, according to Haller, a variety of the former; it is annual, and a native of France, Italy, Switzerland, Cornola, and Germany. The third is a native of Mont- pelier, Spain, and Suevia, was introduced by M. Thunin, in 1776, and resembles the first. The fourth is perennial, and grows well about Montpelier. The fifth is a native of Portugal. The sixth is a native of many parts of Europe, and is quadrival. Haller and Costea rank it amongst the annuals. The seventh is a native of the island of Teneriffe, by Maffn. The twelfth is found in the sandy lands of Malabar. There are two varieties of the thirteenth, the rough and the smooth, which Dr. Stokes in Withering's arrangement, makes a distinct species under the name of A. alpinus, and so called by Gmelin: this is found plentiful in the higher downs in Dorsetshire and the higher parts in the new forest of Hants, and flowers in May and June. But Dr. Smith (Flor. Brit. vol. i. p. 75.) refers the A. canina, (a) of Hudson to the species of A. canina, and also the A. campi of Wallingford, and says it is not in full flower in July, and found in meadows and moist pastures: and the A. campi (a and b) of Hudson, and A. alpina of Withering, is supposed to be a distinct species, viz. A. fuscata, bristle B. with lanceolate calyces and corolla awned at the base; the awn geniculately and the radical leaves fleshy. It is per-ennial, flowering in July and August, and found on dry heaths, frequently in the west of England, and on the sea- coast near Weymouth. The fourteenth is perennial, a native of moist parts of Europe, and found in moist meadows and pastures, and also in stiff cold arable lands, where it is very troublesome; for when such lands are broken up and fallowed, the roots are separated with difficulty from the adhesive soil. It flowers in July and August. Hudson joins this species with the capillaris, plumula, alba, and sylvatica, under the name of polymorph; and Gmelin queries whether this is a variation of the same species, with the difference merely to the soil; some have supposed that this is the famous orHesONTON GRASS. The fifteenth is very common, but chiefly grows on poor, dry and sandy land, and is diffused by cuttie, as are the beans in general; it flowers in May and July. Gmelin queries whether it be not a species of alopecurus. Some have supposed that the A. capillaris of Linnæus, is the same with the A. vulgaris, which has a spreading panicle, branch cup at the base; florets numerous, calyx inner valve smooth, outer furrowed upwards; blossom inner valve, but half the size of the outer; deciduous. Linnæus confounded these two plants; but the error was discovered by Dr. Smith. In general habit, says Withering, the plants are very much alike; but the real A. capillaris has the stem, leaves and huks of the calyx quite smooth, as well as every other part of the plant, whilst in the A. vulgaris the stem-leaves are rough, and the huks of the calyx are furrowed on the
and, as they are in every other British species of agrostis, except the minimum. Again, in the *capillaris*, the valves of the blossoms are equal, but in the *A. vulgaris* the inner valve is only half the size of the other. Dr. Smith (Flor. Brit. vol. i. p. 78.) characterizes the *A. vulgaris*, or fine B. as having a spreading panicle, small branches divaricated and capillary, equal calyces, interior petal twice as fhort as the other: and to this species he refers the *A. vulgaris* of Withering: the *A. capillaris* of others, and the *A. polymorpha* (of) Hudson; and as varieties, the *A. canina* of Withering, the *A. pumila* of Linnaeus, and the third variety of Withering's *A. vulgaris*. It is perennial, flowers in July, and is found in meadows, pastures, and ploogled fields. The sixteenth species is perennial, and grows in moist woods, as Bithop's wood, Hampstead, and also in Howney-wood, near London. It flowers in June and August. The seventeenth is perennial, and grows in ditches, marshes, and moit meadows. Withering mentions four varieties; one with panicle branches, crowded with florets at the base, which flowers in June and July, and is found in other ditches, bogs, and marshes; a second, with calyx, both valves ferrated, supposed to be the spreading plant, when growing in a drier situation, and found amongst wheat, in light sandy loam, flowering from July to September; a third, with the inner valve of the calyx only furnished upward, found in loamy soil, amongst wheat, and in very light sandy soil under the Norfolk course of turnip husbandry, and also elsewhere amongst potatoes; flowering from July to September; the fourth has both valves of the calyx furnished, the inner only on the upper half: it is found amongst wheat, in light land; flowering from July to September. The three last varieties constitute the greatest part of what is called fiquich, in light arable lands; which are called white fiquich, to distinguish it from *A. nigra* and *A. flosnitra*, which are called black fiquich, or couch. Dr. Smith enumerates only two varieties, viz. the *A. alba*, and *A. fyllinga, i.e.* marlith and wood B. which he refers to this same species. The eighteenth is native of Iceland, Sweden, Germany, Switzerland, England in dry places, Wales, and Scotland; found in poor barren soil, e. g., heaths near Harrowgate, perennial, and flowering in July. The nineteenth is a native of France and Germany, and has been discovered by Mr. Stillingsflect, in Wales; it is common in fandy pastures on the south-wefh coast of Anglesea. By fome it is denominated spring-plant, and said to flower early in March and April, and ripen its feed in May. Dr. Stokes refers this species to the Poa. The twentieth is perennial, and a native of the East Indies. The twenty-first is an elegant little plant, and called by Browne crab-grafs. The twenty-fecond is a native of South America, flowering the fecond year, having the appearance of crans, and introduced in 1780, by Mr. G. Alexander. The twenty-third is a native of Jamaica; the twenty-fourth is a native of India, introduced in 1773, by the Earl of Bute; the twenty-fifth a native of Japan. The twenty-sixth comprehends the *panicus* and *monellfus* of *Alopecurus* in the Linnean Syatem; the firft grows in marfhes and wet pastures, and the fecund in a dry foil, to which the difference is probably owing. The twenty-firft is a native of the East Indies, found there by Dr. Koenig, and introduced in 1778 by Sir Joseph Banks. It is annual, and flowers in July and August. The twenty-eighth is a native of Jamaica; introduced in 1779; perennial, and flowers in July and August. The twenty-ninth is a native of Arabia and Barbary, used by the Arabs in the hemorrhoids; perennial, and found in dry places off the coast in the country of Nice. The thirtieth is a native of Switzerland and the north of England; found on heaths, meadows and moist pastures, which have been long in turf. Some parts of Houndow heath abound with it. Dr. Smith (Flor. Brit. vol. i. p. 78.) refers the *A. vilcaulis* of Withering to the *A. canina*. The thirty-first is a native of New Zealand; the thirty-second of Cochinchina, near the coast, where it is dried and used for perfuming their clothes; the thirty-third a native of the suburbs of Canton. The thirty-fourth and thirty-fifth have been referred by fome to Cinna. Dr. Withering mentions some other species, viz. *A. ptyliris*, with the bulks of the calyx equal, and the outer valve of the bloom twice the length and breadth of the inner; awn ftraight, much shorter than the bloom, fixed a little beneath its point; some confider this as an awned variety of the *A. alta ptyliris* of Hudson, but Dr. W. regards it as a distinct fpecies. It is found in swamps and moit ditches; perennial, and flowering in June and July. *A. pallida*, with the valves of the calyx unequal, the inner valve of the bloom hair like, very fhort, awn somewhat longer than the bloom, fixed below its middle; it is sufficiently distinct from both the *A. alba* and *A. capillaris*; found in the New Fofell, Hants, and flowering in May and June. *A. littoralis*, with panicle somewhat spike-like, the bulks of the calyx awned; first found on the Norfolk coaft by Sir Joseph Banks, perennial, flowering in June. The *A. littoralis*, sea-fide B. according to Dr. Smith (ubi supra) has linear-lancollate awned calyces, naked corolla; awn sub-terfalt ftraight, and decumbent culms. It is perennial, flowers in A uguff, and is found on clayey fea-flores; in falt-marfhes near Cley, Norfolk. *A. nigra*, with scattered panicle, branches bare at the base, florets few; inner valve of the calyx smooth, and creeping root; it is different from the *A. flavifera* of Linneus, to which fome have referred it; found in marly, clayey, and other cold wet foil, both in grafs and under tilage; perennial, flowering from July to October. *A. marinna*, with large, rather spreading panicle; longer branches naked, shorter ones crowded with florets at the base; inner valve of the calyx smooth, outer ferrated upwards; gathered by Dr. Paltency in the fand on our southern fea-coasts; perennial, flowering in June and July. The *A. vulgaris* has been already mentioned. Martyn's Miller's Dict. Withering's Bot. Arr. vol. ii. p. 124-134.

For the propagation and culture of feveral of the above species; fee Grass. For other species, to which the name has been applied, fee ARA, ALOPECURUS, CALAMAGROSTIS, CENCHRUS, MELICA, MILIUM and SCHOENUS.

AGROSTOGRAPHIA, compound of agros, grafo, and 12754, défcription, in Phyfology, the history, or décription of graones, or plants of the grally kind.

Agrographia is alfo the title of a learned and labours work of John Schenckier, containing an exact décription of about 400 species of grafs; particularly dog-tooth, cyperus, cyperoides, rubes, &c. all difpofed in a new method; yet the history is far from being complete.

Agrotirih, in Ancient Geography, the moft southera promontory of the ifland of Cyprus, eafit of Limafio. It is a small peninula, connected with the continent by a very narrow tongue of land, and is now called cape De Gatti, on account of the great number of cats kept by the monks, who, in the 4th century, obtained permission to cultivate themselves there, as well as on mount Olympus, on condition of keeping a great many of those animals for hunting, which had multiplied to an alarming degree; and which, it is faid, have no greater enemies than cats. Sonnini's travels in Greece and Turkey, p. 56.

A-Gr0U0N, in Sea-language, expresses the situation of a fhip whole bottom, or any part of it, rels upon the ground.

Agyila, in Ancient Geography, a city of the island of
of Sardinia, founded, according to Steph. Byz. by a colony of Athenians.

AGRYNIA, *agrynia*, a privation of sleep; otherwise called watching, waking, *vigilia*, *perwiglia*, &c. Among physicians, this is a troublesome symptom in fevers and other disorders. In the Greek church, it is used for the vigil of any of the greater fast-days, observed by the monks and clergy. Du-Cange.

AGUA, in Geography. See OEGWA.

AGUA, Fort Harbour, is situated about a league N. N. E. from Feroe harbour, on the E. coast of Newfoundland.

AGUA de Pao, a small town in the island of St. Michael, one of the Azores. It is situated in a fertile territory, which produces abundance of corn and excellent fruit. W. long. 25° 40', N. lat. 38° 10'.

AGUA Ria del, a river which falls into Bonaventura bay, on the coast of Popayan, in the South Sea; in about W. long. 77° and N. lat. 5° 35'. It affords good anchorage.

AGUA, River, a small place in the province of Tras-os-Montes, in Portugal.

AGUADA, a river which runs into Smienda bay, near cape Roquer, on the coast of Brazil, about W. long. 34° 30' and S. lat. 3°. Also, a river of Spain, which runs into the Duero, E. of Lamago.

AGUADA de Saldana, a gulf on the coast of Africa, 15 leagues north from Table bay.

AGUADIR-Tomn, a town of Africa, in the empire of Morocco, in the province of Sus, 13 leagues south of Santa Cruz.

AGUADORE, a river in the island of Cuba, on the south side, and nearly north from the east end of Jamaica. Its mouth is in W. long. 75° 35', and N. lat. 20°.

AGUAGUIN, in Botany, the name of a fhrub among the Africans, who esteem it greatly as a balsamic and vulnerary. The leaves of this shrub resemble those of our common lilac; they grow alternately, and stand upon foot-flats of half an inch long; and when held up to the light they have a fine texture of the smaller veins. Philos. Trans. No. 232.

AGUAPECACACA, in Ornithology, the name of a Brazilian bird of the moor-hen kind. It is of the size of a pigeon, very long-legged, and has a beak like that of the gallinaceous kind: its back, and the upper part of its wings, are brown, and in each wing they have a sharp horn, or prickle, rising for their defence. Maregrave.

This is the jacana-paca of Buffon, the jacana annata of Brisson, the Brazilian jacana of Latham, and the Parra Brasiliensis of Gmelin's Linnaeus system, characterized by having the hinder claws very long, and the body greenish-black. At Guiana, where it is common, it is called kapusa, and also kinkin, from its shrill note; these birds are gregarious, and are found in flocks in the ditches, and among the reeds on the sides of the lakes; and they live on fish and water-insects.

AGUARA QUIYA, in Botany, a Brazil plant, thought to be the *falanum vulgare*, or common nightshade, by Ray.

AGUARA-PONDA, a plant, otherwise called *viola jatras Brasiliensis*. It grows to the height of a foot and a half, or more, with a smooth, round, green, and jointed stalk; at each joint come forth five, four, or more, narrow, serrated, pointed, green, and unequal leaves; the top of the stalk bears an ear a foot long, smooth, and covered with flowers of a fine violet azure, or the colour of our *viola maritae*, confiding of five roundish leaves. The whole flower is not unlike the *viola maritae*, and has somewhat of its smell; the root is straignt, of a moderate thickness, and shoots out into abundance of lesser ones, and thence again into filaments.

There is another kind, distinguished by the wideness of its ear of flowers, which represents a helmet of a green colour. It is marked with cubic pits, from whence proceed azure flowers. Ray.

AGUAS, in Geography, a people of South America, on the banks of the river of the Amazon. They are said to be less polished than any other of the Indian nations.

AGUAS Beller, a small place in the province of Eiremedura, in Portugal.

AGUATULCO, AGUATULCO, or GUATULCO, a town and port of Mexico. Its harbour is large and much frequented. It is situated in the South Sea. W. long. 96° 46', S. lat. 15° 10'.

AGUBENI, in Ancient Geography, a people placed by Ptolemy upon the frontiers of Arabia Deccara, very near Arabia Felix.

AGUCCHIA, GIUSTANNA, in Biography, was an engraver of the 16th century. He engraved the large design for the dome and cathedral of Milan. Strutt.

AGU 2, in Medicine, a form, belonging to the class of fevers, and consisting of paroxysms recurring at fixed periods, with longer or shorter intervals of apyrexia. Agues are the febrile intermitentes of noological writers.

An ague paroxysm is divided into the cold stage, the hot stage, and the yawning stage. The cold stage is marked by yawning, latitude, coldness of the surface of the body, shivering or trembling of the limbs, paleness of the countenance, and contraction of the skin, more or less numb, and sometimes vomiting, a weak and small pulse, and not unfrequently a considerable degree of turgor. This proceeds the hot stage, in which there is a preternatural degree of warmth over the whole body, accompanied by a redness and turgescence, together with a strong and full pulse, great irritation, and often some degree of delirium. These symptoms are followed by the swaying stage, in which there is a profound exhalation from the pores of the skin, with a flow of urine, depositing a copious sediment, of a laceritious or brick-dust appearance. By these evolutions of sweat and urine, the febrile symptoms are carried off, and the patient generally falls into a refreshing sleep, from which he awakes without any remains of indisposition, except a slight degree of languor and debility. He then continues capable of sitting up and going about, with tolerable appetite and spirits, until the next return of the paroxysm. According to the length of the apyrexia, or intermission between one febrile paroxysm and another, agues are denominated quotidian, tertian, and quartan; which see under their respective titles. Sydenham distinguished them, from the secon of the year in which they appeared, into *vernal* and *autumnal* agues; the former of which are always more easily cured than the latter. By others they have been distinguished into simple and complicated, regular and irregular, mild and malignant, &c. Of all agues or intermitentes, the *quartanas* are the most obilinate, being generally accompanied with more or less of visceral obstruction. Hence they are apt to terminate in dropy, and thus sometimes prove fatal. In general, however, it may be said of agues, that they are rather obilinate than dangerous disorders.

Agues occur chiefly in low situations, where there are shallow flagrant waters. Hence their frequency in Holland and Flanders, and in the flat marshy parts of some counties in England, such as Lincolnshire, Cambridgeshire, Kent, &c. For the same reason they are very common in America, the East and West Indies, &c. The exhalations which arise from flagrant muddy waters (march miasmas, as they are termed) in these situations are considered as their exciting causes. Hence the prophylactic measures are obvious, viz. to avoid or remove from such situations. Where this cannot
be done, the body should be protected from damp by proper wooden clothing; fatigue, and sudden alternations of heat and cold should be avoided, and the whole system should be fortified by proper exercise and a somewhat generous diet.

Intermittents or agues are cured by medicines which, at the same time that they exert a tonic action, produce and keep up an impression upon the system, greater than, and opposite to, that communicated by the causes which occasioned the disease. Such medicines are the Peruvian bark, various bitter and astringent drugs (given alone or in combination with spices and aromatics). certain metallic salts, such as vitriolated iron, vitriolated copper, vitriolated zinc, &c. (See Lind on Diseases of Hot Climates, Appendix, p. 308, and l. q.) But as these medicines are only employed during the intermissions, it will be proper first to mention what should be done during the fits.

In the cold stage it will be sufficient to cover the patient with bed clothes, and to give some warm tea with a teaspoonful of harrow drops; or some weak warm wine and water, with the same quantity of harrow. In the hot stage, an aromatic, joined with tincture and quinine, will be proper, in order to bring on a perspiration, whereby the fit is carried off. The opiate, in conformity with Dr. Lind's directions, should be given in a full dose; viz. 15 or 20 drops of laudanum in some lightly aromatic tincture, or in cafe of collivens, in an ounce or two of aloof wine. The sweating stage will thus be accelerated; and as soon as it is over, the Peruvian bark should be freely administered, in doses of one or two drachms, every two hours. In some instances, however, it may be previously necessary to cleanse the stomach by an emetic, and the bowels by a gentle cathartic. The bark is then to be continued throughout the whole interval of appyrexia, until the next accession of the paroxysm. This method is to be perished in order to disfigure and to even for some time after, in order to prevent a relapse. The bark may be given in various vehicles, in combination with aromatics and other additions, according to circumstances. For examples of which see Thucul Med. or New Collection of Medical Preparations, 3d edition, under the clafs of tonics.

Where the Peruvian bark disaffords, or is refused by the patient, combinations of other tonics and bitters may be given; such as powders composed of dried chamomile flowers and myrrh, each a scruple, prepared kali ten grains; or bulbules composè of alum fifteen grains, nutmeg and extract of gentian, each ten grains. These may be given every five or six hours during the intermissions. Some agues have been cured by giving a quarter of a grain of the cuprum vitriolatum every three or four hours during the appyrexia; this, however, is a very rough medicine, and commonly produces too much thirst to be perished in Vitriolated zinc has been employed with better success, in doses of three grains every fourth hour. Some practitioners recommend certain preparations of arsine; but while so many other powerful and safer remedies are presented themselves, arsine (in our opinion) should rarely be report to.

Among the bell authors who, in this country, have written upon agues, may be mentioned Sydenham, Morton, Cleghorn, Lind, Fordyce; also Wilfon on Febrile Diseases. Among foreigners, Torii, Werlhoff, Quaria, &c.

AGUE-cate, the popular name for a hard tumor on the left side of the belly, lower than the false ribs, said to be the effect of intermitting fevers.

AGUE-drops. See ARSENIC.

AGUE-tree. See LAURUS.

AGUE-free, is a name given by some to SASSAFRAS, on account of its febrifuge virtue.

AGUEDA, in Geography, a town of Portugal, in the province of Beira, upon a branch of the river Vouga, fix leagues N. of Coimbra. W. long. 08° 26'. N. lat. 40° 36'.

AGUEDA, a river of Leon, which falls by Ciudad-Rodrigo. AGVH, a town of Alaví, Turkey, in the province of Natalia; 8 leagues N.E. of Izrail.

AGUELIAON, one of the LACDIEVE islands, in the Indian seas. E. long. 75° 25', N. lat. 11°.

AGUERPESE, or AGUERPESE, a town of France, in the department of Puy-de-Dome, levèed leagues north-north-east of Rome.

AGUE, a sea-port town of Africa, situated at the foot of Mount Atlas, in the kingdom of Morocco. This town was built by the Portuguèse, near a remarkable cape, on the north-west of the mouth of the river Sus, now called Cape Cerer. It was taken by Diego Lopez de Seguerra, who afterwards made a voyage to the East Indies. As the town had a convenient harbour, and was famous for its fishery, this adventurer erected a strong fort to defend it. He called it Emanuel, king of Portugal, who added other fortifications, and a strong garrison. But after a vigorous defence, in which the enemy lost 1000 men, it was surrendere, A. D. 1536, to Mohammed, who became emperor of Morocco and Fez; and in revenge for his loss, he put the whole garrison to the sword, except the brave governor Mont Roy, whom he spared and favoured for the sake of his daughter Donna Maria, who consented to marry him, on condition of being allowed the free exercise of her religion, and of being regarded as his lawful wife.

AGUESSEAU, Henry Francis D'E, in Biography, a chancellor of France, was born at Limoges in 1606, of an ancient family of Saintonge. He owed the first rudiments of that literature to which he was devoted, to the instruction of his father, and to his distinguishing taste for poetry to the courtesy of Bolcana, Rainer, and other eminent writers of that clafs. After having held the office of advocate-general of Paris for ten years, he was appointed procureur-général in 1700; and in this situation he distinguished himself by introducing several regulations, which contributed to the improvement of jurisprudence. He also directed a particular attention to the hospitals, and to the hardships occasioned by the scarcity in 1700, which indicated the amiable philanthropy of his temper, and in which he was singularly useful. He also approved himself the firm and invincible defender of the liberties of the Gallican church, in opposition both to Lewis XIV. and the chancellor Voisin, who solicited his concurrence in favour of the bill Unigenitus. After the death of Voisin, and in the regency of the duke of Orleans, he was made chancellor; and performed the duties of this office with that eminence wisdom and firmness, which the circumstances of the times demanded. In his reliance of the financial project of Law, he was for some time successful; but when the regent determined to adopt it, he was constrained in 1718 to retire to his country seat at Frines; but in 1729 he was recalled and reinstated in his office. He was again deprived of it in 1722, recalled by Cardinal Fleury in 1727, and reinstated with the title in 1737, which he held till his death. From the year 1729 to 1749 he was sedulously employed in reforming the laws, and remedying many notorious abuses that disgraced and obstructed the administration of them. His object was to supply their defects, and to facilitate the execution of them, without changing their fundamental principles; but in this extensive and laborious employment his progres was slow; and he met with difficulties, from his extensive views and from a regard to the profits of the legal profession, which produced indolence in his own judgment, and served to retard his dispatch of busines. For the flower of some of his determinations, he makes this very reasonable apology; "when I recollect (said he) that the
the decree of a chancellor is a law, I think myself permitted to take a long time for consideration." His life, though affluently occupied, was prolonged by his temperance and equanimity; but in the year 1752 his increasing infirmities manifested him of the necessity of withdrawing from public employments; and in 1751 he closed his life at the advanced age of 85 years.

Voltaire calls him the most learned magistrate ever possessed by France. Besides the languages of antiquity, he was acquainted with all the principal modern ones; and to his knowledge of the history of all ages and nations, he added that of jurisprudence in its most extensive sense. During his exclusion from office, he made no attempts for being restored; but always manifested a disposition superior to the honours which his talents and merit claimed, and a defer to be useful rather than to aspire after power and to accumulate wealth. Of his frugality, and of the various emoluments annexed to the dignities he possessed, the only fruit that remained was his library, in the improvement of which he limited himself to a certain annual expense. In the period of his retirement, which he called "the fairest days of his life," he devoted himself to the maturity of his plan of legislation, to the education of his children, and to a variety of literary pursuits, among which were mathematics and the belles lettres; and these, together with agriculture, he deemed his recreations in the intervals of his severer occupations.

However, when the public demanded his services, he surrendered the satisfactions of retirement and the pleasures of domestic life. Having in 1694 married Anne le Feuvre d'Ormeflon, it was said on this occasion, that virtue and the graces were now first seen in alliance; but he had the misfortune to lose her in 1735. His grief corresponded to the affliction that followed between them. Nevertheless he had to devote himself to the functions of his office; alleging, "that his services were due to the public, and it is not just (said he) that it should suffer by my domestic affliction." We are informed, that he never passed a day, from his childhood, without reading some parts of the scriptures; and he was heard to say, that this was the bane of his life. Of his works nine volumes 4to. have been published. In these he is said to have thought like a philosopher, and spoken as an orator. His eloquence has the force of logic and the order of geometry, united to the riches of erudition and the charms of persuasion. His style is chaste and harmonious, but deficient in warmth. When he once confided his father on a discourse which he had taken pains to compose, and which he wished farther to improve, his father gave his opinion: "the fault of your discourse is its being too elegant; it will certainly be left to you to touch it again." Nuov. D. C. Filos. Elog. Dict.

AGUAGUA, Cape, southward of Peru, on the coast of South America. 8 lat. 61°. W. long. 82°.

AGUAGUA. See OUBEKIS.

AGUAGUA is also the name given by the Italian fishermen to the small coast of Opium, called in English the GARI-FISH. AGUAS, a small town of Portugal, in Alentejo, to the west of Elvas, and to the east of Lisbon. The territory about it produces grain and oranges. W. long. 6° 41'. N. lat. 38° 10'.

AGUIGUAN, or the island of the Holy Angel, in Geography, one of the Ladrones or Marianne islands, lies in the Southern Sea, in lat. 14° 43'; about forty miles from Zarpansa; and about a league south-west of Tinian. It is a small island, about nine miles in compass, mountainous, but pleasant, and formerly well inhabited.

AGUILA, AGUGELA, or OUGUELA, a town of Africa, in the kingdom of Fuz, situate on the river Aguila or Erguela, and giving name to a district, which is for the most part sandy and barren, but in some places so well watered as to afford plenty of dates; and it is separated from Barea by a mountain called Mays, which affords excellent pasture.

AGUILLAR, a town of Spain, in Navarre, four leagues south-west of Estella. E. long. 49° 35'. N. lat. 42° 37'.

AGUILLAR DEL CAMPO, a town of Spain, in Old Castile, situate on the Albania; three leagues from Calahorra.

AGUILLANEO, or AGULIENEO, compounded of the French, a, to, gui, mille, and Van neuf; i.e. the new year; a form of rejoicing used among the ancient Franks on the first day of the year.

Its origin is traced from a Druid ceremony: the priests used to go yearly in December, which with them was reputed a sacred month, to gather mistletoe off the oak in great festivity. The prophets marched in the front, singing hymns in honour of their deities; after they came a herald with a caduceus in his hand; these were followed by three Druids-abhor, bearing the things necessary for sacrifice. Last of all came the chief, or arch-druid, accompanied with the train of people.

The chief would climb the oak, cut off the mistletoe with a golden sickle, and the other Druids received it in a white cloth. On the first day of the year it was distributed among the people, after having bled and consecrated it by crying au gui l'an neuf, to proclaim the new year.

Of later times the name aguillanue was also given to a fort of pagans, practised in some dioceses, for church tapers, on a new year's day, by a troop of young people of both sexes, having a chief, &c. It was attended with divers ridiculous ceremonies, as dancing in the church, &c. which occasioned the synods to suppress it.

AGUILLAS, Cape, in Geography, lies to the east of the Cape of Good Hope. See Cape Needles.

AGUILLES, or AGUIGUELS, cotton cloth, manufactured at Aleppo.

AGUILLON, FRANCIS, in Biography, a Jesuit of Brufells, was professor of philosophy at D-away, and of theology at Antwerp. He was distinguished by his knowledge of mathematics, and is said to have first introduced studies of this kind into Flanders. He wrote a book of optics, intituled, "Opticonium, lib. vi. Philosophiae juxta Mathematicae utilitas," which was printed at Antwerp, in 1613, fol. He was employed in finishing his "Catoptics and Dioptrics" at the time of his death, which happened at Antwerp, in 1617, in the 52nd year of his age. He is also said to have written a treatise of "Projections of the Sphere." He understood several languages: his judgment was accurate; his learning extensive; and his patience and fortitude under severe trials were very signal. Under the paroxysms of the asthma, to which he was subject, and which were very trying, just before his death, he repeatedly said: "Let God's will be done—I submit to it—I am willing to form myself absolutely upon the divine pleasure—I have now the torments which I often wished for, and desired of God." God's Dict.

AGUILLON POINT, in Geography, a long narrow point, in a curvilinear form, north-east of the Isle of Ribe, on the coast of France, and about three leagues north-west of Rochelle. To the east of Aguillon the bay contracts and terminates.

AGUIRRE, JOSEPH SANCZ DE, in Biography, a learned Benedictine of the 17th century, was born in 1639, at Logroño, in Spain, and read lectures in theology at the university of Salamanca, where he took his degree of doctor of divinity. He was also censor and secretary of the supreme council of inquisition, and was honoured with a cardinal's hat by pope Innocent XI. in 1686. He died at Rome, in 1699. His life was exemplary; and his writings numerous. He is said to have retracted the doctrine of probability, which he had maintained, as soon as he found that it was inconsistent with the doctrines and purity of the Christian morals. His publications,
Aguti, in Botany, a small shrub very prickly; its leaves are long, and resemble those of the knot-grass; it abounds with flowers of a reddish colour; there are succeeded by red husks; its root is long, and of a purplc colour. This plant is otherwise called alhagi Inaturum, by Rauwolf; it grows in Arabia, Persia, and Mopotamia. See Hedysarum.

Agul, in Geography, a river of Russian Siberia, which runs into the Kan. E. long. 95° 21', N. lat. 55° 16'.

Aguna, a town of Africa, in the kingdom of Beain.

Aguntum, in Ancient Geography, now Unikel, a town of Rhiixia, placed by Ptolemy in Norica, and by M. d'Anville to the north of the Carnic Alps, and north-west of Iulium Caracenum.

Agurah, in Hebrew, Antiquity, the twentieth part of an ancient silver shekel. It was otherwise called gerah and kehitah. The Seventy render it sohlo.

Agurium, Agyrium, Agirium, or Agyrena, now S. Philipo d'Agyrone, in Ancient Geography, a town in the interior part of Sicily, placed by M. d'Anville in the road from Enna to Catania.

Agusadora, in Ancient Cutsoms, a fee due from vassals to their lord, for sharpening their ploughing tackle. Anciently the tenants in some manors were not allowed to have their rural implements sharpened by any but those whom the lord appointed; for which an acknowledgment was to be paid, called agusadora, in some places agofage, which some take to be the same with what was otherwise called relofta, from the ancient French relas, a plough share. Du-Cange.

Agustine, in Mineralogy, a barbarous term, compounded of Greek and Latin, meaning without taffes, infipid, by which professor Trommsdorf has distinguished a sapphoed new earth, discovered by him in the year 1802.

The mines of Johan-Georgenlacht contain a mineral, which hitherto has been taken for the beryl: this being analysed for the purpose of ascertaining whether glycine was one of its constituent parts, yielded unexpectedly a new earth, which, from its forming infipid salts with acids, has been called by its inventor, Agulina.

This earth, when pure, has a great resemblance to alumine, adheres very feebly to carbonic acid, hardens by exposure to fire, and is insoluble in water. It differs, however, from pure clay, in the following particulars: 1. It is absolutely insoluble in any of the three alkalies, whether cauile or carbonated, in the moist or the dry way. 2. With acids it combines, readily forming nearly infipid flats. 3. It is equally soluble after induration by fire, as before. 4. Sulphuric acid forms with it a salt of difficult solution, and perfectly infipid, but which by a slight excess of acid, becomes soluble and crystallizes in flars. 5. Its acidulous phosphate is also very soluble. 6. But the acetate of Agugtine is scarcely at all fo.

These are all the facts that are as yet known concerning this substance: it relates entirely upon the authority of Trommsdorf, and as neither he nor any other chemist have since made the smallest mention of it, even this slight notice might here seem superfluous. Annales de Chimie, vol. xxxiv. p. 135.

Aguti, the cavia aguti of Linnaeus, in Zoology, has a very short tail; the upper parts of the body are of a brown colour, mixed with red and black, the rump of a bright orange, and the belly yellowish. Authors mention three varieties, viz. the lesser aguti, or cavia aguti circumcarinatus, with a very short tail, four toes before and three behind, and a yellowish belly. This is the circumcucis aguti of Driffon and Gronovius, the larger mouse of Brown, the American wild mouse of Ray, with the hair and voice of a pig; the aguti or acuti of Marengræve, &c. the long-nosed cavy of Pennant, and the aguti of Buffon. It is about the size of a rabbit, and inhabits Brailil, Guinea, Cayenne, and other parts of South America and the West Indian islands. 2. The larger aguti, or cavia A. leporsina, with a very short tail; the upper parts of the body reddish, and the under white. This is the hair-like monot of Linnaeus, having four toes on the fore, and three on the hinder feet; the Javan cory of Brillouin; the Java hare of Catesby; and the Java cavy of Pennant. It is of the size of a hare, and inhabits Surinam and the hotter parts of South America. 3. The American aguti, cavia A. Americana of Gmelin, and the American cory of Brillouin and Seba; has a very short tail, and is clothed with coarse reddish fur. These three varieties inhabit South America, and some of the West Indian islands, particularly the Antilles. The first has a long rofe, the upper lip divided; short, broad, rounded ears; black eyes; flender, and almost naked legs, of a black colour. The second has a small flender head, with prominent naked ears, rounded at the extremity. The hinder parts in both are larger than the fore parts, and the legs are long. The third variety is little known. These animals inhabit hollow trees, and burrow in the ground. They live on vegetables, which they collect in the day, and carry to their dwellings; they sit on their hind legs, and feed themselves with their paws; and when fattened with food, conceal the remainder; they gront like pigs: when hunted with dogs, they run fast, with a kind of hopping or leaping pace, like that of a rabbit or hare, and take shelter in their holes or hollow trees; when irritated, the hair rises on the back, and they flrike the ground with their hind feet; when young they are cally tamed; and will of their own accord, go out and return again. They are very voracious, and grow fat; and their flesh is white and favourly, and eaten in South America. The female brings forth at all times of the year, and produces three, four, and sometimes five at a time.

Aguti Treva infula Marisgala, in Botany, a plant mentioned by de Laet. It has the leaves of the orange-tree, only thinner, a dewy flower, a large fruit, with a greenish rind, which contains kernels like those of the pomegranate, thin, sweet, and not ill-taile.

Agutigepa obi Brasiliensis, in Medicine, the name given by many authors to the arrow-root, or Sagittaria alephorica of the West Indies.

Agyil, in Antiquity, a kind of obelisks consecrated to Apollo, and placed in the vehicles of houes, for their security.

The agyci were no other than huge fones, or perhaps sometimes timber, having either a circular or square bals, and terminating in a point at the top, faced to Apollo, or, as some fay, to Bacchus, as protector of the high ways. Others will have them to have been erected to both those deities. Suidas and Pitsicus. They had sometimes the head of Apollo, Bacchus, or Mercury; and Steph. Byz. fays, that they served, like our direction-pulls, to shew the way to any place.

Agylla, (Cervatari), in Ancient Geography, a town of Etruria, near the Ica, so called by the Lelagi, who came
thither from the Sicily. It was afterwards called Ceret, as Strabo (Geog. tom. i. p. 337.) informs us, from this circumstance, that the Lydians, hearing the inhabitants frequently repeating to them the Greek expression κράτερ, i.e. réiger, took this to be the name of the city, which it afterwards retained. Others, thinking this etymology more fanciful than just, deduce Agylla from gillab, water, as they had fountains in the neighbourhood; and Cere might be formed from cari or cariab, a town, in the language of the Lydians. The sons of Tarquin were banished to this town; and hither the vellata retired when, in the year 363, the Gauls laid siege to Rome. The laws and police of this city are much commended. History informs us that it united with the adherents of Tarquin against Rome; and that it afterwards demanded and obtained a truce of 10 years. It was one of the first cities which became municipal. Strabo says, that in his time, there remained only the ruins of this famous city; and it was known only by its baths.

AGYLLAEI, in Ancient History, a denomination given to the Pelagi in Etruria. Inhabited, as it were, in this country, theypreferred, with little alteration, the manners and religion of the ancient inhabitants of Greece; they furnished considerable deers, and aided the Carthaginians with 60 vessels in their war with the Phœcians, who had established themselves in the island of Sardinia; and though they were vanquished, they made many prisoners, whom, according to Herodotus (lib. i. 167. p. 79.) they put to death. They assisted a treachure at Delphi, by transmitting thither a tenth of their maritime profits; and by their commerce, and their piracies on the coast of Italy, and amidst the islands of the Ægean sea, they acquired a degree of power, which rendered them important allies or formidable enemies to their neighbours. Herodotus says, that their power was considerable in his time; and that, in consequence of an oracle, they had instituted funeral sacrifices and annual games, which they then celebrated. These people, who were sometimes called Tyrhenians, sent as couriers to the Athenians in the Sicilian war, not long before the ruin of the Veii by the Romans. They formed an alliance with the Romans, which gave them all the advantages belonging to Roman citizens, without the charges attending them; and they formed, under the name of Cereates, the third order of the republic. The Cereites bore arms in the Roman army, and were almost always united to the Romans, as Livy (lib. vii. c. xx.) informs us; and they were considered, not merely as allies, but as a part of the nation. At length, defeated by the Roman marine, which found more spacious and convenient ports, and losing its commerce, Cere declined, and the inhabitants, who were Romans, were indiscriminately blended with the other citizens.

AGYNEIA, formed of άπριπνος, a wife, in Botany, a genus of the monoea monadelphus class and order, according to Martyn; but in Gmelin's Linnaeus, of the triandria monogyne, of the natural order of tricoe, and the Euphorieae of Jussieu. Its generic characters are, that the male flowers are below the female; the calyx is fix-leafed; the leaflets oblong, obtuse, equal, and permanent; no corolla; in the male, instead of filaments, a column shorter than the calyx; three or four anthers, oblong, growing to the column below the top; in the female flowers, the germ of the size of the calyx, sub-ovate, obtuse, perforated at top with a fix-notched hole; neither style nor stigma; the pericarpium supposed to be a tricoccos capitule. There are two species, viz. 1. A. improble, with leaves smooth on both sides. 2. A. pulvra, with leaves downy underneath; both species are natives of China.

AGYNIANI, in Church History, a sect who condemned all use of flesh, and marriage, as not instituted by God, but introduced at the inclination of the devil. The word is compounded of the privative α, and υγις, woman. They are sometimes also called Agymenias and Agynias and are said to have appeared about the year 694.

AGYRTIS, in Antiquity, a kind of raving impostors running about the country, to pick up money by telling fortunes at rich men's doors, pretending to cure diseases by charms, sacrifices, and other religious mysteries; also to expiate the crimes of their deceased ancestors by virtue of certain odours and fumigations; to torment their enemies by the use of magical verses, and the like. The word is formed of the verb τίνης, to expiate; alluding to the practice of quacks, who gathered a crowd about them. See Ερυσκαστορες.

AGYRTUS, in Entomology, a name given by Cramer to the papilio phe.Locale of Gmelin's Linnaeus.

AHA, or AEU, in Zoology, a name given by the Persians to the cerus pyococcus of the Linnaean system, or the tail-less rose of Pennant, which has no tail, and three-torned horn. It inhabits the lofty mountains of Herca, as and of Russia and Siberia, beyond the Volga; and at the approach of winter descends into the plains and becomes hoary: it is called by the Russians dikar roza, and by the Tartars faiga. This animal resembles the rose, but is much larger, being of the same deep red colour, with a large bed of white on the rump and buttocks, extending up the back; the fur is thick, in spring rough and crect, on the limbs and belly yellowish; the sides of the under lip and the space about the nose are black; but the point of the lip is white; the hairs of the eye-lids and round the orbits are long and black; the horns are very rugged at the bases, and full of knobs; the ears are covered on the inside with a very thick white fur. Gmelin's Linn.

AHA, in Scripture Biography, one of the kings of Israel, was chiefly distinguished by his impieties. He succeeded his father, A. M. 3586; married Jezebel, the daughter of Ethbaal, king of the Sidonians, or rather the Tyrians; and at her instigation introduced the idolatrous worship of Baal among the Israelites. In his wicked reign there was a drought of three years' continuance, probably the same famine that was mentioned by Josephus, (Ant. lib. viii. c. xv. § 2,) which happened, A. M. 3566. With a small force he obtained a signal victory over Benhadad, king of Syria, who had besieged Samaria. In a subsequent war, he endeavoured to elude the enemy by a change of clothes, but was accidentally killed by an arrow, about the year 897 before Christ. The despotic character of this prince, and the savage cruelty of his wife Jezebel, are strongly marked in the anecdote related concerning Naboth's vineyard.

1 Kings xvi. 29-33; xx. xxxi. xxii. Gen. Dc

ALETULLA, in Zoology, a species of colorer, in the order of Serpents. It is found in Asia and America, about three feet 14 inches long, of a greenish-gold colour, with the skin, sometimes visible between the scales, black. Its head is elongated and narrow, with a black band over the eyes, and a tetrahedral tail. By some authors it is called the long green Borneo snake, and the burgondium of Ambonya. Gmelin.

AHALOTH, in the Materia Medica, the Hebrew name used by some writers for the lignum aloes, or aloes wood.

AHANIGER, in Ichthyology, a name given by Alber tus and others, to the fish called by authors ACUS vulgaris, and by us the gar-fish.

AHAUSZ, See AABUS.

AHASURUS, in Scripture History, was the king of Persia.
Kings 19.) have delivered two messages from God to Solomon, one encouraging, whilst he was building the temple (1 Kings vi. 11), and another threatening, expressive of displeasure, on account of his idolatry, (1 Kings xi. 6.) He is one of those who wrote the annals of this prince, 2 Chron. ix. 19. He also predicted the usurpation of Jeroboam, declared the calamities that would befal his house on account of his idolatry, and also foretold the death of his son Abijah, 1 Kings xiv. He lived to an advanced age; but the time and manner of his death are not recorded.

AHIMAAZ, son of Zadok, the high priest, succeeded his father about A. M. 3620, under Solomon. During the rebellion of Abishalom, he informed David of the resolution adopted in his council; and he and Jonathan escaped their pursuers by being concealed at Bahamin. Ahimaz was the first who gave intelligence to David of Abishalom's death. He was succeeded in the priesthood by Azariah.

AHIJAH, in Scripture History, a prophet of Shiloh, who is supposed to have delivered two messages from God to Solomon, one encouraging, whilst he was building the temple (1 Kings vi. 11), and another threatening, expressive of displeasure, on account of his idolatry, (1 Kings xi. 6.) He is one of those who wrote the annals of this prince, 2 Chron. ix. 19. He also predicted the usurpation of Jeroboam, declared the calamities that would befal his house on account of his idolatry, and also foretold the death of his son Abijah, 1 Kings xiv. He lived to an advanced age; but the time and manner of his death are not recorded.

AHITOPHEL, a native of Gibeah, who, after having been David's counsellor, joined in the rebellion of Abishalom, and allied himself with his advice. Hitherto, the friend of David, was employed to counterfeit the counsels of Ahithophel, and to deprive Abishalom, under a pretence of serving him, of the advantage that was likely to result from the measures which he proposed. One of these measures was calculated to render David irreconcilable, and was immediately adopted; and the other to secure, or to defy him. Before the last council was followed, Hitherto's advice was defined; and he recommended their assembling together the whole force of Israel, putting Abishalom at their head, and overwhelming David by their number. The treacherous council of Hitherto was preferred to that of Ahithophel; with which he was disgraced and banished to his house at Gibeah, where he put an end to his life. He probably forewarned Abishalom's defeat, and dreaded the punishment which would be inflicted on himself as a traitor, when David was re-established on the throne. A. M. 2981. Ante Chirli. 1223. 2 Sam. xv. xvii.

AHILEON, in Geography, a bailiwick of the principality of Luxemburg-Zell, in Germany, lying on both sides of the Aller, which in this bailiwick receives the Leine and Bohme. It is a German mile and a half in length, and as much broad; and consists of champagnes, heaths, and sandy grounds; and, to the south of the Aller, has good marsh lands and paturage. Its woods are chiefly oak; and great quantities of timber are conveyed in float to Bremen. The inhabitants carry on a considerable trade in horels, cattle, wool, honey, and wax.

Ahilen is also the name of a town situate on the old Leine, near the Aller, from the estuary of which it derives its name. Sophia-Dorothea, daughter to king George I., after her separation, resided in the palace of this town, from 1654 to 1726.

AHLEMAN, a voguey, or district of the principality of Calenberg, in Germany, containing seven villages: the chief of which is Limmer.

AHLEN, a small town of Munster, in Westphalia, situate on the Werle, which is summoned to the land-diets, contains a collegiate church, two nunneries of Augustines, and a priory and rural court. See Ailen.

AHLOWARDT, Peter, in Biography, professor of logic and metaphysics at Greifswardi, was born of mean parentage, in that city, February 14, 1710. Having made
AHM

made considerable proficiency in the Greek and Latin classics, he became a student of theology in 1727; but applied chiefly to mathematics and philosophy. In three years he removed to the university of Jena; and in 1732, returned to Grieswalde, where he read a course of lectures on mathematics and philosophy. In 1742, he became his conjunct of the philosophic faculty in that place, and nine years after was chosen professor; he also preached often with great approbation. He largely contributed to the critical researches of the society at Grieswalde, of which he was a member. He founded also the order of the Abélites, and wrote a treatise on the occasion, entitled, 'The Abélite.' His other principal works are, 'Considerations on the Confession of Augsburg;' 'Thoughts on the Powers of the Human Understanding;' 'An Introduction to Philosophy;' 'A Treatise on the Immortality of the Soul;' and 'Brontothecologia, or Thoughts on Thunder and Lightning.' He is said to have been so accurate in his composition, that he never corrected what he had once written. He died March 18, 1791. Gen Bog.

AHMED Khan, one of the race of Jenghis or Zingis, was the son of Nekhoke, and brother of Abaka Khan, whom he succeeded as emperor of the Moguls, in 1232. He assumed the name Ahmed, on his embracing Muhammadism; and on this occasion, he offered protection to all Mufful-mans, in a letter to the Sultan of Egypt and Syria. This change of religion offended the princes of his family to such a degree, that he could never regain their affection. His nephew Argun raised an army against him, but he was soon defeated and taken prisoner. He was afterwards released by some conspirators, and having killed the emperor's principal officers, he pursued and overtook him; and delivered him up to his mother-in-law, who, in revenge for the loss of her own sons whom Ahmed had castrated to be plain, put him to death, after a reign of two years and two months. A.D. 1284. Mod. Un. Hist. vol iv.

AHMEDABAD, or Ahmed's City, in Geography, the capital of the province of Guzerat in India, so called from Sultan Ahmed, who was king of that province, and kept his court in that city. It is 20 miles south of Delhi, and 56 miles from Surat. N. lat. 22° 58' 30". E. long. 72° 35'. The city is situated in a delightful plain, watered by the little river Sabarmatty. The walls are built with brick and stone, flanked at certain distances with large round towers and battlements. It has 12 gates; and, including the suburbs, is about four and a half miles in length. On the west side is the castle, walled with freestone, and as spacious as a little city: the caravansy is on the south of the king's square, which is 750 paces long and 450 broad, planted round with trees, and is its chief ornament. Near this square is the king's palace, with apartments richly ornamented; and in the midst of the city is the English factory. The Hindus have in this place, which, from an eminence, appears like a wood, being full of gardens, an hospital for sick birds, and another for sick beasts. For magnitude and wealth, this city is little inferior to the best in Europe; and the revenue which it yields, is generally reckoned to be ten times as much as that of Surat. It is one of the best fortified cities in Hindostan. On the peace of 1783, it was restored to its former pillar-flors the Poona Marattas. Frazer's Kuli Khan. p. 29. Mod. Un. Hist. vol. v. p. 293.

AHMEDNAGUR, a city, once the capital of the Soubah of the same name, but now better known by that of Dowlatabad, which fee. Aurungzebe died in this city.

AHMELLA, in Botany. See ACNELLA.

Vol. I.
out the king of Ai with his troops; and upon a signal given, by elevating his shield on the top of a pike, the men in ambush entered the city and set fire to it; and thus the soldiers of Ai, placed between two divisions of Joshua's army, were all destroyed; the king alone being preferred for a more ignominious death on a gibbet, where he continued till fun-fet. The spoils of the place was afterwards divided among the Israelites. The men appointed for ambush are, in one place, said to be 30,000, and in another 5000. For rescinding this apparent contradiction, most commentators have generally supposed, that there were two bodies placed in ambuscade between Bethel and Ai, one of 25,000 and the other of 5000 men; the latter being probably a detachment from the 30,000 first sent, and ordered to lie as near to the city as possible. Maimus allows only 5000 men for the ambuscade, and 25,000 for the attack. As for the signal, used by Joshua on this occasion, the Rabbinis suppose that the shield was too small for this purpose, and that it must have been the flail belonging to one of their colours; in which opinion Chevalier Polard acquiesces; adding, that the whole colours were tied on this occasion, the part being subliminated, agreeably to the figurative language of the call, for the whole. It has been suggested, that this was one of the fire-pots, which are employed as altars by the eastern cabals, whose smoke would ascend to a great height, be easily seen, and signify the fate intended for the city; and as the flame and flail of this instrument were of iron, it answers to the translation of the LXX and Aquila. Joshua viii. Patrick in loc.

Calmet.

Ai, in Zoology, the Brathypus iridum of Linnaeus, or sloth, with thee-toed feet and short tail.

AIA, or Allia, in Ancient Geography, a river of Italy which discharged itself into the Tiber, about 19 miles above Rome. On the banks of this river, 200 Fabians were destroyed in their engagement with the Veii, and the Romans were defeated by the Scenones of Gaul, conducted by Brennus.

Ajabire, or Ajaviva, in Geography, a town of South America, in Peru; 35 leagues south of Cuco. Ajab, in Geography, a town in South America, in Peru; 35 leagues south of Cuco.

Aja, a Hebrew term, which St. Jerome translates vulture. Bochart supposes that it denotes the merlin; the Syriac renders it raven, and the Arabic owl. Our translation (Job xxiv. 19) renders it vulture; but (Lxx. xi. 44, Deut. xiv. 13) kite. It is evidently a species of unclean bird, and most probably the vulture or kite, so called from its gluttony, or from its note. Aima (Jer. l. 39) may perhaps be the plural of Aja, and signify flights of vultures, which in some countries are very numerous; though Bochart conceives them to be jackals. Calmet. Bochart Op. tom. iii. p. 193, &c. Ed. Villem.

Aiaia, in Ornithology, the name of a Brazilian bird, of the platelae, or spoonbill-kind, called by the Portuguese colorado. Its specific character is, that its body is blood-coloured. It is exactly of the same shape, but somewhat smaller than the European species, and its beak is in the very same manner broad at the end, with a furrow parallel to the margin, and of a cinnereous-white colour. It differs from the European species, by the rose or carnation which paints the white ground of its plumage on the neck, the back, and the sides; the wings are more strongly coloured, and the red tint turns into a crimson on the shoulders and the covers of the tail, of which the quills are rufous; the shaft of those of the wing is marked with fine carmine; the head and throat are naked and whitish; the legs grey; and the claws blackish. These beautiful colours, says Buffon, are found only in the adult.

This species is the platea rosea of Bignon, the p. incarnata of Sloane and Ray, the Brasilian spoonbill, called ajaja, of Maregrave and Willughby, the rofate spoonbill of Laathom, and the ptilotus couleur de rofe of Buffon. There is a variety, called lauquecheul, which Buffon supposes to be the same bird in its adult state. This rose-coloured form is its common appearance, and its presence in the rivers, feeds on small fish, and is, says Maregrave, of an agreeable taste. It is diffused in the new continent from north to south, from the coasts of Mexico and Florida to Guiana and Brazil. It is also found in Jamaica, and probably in the adjacent islands; but the species is no where numerous. In the morning and evening the spoonbills are seen on the seashore, or settling on trunks that float near the beach; but about the middle of the day in very fultry weather they enter the creeks, and perch high on the aquatic trees. However, they are not very wild; as they pass at sea very near the canoes, and on land they will allow a peron to approach them within gun-shot. Buffon's Birds, vol. vi. p. 437. Eng. Ed.

AJALON, in Scripture Geography, a name given to four different cities, viz. one in the tribe of Dan, between Tinnah and Beth-hemem, assigned to the Levites; probably that referred to by Joshua, chap. x. 12; another, in the tribe of Benjamin, between Bethel to the north, and Jerusalem to the south: a third, in the tribe of Ephraim, about two miles from Shechem; and a fourth, in the tribe of Zebulun, whose precise situation is not known.

Ajan, or Asan, in Geography, a country extending along the southern coast of Africa, from Magadoxo to Cape Guardatuni, comprehending about 10 degrees of latitude. This maritime tract contains several petty kingdoms and states; the principal of which are the kingdoms of Adel or Zela, and Magadoxo or Madagascar, on the coasts, and some others inland, hardly known even by their names. The eastern coast of Ajan is sandy and barren, the habitation merely of wild beasts, and therefore called the desert coast; but farther towards the north the country is fertile, producing all sorts of provision, and furnishing means of commerce, and particularly an excellent breed of horses, which foreign merchants take in exchange for silks, cottons, and other cloths. The inhabitants along the coast are generally white with long hair; but towards the south they become more tawny, and even black. The negroes intermarr with the Bedowin Arabs, and carry on a great commerce with them in gold, slaves, horses, and ivory, which they commonly bring from Abyssinia, whither they occasionally repair for the sake of plunder. As they are all either zealous Mohammedans or Bedowins, they are enemies to the Abyssinians, who are Christians; and their irritations into Abyssinia accustom them to war. Thos. of them, and especially of the Bedowins, who live near the trading coasts, are ardent thieves. Mod. Un. Hist. vol. xii. p. 304, &c.

Alandum, a town of Asiatic Turkey, in the province of Natolia; eight leagues well-south-west of Sinope.

AJAR, in Natural History, the name given by Adamson to the chama antiquata of the Linnaean systen.

AJAFA, in Geography, a fertile district of Spain, in the kingdom of Seville; in which there is a little town situated on the Guadalquivir, called Ciudad of St. Lucar la Mayor.

AJAS MONG, a mountain of Marmaria, in Africa, according to Ptolemy.

AJAS, a small town of Afa, in Natolia, famous for its mineral waters; called also Therma.

AJA is also a small town of Arabia Felix, situated in a valley, and about two days journey from Edom.
AJASALUCK, a name given by the Turks to the ancient Ephesus. The name denotes the temple of the moon, and is derived from the magnificent structure formerly dedicated to Diana.

The ruins of this famous city serve now merely as a place of accommodation and shelter for the sheepfolds and their flocks, and in the occasional habitation of birds and beaks of prey. The glorious pomp, says Dr. Chandler, (Travels, p. 131) of its heathen worship is no longer remembered; and Christianity, which was there nurtured by apostles, and fostered by general councils, until it increased to fulness of stature, barely lingers on in an excellence hardly visible. By this writer it is defribed as exhibiting a very gloomy and melancholy appearance, though not absolutely without people. The fires which were lighted in the night among the bushes, and round which the villagers collected, afforded a dim prospect of ruin and desolation. A shrill owl, called Cucavia from its note, with a night-hawk, flitted near them; and a jackal cried mournfully, as if forlorn by his companions on the mountain. The biblical critic may possibly consider this description as a lively comment on the language of the prophet: Zeph. ii. 7, &c.

AJATOCHTI, in Zonurgi, a name given by Hernandez to the Dasyapus abdicans, or right-handed armadillo.

AJAX OILADES, in Classical Biography, one of the leaders of the Greeks, in the expedition against Troy, was the son of Oileus, a powerful chief of the Locrians. Homer (Iliad lib. xiv. v. 520) affirms to him agility, and a promptitude in executing whatever he undertook, and he is said to have excelled in the use of the bow and javelin, and in swiftness of foot. Horace is by some commentators supposed to refer to him, Od. xvi. 1. i. v. 19. Such was his daring resolution, that even the Gods could not awe and subdue him. Homer Odys. lib. iv. 502.

"Impious he roar'd defiance to the Gods,
    To his own prowess all the glory gave.

Pope.

The offence which is reported to have incurred the displeasure of the Gods, was his violation of Callandra, the daughter of Pism, in the sanctuary of Minerva, where she had taken refuge. Ajax however denied the fact, and imputed the charge to the artifice of Agamemnon, who wished to keep Callandra for himself. In his return home, he and his whole fleet were wrecked by the vengeance of Minerva. Some say that he escaped; and that in the moment of danger he impiously exclaimed: "In spite of the Gods, I will escape."—Homer ubi supra. v. 504.

"The power defrauding who vouchsafed to save.

AJAX Telamius, was the son of Telamon, prince of Salamis, and one of the principal heroes of the Iliad, whom Homer represents as inferior only to Achilles in strength and valour, and as the chief bulwark of the Greeks, after the decease of that warrior. "His character," says a much approved biographer, "seems to be intended as the model of that steady, agreeable courage which is ever at hand, when its exertions are wanted, and requires no aid of circumstances to excite its energy. He is the only hero, who neither asks nor receives the assistance of a deity:"—and his character is exhibited as a striking instance of impiety and irreligion. It is said, that when he was going to the army, his father recommended to him always to join the assistance of God to his own personal courage. Ajax replied, that evenowards themselves were very often victorious by such aid; but for his part he should have no regard to it, and that he was sure of being able to conquer without it. Thus Sophocles, in Ajax, represents the matter. Homer, however, partly vindicates him from this charge of total irreligion: for though he did not pray to Jupiter himself, when he prepared to engage the valiant Hector, he desired others to pray for him, either with a low voice, lest the Trojans should hear, or louder if they pleased: "for," says he, "I fear no perfon in the world." Iliad lib. viii. v. 104.

When the arms of Achilles were adjudged by the Greek chieftains to his rival Ulysses, Ajax was bereaved of his understanding; and first venting his rage against a flock of sheep, taking them to be Greeks, he then turned his sword against himself. Fable reports, that the flower called Hyacinth sprung from his blood. The Greeks erected a noble monument to him on the promontory of Rhoeaum. Paulyanias says, (lib. i.) that one of their tribes bore the name of Ajax, and that the people of Salamis built a temple to him. Herodotus (lib. viii. c. 64. c. 121.) informs us, that the whole country of Greece invoked him a little before the battle of Salamis, and dedicated to him, as part of the first fruits due to the Gods, one of the ships which they had taken from the Persians in that battle. Paulyanias relates, amongst other wonderful tales, that the waves call the arms of Achilles upon the tomb of Ajax, after the shipwreck of Ulysses. The fate of Ajax was the subject of several eminent tragedies. Gen. Dict.

In his last martial exploit, when he was endeavouring to preserve and rescue the dead body of Petruchus, and when he was overwhelmed with a mill or darkness, which intercepted his view of the Grecian host, he made the following address to Jupiter, which has been much admired for its moral sublime:

"Lord of earth and air,
Oh king! oh father! hear my humble prayer:
Disper this cloud, the light of heaven restore:
Give me to see, and Ajax asks no more:
If Greece must perish, we thy will obey,
But let us perish in the face of day."

An ingenious writer has justly appreciated the character of this hero. After a concise abstract of his history, and a detail of his principal exploits, he adds, "Such is the Ajax of the Iliad—a hero (as far as to rude an age admits of heroism) in grains; tried and proved by every difficulty and danger; not the meteor of a day, but shining with equal lustre through the whole period of action; always in his place; returned to on every emergency, and never in vain; not hurried along by idle bravado or enthusiasm, but making utility the guide of his actions; finally, never yielding but when mortal affliction was unavailable, and when a heaven-born champion, with celestial aid, was necessary to turn the tide of fortune. He may then stand in the number of able and useful men, whole value is superior to their fame—a class of which there are members in every profession and rank of life, and to whose affluence, the first-rate characters owe great part of their celebrity and success."

"Such was the Antipater of Philip of Macedon:"—"Such was the Labienus of Caesar, the Agrippa of Augustus, the Sulky of Henry IV., the Cecil of Elizabeth, the Ireton of Cromwell. Such appear to be the grandeur of those officers in the British navy, under whose conduct
conduct the empire of the ocean has been maintained for their country everywhere, against all foes, by dint of equal valour and unvarying skill. In science, in the arts, in the common business of life, such men might be pointed out. In general, they are those whom the leaders in important affairs would choose for their seconds, to supply their places on occasion, according to their plans, and take the management of separate and dependent parts. Their essential qualifications are, a perfect fitness for their polls, and a constant readiness to bring all their powers into full exertion: firmness, vigilance, order, and the habit of fixing the attention upon particular objects." See Aikin's Letters to his Son. vol. ii.

Ajax, in Antiquity, a curious kind of dance, in use among the Grecians; intended to represent the madness of that hero, after his defeat by Ulysses, to whom the Greeks had given the preference in his contest for Achilles's arms.

Lucian, in his treatise of dancing, speaks of dancing the Ajax. There was also an annual feast, called Ajaxia, Ajaxia, consecrated to that prince, and observed with great solemnity in the island of Salamin, as well as in Attica; where, in memory of the valor of Ajax, a birer was exposed, let out with a complete suit of armour. Potter, Archael.

Ajax, in Entomology, a species of the papilio equs, with wings boldly cased and brown colour, yellowish bands and tawny anus. It is the papilio marcellus of Cramer, and found in North America.

Ajax, in Conchology, is a variety of the murex lampas of Gmelin's Linnaean System; called also Rubeta.

AJAZZO, in Geography, a sea-port town of Natolia, on a gulf of the same name, in the province of Caramania, anciently Cilicia, at the north-east extremity of the Mediterranean sea, 30 miles north of Antioch, and 50 miles of Aleppo; where the city of Bifus anciently stood. It is situated near the gulf of Scanderoon. Here Alexander the Great defeated Darius a second time, and took his family prisoners. In the time of the crusades, this belonged successively to Christlians, Saracen, and Turks, who now possess it. N. lat. 37°. E. long. 33° 10'.

AJAZZO or AJACCO, is a sea-port town, in a bay of the same name, in the fourth part of the island of Corfica, with a bishop's see under the archbishopric of Pisa. It is situated in a fertile territory, abounding with excellent wines. It is guarded by a small citadel; the streets are straight and large; the houses well built; the adjacent walks agreeable; and the number of inhabitants about 4000, many of whom are Greeks. Its commerce is supplied by a fishery of black, red, and white coral, and by its timber. The bay, though incommoded by rocks, affords secure anchorage for ships of considerable burden. The ancient town was situated about a league from the present, which was built in 1435; and many ruins of it are still remaining. A colony of Greeks was established in the vicinity of Ajazzo in the year 1677; but the protection of the Genoese could not prevent its being deserted and partly destroyed by the Corsicans. N. lat. 41° 50'. E. long. 8° 50'.

AIDAN-KERSIA, an old castle of ancient Babylonia, situated on the banks of the Tigris, in the government of Bagdad, and supposed to have been the residence of Cofroes, and other Persian kings.

AELLING, a town of Germany in Upper Bavaria, near the river Mangnuld, and not far from its junction with the Inn. N. lat. 34°. E. long. 55°.

AICH, a small town of Upper Bavaria, situated on the Paar; four leagues east-north-east of Augsburg. It was taken by the Swedes in 1633; and in 1634 laid in ashes by them. N. lat. 48° 30'. E. long. 35° 40'.

AICHERBERG, a town of Germany in Storia; four miles south-south-east of Friedberg. There is also a town of the same name in the archduchy of Austria; eight miles north-west of Efferding.

AICHERKIRCHEN, a town of Germany in the archduchy of Austria; seven miles west-north-west of Schwanenfalt.

AICHERBERG, a town of Germany in Carinthia; four leagues west south-west of Villach.

AICHEMALOTARCA. See AICHEMALOTARCA.

AICHERSTADT, a city of Austria, the capital of a sovereign bishopric of the same name in Franconia, situated in a fertile valley on the river Altmuhl, and founded in the year 748, by St. Boniface archbishop of Mentz. The diocese is 18 leagues long and 7 broad; and its inhabitants generally profess the catholic religion. The place of the bishop in the general diet of the empire is between the bishoprics of Worms and Spe, and he is the suffragan of the archbishopric of Mayence. The bishop has for his guard three companies of infantry, a company of catarrickers, and a company of dragons. At the the cathedral of the city, the eucahris is exhibited in a vessel of gold, denominated the fun, of the weight of 40 marcs, enriched with an incredible quantity of diamonds, pearls, and rubies. They reckon 350 diamonds, 1400 pearls, and 250 rubies, with many other precious stones. It was presented to the cathedral by the bishop of the diocese in 1611. It is no doubt, whether some of the precious stones have not been exchanged, in some period of public dillets, or by some artifice, for others of less value, that equally answer the purpose.

Aichlacht, is four leagues north of Neuburg, five north-west of Ingolstadt, and 15 south of Nuremberg. N. lat. 49°. E. long. 11°.

AICHERSTADT ober, is a town on the Altmuhl, one league south of the former.

AID, or AYDE, AUXILIUM, literally denotes the help, succour, or assistance, which any person lends another, when too weak to do, or avoid, something.

The word is French; formed, according to M. Menage, from the Italian altare; and that from the Latin adiutare, to help or assist.

AID, or AYDE, in Law, is when a petition is made in court, for the calling in of help from another person interested in the matter in question; who, it is probable, may not only strengthen the party's cause, who thus prays for aid, but also prevent a prejudice arising to his own right. Thus in real actions, the tenant may pray in aid, and call for assistance of another to help him to plead, because of the feebleness of his own estate. A tenant for life may also pray in aid of him that hath the inheritance in remainder or reversion; and an incumbent may pray in aid of the patron or ordinary; that is, that they shall be joined in the action, and help to defend the title. — This is called aid prior; but this course of proceeding is now much diluted.

Aid de camp, an officer in the army, whose business is to attend
attend the general officers, and receive and carry their orders as occasion requires. When the king is in the field, he usually appoints young volunteers of quality to carry his orders, who are called the King's aids de camp.

An major, or adjutant, is an officer whose business is to escort the major of part of his duty; and to perform it all in his absence.

Some majors have several aid majors.—Each troop of guards has but one major, who has two aid majors under hire, or more, according as the burthen requires.

Every regiment of foot has as many aid majors as it contains battalions. When the battalion is drawn up, the aid major's post is on the left, beyond all the captains, and behind the lieutenant-colonel.

Aid, Auxilium, in our Ancient Customs, denotes a subsidy or sum of money due to the lord, from his tenants, on certain occasions. It differed from a tax, which is imposed at any time when wanted; whereas the aid could only be levied where it was customary, and where the particular occasion fell out.

Such was the aid de relief, due from the tenants in fee, upon the death of the lord, to his heir, towards the charge of a relief of the fee, of the superior lord. This was abolished by King John's magna charta.

Such also was the aid chivalry, or capital aid, due by vassals, to the chief lord, or the king, of whom they held in capite.

Of this there are three kinds. The first, of chivalry; or, as they call it, par fair sale chivalry, toward making his eldest son a knight, when arrived at the age of fifteen years; the second of marriage, or par fille marier, towards marrying his eldest daughter.—Both these, with all charges incident thereto, are taken away by Hat. 12 Car. II. See Tenure, Service, &c. Some will have them to have been first established in England by William the Conqueror, and afterwards transferred to Normandy; but the more common opinion is, that the Conqueror brought them with him.—The third was of a ransom, due when the lord was taken prisoner by the enemy.

It appears from Bracton (lib. ii. c. 16. § 5) that, in the time of Henry III. these aids, which were allowed by the charter of King John, were suppressed to be paid by the vassals, rather as tokens of good will and affection to their lords, than as proper concomitants of the service they owed. Glanville, on the contrary, considered them as due by their tenures. But, both by that author, and in the charter, it is said, that they ought to be taken in reasonable proportions. Glanville questions, whether the feudal lord could demand an aid of his tenants for the support of his war? And replies by saying, that he could not dilate for such aid; but they might give it, as a beneficence, and out of affection to their lord; whereas he considers the aid of relief, as a due, for which the lord, in virtue of his seisin, had a legal right to dilate. Lyttelton's Hist. Henry II. vol. iii. p. 186. Svo.

In some provinces there was a fourth kind of aid; due whenever the lord should undertake an expedition to the Holy Land.

We also read of aids paid the lord, when he was dispossessed to purchase any new land or tenement. These were only granted once in his life. — Also aids for the repairing and fortifying of castles, seats, &c. and also aids to pay the lord's debts. To prevent this abuse, King John's magna charta ordained, that no aids be taken by the king without confent of parliament, nor in any wise by inferior lords, except only the three ancient ones above-mentioned, viz. for making the lord's eldest son a knight, for marrying his eldest daughter, and for ranenting the lord's person, if taken prisoner. But this provision was omitted in Henry III.'s charter; and the same oppressions were continued till the 25 Edw. I. when the statute called confirmation charterum was enacted; which in this respect revived King John's charter, by ordaining that none but the ancient aids should be taken. But though the species of aids thus remained arbitrary and uncertain, King John's charter, indeed, ordered, that all aids taken by inferior lords should be reasonable; and that the aids taken by the king of his tenants in capite should be settled by parliament. But they were never completely ascertained and adjusted till the statute of Westminster, 1. 3 Edw. I. c. 36, which fixed the aids of inferior lords at twenty shillings, or the supposed twentieth part of the annual value of every knight's fee, for making his eldest son a knight, or marrying the eldest daughter; and the same was done with regard to the king's tenants in capite, by the 25 Edw. III. c. 11. The other aid, for ranenting of the lord's person, being not in its nature capable of any certainty, was therefore never ascertained. Blackil. Com. lib. ii. c. 5. vol. ii. p. 74. Svo.

By the 3d. 34 Edw. I. it is ordained, that the king shall levy no aid or tax without his parliament.

Aids seem to have been first established with a view to the clients and freedmen of ancient Rome, who made presents to their patrons towards his daughter's fortune, as also on his birth-day, and on other solemn occasions.—Accordingly, Bouteiller relates, that in his time these aids depended on the courtesy and good will of the vassals; for which reason they were called, droits de complayance.

The bishops also received aids from their ecclesiastics, called fynodals, and ponteficals. They were to be paid at the time of their consecration; or when they had a king to entertain; or when called by the pope to his court, or to a council; as also when they went to receive the pallium.

Add, that the archdeacons also exacted aids from the clergy of their jurisdiction. See Procuration.

A kind of feudal aids are ill levied in Germany, &c. under the title of Abgaben. These aids, which were at first used in matters of policy, for any extraordinary taxes, or impositions, occasionally levied by the king and parliament, upon the subjects, to support the charges of the government, when the ordinary revenue is deficient.

Aid, regia, is a name frequently given to the land-tax.

Aid, in Theology, the aids or assistances of divine favour which are offered to man, have been the subject of much dispute between the Jansenists and Jansenists; for the composing whereof, a celebrated congress was erected at Rome under the title of congregation of aids, congregatio de auxiliis.

Some divines, after St. Augustin, distinguish two kinds of aids, viz. fine quo, and quo.

Aid, fide quo, that which the mind is at liberty either to use or refuse; such is fupposed to have been the aid ministered to man in the state of innocence, while his mind and will were found and upright.

Aid, ad quo, amounts to what is otherwise called efficacious grace, which furnments and subdues the will; fuch, according to the Calvinists and Jansenists, is supposed to be the aid ministered by grace, in the present fallen state of human nature.

Aids, in the Marque, are Helps or assistances by which the horsemance contributes towards the motion or action required of the horse, by a judicious use of his body, or the appointments of the horse.
AIDBEITZAN, ABERBIAN, or, as the Persians call it, ABBEBAYAN, in Geography, a province of Persia, borders to the east on the province of Ghilan, the Caipian Sea and Tabrazil, to the south on Irach-Ajemi, to the west and north-west upon Curdistan and Upper Armenia, and to the north on Shirwan and Georgia. The etymology of the name given by the Persians to this province imports a country of fire, so called on account of the temple erected in it for keeping their sacred fire. The soil is fruitful, and the climate healthy, though cold. The most considerable cities in it are Tauris, Ardibil, and Sultania. The province extends from about 48° to 54° E. long., and from 36° to 3° N. lat.

AIDHAB, or GADDAB, or ARDAN, a town of Africa, and sea-port of Nubia, on the coast of the Red Sea. N. lat. 22° 12'. E. long. 35° 59'.

AIDONA, a town of Sicily, in the valley of Noto; four miles north-east of Piazza.

AIELLO, a small town and duchy of Naples, in the Abruzzi Ultra, belonging by marriage to the hereditary prince of Modena.

AIELLO is also a town of Naples, in the district of Calabria Citra, with the title of a principality; nine miles south-west of Cosenza.

AIEREBA, in Ichthyology, the name of a fish of the pinnacra marina kind, but differing from all the others, in that the form of its body is regularly round, or oval, and its head placed far within the verge of its thin part. It is common in the Western Ocean; but it is not much esteemed for the table, being more loofe and flabby in its flesh than the other kinds. Maregrave.

AIGEN, in Geography, a town of Germany in the archduchy

AIDS are of the greatest service in the manage, and form the only true language between the master and the horse; by these he is encouraged to act with propriety and energy, and the necessity of correction is prevented; consequently it must be evident that a great mixture of gentleness and spirit are requisite in their exhibition.

The principal aid is derived from the bridle; indeed the different management of this appointment forms several distinct aids, each of which is so useful and necessary that it might constitute a distinct lesson. The cavalet forms at once an aid and a correction of the mall powerfeul kind, and in no way is the obedience of a horse so well secured as by this means. The spur is of this number likewise; when made use of as an aid it is by gently clothing the heels and applying the points only to the skin; but the calves of the legs are perhaps the best aids of this kind.

The whip is used as an aid to keep the attention of the horse alive, by elevating the hand and striking the aid, or gently patting the animal in different parts; judiciously managed to a well drested horse, it forms a very lively and animating aid. The voice is likewise made use of as an aid. The motions of the thighs, knees, and the calves of the legs, form separate aids; that of the calves is the most important and useful, without a proper knowledge of which, both horse and rider must be defective. The calves are used together, or separately; when one calf alone is employed, it is usually accompanied with the hand, to alter the position of the body, or change the leg, by which any action is led.

The elevation of the body in the stirrups forms another aid.

The aids made use of to make a horse go in airs, are either different in themselves, or differently applied, to those made use of on the ground. The general application of these aids on the road is a branch of riding in which English horsemen are by foreign masters deemed defective. The inner heel, inner leg, and inner rein, are called inner aids. The outer heel, outer leg, &c. are outer aids. See Berenger's Art of Horsemanship, vol. ii. p. 94, &c.

Aids in the French Langua, denote a duty paid on all goods sold and transported either out of, or into the kingdom. In this sense aids answer to what the Latins call veligalilis, vexenitis mercius, and are paid by all kinds of persons, privileged, or non-privileged; by which they differ from taille, taxe, which are only paid by the peasants, being a sort of capitation, answering to what the Latins call tributum.

Aids, court of, in France, a court erected for the cognizance of matters relating to the taxes. Appeals come to this from the court of elections, where matters relating to the taille are first heard. The court of aids, of a province, is sometimes separated from the parliament of the province, and fixed in another city, as at Montpellier, Montauban, &c. There are twelve courts of aids, of which the principal is that at Paris.

AIDAN, in Biography, a British bishop of the 7th century, was employed in instructing the inhabitants of the Northern parts of England in the Christian religion. He was a monk in the monastery of Yfli, or Jona, one of the Hebrides, which was subject to Britain, but given to the Picts, who inhabited those parts of Britain, in recompense of the zeal with which they had preached to them the faith of Christ. The kingdom of Northumberland, though it had received the Christian doctrine from Paulinus, archbishop of York, relapsed into idolatry. When Oswald, in 634, became king of Northumberland, he sent to Scotland for a missionary, qualified for instructing his subjects in the doctrines and duties of Christianity. It happened that a very improper person, an ecclesiastic named Cormian, of severe disposition and rugged manners, was first deputed for this purpose; but it soon appeared that Aidan, who was mild and prudent, was much fitter for the office; accordingly he was consecrated a bishop and sent to the court of Oswald. At his solicitation the episcopal fee was removed from York to Lindisfarne, a peninsula adjoining the Northumbrian coast by a narrow isleth, called also Holy Island, because it was chiefly inhabited by monks. Here Aidan exercised an extensive jurisdiction, and preached the gospel with great success; deriving encouragement and assistance in his labour, from the surrounding services of the king himself. After the death of Oswald he continued to reside in the church of Northumbland, and died in the year 651. We have an extraordinary instance of this bishop's liberality to the poor. Having presented a precent from king Oswin of a fine horfe and rich houings, he met with a beggar, and dismounting, gave him the horfe thus caparisoned. When the bishop expressed some displeasure at this singular act of humanity, and the sight put upon his favour, Aidan quaintly but forcibly said, 'which do you value most, the loss of a mare or a son of God?' the king was so affected that he fell upon his knees and intreated the bishop's favours. Bede describes the character of Aidan in terms of high commendation, and ascribes to him miracles, which the credulity in the times in which he lived would be disposed to admit. To the report of one of his miracles we are inclined to give our assent. When the bishop gave the priess, who was to conduct the betrothed wife of Oswin by sea to Northumberland, a phial of holy oil, instructing him, in case of a storm, to pour it into the sea, and assuring him that it would soon become calm, it is possible he might not be unacquainted with the efficacy of oil thus applied, which has been long known, and is now sufficiently established by observation and experiment. Biog. Brit.
duchy of Austria, on the confines of Bohemia; 35 miles
west of Vienna. N. lat. 45° 33'. E. long. 13° 52'.

AIGHENDALE, a liquid measure in Lancashire, con-
taining seven quarts.

AIGITHALUS, aspidaon, in Ornithology, a name by
which Aristotle, and some of the old authors call the
Parus, or SITMOW.

AIGLANDE, in Geography, a town of France, in the
department of the channel, and principal place of a canton,
in the district of St. Lo; four leagues north-east of Con-
tances.

AIGLE (L'), AQUILA, a small well-built town of
France, and capital of a district situated on the Rille, in
the department of Orne; 1 1/4 leagues north-east of Alençon.
Its principal commerce is corn, rams, and live stock. It
contains three parish churches, two convents, and a hospital;
and is surrounded with walls, and has six gates. N. lat. 45° 46'.
E. long. 1° 31'.

AIGLE, a town of Switzerland, in a part of the Lower
Valais, which belongs to the seignory of Berne, and forms
part of a canton. It is situated on a small river, which runs
into the Rhone, about a league below it; 12 leagues call
north-east of Geneva. The country about it has rich paf-
tures, and good wines and fruit; but it often suffers from
the inundations occasioned by the high mountains that bound
it towards the north. The salt that is collected from the
sulphur water, in its vicinity is refined at Aigle. N. lat. 46°
22'. E. long. 6° 51'.

AIGLE, a river of France, which waters part of the
government of Orleans, rises near Méc in Beauce, and dis-
charges itself into the Loir, between Châteaudun and
Cloye.

AIGLETTE, in Heraldry. See EAGLET.

AIGN, in Geography, a town of Germany, in the circle
of Bavaria, and archbishopric of Salzburg, near which is
a medicinal spring; two miles south-east of Salzburg.

AIGNAN, a town of France, in the department of Gers,
and district of Nogaro; seven leagues west of Auch.

AIGNÉY LÉ-DUC, a town of France, in the depart-
ment of the Cote d'Or; a district of Chatillon; 4 1/2 leagues
south-south-east of Chatillon. It is situated on a small moun-
tain, on the foot of which runs a stream of the same name.
Its chief sub falsity is derived from bleaching and the com-
merce of linen cloth.

AIGRE, a town of France in the department of the
Charente and district of Ruffiac; 5 1/2 leagues north of
Angoulême.

AIGREFEUILLE, a town of France in the department
of the Lower Loire and district of Clisson; 3 1/2 leagues
south of Nantes.

AIGREMONTE, a small town of Burgundy in France,
in the generality of Dijon.

AIGRETTE, in Ornithology, a name given by Buffon
to different species of ADEA, or the EGrets of other
authors.

AIGRETTE, in Zoology, a name given by Buffon to the
SIMIA AYGUL.

AIGUE MARINE, in Natural History. See AQUA
MARTIA.

AIGUEBELLE, in Geography, a small town of Savoy,
on the river Arc, surrounded by high mountains; five leagues
east from Chambery. The manufacture of this place is
fish.

AIGUEBELLE is also a small town of France, in the
department of the Drome; two leagues south-east of Mont-
telmair.

AIGUE-PERSE, a small town of France, in the de-
partment of Puy-de-Dôme, and late province of Auvergne;

18 miles north of Clermont and south of Paris. The
cold water of a fountain near it has the appearance of boil-
ing, and is said to be fatal to the animals that drink it. E.
long. 3° 20'. N. lat. 4° 55'.

AIGUES, a river of France, which runs into the Rhone,
near Orange.

AIGUESCAUVES, is situated in the valley of Ollas,
in the principality of Bearn, in France; and is famous for a
spring of water, foamy and sulphureous, and smelling like
a rotten egg, which is deemed salutary in many inward
and outward disorders.

AIGUES-MORTES, a town of France, in the de-
partment of the Gard and district of Nimes; 42 leagues
east south of Montpellier. The soil in the neighbourhood is
fertile, and the air wholesome on account of the flagrant
waters that surround it. It formerly stood on the sea and
had a harbour; but it is now above two leagues up the coun-
ty, and the harbour is filled up. This place is famous for
an interview which took place in 1538, between Charles V.
and Francis I. after 20 years of open hostility or secret enmity;
on which occasion they vied with each other in expressions
of respect and friendship. N. lat. 44° 34'. E. long. 5° 5'.

AIGUES-VIVES, a town of France, in the depart-
ment of the Gard and district of Sommieres, five leagues north-
est of Montpeller.

AIGUILLON, a town of France in the department of
the Lot and Garonne, and district of Tournes; six leagues north-west of Agen. This town carries on a con-
iderable trade in wines, brandy, and hemp. N. lat. 44° 1'.

AIGUINES, a town of France in the Var and district of Barjols; 5 1/2 leagues north-east of
Barjols.

AIGUINO, PADRE FRATE ILLUMINATO, in Biogra-
phy, of Brescia, author of a musical treatise, intitled, 'Il
Teforo illuminato di tutti i tuoni di Canto figurato;'—all
the tones or keys of figurative music illustrated, with some
choice secrets never before divulged. Venezia, 1581. Coun-
terpoint constitutes no part of this treatise.

AIGUICE', AIGUICE', or EUGUIS', in Heraldry,
a term applied to a cross, when its four arms are sharpened,
but so as to terminate in obtuse angles.

The crois aiguice' differs from the crois fitchée', in that
the latter goes tapering by degrees to a sharp point; whereas
the former of the four are tapering.

Croiss were so formed by the Christians in their pilgrim-
geages for the convenience of fixing them in the ground at
their devotion. In the English blazon, this kind of crois
is called a crois arde.

AIGURANDE, or AGURANDE, in Geography, a town
of France, in the department of the Indre, late province of
Berry, and district of La Chetre; 8 1/2 leagues south of Chas-
tauroux. The country round it furnishes fat cattle. N.
lat. 46° 27'. E. long. 1° 44'.

AII, a people of India, placed by Ptolemy on this side
the Ganges.

AIIES, a town of Transylvania, six leagues north-east of
Clauzenburg.

AIKMAN, WILLIAM, in Biography, a painter of
considerable eminence, the son of William Aikman, Esq.
of Cairney in Scotland, was born October 24th, 1682, and
intended by his father, who was an advocate at the Scots
bar, for his own profession; but the son declined the study
of the law, and devoted himself to the fine arts, par-
ticularly to that of painting. Having prosecuted his studies
for some time in Britain, he removed to Italy in 1707, and
resided for three years at Rome. He then travelled to Con-
stantinople and Smyrna, and in 1712 returned from Rome
to his own country; and in 1723 he settled in London, and followed the profession of painting under the patronage of the Duke of Argyle, the Earl of Burlington, Sir Godfrey Kneller, and some other encouragers of the arts of that period. For the Earl of Burlington he painted a large picture of the royal family, which his death prevented his finishing. It is now in the possession of the Duke of Devonshire. Towards the close of his life he painted many other portraits of persons of the first rank in England; and there are several portraits painted by him in Scotland, which are now in the possession of the Duke of Argyle, the Duke of Hamilton and others. This ingenious artist died in London, June 4th, 1731; and having lost his son about six months before, at the age of 17, their remains were removed to Edinburgh, and interred on the same day in the Greyfriars church-yard. Amongst his intimate friends we may reckon Mr. W. Somerville, the well-known author of the Chase, &c. Mr. Mallet, Mr. Allan Ramsay, and Mr. Thomson, each of whom paid an elegiac tribute to his memory. The following epitaph by Mr. Mallet, was engraved on his tomb.

"Dear to the good and wife, displeas'd by none, Here sleep, in peace, the father and the son; By virtue, as by nature, close ally'd, The painter's genius, but without the pride; Worth unambitious, wit afraid to shine; Honour's clear light, and friendship's warmth divine: The fan fair rising, knew too short a date; But, oh! how more fervor the father's fate! He saw him torn untimely from his side, Felt all a father's anguish—wont and died." Mr. Thomson's poem on the death of Mr. Aikman, closes with the following lines:

"A friend, when dead, is but remov'd from sight, Sunk in the lute of eternal light; And when the parting forms of life are o'er, May yet rejoin us on a happier shore. As those we love decay, we die in part; String after string is fever'd from the heart, Till loof'd life, at last, but breathing clay, Without one thought, or wish to say. Unhappy he, who late'd feels the blow. Whole eyes have wept o'er every friend laid low; Drange'd ling'on from partial death to death, Till dying, all he can reign is breath."

For the last eight lines, see Thomson's Works, vol. ii. p. 283.

In his style of painting, Mr. Aikman seems to have aimed at imitating nature in her plainest simplicity; his lines are soft, his shades mellow, and his colouring mild and harmonious. His touchses have neither the force nor harshness of Rubens; nor does he seem, like Reynolds, ever to have aimed at adorning his portraits with the elegance of adventitious graces. His mind, tranquil and serene, delighted rather to wander with Thomson in the enchanting fields of Temps, than to burth, with Michael Angelo, into the rude scenes of the terrible and sublime. His compositions are distinguished by a placid tranquillity of ease rather than a striking brilliancy of effect; and his portraits may be more readily mistaken for those of Kneller than any other eminent artist; not only because of the general resemblance in the drests, which were those of the times, as they were contemporaries, but also for the manner of working, and the similarity and bland smoothness of their tints. Biog. Dict.

AILAH, formerly AILANA and ELLATA of Scripture, a minned town of Arabia Petra, on the north west coast of the gulf of Akaba or Allaha; about 140 miles south-east of Suez. N. lat. 29° 20'. E. long. 35° 0'.

AILAN, a river of Siberia, which runs into the Penzinskij gulf near Okiansk.

AILANTHUS, derived from the Ambon name Ailanto, which denotes the tree of heaven, so called on account of its lofty growth, in Botany, a genus of plants, the claft and order of which are not ascertained. Prof. Martyn refers it to the polygonum monacica, Schreber to the diecica candrea, and Gmelin to the diecica trigyna. Its characters are, that it has male, female, and hermaphrodite flowers. The calyx of the male, is a one-leaved, five-parted, very small perianthium; the corolla has five petals, lanceolate, acute, convolute at the base and spreading; the flower has ten filaments, composed of the length of the corolla; the anthers are oblong and vermalte. The calyx of the female is like that of the male, permanent; the corolla the same; the pistilium has from three to five germs, curved inwards; the styles are lateral and the stigma capitate; the pericarpium has as many capsules as there are germs, composed of membranaceous, filamen-shaped, acute, on one of the edges emarginate; the seeds are follicular, lea-shaped, bony, close to the corolla in the fruit. The calyx of the hermaphrodite is the same with that of the male and female; the corolla the same as in the male; the pistilium has two or three filaments, as in the male; the pistilium, pericarpium and seed as in the female. There is one species, Ailantus glandulosa, or tall antilthus, which is a tree with a straight trunk, 40 or 50 feet high, a native of China, and first raised in England about the year 1751. It grows tall in our climate, and as it rises to a considerable height, it is proper for ornamental plantations. A retinuous juice, which soon hardens, flows from the wounded bark. The wood is hard, heavy, glossy like fatin, and sucbelute of a very fine polish. This is the Rhus Sinews, &c. of Ellis. See Phol. Trans. vol. xxxix. p. 870, and vol. i. p. 436. Martyn's Miller.

AIL, or AILLE, formed of Fr. aicul, aicus, grandfather, in Law, a writ which lies where the grand-father, or great-grandfather, called defails, was seized of lands or tenements in fee-fimple, on the day he died: and he living at or after the same day, and disposing the heir or grandchild. See AYMENT.

AILLEPONS, a diminutive of the French aile, wing, in Natural History, petty wings, a French term expressing two small flashy sublustrera, resembling parts of wings, or young and just growing wings, and found in the two-winged flies, situated at the root of the larger wings. Reaumur.

AILLES visces, in Natural History, a French term used to express the wings of a series of insects, which feed of a middle nature, between the fly and the butterfly kind, and are therefore called papilion nouches by thele writers. The wings of these insects are in part covered with dust, or feals, and in part free from it and transparent. In these parts they look glossy; whence their name—signifying glossy wings. See AILLESBURY, in Geography. See AYLESBURY.

AILLAN-SUR-THOLON, a town of France, in the department of the Yonne, and district of Irigny; 35 leagues north-west of Auxerre.

AILLAS, a village of France, in the department of the Gironde, and district of Bazas; two leagues north-east of Bazas.

AILLY, a village of France, in the department of the Somme, and district of Abbeville; five leagues north-west of Amiens.

This is also the name of a town of France, in the same department. and district of Montdidier; three leagues south-east of Amiens.

AILLY, Peter D', in Biography, bishop of Cambray, and a bigotted ecclesiastic, was born of an obscure family at Compiègne in 1530. He finished his studies at Paris, and gave
gave proofs of a superior understanding at the college by his treatises "On Logic," "On the Nature of the Soul," and "On Meteors." Before he was appointed grandmaster of the college of Navarre, where he had been educated. His zeal for the Catholic faith contributed to his advancement as much as his learning. Having pleased in 1387, in favour of the miraculous conception, before the pope, he was appointed coadjutor to Charles VI, and chancellor of the University, and in 1391 bishop of Cambrai. He distinguished himself on various occasions as an advocate for the doctrines and ceremonies of the Church; and at the general council of Constance, which lasted from the year 1414 to the year 1418, he was principal agent in the proceedings, which convicted Wickliff and Hes of heresy, and at last brought the latter to the stake, upon whom he pronounced the sentence of death. Notwithstanding his zeal against heresy, he is said to have been a friend to reformation, and that he wrote a book "On the Reformation of the Church", which, however, is not found among his works. His ideas of reformation must have been very partial and restricted, as he took pains to obtain a general council for terminating schism, and was attached to the absurdities of judicial annihilation. On this subject he wrote a treatise, in which is maintained, that Noah's flood, the birth of Christ, and other such miraculous events, might have been predicted by astrology. He died in 1425, as some say, and according to others in 1429 or 1430, with the character of "the Eagle of France, and the indefatigable Mallet of Heretics." The epitaph on his tomb is as follows:

"Mors rapuit Petrum; petram fulbit putre corpus:
Sed petram Christum spiritus ipse petit."

i. e. "Death seizes Peter, and under this stone,
His body decays; his spirit is flown
To Jesu his rock."

Of his numerous works several treatises and sermons were printed at Strafburg in 1455; his "Quæstiones in Sphenarch Mundus" was printed at Paris in 1455, and at Venice in 1504; his "Treatise of Meteors" appeared at Paris in 1504, and his "Life of Cælætlin V." in 1559. Cave Hill. Lit. vol. vii. Append. p. 842. Gen. Dict. AILRED, Ethelred, or Ealred, abbot of Revesby, in Lincolnshire, was born in 1009, and educated in Scotland, with Henry, son of David. He declined eclesiastical preferment, and lived in studious retirement. His "History of the War of the Standard in the reign of Stephen;" "Genealogy of the English Kings;" "History of the Life and Miracles of Edward the Confessor;" and "History of the Nun of Watthun," written in Latin, are extant in the Decem Scritores, published by Tsywden, in London, 1652. His "Sermons," "Mirror of Charity," treatise "On the Child Jesus," and another "On Spiritual Friendship," were published at Douay, in 1632, and may be found in the Bibliotheca Patrum, tom. xxvii. He died in 1166. Cave Hill. Lit. vol. ii. p. 227. Biog. Brit. AILSA, in Geography, an inflated rock near the isle of Bute, in Scotland, about two miles in circumference and 600 feet high, accessible on the north-east side, and the habitation of goats and rabbits, and sea-fowl, particularly the Solan gull, some of which are taken for food, and others for their feathers. The banks about it are well-rocked with cod and other fish.

AIMAKAN, a river of Siberia, which runs into the sea of Ochotkoi. N. lat. 54° 44' E. long. 139° 14'.

AIMARGUES, or AVMARGUES, a town of France, with the title of a barony, in the department of the Gard, and diocese of Nîmes, situated in a marshy country on the river Vézère; 5 leagues west of Arles, and 54 south of Nîmes. N. lat. 44° 5'. E. long. 3° 4'.

AIMÈ, AIMO, or AXIMA, a small town of Savoy, on the river Ère; 6 leagues north-east of Molfing.

AIMIE, one of the Soubs, or grand divisions of Hindostan, according to the Ayeen-Akberry, or distribution of the emperor Akbar, is entirely in the possession of Sindah and the Mahtrasses, and contains seven curshars or countires, and 197 pargonnas or hundreds. Its revenue is 22,841,507 daams, 920 daams being equal to a pound sterling. It has 56,700 cavalry, and 347,000 infantry.

AIMON, in Biography, a Benedictine Monk, wrote about the year 849, and is chiefly known as the author of a "History of France."

AIMONTE, in Geography, lies on the east side of the river Guadanua near its mouth, which is the boundary from Portugal on the west, and is one of the belt havens on the whole coast. N. lat. 37° 5'. W. long. 7° 15'. See AYAMONTE.

AIMOUTIER, a town of France, in the department of Upper Vienne, and district of St. Leonard; seven leagues south-east of Limoges.

AIN, θυρίς, signifying fountain, is an initial word prefixed to several Hebrew and Arabic appellations of places.

Ain, a river of France, whence one of the departments derives its name. It rises in Mount Jura, near Nozerol, and after traversing a course from North to South of about 55 leagues, discharges itself into the Rhone, about five leagues above Lyons. The department of the Ain is one of the four departments, which are comprised of the ci-devant Breffy, Bugey, and Velay, and principality of Dombes; and into which the former province of Bourgogne is divided. It is bounded on the north by the department of Jura; on the east, by those of Leman and Mont Blanc; on the south, by the river Rhone, which separates it from that of Iure; and on the west, by the department of the Rhone. Its surface is about 1,077,432 square acres, or 549,205 hectares; its population amounts to about 248,700 persons; and it is divided into four communal districts. Its chief town is Bourg.

Aix, a town of Asia, in the Arabian Irak; 50 leagues north of Baffora.

AINAD, a town of Arabia, in the province of Hadramaut.

AINAY-LE-CHATEAU, a town of France, in the department of Allier and district of Cerilly; eight leagues north-west of Moulines.

AINCREVILLE, a town of France, in the department of the Meuse, and district of Stenay; one league south-west of Dun.

AINEB-GUL, a town of Arafic Turkey, in Notola; 40 miles north-west of Derginzu.

AINEL-CALU, a town of Africa, in the province of Tremean, and kingdom of Fez.

AIN EL CALU, a town of Aïn, in the province of Djerbeker; 16 leagues south-west of Molfi.

AINLING, a market town of Germany, in Upper Bavaria; ten miles north-west of Augsburg.

AINOD, a town of Germany, in the duchy of Sireia; eight miles north of Ciley.

AINSA, a small town of Spain, in the kingdom of Aragon, on the river Ara; 6 leagues north of Balbaito.

AINSWORTH, Henry, in Biography, an eminent Nonconformist divine, and Biblical commentator, flourished at the close of the 16th, and commencement of the 17th century. About the year 1590, he united with the Brownists; and after struggling for some years with the dangers and troubles to which persons of this persuasion were exposed by the indirect zeal of the bishops and the intolerance of
of queen Elizabeth, he retired with many others of similar sentiments to Holland. At Amsterdam, Ainsworth and one of his brethren in exile, whose name was Johnfon, established a church; and in 1662 published a confession of faith of the people called Brownists. But trivial points of discipline occasioned dissensions in the church, and these two leaders, with their respective parties, though they had fell from perfection at home, could not tolerate each other, nor live harmoniously in the same city. Johnfon with his adherents removed to Embiden, where he soon died, and his congregation was disolved. Ainsworth withdrew to Ireland; and after some time returned to his friends at Amsterdam, and continued with them till his death, which was sudden, and not without suspicion of violence. The circumstance that is said to have occasioned it was somewhat extraordinary and deserves to be mentioned. Having found a diamond of great value in the streets of Amsterdam, he advertised it; and when the owner, who was a Jew, came to demand it, he offered him any acknowledgment which he would desire. Ainsworth, though poor, would accept of no remuneration but a conference with some of the Jewish rabbis, upon the prophecies of the Old Testament relating to the M. Shiah, which the Jew promised; but not having interest sufficient to obtain it, some have supposed that through flame or vexation, or from some other motive, he poisoned Ainsworth. This event happened about the year 1620. Mr. Ainsworth's distinguished talents and biblical learning were universally acknowledged. To the Bishop Hall paid a tribute of respect, even whilst he was writing against the party to which he belonged; and his annotations on the scriptures, though less regarded in England than they deserved, were much sought after and commended by persons of various sects in other countries. These "Annotations" appeared at different times; but in 1627 they were printed in one volume in folio, and another edition appeared in 1639, which is now become very scarce. To this work, it is said, the learned Lightfoot was much indebted. Of the other pieces of Ainsworth, we shall only mention his "Arrow against Idolatry," Neal's Hist. of the Puritans, vol. 1 p. 380. 447. 448. Biog. Brit.

AIR

AINSWORTH, Robert, an learned grammarian, was born at Woodyale, near Mancheller, in Lancashire, in the year 1665, and was educated at Bolton in the same county, where he afterwards kept a school. From Bolton he removed to Bethal Green, near London, and there continued the profession of school-master. At this period he published his "Short Treatise of Grammatical Instruction." After pursuing in different places the labour of tuition till he had acquired a decent competency, he retired from business; and amused himself by searching the shops of brokers for old coins and other valuable curiosities, which he purchased at a small expense. He died at London in 1743, and was buried at Poplar. The following monumental inscription was written by himself:

"Rob. Ainsworth et uxor ejus, admodum fames, Dormituri, veltem detritam hic exurent, Novam, primum manu fragrentes, indaturi, Damn fat. mortalis, fapias, et reficie finem, Hoc audacit manes, hoc curit Amaramides."

Thus imitated—"Here Robert Ainsworth and his wife, Put off the worn-out veil of life; Heping the morn will soon appear, When they a brighter robe shall wear. To thy reflection, mortal friend, Th' advice of Moses I commend, Be wise, and meditate thy end." To Ainsworth's judgment, industry, and perseverance in compiling a dictionary for the use of schools, great commendation is due. This useful work was undertaken by him in 1744; and after many interruptions and delays was completed in 1756, and dedicated to Dr. Mead. It has been since improved by Patrick, Ward, Young, and other learned men; and in 1773 there appeared a new edition, farther enlarged and improved by Morell. We have an useful abridgment of this dictionary by Mr. Thomas, in two large 8vo volumes. Patrick's Pref. to the second edition of Ainsworth's Theaurus. Biog. Brit.

AINZAMIEL, in Geography, a town of Africa, in the province of Tremecen and kingdom of Fez.

AIONAMA, or AIONANO, a town of European Turkey, on a gulf of the same name, in the province of Rodalia; 14 leagues south-east of Salonnico. Cape Paillois is the south-east limit of the gulf, and Cape Dramiso its north-east extremity. The south point is about N. lat. 39° 50'; and E. long. 24° 40'.

AJOVEA, in Botany, a genus of the 'hexandra monogynia claefs and order; the characters of which are, that the calyx is single-leaved and tridentated, the corolla has three petals, the filaments are terminated with two glandules, the antheres are doubly excrated, the stigma is divided in five segments, and the fruit is a roundish, single-celled, monoporous berry. There is one species, viz. A. guainiensis; which grows in the forests of Guiana.

AIOTOCHTLI, in Zoology; the Mexican name of the Armadillo.

ALPINIXIRA, in Ichtyology, the name of an American fish, more usually known by the name of Pudiano. It is a small fish, of the shape of the perch, with a purple back, and yellow sides and belly. Maregrave.

AIR, in Physics, a thin, fluid, elastic, transparent, ponderous, comprifensible, and dilatable body; surrounding the terraqueous globe to a considerable height. Air was confidered by some of the ancients as an element; but then, by element, they underltood a different thing from what we do. See Elements.

It is certain, that air, taken in the popular sense, is far from the simplicity of an elementary substance; though some of its properties and ules in a state of combination with various substances, from which it has been extirpated by modern analyses, may entitle it to this appellation. Hence air may be disinguished into proper or elementary, and vulgar or heterogeneous.

AIR, elementary, or Air properly so called, is a subtle, homogeneous, elastic fluid; the bals, or fundamental ingredient of the atmospheric air, and that which gives it the denomination.

In this sense, it likewife enters into the composition of moth, or perhaps all bodies, existing in them under a fold form, deprived of its elasticity and moot of its distinguishing properties, and serving as their cement, and the univerfal bond of nature; but capable, by certain procces, of being disengaged from them, recovering its elasticity, and refbruishing the air of our atemphere. See Hale's Vegetable Statics, chap. vi. See Gas.

The peculiar nature of this aerial matter we know but little of; what authors have advanced concerning it being chiefly conjectural. We have no way of altogether separating it from the other matters with which in its puret state it is more or less combined, and consequently no way of ascertaining, with satisfactory evidence, its peculiar properties, abstractedly throug of other bodies.

Dr. Hook, and some others, maintain, that it is the same
fame with their other, or that fine, fluid, active matter, diffused through the whole expanse of the celestial regions; which coincides with Sir I. Newton's 

fable medium, or spirit. In this view it is supposed to be a body 

fui generis, ingenere, incorruptibile, immutabile, pereant in all places, and in all bodies. 

Others, considering only its property of elaticity, which they account its effental and constituent character, suppose it to be mechanically producible; and that its laws are mutually the same in all bodies, so modified and altered, as to become permanently elastic. Sir Isaac Newton observes, that the particles of d.efe, compact, and fixed substances, cohering by a strong attractive force, are not separable without a vehement heat, or perhaps not without fermentation; and such bodies being at length rarefied by such heat or fermentation, become true permanent air; and distinguished from vapour, which is only apparent, or transient air, as is evident from the experiment with the siphile. 

Optics, Qu. 31, p. 371; 372. ed. 2. See Air, atmospheric. 

Air, vulgar or heterogeneous, is a coalition of corpuscles of various kinds, constituting together one fluid mass, in which we live and move, and we are continually receiving and expelling by respiration. The whole assemblage of this makes what we call the atmosphere; where this air, or atmosphere, terminates, there ether is supposed to commence; which is distinguished from air by its not making any sensible refraction of the rays of light, as air does. 

Air, in this popular and extensive meaning of the term, is acknowledged by Mr. Boyle to be the most heterogeneous body in the universe. Boerhauve shews it to be an universal chaos, or colliuvia, of all kinds of created bodies. Besides the matter of light or fire, which continually flows into it from the heavenly bodies, and probably the magnetic effluvia of the earth; whatever fire can volatilize is found in the air. 

Hence, for instance, 1. The whole volatil kingdom must necessarily be found in it; for all of that tribe, as fall, sulphur, stones, metals, &c, are convertible into flame, and thus capable of being rendered part of the air. Gold itself, the most fixed of all natural bodies, is found to adhere close to the sulphur in mines, and thus to be raised along with it. Mr. Boyle observes, that besides the false effluvia of the common fames, such as the nitrous, vitriolic, marine, &c, there may be many compound kinds of falls in the air, which we have not on earth, arising from different feral spirits, fortuitously meeting and mixing together. Thus, the glases windows of ancient buildings are sometimes observed to be corroded, as if they had been worm-eaten; though none of the fimple falls above-mentioned have the faculty of corroding glass. 

Sulphur too must make a considerable ingredient of the air, on account of those many volcanos, grottoes, caverns, and other spiceries chiefly affording that mineral, diffused through the globe. 

2. All the parts of the animal kingdom must also be in the air: for besides the copious effluvia continually emitted from their bodies, by the vital heat, in the ordinary process of perspiration; by means of which an animal, in the course of its duration, impregnates the air with many times the quantity of its own body; we find that any animal when dead, being exposed to the air, is in a certain time wholly incorporated with it. 

3. As to vegetables, none of that class can be supposed wanting; since we know that all vegetables, by putrefaction, become volatile. 

The associations, separations, attritions, dissolutions, and other operations of one sort of matter upon another, may likewise be considered as sources of numerous other neutral, or anonymous bodies, unknown to us. 

4. Water is also diffused through the air in great abundance. Many familiar instances might be alleged to this purpose. A bottle of wine, when taken out of the cellar in the dead and hottest day of summer, will soon be covered with a dense vapour, which is water deposited by the air. The same appearance is observed on the outside of any metallic vessel, which, in warm weather, contains water cooled by ice or the solution of salt, or even spring water, which is some degrees colder than the air. For other facts of similar kind, see Water. 

Air, in this general sense, is one of the most considerable and universal agents in all nature; being concerned in the preservation of life, and the production of most of the phenomena relating to our world. Its properties and effects, including a great part of the researches and discoveries of the modern philosophers, have in a considerable degree been reduced to precise laws and demonstrations, in which form they make a very extensive and important branch of the mixed mathematics, called pneumaticks. 

Air, mechanical properties and effects of. The most considerable of these are its fluidity, weight, and effluviality. 

I. Fluidity. That the air is a fluid, is evident from the easy passage it affords to bodies through it; as in the propagation of smells, and other effluvia, and the easy conveyance it affords to sounds: for these and similar effects prove it to be a body, whose parts give way to any force impressed, and, in yielding, are easily moved among themselves; which is the definition of a fluid. Besides, it is certain, that no condensation by pressure, nor any degree of cold that has ever yet been produced, natural or artificial, has been sufficient to deprive it of its fluidity. It is true, indeed, that real permanent air may be extracted from solid bodies, and may be also absorbed by them; and in this state it must be very much condensed; but under what form it exists in the bodies, or how its particles are combined together, the researches of philosophy and chemistry have not yet been able to explore. 

They who, with the Cartesians, make fluidity consist in a perpetual intermixture of the parts, find that air answers also to that character: thus, in a darkened room, where the species of external objects are brought in by a single ray, they appear in a continual fluctuation; and thus even the more accurate thermometers are observed never to remain a moment at rest. 

The cause of this fluidity of air is attributed by some later philosophers to the fire intermixed with it; without which, they imagine, the atmosphere would harden into a solid impenetrable mass. And hence, the greater the degree of fire, the more fluid, moveable, and pervious is the air: and thus, as the degree of fire is continually varying, according to the circumstances and position of the heavenly bodies, the air is kept in a continual reciprocation. See Buffon's Hist. Nat. Supp. vol. i. Hence, in a great measure, it is said, that on the tops of the higher mountains, the fumes of smelling, hearing, &c, are found very feeble. The increased rarity of the air at a considerable height may account for this effect; but the above hypothesis is contradicted by the more sensible experience of cold: the air, near the surface of the earth, deriving greater heat from the reflected than from the direct rays of the sun. See Mountains.

3 M 2 II. Weight
II. Weight or gravity. Of this property of air the ancients were not altogether unapprised; though their sentiments on the subject were confused and unsatisfactory. Aristotle (de Celo, lib. iv. c. 1. op. tom. i. p. 435.) observes, that all the elements, fire excepted, have weight; and he adds, that a bladder inflated with air, weighs more than when it is quite empty. Plutarch (de Placitli. lib. i. c. 13. tom. ii. p. 333.) and Stobaeus (Eclog. Phyf. lib. i. c. 17. p. 32.) Ed. 1665.) quote Aristotle as teaching, that the weight of air is between that of fire and earth; and he himself, treating of respiration, (cap. viii. oper. tom. i. p. 722.) reports the opinion of Empedocles, who ascribes the cause of it to the weight of the air, which by its pressure inures itself with force into the lungs. Plutarch (de Placitli. lib. iv. c. xxii. tom. ii. p. 908.) expresses, in similar terms, the opinion of Ailepides on this subject; and represents him as laying, that the external air, by its weight, opened its way with force into the breast. Heron of Alexandria, in his treatise intitled "Spiritualia," constantly applies the efficacy of the air to produce such effects as arc sufficient to convince us that he well understood the property of it; and Ctesibius, admitting the principle of the air's efficacy, invented windmills and other machines which have been considered as a modern contrivance. Philo of Byzantium (in van. Math. lib. v. p. 77. Ed. Paris,) de- }
A R.

it. That this is the case, is evident: because, if the whole apparatus be included in the receiver of an air pump, the mercury will fall in proportion as the air is exhausted; and on gradually letting in the air again, the mercury re-ascends to its former height. This makes what is usually called the Torricellian experiment.

To say no more, we can actually weigh air; for a vessel, full even of common air, is found, by a very nice balance, to weigh more than when the air is exhausted; a quart of air weighing about 17 grains; and the effect is proportionally more sensible, if the same vessel be weighed full of condened air, and more especially in a receiver void of air.

The weight of air is continually varying, according to the different degrees of heat and cold, and the concurrence of other causes. Paschal observed it in France; and Des Cartes in Sweden, in 1650. Mr. Boyle, and others, observed it in England, in 1656. Some observers noticed, that it was generally greatest in the night and in winter; and that its variations were most considerable during winter; and in the northern regions. Hence arose the application of the barometer to the uses of a weather-glass. Ricciolus estimates the weight of air to that of water, to be as 1 to 1000; Mercurius as 1 to 1500; or 1 to 1535; Lana, as 1 to 640; Galileio only makes it as 1 to 400. Mr. Boyle, by a more accurate experiment, found it about London, as 1 to 938: and thinks, all things considered, the proportion of 1 to 1000 may be taken as a medium; for there is no fixing any precise ratio, since not only the air, but the water itself, is continually varying.

Besides, experiments made in different places necelarily vary, on account of the different heights of the places, the feasons of making the experiment, and the different densities of air corresponding to these circumstances. It may be added, however, that by experiments made since, before the Royal Society, the proportion of air to water was first found as 1 to 840; then, as 1 to 852; and a third time, as 1 to 860. Phil. Trans. N° 181. And lately, by a very simple and accurate experiment of Mr. Haukflee, the proportion was settled as 1 to 885. Phys. Mechan. Exper. But these experiments being all made in the summer months, when the barometer was 28 inches high, Dr. Jurin thinks, that at a medium between heat and cold, when the barometer is 30 inches high, the proportion between the two fluids may be taken as 1 to 800; which agrees with the observation of the honourable Mr. Cavendish, the thermometer being at 50°, and the barometer at 29 inches. Phil. Trans. vol. lv. p. 152.

Sir George Shuckburgh, (Phil. Trans. vol. lvii. p. 560.) by a very accurate experiment, found it as 1 to 836; the barometer being at 29.27 inches, and the thermometer at 50°; and the comparative gravity of quicksilver to air, as 1184.6 to 1. The medium of all these is about one to 832 or 835, when reduced to the pressure of 30 inches of the barometer, and the mean temperature of 50° of the thermometer. Upon the whole, it may be concluded, that when the barometer is 30 inches, and the thermometer at the mean temperature of 50°, the density or gravity of water is to that of air as 835:1; that is, as 2500 to 1, or as 2500 to 3; and for any changes in the height of the barometer, the ratio varies proportionally; and also that the density of the air is altered by the same part, for every degree of the thermometer above or below temperate. This number, which is a very good medium, having the fraction 4, gives exactly 13th of an ounce for the mean weight of a cubic foot of air; the weight of the cubic foot of water being just 1000 ounces avoidupois, and that of quicksilver equal to 17600 ounces.

Air, then, being heavy and fluid, the laws of its gravitation, or pressure, may be inferred to be the same as those of other fluids; and consequently its pressure must be proportional to its perpendicular altitude. This is also confirmed by experiment. For removing the Torricellian tube to a more elevated place, where the incumbent column of air is shorter, a proportionally shorter column of mercury is sustained; and that nearly at the rate of 100 feet for 1/3 of an inch of quicksilver. On this principle depend the structure and office of the barometer.

From hence, also, it follows, that the air, like all other fluids, must pres equally every way. This is confirmed by observing, that soft bodies sustain this pressure without any change of figure, and brittle bodies without breaking; though the pressure upon them be equal to that of a column of mercury thirty inches high, or a column of water of thirty-two or somewhat more feet. It is obvious, that no other canfe can preserve such bodies unchanged, but the equal pressure on all sides, which results as much as it is reduced. And hence, upon removing or diminishing the pressure on one side only, the effect of the pressure is soon perceived on the other. For the quantity and effect of this pressure of the atmosphere on the human body, and on the surface of the earth, and the laws of different heights, see Atmosphere.

From the gravity of the air, considered in connection with its fluidity, several of its uses and effects may be easily deduced.

1. By means of its weight, &c. it closely invells the earth, with all the bodies upon it; and constrings and binds them down with a force amounting, according to the computation of M. Paschal, to 2332 pounds weight upon every square foot, or upwards of 15 pounds upon every square inch. Hence it prevents, e. gr. the arterial vessels of plants and animals from being too much distended by the impetus of the circulating juices, or by the celtic force of the air, to plentifully contained in the blood.—Thus we see, in the operation of cupping, that, upon a diminution of the pressure of the air, the parts of the body grow tumid; which necessarily alters the maner of the circulation through the capillaries, &c.

The same cause hinders the juices from oozing and escaping through the pores of their containing vessells: this is experienced by inch as travel up high mountains, who, in proportion as they ascend, find themselves more and more relaxed; and at length become subject to a spitting of blood, and other hemorrhages; because the air doth not sufficiently constringe the vessels of the lungs. Similar effects are observed in animals that are enclosed under the receiver of the air-pump, who, as the air is taken from them, pant, fiew, vomit, and discharge their urine and excrements. See Vacuum.

2. The weight of the air promotes the mixture of contiguous fluid bodies. Hence many liquids, as oils and fats, which readily and spontaneously mix in air, remain, on the removal of it, in a state of separation.

3. This gravity of air does in some cases determine the action of one body above another.

4. To the same principle are chiefly owing our winds, which are only air put in motion by some alteration in its equilibrium. It is the weight of the air that causes the clouds and vapours to float in it.

111. Elasticity—or a power of yielding to an imprefion by contracting its dimensions; and, upon removing or diminishing the impreffive caufe, of returning to its former figure or plane, is another quality of air. This celtic
force has been long accounted the distinguishing property of air; the other properties hitherto enumerated being common to it with other fluids; though, from late experiments, it appears more than probable, that the capacity of being compressed and expanded is not peculiar to air. See Water and Compression.

This property of air has been long known, and was ascertained by some experiments of lord Bacon, who, upon this principle, constructed his vitrum calendare, the first thermometer. Bacon. Nov. Organ. lib. ii. aph. 13.

Of this power we have numerous proofs.—Thus, a blown bladder being squeezed in the hand, we find the included air feebly reful; for that, upon causing to comprefs, the cavities or impressions, made in its surface, are readily expanded again, and filled up.

On this property of elasticity, the structure and office of the air-pump depend.

Every particle of air always exerts this niusus, or endeavour to expand, and thus strives against an equal endeavour of the ambient particles, whose resistance happening by any means to be weakened, it immediately diffuses itself into an immense extent. Hence it is, that thin glass bubbles, or bladders filled with air, and exactly closed, being included in the exhausted receiver of an air-pump, burst by the force of the included air. So a bladder quite flaccid, containing only the smallest quantity of air, swells in the receiver, and appears quite full. The same effect is also found by carrying the flaccid bladder to the top of a high mountain. This experiment shews, that the elasticity of air is different from that of solid bodies; after these have been comprized, they only resume the figure which they had lost; whereas air, when the compressing force is removed, not only dilates, but occupies a much greater space than it did before; nor is it easy to assign the limits of its expansion. From some experiments of Col. Roy (Phil. Trans. vol. 67. p. 708.) it would seem, that the particles of air may be so far removed from one another, by the diminution of preffure, as to leave a very great part of their elastic force. It also appears that the elastic force of common air is greater than when its density is considerably augmented or diminished by an addition to, or subtraction from, the weight with which it is usually loaded; a fact which contradicts the experience of Boyle, Mariotte, and others. These experiments also shew, that the elastic force of moist air is greatly superior to that of dry air; in some cases the total expansion of the former was more than four times that of the latter.

It has been questioned among philosophers, whether this elastic power of the air is capable of being destroyed or diminished. Mr. Boyle made several experiments, with a view to discover how long air, brought to the greatest degree of expansion to which he could reduce it in his air-pump, would retain its spring; and could never observe any sensible diminution. Delagiers found that air, after having been enclosed for half a year in a wind-glass, had lost none of its elasticity; and Roberval, after preserving it in the same manner for sixteen years, observed, that its expansible force was the same as if it had been recently condensed. Nevertheless, Mr. Hauksbee concludes, from a later experiment, that the spring of the air may be so disturbed by a violent preffure, as to require some time to return to its natural tone. Dr. Hales inferred, from a number of experiments, that the elasticity of the air is capable of being impaired and diminished by a variety of causes, and of being actually destroyed, so that it is reduced to a fixed state. Hence he also concludes, that elasticity is not an essential immutable property of the particles of air; and that the atmosphere is a chaos, confounding not only of elastic, but also of unelastic air-particles, which copiously float in it. Stautical Essays, vol. i. p. 316.

The weight or preffure of the air, it is obvious, has no dependence on its elasticity; but would be the same, whether the air has such a property or not. But the air being elastic, is necessarily affected by the preffure, which reduces it into such a space, as that the elasticity which re-acts against the compressing weight, is equal to that weight. Indeed, the law of this elasticity is, that it increases as the density of the air increases; and the density increases as the force increa5es by which it is preffed. Now, there must necessarily be a balance between the action and re-action; i.e. the gravity of the air, which tends to comprefs it, and the elasticity of the air, which endeavours to expand it, must be equal. And the elasticity of the air not very different from its natural state, being as the density will, of course be inversely as the space which it occupies.

Hence the elasticity increasing, or diminishing, universally, as the density increas5es or diminishes, i.e. as the distance between the particles diminishes, or increases, it is no matter whether the air be comprized and retained in such a space, by the weight of the atmosphere, or by any other means; it must endeavour, in either case, to expand with the same force. And hence if air near the earth be pent up in a vessel, so as to cut off all communication with the external air, the preffure of the inclosed air will be equal to the weight of the atmosphere. Accordingly, we find mercury sustained to the same height, by the elastic force of air inclosed in a glass vessel, as by the whole atmospheric preffure.

On the same principle air may be artificially conden5ed; and hence the structure of the air-pump.

Although it may be admitted as a general principle, that the density of the air is proportional to the force by which it is comprized, as the experiments of Mr. Boyle and Mr. Mariotte have evinced; yet in the cave of condenced air, the rule will not be strictly applicable. When air is very forcibly comprized, so as to be reduced to 2/4 of its ordinary bulk, it makes a greater resistance, and requires a stronger force to comprim5 it than the above principle allows. Hence it appears probable, that the particles of air cannot, by any possible preffure, be brought into perfect contact, or form a solid mass; and therefore that the degree of condensation has its limit. Thus also in very high degrees of rarefaction, the elasticity is decreased rather more than in an exact proportion to the weight or density of the air; whence it may be concluded, that there is a limit to its rarefaction or expansion, so that it cannot be expanded to infinity. Nevertheless, the utmost limits to which air of the density which it possesses at the surface of the earth, is capable of being comprized, have not been ascertained. Mr. Boyle reduced it at one time to the 14th part, and at another to the 40th part of its natural space. (Works, vol. iii. p. 527.) Dr. Halley says, that he has seen it comprized so as to be 60 times denser than its natural state, which is farther confirmed by Mr. Papin, and M. Huygens. Dr. Hales (Stat. Exp. vol. ii. p. 343, &c.) by means of a preff, conduced it 38 times; and by freezing water in an iron ball, or globe, into 1522 times less space than it naturally occupies; in which state its density or specific gravity must be nearly double that of water; and as water is very slightly comprimable, the particles of air must be in their nature different from those of water; since it would otherwise be impossible to reduce air to a bulk 800 times less than that which it occupies in its natural state.

However, Dr. Halley has ascertained, in the Philosophical Transactions, (Abr. vol. ii. p. 17.) that from the experimen5
AIR.

M. Amontons first discovered that air will expand, in proportion to its density, with the same degree of heat. On this foundation, the ingenious author has a difficulty to prove, that the spring and weight of the air, with a moderate degree of warmth, may enable it to produce even earthquakes, and other of the most vehement commotions of nature.

According to the experiments of this author, and M. de la Hire, a column of air on the surface of the earth, 39 fathoms high, is equal in weight to three lines depth of mercury; and it is found that equal quantities of air poise spaces reciprocally proportioned to the weights with which they are press'ed; the weight of the air, therefore, may fairly be supposed to fill the whole space poise'd by the terrestrial globe; which would be equal to a cylinder of mercury, whose base is equal to the surface of the earth, and its height containing as many times three lines, as the atmospheric space contains orbs equal in weight to 30 fathoms of that wherein the experiment was made. Hence, taking the density of all bodies, &c. gold, whose gravity is about 4,630 times greater than that of air in our orb, it is easy to compute, that this air would be reduced to the same density as gold, by the pressure of a column of mercury 14,630 times 28 inches high, &c. 4096,640 inches, since the bulks of air, in that case, would be in the reciprocal ratio of the weights by which they are press'ed. These 4096,640 inches, therefore, express the height at which the barometer must stand, where the air would be as heavy as gold, and the number 21,040,508 lines, the thickness to which our column of 36 fathoms of air would be reduced in the same place.

Now, we know, that 43,518 fathoms, which is the depth, where the above pressure, and consequent reduction take place, are only the 74th part of the semidiameter of the earth; and therefore, beyond that depth, whatever matter exists, it must be heavier than gold. It is not improbable, therefore, that the remaining sphere of 6,451,638 fathoms diameter may be full of dense air, heavier by many degrees than the heaviest bodies which we know. Hence, again, as it is proved, the more air is press'ed the more does the same degree of fire increase the force of its firing, and render it capable of a proportionately greater effect; we may infer, that a degree of heat, which in our orb can only produce a moderate effect, may have a very violent one in such lower orbs; and that, as there may be many degrees of heat in nature, beyond that of boiling water, it is probable there may be some, whose violence, thus affix'd by the pressure of the air, may be sufficient to tear asunder the solid globe.

Mem. de l'Acad. an. 1753. See EARTHQUAKES.

This clastic property of air is supposed by many philosophers to depend on the figure of its corpuscles, which they apprehend to be ramous; some maintain that they are so many minute flocculi, resembling fleeces of wool; others conceive them rolled up like hoops, and curled like wires, or shavings of wood, or coiled like the springs of watches, and endeavoring to relieve themselves in virtue of their texture: so that to produce air, must be to produce such a figure and disposition of parts; and those bodies only are proper...
 proper subjects, which are susceptible of such disposition; which fluids, from the smoothness, roundness, and slipperyness of their parts, are not.

But Sir Isaac Newton (Optics, p. 371.) explains the matter otherwise; such a texture, he thinks, by no means sufficient to account for that vast power of elasticity observed in air, which is capable of diffusing itself into above a million of times more space than it before possessed. — But, as all bodies are thrown to have an attractive and repelling power; and as both these are stronger in bodies, the denser, more compact, and solid they are; hence it follows, that when by heat, or any other powerful agent, the attractive force is surmounted, and the particles of the body separated so far as to be out of the sphere of attraction; the repelling power which then commences makes them recede from each other with a strong force proportional to that with which they before cohered; and thus they become permanent air. And he has proved, that particles, endeavouring to recede from each other with forces reciprocally proportional to the distance between their centres, will compose an elastic fluid, whose density shall be proportional to its compression.

He says the same author, it is, that as the particles of permanent air are groffer, and rife from denser bodies, than those of transient air, or vapour, true air is more ponderous than vapour; and a moist atmosphere is lighter than a dry one.

The elastic power of the air above illustrated and evinced, is the second great source of the effects of this important fluid. By this property, it infuses itself into the pores of bodies, and by poifficing this prodigious faculty of expanding, which is so easily excited, it must necceffarily put the particles of bodies into which it infuses itself into perpetual oscillations. Indeed, the degree of heat, and the air's gravity and density, and consequently its elasticity and expansion, never remaining the fame for the lead space of time, there must be an incessant vibration, or dilatation and contraction of all bodies.

We observe this reciprocation in severall instances, particularly in plants, the trasher, or air-vessels of which perform the office of lungs; for the contained air alternately expanding and contracting, as the heat increases or is diminished, by turns compreffe the vessels, and cæs the vapors of the vejcules; and thus promotes a circulation of their juices. See Air-vessels.

Hence, we find, that no vegetation nor germination will proceed in vacuo. Indeed beans have been observed to grow a little timid therein; and this has led fome to attribute that to vegetation, which was really owing to no other cause than the dilatation of the air within them.

The air is very instrumental in the production and growth of vegetables, not only by invigorating their fewera juices, while in an elastic active state, but also by greatly contributing in a fixed date to the union and firm connexion of their several constituent parts, and by supphying them with that food or pabulum, which contributes to their growth.

From the fame cause it is, that the air contained in bubbles of ice, by its continual action, burst the ice; and thus also, as well as by the expansion of freezing fluids, glasses, and other vessels frequently crack, when their contained liquors are frozen. Thus also, entire columns of marble sometimes cleave in the winter time, from some little bubble of included air's acquiring an incresed elasticity; and to this it is owing, that few snows will bear to be heated by the fire without cracking by the expansive force of the air confined within their pores. From the fame principle arife putrefaction and fermentation; neither of which will proceed, even in the boldest subjects, in vacuo.

Since we find such great quantities of elastic air, generated in the solution of animal and vegetable substances, a good deal must constantly arise from the dilatation of these elements in the stomach and bowels, which is much promoted by it: and respiration, and even animal life, depend in a great measure upon the air.

In reality, all natural corruption and alteration seem to depend on air; and metals, particularly gold, only seem to be durable and incorruptible, in virtue of their not being pervious to air.

Air, effects of the different ingredients of. Air not only acts by its common properties of gravity and elasticity, but there are numerous other effects, arising from the peculiar ingredients of which it consists.

Thus, 1. It not only dissolves and attenuates bodies by its prehure and attrition, but as a chas containing all kinds of mendrums, and consequently polishing powers for dissolving all bodies. It is known that iron and copper readily dissolve, and become rusty in air, unless well defended with oil. Boerhaave affurs us, that he has seen pillars of iron reduced by air, that they might be crumbled to dust between the fingers; and as for copper, it is converted by the air into a substance much like the verdigris produced by vinegar.

Mr. Boyle relates, that in the southern English colonies the great guns rust so fast, that after lying in the air for a few years, large cakes of coccus munitis may be separated from them. Acosta adds, that in Peru the air dissolves lead, and considerably increases its weight. Yet gold is generally esteemed indissoluble by air; being never found to contract rust, though exposed to it ever so long. In the laboratories of chemists, however, where aqua regia is prepared, the air becoming impregnated with an unusual quantity of this menstruum, gold contracts a rust like other bodies.

Stones also undergo the changes incident to metals.—Thus, Purbeck stone, of which Salisbury cathedral confifts, is observed gradually to become softer, and to mould away in the air; and Mr. Boyle gives the fame account of Blackington stone. He adds, that air may have a considerable operation on vitriol, even when a strong fire could act no further upon it. And he has found, that the fumes of a corrosive liquor work more suddenly and manif fically on a certain metal, when suffufed in the air, than the menstruum itself did, which emitted fumes on those parts of the metal which it covered; referring to the effeets of the effluvia of vinegar on copper.

The dissolving power of air is increased by heat, and by other causes. It combines with water; and, by access of cold, deposits part of the matter which was kept dissolved in it, by a greater degree of heat. Hence the water, by being depofited and condenfed upon any cold body, such as galls, &c. in windows, forms fogs, and becomes visible. Air, likewise, has been fupposed, by means of its dissolving power, to accelerate evaporation and distillation.

2. Air volatilizes fixed bodies. Thus, sea-falt, being first calcined, then fused by the fire, and then fused, exposed to the air to liquify; when liquified set to dry, and then fused again, repeating the operation, will, by degrees, be almost wholly evaporated; nothing but a little earth remaining. Helmont mentions it as an arcanum in chemistry, to render fixed falt of tartar volatile; but this is easily affected by wind alone: for, if some of this falt be exposed to the air, in a place replete with acid vapours, the falt draws the acid to itself, and when faturated with it, is volatile.

3. Air also fixes volatile bodies. Thus, though spirit...
of urine, or aquafortis, readily evaporates by the fire; yet if there be any putrefied urine near the place, the volatile spirit will be fixed, and fall down in form of *Aqua secunda*.

4. Air brings many quiescent bodies into action; i.e. excites their latent powers. Thus, if an acid vapour be diffused through the air, all the bodies of which that is the proper menstruum, being diffused by it, are brought into a state proper for action.

In the various operations of chemistry, air is a very necessary and important agent; the result of particular processes depending on its presence or absence, on its being open or enclosed. Thus the parts of animals and vegetables can only be calcined in open air; in clofe vessels they never become any other than black coals. And these operations are effected by the changes to which the air is liable. Many infirmities might be ascribed to this purpose. Let it suffice to observe, that it is very difficult to procure oil of sulphur, *per campanam*, in a clear dry atmosphere; but in thick moist air it may be obtained with greater ease, and in larger quantities. So pure well-fermented wine, if it be carried to a place where the air is replenished with the fumes of new wine, then fermenting, will begin to ferment afresh.

The changes in the air arise from various causes, and are observable not only in its mechanical properties, such as gravity, density, &c. but in the ingredients that compose it. Thus, at Falun, in Sweden, noted for copper-mines, the mineral exhalations affect the air in such a manner, as to discolor the silver coin in purses; and the fame effluvium change the colour of brafs. In Carniola, Campania, &c. where are mines of sulphur, the air sometimes becomes very unwholesome, which occasions frequent epidemic diseases, &c.

The effluvia of animals also have their effect in varying the air, as is evident in contagious diseases, plagues, murruns, and other mortalities, which are spread by an infected air.

The sudden and fatal effect of noxious vapours has generally been supposing to be principally, if not wholly, owing to the lofs and waft of the vivifying spirit of air. But Dr. Hales attributes this effect to the lofs of a considerable part of the air's elasticity, and to the grossines and density of the vapours with which the air is charged. He found by an experiment made on himself, that the lungs will not rife and dilate as usual, when they draw in such noxious air, the elasticity of which has been considerably diminished. For having made a bladder very fupple by wetting it, and then cutting off so much of the neck as would make a hole wide enough to admit the bigges end of a large fofet, to which the bladder was bound, and then having blown the bladder, he put the small end of the fofet into his mouth, and, at the fame time, pinched his noftrils fO close, that no air might pafs that way, and he could only breathe to and fro the air contained in the bladder, which, with the fofet, contained seventy-four cubic inches. In fels than half a minute, he found a considerable difficulty in breathing; and at the end of a minute, the bladder was become fo flaccid, that he could not blow it above half full, with the greatest expira- tion which he could make; and at the fame time, he could plainly perceive that his lungs were much fallen, in the fame manner as when we breathe out of them all the air we can at once. Hence he concluded, that a considerable quantity of the elasticity of the air was destroyed; and that when the fuffocating quality of the air was the greateft, it was with much difficulty that he could dilate his lungs in a very small degree. From this, and several other experiments, he inferred, that the life of animals is preferred rather by the elastic force of the air acting on their lungs than by its vivifying spirit; and that candles and matches escape to burn, after having been confined in a small quantity of air, not because they have rendered the air effe&te by confuming its vivifying spirit, but because they have discharged a great quantity of airfulfulious vapours, which partly destroys its elasticity, and retard the elastic motion of the remainder. He likewise found, that air which passed through cloths dipped in vinegar, could be breathed to and fro as long again as the like quantity of air, which was not thus puri- fied; so that sprinkling the decks of ships with vinegar may refresh the air: and this is confirmed by experience.

But where the corruption of the air is much greater, as in clofe prisons, &c. nothing can be an adequate and effectual remedy but a ventilator. He observed, likewise, that air is not disqualified for respiration merely by the additional moisture which it receives, but by some bad quality in that moisture. See his Statical Essays, vol. i. p. 252. vol. ii. p. 320. &c.

Dr. Priestley observes, that, when animals die upon being put into air, in which other animals have died, after breathing in it as long as they could, it is plain that the cause of their death is not the want of any *pickulum utr*, which has been supposed to be contained in the air; but because the air is impregnated with something stimulating to their lungs; for they almost always die in convulsions, and are sometimes affected so suddenly, that they are irreco- verable after a single inspiration. And he has found the same effect from many other kinds of noxious air. He con- cludes from subsequent experiments, that the air becomes phlogificated in its passage through the lungs, by means of the blood. Experiments and Observations on Air, vol. i. p. 71. vol. ii. p. 31. vol. iii. p. 55. See *Azot, Blood, and Respiration*.

Vegetables likewise produce a change in the state of the air. Thus when a great part of the clove trees, which grow so plentifully in the island of Ternate, was felled at the solicitation of the Dutch, in order to heighten the value of that fruit, such a change ensued in the air, as showed the falutory effects of the effluvia, or rather of the vegetation of the clove-trees, and their blossoms; the whole island soon after they were cut down, being exceeding fickly. See *Azot.*

The air is also liable to alterations from the season of the year. Thus few subterraneous effluvia are emitted in the winter, because the pores are locked up by the froff, or covered by snow; the subterraneous heat being at work, and preparing a heat to be discharged in the ensuing spring. Again, from the winter sottice to the summer sottice, the fum's rays become more and more perpendicular, and consequently their impulse on the earth's surface more powerful; so that the gieb, or foil, is more and more relaxed, softened, and putrefied, till he arrives at the tropic; where, with the force of the chemical agent, he resolves the superficial parts of the earth into their constituent principles, water, oil, falt, &c. which are all swept away into the atmosphere.

The height and depth of the air produce a farther alteration; the exhalations not rising high enough in any great quantity, to ascend above the tops of high mountains.

From some experiments with air-balloons, it has been proved, that the air of the higher regions is more impure than that at the surface of the earth; which is reasonably ascribed to the oxygen supplied by vegetation to the lower and contiguous stratum of air.

Nor must drought and moisture be denied their share, in varying the state of the atmosphere; in Guinea, the heat, with the moifure, conduces fo much to putrefaction, that the pureft white figs are often full of maggots; and their
For the refracting power of air; see Refraction.

After all, some of the most curious and penetrating naturalists have observed certain effects of air, which do not appear to follow from any of the properties, or materials above cited. In this view, Mr. Boyle has composed a treatise of fulpicious about some unknown properties of the air. The phenomena of fire and flame in vacuo seem, according to him, to argue some unknown vital fluidity, diffused through the air, on account of which that fluid becomes so necessary to the suffulence of flame. Baffon supposed that air is necessary to the suffulence of fire, because it is most adapted to acquire that expansive motion, which is the principal property of fire. On this account fire combines with air; in preference to any other sub stance, and in a more intimate manner, as being of a nature most nearly approaching to its own; and, therefore air is the proper aliment and most powerful assilant of fire. Hill. Nat. Supp. vol. i.

According to Dr. Priestley, the air is a men rubrum for the phlogiston emitted by burning bodies; which must cease to burn when that men rubrum is saturated with it. And he accounts in the same manner for the suffocation of animals in a confined space. When the phlogiston, emitted by burning bodies and breathing animals, can no longer be absorbed by the ambient air, both life and flame are extinguished. Exp. and Obl. &c. vol. i.

For the modern hypothesis, with regard to this subject, see Combustion and Phlogiston.

Thus we find, that many causes combine to produce very considerable alterations in the state of the air, whereby it becomes less fit for respiration, and other purposes of nature; and if there were no provision for restoring its salubrity, it must, in time, become universally injurious and fatal. Dr. Priestley, in the course of his inquiries on this subject, has discovered the great restoratives, which are provided for this purpose. One of these is vegetation. In order to ascertain this fact, he put a sprig of mint, in a vigorous flask, under a glafs jar, inverted in water; and he found, contrary to his expectation, that this plant not only continued to live, though in a languishing way, for two months; but that the confined air was so little corrupted by the effluvia of the mint, that it would neither extinquish a candle, nor kill a small animal, which he conveyed into it. He found, likewise, that air, vitiated by a candle left in it till it was burnt out, was perfectly reftored to its quality of supporting flame, after another sprig of mint had been vegetated in it for some time. And, in order to shew that the aromatic flavour of the plant had no share in producing this effect, he observed, in a variety of other experiments, that vegetables of an offensive smell, and even fuch as had fcarce any smell at all, but were of a quick growth, proved the belt for this purpose. Nay, more, the virtue of growing vegetables was found to be an antidote to the baneful quality of air, corrupted by animal respiration and putrefaction; and he infers from a number of fimilar facts, that the injury, which is continually done to the atmosphere, by the respiration of fo many animals, and the putrefaction of fuch mafs of both vegetable and animal matter, is, in part at leaft, repaired by the vegetable creation; and notwithstanding the prodigious mafs of air that is corrupted daily by the above mentioned caufes; yet, if we consider the immense profusion of vegetables upon the face of the earth, growing in places fuitable to their nature, and confequently at full liberty to exert all their powers, both inhaling and exhaling, it can hardly be thought, that the remedy is not adequate to the evil. Dr. Franklin, in a refletion on this discovery, expresseth his hope, that it will give some check to the rage of destroying trees that grow near houses, which has accompanied our late improvements in gardening, from an opinion of their being unwholesome; adding, from long observation, that there is nothing unhealthy in the air of woods; “since the Americans have their country habitations in the midst of woods, and no people on earth enjoy better health, or are more proflic.” Dr. Priestley has since discovered that light is necessary to enable plants to purify air; however, pure air is not produced by light or plants, but only by the purification of the impure air to which the plants have access. Obs. and Exp. on Air, vol. v. p. 18, 24, &c.

The sea, and other large bodies of water, are the second resource, which nature has provided for retoring the salubrity of corrupted air. Dr. Priestley found, that all kinds of manufacture and water, reftored by continued agitation in a great bulk of water; the noxious effluvia being imbibed by the water, and thereby transmitted to the common atmosphere. And he hence concludes, that the agitation of the sea, and of large lakes and rivers, must be highly useful for the purification of the atmosphere; the putrid matter being absorbed by the water, and imbibed by marine, and other aquatic plants, or applied to purpofes yet unknown. Exp. and Obl. vol. i. feet. 2. and 4.

This ingenious philosopher apprehends, that the agitation of water, and the vegetation of plants, purify noxious air, by abforbing part of the phlogiston with which it is loaded; and that this phlogistic matter is the moft essential part of the food and support of both vegetable and animal bodies. Ib. vol. i. p. 128, 139.

Dr. Priestley, improving upon the experiments and investigations of Boyle, Hales, Brownrigg, Black, Macbride, Cavendish, and others, has discovered many species of air, expelled by various processes from different kinds of substances; of which a summary account will be given in the course of this work. See also his curious and valuable Experiments and Observations on different Kinds of Air, in five volumes. And for a compendium of the history of discoveries on this subject, Lavoisier’s Essays Physical and Chemical, vol. i.

Air, in Chewiftry. See Gas.

Air, Atmospheric, common air. Gas atmosphérique. Fr. Atmospheric air does not appear to have been the subject of chemical investigation before the time of Boyle; for though Arioloté, Phin, and Paracélus have written largely concerning this fluid; they have confined themselves to the imperfect examination of some of its physical properties; to the mention of a few obvious facts; and to the invention of hypotheses, which, as they do not profess to be founded on experiment, may, in the present state of knowledge, be safely neglected.

It was, indeed, natural, that the great improver of Otto Guericke’s original air-pump, found as he was of chemical pursuits, should exercise his talents in researches on the properties of the atmosphere, more especially as, from the number of substances continually acquiring the form of vapour, it was not improbable that common air should prove a very heterogeneous and easily decomposable mixture. The difficulty,
AIR.

difficulty, however, of separating, by the only method then known, a portion of air from the rest of the atmosphere, and the necessary uncertainty of the first rude attempts to operate upon an invisible elastic substantia, occasioned the progress of discovery in this department of chemical science to be unusually slow. The following facts, however, were ascertained by Boyle, which, when we consider the numerous obstacles from bad and imperfect apparatus, that he had to contend with, are highly creditable to his industry and sagacity. He proved, that the presence of air was necessary to combustion and to animal life. By blowing, that in the exhausted receiver flame was almost immediately extinguished, and various small animals, and even fish, while in water, were in a short time killed; that the same phenomena take place, but more gradually, in a confined portion of atmospheric air; and that the death of animals, in this situation, was not owing to the heated exhalations from their bodies, as was then supposed, since the same effects took place when the apparatus was put into a frigoric mixture: he also ascertained, that animals live longer, catvis putidos, in a given bulk of condensed than of rarefied air.

On account of the imperfection of his apparatus, he was induced to believe, that no abstraction of air took place in respiration; and he appears to have had no suspicion that pure atmospheric air was a compound substance.

Immediately after Boyle, succeeded Mayow, unquestionably the great and chemical genius of that age, whose whole works, by a singular fatality, excided little or no interest among his contemporaries, and were soon totally forgotten. In this state of unmerited neglect they remained for more than a century; and it is only within a very few years, that the public attention has been directed to the writings of a philosopher, who nearly anticipated those discoveries of Priestley, Lavoisier, and Cavendish, upon which are based almost all the modern improvements in chemistry. The first great improvement of Mayow in the analysis of atmospheric air, was the invention of a proper apparatus: for this purpose, rejecting the use of the air-pump, he made choice of glass jars, invested in water, as the bell method of confining the gasses upon which he experimented. Setting out from the facts discovered by Boyle, he argues, that since a lighted candle is extinguished much sooner in an exhausted receiver than in the same when filled with air, there must be something contained in the atmosphere necessary to the continuance of flame; and that a candle, in confined air, is not suffocated by its own fulguritious exhalations, but dies away for want of an aerial pabulum. The necessity of air to combustion is also proved, says he, from the impossibility of kindling a combustible body in vacuo by the concentrated solar rays, or by any other method. Having established this first position, he proceeds to infer, that it is not the whole air, but only its more active particles, that are capable of supporting flame, because a candle goes out in confined air, while yet the greatest part of the elastic fluid remains unconsumed. Also, since sulphur, when mixed with nitre becomes capable of inflammation in vacuo, or even under water, it follows that nitre and atmospheric air contain some substance in common, which he calls fire-air particles (particula igneo-aeris.) He next determined the analogy between flame and animal life; and showed, that each depended for their continuance on a supply of fire-air particles: that there was an actual consumption of air in combustion and respiration he proved, by the rife of water in the jars in which a live animal or a lighted candle was incubated; and that the loss of bulk was owing to the abstraction of fire-air, appeared from the inability of the residence to support animal life. He also inferred, that the fire-air particles were the heaviest part of atmospheric air, because, if two nice or two candles were confined in a tall cylindrical jar, inverted in water, so as that one should be near the upper part of the vessel, and the other at the bottom, the upper one, whether a candle or animal, would be extinguished some time before the lower one. With regard to the proportion of fire-air in the atmosphere, he only observed, that air rendered unfit for combustion by the breathing of an animal, lost about one fourteenth of its bulk; at the same time remarking, that there was probably only a part of the fire-air confined: he afterwards, indeed, found, that the solution of iron in aquafortis occasioned a diminution of about 25 per cent. in atmospheric air; but though, in this case, he produced nitrous gas, and thus abstracted the oxygen of the atmosphere, yet, as he himself draws no conclusions from it, we should rather consider this as an accident than a discovery. Mayow never obtained the fire-air of the atmosphere in a separate state, and therefore was unable to confirm his analysis of atmospheric air by the synthetic proof; nevertheless, he was warranted by a very high probability in affirming that the atmosphere consisted of two kinds of air, of which the igneo-aerial was in the proportion of at least one to 13; that it exceeded the other part in its specific gravity, and was absolutely essential to the continuance of flame and animal life. The influence, however, of the prevalent hypothesis was at that time too strong to be shaken by sober experiment; and the labours and very name of Mayow, shortly sunk into oblivion: the atmosphere was still supposed to be an indecomposable element, and its effect on chemical proceed was very generally overlooked.

In 1774, exactly a century after the publication of Mayow's work, the important discovery of dephlogiñated air, by Dr. Priestley, took place. This philosopher having included some mercurial precipitate per se, in a jar filled with mercury, and inverted over the flame, procured from it, by means of heat, a quantity of gas, in which a candle burnt with an enlarged flame, and increased light: the coincidence of this, with the effect produced by dephlogiñated nitrous gas in the same circumstances, as had been already observed by Dr. Priestley, induced him to believe that there was some common principle in nitrous acid and atmospheric air; and this supposition was still further confirmed by the discovery, that common red precipitate, which is prepared by means of nitrous acid, yielded dephlogiñated air in the same manner as the precipitate per se. Hence, too, he concluded, that pure atmospheric air was not an element, and that dephlogiñated air was that of one of its component parts to which the continuance of flame and animal life was entirely owing. Thus we find both Mayow and Priestley arriving at the same general conclusions, through the medium of entirely different experiments: the fire-air of the one, and the dephlogiñated air of the other, being only two words for the same substance: the experiments of the latter poffed, however, this capital superiority, that they exhibit in a separate uncombined state, that vital part of the atmosphere, the existence of which was only to be inferred from those of the former. There yet remained, however, for the complete proof of the composition of the atmosphere, that a part of it should be actually decomposed, so as to shew its elements separated; and then, by their union, to recompose atmospheric air. This deficiency was supplied by Lavoisier. He confined a few ounces of mercury and a certain portion of atmospheric air in a proper glass apparatus, and exposed the mercury for 12 days to a heat nearly equal to that of ebullition; during this period a part of the mercury was converted into a red oxyd, a certain portion of
the air disappeared, the remainder was incapable of supporting flame, and the weight of the red oxyd exactly corresponded with the lbs furnished by the mercury and the air; the red oxyd, being then heated in a small retort, was decomposed into running mercury and a gas which exhibited all the properties of dephlogisticated air; finally, this air, being mingled with the unexpirable refuse, recomposed atmospheric air. From these and various other similar experiments, it appeared that the lower part of the atmosphere consists of 27 parts oxygen gas, and 73 of a mephitic air, which, upon a further analysis, yielded about 72 parts of azotic gas, and one of carbonic acid. These experiments will be further detailed under the term phlogistics.

From the slight adherence of these gasses with each other in the air, it is probable that they are not so much in a state of combination as of intimate mixture; and hence there are scarcely any chemical actions produced by the atmosphere, which are not more properly referable to some one or other of its constituent parts.

Atmofherical air, as such, is soluble in water; from which it may be separated by the action of the air-pump, or by long boiling or distillation: hence fish, confined in fresh distilled water, soon die for want of air; if, however, the water has been previously exposed to the atmosphere, a sufficient portion is absorbed to supply the demands of these animals. In like manner water is soluble in air, but the proportion of this must necessarily vary according to the differences in temperature and barometrical pressure. Boyle's works, vol. ii. Mayow, Tractatus, &c. Priestley on Air. Lavater's Elements.

Air, fictitious. While pneumatic chemistry was in its infancy, all those chalybated fluids produced in chemical experiments, were distinguished by this appellation from the air of the atmosphere; since, however, these fictitious airs have acquired peculiar names, the term has fallen into disuse.

Air, acid. See Muriatic acid.

Air, fixed. See Carbonic acid.

Air, mephitic. See Phlogisticated.

Air, nitrous. See Nitrous gas.

Air, phlogisticated nitrous. See Nitrous oxyc.

Air, mephitic atmospheric. See Azot.

Air, vital.

Air, pure.

Air, phlogisticated.

Air, inflammable. See Hydrogen.

Air, sulphurated inflammable. See Hydrogen sulphurated.

Air, heavy inflammable. See Hydrogen carbonated, or Carbon, gaseous oxyc of.

Air, alkaline. See Ammonia.

For an account of Dr. Priestley's numerous experiments and observations on these several species of air, the reader is referred to the excellent work already cited.

Air, innate, in Anatomy, is a fine aerial substance, supported, by some anatomists, to be enclosed in the labyrinth of the inner Ear, and to minister to the due conveyance of sounds to the fonsory.

But the existence of such innate air has been called into question, and rendered very improbable. See Ear.

Air, in Geography. See Air.

Air, a mountain of Arabia Felix, to the north of Medina, all the parts of it abounds with trees that yield frankincense.

Air, atmospherical, in Medicine, when combined with moisture, different degrees of heat, electricity, and various effluvia and misfortunes, constitutes the atmosphere; and forms one of those fixed external circumstances to celebrate in the schools, called non-naturals. Simple atmospherical air is no farther an object of medicine or physiology than as it forms the medium of respiration. See the preceding and subsequent articles.

Air, in Music, signifies the melody, or treble part of a musical composition.

The word is also used for a tune, or song itself, that is for a series of sounds whose motion is regular and graceful. Rhythm is as necessary in a musical air, whether vocal or instrumental, as in the words of a song. Each bar of an air should be well accentuated, and the periods well phrased.

The rules for harmony are mechanical, and neither difficult to learn nor teach, as may easily be conjectured from the innumerable treatises in all languages for combining sounds in composition. Aristotle, Horace, Boileau, and Pope, have told us how good poems are constructed; but who shall tell us how to think, how to invent, to ferment ideas? Among all the receipts for constructing harmony, we have none that are intelligible for melody: we are told what may be done, but what has been already successfully achieved; but this is only telling us what we may imitate, and whom we may plunder. There are no magic wands to point out, or vapours hovering over springs of invention; no indications where the golden mine of new conceptions lies hidden. So that from age to age, memory and compilation supply common minds, and satisfy common hearers. It has been said:

"Sometimes a hero in an age appears; But scarce a Purcell in a thousand years."

Handel was our magnus Apollo during the last century, and Rameau that of France. At present, Haydn and Mozart "are the gods of our idolatry," and those of all Europe. But it is only such gifted men as these who furnish the rest of mankind with ideas.

The origin and progress of melody, derived from harmony, and phrased and formed into Air, have been fully detailed in the Gen. Hist. of Music, in tracing the progress of the musical drama or opera. National music every country, not wholly savage, has had from time immemorial. In Europe, Sicily, Spain, Provence, Venice, Scotland, Ireland, and France, have characteristic melodies or tunes, of great antiquity. But the first preserving Airs, in cultivated music, that Dr. Burney has been able to find harmonized, and in regular modulation, were printed in three and four parts in separate books at Naples, at 1565. Of these the measures are airy, the intervals pleasing, and the counterpart simple: they are printed without bars. The modulation borders a little on that of the ecclesiastical modes, but it begins and ends in the same key, which does not often happen in national tunes.

Air, in music, has various applications: in the melodrama, or opera, it distinguishes measured melody from recitative. A bal-
AIR.

A ballad, tune, or short instrumental air, consists of two strains or parts.

No very satisfactory etymology has been found for the word Air.Saumaise believes that it comes from 

\textit{arar,} L., but Menage disputes this derivation, in his Etymological Dictionary, without furnishing a better. The term \textit{ара} in Italian, is of no high antiquity: the first instance of its use in the Cruxen Dictionary is from Redi, who died in 1695. We know, however, that the word became of general use about the middle of the 17th century.

Though Air sometimes implies the words of a song, as well as the melody in general; nice discrimination requires that we should confine its import to melody, a tune, alone, and \textit{fong} to the words. A fine or pleasing air has nothing to do with the poetry, which may be fine, though ill let. And the air may be beautiful, even to nonsensical words.

Measured air, in an opera, is opposed to recitative, where no regular time is observed. This musical declamation, which needs only two kinds of notes, crotches and quavers, with pauses at the end of a verse, approaches nearer to what we conceive to have been the vocal music of the ancients, confined to longs and shorts, than any of our airs, except such as are very simple, can do. Chanting, in the Cathedral service, is more rapid than recitative; but resembles it by the absence of regular measure, more than Air, which must be arranged in some one of the divisions of common or triple time.

In accompanied recitative, short passages or fragments of Air occur in the instrumental parts, in measured melody, which is often called symphony: but the Italians, with more propriety, style these fragments Ritornelli; which fce. Sometimes indeed the instruments accompany the reciter in regular time, which obliges the finger to pronounce the recitative in measure, which likewise fce. Of this the performers are informed by the words \textit{a tempa}, in time.

A vocal air is only the melody of a single part or voice. If another part is added to it, in different intervals, it is styled a \textit{Duo, or Duet} in three parts, a \textit{Trio} in four, a \textit{Quartet, or Quartet}, &c.

The Ancients had Airs, both vocal and instrumental, called \textit{Nome.} The words of lyric measures, which we should call songs, were styled Scolia, (which fce under their several articles).

In the work of Philodemus on music, which has been recovered from the cinders of Herculaneum, the best and only musical information it contains, after being so long expected, and with such difficulty deciphered, is the solution of the miraculous powers ascribed by the poets to Amphion, of building cities by music. We find in this tract, (which is but a fragment, and neither a treatise nor an eulogium on music, but a severe fatica) that every trade, occupation and profession, had its names or peculiar and appropriate Airs, which were played to the workmen; so that towns were not built \textit{by music,} but to \textit{music,} \textit{Φαιλομοιχης.} We fce in \textit{Boiio-reliquis} and ancient sculpture, that there was a musician at the stern of every velle, to regulate and animate the rowers. Orpheus, civilizing the world, and introducing religion and order among mankind, implied only that religious rites were accompanied by music. See \textit{Philo-

demus.

The derivation and progress of air in dramatic music will be found under the article \textit{opera,} in which lyric poetry became subordinate to music. We fear the word \textit{subordinate} will offend the poets, and such as love poetry better than music. "The words (says Franklin) are only an excuse for finging." And Stillingsale asks "Who reads the words of a song but the author?" In a musical drama, the buffoons is all transfused in recitative, or declamation: which buffoons at the end of a scene, is illustrated by a timbrel, or a few passionate lines, set to measured music, in florid counterpoint; and these are calculated to display the talents of a finger, and the genius and abilities of a composer. Were this not the case, and if the poetry would be better felt and understood by the mere articulation and in passioned communication of common speech, why dignify and involve it in a tune, accompanied and incumbered by different melodies? "A song, or the words of an air for a great composer to 

"fet, and a capital finger to execute, should consist only of 

"one subject or passion, expressed in as few and soft words as possible." Metastasio has furnished the bell models of words for airs in the Italian opera. And with respect to English dramas for music, on the Italian plan in all things, except the dialogue being declaimed in common speech, instead of the musical tones of recitative, we shall venture to quote on the subject of long-writing, opinions which we thought just 30 years ago, and which, during that period, we have been no reason to retract.

"Since the refinement of melody, and the exclusion of 

"recitative, a song, which usually recapitulates, illustrates, 

"or cloes a scene, is not the place for epigrammatic points, 

"or for a number of heterogeneous thoughts and clashing 

"metaphors: if the writer has the least pity for the com-

"poser, or love for music, or wishes to afford the least op-

"portunity for symmetry in the air, the thought should be 

"one, and the numbers as smooth, and the expression as 

"calm and laconic as possible. What sublime ecclesiastical 

"music has Handel composed on the single words \textit{Allabojus}, 

"and \textit{Amens!} But, in general, every new line in our songs, 

"introduces a new thought; so that the composer is 

"more tender of the poet's reputation than his own, he 

"must, at every line, change his subject, or be at fife 

"with the bard; and in either case, the alternative is in-

"jurious to the general interest of the music, poetry, and 

"audience.

"In an air, it is by reiterated brokes that passion is in-

"creased; and the most passionate of all strains, is, perhaps, 

"that in which a beautiful passage is repeated and varied, 

"and when the finger, by a few appropriate notes of music, 

"feeling, or spirit, returns to the first fubject; while it still 

"vibrates on the ear, and is recent in the memory; this 

"licence, no doubt, may be, and often is, abused; but not 

"by men of true genius and taste." \textit{Preface} of \textit{Music} in 

France and Italy.

Alessandro Scarlatti, Vinci, and Pergolephi, were the first who refined, pirated, and polished vocal melody, and settled the form and canthens of dramatic airs But these elegant strains composed for great singers, and a polite audience, are totally different from national melodies, which are traditional, and were invented long before either the gammut or modulation was settled; as may be discovered by innumerable old tunes of different nations, that begin in one key, and end in another. Indeed the ancient chants of the Roman church did the same. See \textit{ chant} and \textit{canto-

erso.

The Gluckasts, in France, censure all airs that they are \textit{unable to sing}, or that are likely to draw the attention of the audience from the poet to the musician. M. Suard, in a long and very written article of the new \textit{Encyclopedia Methodique}, has analyzed several of the most exquisite and renowned Italian opera airs that have ever been sung on the stage, with a severity that borders on inflexibility. All the
Since airs have been abandoned in the opera *Air*, which occasioned many dramatic absurdities, the *cavatine*, or single strain, without a second part, prevailed; but that not furnishing an opportunity for fingers of great abilities to manifest all their powers of execution, taste, and expression, in the fame air of late, every air for a great singer is a *duet character*, of two characters, consisting of two distinct movements, usually an *andante* and an *allegro di bravura*. It is often difficult from the force of the words, to assign any other reason for these sudden gusts of passion, after a soothing and pathetic movement, but that of con- vince the audience of a singer's marvellous agility of throat, and powers of exciting surprife by *de tout de force*. If such airs were composed purposely for a concert, at which a performer, from the multiplicity of his or her engage- ments, could only play to one long, and that connected with nothing else, airs of two characters might encrease the finger's fame, and the pleasure of the audience without abridging; but in a serious drama, where character, con- nexion, and propriety should be supported, after labouring through a slow movement in a melancholy drall, as every finger does, if not gifted with powers of new and appropriate embellishments, the setting off full speed without a word appearing in the *libretto*, or opera book, for the nec- essity of taking flight in such an outrageous manner, we pity the poet and ourselves for being thus defrauded of all dra- matic interest. In the course even of two acts, to which an opera is never cut down, opportunities for displaying all the powers of a singer, however extraordinary and various, may be found in every principal part, without violating the dignity of character, and rules of common sense. See *Mel- ody, Song, Tune, and Opera*.

**Air.** In *Mythology*, the wind was adored by the heathens under the names of Jupiter and Juno; the former representing the superior and finer parts of the atmosphere, and the latter the inferior and grofter parts. The *angura* also drew fпреces from the clouds, thunder, lightning, &c.

**Air**, in *Painting*, &c. denotes the manner and very life of action; or it is that which describes fitch of those refined expressions, that do not arise from the motion of the features of the face, which are to be considered as the more immediate agents expressing the passions of the soul (see *Passions*); but from the turn of the body, and especially of the head and neck. This term *air* is more particularly synonymous with *gesture*, or graceful action of *attitude*. Painters are in danger of falling into this fallacy, while they attempt to give an air of elegance above vulgar ideas. Correggio and Guido have excelled in the arts of the heads, as well as of the whole figures they painted; but perhaps, in some instances, even they may have exceeded the due bounds of nature.

**Air**, in *Painting*, is also a great subject of consideration, as the interpolating medium which tends to diminish the force or strength of objects and colours. See the article *Perspective Aerial*.

**Air**, in *Surgery*. The application of gaseous matters to the purposes of surgery, has not been sufficiently at- tended to. There is reason to believe that several aeriform substances might be employed locally, as well as internally, to considerable advantage; but it would exceed the bounds we have preferred to this department of our work, were we to adumbrate all the facts that might be brought forward to
illiterate the medicinal powers of air, in its different combinations. The application of fixed air, or carbonic gas, by means of the fermenting caustic, is pretty generally known, in cases of fistul and gangrenous sores. It has been advantageously used also in malignant ulcers of the nose, tongue, and mouth, as well as in cancers of the bones.

Fixed air is plentifully obtained from a mixture of alkaline or chalky substances with vitriolic acid; and during the effervescence, applying the gas which is extricated immediately to the morbid part; or by impregnating water with it, composites may be foaked in the water, and laid frequently over the seat of the diseafes.

Mr. Loeffer, a German surgeon, has recommended a particular apparatus for this purpose, which may be easily contrived, and which he employs for saturing water with fixed air, by the mixture of chalk and vitriolic acid, or during the process of fermentation.

When we wish to apply the air to a cancerous breast, for example, we are to fill a bladder with the air as it rises from the above mixture. Then introduce a tube, fixed to its orifice, into another bladder, which is to be cut round in such a manner that it can be applied like an open bag around the breast, and held close to it with the hands. When it is fastened below, it must be united, so that the fixed air may pass out of the first into the second bladder, and find access to the ulcerated part. In order to facilitate this process, a gentle degree of pressure is to be applied to the bladder; and, as one bladder will not be sufficient, a number of them should be provided in readiness, and filled for immediate use in succession. This operation is to be continued half an hour or longer each time, and repeated twice or thrice a day.

Mr. Witlock, who has written a German treatise on this subject, and with extraordinary success, recommends us to apply the carbonic acid gas, by means of a receiver or air-bell, connected with a flexible tube or pipe, sufficiently air-tight; but as the vitriolic acid produces too strongly a combustion, the gas is extricated for such purposes from a mixture of fixed alkali and vegetable acid.

The medicinal use of actious airs is a subject which has been diligently considered by Dr. Beddoes, Dr. Thornton, Mr. Hill, Mr. Davy, and some other gentlemen in England; but the enquiry is still in its infancy, and has not been productive of so much public benefit as its zealous friends anticipated. Perhaps the attention of medical men to the local and external influence of gaseous matters, would better repay them for their trouble. Surgeons are not exactly agreed, whether the atmospheric air be hurtful to wounds and internal cavities, merely as air, or as it may be cold, hot, moist, dry, or variously modified. We hope these superficial hints will serve to excite the attention of professional gentlemen to this branch of the healing art. It likewise deserves further inquiry, whether the injection of fluids into the urinary bladder, impregnated with fixed air, &c. &c. be so efficacious, in calculous cases, as some persons have pretended.

From observations on bleeding in rheumatism, and after taking cold, it is evident, the air can enter with all its qualities, and vitiate the whole texture of the blood, and other juices.

From the colics, vertigoes, and other nervous affections caufo by damps, mines, &c. it is evident, that air thus qualified can relax and obtruct the whole nervous system. And from the colics, fluxes, coughs, and consumption, produced by damp, moist, and nitrous air, it is evident it can corrupt and spoil the noble organs, &c. See Atmosphere, and preceding article.

Air-bags, in Botany, a dilated bladder-like seed vessel, opening on one side, as in the periwinkle, or bladder-fen. It signifies also other kinds of dilated air-vesicles. See Folliculus.

Air-balloons, a name lately given to those aereostatic machines that have been employed in aerial navigation. See Aerostation.

Air-bladder, in Ichthyology, a kind of vesciula, containing challic air, found in the bodies of fish, by means whereof they are enabled to sustain themselves in any depth of water, and either to rise or sink at pleasure.

The air-bladder is the same with what is otherwise called the swim, or swimming-bladder. This membranous bag lies close to the back-bone, and is furnished with a strong muscular coat, by which it has the power of contraction and dilatation. It is connected with a glandular substance, which contains a quantity of red blood; and some have supposed that the air contained in the swimming-bladder, is derived from this substance. Two processes or appendices issue from its anterior part, and terminate in the fauces; and it is supposed by some writers to be that part which is called the faunt.

The discovery of the use of the air-bladder took its rise from observing, that a bubble of air in rising from the bottom of a fluid, continually dilates till it reaches the top, by reason of the continual diminution of the weight, or pressure of the incumbent water. For the air, in the bladder, is like the bubble, more or less compressed, according to the depth the fish swims at, and takes up less or more space; and consequently the body of the fish, part of whose bulk this bladder is, is greater or less according to the several depths, though it retains the fame weight. The rule of hydromaties is, that a body heavier than so much water as is equal in quantity to the bulk of it, will sink; a body lighter will swim; a body of equal weight will rest in any part of the water. By which rule, if the fish in the middle region of the water be of equal weight with an equal bulk of the water, the fish will rest there, without any tendency either upwards or downwards; and if the fish be deeper in the water, its bulk becoming less by the compression of the bladder, and yet retaining the same weight; it will sink and rest at the bottom: on the other side, if the fish be higher than the middle region, the air dilating itself, and the bulk of the fish consequentely increasinf, without any increafe of the weight, the fish will rise and rest at the top of the water.

Perhaps the fish by some action can emit air out of the bladder, and afterwards out of its body; and also when there is not enough take in more air, and convey it to this bladder; in which case it will be no wonder that there should be always a fit proportion of air in the bodies of all fishes, to serve their use, according to the depth of water they live in; perhaps also, by some mufeles, the fish can contract this bladder beyond the pressure of the weight of water; and perhaps it can by its sides, or some other defence, keep off the pressure of the water, and give the air leave to dilate itself. In these cases, the fish will be helped in all intermediate distances, and may rise or sink from any region without moving a fin.

If the air-bladder of a fish be pricked or broken, the fish presently sinks to the bottom, unable either to support or raise itself up again. Flat fishes, as soles, plaice, &c. which always lie groveling at the bottom, have no air-bladder.
Dead fishes are found swimming on the surface of the water, because the muscles of the membrane cease to act; and their bellies areumpermol, as the back-bone cannot yield, and the dilated face is protruded into the abdomen, and the back becomes consequently heaviest at its upper part.

In most fishes there is a manifest channel, leading from the gullet or upper orifice of the stomach to the air-bladder, which doubtless serves for conveying air into it. In aurgeon Mr. W'sloughby observed, that upon pressing the bladder the stomach previously swelled; so in that fish it seems the air passes freely both ways. Possibly the fish while alive may have a power to raise up this valve, and let out air on occasion.

In a variety of other fishes there are communications with some parts of the alimentary canal, particularly the oesophageus and stomach. The salmon has an opening from the fore end of the air-bladder into the oesophageus, which is surrounded by a kind of mucous fibres. The herring has a sort of funnel, connecting the bottom of the stomach with the air-bag; by which the air probably comes out from them.

All the fishes of the cartilaginous kind want air-bladders: by what means it is they ascend and descend in water is yet unknown. The cetaceous kind, or sea-beasts, are also without the air bladder: indeed, as these differ little from quadrupeds, but in the want of feet, the air which they receive into their lungs in inspiration, may serve to render their bodies equisponderant to water; and the contraction or dilatation of it, by the help of the diaphragm and muscles of respiration, may possibly affit them to descend, or ascend, in the water, by a light impulse thereof with their fins. Most of the cet-kind have bladders, yet they can hardly raise themselves in the water, by reason of the length and weight of their tails; the air-bladder being near their heads, may help them to lift up their heads and fore part. Ray's Wild. of God, 8e. part i. p. 25. Phil. Trans. No. 114, Abridgement, vol. ii. p. 845.

There is great diversity in air-bladders, in respect of figure, substance, situation, and connection, in different fish. In some, the air-bladder is divided into two, e. g. in carp; and in others, into three. Needham maintains, that all fish which have teeth in their jaws have only a single air-bladder; whereas those without teeth have a double one; or, which amounts to the same, the air-bladder of these last is divided into two cells. Sig. Redi refutes this distinction; giving influences of fish with teeth, whose air-bladder is double; and of others without teeth, which have only a single air-bladder.

Dr. Priestley conjectures that the air, enclosed in the air-bladder of fishes, serves some further purpose in their economy besides that of enabling them to live or sink in water. Some fishes have no air-bladder, and yet rise or sink without difficulty. That fishes cannot live without air is a well-known fact, established long ago by the experiments of Dr. Haukebue.

The fishes he employed were gudgeons, which are lively in the water, and which subsist for a considerable time when taken out of it. Having put three of these into a vessel of water, which had no communication with the external air, and which was designed to resemble a frozen pond, and other three into a vessel of water exhausted of its air; he observed, that in about half an hour the latter manifested signs of uneasiness by an unusual motion of their mouth and gills; and the former frequently ascended to the top of the vessel in which they were confined and then sunk down again, without any sensible alteration. After five hours the gudgeons in the vessel exhausted of its air, became less active; and in about three hours more those in the confined air lay at the bottom of the vessel with their bellies upwards, without moving their fins or tail, but indicating life by a motion with their mouths. On uncovering the vessel, they revived in two or three hours, and were perfectly well next morning, at which time those in the vessel purged of its air were also recovered. When this last vessel was put under the receiver of an air-pump, and the air was exhausted, they all died. When the air was exhausted, they remained at the top, but on its introduction, they sink to the bottom. It is not easy to explain the manner in which these fishes are supplied with air, nor the benefit they derive from it; nor are the nature and qualities of the air, contained in their air-bladder, satisfactorily ascertained. Dr. Priestley (Exp. and Ob. relating to Nat. Philos., vol. ii. p. 138), confined minnows, and other small fishes in water without any access of common air, till they died, and upon examining this water, he found that it was somewhat worse than air in which a candle might go out. Hence he infers, that air contained in water, in an unstable state, is as necessary to the life of fishes, as air in an elastic state is to that of land-animals. Upon putting fishes into water impregnated with phlogisticated air, he found that it was not only injurious, but in process of time fatal to them; although he observes, that fishes, like insects and other extraneous animals, can live a considerable time without any thing equivalent to respiration. In mentioning some experiments on the state of the air, which is contained in the air-bladder of fishes, he remarks, that when these are taken out of the fish, the air cannot be discharged from them by pressure through any existing aperture, but he was always obliged to cut or burst them. The air itself, obtained from many of them, was not affected by nitrous air; but that of some, particularly of roaches, exhibited slight indications of the effect of this air. Upon the whole it thus appears, that he seldom met with oxygen, and with that only in a small quantity. Pourcress made experiments on the air contained in the air-vessel of the carp, and found that for the most part it was perfectly pure atoxic gas, though it sometimes contained a small quantity of carbonic acid gas. From the nature of the fluid, he infers, that the air in the bladders of fishes is produced in the stomach. Ann. de Chim. i. 47. Dr. Monro, in his lectures, led his auditors to conclude, that it was fixed air. But Dr. Brodbelt of Jamaica, collecting about a quart of the air from the bladder of a large sword-fish, which, he says, consisted of innumerable cells that had no communication with one another, found, to his surprise that it was oxygen. A flame was brightened and an ignited fox was reckindled by it; and it was so strong and pure, that the common experiment of a piece of steel-wire, heated and put into it, succeeded well, and threw out a most vivid light when melting. This pure air, he supposes, is adapted to serve the purposes of life, when the fish is far below the surface of the water. Dun-can's Ann. of Med. for 1796, p. 393.

The water-fall, in lieu of a bladder, has a large membranous air-bag on its back, which empties and fills with air or pleasure, by an aperture, which it can flit very close, from without inwards, by means of a sort of valve, so that the leaf globe of water cannot enter without its consent. By this artifice it can enlarge or lessen the bulk of its body, and inhabit all depths of the water; though a conjecture has been advanced by Mr. Ray, that it is by the help of water, which they take in and let out by two holes in the lower part of their abdomen, near to the ventricle. They sink in the water, by letting in some of it at those holes; the orifices whereof are opened and shut at pleasure, by means of proper muscles. The water being thus received into
into the cavity of their abdomen, serves to make them preponderate the water, and defend; and when they would ascend again, a compulsion is made by the muscles of their abdomen, and the water forced out again, at least so much as suffices to give the degree of levity wanted. R3's Wild.
of God, part ii. p. 346.

Air-dollars, or Air-bags, in Ornithology, are cells or receptacles of air in the bodies of birds, which communicate with the lungs, and which are lodged both among the fleshy parts, and in the hollow bones of these animals. Mr. 

John Hunter, F. R. S. (Philos. Trans. vol. iv. part i. p. 207, &c.) has published some curious observations on this subject, leading to a more particular inquiry into the final cause of this peculiarity in the structure of birds, which had not been sufficiently noticed and examined by anatomists and natural historians. He informs us, that the air-cells, which are found in the soft parts of birds, have no communication with the cavity of the common cellular membrane of the body; some of them communicate immediately with one another; and all of them may be said to have a communication together, by means of the lungs as a common centre. Some of them are placed in larger cavities, such as the abdomen; others are so lodged in the interstices of parts, that they would, at first, appear to be the common connecting membrane, as about the breast, axilla, &c. The bones which receive air are of two kinds; some, as the sternum, ribs, and vertebrae, have their internal subsidence divided into innumerable cells; whilst others, as the os lumeri and the os femoris, are hollowed out into one large canal. These bones may be distinguished from those that do not receive air by their less specific gravity; by being less vascular, and consequently whiter, than others; by containing little or no oil; by having no marrow nor bloody pulpy subsistance, even in their cells; by not being, in general, so hard and firm as other bones; and by the ease with which the passage that conveys the air into the bones may be perceived.

The mechanism by which the lungs are adapted for communicating air to the above-mentioned parts consists principally in the attachment of the lungs to the diaphragm and their connection with the ribs and fides of the vertebrae. These adhesions are peculiar to this tribe of animals. For the communication of the air from the lungs to the other parts, the diaphragm is perforated with large holes, which open a free passage between the cells of the lungs and the abdomen: and to each of these perforations is annexed a distinct bag, which is very thin and transparent, and these bags, which receive the air, are extended over the whole abdomen. The lungs open at their anterior part, or towards the sternum, into membranous cells, which lie upon the fides of the pericardium, and communicate with the cells of the sternum. The superior part of the lungs opens into large cells of a loofe net work, through which the trachea, oesophagus, and large vessels, in their way from and to the heart, pass. When these cells are dilated with air, the fize of the part where they lie is enlarged, and this dilatation indicates paestion, as appears in the turkey-cock, pouting-pigeon, &c.; and in the amidst of a goose, when it cackles. These cells communicate with others in the axilla, under the large pectoral muscle, &c.; and those again with the cavity of the os lumeri by small openings in the hollow surface, near the head of that bone. The posterior edges of the lungs, which lie on the sides of the spine, and project backwards between the ribs, open into the cells of the bodies of the vertebrae, ribs, canal of the medulla spinalis, sacrum, and other bones of the pelvis; and thus the air finds a passage to the cavity of the thigh-bone. This supply of the bones with air is not wholly by means of the lungs; for the cells of the bones of the head, in some birds, are filled with it, as in the case of the owl, which has the interposition between the two plates of the skull cellular, and capable of admitting a considerable quantity of air from the Lullianian tube. Mr. Hunter, in his conjectures concerning the use of these cavities, concluded at first that they were to be considered as appendages to the lungs, and that they answer the same purpose with the two bags that form the lungs of amphibious animals which are continued down through the belly, the upper part of which performs the office of respiration, and the remainder of which is a reservoir of air. In consequence of this conformation, these animals can breathe less frequently than others; and birds are thus aided in their flight, which must render frequency of respiration difficult, and a reservoir of air singularly useful. He further suggests that this construction of the respiratory organs may afford birds in flying; and that the long continuance of the song of a canary-bird between its breathings may be owing to this cause. Dr. Latham (Linnaeus Transact. vol. iv. p. 64.) queries, whether this construction may not enable fome birds to dive and stay for a considerable time under water. These air vesicles, according to Dr. Monro, are of considerable use in two respects. They serve, by dilating the lungs with air, to render the bodies of birds specifically light, and also to flatten the trachea arteriS, and thus return the air; and moreover to supply the place of a muscular diaphragm and strong abdominal muscles, and thus to aid the suction of the eggs and faces.

Air-chamber, is a name given by Dr. Henflew to a room contrived for obtaining the benefit of change of air, without going out of the house. According to his whimsical proposal, it is to be twelve feet square, and air-tight, furnished with a very large pair of organ bellows, to or from which air is to be conveyed through the wall by a copper pipe, with valves for opening inwardly and outwardly as occasion shall require. With these bellows, the air in the room is either to be condensed and made heavier, by forcing air in, or lighter and rarer by conveying air out of the room. See his Aero-Chalino, or Phil. Trans. No. 133. See Ventilator and Blowing-Wheel.

Air-gun, or Wind-gun, a machine which serves to explode bullets, and other shot, with great violence, by the expansive force of the air. This sort of implement, charged with air, has an effect scarcely inferior to that of a common firearm charged with gun-powder; but it discharges itself with a much less report, and it is this which probably gave occasion to the fable of white gun-powder. The first account of an air-gun, that has been noticed, is found in the Elements d'Artillerie of David Rivaut, who was preceptor to Louis XIII. of France. He ascribes the invention to one Marin, a burgler of Lifieux, who prefented one to Henry IV.

The common air-gun (Pneumatics, Plate iii. fig. 14.) is made of brass, and has two barrels: the inside barrel K A of a small bore, from which the bullets are shot, and a larger barrel ECD R on the outside of it. In the stock of the gun there is a syringe, S M N P, whose rod M draws out to take in air, and piston S N drives the air before it through the valve E P into the cavity between the two barrels. The ball K is put down into its place in the small barrel with the rammer, as in another gun. There is another valve at S I., which, being opened by the trigger O, permits the air to enter behind the ball, so as to drive it out with great force. If this valve be opened and shut suddenly, one charge of condensed air may make several discharges of bullets; but only part of the injected air will go out at a time; and a new bullet may be put into the place K; but if the whole air be discharged on a single bullet, the ball
ball will be expelled more forcibly. This discharge is
effected by means of a lock k (fig. 15.) placed here as in
other guns; for the trigger being pulled, the cock k will
go down, and drive a lever a, that will open the valve, and
let in the air upon the bullet K.

An air gun of the most modern and approved construc-
tion is represented in fig. 16. A is the iron gun-barrel, with the
lock, lock, ramrod, &c. of about the size and weight of a
common fowling-piece. Under the lock at k is a round
fired-tube, within which is a movable pin in the inide, which
is pushed out by the spring of the lock, when the trigger a
is pulled. To this tube, k, is screwed a hollow copper-ball,
c containing a spring-valve at its aperture; and perfectly
air-tight. Each gun has usually two of these balls, which
are fully charged with condenfed air by means of the con-
denfing syringe B, fig. 17. Having rammed down the
leaden bullet into the barrel, and screwed the copper ball
home to the lock at k, let the trigger, a, be pulled, and
the pin at k will be forcibly and instantly driven out against
the valve in the ball, and will thus liberate a portion of the
condenfed air; which, rushing up through an aperture in
the lock into the barrel immediately before the ball, will
impel it to the distance of, at least, 65 or 70 yards. By
re-cocking the piece, another discharge may be immediately
made, and thus repeated 15 or 16 times, with a very
small firing noise, and the distance is not audible. The con-
denfed air is forced into the ball by the following apparatus.
The ball, c, is screwed to the brass syringe B (fig. 17.)
quite close. In this syringe is adapted a movable piston
and iron rod, a, at the end of which is a strong ring, into
which is placed a stout iron rod, k, y upon this rod the feet
are firmly placed, and the hands are applied to the wooden
handles, i, i, fixed to the syringe. By readily moving the
barrel, B, up and down on the rod a, the ball, c, will become
charged with condenfed air; and it is easily known when it
is filled to the utmost by the irresistible action which the air
makes against the piston, when you are working the syringe.
At the end of the rod k, is usually an eight-square hole,
which serves as a key to make the ball fall on the screw, b,
and, of the gyn, and on the syringe. The piston-rod works air-
tight by a collar of leathers on it, in the barrel, B; and
therefore, when the barrel is pulled up, fresh air will rush in
at the hole b; when the barrel is pushed down, the air can
only pass into the ball at top of the barrel being drawn
upwards, the operation is repeated, until the condensation is
so strong as to refit the action of the piston.

Dr. Macbride (Exper. Eff. p. 81.) mentions an improve-
ment of the air-gun by Dr. Ellis, in which the chamber for
containing the condenfed air is not in the lock, which makes
the machine heavy and unwieldy, but has five or six hollow
spheres belonging to it, of about three inches diameter,
fitted to screw on the lock of the gun. These spheres are
crowned with valves for condenfing the air, which is forced
into their cavities, so that a servant can carry them ready-
charged with condenfed air; and thus the gun of this con-
duction is rendered as light and portable as one of the
smaller fowling-pieces.

The magazine air-gun is an improvement of the common
air-gun, invented by an ingenious artist called L. Colbe.
By his contrivance ten bullets are fo lodged in a cavity, near
the place of discharge, that they may be drawn into the
shooting barrel, and successively shot so quickly, as to be
nearly of the same size with so many different guns; the
only motion required, when the air has been previously
injected, being that of shutting and opening the hammer,
and cocking and pulling the trigger. In fig. 18., is
exhibited a fection of the gun, as large in every part as the gun
itself; and so much of its length is shown as is necessary
to give a complete idea of the whole. A E E is part of
the lock ; G is the end of the injection syringe, with its
valve, H, opening into the cavity, FFF, between the
barrels. K K is the small or floating barrel, which receives
the bullets, one at a time, from the magazine, E D E which
is a serpentine cavity, wherein the bullets, b, b, &c. are
lodged, and closed at the end D. The circular part, S 1 2 3 4,
is the key of a cock, having a cylindrical hole, I K, through
it, equal to the bore of the small barrel, and forming a part
of the in present situation. When the lock is taken off,
the several parts, Q, R, S, T, &c. come into view, by
means of which the discharge is made, by pulling up the
pin, P P, which raises and opens a valve, V, to let in the
air against the bullet, I, from the cavity, FFF; which valve
is immediately shut down again by means of a long spring
of brafs, NN. This valve, V, being a conical piece of
brass, ground very true in the part which receives it, will
of itself be sufficient to confine the air. To make a dis-
charge, pull the trigger, ZZ, which throws up the feer,
y x, and difengages it from the notch, x; upon which the
strong spring, W W, moves the tumbler, T, to which the
cock is fixed. The end, u, of this tumbler bears down the
end w, of the tumbler lever, R, which, by its other end, m,
raises the flat end, i, of the horizontal lever, Q, by which
means the pin, P P, is pulled up, and opening the valve, V,
discharges the bullet; all which is evident from a bare view
of the figure.

To bring another bullet instantly to succeed I, there is a
part H, called the hammer, represented in fig. 19. and fig. 20.
which by a square hole goes upon the square end of the
key of the cock, and turns it about, so as to place the
cylindrical bore of the key I k, in any situation required.

Thus, when the bullet is in the gun, the bore of the key
coincides with that of the barrel K K; but when it is dis-
charged, the hammer H is instantly brought down to flout
the pan of the gun; by which motion the bore of the key
is turned into the situation k, so as to coincide with the ori-
cifice of the magazine; and upon lifting the gun upright,
the ball next the key tumbles into its cavity, and falling
behind two small springs, i t, fig. 19. is by them detained.
Then opening the hammer again, the ball is brought into
the proper place, near the discharge valve, and the bore
of the key again coincides with that of the floating barrel.
It appears how expeditious a method this is of charging and
discharging a gun; and if the force of condenfed air was as
great as that of gunpowder, such an air-gun would actually
answer the end of many guns, and prove the belt defence
against highwaymen or robbers; because, when there is
reason to suspect them, they might then make five or six dis-
charges before the robber can come within pifloll-shot.

From the experiments of Mr. Robins, in his New Prin-
ciples of Guncnery, (See Mathem. Tracts of Robins, by
Willon, vol. i. p. 73.) it appears, that the force of gun-
powder, at the moment of its expolation, is 1000 times
greater than that of the elafficity of common air; and,
therefore, that the latter may produce the fame effect with
the former, its condensation must be 1000 times greater
than that of its natural flate. But as the velocities with
which equal balls are impelled are direedly proportional
to the square roots of the forces, the velocity with which
an air-gun, containing air condenfed only ten times, will
project a ball, will be \( \frac{1}{10} \) th of that arising from gun-powder;
and if the air were condenfed 20 times, it would com-
municate a velocity of \( \frac{1}{5} \) th of that of gun-powder.
In the air-gun, however, the refevoir of condenfed air is
commonly very large, in proportion to the tube which
contains
AIR

contains the ball, and its density will be very little altered by expanding through that narrow tube; consequently the ball will be urged by nearly the same uniform force with that of the first infant; whereas the elastic fluid of inflated gun-powder bears a small proportion to the barrel of the gun, and by dilating from the small portion of it near the but-end into a comparatively large space, its elastic force will be proportionally weakened, and its action on the ball in the barrel will become gradually less and less. Hence it appears, that the air-gun will project its ball with a much greater proportional degree of velocity than that which is above stated; insomuch that air condensed ten times will produce a velocity not much inferior to that arising from the gun-powder.

However, in this kind of gun, and in all cases which require a very considerable condensation of air, it will be requisite to have the firing of a small bore, viz. not exceeding half an inch in diameter; because the press of the air against the ball in every square inch is about 15 pounds, and against every circular inch about 12 pounds. If, therefore, the firing be one inch in diameter, when one atmosphere is injected, there will be a retort of 12 pounds against the piston; when two, of 24 pounds; and when ten are injected, there will be a force of 130 pounds to overcome; whereas the pressure in the barrel of a gun, is about one-fourth pound per inch, whole area is but one-fourth part to bolt, with a force but one-fourth as great, viz. 30 pounds; or 40 atmospheres may be injected with such a firing as well as ten with the other. Delaguerier's Exp. Phil. vol. ii. p. 398, &c. Martin's Phil. Brit. vol. ii. p. 180, &c. Adams's Lect. on Nat. and Exp. Phil. by Jones vol. ii. p. 133.

Air-jacket, a jacket of leather, furnished with bags or bladders of the same material, inflated with air, and serving to buoy up the person who wears it, and to prevent his sinking in water, without any effort of swimming. These bags communicate with each other, and are filled with air by means of a leathern pipe, having at the end of it a stop-cock, accurately ground, so as to admit the air into it, and, when closed, to prevent its escape. The jacket must be well moistened with water before the bags are filled; otherwise the air will escape through the pores of the leather.

Air-lamp, a pneumatic machine, formed by the combination of inflammable air and electricity, which, by turning a stop-cock, produces a flame that may be restrained or continued at pleasure. The contrivance of machines of this fort was suggested by the experiments of Mr. Volta, Dr. Ingenhousz, &c. The air-lamp is now constructed in the following manner. A, (Plate iii. Pneumatici; fig. 21.) is a glass jar containing the inflammable air; B, an open glas urn, that contains water, by the preface of which the air is forced out of the jar A, through the bras-pipe a; C, is the stop-cock, &c., so perforated, that the water may descend from B into A, and the air pass out through the pipe a. By turning the bar of the stop-cock to an horizontal position, the communication between the two vessels is closed, and the passage of the air obstructed; and by turning it into a vertical position, the communication is opened. The lower jar A, is supplied with inflammable air by means of the bladder, (fig. 21.); and two bladders of this kind accompany each lamp. It is used in the following manner: Take off the cover D, from the lamp, and turn the stop-cock upwards; then pour as much clear water into it as will fill the vessel, A, up to the pipe a; unscrew this pipe, and in its stead screw the small brass piece (fig. 23.) and to this screw one of the stop-cocks and bladders, (fig. 22.) With the bladder under one arm, one hand to the cock at C, and the other to that of the bladder, open the apertures and press the bladder at the same time; and thus the air will be forced upon the water in A, and driven up the glass pipe through the tube into B, with a bubbling noise. When the vessel, A, is thus charged with air, the stop-cocks are to be turned, so as to cut off the communication with the external air. Care must be taken that the common atmospheric air does not mix with the inflammable, for if a mixture of these airs were fired, the explosion would be great and dangerous.

The apparatus for lighting this lamp is of the electrical kind; and it is as follows: The mahogany basin, E, is a sort of box, about 12 inches square, and 5 inches deep, and in this is placed an electrophorus, containing a refrigerous cake c, and metallic plate d, which by a hinge at its back, admits of being pushed upwards and let down by the filament flying b, connected both with it and with the stop-cock C. When this cake is once excited, its electrical effect upon the metal plate will be continued for a long time. A metallic chain, G, communicates with a wire and ball e, passing through a glass tube below, in the box over the plate, and above with a fine wire passing through a glass tube. This upper wire is bent to about 1/4 of an inch distance from the flame-pipe. It is evident that when the electrophorus in the box is previously excited, and the stop-cock, C, turned, the filament flying, b, will raise the metallic plate; and this will give an electric spark to the ball and wire above, which will convey it instantly to the flame-pipe, and inflame the air flowing out of the pipe, in consequence of the pressure of the water in its descent into the vessel A. The cock, C, being turned back, the flame ceases; and turned again, appears; and will serve to light a candle, match, &c. whenever it may be thought proper. The number of times in which light may be produced will be very great, and will depend on the quantity of the inflammable air in the vessel A. If the cock is not turned back, the flame will continue till the whole of the inflammable air is consumed. The light thus produced will be sufficient for reading a large print in the night, or seeing the hour by a watch. When the electrophorus is to be excited, the filament flying, b, is unhooked from the plate, and the apparatus taken out of the box; and the metallic plate is lifted up, whilst, with a filament or dry catkin rubber, you briskly rub the surface of the refractory cake. About 20 revolutions in rubbing will be sufficient, so that the plate will give a spark to the knuckle about the distance of an inch; and by the strength of the spark the degree of excitation is to be estimated. The filament flying and small glass tubes, through which the wire, G, passes, should always be very dry, that the passage of the electrical spark may be quite perfect. The whole length of this apparatus is about 22 inches; but it may be made of any dimensions. Dr. Ingenhousz used a small apparatus, constructed upon a similar principle, in obtaining light for domestic purposes, both when at home and on his travels. Adams's Lectures by Jones, vol. ii. p. 99, &c.

Air-pipes, a contrivance invented by Mr. Sutton, a brewer of London, for clearing the holds of ships and other close places of their foul air. The principle upon which this contrivance is founded is well known. It is no other than the rarefying power of heat, which, by causing a diminution of the density of the air in one place, allows that which is in contact with it to rush in, and to be succeeded by a current supply from remoter parts, till the air becomes everywhere equally elastic. If a pipe, then, be laid in the well, hold, or any other part of a ship, and the upper part of this tube be sufficiently heated,
heated to rarefy the impeding column of air, the equilibrium will be maintained by the putrid air from the bottom of the tube, which being thus drawn out, will be succeeded by a supply of fresh air from the other parts of the ship; and by continuing the operation, the air will be changed in all parts of the ship. Upon this principle, Mr. Sutton proposed to purify the bad air of a ship, by means of the fire used for the copper, or both ends, with which every ship is provided. Under every such copper or boiler there are two holes separated by a grate, one for the fire and the other for the ashes; and there is also a flue, communicating with the fire-place, for the discharge of the smoke. The fire, after it is lighted, is preserved by the conical draught of air through these two holes and the flue; and if the two holes are closed, the fire is extinguished. But when these are closed, if another hole communicating with any other airy place, and also with the fire, be opened, the fire will of course continue to burn. In order to clear the holds of the ships of the bad air, Mr. Sutton proposed to close the two holes above mentioned, viz., the fire-place and ash-place, with substantial iron doors, and to lay a copper or leaden pipe of sufficient size from the hold into the ash-place, and thus to supply a draught of air for feeding the fire; a conical discharge of air from the hold will be thus obtained, and fresh air will be supplied down the hatches, and by such other communications as are open into the hold. If other pipes are connected with this principal pipe, communicating either with the wells or lower decks, the air that serves to feed the fire will be drawn from such places.

In large ships, there is not only a copper, but a fire-grate, like those used in kitchens; behind this grate an iron tube might be fixed, and inlaid quite through the brickwork and through the deck, so that one end of it might stand about a foot, or somewhat more, in the chimney above the brick-work, and the other made to enter into the hold or any other part of the ship. When the upper end of this tube is heated, the draught of air will be supplied from below, as in the other case. Mr. Sutton’s practicable and useful contrivance was much opposed at its first proposal; and though his pipes were recommended by Dr. Mead and Mr. W. Watson, after several trials of their effect, they were very slowly introduced, and in process of time very much neglected. Mr. Sutton, after considerable delay, and with no small difficulty, obtained a patent for his invention.

Mr. Watson recommends the use of these pipes for the circulation of fresh air in houses, prisons, hospital’s, wells, &c. and they have undoubtedly this obvious advantage, that by causing the putrid and noxious air to pass into the fire, they not only dilute but destroy it. Phil. Trans. abr. vol. viii. p. 688. 690. Mead’s Works, p. 397—437.

For other inventions adapted to the same purpose, see Air-trunk, Bellows, Ship’s-lungs, Ventilator, Blowing-wheel, and Wind-fails.

Air-pump, a machine, by means of which the air may be exhausted out of proper vessels.

The use and effect of the air-pump is to make what we popularly call a vacuum; but this, in reality, is only a degree of rarityfication sufficient to suspend the ordinary effects of the atmosphere. By this machine, therefore, we learn in some measure, what our earth would be without an atmosphere; and how much all vital, generative, nutritive, and alternative powers, depend upon it.

The principle on which the air-pump is contrived, is the elasticity of the air; as that on which the common, or water-pump is founded, is the gravity of the same air. The structure of the air-pump is, in itself, more simple even than that of the water-pump.—The latter supposes two principles, gravity and elasticity likewise: so that the water-pump must first be an air-pump, i.e. it must rarely the air before it can raise the water.—In effect, water being a dormant unelastic fluid, needs some external agent to make it ascend; whereas air ascends in virtue of its own elastic activity: its natural tendency is to separate and leave a vacuum; and all that remains for art is to prevent the ambient air from supplying the place of that which thus escape.

To make water ascend, the force wherewith it is pressed downwards is either to be diminished or increased in one part more than another; like a balance in equilibrio, one of whose scales may be made to rise, either by diminishing its own weight, or increasing that of the other; the water, therefore, recedes from the common centre of gravity by the very power with which it tends towards it indirectly or secondarily applied; because, two similar centripetal forces being made to act contrary to each other, what in the one over-balances the other must have the effect of a centrifugal force. —Whereas, the principle whereby air is rarefied or diminished, does not respect the centre of the earth, but the centres of its own particles; being no other than a certain implanted power, whereby they immediately tend to recede from each other.

The invention of this noble instrument, to which the present age is indebted for so many fine discoveries, is ascribed to Otto de Guericke, the celebrated confal of Magdeburg, who exhibited his first public experiments with it, before the emperor and the states of Germany, at the breaking up of the imperial diet at Ratisbon, in the year 1654: but his description of the instrument, and of the experiments performed with it, is contained in his “Experienta nova Magdeburgica de Vacuo Spatio,” and was not published before the year 1672, at Amsterdam.

Dr. Hooke and M. Duhemel, indeed, ascribe the invention of it to Mr. Boyle; but that ingenious author frankly confesses de Guericke to have been beforehand with him. In a letter which he wrote to his nephew, Lord Dungarvan, at Paris, about two years after Schottus’s book was published, he introduces the acknowledgment of his obligation, for the discovery of this useful machine, to what he had heard of it, though he had not then perceived it, by that well-applied passage of Pliny, benignus effet plenum ingens pudoris fateri per quam profeceris. Some attempts, he affirms us, he had made upon the same foundation, before he knew any thing of what had been done abroad: but the information he afterwards received from Schottus’s Mechanica Hydraulica Pneumatica, published in 1657, wherein was an account of de Guericke’s experiments, first enabled him to bring his design to any thing of maturity. From hence, with the assistance of Dr. Hooke, after two or three unsuccessful trials, arose a new air-pump more easy and manageable than the German one; and hence, or rather from the great variety of experiments that illustrious author applied it to, the engine came to be denominated machina Boyleana, and the vacuum produced by it, vacuum Boyleana.

Air-pump, structure and use of the. The basis or essential part in the air-pump, is a metaline tube, answering to the barrel of a common pump, or syringe; having a valve at the bottom, opening upwards; and a moveable piston or embolus, answering to the sucker of a pump, furnished likewise with a valve opening upwards. The whole must be duly fitted to a vessel or recipient or receiver. The ret being only circumstances chiefly respecting convenience, have been diversified and improved from time
to time, according to the several views and address of the makers.

In our further account of the air pump, we shall trace the various alterations it has undergone from the rude and inconvenient construction of Otto de Guericke to its present improved form. Guericke's machine is exhibited in Plate iv. Pneumatics, fig. 24. It consists of an iron three-legged frame, $a b c d f$, supporting a round iron plate, $b c$, in the middle of which is inserted a brass syringe, $g h$. The upper part of this syringe is furnished with a rim of lead, $y$, (fig. A.) and it is fastened below by means of an iron ring, $k k$, and three iron arms, $a o o$, to the legs of the frame. Within the rim $y$, there is a brass plate $m n$, (fig. B.) encompassed by a ring of leather, and fixed by three screws which terminate upwards in a small tube $n$, into which the pipe connected with the vessel to be exhausted is inserted, as occasion requires, and to which, on the lower side, is adapted a valve of leather, through which the air passes into the syringe. In this plate there is also another small valve at $z$, opening upwards, through which the air escapes. This plate is covered by a copper vessel, $x x$, intended for containing water. The piston of the syringe $b h$, (fig. 24. and fig. C.) is connected by a joint at $t$, with the iron rod $u n$, which is fastened to the handle, $u v y$, and this moves round the pin at $z$, by which it is connected with one of the legs of the frame. In order to prevent air from entering into the syringe, a copper vessel of water is suspended by hooks to the arms, $a o o$, so that the lower part of the syringe at $k k$, and the piston, may be always covered with water, when the machine is at work. The receiver, $I$, is a glass sphere, adapted to a brass cap, $P P$, which has a pipe with a flat-cock, $q r$; and this pipe is fitted to the tube, $n$, above mentioned. From this brief description of the machine, its operation will be easily understood. When the piston, $b h$, is depressed, the air will be expanded in the syringe, $g h$, and that of the receiver will descend into it through the valve in the lower surface of the plate, $m n$; but when the piston is elevated, and the air is compressed, this valve shutting upwards will close the passage to the receiver, and make its escape through the valve $z$, which opens upwards. In order to render the exhaustion more complete, a small exhausting syringe is adapted to the plate, which is represented at $m$. See Guericke's Expier. Nov. Magdeb. April 1719, page 166, and vol. ii. p. 10.

This machine, though it might be deemed an excellent contrivance at the time of its invention, when the doctrine of the elasticity and expansion of the air was new, had many defects which it is hardly necessary now to mention. The force necessary for working it was very great, and the progress of its operation very slow. Besides, it was to be wrought under water, and it allowed of little change of subjects for experiments. Mr. Boyle, whose ideas of this machine, first suggested to him by Schottus's report of Guericke's construction, were executed by Dr. Hooke, whom he then employed as his operator, removed some of these inconveniences and diminished others.

The form of Mr. Boyle's air-pump appears in Plate iv. Pneumatics, fig. 25. It consisted of a spherical receiver, $A$, with a round hole at the top, whose diameter, $B C$, was about four inches; this was covered with a plate, having a brass rim, $D E$, which was firmly cemented to the rings of glass that surrounded the hole; and to the taping orifice of the brass rim was adapted a brass flap $F G$, ground so exactly as to exclude as much as possible the admission of air. In the centre of the cover was a hole, $H I$, of about half an inch in diameter, provided with a cock, to which the brass flap $K$, was so fitted as to prevent the entrance of air; and the lower part of this flap was perforated with a hole, through which passed the flaring, $S, G$, for the convenience of moving to and fro the subjects of experiments. To the neck of the receiver a flat cock, $N$, was fastened; and to the Shank of the cock, $X$, a tin-plate, $M T U W$, was so cemented as to preclude the admission of air. The lower part of this machine consisted of a wooden frame with three legs, $1 2 2$, and a transverse board, $2 2 2$, on which the pump rested. The cylinder of this pump was cast brass; and it was fitted with a filler, $4 4 4 5 5 5$, of which one part, $4 4 4$, was covered with shoe-leather, so as exactly to fill the cavity of the cylinder; and to this was fastened the other part, which was a thick and narrow plate of iron, $5 5 5$, somewhat longer than the cylinder, indented on one edge with narrow teeth, so as to admit the corresponding teeth of a small iron nut, fastened by two flaps to the inner side of the transverse board, $2 2 2$, on which the cylinder rests; and this is turned to and fro by the handle, $7$. The face of this cylinder is the valve, $R$, consisting of a hole bored through at the top of the cylinder, somewhat tapering towards the cavity; into which hole is ground a tapering peg of brass, to be thrust in and taken out at pleasure. In order to prevent more effectually the admission of air, and to prepare the filler of the pump for motion, a quantity of fallad oil was poured in at the top of the receiver and also into the cylinder. The operator, having fixed the lower flank, $O$, of the flat-cock into the upper orifice of the cylinder, turns the handle, and thus forces the filler to the top of it, so that no air may be left in its upper part. Then shutting the valve with the plug, and turning the handle the other way, he draws down the filler to the bottom of the cylinder, and thus its cavity, into which no air is admitted, will be in an exhausted state. By turning the flat-cock, and opening a passage between the cylinder and the receiver, the air contained in the one will descend into the other; and this air being prevented from returning, by turning back the key of the flat-cock, will be made to open the valve and to escape into the external air by forcing the filler to the top of the cylinder; by alternately moving the filler upward and downward, turning the key and flopping the valve, as occasion requires, the exhaustion may be continued. See Boyle's Works, By Borough, vol. iv. p. 182. Mr. Boyle has described a second air-pump in the first continuation of his Physico-mechanical experiments. See his works, vol. iii. p. 185. This, like the former, had only one barrel, by which the receiver was exhausted; but it was so contrived as to be everywhere surrounded with water, that the ingress of air might be more effectually prevented. Besides, the receivers, which were of several forms and sizes, were fastened to an iron plate by means of a soft cement, so that they could be removed and changed at pleasure. The interpolation of a moistened leather for fixing them, does not seem at this time to have occurred to him.

Notwithstanding all the precautions of Mr. Boyle, and his contrivances for excluding air by oil and leather, he found that the working of his pump by a single barrel was laborious, on account of the prelude of the atmosphere, a great part of which was to be removed at every elevation of the piston when the exhaustion was nearly completed; and he himself candidly acknowledges, that it was rarely and with great difficulty, that he was able to produce any great degree of rarefaction. This useful machine was gradually improved by Papin, Merffenne, Mariotte, and others; but the introduction of a second barrel and piston was the principal
principal improvement which it received about this period. To whom this was owing, it is not easy to decide; some ascribe it to Dr. Hooke, others to Papin, and others again to Haukibee. An engine of this kind, with a double tube, is described by Mr. Boyle, in the second continuation of Physico-mechanical Experiments, (works, vol. iv. p. 310): but the manner of working it, by means of a pulley and of iron flippers or trestles, upon which the operator stood, must have been extremely inconvenient. However, by the use of a second barrel and piston, contrived to rise and fall alternately with the other, and by the introduction of valves, which in this third air-pump of Mr. Boyle supplied the place of the plug and stop-cock which he had before used, as well as by the subsequent improvements of Haukibee, the pressure of the atmosphere on the descending piston always nearly balanced that of the ascending one; so that the winch which worked them up and down was easily moved by a gentle force with one hand; and the exhaustion was also made in much less time. See Haukibee's Physico-Mechanical Experiments, p. 1, &c. Mr. Cream, a pneumatic operator, employed by Defaguliers, made an improvement in Haukibee's air-pump, by reducing the alternate motion of the hand and winch to a circular one. In his method the winch is turned quite round, and yet the pistons are alternately raised and depressed; by which the trouble of shifting the hand backwards and forwards, as well as the loss of time, and the slacking of the pump, are prevented. See Defaguliers's Courde of Exp. Philos. vol. ii. p. 378. For a brief account of the progressive improvements of the air-pump, see Cotes's Hydrostatical and Pneumatic Lectures, lect. xii. p. 156, &c.

The structure of the air-pump, thus improved, is represented in Plate v. Pneumatics, fig. 33. It consists of two brafs barrels or cylinders, a a a a, which communicate with each other by the cittern d d, and with the receiver o o o o, which is ground level at the bottom, and let over a hole in the plate, by means of the bentine pipe, b b. In these barrels the pistons, which are fastened so tight that no air can get between them and the barrels, are worked by a toothed wheel, turned by the handle, b b; and thus the racks, c c, with their pistons, are worked alternately up and down. The gage tube, l l, is immered in a bason of quicksilver m, at the bottom, and communicates with the receiver at the top of which it may be occasionally disengaged by turning a cock; and a is another cock, by turning of which the air is again let into the exhausted receiver, passing into it with a hissing noise. The action of the toothed wheel and pistons is represented in fig. 34.

As the handle is turned backwards, it raises the piston d d, in the barrel B B, by means of the wheel E, and rack D d: and as no air can get between the piston and barrel, all the air above d is lifted up towards B, and a vacuum is made in the barrel from e to b: upon which part of the air in the receiver by its spring rushes through the hole in the brafs plate of the pump along the pipe G G, communicating with both barrels by the hollow trunk I H K, and pushing up the valve B, enters into the vacant part b e of the barrel B. Then, as the handle, F, is turned forward, the piston, d d, will be depressed in the barrel; and the air which had got into the barrel, finding no way of escape through the closed valve b, will ascend through a hole in the piston, and make its way to the external air through a valve at d: and it will be prevented by that valve from returning into the barrel, when the piston is again raised.

At the next elevation of the piston, a vacuum is again made in the same manner as before, between b and e; upon which more of the air that was left in the receiver will get out by its spring, and flow into the barrel, B K, through the valve b. The other piston and barrel act in the same manner; and as the handle, F, is turned backwards and forwards, it alternately raises and depresses the pistons in their barrels; one being raised whilst the other is depressed. By thus repeating the operation again and again, the air in the receiver is at length rarefied to such a degree, that its density does not exceed the thin air remaining in the barrel when the piston is raised: which done, the effect of the air-pump is at an end; the valve cannot now be opened, or if it could, no air would pass through; there being a just equilibrium between the air on each side.

To judge of the degree of exhaustion, there is added the gage-tube, l l, open at both ends, and about 34 inches long (fig. 33), affixed to a wooden ruler, which is divided into inches and parts of an inch, from the bottom where it is even with the quicksilver in the bason, m, and continued to the top, a little below the plate of the air pump, to 30 or 31 inches. Hence the air in the tube rarefying as fall as that in the receiver, in proportion as the exhaustion advances, the rapidity being a measure of the pressure of the column of external air, prevailing over that of the column of air included; till the column of air, and mercury together, become a balance to that of the external air. When the mercury is thus risen to the same height as it stands in the barometer, which is indicated by the scale of inches added to the gage, the instrument is a full Torricellian tube; and the vacuum may be concluded to be as perfect as that in the upper end of the barometer. When the cock, n, is turned, fo as to make a communication with the external air; this rushes in and the mercury in the gage immediately subides into the bason. See GAG.}

In estimating the gradual acent of the quicksilver in the gage, it is evident that, as we continue to pump, the mercury continues to ascend; and that it approaches always more and more to the standard altitude, or about 29½ inches, more or less according to the variety of leasons. And it is easy to prove, that the defcent of the height of the quicksilver in the gage from the standard altitude is always proportional to the quantity of air which remains in the receiver; that the altitude itself of the quicksilver in the gage is proportional to the quantity of air which has been exhaunted from the receiver; and that the acent of the quicksilver, upon every turn of the pump, is proportional to the quantity evacuated by each turn. Let it be considered, that the whole pressure of the atmosphere upon the cifer of the gage is equal to, and may be balanced by, a column of quicksilver of the standard altitude; consequently, when the quicksilver in the gage has not yet arrived to the standard altitude, the defect must be supphed by some other equal force; and that force is the elastic power of the air remaining in the receiver; which communicating with the upper part of the gage, hinders the quicksilver from ascending, as it would otherwise do, to the standard altitude. The elasticity of the air in the receiver is then equivalent to the weight of the deficient quicksilver; but the weight of this is proportional to the space it should occupy, or to the defect of the height of the quicksilver in the gage from the standard height; therefore the elasticity of the remaining air is also proportional to the same defect. But the density of any portion of air is proportional to its cificity, and the quantity in this case is proportional to the density; and therefore the quantity of air remaining in the receiver is proportional to the defect of the quicksilver in the gage from its standard altitude. Hence
AIR PUMP.

Hence it follows, that the quantity of air which was at first in the receiver before you began to pump, is proportional to the whole standard altitude; and consequently the difference of this air, which was at first in the receiver, and that which remains after any certain number of turns, that is, the quantity of air exhausted, is proportional to the difference of the standard altitude and the before-mentioned defect, that is, to the altitude of the quicksilver in the gage after that number of turns. Hence it appears, that the quantity of air exhausted at every turn of the pump is proportional to the ascent of the quicksilver upon each turn. See Cotes’s Hydrost. and Pneum. Lectures, etc. 12. See Gage.

There are several inconveniences attending air-pumps of the common form, though much improved from what they used to be formerly, and many attempts have been made to remedy them. It is a well-known fact, that pumps merely serve to rarely the air to a considerable degree, and that none of them can produce a complete exhaustion; as the mercury in the gage is not raised by any of them to the height which it occupies in the Torricellian tube, when well purged of air. Few pumps will bring it within $\frac{1}{3}$th of an inch. Hawkfield’s, fitted up according to his own instructions, will seldom bring it within $\frac{1}{4}$th; pumps with cocks of the best construction, and in the most favourable circumstances, will bring it within $\frac{1}{3}$th; but none with valves fitted up with wet leather, or to any part of which water or any volatile fluids have access, will bring it nearer than $\frac{1}{4}$th. Before we proceed to give an abridged account of the improvements that have been made in air-pumps we observe, that the air-pumps most commonly used are made either with brass stop-cocks, or with valves of oil-skin or of leather, for preventing the return of the air into the receiver, out of which it had been exhausted. Pumps with stop-cocks, when well made and newly put together, are generally found to rarely the air to a greater degree than those which are made with valves; but after having been used for some time, they become less accurate than those with valves. But the valves are also imperfect; as the external air, prefing upon that in the piston, prevents its rising, when the elastic force of the air in the receiver, under exhaustion, is much diminished. Attempts have been made, particularly by the abbé Nollet and Mr. Gravefande, to perfect the construction of the cocks. In Gravefande’s double-barrelled pump, the cocks at the bottom of the pilons are turned by an apparatus that is moved by the handle of the pump: the piston has no valve, and the rod is connected with it by a flirrup, as in a common pump. This rod has a cylindric part, which passes through the flirrup, and moves it always in it through the space of about half an inch, between a shoulder above and a nut below. The flirrup supports a round plate, which has a short square tube, that fits tight into the hole of a piece of cork, and which has also a square Shank, that goes into the square tube. Between the plate and the cork is put a piece of thin leather, soaked in oil, and another is placed between the cork and the plate which forms the sole of the flirrup. When the winch is turned to raise the piston from the bottom of the barrel, the friction of the piston against the barrel keeps it in its place, and the rod is drawn up through the flirrup. The wheel has thus liberty to turn about an inch; and this is sufficient to turn the cock, so as to cut off the communication with the external air, and to open that with the receiver. When this is done, the continued motion serves to raise up the piston to the top of the barrel. When the winch is turned in the opposite direction, the piston remains fixed till the cock is turned, so as to flit the communication with the receiver; and open that with the external air. The cock has one perforation diametrically through it, and another in a perpendicular direction to this; and after reaching the centre, it passes along the axis of the cock, and communicates with the open air. By this communication, when it is opened, the air rushes in, and balances the pressure on the upper side of the piston in this barrel, so that the piston on the other must be counteracted by the person who works the pump. In order to obviate this inconvenience, Gravefande put a valve on the orifice of the cock, by tying over it a slip of wet bladder or niled leather; and by means of this the piston is pressed down, as long as the air in the barrel is rarer than the outward air, just as if the valve was in the piston itself. Gravefande, and also Müllchenbruck, extol the operation of this pump, as exceeding that of pumps with valves. But it is evident that no precise estimate of its performance can be obtained, whilst the pistons, valves, and leathers of the pump are prepared by steeping them in oil, and afterwards in a mixture of water and spirits of wine. With this preparation the gage could not be brought within $\frac{1}{3}$th of an inch of the barometer. Besides, a considerable space is left between the piston and cock, from which the air is never expelled; and if this be made very small, the pump must be worked very slowly; otherwise the air will not have time to diffuse itself from the receiver into the barrel, especially when the expelling force or the elasticity of the air, towards the close of the operation, is very small. The rarefaction will likewise be retarded by the valve, which will not open till the air below the piston is considerably denser than the external air. The cocks in pumps of this kind are subject to become loose by use, and to admit air: an inconvenience which might, indeed, be prevented by placing the barrels in a dish filled with oil. For a figure and description of Gravefande’s pump, see Gravefande’s Mathem. Elem. of Natural Philosophy, by Defagugiers, vol. ii. p. 17, &c. Thesepumps, if they were ever used in England, have been long superceded by the cheaper and more simple contrivance of valves, formed by tying a strip of bladder over a small hole, through which the air is allowed to pass in one direction only.

In the year 1758, the ingenious Mr. Smeaton directed his attention to the improvement of valve pumps. In considering the structure of these pumps, he observed, that the principal causes of their imperfection are, partly, the difficulty of opening the valves at the bottom of the barrels, and, partly, the piston’s not fitting exactly, when put down to the bottom, which leaves a lodgment of air that is of bad effect. The first of these imperfections is owing to the smallness of the common valves, which are made of a piece of thin bladder stretched over a hole generally much less than $\frac{1}{3}$th of an inch in diameter, and to the adhesion of the bladder to the plate upon which it is spread, by reason of the oil or water with which it is moistened; as the rarefaction of the air in the receiver is continued by the operation of the pump, its firing becomes so weak, that it is not able to overcome the cohesion of the bladder to the plate, the weight of the bladder, and the resistance occasioned by its being stretched. The larger the hole is, over which the bladder is laid, a proportionably greater force is exerted upon it by the included air in order to lift it up; and yet the aperture of the hole cannot be made very large, because the pressure of the incumbent air would either burst the valve, or so far force it down into the cavity as to prevent its lying flat and close upon the plate. In order to avoid these inconveniences, instead of one hole, Mr. Smeaton makes use of seven, all of equal
A I R - P U M P.

size and shape, one being in the centre, and the other fix round it, so that the valve is supported at proper distances by a kind of grating, formed by the solid parae between these holes, and resembling a honeycomb; and that the points of contact between the bladder and grating may be as few as possible, the holes are hexagonal, and the partitions are held almost to an edge. The breadth of these hexagons is \( \sqrt{\frac{1}{2}} \)ths of an inch, and consequently the surface times larger than common; and as the circumference is three times greater than that of the common valve, and the cohesion to be overcome is, in the first moment of the air's exerting its force, proportional to the circumference of the hole, the valve over any of these holes will be raised with three times more ease. Besides, the raising of the valve over the centre-hole is aided on all sides by those that are placed round it; and as they all contribute as much to raise the bladder over the centre-hole, as the air immediately acting under it, the valve will be raised with double the ease already supposed, or with a sixth part of the force commonly necessary. After the bladder begins to rise, it will expel a greater surface to the air underneath, which will cause it to move more easily.

The other defect in the common construction would fill hinder the rarefaction from being carried on beyond a certain degree. For as the piston does not fit so closely to the bottom of the barrel, as to totally exclude the air, the air, as the piston rises, will expand itself, and preying upon the valves in proportion to its density, hinder the air within the receiver from coming out. Hence, if the vacuum were equal to the 1295th part of the capacity of the whole barrel, no air could pass out of the receiver, when expanded 190 times, though the piston were constantly drawn to the top; because the air in the receiver would be in equilibrium with that in the barrel, when in its most expanded state. In order to obviate this inconvenience, Mr. Smeaton shut up the top of the barrel with a plate, having in the middle a collar of leathers, through which the cylindrical rod works that carries the piston. The external air is thus prevented from preying upon the piston; but for the discharge of the air that passes from below through the valve of the piston, there is a valve applied to the plate at the top, which opens upwards. By this construction, when the piston is put down to the bottom of the cylinder, the air under it will evacuate itself, and the valve of the piston opens more easily, when preying by the rarefied air above it, than when preying by the whole weight of the atmosphere; and as the piston may be made to fit as nearly to the top of the cylinder as it can to the bottom, the air may be rarefied as much above the piston, as it could before have been in the receiver. Hence it follows, that the air may now be rarefied in the receiver in duplicate proportion of what it could be upon the common principle. By this construction, the pump, consisting of a single barrel, may be worked with more ease than the common pump with two barrels, because the preying of the outward air is taken off by the upper plate; and when a considerable degree of rarefaction is defied, it will produce it more speedily.

Mr. Smeaton has also contrived a new gage, which measures the expansion with certainty, to much less than the 1000th part of the whole. It consists of a bulb of glass, in shape resembling a pear, and sufficient to hold about half a pound of quicksilver. It is open at one end, and the other is a tube hermetically sealed at top. A scale divided into parts of about \( \frac{1}{1000} \)th of an inch each, and answering to a 10000th part of the whole capacity, is annexed to it. This gage, during the exhaustion of the receiver, is suspended in it by a flip-wire. When the pump is worked as much as is thought necessary, the gage is pushed down, till the open end is immersed in a cistern of quicksilver placed underneath. The air being then let in, the quicksilver will be driven into the gage, till the air remaining in it becomes of the same density with the external; and as the air always takes the highest place, the tube being uppermost, the expansion will be determined by the number of divisions occupied by the air at the top. See Gages.

This ingenious artist has succeeded so well in his construction of the air-pump, as to be able to rarefy air about 1090 times; whereas the best of the common air-pumps, esteemed good in their kind, and in complete order, never rarefied it above 140 times. Mr. Smeaton's air-pump acts also as a condensing engine, by the very simple apparatus of turning a cock; see Condenser. This air-pump is thus easily made an universal engine, for shewing any effect arising from an alteration in the density or spring of the air; and with a little addition made may be shewed the experiments of the air-fountain, air-gun, &c. Phil. Trans. vol. xlvii. p. 415—473.

A perspective view of the principal parts of this pump is exhibited in Plate VI. Pneumatics, fig. 45. A is the barrel, B the cistern, in which is included the cock, with several joints, which are contrived of leather to keep them air-tight; and a little cock to let the water out of the cistern is marked c. C e e is the triangular handle of the key of the cock, which, by the marks on its arm, shews how it must be turned, that the pump may produce the effect desired. D H is the pipe of communication between the cock and the receiver. E is the pipe that communicates between the cock and the valve, on the upper plate of the barrel. F is the upper plate of the pump which contains the collar of leathers d, and V is the valve, which is covered by the piece f. G I is the fthuron-gage, which is fitted on and off, and adapted to common purposes. It consists of a glass-tube hermetically sealed at e, and furnished with quicksilver in each leg, which, before the pump begins to work, lies level in the line a b; the space b c being filled with air of the common density. When the pump exhausts, the air in b c expands, and the quicksilver in the opposite leg rises, till it becomes a counterbalance to it. Its rise is marked a c. When the expansion of the air in the receiver may be nearly estimated. When the pump concedes, the quicksilver rises in the other leg, and the degree may be nearly judged of by the contraction of the air in b c; marks being placed at \( \frac{1}{10} \) and \( \frac{1}{100} \) of the length of b c from c, which shews when the receiver contains double or treble its common quantity. K L is the screw-frame to hold down the receiver in condenfing experiments, which takes off at pleasure, and is sufficient to hold down a receiver, the diameter of whose base is seven inches, when charged with a treble atmosphere; in which case it acts with a force of about 1200 pounds against the screw-frame. M is a screw that fastens a bolt, which slides up and down in that leg, by means of which the machine is made to stand fast on uneven ground. The stricture, connection, and relative uses of the several parts of this pump will be further perceived in the following account of Smeaton's air-pump, constructed and improved by Mr. Nairne.
AIR-PUMP.

receiver; the pifton gage \( f \) is made in the usual manner; but the ciphers \( x, x \), prevent the gages from being directed by the oil, on the re-admission of the air. The large barrel \( C \) has a solid plunger, worked by the rod \( R \), which passes through the collar of leathers \( a \); for the construction of which, as well as the internal structure of the barrel \( C \), see \( f, 3, 4 \).

This is a vertical section of the barrel, &c.; the top or cup \( U \) is screwed on to the screw \( a \), and the cavity \( b \) is made conical; the holes \( e, e \), are made just large enough to let the pilton rod pass freely; the cavity \( b \) is filled with circular greased leathers, through the centre of which a hole is made, that barely admits the pilton rod to pass; these leathers are crowded into \( b \), and three or four thinnesses of them are left above the surface, \( f \); and consequently, when the cup \( U \) is screwed down, these leathers are forced into the smaller part of the conical hollow, \( f \); and therefore bind as much or as little as is requisite on the pilton rod.

The head \( a \) is screwed with eight screws on the upper flange or part of the barrel \( C \); the bottom \( B \) screws on the lower flange or lower end of \( C \); the plug \( D \) is accurately ground into a conical hole in the bottom \( B \), and has the lever \( L \) slanting at right angles. As the whole nicety of the exhaustion of this air-pump depends upon this part, it should be very particularly described. The lever \( L \) is represented as slanting to the left hand; and the hole \( 2 \) with its axis is set in connection with the pipe \( P \) and consequently with the receiver; see the horizontal section \( L, D, P \). But if the lever \( L \) is brought towards the word "closed," the hole \( 2 \) with its valve \( 1 \) has moved onwards towards \( D \); no hole is opposite to the hole of \( P \), and consequently all communication between the receiver and the inside of the barrel \( C \) is cut off; but upon moving the lever \( L \) more towards the right hand, the hole \( 3 \) having the words "no valve" will be in connection with \( P \), and consequently there will be a direct or uninterrupted passage between the receiver and the inside of the barrel \( C \). Upon attentively inspecting the section, it will be perceived by the directions in which the valves open and close, and the position of the passages which are drilled through the thickness of the barrel, that the ascent or descent of the solid plunger \( N \) equally exhausts the pipe \( P \), and consequently the receiver. It must be remarked, that the valves exhibited in the section are drawn like hogs of boxes, with holes large enough to permit the oil flowing in what direction they open; but in reality the valves are made of oiled silk; and as on the nice construction of these the good action of the pump much depends, the best mode of making them will be illustrated in the section, \( f, 7, A, A \), which shews the plug \( D \), on which the valve is to be fixed. In the first place, a groove must be turned, of a convenient fize, so as to leave a cylindrical knob \( F \), whose diameter may be four or five eighths, or more, of an inch; the hole which the oiled silk valve is intended to cover, is made through the axis or centre of this knob, as is shown by the dotted lines \( H \); the ring \( G \) is to fit nicely into the groove, and to be fluted with the general surface of the brass; the surface of the knob \( F \) must be turned away about double the thickness of the oiled silk for the purpose of preferring the oiled silk from injury by the pilton's striking it; a lip of oiled silk about the width of four times the diameter of the hole, which it is to cover, must be laid over the hole in the centre of the knob \( F \), and the ring \( G \) carefully put in its place and there fixed by two or three screws. \( f, 7, B \) shews the construction of the referov \( x, x \), \( f, 4, 46 \), for the purpose of keeping the gages clean. The end of the gage \( G \), for instance, passes through the bottom of the referov \( x \), and reaches nearly to the top; and a piece of metal, flat or like an inverted tea-facer, is fixed to the top of \( x, f, 7, B. B. \) The oil which comes from the pump through \( x \) is thrown on the back of the face; and running to its edges drops into the bottom part of the referov, and thus prevents any filth from getting into the tube \( G, f, 46 \).

Having described the particular parts of this pump, we shall next explain the mode of working it, so as to obtain the greatest degree of exhaustion. A receiver well ground and made dry, with oil put upon its edge, is to be placed on the pump plate \( T \) (\( f, 45 \)), over the aperture of the pipe \( P \); and the lever \( L \) is to be moved so as to stand under the word "valve." By working the pilton of the cylinder \( C \) up and down, from the top to the bottom, the receiver becomes partly exhausted, and the mercury will rise from the cylinder \( M \) up into the tube of the barometer gage \( G \); the exhaustion must be continued till it will rise no higher; and turning the lever \( L \) under the word "closed," the pilton must be moved two or three times up and down; let it then be left at the bottom of the barrel \( C \); move the lever \( L \) under the words "no valve," and gently raise the pilton to the top of the barrel. As there is now a direct communication between the receiver and the barrel \( C \), without the intervention of a valve, the air will expand itself freely into the barrel, and the mercury of the gage will rise; keeping the pilton at the top of the barrel, turn the lever again under the word "closed," and repeat the operation as before; unfcrew the receptacle for dirty oil, \( O \), and screw in its place the complete small exhausting syringe \( B \); work this a few times; and repeat the operation with the barrel and the lever \( L \) as before, till the mercury will rise no higher in the gage.

By the process now described, the exhaustion has been made so perfect, that when an open eideron barometer, suspended in the room, has been on the rife, the mercury in the gage \( G \) has risen within \( \frac{1}{2} \)th of an inch high.

The double-barreled air-pump \( A, A \) being placed on the same stand, and having a communication with the pump plate \( T \), as well as the improved pump \( C \), it is intended for exhausting large receivers very expeditiously; as both pumps may be worked at the same time; and more especially for preventing the improved pump from being used for trifling experiments, or those where water is made use of. In the pump plate \( T \) are two holes, situated near each other, one communicating with the double-barreled, and the other with the improved pump, and for the purpose of cutting off the communication of either with the receiver at pleasure. Indeed, when the double-barreled pump is only used, the hole of the pipe \( P \), leading to the barrel \( C \), should always be carefully stopped to prevent moisture of any kind from getting into it.

Since the time of Mr. Smeaton the air-pump has received very material improvements; for which we are indebted to the Rev. Mr. Prince, of Salem, in North-America; and to Mr. Cuthbertson, late of Amsterdarm, and since settled in London.

Mr. Smeaton's success in facilitating the opening of the valves, at the bottom of the barrel and in the pilton, led Mr. Prince to conceive, that if these valves were entirely removed, and the remaining air in the barrel could be more perfectly expelled, the rarefaction might be carried still farther. Upon this plan he constructed his air-pump. He removed the lower valve, and opened the bottom of the barrel into a ciferon on which it was placed, and which had a free communication with the receiver; for the valve on the upper plate, at the top of the barrel, constructed like Mr. Smeaton's, made it unnecessary that there should be any at the bottom, in order to rarely the air in the receiver. The ciferon was made deep enough to admit of the pilton's descending into it below the bottom of the barrel. If the pilton be solid, that is, without a valve, when it enters the barrel...
barrel and rises to the top-plate, which is made air tight with a collar of leathers, like Smeeaton’s, it forces out all the air above it; and as the air cannot return into the barrel on account of the valve in the top-plate, when the piston descends, there will be a vacuum between it and the plate; every thing being supposed perfect. But in working the pump, the piston is not allowed to descend entirely into the cistern so far as to leave the bottom of the barrel open; but it descends below a hole in the side of the barrel near the bottom, which opens a free communication between the barrel, cistern, and receiver. Through this hole the air rushes from the cistern into the exhausted barrel, when the piston has dropped below it; and by its next ascent this air is forced out as the other was before. If the capacity of the receiver, cistern, pipes, &c. below the bottom of the barrel, taken together, be equal to the capacity of the barrel, half the remaining air will be expelled by every stroke. But as the working of this pump with a solid piston would be laborious, on account of the resistance it would meet with in its descent from the air beneath, though it would be relieved by every stroke as the air became more rarefied, Mr. Prince pierced three holes in the piston at equal distances from each other, and by a circular piece of bladder, tied over the top of the piston, formed a kind of valves over the holes, which opened with sufficient ease to prevent any labour in working the pump, by allowing the air to pass through the piston in its descent. The escape of the air does not, however, depend upon a passage through the piston into the barrel; for when the air, weakened by rarefaction, cannot open this valve, it will fill get into the barrel when the communication is opened by the hole at the bottom. This piston will therefore descend as easily as any other, nor will the valves impede the rarefaction. By this construction the valves, made to open with more ease by Mr. Smeeaton, are rendered unnecessary for rarefying the air; and that at the bottom of the barrel is entirely removed; the valve on the top-plate being the only one necessary in rarefying the air.

Having set aside the valves, which partly prevented the air from entering the barrel above the piston, Mr. Prince’s next attempt was to expel the air more perfectly out of the barrel than Mr. Smeeaton had done, by making a better vacuum between the piston and the top-plate, so that more of the air might be allowed to expand itself into the barrel from the receiver. Mr. Prince also contrived to connect the valves on the top-plate with the receiver occasionally by means of a pipe and cock, by the turning of which the machine might be made to exhaust or condense at pleasure. In order to remove the pressure of the atmosphere from the valve on the top-plate, so that this valve might open as easily as the piston valve, he connected with the duct on the bottom piece, which conveys the air from the valves to the cock, a small pump of the same construction as the large one; having the barrel opening into the cistern, the piston rod, which is solid, moving through a collar of leathers, and a valve near the top, through which the air is forced into the atmosphere. This pump with one barrel is called the valve-pump; its chief use being to rarefy the air above the valves, or to remove the weight of the atmosphere from them. When this valve pump is used, the passage through the cock is shut up; and, therefore, instead of placing three ducts at equal distances round the cock in the manner of Mr. Smeeaton’s, Mr. Prince divided the whole into five equal parts, leaving the distance of one-fifth part between the ducts leading from the cistern and the valves to the cock, and two-fifths between each of these and the one leading from the cock to the receiver. By this adjustment, when the communication is open between the receiver and the valves for condensation, the other hole through the cock opens the cisterns to the atmosphere; but when the communication is made between the cisterns and the receiver for exhausting, a solid part of the key comes against the duct leading to the cock, and thwarts it up, and the air which is forced out of the barrel passes through the atmosphere into the valve-pump; for the valve of the small pump may be kept open while the great one is worked.

Upon this construction, the pump with two barrels may be made like the common pump, which cannot be conveniently done where the lower valve is retained. In this pump the pistons do not move the whole length of the barrels; an horizontal motion being made in them a little more than half way from the bottom, where the top-plates are inserted. The pump is thus made more convenient and simple, as the head of it is brought down upon the top of the barrels in the same manner as in the common air-pump. The barrels also stand upon the same plane with the receiver plate, and this plane is raised high enough to admit the common gage of 32 or 33 inches to stand under it without inconvenience in working the pump; as the winch moves through a less portion of an arch at each stroke than it would do if the pistons moved through the whole length of the barrels.

A gage for measuring the degree of condensation having a free communication with the valves, cock, &c. is placed between the barrels in this pump; and the gage is so constructed that it will also serve to measure the rarefaction above the valves when the air is worked off by the valve-pump. It consists of a pedetal, the die of which is made of glass, which forms a cistern for the mercury, a hollow brass pillar, and glass tube hermetically sealed at one end, which moves up and down in the pillar through a collar of leathers. When the pump is used as a condenser, the degree of condensation is flown by a scale marked on one edge of the pillar; when it is used as an exhaust, the degree of rarefaction of the air above the valves is flown by a scale on the other edge of the pillar. This gage will also show, when the valves have done playing, either with the weight of the atmosphere on them or taken off, in the manner which the author has described. The degree of condensation may be also measured by the number of strokes of the winch. For the purposes of great condensation, Mr. Prince has fitted a condenser of a smaller bore than the barrel of the great pump to the cistern of the valve-pump, to be screwed on occasion. Or, without this condenser, the valve-pump may be adapted to the purpose by being made a little larger, and by having a plate made to screw into the bottom of the cylinder, with a valve on it opening into the cistern; a hole must be made to be opened on the same occasion near the top of the cylinder, to let air in below the piston when this is drawn up above it.

The common gage, which is generally placed under the receiver-plate, is placed in the front of this pump, that it may be seen by the person who works it, and that the plate may be left free for other uses. The plate is fixed to the pipe leading to the cock, that it may be taken off at pleasure, and used as a transferer; and it may also serve for other purposes.

The head of this pump is made whole, except a small piece on the back, where the wheel is let in; and the wheel is fixed from the piston-rods by pushing it into the back part of the head, and it is kept in its place by a button screwed into the socket of the axis behind. By this apparatus the piston-rods are dislodged from the wheel; and let down into the cisterns, when the pump is not used; and in these cisterns they may also have the advantage of being covered with oil. The principal joints of this pump are sunk into sockets, that
the leathers which close them may be covered with oil to prevent leaking. The lower part of the pump is fitted with drawers to contain the necessary apparatus.

A perspective view of a double-barreled pump, made by Mr. Jones, according to the construction of Mr. Prince, may be seen in Plate VII. Pneumaticus, fig. 48. A, A, are two brass barrels in which the pistons move; the barrels communicate with the receiver placed on the pump by means of the pipe B C, and canal D E; the rods of the pistons are seen at FG; each of these is connected with a rack or piece having teeth on one side. At A is a wheel, whose teeth are laid hold of by those of the rack; so that by turning the handle H the pistons are alternately raised or depressed, and the air is exhausted out of the receiver K L, the tube B C, and the canal D E, which communicate with one another. At the top of each barrel is a plate, on which is a box m n, containing a collar of leathers; through this the cylindrical part of the piston rod moves, air-tight; o o is the place of the valve on the top plate, into which a pipe is folded that conveys the air from the valve to the duct, passing under the valve pump P, which is designed for preventing the escape of the atmosphere from acting on the valve of the top plate. Q is the piston rod of this pump, and R the handle by which it is worked. Y is a cock to cut off occasionally the communication between the receiver and the working parts of the pump. At S is a screw, which closes the orifice of the canal D E, by unfastening which the air may be admitted when required. Z is an oil-veil for receiving the oil driven over by the action of the pump; and there should be always a small quantity of oil in the cups of the boxes m n, that hold the collar of leathers through which the piston rods move; a b c is the barometric-gage; d e the box or cistern containing the mercury; and there is a divided box f e a f, fixed to the tube, for ascertaining the rise or fall of the mercury; a small ivory tube en-compasses the lower end of the glass tubes, and floats upon the quicksilver in the cistern; the upper end of this is always to be brought to coincide with the lower division of the box f e a, by means of the screw under the cistern; and when it thus coincides, the divisions on the scale give the true distance from the surface of the mercury in the balance. The key f serves for tightening or loosening the screws of the pump. When either piston is down, in the operation of this pump, there is a free communication from the receiver through the tubes and the canal to the part of the barrel above the piston; when the piston rises, it forces out the air above it through the valve in the top plate; and as this valve prevents the air from returning into the barrel, when the piston descends, a vacuum is formed between it and the under surface of the top plate; as soon, therefore, as the piston has descended below the holes communicating, by the tubes and pipe, with the receiver, the air rushes into the exhausted barrel; on the next ascent of the piston, this air is forced out as before. To prevent the piston from meeting any resistance in its descent, there is a valve in it through which the air passes as the piston descends; but the air does not necessarily depend upon a passage through the piston in order to get into the barrel. By these means the piston descends as easily as in any other construction, while the valve in it does not impede the rarefaction. The valve pump P, as we have observed, used for taking off the pressure of the atmosphere from the valve on the top plate of the pump, and for forming a more perfect vacuum between this plate and the piston, that nothing may prevent this instrument from exhausting as far as its expansive power will admit. The barometer gage a b c, serving to measure the exhaustion of the receiver, consists of a tube, divided by an annexed scale of inches and fractional parts of an inch, whose higher orifice communicates with the receiver, and the lower is immered in a cistern of mercury. Before any exhaustion has taken place the mercury in the tube and cistern is upon the same level; and after any number of turns of the handle of the pump, the air in the tube and receiver is equally rarified, and the mercury will descend in the tube till the weight of the column above the surface of that in the cistern, and diffuseness of the air in the receiver, taken together, be equivalent to the weight of the atmosphere; and if the altitude of the column is equal to the standard altitude, the vacuum in the receiver, and that above the mercury in the barometer, are the same. For an account of the syphon-gage, occasionally substituted for the barometer gage, and the pear gage; see GAGE.

In a contrivance, suggested by an ingenious workman of the late Mr. Adams, and annexed to the pumps constructed by Mr. Jones, one of the lower flexible oil-hoses, or leather valves in the two barrels, is attached to a brass ring, which is allowed an interval of motion of half an inch; a long wire is fixed to a bar over the diameter of the ring, which were paffed along the body of the piston and rod through a collar of leathers in the piston. By the friction of these leathers upon the rod, as they move up and down, the lower valve is occasionally raised and depressed; and thus a communication is opened between the barrel and receiver, and of course the exhaustion is carried to as great a degree as the nature of the air itself appears to admit. By a comparison of the height of the mercury in a good barometer tube, Mr. Jones did not observe the half-th of an inch difference between this and that of the barometer gage to the pump; and consequently the rarefaction was about 1600 times; and hence he concludes that it was equal in power to that of Mr. Cuthbertson, or any pump whatever.

We shall now describe more minutely the parts of which Mr. Prince's improved air-pump consists. Fig. 49, Plate VII. represents a perpendicular section of one of the barrels, the two cisterns, condensing gage, &c.; where A B is the barrel, C D is the cistern on which it stands, a a a a a the leathered joint, sunk into a socket, and buried in oil; E F is the barrel, with the cylindrical rod passing through a collar of leathers, G G, in the box H H. K shews the place of the valve on the top plate K, covered by the crofs piece M M, into which is folder the pipe O O, that conveys the air from the valves to the duct going under the valve pump, as may be seen in fig. 51: p is part of the said duct; p is the joint sunk into a socket in the crofs piece P P, which connects the cisterns, and has a duct through it leading to them. Into this duct open the ducts q and r, the first leading to the gage in front of the pump, and the other to the cock and receiver. The other barrel is left out of the figure, except Q, which is the top of it brought down out of its place for the purpose of shewing the top plate that shuts up the barrel, separated from the box, which contains the collar of leathers. S is one of the holes in the plate over which the valve lies, and which is covered by R in the crofs piece. V W is the pipe shewing the valve open on the top, which is to prevent labour when the pump con- denses. W X is the cistern, in which is more distinctly seen the slasher for the leather, which closes the point between this and the barrel, and also the socket in which the oil lies over the leather. Y Z is the condensing gage, with the orifice of the tube raised above the surface of the quicksilver; e e is the collar of leathers, through which the glass tube moves; and i is a small pipe coming up through the quicksilver to form a communication between the valves and the gage. In fig. 50, o, is seen the upper surface of the top plate.
plate which cloths the barrel, being folded into it, shewing the place of the valves over the three small holes. Fig. 51 is a perpendicular section of the bottom-piece, pipes, valve-pump, cock, &c., at right angles with the other section, fig. 49. The button s is screwed here into the top instead of the gauge. C D is the valve-pump and cillern, r the place of the valve, under the cup; E F the cock, let into the duct through it leading to the atmosphere; G H the pipe leading from it to the item of the receiver plate, in which is the cock l, to shut up the duct when the plate is used as a transverser. K L is the plate; L a piece to shut up the hole, into which tubes, &c., are sometimes forced to perform experiments without removing the plate. The dotted line at O shews the place of the cillern which presses the plate against the pipe; P Q the pipe and common gage landing in front of the pump. Fig. 52 is a horizontal section of the cock, and pieces containing the ducts leading from it to the receiver, the cillerns and the valves on the top of the barrels; A B the duct, connecting the cillerns together; C D the duct leading from the cillern to the cock; G H the duct leading from the cock through the pipe A B (fig. 51.) to the valve D E the duct through the cock, which occasionally connects the two half-mentioned ducts with the duct E F, leading from the cock to the receiver, I the duct in the cock leading to the atmosphere, which, when connected with the duct at D, lets the air into the cillerns and barrels for condensation; the other duct through the cock at the same time connecting H and E. This duct also, when connected with E, refires the equilbrium in the receiver. K L is part of the duct leading from the cillerns to the gage. The dotted circles shew the places of the pipe and valve-pump on the piece, and r the place where the air enters the valve-pump from the duct G H, and is thrown into the atmosphere when the pump exhausts. Fig. 53 shews the under surface of the boxes which contain the collars of leathers with the cross piece which connects them together, having a duct through it, as represented by the dotted line, through which the air passes from the cillerns into the pipe. This figure is chiefly designet to shew the places in which the valves play, as at T. American Transacations, vol. i. Boston, 1785. Nicholson's Journal, vol. iv. p. 121—128. Adams's Lectures on Nat. and Exp. Philos. by Jones, vol. iii. p. 54—P. 152.

The arm-pump of Mr. Cuthbertson is so excellent in its structure, and so powerful in its effect, that it claims considerable notice and description. A perspective view of it appears in Plate VIII. Pneumatics, fig. 56. Its two principal gages are screwed into their places; but these need not be used together, except in cases where the utmost exactness is required. In common experiments, either of them may be taken away, and a stop-fretter put into its place. When the pear-gage is used, a small round plate, large enough for the receiver to stand upon, must first be screwed into a hole at A; but when this gage is not used, this hole must be closed with a stop-fretter. When all these gages are used, and the receiver is exhausted, the stop-fretter B, at the bottom of the pump, must be uncrewed, to admit the air into the receiver; but when the gages are not all used, the stop-fretter at A, or either of the other two which are in the place of the gages, may be uncrewed for this purpose. In fig. 57, C D represents one of the barrels of the pump. E is the collar of leathers, G a hollow cylindrical velel to contain oil; R is also an oil-velel, which receives the oil that is drawn with the air through the hole a a, when the piston is drawn upwards; and when this is full, the oil is carried over with the air along the tube T, into the oil-velel G: r e is a wire which is driven upwards from the hole a a, by
A I R- P U M P.

will rest upon a, a, fig. 63, which will then be so far open as to permit the air to pass freely through it, while at the same time the end of g, q is forced against the top of the hole, and elides in order to prevent any air from returning into the receiver. Thus the piston, while moved downwards, forces the air to pass out between the sides of fig. 63, and fig. 61, and when it is at the bottom of the barrel, will have the column of the air above it; and, consequently, when drawn upward, it will shut and drive out this air, and by opening the hole L, give a free passage to more air from the receiver. This process being continued, the air will be exhauster out of the receiver as far as its expansive power will permit; for in this machine there are no valves, as in the common air-pumps, to be forced open by the air in the receiver, which, when its elasticity is diminished, it becomes unable to affect; nor is there any thing to prevent the air from expanding to the greatest degree.

In using this machine for exhaustion, no directions are necessary besides those which relate to common pumps, nor is any peculiar care required to keep it in order, except that the oil-vessel, G, be always kept about half full of oil. When it has stood for a considerable time without being used, it will be proper to draw a table-spoonful or two of oil through it, by pouring it into the hole in the middle of the receiver; plate, when the piston is at the bottom of the barrel; then, by moving the winch backward and forward to raise and depress the piston, the oil will be drawn through all the parts of the machine; and the superfluous part will be forced out through the tube T, into the oil-vessel G. Near the top of the cylindrical wire H, is a square hole, which is intended to let in some of the oil from the vessel G, that the oiled leathers, through which the wire q q slides, may always be duly supplied with it.

When the pump is required to condense, either at the time when it exhausts, or separately, the piece which contains the bent tube T, must be taken away, and fig. 64 put into its place, and fastened by the same screws. In the plate, fig. 64, is drawn as it is made for a single-barrelled pump; but for a single barrel, one piece is used, represented by b d a, the double piece being cut off at the dotted line a a. In this piece is a female screw, for receiving the end of a long brass tube; to which a bladder, if sufficient for the experiment, must be tied; or else a glass, properly confined for this purpose, must be screwed to it. Then the air, which is exhausted, but is of a red hot condition, on the plate, will be forced into the bladder or glass connected with the brass tube. But if the pump be double-barrelled, the apparatus, as represented by fig. 64, must be used, and the long brass tube screwed into the female screw at C.

The two gages are represented in fig. 65 and fig. 66; the one is the pyfon-gage, and the other the barometer or long gage. When these are used, fig. 65 must be screwed into the female screw, c, or into that at the other end, e, fig. 65; and fig. 66 into the female screw a b, fig. 63.

If it be used as a single air-pump, either to exhaust or condense, the screw K, which fastens the rack to the cylindrical wire H, must be taken out; then turning the winch till this wire is depressed as low as possible, the machine will be rendered fit to exhaust as a single air-pump; and if it be required to condense, the directions already given with regard to the bent tube T, and fig. 63, must be observed.

Mr. Cuthbertson has, by a variety of experiments with this air-pump, shewn its great powers of exhaustion. With the double pyfon gage, and also with the long gage, compared with an attached barometer, in which the mercury had been repeatedly boiled, the difference between the heights of the mercurial column proved to be no more than 1/10 of an inch, the barometer standing at 30 inches, which gives an exhaustion of 1200 times. On some occasions, when the air was in a very dry state, he observed the difference to be as low as 1/100 of an inch, which indicates more than double the rarefaction. See Description of an improved Air-pump, by John Cuthbertson, 5to. London; for an abstract, Nichollson's Journal, vol. i. p. 128—130.

We shall close our account of the two pumps of Prince and Cuthbertson with the following judicious remarks of Mr. Nichollson (in his Journal, vol. i. p. 131.) on their respective merits and imperfections. "There is no provision to open the upper fixed valve of Prince's greater barrel, except the difference between the preliures of the elastic fluid on each side of the strip of bladder; and this may reasonably be inferred to limit the power of his small pump. In Cuthbertson's pump, the same valve is exposed to the action of the atmosphere, together with that of a column of oil in the oil-vessel. The mischief in either instrument is probably triiling; but in both, the valve might have been opened mechanically. If this were done, the small pump of Prince might perhaps be unnecessary in most plates of the atmosphere. With regard to the lower valves, Cuthbertson, by an admirable display of talents as a workman, has injured their action. Prince, on the other hand, has, by the process of reasoning, so far improved the instrument, that no valves are wanted. In this respect he has the advantage of simplicity and cheapness, with equal effect. The mechanical combination of Cuthbertson's pump reduces the operation to one simple act of the handle; but Prince's engine requires some manipulation with regard to the play of the small pump; though this might have been remedied by a more skilful disposition of the first mover."

"The most perfect scheme for an air-pump, taking advantage of the labours of these judicious operators, seems to be that in which two pilons of the construction of Prince should work in one barrel; one piston being fixed at the lower end of the rod, and the other at the middle. The lower piston must come clear out of the barrel when down, and work air-tight through a diaphragm at an equal distance from the effective ends of the barrel. In the diaphragm must be a metallic valve, of the form of Cuthbertson's lower-valve, but with a short tail beneath, that it may be mechanically opened when the piston comes up. Above the diaphragm must work the other piston, similar to the first; but so it cannot quit the barrel. When then, a small portion of the barrel must be enlarged, just above the diaphragm, so that the leathers may be clear in that position. Lastly, the top of the barrel must be closed and fitted with a valve and oil-vessel, according to the excellent contrivance of Cuthbertson."

"If we suppose the workmanship of such a pump to leave the space between the diaphragm and lower piston, when up, equal to one-thousandth part of the space passed through by the stroke of that piston, the rarefaction produced by this part of the engine will in theory bear the same proportion to that of the external air; and the same supposition applied to the upper piston, would increase the cleft one thousand times more: whence the rarefaction would be one million times. How far the practical effect might fall short of this from the imperfections of workmanship, or the nature of the air, which in high rarefactions, may not diffuse itself equally through the containing spaces, or from other yet unobserved circumstances, cannot be deduced from mere reasoning without experiment."

It is observed in the Encyclopaedia Britannica, (vol. xv. p. 107.) that a construction of the air-pump, similar to that of
of Mr. Cuthbertson, was invented, and, in fact, executed, before the end of 1779, by Dr. Daniel Rutherford, afterwards professor of botany in the university of Edinburgh. He made a drawing of a pump, having a conical metal valve in the bottom, furnished with a long flender wire, sliding in the inside of the piston-rod with a gentle friction, sufficient for lifting the valve, and secured against all chance of failure by a spring at the top, which took hold of a notch in the inside of the piston-rod, about a quarter of an inch from the lower end, so as certainly to lift the valve during the half quarter of an inch of the piston's motion. He had executed a valve on this principle; but his thoughts were diverted from the further prosecution of the business.

In Phil. Trans. (vol. lxix. p. 435) we have a description by Mr. Cavally, of an air-pump contrived and executed by Melch. Haas and Hurter, instrument-makers in London, in the construction of which these artists have revived Guericke's method of opening the barrel-valve during the last strokes of the pump, by an external force; of this pump Mr. Cavally says, that when it had been long used, it had, in the course of some experiments, rascaded 600 times.

The drawing and description of a new air-pump, acting by means of a quantity of oil in the barrel, and invented by James Sadler, Esq. have been published by Mr. Nicholson, in his Journal, vol. i. p. 441, &c. He says, that it possesses the desirable requisites of simplicity, cheapness, and power; though at the same time he very properly fuggels, that the oil, in process of time, may become changed by the circulation, and fels fit for the purpose, and probably carry with it bubbles of air. He does not mention its practical effects.

A new air-pump, similar in its principle to those of Mr. Smeaton and Mr. Cuthbertson, has lately been constructed by the Rev. Mr. Little, of the county of Mayo in Ireland. The principal parts of this machine are one barrel and piston, one stop-cock, one valve, and two pipes of communication. It is of a portable size, and so contrived as to be confined in a very small space. The barrel is placed horizontally, and the rack, by which the piston is moved, underneath the barrel; so that the machine may be packed in a box two feet long, 18 inches wide, and seven in depth. It is adapted to the purposes of a condensing as well as of an exhausting engine. As to the effects of this pump, the author informs us, that in several trials of exhaustion, in the months of July, August, and September, 1795, the air being generally very dry, the rarefaction produced, as shown by the pear-gage, was, five times, between 3000 and 4000; the mercury in the barometer gage standing at the same time always above \( \frac{1}{4} \) th part of an inch higher than it floated in a standard barometer of a wider bore, which was filled with mercury made very hot and poured into a hot tube, and the mercury in the reduced barometer gage sunk below the level of the surrounding mercury. In the other nine trials, the rarefaction, as shown by the pear-gage, was from 4000 to 26000; when the barometer gage stood at \( \frac{1}{4} \) th of an inch higher than that in the standard barometer, and sunk in the reduced barometer still lower than before beneath the flagrant mercury. For a particular description and drawing of this instrument, and a minute detail of its practical effects; see Transactions of the Royal Irish Academy, vol. vi. p. 316—391.

The portable or table air-pump differs principally in size and the structure of the gage from the common air-pump described at the beginning of this article. It has two brass barrels, which are firmly retained in a perpendicular situation to the square wooden table on which they rest by a transverse beam, which is profiled upon them by ferews at the top of two pillars. From the hole in the centre of the pump-plate, there is a perforation or canal in a brass piece, to the fore part of the frame of the pump; and from this canal there is a perforation right-angular to the former, paring to the centre of the base of each barrel. At each of these centres a valve is placed opening upwards to admit the air into the barrels. To each barrel a piston is fitted that the air cannot pass between it and the sides of the barrel. Each piston has a valve opening upwards, that the air in the lower part of the barrel may escape through them into the common air. They are all connected with a rack, and are raised or depressed by a handle, the lower part of which is fixed to the side of a cog-wheel, whose teeth by hold of the rack. One piston is raised and the other is depressed, by the same turn of the handle. The operation of exhausting is the same as in the common pump. Two barrels are advantageous, because they perform the work more speedily, and also because the weight of the atmosphere, preluring upon the rising piston, is counterbalanced by the fame weight preluring upon the other piston descending.

Behind the large receiver upon the pump-plate, there is a small plate for sustaining a small receiver. From the hole at the centre of this plate there is a canal communicating with that which passes from the large receiver to the barrels. Under the receiver is a small bottle containing mercury, a small tube filled with mercury and freed from air, and inserted with the open end in the mercury; this is called the short barometer-gage. As the air is taken out of the receiver on this small plate, it is taken at the same time from the larger one; and the decrease in the mercury in the tube will point out the degree of rarefaction in the receiver.

The mercury, however, does not begin to descend in this tube till near three-fourths of the air have been exhausted; and the air is said to be as many times rarer than the atmosphere, as the column of mercury sustained in this tube is less than the height at which the mercury stands, at that time, in a common barometer. The syphon-gage, which is sometimes used, is a glass tube, bent in the form of a syphon, hermetically sealed at one end and open at the other. The longest leg is four inches, each of which is divided on an adjoining scale, into 20 equal parts. After considerable exhaustion the gage begins to act; and whilst the mercury falls in one leg, it rises in the other; and the quantity of air remaining will be determined by the difference of the height at which it stands in both tubes. This gage is placed in the same position with the short barometer-gage. See Gage.

The small single-barrelled pump has two plates, one for receivers, and the other for a short barometer-gage. Its principle is the same with that of the air-pump just described; excepting that it has only one barrel, and that its piston is merely worked by the hand. In general the single-barrelled pump is made only with one receiver-plate and a mahogany basin, to save expenses, and with its small apparatus, to be packed in a portable mahogany case.

**AIR-PUMP.** *Laws of rarefaction in the receiver of it.*

1. For the proportion of air remaining at any time in the receiver, (supposing no vapoour from moisture, &c.) we have the following general theorem.--In a vessel exhausted by the air-pump, the primitive or natural air contained therein, is to the air remaining, as the aggregate of the capacity of the vessel and of the pump, (i.e. the cylinder left vacant in an elevation of the piston, with the pipe and other parts between the cylinder and the receiver) raised to a power whose exponent is equal to the number of strokes of the piston, to the capacity of the vellon alone raised to the same power." M. Vargion gives an algebraical demonstration.
A I R- P U M P.

This may be illustrated by an example. Suppose the capacity of the receiver to be twice as great as the capacity of the cylinder or barrel, then will the capacity of the barrel be to that of the barrel and receiver together as one to three; and the quantity of air exhausted at each turn of the pump is to the quantity of air which was in the receiver immediately before that turn, in the same proportion. So that by the first stroke of the pump, a third part of the air in the receiver is taken away; by the second stroke a third part of the remaining air is taken away; by the third stroke a third part of the next remainder is exhausted; and so on continually; the quantity of air evacuated at each stroke decreasing in the same proportion with the quantity of air remaining in the receiver immediately before that stroke; for it is very evident that the third part, or any other determinate part of any quantity must be diminished in the same proportion with the whole quantity itself. And as the quantity of air in the receiver is by each stroke of the pump diminished in the proportion of the capacity of the receiver to the capacity of the barrel and receiver taken together; each remainder will therefore be always less than the preceding remainder in the given ratio; or, in other words, the remainders will be in a geometrical progression continually decreasing. To recur to the preceding example; the quantity exhausted at the first turn was a third part of the air in the receiver, and therefore the remaining air will be two-thirds of the same; and for the like reason, the remainder after the second turn will be two-thirds of the foregoing remainder; and so on continually; the decrease being always made in the same proportion of two to three; consequently the decreasing quantities themselves are in a geometrical progression. And as the quantities exhausted at every turn decrease in the same proportion with these remainders; therefore the quantities exhausted at every turn are also in a geometrical progression. Thus it appears, that the evacuations and the remainders do both decrease in the same geometrical progression. If the remainders decrease in a geometrical progression, it is plain that, by continuing the agitations of the pump, you may render them as small as you please; that is, you may approach as near as you please to a perfect vacuum; but you can never entirely take away the remainder.

From the above reasoning it appears, that the product of the primitive air, into the first, second, third, fourth, &c. remainders, is to the product of the first residual into the second, third, fourth, fifth, &c. as the product of the capacity of the receiver and cylinder together, multiplied as often into itself as the number of strokes of the piston contains units, is to the factum arising from the capacity of the receiver alone, multiplied so often by itself; that is, as the power of the aggregate of the capacity of the receiver and cylinder together, whose exponent is the number of strokes of the piston, to the capacity of the vessel alone, raised to the same power. Consequently, the primitive air is to the last residual, in the ratio of those powers.

2. The number of strokes of the piston, together with the capacity of the receiver and cylinder with the wire, &c. being given; to find the ratio of the primitive air to the air remaining.

Subtract the logarithm of the capacity of the receiver from that of the sum of the capacity of the receiver and the cylinder; then, the remainder being multiplied by the number of strokes of the piston, the product will be a logarithm, whose natural number shows how often the primitive air contains the remainder required.

Thus, if the capacity of the receiver be 460, that of the cylinder 580, and the number of strokes of the piston 6; the primitive air will be found to the remaining air as 1335 to 1, or 1335 to 10.

For, suppose the capacity of the vessel = v, that of the cylinder and vessel together = a, the number of strokes of the piston = n, and the remaining air = 1. Since the primitive is to the remaining air as a to v, the primitive air will also be to the remaining air, as a^n ÷ v to 1. Consequently, if the remaining air be 1, the logarithm of the primitive air is log. a = log. v × n.

3. The capacity of the receiver and the barrel being given; to find the number of strokes of the piston required to rarely the air to a given degree.

Subtract the logarithm of the remaining air from the logarithm of the primitive air; and the logarithm of the capacity of the receiver from that of the aggregate of the capacity of the receiver and cylinder; then, dividing the former difference by the latter, the quotient is the number of strokes required.

Let the primitive air be p, the remaining air r, and the other quantities as before: and we shall have p : r = a^n : v; and the log. p — log. r = n × log. a — log. v; and n = log. p — log. r ÷ log. a — log. v.

Thus, if the capacity of the cylinder be supposed 580, that of the receiver 460, and the primitive air to the remaining air, as 1335 to 10: the number of strokes required will be found to be 6.

4. The proportion of the primitive air to the remaining air, together with the capacity of the receiver and the number of strokes of the piston, being given; to find the capacity of the barrel.

Let the first-mentioned proportion be that of p to r; the capacity of the receiver, v, that of the barrel, x, and the number of strokes of the piston, n: then p : r = v + x : v; and log. p — log. r = x × log. v + x — n × log. v: consequently, log. v + \[ \frac{\log. p - \log. r}{n} \] = log. v + x. Hence, find the logarithm of the capacity of the receiver and barrel, and from this the capacity itself, and subtracting that of the receiver, the capacity of the barrel will be known.

AIR-PUMP.

To the air-pump belongs a large apparatus of other vessels, accommodated to various kinds of experiments.

Besides the effects, and the phenomena of the air-pump, recounted under the articles Vacuum, Air, &c. we may add some others, which, related at large, make the substance of Mr. Boyle’s Physico-Mech. Exper. As. That the flame of a candle in vacuo usually goes out in a minute, though it sometimes last two, but the wick thereof continues ignited after; and even emits a smoke, which ascends upwards. — That a kindled charcoal is totally extinguished in about five minutes, though in open air it remains half an hour; that it goes out by degrees, beginning from the top and the outside. — That red-hot iron is not affected by the absence of the air; and yet that sulphur or gunpowder will not be lighted thereby, but only fused. — That a match, after lying seemingly extinct in vacuo a long time, revives again upon the re-admission of the air. — That a flint and steel strike sparks of fire as copiously in vacuo as out of it; and that the sparks move in all directions, upwards, downwards, &c. here as in the air. — That magnets and magnetic needles are the same in vacuo as in air. — That smoke in an exhausted receiver, the luminary being extinct, gradually settles to the bottom in a darkish body, leaving the upper part clear and transparent; and that inclining the vessel sometimes on one side, and sometimes another, the same keeps its surface horizontal, after the nature of other fluids. — That the syphon does not run in vacuo. — That water freezes in vacuo. — That heat may be produced by attrition in the exhausted receiver. — That camphor will not take fire in vacuo; and that gun-powder, though some grains of a heap be kindled by a burning-glass in vacuo, will not give fire to the contiguous grains. — That glow-worms lose their light in proportion as the air is exhausted, and at length become totally opaque; but upon the re-admission of air, presently recover it all. — That electricity appears like the Aurora borealis. — That vipers and frogs swell much in vacuo, but will live an hour and half, or two hours; and though seemingly quite dead in that time, come to life again after being some hours in the air. — That flies survive ten hours; and efts or low-worms, two or three days; leeches five or six. — That fishes will rise up to the top of water, placed under an exhausted receiver, because the air-bladder is expanded, and they are thus made specifically lighter than water; but if the bladder breaks, they sink down to the bottom, and rise no more. — That animals who live in water will not die by exhausting the air out of the receiver, unless they are kept for a considerable time in vacuo. — That otters will remain alive in vacuo 24 hours without harm. — That the heart of an ed taken out of the body, continues to beat in vacuo more nimby than in air; and this for a good part of an hour. — That warm blood, milk, gall, &c. undergo a considerable intumescence and chullition in vacuo. — That a mouse, or other animal, may be brought, by degrees, to survive longer in rarefied air, than naturally it does. — That air may retain its usual preffure, after it is become unfit for respiration. — And that fijk-worms’ eggs will hatch in vacuo.

Besides the above-mentioned phenomena, many others are recited by different writers on this subject, and they may be found in the Philosophical Transactions of various Academies and Societies, and in the works of Torricelli, Pafcal, Merfene, Giericke, Schottus, Boyle, Hooke, Haukibee, Duhamel, Mariotte, Hales, Mufchenbrook, Gravзвande, Deferukhes, Franklin, Cotes, Helhain, Matte, Fergafon, Adama, &c. &c. We shall subjoin for the execut and amusement of our readers some farther experiments, arranged under distinct heads. For experiments that require peculiar accuracy, the receiver should not be placed upon leather, either oiled or soaked in water; but the plate of the pump should be made very dry, and the muzzle of the receiver should be dried and rubbed with a warm cloth. The receiver may then be set upon the plate, and hog’s-lard, either alone or mixed with oil, be smeared round its outward edge. After performing any experiments, the pump should be cleared of any vapour that has been generated, by exhausting a large receiver to as great a degree as possible; and the vapour that remained in the barrel and pipes will be diffused through the receiver, and if this be large, one exhaustion will be sufficient for clearing the pump. With small receivers the operation should be repeated two or three times. In some of the best pumps, the plate and edges of the receiver are ground so accurately as not to require any leathers; but as the plate is liable to be scratched by fitting the receivers upon it, hog’s-lard or tallow spread upon their edges will be useful. This will prevent the edges from damaging the plate, and will not admit any vapour. When leathers are used for connecting the receiver with a pump plate, and for making the junction air-tight, they are previously soaked in water, oil, or a mixture of melted bees’ wax and hog’s lard. When experiments are performed that require the use of mercury, a small pipe should be ferewed into the hole of the pump plate, in order to prevent any of it, that may be accidentally shot, from passing into the air-pipe and barrels; which would loosen the folder and corrode the brass.

I. Experiments for shewing the weight and preffure of the air.

1. Exhaust of its air a copper ball, such as C (Plate V. Pneumatics, fig. 26.) the neck of which is furnished with a stop-cock and a screw by means of which it may be fixed to the plate of an air-pump; suspend it, when exhausted, on the end B of one arm of a balance, A B, and lay upon it the small weight p, which must be counterpoised by a weight P in the opposite scale of the balance. Turn the cock of the ball, and the air will rush in and render it so much heavier, that the weight p must be removed in order to restore the equilibrium. If the ball holds a gallon, it will thus be found that a gallon of air weighs about the fifth part of an ounce. See Weight of the Air.

2. Place the small receiver O (fig. 35.) over the hole of the pump plate, and, upon exhausting the air, the receiver will be fixed down to the plate by the preffure of its outside; and this preffure will be equal to as many times 15 pounds as there are square inches in that part of the plate which the receiver covers. By turning the cock of the pump and readmitting the air, the receiver will become loose. In order to prove that the receiver O is held down by the preffure of the air, suspend it on the hook of the wire P P passing through the collar of leathers at the top of the receiver M, by which it is covered, and thus let it down on the plate of the pump; and when the air is exhausted from both receivers, the large receiver M will be fixed to the plate by the preffure of the external air; but the small one O will be loose and may be easily removed; on letting in the air, the lefser O will be fixed down upon the plate and the other will be released.

3. Place a small brass or glass vessel A B (fig. 27.) which is open at both ends over the hole of the pump plate, and cover the top of it with the lid; which, when the air is exhausted, will be pressed down by the weight of the exterior air, so that it cannot be released without difficulty till the air is readmitted.

4. Tie a piece of wet bladder, as b (fig. 28.) over the open top of the glass A; when it is dry, let the open end A over
AIR-PUMP.

A over the hole of the pump plate, and as you exhaust the air, the bladder will be pricked down and asfume within the glass a concave figure, and its length it will break with a loud report. If a piece of flat glass be laid upon the top of this receiver, and joined to it by a rim of wet leather, the pressure of the outward air will break the glass, when the internal air is exhausted.

5. Immerse the neck of the hollow glass ball e b (fig. 25.) in the water of the phial a a; place it on the plate of the pump, and cover it and the hole of the plate with the receiver A; exhaust this receiver, and the air will escape by its spiring from the ball e b, through the neck d e, rise in bubbles through the water, and pass off into the external air. When it has done bubbling, turn the cock of the pump, and the air that is admitted will by its pressure on the surface of the water force it up in a jet into the ball e b, and almost fill it; the small quantity of remaining air, which occupied the whole ball, and which is now reduced to a small space of condensation, preventing the water from filling the whole cavity of the ball. This experiment may be varied by severing the end of the brass pipe A B (fig. 30.) into the hole of the pump plate, and placing, by means of wet leather, upon the plate e d a tall receiver G H close at the top, exhausting the receiver of its air and filling the pipe by the cock c; when this is done remove the apparatus from the pump, fill its end A in a basin of water, and open the pipe by turning the cock c; and the pressure of the air on the water will force it up through the pipe, so that it will ascend in a jet to the top of the receiver. See Fountain.

6. Set the jar D (fig. 31.) containing quicksilver, near the hole of the pump plate, and cover both with the tall open receivers A B. Into the plate C, placed upon the upper end of this receiver, introduce the open glass tube g f, immersed at its lower extremity in the quicksilver of the jar D, and screwed by a brass top annexed to it b to the syringe H, which is itself fixed to the plate C. By the ring I draw up the piston of the syringe, and thus exhaust the tube of its air; and the quicksilver in the basin prefixed by the undulated air of the receiver A B will ascend in the tube. That this ascents is owing to the pressure of the air, and not to what some have called suction, may be evinced by exhausting the receiver of its air, which will cause the quicksilver to descend into the jar, and by readmitting the air, which will raise it again in the tube, although the piston of the syringe be not moved. If the tube be about 32 or 33 inches high, the quicksilver will rise nearly as high in the tube as it stands at that time in the barometer. If the syringe has a small hole at m, and the piston be drawn up above that hole, the air will pass through it into the syringe and tube, and the quicksilver will immediately fall down into the jar.

7. Place the jar A (fig. 32.) with quicksilver in it on the pump plate, cover it with the receiver B, and push the open end of the glass tube d e through the collar of leathers in the brass neck C, almost down to the quicksilver in the jar. Exhaust the receiver B of its air, and the tube d e, which is close at the top f, will at the same time be exhausted. When the receiver has been well exhausted, push the open end of the tube into the quicksilver of the jar; and though the tube be exhausted of its air, the quicksilver will not rise in it, because there is no pressure on the surface of that in the jar. But upon admitting the air into the receiver, the quicksilver will immediately rise and stand as high as it did in consequence of the action of the syringe in the preceding experiment.

These two last experiments not only exhibit the weight and pressure of the air, but they also shew that these are increased or diminished in proportion to the increase or decrease of the air's depth. See Barometer and Torricellian Experiment.

8. Join the two brass hemispheres A and B together (fig. 36.) by the interposition of a wet leather, with a hole in the middle of it; then screw the end D into the place of the pump, and turn the cock E of the pipe, C D, communicating with the hemispheres; and having exhausted the air, turn the cock F so to stop the pipe. Having removed it from the pump, screw at the end D, the piece F b; and two strong men pulling at the handles g and h will find it difficult to separate the hemispheres; for if the diameter be four inches, they will cohere together with a force equal to 183 pounds, the area being equal to the square of the diameter multiplied by .7854, and the pressure on every square inch being 15 pounds; i. e. 16 x .7854 x 15 = 188.496 pounds. If they be suspended by either of the rings on the hook P of the receiver M (fig. 35.), and the receiver be exhausted of its air, they will separate of themselves.

9. Set the square phial H (fig. 37.) upon the pump plate, and cover it with the wire cage B; then placing it under a close receiver, exhaust the receiver and the phial which has a small hole under a valve at b of their air; and the air upon its re-admission into the receiver, being prevented from passing into the phial by the valve b, will break it into a number of pieces by its pressure. Quicksilver may be also forced into wood, and made to pass through it by the pressure of the air.

II. Experiments for shewing the elasticity or spring of the air.

1. Place a bladder, containing a small quantity of air and well tied up, under a receiver; and when the receiver is exhausted, the air will expand and fill the bladder so that it will appear as if it were blown with common air. Upon letting in the air, the bladder pressed by it will be reduced to its original flaccid state. This bladder put into a box under a weight of 20 or 30 pounds, and covered with a receiver, will, upon the exhaustion of the receiver, raise the weight by means of the spring of the internal air.

2. Take the glass ball (fig. 29.) which was filled with water, a small bubble of air at the top of it excepted, and having placed it with its neck downward into the empty jar a a, and covered it with a close receiver, exhaust the receiver of its air, and the air-bubble will expand itself, and by its elastic force protrude the water out of the ball into the jar. Or, screw the pipe A B (fig. 30.) into the pump plate, and place the tall receiver G H upon the plate e d; exhaust the receiver, and then remove the apparatus and screw it into the copper vessel C C (fig. 38.) half filled with water. Then turning the cock e (fig. 30.) and the air confined in this vessel will by its spring force the water through the pipe A B, and cause it to form a jet into the exhausted receiver, equal to that which was produced by the pressure of the air in a former experiment; other circumstances being alike.

3. Let the balls annexed to the heads of the hollow glass images (fig. 39.) contain water sufficient to render them specifically heavier than water. Place them under a receiver and exhaust it; and the air in the balls will dilate, force part of the water out, and render the images lighter than water, so that they will ascend. On re-admitting the air, they will descend. Small apertures made in the sides of these images will vary the experiment, and answer the same purpose.
AIR-PUMP.

7. Animals that die in an exhausted receiver are evidently oppressed at first as with a great weight, then convulsed, and at last expire in apparent agony. Instead of repeating experiments of this kind, the effect of exhaustion is ascertained by what is usually, though improperly, called the lungs-grafs. This consists of a bladder tied round a small tube which pales into a bottle, and sealed so tight, that the air cannot escape any way but through the tube. When this machine is put under a receiver, and the air begins to be exhausted, the spring of that, which is contained in the bottle, and which cannot escape, compresses the bladder; and when air is again let in, the bladder expands; and these alternate motions of compaction and dilatation have been compared analogous to those of the lungs. See fig. 40.

4. Pour quicksilver into the bottle A (fig. 31.) and screw the brass collar c, of the tube D C, into the brass neck b of the bottle, and let the lower end of the tube be immersed into the quicksilver, so that the air above the quicksilver may be confined there. Cover this tube, which is open at the top, with the receiver G and large tube E F, fixed by brass collars to the receiver and close at the top. Exhaust the receiver and its tube; and the air will be thus exhausted out of the inner tube B C through its open top C; and then the air confined in the bottle A will, by its spring, force the quicksilver in the inner tube as it was raised in a former experiment by the pressure of the atmosphere; and thus it appears that the elasticity of the air is equivalent to its weight.

5. Screw the end C of the pipe C D (fig. 42.) into the hole of the pump-plate, and open the communication between the three pipes E, F, and D C, and the hollow trunk A B, by turning the three cocks d, G, and H. Cover the plates g and b with wet leathers, leaving holes in their middle, so as to communicate with the pipes: place the close receiver I upon the plate g; shut the pipe F, by turning the cock H; and exhaust the air out of the receiver I. Shut out the air by turning the cock d; remove the machine from the pump; screw it to the wooden stand L; and put the receiver K upon the plate b, on which it will be loose while it is full of air; but upon turning the cock H, and opening the communication between the pipes F and E, through the trunk A B, the air in K will, by its spring, pass from K to I, till it becomes of equal density in both receivers; and then they will be held down with equal force upon their respective plates by the pressure of the atmosphere, and the force with which K was held down will be divided between K and I. Thus it appears, that a force equal to half the elastic force of common air will act within the receivers against the whole pressure of the common air on their outsides. This instrument is called a double transferrer, and it serves to transfer the air from one vessel into another.

6. Take a cork in the square phial A (fig. 37.) with wax or cement; put it upon the pump-plate, cover it with the wire cage B, and place a close receiver over the cage. Upon exhausting the receiver of its air, that which was enclosed within the phial will dilate infinitly, and having no counter pressure on the outside, will break the phial outwards by the force of its spring.

7. Place a thrivelled apple under a receiver, and as it is exhausted, the spring of the air within the apple will pump it out and cause the wrinkles to disappear; but upon readmitting the air, it will return to its thrivelled state.

8. Put a fresh egg, from the small end of which a little of the shell and film is removed, under the receiver; and when the air is pumped out, the small bubble of air contained between the shell and film at the larger end, will dilate itself, and protrude the contents of the egg into the receiver. If the egg be placed in a jar of water under the receiver, its surface will be covered with bubbles of air in the progress of exhaustion.

9. Warm beer put under a receiver, exhausted of its air, will discharge bubbles, which will rise to the surface, and at length give it the appearance of boiling.

10. A piece of dry wainscot or other wood, being put into warm water and covered with a receiver, will discharge air, as the receiver is exhausted, and exhibit bubbles of air, especially about its ends, because the pores lie lengthwise. A cubic inch of dry wainscot has so much air in it, that it will continue boiling for half an hour together.

毒 piece of wood be made to pass through a plate covering the top of a receiver, with one part exposed to the air and the other immersed in a jar of water under the receiver, and the thumb be put on the top of the wood while, the pump is working, the air contained in the pores of the wood will rush in bubbles through the water; but if the thumb be taken off, a stream of air will flow in through the wood; and thus by alternately taking off the thumb and placing it on the wood, the influx of the air will be alternately admitted and interrupted. See Air and Elasticity of the Air.

III. Experiments for shewing the resistence of the air.

1. The machine (fig. 43.) consists of two mills, a and b, of equal weight, and moving independently and freely on their axes. Each mill has four thin vans or fans, fixed in the axis; those of the mill a having their planes perpendicular to the axis, and those of the mill b having their planes parallel to it. When the mill a turns round in common air, it will suffer little resistance, because its fans cut the air with their thin edges; but the mill b is much refitted, because the broad sides of its fans move against the air when it turns round. Each axle has a pin near the middle of the frame, which passes through the axle and prevents a little on each side of it; upon these pins the slider d may be made to bear, and thus hinder the mills from going, when the strong spring e is fet on bend against the opposite ends of the pins. Having fet the machine upon the pump plate, draw up the slider d to the pins on one side, and fet the spring e at bend upon the opposite ends of the pins; then push down the slider d, and the spring acting with equal strength on each mill will fet them at work with equal forces and velocities; but the mill a will run much longer than b, because it meets with much less resistance. Draw up the slider again, and fet the spring upon the pins as before; then cover the machine with the receiver M (fig. 35.) upon the pump plate; and having exhausted it, push down the wire F P, through the collar of leathers in the neck g, upon the slider, which dilengaging it from the pins will allow the mills to turn round by the impulse of the spring; and as there is no air in the receiver that yields any sensible resistence, they will move for a longer time than in the open air, and when one stops, the other will stop also. Hence it appears, that the air refits moving bodies, and that equal bodies meet with different degrees of resistence, according as they present greater or less surfaces to the air, in the planes of their motions.

2. Put the guinea a and feather b (fig. 44.) upon the brass flap c; turn up the flap, and shut it into the notch d. Then putting a wet leather over the top of the tall receiver A B, which is open at both ends, cover it with the plate C, so that the tongs e d may hang within the receiver. Then having exhausted the receiver, draw up the wire f, and the tongs e d will be opened by a piece at its end, and the flap c falling...
falling down, the guinea and feather will be observed to
defend with equal velocities, and by looking steadily to
the bottom of the receiver, to fall to the pump plate at the same
instant. When air is in the receiver, the guinea will fall in
an instant, and the feather will defend gently and by an in-
direct motion. This apparatus is sometimes so contrived as
to let three guineas with their feathers fall separately at
three different times, without taking it off or exhausting
the airbreth. See Resistance of the Air.
IV. Miscellaneous Experiments.
1. Screw the yzinge H (fig. 51.) to a piece of lead,
weighing at least one pound; pull up the pinion, which will
cause a vacuum in the yzinge, and the air by its preffure
will drive back the lead upon it; raising it and counteracting
its natural weight. But if the yzinge and annexed weight
be placed in an exhausted receiver, they will fall upon the
pinion by their natural gravity, and upon readmitting the air,
they will be drove upward again, fo that the pinion will be at
the bottom of the yzinge.
2. Toa balance AB, Plate vii. Pneumatics, fig. 51, suspend a
weight of lead, and let it be in equilibrio with a piece of cork.
Place this apparatus under a receiver and exhaust the air,
and the cork will preponderate; but let the air be admitted, and
the equilibrium will be restored. As the air is a fluid, all
bodies lose as much of their weight in it as is equal to the
weight of an equal bulk of the fluid; and as the cork is
larged, it loses more of its absolute weight than the lead,
and of course must be heavier in order to compensate this
greater loss; but when the air is removed, all bodies gra-
ivate according to their quantities of matter, and therefore
the cork, which balanced the lead in air, will appear to be
heavier in vacuo. A more elegant apparatus for this expe-
riment, confifting of a light glass bulb $\lambda$, and a brafs weight
$S$, is exhibited in fig. 55.
3. Set a clean receiver upon the plate of a pump, and
when you begin to exhaust it, hold a candle to the fide
of the receiver opposite to your eye, and feveral colours, re-
fembling a halo, will appear about the candle, which are oc-
cafioned by the vapours that arise from the wet leathers and
their refraffion of the light.
4. Place a lighted candle under a tall receiver, and if it
holds about a gallon, the candle will continue to burn about
a minute; and its light will gradually decay and at length
be extinguifhed. The fmoke of the candle will ascend and
form a kind of cloud at the top of the receiver; but upon
exhausting it, the fmoke will fall down to the bottom; thus
fowering, that fmoke does not ascend because it is positively
light, but because it is lighter than air.
5. Let the pipe represented in Plate viii. Pneumatics, fig. 68,
be annexed to the top of an open receiver, and the air be ex-
haufted; then place one end of the pipe in the middle of a
charcoal fire, and open the cock; and thenoxious air of the
charcoal will pafs through the pipe into the receiver; remove
the pipe from it, and let down a small lighted wax taper into
the receiver, and it will be immediately extinguifhed. A moufe
or bird let down into the receiver will be killed by the air
which it contains. If a candle be let down gently, it will
purify the air as it defcends.
6. By connecting the wire that passes through the collar
of leathers of a receiver with the trigger of a piftol lock,
placed under it, exhaufting the air, and then drawing the
trigger, the flint will strike the fheel and produce fparks of
fire, which will not be visible in the open air. Or, if
two iron bullets be made red-hot, and one of them be under
an exhausted receiver, it will not appear luminous, like the
other which remains in the open air.

7. Set a bell upon a cushion undera receiver on the pump
plate; and shake the pump fo as to make the clapper
strike againfth the bell, and the found will be distinctly
heard; but exhauft the receiver, and if the clapper be
made to strike with great force againft the bell, it will make
no audible found; hence it is interred, that air is neceffary
for the propagation of found.

Air-shafts, among Miners, denote holes or ftahls let
down from the open ait to meet the aditus, and furnish fresh
air. The damp, want, and impurity of air, which oc-
curs, when adits are wrought 30 or 49 fathoms long, make it
necofary to let down air-shafts, in order to give the air
liberty to play through the whole work, and thus displace
bad vapours, and furnish good air for respiration: the ex-
pence of which ftafs, in regard of their vall depths, hard-
nefs of the rock, drawing of water, &c. sometimes eafies,
may exceeds, the ordinary charge of the whole aditus.
Sir Robert Murray defcribes a method, used in the con-
mines at Lielie, of working mines without air-shafts. Phil.
Tranf. No. 5.

When the miners at Mendip have funk a groove, they
will not be at the charge of an air-shalt, till they come at
one; and for the supply of air have boxes of elm exactly
cloded, of about five inches in the clear, by which they
carry it down about twenty fathoms. They cut a trench
at a little distance from the top of the groove, covering it
with turf and rods disposed to receive the pipe, which they
contrive to come in fide-ways to their groove, four feet
from the top; which carries down the air to a great depth.
When they come at one, and need an air-shalt, they fix
four or five fathoms distant, according to the convenience
of the breadth, and of the fame fahlon with the groove,
to draw as well ore as air. Phil. Tranf. No. 59; See
Mining.

Air-threads of Spiders. See Threads.

Air-trunk, a fimple contrivance by Dr. Hales, for
preventing the stagnation of putrid effluvia, and purifying
the air in jails and clofe rooms; which confifts of a square
trunk open at both ends, one of which is fixed in the ceiling
and the other is extended to a confiderable height above
the roof. The noxious effluvia, ascending to the top of the
room, efcape by this trunk. Some of these have been nine
and others fix inches in the clear; but whatever be their
diameter, their length should be proportionable, in order to
promote the aefcent of the vapour. As the pressure of
fluids, and consequently of the air, correponds to their
perpendicuJar altitude, the longer thefe trunks are, fo much
the greater will be the difference between columns of air
prefling at the bottom and at the top; and of course so
much the greater will be their effect. See Ventilator.

Air-vessel, in Hydraulics, is a name given to thofe me-
talline cylinders, which are placed between the two forcing-
pumps in the improved fire-engines. The water is injected
by the action of the piitons through two pipes, with valves,
into this veffel; the air previously contained in it will be
compreffed by the water, in proportion to the quantity
admitted, and by its spring force the water into a pipe, which
will discharge a conflant and equal fream; whereas in the
common fquirting engine, the fream is difcontinued between
the feveral strokes. Other water-engines are furplied with
veffels of this kind.

Air-vessels, in Botany, are certain canals, or ducts, where-
by a kind of abforption and respiration is effected in vege-
table bodies.

Air-vessels have been f distinguished from sap-veffels; the
former being fuppofed to correpond to the trachae, and

5 Q 2
lungs of animals; the latter to their lacteals and blood-veffels.

Dr. Grew, in an inquiry into the motion and cause of the air in vegetables, shews, that it enters them various ways, not only by the trunk, leaves, and other parts above ground, but at the root. For the reception, as well as expulsion of air, the pores are so very large in the trunks of some plants, as in the better sort of thick walking canes, that they are visible to a good eye without a glafs; but with a glafs, the canes feem as if they were full of large pin-holes rellembling the pores of the skin in the ends of the fingers, and half of the hand. In the leaves of the pine, through a glafs, they make an elegant show, handing almost exactly in rank and file throughout the length of the leaves.

But though the air enters partly at the trunk and also at other parts, especially in some plants, yet its chief admission is at the root: much as in animals, some part of the air may continually pass into the body and blood by the pores of the skin; but the chief draught is at the mouth. If the chief entrance of the air were at the trunk, before it could be mixed with the sap in the root, it must defend; and so move not only contrary to its own nature, but in a contrary coure to the sap; whereas by its reception at the root, and its transition from thence, it has a more natural and easy motion of ascent. See Circulation of sap.

The fame fact is farther deduced, from the finer fels and small-nels of the diametral apertures in the trunk, in comparison of thofe in the root; which nature has plainly deigned for the seperation of the air from the sap, after they are both together received into them. Grew, Anat. of Root, chap. iii. p. 127.

Air-veffels are found in the leaves of all plants, and are even discoverable in many without the help of glaffes; for upon breaking the falk or chief fibres of a leaf, the like-nels of a fine woolly fubflance, or rather of curious small cab-webs, may be feen to hang at both the broken ends. This is taken notice of only in some few plants, as in ficabius, where it is more visible; but may alfo be feen more or less in moft others, if the leaves be very tenderly broken. This wool is really a ficin of air-veffels, or rather of the fibres of the air-veffels, lofted from their spiral position, and fo drawn out in length. Id. ibid. chap. iv. p. 155.

That air is inspirèd by vegetables, has been fully proved by Dr. Hales, in his Statical Efays. (vol. i. p. 155, &c.) and he has in many instances feen, that air freely enters the veffels of trees, and that it is in great abundance wrought into their fubflance. But as to particular air-veffels in plants, he feems to fpeak doubtfully. He fays, by way of quëtion, may not the use of thofe spiral wrenches, that are coiled round the infides of thofe veffels, which are fuppofed to be air-veffels, and which are manifestly to be fen in fever- al trees, and also in the leaves of the vine and feabious, may not thofe be defigned by nature to promote the quicker aerf of air, by being in fome manner confeated to thofe elastic contortions? For fuch spiral wrenches fceem to be altogether uselefs, for promoting the aerfent of any liquor, as the sap, which afcends moft freely through innumerable other capillary veffels, having no fuch spiral coils in them: not that we are to fuppofe the air in its elastic flate actually to touch, and thereby to be determined in the coure of fuch spirals, as any liquor would be. But as the rays of light, when they are reflected from a folid body, are fuppofed to be reflected, without actually touching the reflecting body in the point of reflection; fo it is not unreafoonable to

suppofe, that elastic air may, like light, be diverted from one coure, and fo be determined to another, by the folid bodies it approaches, without touching them, but rebound- ing like light from thofe folid bodies near the point of contact.

Dr. Hales has obferved, that thofe spirals are coiled in a coure oppofite to the coure of the fun, that is, from west to eait. Vide Static. Ef. vol. ii. p. 265, 266.

Dr. Darwin, in his Phytologia, obferves, that the veffels which Malpighi, Grew, and many others, have denomi- nated bronchia, and erroneously thought to be air-veffels, and to ferve the purpofe of respiratory organs, are abor- vent veffels, defigned to imbibe the nutrient of plants, and that they are the genuine lungs of vegetables. These abortent veffels, he fays, which refembl the lacteals of animal bodies, are found in the roots of plants for imbibing nourishment from the moist earth, on the external fuperfices of the bark and leaves, for abforbing the humidity of the atmo- sphere, and also in the internal fuperfices of the cells and cavities of the vegetable fystem, where they abforb the fe- creted fluids, after they have performed the oflices to which they are adapted. The exiftence of the firft fort of abor- bents, is evinced by the growth of plants, whilst moisture is applied to their roots, and by their withering when it is withdrawn. Thofe of the fecd fort are manifefted by plucking off a leaf and laying it in water, which is found not to wither fofoon as if it were left expofed to the dry air. The third clas of veffels of this kind will be perceived to perform its oflice by moistening the alburnum or sap-wood, and the inner fuperfice of the bark of a branch fevered from a tree, which are thus preferred, whilft the fame parts left unmoiftened in the dry air are obferved to wither. Besides, if vegetables be infected in glafs-tubes or narrow veffels, filled with water, the furface of the water will be fen to fubfide much sooner than by evaporation alone in fimilar circum- ftances. Dr. Darwin alfo contrived to evince thofe abor- vent veffels to the eye, by dipping twigs of a fig-tree in a decocation of madder and of logwood, which after fome time, upon cutting off about an inch of the falk near the bottom, exhibited a circle of red points, believed by him to be the coloured ends of the aborments, that exifted in the newly formed alburnum. This ingenious writer expresses his allocution that any perfon fhouid have conceived thofe veffels, that are found in the alburnum, and which confift of a spiral line, to be air-veffels or tubes. He farther ob- serves, that the abortent veffels of trees in pafling down their trunks, confift of long hollow cylinders, of a spiral form, and of fuch large diameters in fome vegetables, e. g. in cane, as to be visible, when dry and empty, to the naked eye. Through thofe air will pass rapidly upward and downward; and hence Dr. Hales has been led to confide with Grew and others in opinion, that they are air-veffels or lungs deigned for respiration, and receiving atmo- fpheric air in their naturalflate. But to their use as air-veffels he objects, because they have no communication with the hori- zontal air-veffels of plants, and they exit in the roots as well as in the trunks of plants, where, not being expofed to the atmo- sphere, they cannot ferve the purpofe of respiration. Air, however, in its combined state, or difolved in water, may be abforbed by thefes veffels; and may appear when the prelure of the atmo- sphere is removed in the exhaluted receiver, or when it is expanded by heat, as is the cafe in the froth obferved at one end of a green flack, when the other is burning in the fire. Dr. Darwin apprehends, that the ftructure of thofe large vegetable abortents, which have been erroneously called air-veffels, confifts of a spiral line,
AIR

fine, and not of a vellum interrupted with valves; and in this
respect it differs from that of animal lymphatics.

According to this writer, the proper air-vessels are hori-
зonal vellus of large diameter, which pass through the
bark of the trees to the alburnum. Malpighi has given a figure
of these vellus, and Duhemel mentions fine horizontal per-
fusions through the bark of trees, which he believes to
be perforatory or excretory organs; and besides these, he
takes notice of others, that are larger, standing prominent
in the birch-tree, and piercing the exterior bark; which
probably contain air during the living state of the tree. Dr.
Darwin supposes, that the horizontal vellus first mentioned
contain air, enclosed in a thin moist membrane, which may
serve the purpose of oxygenating the fluid in the extremities
of some fine arteries of the embryo buds, in a manner simi-
lar to that by which the air at the broad end of the egg is
thought to oxygenate the fluids in the termination of the
placental vellus of the embryo chick.

AIRA, Gea of Hippocrates and Theophrastus, hair-
grafts, in Botany, a genus of the triandra digynia chal
order, and of the natural order of gramina or grasses.
Its characters, are, that the calyx is a two-flowered; two valued
glume; the valves ovate-lanceolate, acute and equal; the
corolla bivalve, the valves like the bracts, sessile, two
leaved, leaflets acute, gibbos at the base; the flaminea have
capillar filaments, of the length of the flower, with oblong
anthers, forked at each end; the pistillum is an ovate germ,
the filices aecorous spreading, with pubescen fllagmas; no
pericarpium; the seed subovate, crowned with the corolla.
It differs from Melica, in having no rudiment of a third
between each pair of floecules, the number of which varies.
Martyn enumerates 14, and Gmelin, in his edition of Lin-
neus, 25 species; some of which are annuals or biennials,
and others annual.

Of the former, Martyn specifies, 1. A. arundinacea,
or reedy hair-grafs, with oblong anthers, on one side
imbricate, and flat leaves, found in the Levant and in
Cochinchina. 2. A. minutia, with loose panicle, almost
level-topped, and very branching; an annual grafs found in
Spain. 3. A. equitata, water hair-grafs, with panicle spreading,
flowers smooth, longer than the calyx, and leaves flat.
This grafs usually grows in the margins of pools and
water places, running in the water to a considerable dis-
tance, and is known by the purple or bluish colour of the
panicle, and sweet taste of the flowers: perennial, flowering
in May and June. This, says the author of the Farmer's
Dictionary, is the grafs which contributes chiefly to the
sweetness of Cottenham cheese, and the finesnes of Cam-
bridge butter. There is a variety of this which grows in
dry soils, with the calyces five flowered, and the flowers
very remote from each other. It occurs in sandy lands near
Exmouth, about Northfleet in Kent, in Lancashire, and
Yorkshire. In Dr. Withering's arrangement it is the poa
difanus; and Dr. Stokes supperct the poa retrofaisa of Mr.
Curris to be the same with this. Gmelin adds to the clasfs
of the naked aires. 4. A. caput, with a ramoife calum,
racemose flowers, and hairy corolla. 5. A. loenigii, with
dense panicle, smooth calyces, and ascending culm; the poa
lefforia of some authors. 6. A. bengalenis, with erect pan-
cle, three-flowered pedicles, and petals woolly within;
the arundo bengalenis of other writers. 7. A. milacea,
with very numerous panicles, with floecules in three's, obtuse
and dilated, and smooth flirated leaves. 8. A. egglipoides,
with flowers turning to one side, with one valve of the
corolla ovated and acuminate, and the other columnar
and obtuse. Dr. Smith (Flor. Brit. vol. i. p. 83.) adds, A. eri-
tata, with panicle flirated, calyces longer than the peduncle,
petals acuminate and unequal. It grows in high barren
paturtes and walls; perennial; flowering in July and August.
The added aire enumerat by Martyn are as follow:
9. A. fuligata, with leaves flat, panicle spiicked, flowers
awned on the middle, awn reflex and leafe; found on the
mountains of Switzerland, Savoy, Denmark, and Lap-
land; perennial. 10. A. ecrugata or hairy hair-grafs, with
leaves fasciculate; panicle spreading, petals villous, and
awned at the base; awn flat and short; growing in moist
meadows and woods, perennial, flowering in June and July, some-
times trailing on the ground to the length of several feet,
and the panicle exhibiting a beautiful purple silky appear-
ce. Dr. Withering mentions a variety of this with pan-
icle viviparous, flowering in October, and found on Highland
mountains. This is apt to grow in tufts, and occasion irregular-
ities in the surface of meadows. Cows, goats, and
swine eat it; but horses are not fond of it. It is the roughest
and coarsest grafs that grows in paturtes or meadows; and
battle will not touch it, unless compelled by hunger. It is
called by the vulgar halflocks, rough caps, and bull's faces.
To get rid of it, the hand should first be drained, and the
tufts of this noxious weed pared off and burnt; and the
ashes they yield will be a good manure. 11. A. flexuosa,
or waved mountain hair-grafs, with leaves fettaceous, culms
almost naked, panicle spreading, trichomous, peduncles
flexuose, and awns geniculat; perennial, flowering in July,
and growing in heaths, woods, and barren paturtes, eaten
by hores, kine, and sheep. Dr. Withering fuggs, that
this is a variety of the A. montana, or rather the fame in a
more mature state. This is a principal grafs on Banfleed
Down, Mendip, &c. and is equally fine and nutritive with
sheep's fucces. It is of difficult cultivation. Dr. Smith
(Fl. Br. vol. i. p. 85.) mentions two varieties; one with a
panicle, lees spreading, and peduncles feecrely flexuose.
This is the A. montana of Hudson, Withering, Robhan,
and Leers, but not of Linneus. The A. fitaceae of Hudson
does not differ from this; but the A. montana of Linneus
is a very different grafs, and has not yet been found in Britain.
The other has a culm more leafi, a white panicle, scarcely
flexuose, and grows in flthy places. 12. A. montana,
with leaves fettaceous, panicle narrowed, flowers hairy at the
base, sinuaturn, awn twisted and very long; fopped to be
a variety of the former: perennial, flowering in July, ef-
tative of high heaths and sandy paturtes; eaten with avidity
by sheep. A variety, called fteacae, with awns twice the
length of the florets, is mentioned by Hudson. 13. A.
alpina, with leaves fublate, panicle dense, flowers hairy at
the base and awned, awn short; growing on the mountains
of Germany, Savoy, and Lapland. 14. A. aiflofa, with
leaves fublate, panicle long and narrow, flowers efpercular-
ter, shaggy, awned; awn straight and short; found by
Thunberg at the Cape of Good Hope. 15. A. canefaces,
grey hair-grafs, with leaves fettaceous, culm leafi, the upper
one involving the panicle at bottom, like a fpathe; awns
clavel at the apex, shorter than the calyx; a native of
fandy fhores, on the coasts of Norfolk and Suffolk, the
walls of Baili, and the fandy fields of Germany and Pied-
mont; perennial, flowering in July; the avera canefacea of
Wiggers. 16. A. poecon, early hair-grafs, with leaves fe-
taceous, fheaths angule, flowers panicle-falked, floecules
felfie, naked at the base and awned on the back; found on
dry commons, in ditches, on banks of freams, and in wet
meadows; perennial, flowering in May and June, ripening
its feeds in June; and called by Wiggers, avera fulfila. It
has a sweet fave; cows are very fond of it; and it is eaten
by hores and sheep. 17. A. carephilla, silver hair-grafs,
with leaves fettaceous, panicle divaricate, trichomous,
floecules felfie, dorval awn genicated; a native of fandy
paturtes, and heaths of England, France, Switzerland,
Piedmont,
Piedmont, Germany, and Denmark; annual, flowering in July. 18. A. antarctica, south-ka hair-grass, with leaves flat, panicle compound, spreading, calyces three-flowered, florets awned in the middle, awn elongated straightish; a native of New Zealand. 19, A. involucrata, with panicle spreading, involucres with bristles at the base; florets awned; a native of Spain, on barren hills near Madrid; annual, and flowering in June and July. To these: Gmich adds, 22, A. paludosus, with flat leaves, patent panicle, florets hairy at the base, and the axon jerk and bent inwards. 21. A. filiculoides, with filiform leaves, erect panicle, leaves coloured, and awned beyond the middle. 22. A. juncea, with leaves subulate, panicle patent, very obtuse, awn from the base of the length of the calyx. 23. A. filiculoides, with setaceous leaves, erect panicle, and villous florets. 24. A. media, with setaceous leaves, narrow panicle, florets hairy at the base, awn subterminal, shorter. 25. A. purpurea, with leaves subulate-setaceous, panicle scattered, one valve of the corolla entire, plumoie, and culm erect. For the propagation and culture of Aira; see Grass. Gmich's Linnaeus. Martyn's Miller. Withering's Botanical Arrang., vol. ii. p. 137, &c.

Aira Indica. See Panicum.

Aira Varia. See Cynosurus.

Airlan, in Church History, a sect of Arians, in the fourth century, who denied the confubstantiality of the Holy Ghost with the Father and the Son.

They are otherwise called Airarnossa, and are said to have taken their name from one Airas, who distinguished himself at the head of this party, in the reigns of Valentinian and Gratian.

Airano, in Geography, a town of Italy in the Milanese, 10 leagues south-east of Como.

Airault, Peter, in Latin Aëriadius, in Biography, lieutenant-criminal in the predial of Angiers, was born there in the year 1325, and executed the office in a manner that obtained for him the title of the "Rock of the Accused." He died in 1601, and left several treatises. His eldest son was educated by the Jesuits, and retained in their society, notwithstanding all the remonstrances and efforts of his father. Biog. Dict.

Airay, Henry, an English divine, was born in Welford, educated under the care of Bernard Gilpin, and sent to St. Edmund's Hall, Oxford, in 1579, at the age of nineteen years. He was afterwards removed to Queen's college, where he was successively svervor, fellow, and master. In 1598, he was chosen profitor, and in 1606, vice-chancellor of the university. He was a conflant and zealous preacher, and a zealous Calvinist. He was much esteemed for his learning, gravity, and piety, and for his industry in discharging the duties of his office; and died in 1616. The following treatises, written by him, were published after his death, viz. "Lectures on the Epistle to the Philippians, 4to. 1618." "A Treatise against Bowing at the Name of Jesus." And, "A full and necessary Apology relating a Suit at Law." Biog. Brit.

Aire, in Geography, a town of France, in the department of Landes, formerly Galcony, and in the district of St. Sever, situate on the Adour, 155 leagues from Paris, and 5 leagues south-east of Mont-de-Marsan. It is a very ancient town, and the seat of the suffragan bishop of Auch, containing 241 parishes. Its ancient name was Vicus Julia, having been taken by the Romans, under the command of Julius Cesar. The Vicioga afterwards took possession of it; and Aleric, one of their kings, adored it and fortified it with a castle. It has often since changed masters, and suffered much during the religious wars in France. The place contains 5,699, and the canton, 16,266 inhabitants. The extent of the territory includes 235 kilometres, and 13 communes. N. lat. 43° 31'; E. long. 3° 30'.

Airé, a town of France, in the department of Pas-de-Calais, formerly Artois, and district of St. Omer; situated on the Lys, fortified by a castle, and communicating with St. Omer by a canal; and also with the town of St. François. It was taken by the allies in 1572, and restored to France by the peace of Utrecht. It is 9 leagues from St. Omer, 9 from Dunkirk, and 51 north of Paris. The place contains 6,837, and the canton, 14,882 inhabitants. The territory comprehends 125 kilometres, and 20 communes. N. lat. 50° 30'; E. long. 2° 17'.

Airé, a river of England, flowing into the Humber, and navigable to Leeds in Yorkshire.

Airing, in the general sense of taking, or going into the fresh air, is too well known to need any explanation. See Aerophobia.

The word is particularly used for exercising horses in the open air, which is of the greatest advantage to these animals. Many of the diseases to which horses are liable, are brought on by neglecting to exercise them.

Airing a horse, should be distinguished from that species of exercice used in training horses for racing, as this is conducted at regular periods, and has in view not only the general health, but particularly the acquisition of wind and speed. Airing a horse, in a general way, may be done at any part of the day, but when the heat of the sun is too intense, as by this means it perpieres too much, and is rendered irritable from the fings and bites of insects. It is better to give a horse a moderate airing twice a day, than a longer one at one time. It should be avoided immediately after a full meal; at those times the chesf has not room to expand, therefore the wind is endangered; the food is likewise hurried, by the pressure of the abdominal muscles, too soon through the stomach to be digested, and too soon through the intestines, to be properly absorbed by the lachetae. In an airing the horse should first be walked, then trotted, and lastly moderately galloped; it is usually practised in a snaffle bridle, the propriety of which depends on the horse's mouth and the hand of the rider. If the grooms is not perfectly acquainted with the art of riding with a fine hand, which few of them are, a large bitted snaffle should be used. An airing should be continued long enough to give a horse an appetite, but not so long as to weaken its stomach. When horses are very fat it should be continued longer, that the aborbents may be stimulated to take up more of the adeps of the body. In foul, grooms, greedy horses, the airings should be gentle, but continued for some time; in fancy this should be particularly observed. And in all diseases where there appears a defect in the aborbents, the exercice should be gentle, continued long, and frequently repeated. The numerous cautions made use of to air such particular horses, at particular times, have their foundation in whims and caprices: reason and science point out, that any time between the meals, when the fun is not in its full luftre, is proper for airing them. See Exercise.

Airola, in Geography, a town of the canton of Uri, in Switzerland, six leagues north of Altorf.

Airon, a river of France which runs into the Loire near Decize.

Airs, in Horsemanly, denote the artificial or practised motions of a managed horse. Such are the demi-volt, curvet, capriole, croupade, balance, step, and leap; also, advancing, yoking, and bounding. Some authors take airs in a more extensive sense; and divide them into low and high. The low airs include the natural walking, trotting,
ting, galloping, and terra-a-terra. To which may be added, prancing, bidding, stamping, and turning.

The high, or raised airs, are all such motions as rise higher than the terra-a-terra; as the demisemiquoit, curvet, &c.

AIRVAULT, in Geography, a town of France, in the department of the two Sèvres, and district of Parthenay, four leagues N.N.E. of Parthenay. The town contains 2,068, and the canton 6,250 inhabitants; the extent of the territory includes 160 Kilometres and 9 communes.

AIRY trilicity, among Aloysians, the signs of Gemini, Libra, and Aquarius. See Trilicinity.

AISA, in Geography, a town of Spain, in the kingdom of Arragon, two leagues and an half north of Jaca.

AISCH, a river of Germany, in Franconia, which rises near Ithheim, and discharges itself into the Regnitz, between Bamberg and Forchheim.

AISE, a river of France, which runs into the Orne, three leagues above Caen.

AISEAU, a town of Germany, in the circle of Welfphalia, three miles east-south-east of Chalet.

AISEDABAD, a town of Peria, in the province of Arak Agami; 22 leagues north-north-east of Amadan.

AISEREY, a town of France, in the department of the Côte d'Or, in the district of St. Jean de Lofae, three leagues south-south-east of Dijon.

AISÉY-LE-DUC, a town of France, in the department of the Côte d'Or, in the district of Châtillon, 2½ leagues south of Châtillon.

AISIAMENTA, in Law. See Easement.

AISNE, in Geography, a river of France, which rises in Champagne, runs by Soissons, and falls into the Oise above Compiegne. It gives name to a department which is one of the six formed of the ci-devant Soissonois, le Beauvois, and le Vexin Francos; and it is one of the five into which the ancient Ile de France is divided. It is bounded on the north by the department of the North; on the east, by that of the Ardennes, and part of that of Marne; on the south, by part of Marne, and the department of Seine and Marne; and on the west, by the departments of the Oise and Somme. The extent is about 1,467,884 square acres, or 749,183 hectares; its population about 408,172 individuals; and it is divided into five communal districts. Its chief town is Laon.

AISTULPH, or Astulfus, in Biography and History, king of the Lombards, was chosen to succeed his brother Rachi, who reigned the crown, A.D. 754; and by his gallantry in the field and wisdom in council advanced the kingdom to a pitch of grandeur, which occasioned its total ruin. Having ratified a peace with pope Stephen, and extended the term of it for 40 years, he fixed the opportunity, which was afforded him by a war with the Saracens, and Bulgarians, that engaged the attention of the eastern emperor Conстанtine Copronymus, to invade the exarchate of Ravenna, which he subdued, with all its dependencies, and added to the kingdom of the Lombards. Thus terminated the exarchate, which was reduced by the Lombards to a dukedom. Aistulfus proceeded to invade the Roman dukedom, and marching towards Rome, threatened to plunder the city and muzzle the inhabitants, unless they acknowledged his sovereignty and paid him a yearly tribute. Pope Stephen was alarmed, and applied to the emperor for succour; but deriving no effectual assistance from the emperor, he recurred to Pepin king of France, who marched an army into Italy, and after routing Aistulfus and his army invaded Pavia, where he had taken refuge. The Lombard king was glad to purchase peace by retaking all the places he had taken, and even the exarchate, which was surrendered to Pepin the fee of Rome. But as soon as Pepin had departed, the Lombard king, in violation of his engagements, and regardless of his oaths, approached Rome with his army, and closely beleaguer it. Stephen renewed his application to his protector, and by the flippant style of the letters which he addressed to him engaged him again to have recourse to arms. Aistulfus threw himself a second time into Pavia, whether he was pursued by Pepin, who closely invested the city. The siege was pressed with vigour, and Aistulfus reduced to such distress, that he was under a necessity of having again for peace, which he obtained upon a promise to perform immediately the treaty that had been made the year before, and as an additional security to deliver up to the pope the city of Commachio, which was a place of great importance. Upon this Pepin renewed his donation to the pope; yielding to St. Peter and his successors the exarchate, Romilia now Romagna, and Pentapolis now Marca d'Ancona, with all their cities, to be held by him for ever. See Exarchate. Aistulfus, lamenting the humbled state to which he was reduced, began again to prepare for recovering by force what he had been obliged to resign; but in the midst of his hostile preparations, he was killed whilst he was hunting, A.D. 758, and left no male issue. The code of laws which he published in the 5th year of his reign is still extant. Anc. Un. Hist. vol. iv. p. 482.

Aistulfus and his queen are made the subject of a curious tale, of the free kind, to be found in La Fontaine and other Novellists. Gen. Biog.

AITHALIA, in Geography. See Αἰθαλία and Elba.

AITOCZU, a considerable river of Lesser Asia, which rises in Mount Taurus, and falls into the fourth part of the Euxine sea.

AITON, William, in Biography, an eminent botanist and gardener, was born in 1731 at a small village near Hamilton, in Lanarkshire, in Scotland. Having been trained betimes in the science and practice of horticulture, he came into England in 1754, and was engaged as an assistant by Mr. Philip Miller, well known as the author of the Gardener's Dictionary, who was then superintendent of the physic garden at Chelsea. In this situation he soon attracted notice, and in 1759 he was recommended to the Prince's Dowager of Wales, as a fit person to manage the botanical garden at Kew. In this office to which he was then appointed he continued during life; and here he laid the foundation both of his fame and fortune. As the garden at Kew was destined to be the repository of all the curious plants, that could be collected from the various quarters of the globe, Mr. Aiton had the most favourable opportunity for indulging his taste, and employing his care and skill in their cultivation; and in so doing he acquired distinguished reputation amongst the lovers of this science, and the particular esteem of his royal patrons. Under his superintendence Kew gardens became the principal scene of botanical culture in the kingdom. In 1785 Mr. Aiton was promoted to the more lucrative office of managing the pleasure and kitchen gardens at Kew, which he was allowed to retain in connection with the botanical department which he had before occupied. In 1780 he published his "Hortus Kewensis, or Catalogue of the Plants cultivated in the Royal Botanic garden at Kew," in three vols. Svo. with 13 plates; a work, which had been the labour of many years, and which justly entitles him to respectful commemoration among the promoters of science. The number of species, contained in this Catalogue, is between 5 and 6000. A new and curious article in it relates to the first introduction of particular exotics into the English gardens. The system of arrangement is that of Linnaeus, with such improvements as the
advanced state of botanical science required. To Sir Joseph Banks, Dr. Solander, and Mr. Dryander, Mr. Aiton respectfully acknowledges his obligations for effusion in compiling this celebrated work. The "Hortus Kewensis" was much valued by the belt judges, and a large impression of it was printed in a rapid sale. Notwithstanding the temperature and activity of Mr. Aiton, he laboured under the incurable malady of a furious liver, which occasioned his death in 1793, in his 62d year. His eldest son, devoted to the same pursuits, and distinguished by his talents, was appointed, by the king's own nomination, to all his father's employments. The private character of Mr. Aiton was highly estimable for mildness, benevolence, piety, and every domestic and social virtue. He was interred in the church-yard of Kew, amidst a most respectable concourse of friends. Gen. Biog.

AITONA, in Geography, a small town of Spain in Catalonia, the capital of a marquisate.

AITONIA, in Botany, so called from Mr. W. Aiton, his Majesty's late gardener at Kew, a genus of the monadelphus oitocordia class and order, and of the natural order of columnifera. Its characters are, that the calyx is a one-leaved, erect, four-parted, short perianthium, divided into four ovate, sharp segments; the corolla has four erect, equal, broadly-ovate, concave, very obtuse petals; the stamina have filaments joined as far as the middle, divided above into eight, awl-shaped, furrowed, standing out of the corolla, and having ovate, furrowed anthers; the pistillum has a germ superior, ovate, smooth, subangular, style one, filiform, of the same length with the stamens, stigma obtuse, undivided; the pericarpium is an ovate dry, membranaceous, four-cornered, one-celled, brittle berry, the corners are produced and sharp; the seeds many, fixed to a column, globular and smooth. It varies with five-eleven, ten-flamed flowers. There is one species, viz. A. caper, found at the Cape by Thumberg, and introduced here in 1774 by Mr. F. Maffon. It has a thorny stalk, fix feet high, and a fruit resembling that of the winter-cherry. With us it is of flow growth, and seldom exceeds three feet in height. At a sufficient age it produces flowers and fruit through the greatest part of the year. It is raised only from seeds, and must be kept in the greenhouse or conservatory. Martyn.

AITTERBACH, in Geography, a river of Austria, which runs into the Thunn, near Wels.

AITZEMA, Leo, in Biography, an eminent historian and diplomatist, was born at Doccum, in Friesland, in the year 1600. He was counsellor of the Hans Towns, and their resident at the Hague for 40 years; where he died in 1669, with the reputation of an excellent linguist, an able politician, and amiable manners. His "History of the United Provinces," written in Dutch, contains a large collection of treaties of peace, memoirs of ambassadors, letters, capitulations, and other public acts, which is very valuable. The history is more faithful than elegant, and as far as it concerns religion, it is written with impartiality. The work was published in 15 volumes 4to, and was succeeded by another edition of seven volumes in folio. The period which the history comprehends begins with the year 1624, and terminates with 1663, and it has been continued to 1692. Gen. Dcl.

AJUBATIPITA, Brasilium, in Botany, the name of a shrub that bears a black fruit like an almond, which yields much oil.

AJUGA, Bugula of Jucifus, Towneport, and Miller, bugle, a genus of the dilycanum gymnophorinus class and order, and of the natural order of virectillata or labiata. Its characters are, that the calyx is a one-leaved, short perianthium, cut half-way into five eletes, with the segments nearly equal; the corolla is monopetalous and ringent; tube cylindrical and bent in, the upper lip very small, erect, bifid, obtuse, lower large, spreading, trigl, obtuse, middle division very large and obcordate, side ones small; the stamina have tubulated, erect filaments, longer than the upper lip, anthers tway the pistillum has a four-parted germ, style filiform, and with respect to situation and length as in the stamina, fila coma two, slender, the lowest shorter; no pericarpium, the calyx, which is converging, holds the seeds, which are somewhat oblong. There are six species, viz. 1. A. orientalis, eastern bugle, with flowers inverted; first brought into Europe from the Levant by Towneport, since observed by Thunberg in Japan, and by Loureiro in Cochinchina; cultivated in 1732. Of this there are two or three varieties, differing only in the colours of their flowers. 2. A. pyramidalis, pyramidal bugle, of which the spike is a quadrangular vil- lous pyramid, the leaves approximating, the root leaves very large, the bracteae nearly entire; biennial, flowering in April, or with us later; a native of Italy, France, Germany, Switzerland, Sweden, Denmark, Wales, and Scotland. 3. A. alpina, alpine or mountain bugle, with flom simple, leaves smooth, unequally dentate, fimbriiform, the remotest verticilli bearing many flowers; growing naturally on the Alps, and in mountainous places in Carnarvarshire, Durham, and on the summit of a mountain near Callerton, Derbyshire; admitted into gardens for variety, and propagated by its trailing thalls; requiring a mild shady situation, perennial, and flowering in July. This is the A. py ramidalis of Hudson, and the A. genevensis of Withering. 4. A. genevensis, Geneva bugle, with leaves downy, frieaked with lines, lowermost narrower, calyces thaggy, bracteae or floral-leaves generally three-lobed; growing wild about Geneva, and in many of the southern countries of Europe; cultivated in 1759, by Miller. 5. A. reptans, common bugle, smooth, with solitary stem, and creeping by runners; perennival, flowering in May; growing in moist meadows, pastures, and woods in moist parts of England; becoming somewhat hairy in high and dry situations, with a rounder stem and shorter creepers. Prof. Martyn mentions two varieties, one with a white and the other with a pale purple flower, which grow in several parts of Weilmoreland; but they differ only in the colour of their flowers from the blue form. The common bugle, called by official writers, confolida media, or middle confound, is recommended as a vulnerary herb, both internally and externally. For this purpose, infusions of the leaves, or the expressed juice, have been administered; and also as mild astringents and corroborants in fluxes and other disorders. Decotions of them have been commended by Riverius and others in phthisial and internal ulcerations. Malouin recommends a gargarium of the root in the angina. The roots appear to be considerably astringent, both by their tasts, and by their striking a black colour with solution of chalybeate vitriol. Lewis Mat. Med. Murray Mat. Med. vol. ii. p. 155. 6. A. decemont, japonica bugle, decumbent and villous; leaves obovate and toothed; with flowers in whorls, small and blue; called by Loureiro as a variety of A. reptans.

To this genus Dr. Smith adds (Flor. Brit. vol. ii. p. 605.) the herbium champepiscus of Linnaeus, the ground pine of English writers. Accordingly the A. champepiscus is described as having a spreading ramose stem, trifid linear entire leaves, and solitary axillary flowers. It grows in sandy fallow fields in Cambridgeshire and Kent; is annual, and flowers in April and May. The leaves of ground pine are moderately bitter, and of a rufous smell, approaching in this respect, as well as in their external form, to those of the
the pine-tree. Their virtues are extracted both by water
and spirit, but most perfectly by the latter. The aqueous
juice is yellowish, and the spirituous green. The watery
extract is bitter and astringent; the spirituous is slightly
fleece and warm. The oil, collected by distilling large quantities
of the herb, approaches in quality to that of turpentine.
The leaves are recommended as aperients, and corroborants of
the nervous system; and are said to be particularly serviceable in
female obstructions, paralytic disorders, and when continued
for a long time, in rheumatic, enteric, and gouty pains.
It was denominated by some of the ancient botanists for arthritis,
from its use in arthritic pains. It has been recom-

mended by foreign writers in flow fevers, asthma, and apo-
deptic fevers; and also in inflations of the visera and
jaundice; and especially for cleansing and colostidicating ulcers,
as well as for an antiseptic to the cancer. But its me-
cial reputation has, in later times, considerably declined.
The first species of Ajusta may be propagated by seeds,
when they are ripe in a pot filled with earth, and placed
in a shady situation till Autumn, and then removed under
a frame. The young, in the Spring, they should be transplanted into
separate pots. In the hard fruit of Winter they should be
covered. This species may be also more freely increased by offjets, of which it affords but a few. The sixth foot may be
 propagated in the same manner. As for the red, they are hard
and easily multiplied by the fide droppings; they del-
light in a moist shady situation, and are apt to spread too
much. Marmyn.

AJURU Curato, Phittacus australis, in Ornithology, the
Ajusta Curato of Maregrae, the Ajur Anuran Curato of Buffon,
the middle-sized parrot of Willughby, and the common Ama-
zonian parrot of Latham, is of a green colour, slightly spotted
with yellow; with a blue front, blood-red shoulders, and thick-
coloured orbits. It is 12 inches long, and its body about the
size of a pigeon: the back has a number of tawny yellow
feathers, scattered through its green plumage. The fide
is yellow, with a blue forehead and white crown; the tail-quills are green with paler tips: the first, second, and third on each
side are red on their inner webs near the base; the outer web
of the first being blue; the shoulders are either tawny or blood-
red; the primary wing-quills are black, with bluish tips, the
outer webs being green, and the inner black; the first four or
five of the secondaries have their outer webs red near the
base; the bill is black at the tip. This species of parrot in-
habits Amazonia, Guiana, and Brazil; and it has several va-
rietis, to the four first of which the above description is ap-
plicable: e. g. 1. The A. of Jamaica, with the head and
breast yellow, the front and chin bluish, the edges of the
wings and vented red. This is the phittacus viridis melano-
rinches of Aldrovand, the black-billed green parrot of Wil-
lughby, and the Jamaican parrot of Brown and Latham. 2.
The main A. parrot, with the lesser wing covert red; the
crown yellow, the cheeks and chin paler; the forehead blue;
the under half of the middle wing-quills, and the inner webs
at the base of four tail-quills on each side, red. This
variety inhabits Guiana and Amazonia. 3. Brasilia A. par-
rot, with cap blue, variegated with black; a yellow spot
on the crown, and one on each fide below the eyes, and a blue
chin. This is the pf. Brasilia cyanopictus of Buffon, the
Ajusta curato of Maregrae, Ray and Willughby, and the
blue-tipped parrot of Latham. The primary wing quills,
according to Mr. Latham, are variegated with yellow, red
and violet blue. It inhabits Brazil. 4. Varied A. parrot,
with the crown, cheeks and chin yellow, and the front blue.
The crown is varied with blue, the fereg and upper part of
the back with yellow, and the bill is ash-colored. This is
the Ajusta Curato fleunclus of Maregrae and Ray, and the
Vol. I.

West-India green parrot of Edwards and Latham. 5. Ama-
azonian A. parrot, pale green, with a pale yellow front and
natty temples. This is the pf. amazonicus of Gmelin, and
the Brasillian yellow fronted parrot of Latham. It inhab-
its Brazil and Amazonia. This variety is almost twice the size
of those abovementioned. 6. Coast A. parrot, green, with
a blue forehead; the crown, cheeks and chin, and middle of
the belly yellow. It is nearly as long, to the former, and in-
habits Brazil. 7. Yellow-topped A. parrot, green, with yell-
low head and neck, and red shoulders; of the size of the
former, and like it, the wing-quills are marked with a red
spot, and the lateral tail-quills are red at the base. 8. Coun-
terfeit A. parrot, green, variegated with yellow, having a
blue forehead and red shoulders. It inhabits Brazil. Gmelin's
Linn. tom. i. p. 443. Kerr's Linn. p. 358. Buffon's Birds,

AJURU-CATINGA, the Guiana red billed parrot, a va-
riety of the phittacu australis Lapiaturum inflecte of Buffon,
the Guiana green parrot of Bancroft, and of Latham; has the bill,
legs, feet and claws of a whitish red colour, and the arteries ash-coloured. It inhab-
its South America: and is about the size of a thrush, and
the indes have two coloured circles, of which the outer is
reddish, and the inner ash coloured.

AJURU-PARA, a Brasillian species of parrot of a small
size, all over of a beautiful green, and with white legs, a white
beak, and white feet. Flat circles round its eyes. Maregrae.

ALIUS, or Locustas; i.e. speaking voice, in
Mystology, the name of a Roman deity, to whom a temple
was erected at Rome, on the following occasion.—M. Cali-
tius, a plebeian, informed the tribunes, that, as he was passing
through the New Street in the night, he heard a supernatu-
ral voice near the temple of Vesta, which warned the Romans
of the approach of the Gauls; but the warning was dis-
regarded on account of the meaner of the person who re-
ported it, in consequence of which, the Romans suffered very
much from their invasion. Camillus, however, delivered
them, and advised them to expiate the offence by erecting a
temple in the New Street to this imaginary deity. Cicero,

AJUTAGE; or Ajustage, formed of the verb, aputa-
ter, to adapt, in Hydromes, part of the apparatus of an
artificial fountain, or jet d'eau, being a sort of tube, fitted
for the mouth or aperture of the vessel, through which the
water is to be played, and by it determined into any figure
and direction.

It is chiefly the diversity in the ajutages, that makes
the different kinds of fountains. And hence, by having several
ajutages to be supplied occasionally, one fountain comes to
have the effect of many.

Mariotti inquires into the best kind of ajutages, or spouts,
for jets d'eau, affirming, from experiment, that an even po-
lihed round hole, in the end of the pipe, gives a higher jet
than either a cylindrical, or a conical ajutage; of which,
however, the latter is the better. Vide Trait. du Mouv-

The quantity of water discharged by ajutages of equal
area, but of different figures, is the same. But for those of
like figures, and different sizes, the quantity discharged is
directly proportional to the area of the ajutage, or to the
square of its diameter, or of any fide or other linear dimen-
sion: thus an ajutage of a double diameter or fide will dis-
charge four times the quantity of water, of a triple diameter,
nine times the quantity, &c.; supposing that they are at an
equal depth below the surface or head of water. But if the
ajutages be at different depths, the celerity with which the
water
water flows, and consequently the quantity issuing in any given time, is directly proportional to the square root of the altitude of the head, or the depth of the hole, so that at four times the depth, the celerity, and of course quantity, are double; at nine times, triple, &c. It has been found by experiment, that the jetter is higher or lower according to the size of the orifice; that a circular hole of about an inch and a quarter in diameter jets highest; and that it works as it recedes from that size. Experience also shews, that the pipe leading to the orifice should be much larger than the orifice itself; and if the pipe be long, it should be wider according to its distance from the orifice. Encyclopedie Thivigue, tom. i. p. 152. Hutton's Dict.

For the various sorts of orifices, their structure, application, &c. see Fountain. See also Fluid and Jet d'Eau.

AIX, in Geography, a city of France, the capital of the department of the Bouches du Rhone, formerly Provence, and one of the most pleasant and well-built cities in the kingdom. It is situated north of the river Arc, between hills planted with vines and ches. It is said to have been founded by C. Sextius Calvinus, a Roman consul, who established a Roman colony in it in A. U. C. 636, about 124 years before Christ, and called it Aquae Sextiae from his own name, and the warm baths which he found there. It is rather populous than large; its houses are well built, and its streets are straight and well paved; and within the city there is a spacious walk called O bitelle, which consists of three rows of trees intermixed with fountains, and surrounded by many handsome and spacious buildings. The preacher's square, as it is called, is seated on the side of a hill, about 160 yard long, encompassed with trees and lofty houses built with stone. Of the public buildings some of the principal are the town-hall, the hall of audience, the hotel of the city, the cathedral church, which is a fine Gothic structure, the church of the fathers of the oratory, the chapel of the blue penitents, and the conven of the preachers, in whose church is a silver statue of the Virgin Mary, almost as big as life. There are also other churches and buildings, which contain many paintings and other rarities. At the baths, which were re-discovered in 1701, there are many edifices that have been raised at a great expense for the accommodation of those who use the waters. These waters were formerly supposed to possess peculiar virtues in cases of debility; as several altars consecrated to Prinusa, and bearing inscriptions expressive of gratitude for his assistance, have been dug up in their vicinity. Aix was an archbishopric with five suffragans, and 84 parishes; and it was the place of resort of the nobility of Provence and of literary men. The neighbourhood affords excellent wines; but its chief article of trade is oil. Some flints are also manufactured here. The city contains 23,686, and the two cantons 28,909 inhabitants; the territory comprehends 337½ kilometres, and 6 communes. It is distant five leagues north from Marseille, and 103 south-east of Paris. N. lat. 43° 35' 35". E. long. 5° 26' 15".

AIX, or AIXE, a town of France, in the department of the Upper Vienne, in the district of Limoges; two leagues west-south-west of Limoges. The town contains 2,135, and the canton 6,886 inhabitants; the territory includes 202½ kilometres, and 10 communes.

AIX, Agues Gratianae, or Sabaudia, Allobrogum, a small town of Savoy, chief place of a canton, in the department of Mont-Blanc, and district of Chambey, situate near the lake of Bourget, between Chambey, Aimecy, and Rumilly, with the title of a Marquisate. The hot baths, which were originally constructed by the emperor Gratian, are free of access without expense, and are much frequented. In this place are seen the ruins of a Roman triumphal arch. The town contains 1,596, and the canton 6,260 inhabitants; the number of kilometres in the territory is 1,174, and that of the communes 13. N. lat. 45° 42'. E. long. 5° 48'.

Aix, a small island on the west coast of France, between the isle of Oleron and the Continent; about 12 miles north-west of Rochfort, and as far south-west of Rochelle. Its fort was destroyed by the English in 1557, and again in 1561, but afterwards rebuilt. N. lat. 46° 1'. E. long. 1° 8'.

Aix d'Agiluron, a town of France, in the department of the Cher, and district of Bourges; 3 leagues north-call of Bourges. The place contains 1,127, and the canton 7,885 inhabitants; the territory comprehends 260 kilometres, and 14 communes.

Aix en Othe, a town of France, in the department of the Aube, and district of Troyes; five leagues west of Troyes. The town contains 1,579, and the canton 7,970 inhabitants; the territory includes 200 kilometres, and 11 communes.

AIX-La-CHAPELLE, a free Imperial city of Germany, in the circle of Westphalia and Duchy of Juliers, and the capital of the department of Roer. This city, in Timothe's Statistical View of France, contains 23,442 inhabitants. This is a very ancient city; and appears from the inscriptions of Caesar and Tacitus, to have been occupied and fortified by Roman colonists in their wars with the Germans. It was called in Latin Aquis Grauam, or the waters of Graunus, Aquus, and Urbs Aquenae, in German, the city of Aachen, and also Aesc; and derived its name from its warm baths, which have been long held in high estimation. By the French it is denominated Aix-la-Chapelle, by way of distinction from other places called Aix, on account of a chapel of the Holy Virgin built by Charlemagne, who repaired and beautified the city, which had been destroyed by the Huns in the reign of Attila in 451, and who made it the place of his usual residence. The king of the Romans or emperor was generally crowned in this city, as the place appointed by the golden bull for this purpose; and on this account called the Royal city; and it is the depository of the crown of Charlemagne, the belt, a book of the gospels, and other jewels of the empire, that are tied in the ceremony of coronation. Charles V. was crowned here in 1529, and Ferdinand his brother was crowned king of the Romans in this place in 1531. Charlemagne died and was buried in this city, to which he had always manifested a peculiar attachment, and on which he conferred many signal privileges. On the Rhine bench, in the college of the cities of the empire, and among the Imperial cities which have a seat and voice at the Diets of the circle of Westphalia, Aix-la-Chapelle possesses the second place; and it lays claim to the first on the Rhine bench. The town is situated in a valley, and though surrounded with mountains and woods is not unwholesome. It confinds in reality of two cities, enclosed one within the other. The inner city, which is the most ancient, is flanked with ten towers, and is about three quarters of a league in circumference; the outer, founded about the year 1172, has eight gates, and the circuit of it is about two leagues. There are several rivulets which run through the city, and 20 public fountains, besides several private ones. The principal buildings, which are constructed of stone from quarries in the vicinity of the town, are the fladt-house and the cathedral. The fladt-house is adorned with the statues of all the emperors since Charlemagne; and in the front of it there is a fountain, on the top of which is placed the statue of this emperor, made of brass gilt, holding in his right hand a sceptre, and is his left a globe. The upper story of this building consists of one room, 162 feet long and 60 broad, in which the newly elected emperor formerly entertained all the electors of the empire. The government of this city is entrusted with the great and little senate;
AIX

AIX

The former composed of 139 persons, who judge in criminal cases, and the latter of 41 members, who have jurisdiction over the police and commerce of the city, and the management of the public revenues. The duke of Brabant is protector of the city; and the duke of Julliers is burgomaster or perpetual mayor of the burghers. The title of its magistracy is that of burgomaster, theess, and council of the holy Roman Imperial free city of Aix-la-Chapelle. The prevailing religion is the Roman Catholic; and the Protestant inhabitants, both Lutherans and Calvinists, not allowed the free exercise of their religion within the city, celebrate their worship at Vails, about an hour's journey from the city in the duchy of Limburg. The manufactures of the city are those of cloth, copper, and brass. Councils have been held in this city in the eighth and ninth centuries, and treaties of peace have been concluded here; particularly those between France and Spain in 1668, and between France and England, and other belligerent powers in 1748. Bufching, vol. iv. p. 369. Med. Un. Hist. vol. xxxii. p. 223.

It was taken by the French in 1793, lost after a fierce battle in 1793, and retaken in 1794. It is 21 miles from Spa, 30 feet from Cologne, and 36 north-east from Liege. N. lat. 51° 55'. E. long. 5° 24'.

Aix-la-Chapelle, says Mr. G. Forster, in his Travels 1792, which once contained above 100,000 inhabitants, has not now a third part of this number, and has lost all its ancient wealth and prosperity; owing partly to the rise of rival towns, but principally to religious intolerance and a bad government. The streets now swarm with beggars, and the morals of the people are licentious and corrupt. Those whose skill and industry might have enriched the city are driven from it by the partial and oppressive conduct of the guilds, and have established their manufactories in other places, where they enjoy greater liberty. Those, he adds, of Burghhead, Vails, Eupen, Monaco, and of other places in the duchy of Limburg, are in a very flourishing state; the wool is imported from Spain, and the cloth is exported chiefly to the Levant. Vails, which 39 years ago, was an inconsiderable village, is now become a respectable town; the protestants, weary of the oppression and bigotry which they had experienced at Aix-la-Chapelle, were easily induced to settle in a place where they were allowed the advantages of religious freedom; and it has now five different churches, in which Roman Catholics, Lutherans, Calvinists, Baptists, and Jews, worship the Deity according to their several sentiments, and live peaceably with each other.

AIX-LA-CHELLE, or AKEN Waters. *Therma Aquis-granenfes.*

The thermal sulphureous waters of Aix-la-Chapelle have long held a most distinguished place among the mineral springs of Europe, and have not a little contributed to the celebrity and opulence of this ancient city. These mineral waters rose to very high reputation in the time of Charlemagne, who made Aix his Imperial residence; and he appears to have much delighted in the use of its baths, which he rebuilt and improved.

The hot sulphureous water rises in great abundance from several copious springs in different parts of the town; and is more than amply sufficient to supply the numerous baths and reservoirs in which it is collected. The principal spring is inclosed in a square stone cistern, the upper part of which is vaulted and contracted in its dimensions; and over the top a large stone is fitted in, and closely cemented, to prevent the escape of the sulphureous vapours, on which depends so much of the efficacy of the water. A remarkable circumstance takes place in this cistern, which is, the actual sublimation of a quantity of pure sulphur, which is carried up from the water along with the sulphureous gas, and is deposited beneath the upper stone, to which it adheres in the form of a fine powder. This is taken out from time to time, and sold under the name of Aix sulphur.

The baths of this city are numerous, and very commodious for the purpose of warm and vapour bathing. The natural heat of the water is sufficient for both these purposes; and for the latter, openings are made in the brick channels that convey the water to the baths, through which the vapour ascends. These vapour baths are so constructed that the whole, or any part of the body may be exposed to its action; and likewise many of the baths are furnished with pumps, from which the hot water may be diffused on any part of the patient. This operation is known by the technical name of the douche.

Aken water possesses very striking salubrious properties, particularly to the feeling and the smell. The water rises with great rapidity through the springs; and at the same time lends forth very copious air-bubbles, which break on the surface with a slight explosion. It is at first perfectly clear and colourless, and emits a large volume of steam, mixed with sulphurated hydrogen gas of great volatility and pungency. The odour of this vapour, which resembles that of Harrowgate water, is so powerful as to be perceived by strangers at a considerable distance from the spring head. The inhabitants, from long custom, scarcely regard it.

The temperature of Aix water is various, according to the distance from the spring at which the observation is made. The highest is about 143° of Fahrenheit; and at the pump, where it is drawn for drinking, it is about 112. The heat is therefore so great, that the water requires to stand for 15 or 18 hours before it can be used as a bath. This water, though perfectly clear when first drawn from the spring, becomes turbid and somewhat milky as it cools, and deposits a calcareous sediment, at the same time it loses its sulphureous smell. To the touch, the water is soft and somewhat saporous, owing doubtless to the small quantity of soda which it contains. It will even, in some degree, lather by agitation; and is used for fuling and cleansing wool and linen, to which also, the heat much contributes.

The chemical analysis of this water is curious and interesting. The most striking feature is its gaseous contents, which are a small quantity of carbonic acid, but especially much sulphurated hydrogen gas; not merely in the fumes in which it is found, in the cold sulphureous waters of Great Britain, but highly supersaturated with sulphur, which is sublimed in a solid form, as we have just mentioned. The whole of the sulphur contained in the water is volatilized by evaporation, for no traces of this inflammable substance are to be detected in the residuum of any quantity of the water boiled down to dryness.

The solid contents of this water are few. The most important of these is a quantity of uncombined soda, sufficient to give the water the properties of a very dilute alkaline solution; and which probably afflicts in the union of so large a portion of sulphurated hydrogen, and causes it to adhere to the water with somewhat more force than it would do if no alkali were present. Hence it is, that even after the water has stood for many hours in the baths to cool, it still retains enough of the sulphureous vapour to give it all the requisite medical virtues. The other solid contents are, a small quantity of common salt and carbonated lime, which last is deposited as the water cools, and the carbonic acid escapes.
No trace of metal of any kind are discoverable in this water.

The solid contents of Aix water are variously estimated as to quantity. From Bergman's analysis, we may reckon the following to approximate pretty accurately to the truth. A wine pint (English weight and measure) contains Of carbonated lime, four grains and three quarters. Of common salt, five grains. Of carbonated soda, twelve grains.

The proportion of the gaseous contents has not been ascertained with accuracy. The above analysis will explain the appearances which take place with the common reagents. Solutions of lead and silver, added to the hot fresh water, produce a blackish precipitate, composed of the fulphurated metal, but mixed with the muriate; for, when the same solutions are added to the cold water, the precipitate is white.

A piece of polished lead, suspended in the vapour of the water, is soon blackened, and in a few days corroded throughout.

Syrop of violets changes to a green, even after the carbonate of lime has precipitated by cooling, indicating thereby the presence of an alkali in excess.

The effects of the water, as a medicine, are very striking and well established. Its immediate operation, when drunk in a moderate quantity, is to raise the spirits, and in some persons to produce a degree of vertigo. This is the greater, ceternis paribus, the hotter the water is. It afterwards proves diuretic, increases perpiration, and keeps the skin in a soft, moist state, highly favourable to the removal of many ulcers.

The waters are referred to for a great variety of complaints, particularly in the complicated disorders of the digestive and biliary organs, which follow a long habit of free living. They are also highly serviceable in debility of the kidneys and bladder.

Aken waters, like all the most celebrated thermal springs, were long in high repute as baths, before physicians ventured to prescribe them internally. The vast profusion of water which is thrown up, the high temperature which it possesles, its strong impregnation with sulphur in a very active form, and its alkaline ingredient, give it most valuable properties for external uses. It is employed to stimulate cold paralytic limbs; and to soften the rigidity of the joints and ligaments left by gout and rheumatism. It is also of great use in cutaneous complaints, to the cure of which, the sulphur and the alkali probably highly contribute. A long continued course of this (as of every other) sulphaceous water, causes the whole body to acquire a tincture of sulphur, and tarnishes the silver kept in the pockets.

These waters have been imitated artificially by passing sulphurated hydrogen gas through a hot and very weak alkaline water, but the imitation is attended with much difficulty.

AIXO, or Alxos, flats or shallows within the second fort, at the entrance into Carthagena harbour, on the Spanish main, South America, which stretches nearly south-south-east, towards the main land within the islands that lie before the harbour.

AIHENAY, a town of France, in the department of Vendee, in the district of La Roche fur Yonnc; ten leagues south of Nantes.

AIZOON, An 7, Penn-cunctum, or ever living, in Botany, a genus of the Iousantra pentagonia clafs and order, of the natural order of Stuculata, and of the ficulet of Julieu. In Gmelin's Linnaeus, it is a genus of the polyandra pentagonia clafs and order. Its characters are, that the calcys is a one-leaved perianthium, divided into five lanceolate, permanent segments: no corolla: the floral have very many capillary filaments, inserted by bunches into the fissures of the calyx, the anthers simple: the pistillum has a germ five-cornered, superior, the style five and simple, the stigma simple: the pericarpium is a five-celled, five-valved, swelling and retuse capsule; the seeds are few, roundish or kidney-shapcd. There are ten species, viz. 1. A camarinense, purplish-leaved A, with leaves wedge-ovate, flowers silver; the ficted et Nifilium, and leaf of Plenck : a native of the Canary islands; annual; cultivated in 1751. 2. A. kaba, South A, with leaves lanceolate, flowers silver: the ficted A of Dillenius; an annual plant, growing naturally in Spain and Africa; a variety of this was brought from the Cape, and cultivated in 1725. 3. A. lanceolatum, panicked A, with leaves lanceolate, flowers silver; biennial: growing naturally at the Cape of Good Hope; cultivated in 1759. 4. A. formentajum, with leaves linear filiform, panicile dichotomous, flowers foliary, peduncled; brought from the Cape by Sparrman. 5. A. paniculatum, hairy A, leaves lanceolate, flowers silver, branches erect. 6. A. perfoliatum, downy, leaves ineradicable. conjugated, crystalline-dotted-flowers, peduncled. 7. A. ghiislerii, hairy A. flabby, herbaceous, procumbent, leaves ovate, flowers silver, distinct. 8. A. ficundum, branchy, herbaceous, procumbent, leaves ovate, flowers silver, inbrcate, one-ranked. 9. A. fruticosum, branchy A. flabby, erect, smooth, leaves lanceolate, flowers silver. 10. A. rigidum flib A. flabby, procumbent, downy, leaves ovate, flowers silver. The first six species were brought from the Cape by Thunberg. The three first species may be raised on moderate hot beds, in the spring; and the other species must be managed like other Cape plants.

AIZHON, See Sedum.

AIZU, in Geography, a town of Japan, and capital of a small country of the same name.

AKABA, a gulf or arm of the Red Sea, formed by a tongue of land, which is part of Arabia, that separates this gulf from that of Suez; about 30 leagues long and 3 wide.

AKABAR, or Calaat el Akaba, a town of Arabia, on the gulf to which it gives name; 57 leagues south of Jerusalem, and 53 leagues east of Suez.

AKACHAN, a river of Siberia, which joins the Udoma. N. lat. 63° 8'. E. long. 152° 27'.

AKALCALAI, a town of Georgia, in Asiatic Turkey, about 70 miles south-west of Tbilisi, and 88 miles north-west of Erivan.

AKALZIKA, or Acalzike, a town of Asiatic Turkey, in the province of Sabahago, a country of Georgia. See Acalzike.

AKAM, or Acam, a country of Africa, on the coast of Guinea, near the source of the Volta.

AKANIMIMA, a town or village of Africa, on the Ivory coast, near Cape Apollonia. It stands on rising ground, and commands an extensive sea and land prospect.

AKANNI. See Akem.

AKANS, a town of North America, in South Carolina, situate on the river Phillipin, near a river of the same name. N. lat. 35°. W. long. 89° 46'.

AKAOI, a town of Hindustan, in the district of Benal. N. lat. 21° 13'. E. long. 77° 58'.

AKARA, in Beary, a species of Calophyllum.

AKAS, in Geography, a small town of Transylvania, between the river Carina and a branch of that river, not far from Zutmar.

AKASAKI,
AKASAKI, a town of Japan, in the province of Mikawa.

AKASI, a town of Iran, in the province of Fars.

AKASEB-A-SELOM, a town of Egypt, marking the boundary of Africa and Asia.

AKAST, a town of Arabia, east of Jerusalem.

AKBAR, or ABER, SULTAN, in Biography and History, the sixth of the descendants of Timur Bek or Timur-lan, who reigned in Hindoostan under the appellation of Muzulis, was born in 1522, and succeeded his father Humayun in 1556. He was proclaimed emperor at Delhi, in the province of Lahore, and assumed the title of Salt D. in. 77. d. the grandeur of religion. Having overthrown the Pathans and taken possession of Delhi, he was inaugurated in this city, and assumed the government which had been at first administered by his tutor, Beyrana Khan. He then made himself master of the former fortresses of Chitor, after a severe engagement with a rebel chief, and quelled other insurrections; and having obtained an interval of tranquillity, he made a pilgrimage barefoot, to Amin, at the distance of 200 miles, for the purpose of visiting the tomb of Haji Mundi, and of obtaining children by the intercession of this saint. During his absence at Fettipur, on his return, he was informed of a rebellion at Guzerat, which hastened his march to this province; and having subdued the rebels, reduced the castle of Surat, and secured the province by fortifying Ahmedabad, he returned to Hindostan. In this year he finished the castle of Agra at an expense of two millions 500 thousand rupees, laid out 10 million on the walls and palace of Fettipur, and bade an end to the infamous sepulchres of his family at Schawler, five miles from Agra. At this time he directed his views to the conquest of Bengal, and having, after a long siege, taken possession of Patang, he became master of the whole country. His next acquisitions were Kabul, Kandahar, Khairun, and Sind. Having united these countries to his empire, he employed a powerful army in the invasion of Deccan, which, notwithstanding vigorous resistance on the part of the queen of this country, subdued several provinces and annexed them to the Mogul empire. While Akbar was engaged in the prosecution of the Deccan war, his prosperity was interrupted by a concurrence of domestic misfortunes. He was deprived of two of his sons, viz. Sultan Morad, in 1568, and Sultan Daulat, in 1605, by intemperance; and his son Selim took the advantage of his absence, for feizing his treasures and marching a numerous army towards Agra, in order to take possession of his father's throne. Akbar, as soon as he received intelligence of his son's rebellion, hastened back to Agra, and having made ineffectual overtures of accommodation, in enforcing which his Vizir Abul Fazl lost his life, he resolved to turn his arms against Selim. But as he had lost his other sons, he once more attempted to persuade his son into submission. With this view he employed the tutor of Selim to convey letters to him, in which he reproached him for his rebellion; but at the same time declared, that as he was his only son and heir, he was ready to receive him to favour. The father's letters and the tutor's arguments produced effect; Selim returned to Agra and submitted. Akbar at first treated him with austerity, but at length pardoned him, though he still retained full possession of his son's fideity. The emperor did not long survive this reconciliation. Being incensed against a Mirza, who governed one of his provinces, he resolved to remove him by poison; and for this purpose he ordered two pills of opium, in one of which there was poison. Having held these in his hand for some time, he gave one to the Mirza, and by mistake took the poisoned one himself. The consequence, notwithstanding the use of remedies as soon as the mistake was discovered, was fatal. When Selim paid his dying father a visit, he put his own turban on the prince's head, and gird him with his father Humayun's sword; but on the 14th day after he had taken the poison, Akbar died, A.D. 1605, at the age of 63 years, and was buried in the family sepulchre near Agra.

Akbar was distinguished by his conquests, and by his successes in reducing almost the whole of India to obedience. He was also one of the few sovereigns intitled to the appellation both of Great and Good, and the only one of the Mohammedan race, whose mind was so far dowered with the liberal prejudices of the fanatical religion in which he was educated, as to be capable of forming a plan worthy of a monarch who loved his people, and was solicitous to render them happy. Although he was not attached by prostration to any form of religion himself, he was not a persecutor of any. In 1582 he wrote a letter to the king of Portugal, prefaced by Fracis, and containing an avowal of sentiments, liberal and enlightened; in which he declares that a translation of the Christian scriptures into Arabic or Persian might be sent him, and at the same time a learned person to explain the Christian religion. One Germain Xavier was deputed, and with this view learned the Persian language; but the gospels, which were translated into this language, and presented to the Mogul in 1602, were so intermixed with popular legends, that they were not likely to be very intelligible or to produce any very good effect. As in every province of his extensive dominions, the Hindoos formed the great body of his subjects, Akbar endeavored to acquire a perfect knowledge of their religion, their sciences, their laws, and their institutions; in order that he might conduct every part of his government, particularly the administration of justice, in a manner as much accommodated as possible to their own ideas. In these generous views he was seconded by Abul Fazl, a minister whose understanding was not less enlightened than that of his master. By their affluous researches, and consultations of learned men, such information was obtained as enabled this Vizir to publish a brief compendium of Hindoo jurisprudence to the Ayyen Akbar, which may be considered as the first genuine communication of its principles to persons of a different religion. In what estimation the mild government of Akbar was held by the Hindoos, we may learn from a beautiful letter of Jiffwan Sing, Rajah of Jundpore, to Aurengzebe, his fanatical and persecuting successor. 'Your royal ancestor, Akbar, whole throne is now in heaven, conducted the affairs of this empire in equity and firm security for the space of 52 years, preserving every tribe of men in peace and happiness. Whether they were followers of Jesus, or of Mofes, of Davi, or of Mahomed; were they Brahminns, they of the sect of Dharians, which denies the eternity of matter, or of that which abridges the existence of the world to chance, they all equally enjoyed his countenance and favor; notmuch that his people, in gratitude for the indefatigable protection which he afforded them, distinguished him by the appellation of Juggs Grow, guardian of mankind. - If your Majesty places any faith in those books, by distinction called divine, you will there be instructed, that God is the God of all mankind, not the God of Mahomedans alone. The Pagan and the Mussulman are equally in his presence. Distinctions of colours are of his ordination. It is He who gives existence. In your temples, to his name the voice is raised in prayer; in a house of images, where the bell is shaken, it is He the object of adoration. To viliify the religion and customs of other men, is to set at nought the pleasure of the Almighty. When we deface a picture, we naturally incur the resentment of the painter; and justly has the poet said,
AKBEIK-BABA, in Geography, a town of Natolia, in Ahatic Turkey, 12 leagues north of Kutuaja.

AKDASCH, a large and flourishing market town of Scharwah, in the territory of the Chan of Schekhi; situate to the south of Nuchi, on the bank of the Kur, and containing of about 300 houses. To this town all the neighbouring nations resort for trade and the barter of their commodities.

AKEARADI, a country of Africa on the Gold Coast.

AKFORD BAY, lies on the north side of the island Holmfly, to the west of the North Cape. N. lat. 71° 10'. E. long. 24° 30'.

AKEN, JOHN VAN, in Biography, an engraver, who, from the style of his etchings, is supposed to have lived in the 16th century. He is a different person from Achan the painter.

AKENSIDE, MARK, M. D., more known as a poet than as a physician, was born at Newcastle-upon-Tyne, in 1721, and intended by his parents for a minister among the Protestant Dissenters; and with this view he was sent to Edinburgh, in 1739, at the age of 18. Having here acquired a stronger propensity to the study of physic than to that of divinity, he removed to Leyden in 1742, and took his degree of doctor in that faculty in 1744. In that year, besides his thesis, "De ortu et incremento fetus humani," delivered on the occasion of his degree, he published his celebrated poem on "The Pleasures of the Imagination," which was received with great applause, and advanced the author to poetical fame. It is said, that when Pope was shown the poem in manuscript by Dodley, to whom it had been offered for a larger sum than he was inclined to give, he advised the bookseller not to make a negligently offer, for the author of it was no every day writer. It has been also affirmed, that this poem and some others were written before he went to Edinburgh. The poem, on its publication, was severely attacked by Mr. (afterwards bishop) Warburton, not on account of its poetry, but for some remarks which the author had introduced on the nature and objects of ridicule; and vindicated by an anonymous friend; since known to be Mr. Jeremiah Dyson. The next publication was an Epistle to Curio, which contained a warm invective against Pelotius, earl of Bath, on account of his political conduct. In 1745, our author published ten odes on different subjects, and in different styles and manners. In his subsequent publications he was more flow. His ode to the Earl of Huntington appeared in 1748; and in 1758, he attempted to rout the national spirit by an ode to the country gentlemen of England. Most of his remaining poetical effusions appeared in Dodley's collection: and of these the most considerable is a Hymn to the Naiads. His poems were collected and published in a quarto volume, in 1772, by Mr. Dyson.

On his return from Leyden, he settled as a physician at Northampton; from thence he removed to Hampstead, where he continued about two years and a half; and finally settled in London, where his friend, Mr. Dyson, allowed him 300l. a year, in order to enable him to maintain his rank as a physician. His medical reputation and practice gradually increased, and he was chosen a fellow of the Royal Society, appointed physician to St. Thomas's hospital, admitted by mandamess, to the degree of doctor in physic, to the university of Cambridge, elected a fellow of the Royal College of Physicins in London; and, upon the establishment of the queen's household, advanced to the rank of one of her majesty's physicians. Notwithstanding his acknowledged abilities, and the singular patronage by which he was distinguished, he never arrived at any very considerable eminence in his profession. It has been said, that he had a kind of haphazard and ostentation in his manners, which were not calculated to ingratiate him with his brethren of the faculty, or to render him generally acceptable.

He died of a putrid fever in June 1779, in the 49th year of his age, and was buried in the parish-church of St. James's, Westminster. His books and prints, of which he was a curious collector, came, after his death, into the possession of Mr. Dyson.

His medical writings were his "Dissertatio de Dyfentaria," written in Latin, and much admired for the elegance of the language, published in 1764, and twice translated into English; "Observations on the origin and use of the Lymphatic vesels in animals," printed in the Phil. Trans. for 1757; and vindicated against the remarks of Dr. Alex. Monro, in a small pamphlet, published in 1758; "An account of a Blow on the Heart and its effects," published in the Phil. Trans. for 1753; "Oratio Anniaria, ex inftitu Harveyi, &c." read in 1759, and published in 1760; "Observations on Cancer;" "Of the use of Ipecacuanha in Aëmas;" "A method of treating White Swellings of the Joints," all published in the first volume of the Medical Transactions.

In Dr. Akenside's poems, and the notes annexed to them, we may discover his extensive acquaintance with ancient literature, and his ardent attachment to the cause of civil and religious liberty. His politics were thought to incline to republicanism, but no evidence to this purpose is deducible from his poems; and his theology is sufficient to have verged towards deism; and yet, in his ode to Houdly, and to the author of the Memoirs of the Houfe of Brandenburgh, he has testified his regard for pure Christianity, and his dislike of attempts for setting men free from the restraints of religion. Our readers may be gratified with the following extract from the first of these odes.

"To him the teacher blest is,
Who sent religion from the palmye field
By Jordan, like the morn to cheer—the weft,
And lift up the veil which heav'n from eart conceale'd,
To Houdly thus his mandate he addrest:
Go, then, and rescue my divin'd law
From hands rapacious, and from tongues impure;
Let not my peaceful name be made a lure,
Fell perfection's mortal inues to aid:
Let not my words be impious chains, to draw,
The free-born foul in more than brutal awe;
To faith without affent, allegiance unpaied."

Dr. Akenside's rank among the English poets is assigned to him in conformance of his "Pleasures of the Imagination," founded on Addison's well known papers on the same subject, in the Spectator:—"the most beautiful didactic poem," says Mr. Cooper, in his letters concerning tality, "that ever adorned the English language;" and though abstractive in its nature, so popular, than when it first appeared, it passed through several editions, and "is still read," says an excellent judge (Dr. Aiken), "with enthusiasm by those who have acquired a relish for the lofty conceptions of pure poetry, and the fluenis of numerous blank verse." The merit of this poem, and of the writer,
is so justly appreciated by Mrs. Barbould in an Essay prefixed to an ornamented edition of this poem, published in 1795, that we shall gratefully join our readers by subjoining a part of the summary with which it concludes. "If the genius of Akhenfide is to be estimated from this poem, it will be found to be lofty, and elegant, chaste, correct, and classical; not marked with strong traits of originality, not ardent or exuberant. His enthusiasm was rather of that kind which is kindled by reading and inhaling the spirit of authors, than by contemplating at first hand the works of nature. As a verifier, Akhenfide is allowed to stand amongst those who have given the most finished models of blank verse. His periods are long but harmonious; the cadences fall with grace, and the measure falls with uniform dignity. His muse polishes the vein erect, and high commanding gait. We shall scarcely find a low or trivial expression introduced; a careless and unfinished line permitted to stand. His rhymes, however, is somewhat allied to flinted. His verse is sometimes feeble through too rich a redundancy of ornament, and sometimes laboured into a degree of obscurity from too anxious a defire of avoiding natural and simple expressions." Biog. Brit. Gen. Biog.

AKERKUF, in Geography, a mountain of Asiatic Turkey, east of the Euphrates, in the government of Bagdad. Tavernier placed it between the Euphrates and the Tigris, supposing that the ruins found here are those of the tower of Babel.

AKERMAN, or BIELGORD, in Geography, a town of Bessarabia, on the coast of the Black Sea, at the mouth of the Dnieltor. 22 miles south-east of Bender. E. long. 31° 14'. N. lat. 46° 54'.

AKERSLOOT, William, in Biography, a painter and engraver, who lived at Haerlem, and flourished in 1624.

AKERSUND, in Geography, a bay on the coast of Norway, ten leagues west, north-west of Frederikshald.

AKHISAR, q. d. "white-calf," a name given by the Turks to the ancient Thyatira, on account of the white marble that abounds there. It is a town of Notia, in Asiatic Turkey, 13 leagues east-south-east of Pergamo; not distant in a fertile plain on the river Hermus, abounding with grain and cotton, and carrying on a commerce of opium and Turkey carpets. N. lat. 35° 50'. E. long. 25° 0'.

AKI, a province of Japan, in the western part of the island of Nippon, with a town of the same name.

AKIBA, in Biography, a famous Jewish Rabbi, lived in the first century of the Christian era, soon after the destruction of Jerufalum, and devoted himself to the study of the Cabalistic philosophy. In the earlier period of his life, and till he was 40 years of age, he was a shepherd in the service of a rich citizen of Jerufalum; but his master's daughter having promised to marry him, if he became a learned man, he studiously applied to study. So successful was his application, that he became one of the most famous teachers in the schools of Jewish learning, first at Lydda, and afterwards at Jaffa; and if the Jewish accounts may be credited, he had 24,000 disciples. The Jews of Palatine esteemed him so highly, that they erupped not to fry, that God revealed to him what he had concealed from Moses. The book intitled Jetzarim, which has been ascribed to Abraham, is said to have been written by him, and though it abounds with trites and absurdities, it was quoted by the Jews at this period, as of divine authority. Towards the close of his life, Akiba joined the standard of the Emperor Barchochbas, who appeared under the character of the Messiah, to deliver his countrymen from the power of the emperor Adrian. When this impostor was taken prisoner, and his followers put to the sword, Akiba and his son Papus were flayed alive. This happened, according to the Jewish chronologists, in the year 120; but, according to Bishaghe (lib. viii. c. 13.), in 138. Akiba was honoured by the Jews, after his death, as an eminent doctor of their law; and his tomb, covered to be at Tiberias, was visited with great solemnity. He is said to have altered the Hebrew text of the Bible, with respect to the age of the patriarchs, when they began to have children, which is greater according to the Septuagint than in the Hebrew text; and he did this, it is said, to put off the period of the Mefhah's advent, which, according to the tradition of the Jews, was not to take place till the completion of 6000 years. It has been argued, that the translation of Aquila, which was published in the 11th year of Adria, agrees with the Hebrew text of this time, and that this Aquila having gone over from the profession of Christianity to that of the Jewish religion, and enrolled among the disciples of Akiba, persuaded his master to make this alteration. Pezron Antiq. c. 16. This charge, however, is feebly supported, and the difference between the two texts a difficulty that remains still to be factually resolved. Gen. Dict. Brucker's Philos. By Erford, vol. ii. p. 202.

AKIM, in Geography, a town of Africa, on the Gold Coast.

AKURFECK, a town of Asiatic Turkey, in Notia, eight leagues east-south-east of Kailamond.

AKKER, a city of Syria, situate upon mount Barylus, about nine leagues to the south-east of Tiberias; also a river that runs by it. This, says Dr. Shaw, (Trav. p. 262.) must have been formerly as noted for its strength, extent, and beauty, as it is now for the goodness of its apricots, peaches, nectarines, and other fruit, which it produces; and he observes that it is the Kir, i.e. the city, mentioned in Scripture. Amos. ix. 7.

AKKIA, an island near the west coast of East Greenwich. N. lat. 60° 38'. W. long. 46°.

AKKIAH, a town of Romania, in European Turkey, eight miles east of Burgas.

AKOND, an officer of justice in Persia, who takes cognizance of the causes of orphans and widows; of contracts, and other civil concerns. He is the head of the school of law, and gives lectures to all the纠纷 officers; he has his deputies in all the courts of the kingdom, who, with the following officers, make all contracts.

AKOUSCHY, in Zénobie, the Cavia Acufhy, the olive-easy of Pannon, has short tail, with the upper parts of the body of an olive colour, and the under part white. Some have reckoned this animal a variety of the Agouti; but it differs from it in having a tail, which the other wants, or rather a longer tail than that of the other; in being smaller; and in having its hair of an olive, and not a red, colour; which are differences, says Buffon, sufficient to constitute two distinct species. It is about the size of a half-grown rabbit, is easily tam'd, is hunted with dogs, and reckoned the finest game in South America. Its flesh is white and delicate, and much esteemed by the inhabitants of Guiana, Cayenne, and Brazil, where this animal is found. It inhabits the woods, and lives on fruits; has such a dread of water, that it will submit to be seized by the dogs rather than go into it; and it will sometimes, though rarely, cry like the red-flies easy. Buffon by Smellie, vol. v. p. 61., vol. viii. p. 270.

AKQUEDAN, in Geography, a town of Africa, with a Dutch factory, on the Gold Coast.

AKRIDA, a town of Macedonia, in European Turkey, situate on the Drino, 124 leagues west of Constaninople, and 48 leagues south-east of Ragusa. N. lat. 42° 29'. E. long. 20° 50'.

AKSA,
ALA

AKSA, a river of Georgia in Asia, that runs into the Cofalan Sea, near Zatrich or Terick.

AKSCHINSKA, a town and fortress of Ruffia, 16 leagues south of Dornemile.

AKSERAI, a town of Natolia, in Asiatic Turkey, 20 leagues east-north-east of Konich, or Cogni. N. lat. 58° 26'. E. long. 34° 14'.

AKSHEBESHR, a town of Natolia, nine leagues south-west of Eregri.

AKSEHR, a town of Natolia, 33 leagues west of Konich. N. lat. 38° 26'. E. long. 31° 50'.

AKSU, a province of Little Batouria, to the north of Kafigar, and west of the province of Turfan, about 330 miles long, and 70 in breadth. Its chief town, of the same name, lies on the north side of a small river, which runs south-east, and lies itself in the lands. N. lat. 42° 30'. E. long. 83° 26'.

AKULA, an ancient city of Asia, situated on the easterm bank of the Tigris.

AKUN, AKENT, and AKUTAN. See Fox Islands.

AKURA, a town of Asiatic Turkey, in the government of Tarabuc, or Tripoli of Syria; seven or eight leagues from Mount Libanus. It has a Maronite bishop.

AL, an Arabic particle, prefixed to words, to express, or give them a more emphatical signification. — As, in Alkoran, Algebra, &c.

AL, or A L, in our Ancient Writings, signifies as much as old, ancient. — This being prefixed to the names of places, expresses their antiquity; as Althorham, Aldegate, &c.

ALA, a Latin term, literally signifying wings, used, in Anatomical, for several parts of the body, which bear some resemblance to the figure of a wing.

Thus, the lobes of the liver are sometimes called ala. The soft spongy bodies in the pelvis mullucule, usually called the pylectas, are denominated alae.

The two cartilages of the nose, which form the nostrils, are called alae.

And the same denomination is given to the tip of the auricle; and to the whole cartilaginous part of the ear, by way of distinction, from the tip and pendant part below, called the lobe. It is also applied to the process of the os sphenoidei.

The term ala is sometimes applied to the arm-pits, otherwise called axilla. These parts abound with glands, and are great receptacles of humours; whence a rank small sometimes exhales, called febua alaram.

ALA, in Botany, a name given by the Latin writers of Medicine, in the later ages, to the Pellicum, or Elecampane.

ALA is also used in Botany, for the angles which the leaves, or the stalks, or petals of the leaves, form with the stem, or branches of the plant from which they arise.

This angle is usually acute, and always is directed upwards.

Ala is sometimes ala apin, to the angle formed by the branches themselves, with the stem, which is also obviated to be very regular and uniform.

ALA has several other different significations. It most frequently is used to express the hollow of the flank of a plant, which either the leaf, or the pedicle of the leaf, makes with it; or in that hollow turning, or four, placed between the leaf, or branch of a plant, and its leaf, from whence a new sprigging is wont to put forth. Sometimes it is taken also for a little branch, as when we say, a break, or leaf of a plant, is armed with many ala, because their small branches stand out from it, in form of four wings.

ALA is also used to signify the leaves, or leaves of the papillomaceous flowers, placed between the others which are called the vexillum and the carina, which make the top and bottom of the flower. Indiges of flowers of this nature are seen in the flowers of peas and beans, in which the top leaf or petal is the vexillum, the bottom the carina, and the fide one, the ala.

AL is also used for those extremely slender and membranous parts of some fishes, which appear as wings placed on them, as in the pteropters, the trunk of the trumpet-flower, the foot of the nymph, and the like, which are called by botanists plat. serva.

AL is finally used for those membranous expansions, which run all the way along the stems of some plants, and are therefore called alae.

A L, in the Military Art, the two wings or extremes of an army ranged in form of battle.

An ala of bow, amongst the Romans, consisted of 300 horsemen, and was divided into turmae and decuriae; each turma consisting of 30 men, and each decuriae of ten; so that there were in every ala ten turmae, and in every turma three decuriae.

ALA, in Geography, a town of Japan, in the province of Sakurazuka.

ALAL, or A LAL, a town of Arabia Felix, 21 leagues E.N.E. of Hagiou.

ALABAMA, in Ancient Geography, an episcopal city of Africa, in the Mauritanians Censorinus.

ALABAN, a town of Panorma, according to Antoine.

ALABANA, in Geography, a small district or province of Spain, extending along the river Ebro, from the mountains of Biscay, to the frontiers of Navarre, and comprehending about seven or eight leagues in length, and six or seven leagues in breadth. The soil is fruitful in rye, bulley, vines, and several sorts of fruits; and the iron mines of the country furnish materials for the manufacture of arms and other utensils, which furnish articles of commerce. The chief town is Tiburio.

ALABA, a large kingdom of Africa, forming a part of Monemugi, is situated to the east of Cambel, and extends to the coast of Zanguebar. It is inhabited by a cruel people, called Gallas.

ALABAGUUM, in Ancient Geography, a promontory of Asia, in Carmania, upon the borders of the Ichthypoghyus, according to Ptolemy.

ALABAH, in Geography, a considerable river of America, in East Florida. — Allo, a river of Georgia, which pursues a southerly course to the gulf of Mexico, 100 miles W. of the head of St. Mary's river. The country on the west of this river, though miry and barren, is preferable to that on the east.

ALABAMA, an Indian village, delightfully situate on the banks of the Misisippey. The inhabitants are the remains of the ancient Abama nation, which inhabited the east arm of the great Mobile river, that still bears their name, now possessed by the Creeks, or Micuncoulgees, by whom they were conquered.

ALABAMA is also the name of a river in America, which is formed by the junction of the Cootche or High-town river, and Tallapoofee river, at little Tallatee, and runs in a north-west direction, until it meets Poumbiguee river from the north-west at the great island which it there forms, 90 miles from the mouth of Mobile bay, in the gulf of Mexico. This beautiful river has a great current, pure waters, and excellent wide; and its banks abound with valuable productions in the vegetable and mineral kingdoms. Travellers have felled down this river in boats, in the month of May, in nine days from Little Tallatee to Mobile bay, a distance of about 30: niles.

ALALANA, a town of Arabia Felix, placed by Ptolemy in long. 74° 30', and lat. 20° 15'.

ALABANDA,
ALABANDA, a town of Caria, in Alfa Minor, south of the river Alexander. It was founded by Alabandus, who on this account was worshipped by its inhabitants, called Alabandi, Alabandii, and Alabandenses. In the time of Pliny it was a free city, whence it was proverbially denominated the most fortunate city of the Carians. Strabo (vol. xii. p. 976.) represents the Alabandenses as luxurious and gluttonous, and devoted to pleasure. Some writers have given the name Alabanda to Antiochia.

ALABARCHA, in Antiquity, a kind of magistrate among the Jews of Alexandria, whom the emperors allowed them to elect, to have the superintendency of their policy, and to decide differences and disputes which arose among them.

ALABARDA, the name of a spear anciently used by the Helvetians and Germans.

ALABASTER. William, in Biography, an English divine, was born at Hadleigh, in Suffolk, in the 16th century, educated in Trinity college, Cambridge; and accompanied the earl of Essex, as his chaplain, in his expedition to Cadiz, in the reign of queen Elizabeth. Fickle in his temper, unitary in his principles, and dissatisfied with his situation, and at the same time seduced by the pomp of the Romish worship and the respect paid to his priests, he became a convert to the church of Rome. But in his new connection he was disapponted; and upon his return to England, he refused the Protestant profession, and obtained preferments in the English church; being appointed to a living in Hertfordshire, and a prebend of St. Paul's. He was well acquainted with the Hebrew language; but so much attached to the unintelligible mysteries of the Jewish cabal, that his knowledge of the original language of the Old Testament was of little service to him in the interpretation of Scripture. Of his talents as a Biblical commentator, we may form some judgment by the sermon which he preached on taking his degree of doctor in divinity at Cambridge. His text was 1 Chron. i. 1. Adam, Seth, Enos; and having just touched upon the literal sense, he enlarged on its mythical meaning; explaining Adam by misfortune and misery, and fo of the rest. He wrote a Lexicon Pentaglotton, which was printed in folio, in 1637; and other works of a mythical kind, viz. "Apparatus in Revelationem Jefu Christi," printed at Antwerp, in 1607; "Spiraculum Tubarum feu fons Spiritualem expositionem ex equivoce Pentateuchii significationibus," and "Eccle Sponius venit, feu Tuba pulchrotrudinitis, hoc eft, demonstratio quod non fit illicitem, nec impossibile, computare durationem Mundi et tempus fecundi adventus Christi," all printed in London. He was also the author of a Latin tragedy, intitled Roxana, which, at its exhibition in a college at Cambridge, produced a singular accident. When the last words, sequar, sequar, were pronounced, the voice and manner of the actor so terrified a lady who was present, that the irrecoverably lost her senses. Alabaster died in the year 1640.

Gen. Dict.

ALABASTER, albaire, Fr. albâbrites of Pliny, in Mineralogy. Some derive the word from albus, because of the whiteness of this stone. Others from αλς ἄνθρος, which they form from the priv. α and ἄνθρος, capite, to take; this stone being too smooth and slippery for the hand to falien hold of it. Under this name are confounded two minerals, wholly distinct from each other when pure, but which, in some of the varieties, are occasionally mixed together.

The compact gypsum of Kirwan (Alababrite, La Meth. albâtre gypfix de Lieb, Dichter Gypfirein, Werner) when of white or yellowish, or greenish colour, semitransparent, and capable of receiving a polishing, is known among flintaries by the name of alabaster, which term is also retained as a secondary appellation in most books of mineralogy; and is certainly the alababrites of Pliny, which is characterized by that author as a stone resembling gypsum.

When its colours are disposed in bands or clouds, it is called, in the first case, onyx alabaster, and in the latter, agate alabaster. It not infrequently contains a sufficient portion of carbonated lime to produce a brisk effervescence with nitrous acid; and hence has originated the confusion of authors, who make the circumstance of effervescence an essential distinctive character between the gypsum and calcareous alabasters. Its specific gravity seldom exceeds 2.9. Its fracture is compact—fruity, sometimes verging on the fine-grained foliated. In transparency, it is considerably inferior to white wax, allowing light to pass readily through it, but not transmitting the forms of objects. By flight calcination it is converted into Paris plaster.

Gypseous alabaster is very easily worked, but is not susceptible of a polish equal to marble. It is made into vases, columns, tables, and other ornamental articles of furniture; thin slabs of it have even been used in one of the churches of Florence instead of window glases. Its brittleflens, however, and want of lustre, have caused it to be almost wholly superseded by more durable materials. Among the ancients, the most esteemed came from Carmania, Upper Egypt, and Syria: of the variety called onyx, the boxes for holding perfumes were mosti fabricated; thus, in Horace, we meet with "Nardi parvus onyx."

The calcareous alabaster, or linter (albitre calcinaire), is a stone of the same family as flalactite, consisting chiefly of carbonat of lime, and exhibiting a considerable variety of colours; such as pure white, yellowish, greenish, reddish, and bluish grey; its fracture is flattened or fibrous, the fibres sometimes parallel and sometimes divergent; its hardnes is somewhat inferior to that of marble, which nevertheless does not prevent it from receiving a good polish; its specific gravity from 2.4 to 2.8; its transparency is nearly equal to that of white wax; it effervesces with acids, and burns to lime. Two sorts of alabaster are distinguished by flintaries, the common and oriental; under the latter of these are ranked the hardest, the finest, and the best coloured pieces; a number of sub-varieties are also produced by the colours being in veins, or dendritic, or in concentric undulating zones. Italy and Spain yield the most beautiful specimens; the inferior kinds are found in Germany and France. It is manufactured, like the gypseous alabaster, into tables, vases, statues, chimney-pieces, &c.

Many of the hot sulphureous waters rise out of the ground of a turbid yellowish colour, on account of a large quantity of gypsum and chalk, which they hold suspended, and in a state of half solution; these grow cool, and lose their carbonic acid, the earthy particles are for the most part deposited, lining the bottom and sides of the channels in which they flow with a compact alabaster. Advantage has been occasionally taken of this circumstance to obtain very beautiful impressions of bas reliefs, by exposing the moulds to a current of such water, till they have become filled with the earthy deposit. The most remarkable of these springs in Europe, is that which supplies the baths of St. Philip at Tuscany: it is situated on a mountain near Radicofani, and forms the source of the little river Pola. The water as it issues forth is very hot, springs out with great impetuosity, has a strong sulphureous odour, and holds in solution a large quantity of calcareous matter. From its very source it flows in deep channels, covered with a thick crust of flalactite, of a dazzling white, especially when the sun shines upon it; and which is harder or softer...
in proportion to the rapidity of the stream, and the obliquity of its fall. This circumstance suggested to Dr. Vegni the idea of establishing, on this mountain, a manufacture of artificial alabaster. For this purpose, he first collected a number of plaster models, of the belt bas-reliefs, in Rome and other places of Italy. These models serve to form the hollow moulds, which are made of sulphur, according to the following process. The plaster model is rubbed over with boiled linseed oil, and surrounded with an edging of plaster, of the same height as the intended thickness of the subsequent bas-relief. Then sulphur, melted with just sufficient heat to make it flow, is poured on the plaster model, and fills it to the height of the edging. The sulphur mould thus made, is placed in a kind of wooden tub, roughly put together, open at top and bottom, and of less diameter below than above. This tub has on the inside a false bottom, made of slips of wood laid cross-wise, in order to detain, for a short time, the water which dasheth on them. Just above this, is a row of wooden pegs, fastened to the tub, around its whole inner circumference, on which the sulphur mould is let down, and thus supported. The whole is then placed under the boiling spring, and inclosed with walls, to prevent it from being displaced by the wind. The water, which thus dasheth on the moulds, deposits its earth both within and without them, giving the impression in bas-relief within, and depositing itself in an undulated surface on the outside. The hardness of the alabaster depends on the degree of obliquity at which the mould is placed, in order to receive the dash of the water. The more vertical its position, the harder is the alabaster. However, as the hardest models are not so white as the softer, the water is in some cafes caused to make a circuitous course, in order to deposit all its groser particles before it arrives at the mould. Even the softer ones, however, are as hard as Carrara marble, and surpass it in whiteness. The time required for these productions varies, according to the thickness, from one month to four. When the sulphur mould is sufficiently filled, and the ground of the model has acquired a thickness capable of supporting the figures, the whole is removed from the water: the wooden supports are broken by gentle strokes of the hammer, and the incrustation on the outside of the mould is chipped off by repeated strokes. Then the tub is struck with a smart blow of a hammer, which separates the model from the mould; generally, however, cracking the latter. The brilliancy of the models is completed by brushing them with a stiff hair-brush, and rubbing with the palm of the hand.

The composition of this alabaster is gypsum, mixed with a small proportion of carbonated lime. Dr. de Vegni has, after many attempts, succeeded in giving a fine black, or flesh colour to the figures thus formed, by putting a veiled half full of colouring matter into the water, before it arrives at the mould. The colouring may also be varied, by protecting particular parts of the mould, while the water continues charged with colouring matter. A spring of the same kind as that just described, and applied to similar purpuses, is that of Guancavelica in Peru. The water rises from the ground into a large baloon boiling hot, and of a muddy yellowish white colour. At a little distance from the baloon, the water becoming cool, deposits calcareous matter in rich salt abundance, as to fill large moulds with a compact stone, of which some of the houses of the town are constructed. The moulds of statuaries, in like manner, being exposed to the water, are filled with hard confudently crystallized alabaster, and the bas reliefs thus produced, by polishing, become femintraf-
name of a genus of fossils allied to the marbles, and defined to be bones composed of large separate concretions, of great brightnes, and an elegant, but shattery fracture, not very hard, not giving fire with steel, effervescing with and soluble in acids, and calcining in a flame fire. See ALABASTER.

ALABASTRITES is often used as synonymous with alabaster. But Anfellus Boehtus distinguishes between alabaster and alabastrites, in making the criterion of the former to be so soft, that it may be cut with a knife; and of the latter, that it is so hard that it cannot be cut.

Grew speaks of a sort of alabastrites representing the transverse section of the trunk of a tree. ALABASTRUM dendroides, a name given by authors to a species of alabaster, found in great abundance in the province of Hohenlohe, and famous for the elegant delineations of trees and other figures described in it. See ALABASTER.

ALABASTRUM, in Ancient Geography, a town of the Thebaid, in Egypt, where Pliny says topazes were found. ALABASTRUS, a river of Troas, which flowed from Mount Ida.

ALABATER, a promontory of Carmania.

ALABON, or ALABUS, now Corato, a river of Sicily between Myla and Megara, which Diodorus (lib. iv. c. 75. tom. i. p. 321.) represents as a large river, which discharged itself into the neighbouring sea. Stephanus Byz. (vol. i. p. 78.) mentions the city of this name.

ALABORG, a town of the ancient Rusulf, situate in the present government of Omanetz.

ALABUA, in Geography, a small town of Arabia Petraea, where it is said Abdalla, the father of Mahomet, died, and which is a station of the pilgrims that visit Mecca.

ALABURIAM, in Ancient Geography, a town of Syria, mentioned by Stephan. Byz.

ALACH, in Geography, a prefecture belonging to the territory of Erfurt, containing 13 parishes.

ALACHUAH SAVANNAH, a level green plain in the country of the Indians that name in East Florida, situate about 75 miles west from St. Augustine. It is about 15 miles wide and 50 miles in circumference, and encircled with high floping hills, covered with waving forest, and fragrant orange groves, which rise from a very fertile soil. The ancient Alachua town flood on the borders of this Savannah, but the Indians removed to Cucowilla, about two miles distant, on account of the insalubrity of the situation. The horned cattle and horfe bred in these meadows are large and fat, but they are subject to mortality diseases, such as the water rot or scald, occasioned by the warm waters of the Savannah.

ALACRANES, a range of rocks and shoals on the south side of the gulf of Mexico, situate over against the peninsula of Yucatan; call from Stonebank, and west from Cape St. Antonio, within the 23d degree of north latitude, and between 89° and 91° W. long. They are said to derive their name from the great number of scorpions that are found there.

ALADA, an illand in the Indian Ocean, near the coast of Siam. N. lat. 9° 27'. E. long. 97° 35'.

ALADAG, or AMADAG, the highest mountain of Natolia, in Asia, north of Angora, and not far from the Cape of Coromba. N. lat. 40° 10'. E. long. 51° 40'.

ALADINISTS, a sect among the Arabs, answering to free-thinkers among us.

The Aladinists multiplied greatly under the two learned kings Almanfor and Miramolinus.

ALADULIA, a considerable province of Turkey in Asia, between Amaia and the Mediterranean, towards Mount Taurus. Some have represented it as the third division of Asia Minor, and made it to comprehend Cappadocia and Leffer Armenia. It joyns on the south to Trebizond, and is called by the Turks the begischi of Marach, and sometimes Dologdor. The soil is unfit for tillage, but affords abundance of pasture, which breeds a great number of cattle, especially horses and camels, and large herds of sheep and goats. Cappadocia, besides its pasture grounds, produces wines and fruits in great plenty; and its mountains, particularly the chain called Antitaurus, have mines of silver, copper, iron, and alum. Marach and Cefarea are well built and populous cities. Armenia the leffer, so called by way of distinction from the greater Armenia, has this country which belongs to Persia on the east, Syria on the south, the Euxine on the west, and Cappadocia on the north. The people are addicted to war and plunder.

ALÆNUS, in Ancient Geography, a river of Britain, according to Ptolemy, supposed to be the river Ax, and its mouth Ax-mouth. It was so called perhaps from the British A laun is, the full river.

ALÆSA. See ALESA.

ALAFOENS, in Geography, a district of the province of Beira, in Portugal, containing 37 parishes, and erected into a duchy in 1718, by John V.

ALAGNON, a rapid river of France, in the late province of Auvergne, whose source is at Cantal, and which falls into the Alber.

ALAGOA, a town of Africa, in Upper Guinea, where the Portuguese have an establishment.

ALAGOA bay lies on the eastern coast of Africa, in the Indian Ocean. S. lat. 25° 30'. E. long. 33° 28'.

ALAGOA is also the name of a town of South America, in the country of Brasil, and government of Fernambuque.

ALAGON, a river of Spain, which rises in the mountain of Leon, and runs into the Tagus, a little above Alcantara. It is also the name of a small town of Aragon, standing on a peninsula formed by the rivers Ebro and Xaloc, about four leagues from Saragossa.

ALAGTAGA, in Zoology, the Tartarian name of the Siberian Jerboa, signifies an animal which cannot walk. Buffon (Nat. Hil. by Smelle, vol. vii. p. 202.) characterizes it as having legs like those of the Jerboa, but with five toes on the fore feet, and three on the hind, with a spurt, that may pass for a thumb or fourth toe, much fliorer than the others. ALAGNE, a town of France, in the department of the Aude, and district of Limoux, two leagues north-west of Limoux. The town contains 408, and the canton 7,682 inhabitants; the territory comprehends 190 kilometres and 27 communes.

ALAIN, CHARTIER, in Biography, secretary to Charles VII. king of France, was born in 1380. He was the author of several works in prose and verse; but his considerable work was the "Chronicle of king Charles VII." It is said that Margaret, daughter to the king of Scotland, and wife of the dauphin, finding him asleep faluted him before all who were present: and when they expressed their surprize to her confedence to a person who possessed so few charms, she replied, "I did not kifs the man, but the mouth, from which proceed so many excellent sayings, so many wise discourses, and so many elegant expressions." On this incident Fontenelle has founded one of his Dialogues of the dead. Paquier extols the character of Alain, and compares him to Seneca, on account of the infinite number of beautiful sentences, that are interpersed in his writings. Gen. Dict.

ALAIN, JOHN, a Danish writer, was born in 1563, and died in 1630. He published a treatise "On the Origin of the Cimbri, and their various Establishments;" another "On Logic, natural and artificial; and a third "On the pronunciation of the Greek Language, with an Apology for Saxo Grammaticus."
ALA

Alaun, De Lisle, a native of Lisle, in Flanders, flourished in the sixteenth century, with such reputation for his skill in theology, philosophy and poetry, that he was called the Universal Doctor. He died in 1524, and left behind him many pieces of prose and verse, which were collected into one volume for folio, at Antwerp, in 1593. His fame was so great, that it was thought a happiness to know him; and it was proverbially said, "Suffice it to have seen Alain." Dupin. Eccl. Hist. vol. v. p. 57. Cave. H. L. tom. ii. pp. 287.

Alaine, in Geography, a small river of France, in the department of Nievre.

Alajor, one of the four quarters into which the island of Minorca is divided, so called from a small place near it.

Alais, or Alais, a large and populous city of France, and principal place of the district, in the department of the Gard, situated on the river Gard, at the foot of the Cevennes. Julius Caesar in his commentaries calls it Alesia. A bishopric was founded in this place in 1601, with a view, as it is said, of converting the provincials, who were numerous; and a citadel had been built in 1689, in order to awe them. The diocese extends 80 parishes; the town contains 1,944, and the canton 1,287 inhabitants: the territory comprehends 142,000 square miles, and eight communes. The country about is well cultivated, and produces grain, olives and mulberries, but the principal wealth of the place has formerly arisen from its manufactures of serge and ratteners, and from its exportation of raw and wrought silk. It is distant 14 leagues north of Montpelier, and 140 south-east of Paris. N. lat. 44° 40'. E. long. 3° 46'.

Alaisee, in Heraldry, the fame with humetty, or racourcy.

Alaiskan Mountains, in Geography, a part of the Altay mountains in Russia, comprising that range which advances from the origin of the Aley to the two sides of this river, and between it and the Ouba and Ithi, and runs out into the great, Saline plain, which is skirted by the Aley, the Ithi, and the Obi. See Siblina.

Alalcomenia, in Ancient Geography, a town in the island of Ithaca, where, according to Phurarch, Ulysses was born.

Alalcomenium, or Alalcomine, a small town of Boeotia, south-east of Cherrones, near the lake Copias, founded according to Pausanias (in Boeotia, h. b. ix.) either by Alomicenius, foster-father of Minerva, or by Alalcomenia, one of the daughters of Oggyges, the nurse of Minerva, near which she had a temple, and a statue of ivory, which was removed by Sylla to Rome. Hence Homer deduces the epithet Alalcomeniana, ascribed to Minerva.

Alalcomenius, in Ancient Chronology, the Boeotian name for the Athenian month Mauacterion, which was the fourth of their year, and answered to the latter part of our September and beginning of October.

Alalia, or Alalis, in Ancient Geography, a town of Syria, placed by Ptolemy in the Palmyrene, near the Euphrates, and by M. d'Anville, north-west of Reifisa.

Alaloet, small islands in the Arabian gulf, where, according to the Periplus of Arrius, turtles were found; the fame with the Allouc of Phison.

Alama, a town of Afa, in Mecopotamia, situated on the river Bilicha, north-west of Nicopolis.

Alamagan, or the island of the Conception, in Geography, one of the Ladrone, or Marianas islands, about 10 miles from Guguan, and 18 miles in compass. There is a volcano on the north-west part of this island, which flanks close to the sea, forming a cone in height about 500 yards, with a base of about 400 yards; and the sides are marked by streams of black lava, which, passing through a rich vegetation of cocoa-nut trees, may be traced to the shore, where they have entered the sea. This cone is encompassed with cinders, which, at the distance of about a mile and a half, are covered with a black vegetable soil, which produces trees as large as any upon the island. At a nearer distance there is not for several acres the least sign of vegetation. In the year 1799, the volcano seemed to be preparing by its rumbling noise, and the smoke that issued from it, for a new eruption. The lower parts of the island are covered with trees of a thick foliage; some few open spots produce a thick and long grass; but the most plentiful productions of the island are the cocoa-nuts, which grow in clumps near the shores close down to the beaches, and which may be easily obtained in great abundance. Trees, resembling the pines of Port Jackson, bearing a small cone, and rising to the height of 30 or 40 feet, are very numerous. A supply of the fruit of the papuan tree may be gathered about the middle of August. No quadrupeds have been observed upon this island except green-tailed lizards; land crabs are numerous and large; partridges and quails, owls, thrushes, bullfinches and pigeons are found here. The island may be seen at the distance of 12 or 14 leagues. Its shores are rocky to windward, but in the bay to leeward there are two or three beaches. On the west or left side of the island is a channel leading into a kind of bay, where, as the trade wind in general blows friendly to the caftward, ships might ride securely as long as they had occasion to stay. N. lat. 18° 5'. E. long. 149° 47'.

The variation of the compass in 1799 was 41° 9'.

Alaman, a town of Switzerland, in the canton of Berne, three leagues north-east of Nion.

Alamandus, Lewis, Fr. Alaman, in Biography, archbishop of Arles and cardinal of St. Cecilia, was one of the greatest men in the 15th century. He presided in the council of Baüf, which deposed Eugenius IV. and elected the Antipope Felix V. Anesius Sylvius highly commends him, as a man admirably formed for prefiding in such assemblies, firm and vigorous, illustrious by his virtue, learned, and endowed with a memory, which enabled him to recapitulate every thing that had been said by the orators and disputants. Although he was deprived of his dignities by pope Eugenius, and very injuriously treated, he is said to have performed miracles at his death, and he was beatified by Clement VII. in the year 1527. He died at the age of 62 years, in 1450. Gen. Dict.

Alamanni, Luigi, or Lewis, was born at Florence, of a family of distinction, in 1495; and by his early progres in philolohy and Greek literature, acquired great reputation. He was at first attached to the Medici family, but having entered into a conspiracy against cardinal Julius de Medici, who became pope Clement VII, he was obliged to take refuge at Venice. He was afterwards imprisioned at Brescia, and upon his release he was under a necessity of abandoning his country, and of wandering, as an exile in France and in Genoa, till the year 1527, when he was recalled to Florence, on the expulsion of the Medici family. When the authority of that family was re-established in 1530, he was again disgraced, and retired to France, where he was chiefly occupied in poetical compositions. At length Francais I. called him to court, invested him with the order of St. Michael, appointed him to a considerable office in the household of Catharine de Medici, and employed him in various concerns at Rome and Naples. In 1544 he was sent on an embassy to the emperor Charles V.; and having been entrusted with different negociations by Henry II. he died at Amboise in 1556, and left two sons, one of whom was made bishop of Macon. The works of Alamanni consist of Italian poetry. The first publication of them at Lyons in 1532 and 1533, contained elegies, eclogues, lutes, sonnets, hymns, plaines, &c. and a translation of the Antigone de Sophocles, which
ALA

which are much eftéemed for their elegance. A didactic
poem on Agriculture, in blank verse, "Della Coltivazione,"
first printed at Paris in 1546, added to his reputation.
A piece of greater bulk, intitled, "Giron il Corteco," taken
from a French romance, "Giron the Courteous," was pub-
lished in 1548. His epic poem, called "La Pllarchide," on
the siege of Bourges, and his comedy "La Fiora," which
he left behind him, did not much succeed. But his Tufcan
epigrams, a species of writing, first attempted by himself,
were well received, and produced many imitators. Almani
is considered upon the whole, as a writer to whom Italian
poetry lies under particular obligations.

Antonio Almani, whose burlesque poems were printed
with those of Burchiello, is a relation of Luigi. Gen.
Dict.

ALAMANNICUM, in Antiquitk, a tribute imposed on
the people by the emperor Alexius Angelus, for raising the
sum of sixteen talents of gold, to be paid the Almanni,
ons the conditions of a peace stipulated with them.

The ecclesiastics themselves were not exempted from this
tax.

ALAMATOU, in Botany, the fruit of a tree that grows
in Madagascar, resembling in its taine the black plum, but
instead of the bone of the plumb, it has 10 or 12 flat kernels;
the leaf of the tree is like that of the plum-tree. There are
two sorts of this fruit, one like the plum and the other
like the fig, which is dangerous when taken to excess.

ALAMBAY, in Geography, one of the Sonda islands
in the Pacific Ocean, 30 leagues south of Borneo.

ALAMEH, a town of Atlantic Turkey, in Natolia, 53
leagues south of Kutaja. N. lat. 35° 37'. E. long. 31° 29'.

A-LA-MI-RE, in the Guidonian Scale of Music, or
Gammus, is the octave above A-re, or A in the first space in
the ba-c

As A is the note above G in every
part of an instrument, it is, of course, the third found be-
low each tenor clef; and is likewise the note that occupies
the second space, and the fifth line in the treble. The
letter A itself is an abbreviation of A-re and A-la-mi-re
in the scale of Guido; and is the found to which all in-
struments are tuned at an opera, concert, or other musical
performances. A in the Italian musical language, when it
precedes a syllable, has the power of; as A battuta, in
time, or measure, after recitative, or an ad libitum. A capella,
sacred music, compositions in the church style. See Gam-
mus and Guidonian Scale.

ALAMODALITY, alamodalis, is defined by a late
writer, a flabby or endeavour to accommodate a man's self
in point of behaviour, drees, conversation, and other actions
of life, to the reigning taste or cullum, from a motive of
complaisance, and to avoid the imputation of ill-breeding.

Alamodality of writing, alamodalis scribendi, is de-
ined by the same person, a particular fluildy or endeavour of
learned men to adapt the productions of their minds, both
as to the choice of subject and the manner of treating it,
to the genius or taste of the times, in order to render them
more acceptable to the readers.

A German writer, under the name of Gramoecus, has a
dissertation on Alamodality in writing.

ALAMODE, in Commerce, a thin, light glossy, black
silk, not quilled or crozed; chiefly used for women's hoods,
and men's mourning fences.

The name is French, though not given in that country to
this fabric, for which they have no other name than tafetel
noir luyf.

ALAMOS, Balthazar, in Biography, a Spanish
writer, was born at Medina del Campo, in Castile. He
studied the law at Salamanca, served in a subordinate office
under Philip III. was imprisoned upon the disgrace of his
patron, Anthony Perez, secretary of state to this prince,
and after a confinement of 11 years, released by Philip III.
By the duke of Olivarez, the favourite of Philip IV. he was
called to public employments. He was deemed a man of wit
and judgment. He died in the 88th year of his age; and his
Spanish translation of Tactius, with marginal aperitions,
was published at Madrid, in 1612, in Eng. Dict.

ALAMO, Alamay, or Lay, in Geography, a town
on the gold coast of Africa, east of Ningo, and four leagues
from the mountain Redondo, which presents itself in the
form of a sugar-loaf to the north-north-west. The town is
situated on the declivity of a mountain, which has a northern
aspect; and the adjacent coast is bounded by hills of consid-
erable height, that are covered with palm-trees. The in-
habits are gentle and timid; their principal commerce is
that of slaves. The anchorage of this port is very good.
N. lat. 5°, W. long. 3°.

ALAN, or Lynn, Alanus de Lyuna, in Biography, an
English divine of the 15th century, was born at Lynn, in
Norfolk, educated at Cambridge, and distinguished as a
student and a preacher. He was addicted to allegorical
interpretations of Scripture, and to the application of the his-
torical part of the Old Testament, to the concerns of reli-
gion and moral conduct, a practice blamed by Bale, but
commended by Pits. He wrote tracts on the interpretation
of Scripture, sermons, and expositions of Aristotle; and
he was famous for the pains which he took in making in-
excess to most of the books he read, of which Bale has
given a long list. He at length became a Carmelite in the
town of his nativity, and was buried in the convent of his
order.

Another person of this name was abbot of Tewksbury,
about the year 1177, and died in 1201. He wrote a book,

ALAN, Allen, or Allyn, William, a cardinal-
priest of the Roman church, was born at Rossal, in Lancas-
tire, in the year 1533; and entered, in 1547, at Oriel col-
lege, in the university of Oxford, where he made a con-
ferable proficiency, particularly in logic and philosophy,
and passed through several gradations of honours. In 1556
he became principal of St. Mary's Hall, and one of the profes-
sors of the university; and in 1558, he was made canon of
York.

But on the accession of Queen Elizabeth, as he was a zeal-
ous catholic, he lost all hopes of preference; and in 1560,
retired to Louvain in the Spanish Netherlands, where he
connected himself with the English college, and was much
esteemed on account of his learning and the urbanity of his
manners. In this situation he distinguished himself by
writing in favour of the catholic cause; and his first piece
was "A Defence of the Doctrine of Catholics, concerning
Purgatory and Prayers for the Dead," printed at Antwerp,
in 1565, which commenced a controversy of some con-
sequence. The state of his health, which had been injured
by his application to fluddy, rendered it advisable to return
to his native country, in 1567; but he soon became ob-
noxious by the zeal of his attachment to the principles and
prosecution of popery, and by his industry in making pro-
foles; and he was under a necessity of concealing himself
in the neighbourhood of Oxford. In this retreat he wrote an
apology for his party, entitled, "Brief Reasons concerning
the Catholic Faith; and he prosecuted his labours for re-
claiming apostles and encouraging the wavering, to such a
degree, as to make it necessary for him, notwithstanding the
8
patronage he enjoyed, to leave the country and to retire to Flanders, in 1568. Such was the reputation which he had gained by his learning and labours, that on his settlement at Mechlin he opened a divinity lecture, which was received with great applause; at Douay, he was honoured with the degree of doctor of divinity; and he was advanced to the distinguished preferment of canon of Cambrai, and afterwards to that of Rheims. Having established a seminary at Douay for the education of English scholars, he transferred it to Rheims; he procured others to be established for the same purpose at Rome and in Spain; and he persevered in writing a variety of tracts in defence of the doctrines and practices of the catholics, which were conveyed to England, and which were prohibited, by royal proclamation, to be fold or read. Dr. Allen was now considered as an avowed enemy, not only to the protestant religion but to the English government; correspondence with him was regarded as a treasomible offence; and Thomas Allard, a jesuit, was tried and executed in 1585, for bringing some of his traitorous books into his majesty's dominions. Amongst other exceptionable and offensive passages contained in his writings, and particularly in his "Defence of the Twelve Martyrs in one year," which tend to disprove all focal obligations, he expressly affirms, "that parents who become heretics, lose the superiority and dominion they have by the law of nature over their own children. Therefore, let no man marvel, that in case of heresy, the sovereign lotheth the superiority over his people and kingdom." But Allen was not satisfied with avowing his hostility to the religion and government of England by his writings, he proceeded, under the intimation and with the advice of his friend, Robert Parfons, the jesuit, to unite with some fugitive English noblemen, who resided in Flanders, in persuading Philip II. of Spain to invade England. At the same time he wrote a vindication of the base conduct of Sir William Stanley and the forces under his command, who garnished Daventer, in surrendring it to the Spaniards. In recompence of this treasomible practice, he was created cardinal in 1587, and appointed by the king of Spain, to an abbey of great value in the kingdom of Naples, with assurances of greater preferment, which were duly fulfilled. Thus encouraged, he was active in forwarding the designs of the Spanish armada, in 1588; and for this purpose he either himself wrote, or concurred with Parfons and other jesuits, in writing a book, of which many thousand copies were printed at Antwerp, and which were intended for disperion in England, upon the landing of the Spaniards. This book consisted of two parts; the first was intitled, "A declaration of the sentence of Sixtus V." in which it is maintained, that by virtue of the pope's bull, queen Elizabeth was accurved and deprived of her crown, which was transferred to the king of Spain; and the second part was "An admonition to the nobility and people of England," pronouncing Elizabeth a schismatic and heretic, a pretended queen, and usurper, who had committed actions which rendered her incapable of reigning, and even unworthy of life; and declaring all her subjects abdolved from their oath of fidelity. When the enterprise failed, most of those books were destroyed; but some of them were preferred, and their contents are said to have been universally disliked by all sober catholics as well as protestants. The carl of Arundel, who had been three years in prison under a charge of high treason, was tried and found guilty by his peers, and his chief crime was his correspondence with cardinal Allen. Allen, however, was promoted by the king of Spain to the archibispriph of Mechlin; but continued to reside at Rome, where he lived in great splendour, and employed his interest in serving his fugitive countrymen and the catholic faith. Towards the close of his life he is said to have repented of the meaures which he had been instrumental in promoting against his country, and to have disapproved of the disposition and conduct of the jesuits with whom he had acted. This change of sentiment is inferred from a letter, dated in 1593, and found among the papers of lord Burleigh, in which he professes affection to his native country, solicitude for its welfare, and a desire of effecting a reconciliation between the protestants and catholics. It is further alleged, that he wished on his death-bed to have an interview with the English students at Rome, but was prevailed upon by the attending jesuit. He died in 1594, not without suspicion of being poisoned by the jesuits, and was buried with great pomp, in the chapel of the English college at Rome, where a monument was erected to his memory, with a Latin inscription in the highest style of panegyric.

As a zealous catholic, Allen might unquestionably allledge the obligations devolved upon him by the conviction of his mind; but how far the plea of conscience will justify the avowal of sentiments, and the encouragement of practices, incompatible with the fundamental principles of personal and social virtue, we must leave for those who undertake the vindication of his character to determine. As an English subject, he was undoubtedly a traitor and rebel; and no caluitry can justify his attempts to overturn the government of a country, defeter by himself, but approved by a majority of its inhabitants. As a writer he may be justly considered as one of the adept advocates of the Romish church, at the period in which he lived. His works, besides those already mentioned, are, "A defence of the lawful power and authority of the priesthood to remit sins," to which are annexed two other tracts, viz. "The people's duty in confessing," and "An explanation of the doctrine of the Catholic church, with respect to indulgences;" printed at Louvain in 1567, 8vo; "of Sacraments in general, of the Eucharist, of the face of the mafs; three books, addressed to pope Gregory XIII." printed at Antwerp in 1576; "Of the worhip due to saints, and their relics;" "A true, sincere, and model defence of Christian Catholick, that suffered for their faith at home and abroad, &c." printed in 1583, which was an answer to a book written by lord Burleigh, and esteemed the best of the cardinal's writings; is that the learned Edmund Bolton says of it, "a princely, grave, and flourishing piece of natural and exquisite English is Cardinal Alan's Apology. Biog. Brit.

**ALA**

**ALAN, in Geography, a town and province of Turkeftan in Peria.**

**ALAN, or CAMEL, a river of England, rises north of Camdenford, and runs into the sea two miles below Padley, in Cornwall.**

**ALAN Bay, lies on the west side of Corsica, in the Mediterranean.**

**ALANA, in Ancient Geography, a town of Ethiopia in Egypt, according to Pline.**

**ALANCH, in Geography, a town of France, in the department of the Mouths of the Rhone, two leagues northeast of Marseilles, and four south of Aix.**

**ALAND, an island in the Baltic, at the entrance of the Gulf of Bothnia, situate between the province of Upland in Sweden and Finland, gives name to a cluster of islands, and is about 40 miles in length, and from 12 to 16 in breadth. It contains about 15 villages, and 9000 inhabitants, who speak the Swedish language; but are included under the government**
From the year 15th to 16th, and many of them remained in Spain, and the government of Flanders, which, as to a certain point, the things of the faith and the things of the government were not separated, the people of the countries were so far from being under the influence of the Church, that the inhabitants of Flanders, influenced by the example of the Church, went to the Church, not under the influence of the government, but to the Church, and the Church lived in the country, and the government lived in the Church.
and containing from one to three seeds. There is one species, viz., the A. pungens of Jussieu.

ALAPOLI, in Botany, the name of an East-Indian tree, a species of the bilimbi, which is used in medicine as a pargue and vomit, mixed with the seeds of mulhurd.

ALAPA, in Ancient Geography, a town of Macedonia, near Acanthus.

ALAGUECO, a medicinal root brought from the Indies, in small glossy fragments; much praised by some for its efficacy in hemorrhages, when applied externally.

ALAR, in Geography, a river of Perlia, which runs into the Cafburn.

AL-ARA!, formed from the Arabic verb arafr, to distinguish, in the Mahometan Theology, the partition wall that separates heaven from hell.

Alaraf gives the denomination to the seventh chapter of the Alcoran, wherein mention is made of this wall. Some take it for a fort of limbus for the patriarchs, prophets, &c., others place here such whole good and evil works to exactly balance each other, that they neither deserve reward nor punishment. Others again appropriate this intermediate space to those who go to war without the leave of their parents and die, and are excluded paradise for their disobedience, but escape hell as martyrs. Sale's Prel. Discourse to the Koran, p. 95.

ALARES, a name given to those Arabians who dwell in tents, and who are distinguished by their dres from others who live in towns.

ALARCON, in Geography, a town of Spain, in the western part of New Caftile, on the river Cumar. It was ruined in 1178, under the reign of the Moors, and re-established by Alphonfus IX. N. lat. 39° 40'. W. long. 3°.

ALARES, in Antiquity, are supposed by some authors to have been a kind of soldiery, or soldiery, among the Romans; so called from ala, a wing, because of their lightness and swiftness in the combat.

Others make them a people of Panonnia; but others, with more probability, take alares for an adjective, or epithet, and apply it to the Roman cavalry; because they were placed in the two wings, or alae, of the army; for which reason a body of horse was called ala.

An ala, or wing of auxiliary horse, consisted of 400, and there were two of these wings annexed to each legion; and, therefore, the whole number of cavalry belonging to a legion was 1200, of which 402 were Romans, and 800 auxiliaries.

ALARES insuffl, in Anatomy. See Pterygoideus.

ALARIC I., in Biography and History, king of the Visigoths, was descended from the noble race of the Bali, or bold, the most illustrious of the Gothic nation, next to that of the Amali. With his countrymen, who were expelled by the Huns, and whose number is said to have amounted to near a million of persons, of both sexes and of all ages, and of whom about 200,000 were Gothic warriors, Alaric passed the Danube, A.D. 416; and served with great reputation in the war between the Romans and the Goths, which lasted from that time to the year 382, when they all submitted to Theodosius, and were allowed to settle in Thrace, on condition of serving in the Roman armies. Accordingly, he attended Theodosius in his expedition against the usurper Eugenius, with a body of his countrymen under his command. But being refused that preference to which he aspired, he was disconsolate; and after the death of Theodosius, and, as it is said, at the instigation of his minister Rufinus, he assembled a numerous army, consisting chiefly of his countrymen, and having first ravaged Pannonia and Dacia, he proceeded in 396 to make an irruption into Greece. Having marched through Macedonia and Thessaly, he passed through the straits of Thermopylae without opposition on the part of the Aetolians, ceuxful of Achaia, or Corinth, who was appointed to guard them, and laid waste the fairest realms of ancient Greece. The Athenians preferred their city by delivering to the emperor the greatest part of their wealth; but the whole territory of Attica, from the promontory of Surnium to the town of Megara, was deputed by the march of his army; so that Athens itself, according to the allusive language of a contemporary historian, resembled the bleeding and empty drain of a slaughtered victim. The Gothic prince, having been liberally and splendidly entertained at Athens, penetrated without delay into Peloponnesus, and wherever he came desolation and distress marked his footsteps. Though only could he be deemed happy, whose premature death prevented their witnessing the dishonour of their females, the slavery of their families, the consignment of their cities, and the destruction of every thing valuable and curious which they possessed. In this peninsula, the famous general Stilicho, with his fleet and army, came up with Alaric, and obliged him to retreat to the mountain of Phocoe in Arcadia, and there invested his camp; but either by negligence or confidence permitted him to escape across the gulf of Corinth, to Ephesus. Being in full possession of this important province, Alaric had sufficient time to conclude the treaty, which he secretly negotiated with the ministers of Conftantinople. In conseqnence of this treaty, he was declared master-general of the eastern Illyricum, which comprehended the cities and provinces he had lately laid waste; and the army of Rome became the ally and servant of the emperors of the east. While the Gothic prince was thus preferred by Arcadius, Stilicho was declared a public enemy, and his eastern possessions seized and confiscated. At the same period, A.D. 398, Alaric, with the unanimous consent of the barbarian chieftains, was elevated, according to ancient custom, on a shield, and solemnly proclaimed king of the Visigoths. In the plentitude of power which he had thus acquired, by the grant of Arcadius, and the suffrage of his own nation, he avowed his resolution of invading the dominions of the west; and having annulled both Arcadius the emperor of the east, and Honorius the Roman emperor, by deceitful promises, till he was prepared for the execution of his purposes, entered Italy in the year 410, overran the country, and carried off a great quantity of spoil, and an incredible number of captives. In 402 he ravaged the provinces of Venetia and Liguria: in 403, advanced towards Milan, whence Honorius hastily fled; and pursued the timid emperor to the fortress of Afa, a town of Liguria, on the banks of the Tanarius. In the mean while Stilicho, at the head of a choicer and intrepid vanguard, marched to the relief of the Imperial captive, and arrived soon enough to prevent the indignity of a surrender by capitulation which the barbarians had proposed. By a successful action, in which he forced his way through the Gothic camp to the walls of Afa, he revived the hopes, and vindicated the honour of Rome. On this occasion, a military council of the Gothic nation was assembled, in which Alaric displayed the spirit of the conqueror and concluded an animating speech, by the solemn and positive assurance, that he was resolved to find in Italy either a kingdom or a grave. Whilist the Christian Goths were devoutly employed in celebrating the festival of Easter, Stilicho determined to attack them. The camp of the Goths, which Alaric had pitched in the neighbourhood
neighbourhood of Pollentia, was thrown into confusion by the sudden and impetuous charge of the Imperial cavalry; the engagement which succeeded was long maintained with equal valour and success; but at the moment when the victory of Alaric was almost decided by the defeat of the cavalry, Stilicho led the Roman and Barbarian infantry to the attack, and determined the fate of the day. The Goths retreated from the field of battle; the intrenchments of their camp were forced; and the scene of rapine and slaughter made some atonement for the calamities which they had inflicted on the subjects of the empire. The magnificent spoils of Corinth and Argos enriched the veterans of the fleet; the captive wife of Alaric was reduced to the necessity of imploring the mercy of the inflicting foe; and many thousand prisoners, released from the Gothic chains, diffused through the provinces of Italy the praires of their heroic deliverer. Alaric still maintained that invincible spirit, which rose superior to every misfortune, and derives new resources from adversity; and he boldly resolved to break through the unguarded palis of the Apennine, to spread desolation over the fruitful face of Tuscany, and to conquer or die before the gates of Rome. But Stilicho faved the capital, entered into a negotiation with the enemy, and induced him to repass the Po, with the remains of the starving army which he had led into Italy. In his retreat, however, he took possession of Verona; but having been defeated in a bloody action near the walls of this city, he escaped by the swiftness of his horse. After this disalter he retired with the shattered remains of his army to the mountains, where he left the greatest part of them by hunger and disease, and by defertion; and from hence he finally retreated into Thrace, and thus Italy was liberated.

It was not long after this event before Alaric was recommended by Stilicho to Honorius, and appointed by this weak prince master-general of the Roman armies in Western Illyricum. Whilst Stilicho refused his pretentions to the provinces of the Eilat, and was anxious to employ Alaric and his forces at a distance from Italy, the Gothic king perceived his design; and protracing his languid operations in Thessaly and Epirus, he held a doubtful, and perhaps a treacherous, correspondance with the two rival courts, and advanced to Aemona, on the confines of Italy, with a view of enforcing his demand on the Roman court, for the recompence of ineffectual services. The demand was supported by Stilicho, who lost his life during the hesitation of the senate; and the delay furnished Alaric with a pretext for again entering Italy, in 408. By bold and rapid marches he passed the Alps and the Po; pillaged the cities of Aquileia, Altinum, Concordia, and Cremona, which yielded to his arms; increased his forces by the accession of 30,000 auxiliaries; and at length pitched his camp under the walls of Rome. The city was soon reduced to the utmost extremities of famine and pellimine, and a negociation was commenced and terminated in a random; the payment of which induced Alaric, A.D. 410, to raze the siege, and to withdraw his army into Tuscany. Here the Gothic leand became the refuge of 40,000 Barbarian slaves, who had broke their chains; and aspired, under the command of their great deliverer, to revenge the injuries, and the disgrace, of their cruel servitude. About the same time he received a reinforcement of Goths and Huns, whom Ataulphus, or Adolphus, the brother of his wife, had conducted. at his prefling invitation, from the banks of the Danube to the throfe of the Tiber, and who had cut their way, with some difficulty and los, through the superior numbers of the Imperial troops. Alaric was now at the head of 100,000

Vol. I.
ALARIC II. king of the Visigoths, succeeded his father Euric in 484, and reigned over all the country between the Rhone and the Garonne; adapting to his own states the Theodosian collection of laws, which he published as the law of the Visigoths, and which has since been known by the title of the code of Alaric. By permission of this Arian prince, the orthodox prelates held a council at Agde in 566; but notwithstanding this instance of toleration, Clovis, the powerful king of the Franks, engaged in a war with a view of dispossessing him of his dominions, and aid ed as the motive of it, that he was privileged to see the Arians proprietors of the fairest portion of Gaul: "let us march," says he in his speech to the Nobles at Paris, "and with the aid of God vanquish the heathens, and then possess and divide their fertile provinces." After holding a conference with Alaric, in a small island of the Loire, near Anmoise, which seemed to terminate amicably, Clovis marched against him with the confidence and enthusiasm of a messenger commissioned from heaven, and having passed the ford of the Hart, over the Vivonne, to which he was guided by a white hart of singular size and beauty, he halted, under the direction of a flaming meteor that hovered over the cathedral of Poitiers, to attack the Gothic army, more numerous than his own, but enfeebled by a long and luxurious peace. At a village about ten miles south of Poitiers, still named Champagne St. Hilaire, the two armies engaged; but that of the Goths was prepared for a defense by terror and confusion. They rallied, however, in their extreme distress, and the martial youths, who had clamorously demanded the battle, refused to succumb to the tempest of flight. The two kings encountered each other in single combat. Alaric fell by the hand of his rival, A. D. 507, and the victorious Frank was preferred by the goodnights of his courtiers, and the vigour of his horse, from the srsps of two delicate Goths, who joyfully rode against him, to revenge the death of their sovereign. Alaric was succeeded by a natural son, Gefalaie who took possession of his throne. Mod. Un. Hist. vol. xvi. p. 6. Gibbon's Hist. &c. vol. vi. p. 330-335.

ALARIA, in Ornithology, Cape finch of Latham, or sparrow from the Cape of Good Hope of Albinus, a species of Fringilla, with the head and breast black, the body chestnut-colour and under white, and the four lateral feathers of the tail marked with a small black line. It is in length about 4½ inches, and found at the Cape of Good Hope.

ALARIS venus, in Anatomy, the inmost of the three veins in the bend of the arm.

ALARUM, in the Military Art, properly denotes a sudden apprehension, conceived from some noise, or report, called also alarm, and signified by firing a cannon, beat of a drum, &c., which makes men run to their arms, and stand on their guard.

The word is French, formed from the Italian all' armi, to arms: whence gridere all' armi, q. d. to call to arms.

Alarms are either true, that is, founded on just notice, or false. False alarms are frequently given by an enemy, either to fatigue the other's army, or by way of diversion; to keep themselves safe and quiet from attacks. Alarms of this kind are sometimes designed to try the vigilance of the picket-guard, and to render them strictly attentive to their duty. To remedy the inconveniences of formal alarms, and prevent the horror and confusion of trumpets, and noise of warlike cries, the captains usually give the alarm, by silent advice, without noise.

Alarm bell, which is rung to call the people to-gether, on some fuch occasion as a fire, mutiny, or the appearance of an enemy. Thus is what the French call tofia. See BELFRY.

ALARUM-POLL is the ground appointed to each regiment, by the quarter-master-general, to which it is to march in case of an alarm. In a garrison, the alarm-poll is the place where every regiment is ordered to draw up, on ordinary occasions.

ALARUM, in Fencing, denotes a slip, or flamp, made on the ground with the advancing foot.

This coincides with what is otherwise called an appel, or challenge.

Alarum, or rather ALARUM, is also used for an instrument to awaken persons at a certain hour; one very simple contrivance of this kind, is that used by weavers. See Weaver's Alarum.

ALARO, in Geography, a river of Italy, which rises in the Apennine, and runs into the sea near Cape Stilo, in Calabria Ultra.

ALARODII, in Ancient Geography, a people who probably inhabited a country near Coelis, which was terminated by the western part of the Euxine sea. Stephan. Byz. Not. Herodot, lib vii. c. 79.

ALARUM THRUSH, in Ornithology. See BELFRY.

ALARYS BAY, in Geography, lies on the west coast of Ireland, nearly south-east from Achill-head.

ALASARNE, a nation of the island of Cos.

ALASCANI, in Church History, a sect of Antiluethans, whose distinguishing tenet, besides their denying baptism, is said to have been this, that the words, This is my body, in the institution of the eucharist, are not to be understood of the bread, but of the whole action, or celebration of the supper. They are said to have taken the name from one Joannes a Laco, a Polish baron, superintendant of the church of that country, in England.

ALASCHA, or ALASKA, in Geography, a long peninsula on the north-west coast of America, formed by Bristol bay and the ocean on the north-west and north, and by the ocean and the waters of Cook's river, on the south and south-east. A number of islands, at its extremity, of which the chief in their order westward, are Onemak, Onalaska, and Ocumnak, form part of the cluster of islands, called the Northern Archipelago. N. lat. 55° 30' to 58°. W. long. 150° to 162°.

ALASCHEIR, a town of Natolia, which, according to some Geographers, is the ancient Hypsus; and according to others, Philadelphia.

ALASCO, John, in Biography, a Polish nobleman, uncle to the king of Poland, as Fox (Acts and Monuments, vol. iii. p. 32.) informs us, was a member of the Catholic church, and, as it is said by some writers, possessed episcopal dignity. But imitating the principles of the Reformation, he became a Protestant Divine; and being under a necessity of leaving Germany by the persecution that followed the imposition of the Interim, he and his congregation found an asylum in London, under the protection of Edward VI. This excellent prince granted them the church which had lately belonged to the Augustin Friars; and by a charter, A. D. 1550, erected their congregation into a corporation. John Alasco was appointed superintendant, and four other ministers were associated with him. There were also 350 of the congregation, that were made Denizens of England. Burnet says, that he did not conduct himself with that decency which became a stranger who was so kindly received; as he wrote against the orders of the English church, "both in the matter of the habits, and the pollution of the sacrament, being for sitting rather than kneeling." After the accession of Queen Mary, in 1553, their congregation
gregation was dissolled, their charter revoked, and they were
ordered to leave the kingdom. Some few of them remained
with two of their teachers; but the greater number sought
refuge in foreign countries. Alafco, and many of his com-
panions, embarked for Denmark; but when it was under-
stood that they were of the Helvetic faction, they were
required to depart in the midst of winter within two days.
From thence they emigrated, first to Lubeck, then to Wil-
man, and afterwards to Hamburg; where disputes about the
mode of Churf's presence in the sacrament excited such ani-
magations, that after much barbarous usage, they were banished
out of all these towns, and could find no settlement, till the
spring of the following year, when they were kindly re-
ceived at Embden, in Friesland, and permitted to remain
un molested. Such were the eminent talents and virtues of
Alafco, that, during his short residence in England, he had
formed a friendship with several considerable persons; and
his character was so highly esteemed by queen Elizabeth,
that when she came to the crown, he wrote letters of advice
and encouragement to her on the reformation of religion.
Among his friends were Melancthon and Erasmus. The
former addresses him in terms of high respect, and calls him
his patron, and apprehending the necessity of seeking an
asylum with him, he affirms himself of an hospitable recep-
tion with one who could adopt the sentiment of the exiled
queen. "Non ignara mali, miseris foccurende dicte.'"

"Touch'd with misfortunes I myself have known,
I view with pity woe so like my own."  
Virgil, Æn. i. 634.

Erasmus, in a letter written in 1527, says of him, that
he found him "a man of so amiable a disposition, that he
should have thought himself sufficiently happy in his fingle
friendship;" and in another letter, after enumerating his
excellent qualities, he adds, "that which the young ought
to learn of the aged, I, an old man, have learned of this
youth." The friendship between them continued as long
as Erasmus lived; and Alafco was probably with him in his
last sickness, as he purchased of him, when he lay on his
death-bed, his valuable library.

Alafco, by the favour of Sigismund, passed his last years
in his native country, where he died in 1560; "living, in
times and circumstances of peril, supported a confident,
and respectable character." Burnet's Hist. Reform.

ALA SNAKE, i. e. beautiful city, in Geography, a name
given by the Turks, to the ancient city of Philadelphia, on
account of its beautiful situation.

ALASIA, a province of Thrift in Asia.

ALASSAC, a town of France, in the department of the
Corrèze, and district of Brive, and two and a half leagues
north north-west of Brive.

ALATA, in Ancient Geography, a name given by Ptolemy
to towns, one in Arabia Defera, and another in Arab-
ia Felix.

ALATA CASTEA, a town of Britain, placed by Pto-
lemy near the Ehtuary of Bodotria, supposed to be the site
of Edinburgh.

ALATAMAH, a navigable river of Georgia in North
America, rises in the Cherokee mountains, traverses the
hilly country through a distance of 250 miles, and then
passing through the flat country, under the name of Oak-
mulgee, for 150 miles, and receiving the Oconee, assumes
the name of Alatanma. After this junction, it flows with
a gentle current for 100 miles, and discharges itself by
several mouths into the Atlantic. The north channel enters
the ocean between Sapelo and Woff Islands; the South
channel, which is the largest and deepest, pursues its course
between McIntoan and Broughton islands, and by the west
coast of St. Simon's found, between the north end of the
island of that name, and the north end of Yekil island. At
its confluence with the Atlantic, it is 320 miles long.

ALATED, or winged, in Botany, an epithet applied to
the feed, item, or leafstalk. A feed is alated, when it has
an ala or membrane affixed to it, which by its firing serves
to dispere it. See S.T.ED. The foot-alk, or pinnate
of a leaf, is alated, when it spreads out on the fides, or is
winged with membranes. Alated leaves are those made up
of several pinnated ones, or, when the fides of a single pinnate
connect many folioles. See LEAF.

ALATED QUADRUPOD, in Zoology. See QUADRUPED.

ALATERNOIDES, in Botany. See Phyla, Clu-
tia, Ceanothus, and Myrica.

ALATERNUS. See Rhamnus and Phyllica.

ALATLI, in Ornithology. See Achachactil.

ALATRI, or Alatra, in Geography, an ancient city
of Italy, in the Campagna di Roma, which is the fee of a
bishop, and a dukedom, five leagues south-east of Agna,
and 16 south-east of Rome. N. lat. 41° 44'. E. long. 13° 12'.

ALATUNGA, in Ichthyology, a species of the Scmor-
 ber, with the first pectoral fin very long, and seven small
fins on each side of the tail. It is found periodically greg-
arious in the Mediterranean.

ALATYR, in Geography, a town of Russia, in the go-
vernment of Kafan, and circle of Alatyr, 80 miles west-
north-west of Simbirsk. N. lat. 54° 55'. E. long. 46° 14'.

ALATYR, a river of Russia, which runs into the Sura,
near Alatyr.

ALAVA, ESQUIVEL, DIEGO, in Biography, a Spanish
divine, bishop of Cordova, was born at Victoria in Alava,
and asisted in the council of Trent, where he proposed the
prohibition for holding livings in commendam, and of all ec-
clesiastical pluralities. He died in 1560; and wrote a valu-
able work, entitled, "De Confusis Universalibus, &c." i. e.
of general councils, and the regulations that seem necessary
to reform the religion and state of the church.

ALAVA, in Geography. See ALABA.

ALAUDA, in Entomology, a species of Curculio, cine-
rinous; subglobular thorax, back marked with a transverse
band and black spot, and brown legs: found in Pomerania.

ALAUDA, in Entomology, a species of Alatyr, or
erniflata, in Ichthyology, a name given by Rondeletius and Gesner to the Blennius pholis of Lin-
neus, or Smooth Blenny.

ALAUDA, LARK, in Ornithology, a genus of birds of
the order of passeres; the characters of which are, that the
beak is cylindrical, subulate, and straight, bending towards
the point; the mandibles are of equal size, and opening down-
wards at their base; the tongue is bident; and the hinder
claw is straighter and longer than the toe. Pennant adds,
that the nostrils are covered with feathers or bristles, and
the toes divided to their origin.

The name alauda is, according to Pliny, Suetonius,
and Varro, of Gaulish extraction; and hence the French term,
alouette.

The Greeks were acquainted with two species of larks;
the one had a tuft on its head, and was denominated xoopos,
or xupoboros, from avos, a helmet, which the Latins render
galeata, or cafita; the other, a common lark, wanted this
tuft: though Wulff and Pennant say, that it sometemes
brillest the feathers on its head so as to form an occassional
crest, which M. Buffon affirms also, from his own observa-
tion, with respect to the male. The Germans call it lurche,
pronouncing it sometemes lurche, in imitation of its notes;
for, according to Linneus, it prolongs its turle, turle, turle.

3 T 2
Gmelin
Gmelin enumerates 33 species. 1. *A. arvensis, vulgaris* of Olina, *Coelopa* of Klein, *alauda non crifata* of Génetier and Aldrovand, *Palucette de Buffon, and field-lark or fly-lark* of Ray, Willughby, Pennant, Latham, &c. The specific characters of which are, that the two outermost quills of its tail are white lengthwise externally, and the intermediate ones are ferruginous on the inside; the length is about seven inches. The males of this species are somewhat browner than the females; they have a black collar, and more white on the tail; their size is larger, and their aspect bulkier; and they exclusively possess the faculty of singling. When the female is impregnated, she forms her nest between two clods of earth, and lines it with herbs and dry roots, being no less attentive to the concealment than to the structure of it. It sometimes builds its nest among corn and in high grass. Each female lays four or five eggs, which are greyish, with brown spots; and the period of her incubation is about 15 days. The young may be taken out of the nest when they are a fortnight old, and they are so hardy, that they may be easily brought up. Some have said, that she hatches three times in the year; but this must depend on the temperature of the climate. The parent is very tender of her young; and though she does not always cover them with her wings, she directs their motions, supplies their wants, and guards them from danger. The common food of the young sky-larks is worms, caterpillars, ant's eggs, and even grasshoppers; and in maturity, they live chiefly on seeds, herbs, and all vegetable substances. Those birds, it is said, that are defined for singing, should be caught in October or November; and the males should, as much as possible, be selected; and when they are untractable they should be pinioned, left they injure themselves by their violence against the roof of the cage. As they cannot cling by the toes it is needless to place bars across their cage; but they should have clean sand at the bottom of the cage, that they may welter in it and be relieved from the vermin which torment them. In Flanders, the young ones are fed with moistened poppy-seeds, and foaked crumbs of bread; and when they begin to sing, with sheep's and calves' hearts, bathed with hard eggs; to which are added, wheat, spelt, oats, millet, linseed, and the seeds of poppy and hemp, steeped in milk. Their capacity of learning to sing is well known; and so apt are some cock larks, that, after hearing a tune whistled with the pipe, they have caught the whole, and repeat it more agreeably than any linnet or canary bird. In summer the larks seek the highest and driest situations; but in winter they descend to the plains, and assemble in numerous flocks. In the former season they are very lean, and in the latter very fat, as they are always on the ground, and constantly feeding. In mounting to the air, they ascend almost perpendicularly, by succedent springs, and hover at a great height; but in descending, they make an oblique sweep, unless they are pursued by a ravenous bird, or attracted by a mate, in either of which cases they fall like a stone. Those small birds, at the height to which they soar, are liable to be wafted by the wind; and they have been observed at sea, clinging to the masts and cordage of ships. Sir Hans Sloane observed some of them 40 miles from the coast, and count Marpigli met with them on the Mediterranean. It is conjectured, that those which are found in America have been driven thereto by the wind. Some have suppos'd, that they are not birds of passage, at least in the more southern and milder climates of Europe; but they are occasionally concealed under some rock or sheltered cave; and this concealment was known to Aristotle (Hist. Anim. lib. viii. 16.), and has been ascertained by Klein. Thvenot (Voyage du Levant, tom. i. p. 493.) says, that the larks appear in Egypt in the month of September, and continue there till the end of the year. See Migration.

The lark is found in all the inhabited parts of both continents, as far as the Cape of Good Hope; though Villlaut, says, that it is not found on the Gold coast; nor, according to Averroes, in Andalusia.

This bird, and the wood-lark, are the only birds which sing whilst they fly. The higher it soars, the more it strains its voice, and lowers it till it quite dies away in descending. When it ascends beyond our sight, its music is distinctly heard; and its song, which is full of strett and falls, and is thus delightful for its variety, commences before the earliest dawn. Milton, in his Allegro, has admirably expressed these circumstances; and bishop Newton observes, that the poet gives a fine picture of the state of the mind, whilst he is beautifully describing the scene of rural cheerfulness, in a situation,

"To hear the lark begin his flight,
And singing flatter the dull night,
From his watch-tower in the skies,
Till the dapple dawn doth rise."

In a state of freedom, the lark begins its song early in the spring, which is its season of love and pairing, and continues to warble during the whole of the summer. The Hon. Daines Barrington (Phil. Trans. vol. Liii. part ii. p. 282.), reckons this among the belt of the singing larks; and as it copies the warble of every other bird, he terms it a mocking-bird. See Song of Birds.

These birds, which are esteemed a delicacy for the table, though Linneus thinks the food improper for gravely complaints, are taken with us in the greatest numbers, in the neighbourhood of Dunaff. The season begins about the 14th of September, and ends the 25th of February; and during this time, about 4000 dozen are caught for supplying the London markets. Those caught in the day, are taken in Clap-nets, till the 14th of November. See Doring. But when the weather becomes gloomy, and also in the night, the larker makes use of a trammel-net, 27 or 28 feet long, and five broad, which is put on two poles 18 feet long, and carried by men under each arm, who pass over the fields, and quarter the grounds as a setting dog. When they see or feel a lark flitke the net, they drop it down, and thus the birds are taken. The darkest nights are the most proper for their sport; and the net will not only take larks, but all other birds that roost on the ground; among which are woodcocks, snipes, partridges, quails, field-fares, and several others. In the depth of winter people sometimes take great numbers of larks by nooses of horse-hair. The method is this: take 100 or 200 yards of packthread; fasten at every fix inches a noose made of double horse-hair; at every 20 yards the line is to be pegged down to the ground, and so left ready to take them. The time to use this is, when the ground is covered with snow, and the larks are to be allured to it by some white oats, scattered among the nooses; they will soon fly to thefe, and in eating will be hung by the nooses. They must be taken away as soon as three or four are hung, otherwise the net will be frightened; but though the others are scared away just where the sportman comes, none will be feeding at the other end of the line, and the sport may be thus continued for a long time. As the fly-lark is a kind of mocking-bird, and apt to catch the note of any other which hangs near it, even after its own note is fixed; the bird-fanciers often place it next to one which hath not been long caught, in order, as they term it, to keep the caged fly-lark honest.

The
The method of catching larks by lime-twigs, practised in French Lorraine, is as follows. For this purpose 1500 or 2000 willow rods, about three feet ten inches long, straight and well smoothed, are provided. These are sharpened and slightly bent at one end, and the space of about a foot from the other end is covered with bird-lime. The stakes are planted in parallel rows, in a situation which abounds with larks; the rows are at such a distance as to admit of a perif'-passing between them; and the stakes are fixed at the distance of a foot from each other, and opposite to the interval in the next row. The chief art consists in fastening them, that they shall retain their perpendicular position till they are touched, and fall immediately upon a lark's brushing against them in its flight. When the lined rods are planted, an oblong square is traced, with one of its sides presented to the ground where the larks are lodged, and at each corner is erected a flag, which serves as a mark to the fowlers, and sometimes as a signal for their manoeuvres. In Autumn, about four or five o'clock in the afternoon, the company attending this sport is divided into two detachments; one is affixed at the flag on the right, and the other at that on the left; and each observing the most profound silence, extends itself in an arch, so as to meet at the distance of half a league from the front, and then form one rank, gradually closing as it advances to the rods, and thus driving the larks before it. About sun-set, the middle of the line ought to be within two or three hundred paces from the front; and this is the time when they charge: that is, they proceed cautiously, pausing or lying on the ground, rise up or push forward, according to the commands of their leader. Upon the proper conduct of these manoeuvres depends the success of the sport; for thus the larks will be enclofed, and mounting no higher than three or four feet, they will rush forward and be caught among the lime-rods, and falling to the ground with them, may be picked up by the hand. If it be not too late, a second line is made on the opposite side at the distance of 50 paces, which drives back the larks that had escaped; and this is called tacking about. One hundred dozen of larks or more are sometimes caught in one of these sweeps, and the sport is reckoned bad when only 25 dozen are taken. Although such numbers are taken in this way, and others destroyed by the voracious tribes, their fecundity is very great; and they are naturally long-lived, the term of their existence being, according to Olina, ten years, and others say, 12, 22 and even 24 years. Larks abound in various parts of Germany, and Keyler (Travels, vol. iv. p. 315) informs us, that those about Lippes, where they are very numerous, are very fat, and have a very delicate flavour. The excise on these birds produces 6000 dollars, or about 500L. reckoning annually. They are also taken in great numbers in the country about Naumburg, Meranburg, and Halle. Of this species there are three varieties; viz. the white fly-lark, which is feldom of a snowy white colour, but tinged with yellow or brown, and which is chiefly found on the northern shores of the Baltic, in Denmark and Sweden, and in Norway; and occasionally in the vicinity of Hildesheim in Lower Saxony, and in other places. A second variety is the black fly-lark, represented by Albin as entirely of a dull brown and reddish colour, varying to black, excepting the back of the head, which is of a dun yellow, and the lower part of the belly, which has feathers edged with white; the feet, toes and nails, being of a dirty yellow. The subject of this description was caught in a meadow near Highgate, where such birds are found. A perfectly black lark is mentioned by Mauduit, which was caught in the plain of Mont-
that of the fly-lark, and its numbers are not so great: it breeds earlier, from its young are sometimes flown in the middle of March, and therefore they pair in February, at which time, and not before, they part with their last year's brood; whereas the common lark does not hatch before the month of May. This is a very tender and delicate bird; so that, according to Albin, it is impossible to rear the young out of the nest: but this is the case only in England and such cold climates, for in Italy they are removed from the nest, and reared at first like the nightingale, and afterwards fed upon panic and millet. The wood-lark feeds on beetles, caterpillars, and seeds: its tongue is forked; its stomack muscular and flabby; and it has no claw, but a moderate dilatation of the lower part of the oesophagus, and its ceca are very small. It lives ten or twelve years. The males are distinguished from the females by their larger size; the crown of the head is also of a darker colour, and the hind nails longer; its breast is more spotted, and its great wing-quills edged with olive, which in the female is grey. The wood-larks mount high, warbling its notes, and hovering in the air; it flies in flocks during the winter colds; it is found in Sweden and Italy, and is probably dispersed through the intervening countries, and consequently over the greatest part of Europe. It is also found in Siberia, as far as Kamtchatka, and in the island of Madeira. Of these larks, like the common fort, some are migratory, and some stationary. In autumn the wood-lark is fat, and is then excellent for food. There are three feasons, according to Albin, for catching wood-larks. The first is the summer, or the months of June, July, and August, when the small branchers begin to chirp, before they undergo the molting. The second is the month of September, when they fly in flocks and roam from one country to another, roving over the pasture grounds, and perching on trees near lime kilns. The young birds now change their plumage, and are not distinguishable from the old ones. The third and the most favourable season for catching wood-larks, begins with the month of January, and lasts till the end of February, when they separate to pair. The young birds, which are then caught, make generally the best fingers; they chirp a few days after, and with a clearer tone than those that are caught at any other season. Those that are taken in the summer months are usually taken in nets by the help of a hawk. With this view, the sportsman is to go out in a dewy morning, and fixing on some hill, he is to go to that side of it which faces the rising sun; for this is the place which they are sure to frequent. He is then to take out a hawk, and a small net at the end of a stick; when he sees a bird, he is to throw the hawk, upon which it will fbat down; and on his approaching near, and making the hawk flutter over the place, the bird will only lie so much the closer, so that he may go up and lay the net over it, and thus take it without injury. The best wood-larks that are kept in cages, have been caught in this manner. A better way of taking numbers of them, is to prepare a net made like that for taking partridges, only with much smaller meshes; three or four persons are to go out with this, and one of them is to take out a hawk, which serves in the same manner for the larks, as the setting-dog does for the partridges. Wherever a flock of these larks is seen together, which is very common, the whole flight keeping with the female till the next coupling season, the hawk is to be flown; and on his hovering, they will all lie still, and the net may be easily drawn over them. But if one can escape. The best time for taking this bird for the cage is July, or the preceding or following month. Those that are put into the cage at this time, sing prefently, but their long-time is not failing, for they soon fall to mutualting, in which flate many die; but if they get over it, they commonly prove very healthful afterwards, become very tame and familiar, and sing sweetly. Those which are taken in the latter end of September are generally very strong and sprightly; but they do not sing till after Christmas. Those taken in January and February finally prove the best of all; they generally begin singing in two or three days, or at the utmost in a week after they are taken.

The method of keeping them in health in the cage is this: there must be two pans of food, the one containing meat, the other oatmeal and hempseed. The following is very good food: boil an egg very hard, to which add the crumb of half-penny loaf and as much hempseed; let the egg be chopped very small, and the hempseed bruised in a mortar; when these are mixed, the bread is to be crumbled in among the rest, and the whole to be rolled together with a common rolling-pin, and kept for use. There must be some fine small gravel drewed at the bottom of the cage, and renewed at first sight once in a week. This will prevent the bird's feet from injury by being clogged with dung; and his baking in this will also keep him from being lousy, after which few birds are of much use. A perch must be in the cage, and it should be lined with green baize, or made of fine matting, of which the lark is very fond. When the bird is first taken, some meat should be drewed on the sand in the bottom of the cage; for the bird will be sometimes almost famished before he finds the meat in the pan. The cock-bird of this kind is known from the hen by the londnels and length of his call, by his tail-feathers as he walks about the cage, and by his doubling his notes in the evening, as if he were going with his mate to roost. A better rule than all others, however, is hisinging long; for the hen wood-lark sings but very weakly. Both the cock and hen of this kind are tender, and subject to many disorders; the principal of these are, cramps, giddiness of the head, and breeding lice. Cleanliness is the best cure for the first and last of these complaints; but we know of no cure for the other. A good strong bird will lay very well for five or six years, and frequently improve during the whole of this time. The lark is not only a very agreeable bird for the cage, but it will also live upon almost any food, so that it have once a week a fresh tuft of three-leaved grass put into the cage with it. The wood-lark is one of the sweetest of our singing birds, and is indeed very little inferior to the nightingale, when in good health; but we are not to judge by such as are made feebfe by improper food, or want of cleanliness in their cages.

4. A. campelleri, la spigolere of Buffon, glarana of Gefner, &c. in German giekerin, braackbarte and braackbarte, meadow-lark of Latham, is rather larger than the tit-lark; being six-inches and a half in length. Its specific characters are, that its tail-quills are brown; the lower half, except two intermediate quills, white; the throat and breast, yellow. According to Willoughby, the meadow-lark differs from the other larks by the blackness of its bill and feet; he adds, that its bill is slender, straight, and pointed, and the corners of its mouth edged with yellow; that it has not, like the wood-lark, the first quills of the wings shorter than the succeeding; and that in the male the wings are rather darker than in the female. Though the males are hardly to be distinguished from the females by their external appearance, yet if another male be presented, but up in a tree, they will instantly attack it as an enemy or a rival. This bird has a flanderer body than the fly-lark, and is distinguished from it by the shake of its tail, like that of the wagtail.
wagtail and tit-lark. It inhabits heaths and uncultivated tracts, and frequently the oat-fubbles, after the corn is reaped, where birds of this species gather together in numerous flocks. In spring, the male perches to discover or to woo his mate, and sometimes he mounts into the air, singing with all his might, and then descends quickly to pair on the ground. When a person approaches the nest, the female betrays her fears by her cries; whereas, other larks are silent and unmoved, when danger is apprehended. They make their nest close to the ground, sometimes in furze-bushes, and form it of moss, lined with a saw and horse hair. The egg is half the size of that of the sky-lark, which it resembles, and its tints are lighter. Where the young males are reared for the sake of their song, they require great attention. The cage must be covered with a green cloth, little light be admitted, and plenty of ant's eggs must be provided. By degrees bruised hemp-feed, mixed with flour and yolks of eggs, may be substituted. The meadow larks are caught like the sky larks, with the drag-net and allo with lime twigs, placed in the trees which they haunt. They associate with the finches; and both arrive and depart with these. They are found in Italy, Germany, England, Sweden, &c. They live on small seeds and insects; and their flesh, when fat, is excellent. The meadow-lark of Britain differs from that of Linnaeus; as in that of the latter, all the quills of the tail, except the two middle ones, are white from their origin to half their length, but in that of the former, the two outermost quills only are white. Of this species there is a variety, viz. the spinellata.

5. A. trivialis, A Fpervia of Buffon, pipila f. anhur of Aldrovand, L'alouette ppi of Buffon, the small lark of Ray and Wilkghby, the pipi lark of Albin, the graflopper warbler, of Latham, is distinguished by brown tail-quills, the outermost half white, the second white at its wedge-like tip, with a double whitish line on the wings. The German epithet ppi, and the English pipi, formed from the Latin pipis, which signifies to utter a feeble cry like chickens, alludes to the fibulous notes of this bird. Its cry, sepulcral in winter, is like that of the graflopper, but stronger and shriller, and it utters this, both when perched on the taillet branches among the bushes, and when it is on the wing. Its tones are dull, harmonious and clear. This little bird builds its nest in solitary spots, concealed under a thorn, and its young are frequently a prey to the adders. It lays five eggs, of a light grays green colour, thinly sprinkled with deeper coloured specks. The graflopper larks appear in England about the middle of September, and great numbers of them are caught in the environs of London. They are found in Sweden and Germany, as well as in England: they frequent the heaths and plains, and flutter at a moderate height; they chiefly feed, as the slender form of their bill indicates, on insects and small seeds, and from the diminutive size of this bird, being about five inches and a half long, it may be inferred, that it is not long-lived.

6. A. crislata, a species of Buffon, calandra, t. e. the helmet-lark having a crest of Arizolote; the galerita of Pliny, and galericulatus of Varro; A. crislata of Buffon, A. crislata major of Ray, Aldrovand, and Geeper, laola capellata of Olina, le coecqueur of Buffon, hiberclerica of the Germans, and croesled lark of Wullghby, Albin, and Latham, is distinguished by black tail-quills, the two outermost white at their exterior edge, its head crested, and its feet black. Its length is about six inches and three quarters. It lives in the meadows and fields, on the sides of ditches and the backs of furrows: it is often seen at the margin of water, and on the high roads, rarely in the skirts of woods, perched on a tree, and sometimes on the tops of houes, and of abbeyes, &c. This lark though not so common as the sky-lark, is found in most parts of Europe, in Italy, France, Germany, Poland, Denmark, Russia, Scotland; and does not change its abode in winter. The song of the males is loud, and yet mellow and pleasant: and their warbling is usually accompanied with a quivering of the wings. They are the first to hail the return of spring, and the dawn of the morning, and they sometimes warble in the night; being animated by fine weather, but deprecated and flinced by clouds and rain; and they generally sing till the end of September. The male is distinguished, not only by the excellence of his warble, but by the strength of his bill, the bulch of his head, and by a large portion of black on his breast. The female confects her nest like the common lark, but often near the highways: it lays four or five eggs, which are ash-coloured, with numerous dingy brown spots, and takes little concern in hatching them; but when the young are excluded, the provides for them till they are flown. They are faid to breed twice in the year. They are easily reared, but cannot be supported in a cage, without difficulty, for a whole year: their boft food is ant's eggs, oak and sheep's hearts minced, and bruised hemp-feed and millet. The proper feaon for raising these birds is autumn; and great numbers are then caught in a lump flate on the verge of the forefts. They may be decoyed by the call, and thus differ from sky-larks; besides, they never conform in flocks; their plumage is his varied and more white: the bill longer, the tale and wings shorter; they do not mount so high in the air, are les able to struglle with the wind, and return sooner to the ground. In other respect the two fpecies are alike.

The crested lark is the only one that may be introduced in a month; it learns many airs perfectly, which it repeats without confusion, and retains nothing of its native warble; and in these particulars it is superior to the canary.

7. A. rufa, L'Alouette noire d' Ash fauve of Buffon, the rufous backed lark of Latham, is specifically distinguished by its blackish brown colour; its neck and back rufous orange, the tail-quills rufous at their outward margin, the lefser and middle coatings of the wings blackish and fulvous, or of a deep yellow at their margin. Its length is scarcely five inches, is much smaller than the common sky-lark, and found at Danoes Alayers. Buffon observing its plumage to exhibit so striking a refeonce to that of the sky-lark, considers it as a variety of that species.

8. A. capensis, A capita bona f of Buffon, la crone jaune ou calandare du cap de bonne esperance of Buffon, cape lark of Latham, has its three lateral tail-quills tipt with white, its throat yellow, margined with black, and its eye-brows yellow. Its length is eight inches, and it is found at the Cape of Good Hope.

9. A. calandra, A. son crista major and tetrax parva of Geeper, calandare of Buffon, calandra of other writers, calandare lark of Latham, is specifically described as having its outermoft tail-quills externally altogether white, the second and third tipt with white, and a brown tipt on the breast. This bird is mentioned by Oppian in the second century of the Christian Era, under the appellation of Calandra; and he describes the method of catching it, since recommended by Olina, which is to fence a net near the brook to which it usually reforts to drink. It is larger than the sky-lark, its length being seven and one-fourth inches, and its bill stronger and shorter: in other respects it exactly resembles the common lark. Its warble is more sonorous, but not les pleasant; so that in Italy a person who sings well is complimented.
complimented by saying, that he fings like a calandre. It can, like the common lark, imitate the notes of several birds, and even the chirping of chickens and the love-soun of the pheasant. When calandres are to be caged, in order to have good fingers, they should be taken from the nest before the first moult, and then are to be preferred which are hatched in August. Their food should be paffle mixed with sheep's heart, together with seeds and crumbs of bread; and rubbish should be laid in the cage for whetting their bill, and for them to welter in when teazed with vermin. Their wings should at first be pinioned, and instead of the top of the cage, a canvas should be substituted. When they are reconciled to their situation, they will sing incessantly, and even neglect their food to repeat their warble. The male is larger and blacker round the neck than the female, which has only a very narrow collar. The calandre needle on the ground, like the common lark, under a grefly tuft, and lays four or five eggs. It is found in Italy, Sardinia, Provence in France, the Pyrenees, Syria, near Aleppo, the southern part of Russia, the deferts of Tartary, and even America whither it might have been driven by the winds across the Atlantic, and there thrive and become naturalized.

10. A. alpina, A. virginiana of Buffon, lance-fced noir ofBuffon, lark, with a yellow throat of Catesby, and flave-lark of Pennant, Latham, &c. has these specific characters: the tail quills are half white on the inside, the throat is yellow, the fripe under the eyes, and on its breast, is black. Its length is six and an half inches, and in bulk and habit it resembles the common lark. It inhabits North America, Siberia, Russia, and Poland; migrates in flocks, feeds on oats and other grains and grasse; lives upon the ground; has little or no fong, and its flesh is delicious.

11. A. magna, merula americana tourquet of Buffon, la fer-a-cheval au mere, a colier d'amerique of Buffon, large lark of Catesby, and crecet fleure of Pennant and Latham, is characterized by Linneaus as having the under-fide of the body yellow, a black curved band on the breast, and the three lateral quills of the tail white. Above, says Buffon, it is variegated with rufiy brown and blackish, below yellow, with a black spot on the breast, and the three lateral quills of the tail white. Its length is 8 inches. It is not found only in Virginia and Carolina, but in almost the whole Continent of America; and Linneaus affirms that it occurs also in Africa. In the state of New York it appears in the beginning of April, breeds in June, and retires in September or October. It nests on the ground, and its eggs are whithis. It lives in Sappanas, perches on the tops of bushes, has a brisk motion upwards and downwards of its tail, eats scarcely anything but the small seeds that are found on the ground, such as those of the yellow flowered ortibogam; fings agreeably in the spring; and is reckoned good food.

12. A. minor, lesser field lark of Willughby, field lark of Latham, is of a reddish brown colour, and the two outer quills of the tail are externally white. The throat is yellow; the breast also yellow, marked with large black spots; the belly and vent feathers white; the coverts of the wings dusky, edged with white; and the legs of a very pale brown. It is larger than the tit-lark, but distinguished from it by the very short claw on the hind toe.

13. A. italic, girole of Ray and Willughby, girole of Buffon, and Italian lark of Latham, has the middle quills of the tail bay, the tail but one white at the tip, the two outermost entirely white. Its fize is that of the sky-lark, and it has a long nail projecting from each foot. Its head, neck, back, and wings are of a mottled colour, resembling that of the quail. The general colour of the feathers is a cheufut brown, and their edges are variegated with white, yellow, and red; the back part of its head has a fort of crown or ring of white feathers; its belly is white; its bill red; and the corners of the mouth yelow, and its tail is fo short, that it seems to have none; it is biff, however, and elegantly variegated with chestnut-colour and white. The feet are flesh-coloured and the nails white. It is eight inches long, and inhabits Italy.

14. A. leucovicianu, fryrourzanie of Buffon, and Levouizana lark of Latham, resembles the tit-lark. Its specific characters are, that the half quills but one of the tail are tipt with white; the outermost are partly brown, partly white. Its length is seven inches. It is found in Louisiana.

15. A. rubra, A. Penjyfusana of Buffon, allouette aux joncs brunes de Penjyfusana of Buffon, and red lark of Pennant and Latham, is of a brown colour, and has the space about its eyes black, and the two outermost quills of the tail white. It is about the size of the meadow-lark. Its bill, feet, and nails are of a deep brown colour; its neck, breast, and underpart of the body, of a reddish fulvous colour, speckled with brown; and the brown spot that surrounds the eyes descends on the cheeks and is bounded by a zone, partly white and partly bright fulvous. This is a migratory bird, common to both continents. It appears in Pennsylvania in the month of March, and advances northward at the end of May; and it was seen by Mr. Edwards in the vicinity of London. He remarks, that when the wing is gathered up, the third primary feather reaches to the tip of the frill.

16. A. molliculata, la roufflinie of Buffon, and Marco-lark of Latham, is rufous below rufous white; its checks and breast are marked with brown lines; its tail is black with a rufous margin. Its length is fix and one-fourth inches. The bill, feet and nails are yellowish. It haunts wet situations, frequents the sandy margin of the Mofolle, and sometimes breeds on its banks, near Metz, where it appears annually in October, and some few are caught. It begins its song at dawn, which is said to be very pleasant.

17. A. malabarica, Malabar lark of Latham, has the primary and secondaries wing-feathers and the tail, of a fordist brown colour, tawny at their margin. The bill is black, the feathers that form the crest on the head are brown, and their apex white; those on the neck are tawny with a black longitudinal freak passing along the middle; the throat and abdomen reddish white; the feathers of the back and the coverts of the wings brown, towards their edge tawny, and marked with a white spot, and the feet are tawny. This is a beautiful species and found in Malabar.

18. A. gingica, Gingi lark Latham, has the upper part of the body cimerous brown, its under side black. The bill and feet are reddish grey. Its length is four and one-half inches, and it is found in Coromandel.

19. A. tartarica, A. nigra of Palaek, and black lark of Latham, has a folebifurcated tail, the two intermediate quills of the tail slightly white at their limb, the next whith at the apex, and the lateral very black. This bird inhabits the very dry salt deserts between the rivers Volga and Ural, the Caspian deserts, and the whole southern desert of Tartary; it is gregarious in winter, solitary in summer, and has scarcely any song.

20. A. mutabilis, mutable lark of Latham, has a black forked
forked tail, the outer quills of the tail on both sides unspotted, the red grey at their apex, and the bill whitish. It is about seven inches in length, and inhabits the defects of Atracac. This bird, when young, is wholly cinereous, and the colour gradually changes into black.

21. A. nemorosa. A. crista minor of Rav and Brisson, is found in Buffon, and fter erected lark of Pennant, Wilkibby and Latham, is characterized by black tail quills, the two outermost white on their exterior edge, its head crested, and its feet red. The crest is very long in proportion to its size. This bird is distinguished by its cry, in, in, in, which is disagreeable, and never uttered except it flies; it likewise mimicks oddly the songs of other birds; it frequents heaths, commons, and even woods, where it builds its nest; and in the rigour of winter, when the ground is covered with snow, it retorts to dunghills, and picks up its food about barns, and also haunts the highways for the same purpose. It is found in Italy, Austria, Silesia, and Poland, and seen in flocks in the northern counties of England. It remains in Germany through the winter, and leaves the country about the equinox.

22. A. undulata, capillade of Buffon, undulated lark of Latham, has its tail quills brown. Tawny at the edge, its feet yellowish, and the feathers of its crest black, edged with white. Its length is fix and three-fourth inches. This bird can elevate its crest at pleasure; it is properly the bird of the mowing, as it begins its song with the earliest dawns, and seems to roufe the other birds. The male does not lose his mate when the hatches, and when the one is employed in seeking their food, which consists of caterpillars, grasshoppers, and flies, the other keeps watch, to give signal when danger threatens. It was found by M. Guyse, in Provence; and Soomeret brought a bird very like it from the Cape of Good Hope, only that it had no crest, that the colour of the under part of the body was more yellowish, and that none of the quills of the tail or wings were edged with white. It was perhaps a female, or a young bird of the year’s hatch.

23. A. Senegalensis, A. senegalensis crispata of Buffon, la grisette of Buffon, and Senegal lark of Latham, has the two middle quills of the tail grey, the red brown, the outermost rufous white on the outer side, and the head somewhat crested. Its length is fix and a half inches. It inhabits Africa, and breeds on the trees, which grow on the banks of the Nger; and is also seen in the island of Senegal.

24. A. telesina, telesinaceus lark of Latham, has the four intermediate quills of the tail black, the red tawnycoloured, the body above tawnywhite, and below tawny white. It inhabits the vicinity of Gibraltar.

25. A. Lufana, Portugal lark, has the quills of the tail tawny luteous, the exterior ochreous, the feet flesh-coloured, and the bill red. It is found in Portugal.

26. A. Africana, le frise du cap de bonne esperance of Buffon, African lark of Latham, has the tail, the quills, and the covert of the wings brown, edged with white, the inferior part of the body white, variegated with oblong brown spots. Its length is eight inches. It is found at the Cape of Good Hope.

27. A. cinerea, la cendelle of Buffon, cinereous lark of Latham, is of a cinereous colour; its belly and vent white; the quills of its wings and tail brown, the outermost externally white near the tip. Its length is six inches. Buffon queries whether there be any analogy between this bird and the cinereous lark which Dr. Shaw saw in great numbers near Bilerta, in Africa?

28. A. rufus, la variole of Buffon, rufous lark of Latham, has its tail quills brown, the eight intermediate ones rufly-coloured at the edge, and the outermost white at the edge. The bill is brown; the body blackish above, variegated with rufous tints, and below white; the feet are yellowish; the length five and one-fourth inches. Comerfon brought this beautiful bird from Buenos Ayres, near the river de la Plata.

29. A. Novae-Zelandiae, New Zealand lark of Latham, has white eyebrows, a black bar on each eye, its vent cinereous, and odd, and its feet reddish cinereous. It is seven and a half inches long. The bill is aliy black above; the body black above, white below, the feathers edged with a pale colour; the claws black, the hind one almost straight. It is found in New Zealand.

30. A. mongolica, mong hol lark of Latham, has the crown of the head ferruginous, bound with a white annular fillet, and in the middle a white spot. It is larger than the calandra, which it resembles; it sings sweetly on the ground, and inhabits the saline marshes that lie between the rivers Onon and Argon.

31. A. fabicula has the f-conditions white, the crown of the head, ears and fladers ferruginous, and the outer tail quill externally altogether white. It inhabits the fields of Siberia, near the Irus, feeding on the ground, in its flight and song inferior to the i77, in stature larger, and similar to the calandra.

32. A. flava, la couture de pierre of Buffon, has the upper part of its body red and grey varied with brown, the under part whitish, the face, throat, and sides of the head yellow, the tail quills black, edged with grey, except the outermost which are white at their margin. The yellow of the face, &c. is set off by a black spot between the eye and the bill, that joins to another larger one immediately below the eye; and the breast is ornamented with a broad black girdle. The bill and feet are leaden-grey. Its length is five and three-fourth inches. It inhabits Siberia, but is rarely found. Of all the birds denominated larks, this is the most conspicuous for beauty of plumage.

33. A. obsoleta has the under part of the body white without spots, and the posterior claw shorter than the toe. It inhabits Sardinia, and agrees with the common lark in its size and nearly in its colour, but as the hind claw, though longer than the others, is shorter than the toe, Gmelin quires whether it belongs to the genus alandra.

The alauda hirundinis, or yellow lark, is black, variegated with rufous and white. It is found at the lake Yelton, beyond the Volga; it is gregarious, and in the month of August is fat and delicious.

The A. obsoleta of Latham, or dufky lark of Lewin, is now described under the name of the A. petrosa, or rock lark, by Mr. G. Montagu. Its specific characters are, that it is olive brown, yellowish under the body, the sides of the neck and breast are spotted with brown, and the half of the outermost tail quill is white. Mr. M. in 1791 discovered this bird to be a native of the coast of South Wales, in all the rocky situations; and it was known to the fishermen, under the name of the rock lark. Mr. Pennant is suppos'd to have met with this bird, as in hisfolio edition of British Zoology he has given a variety of the tail (A. petrosa) with downy legs, that on the rocks on the coast of Caenorne; This bird affords only the rocky parts of the coast; and in winter it is occasionally found in the marshes, seeking its food, which is marine insects. It begins its song early in the Spring, which very much resembles that of the A. pratensis; as it mounts in the air like that bird, and returns again to the ground, or to some neighbouring rock, with motion-less wing. It breeds early in the Spring, a nest with five eggs having been found on the 16th of April; it was placed upon the shelf of a rock, between a tuft of coarse grass.
grafs, under a small bulk, and was formed of dry grafs, marine plants, and dry mofs externally, and lined with finer grafs and a few long hairs. The eggs were of a dirty white, sprinkled with numerous specks of brown. The length of the bird was six and three-fourths inches. Mr. M. has lately observed this bird on the coast of Kent and Suffolk. Transact. of Linnæan Society, vol. iv. p. 41—43. Gmelin's Linnæus's Syll. Nat. tom. i. p. 791—801. Buffon's Birds, vol. v. p. 1—77.

ALAUNA, in Ancient Geography, a town of Britain, belonging to the Danni, situated, according to Horfley, near Falkirk, upon the Roman wall, at a place called Ca- melon, where are still some vestiges of a Roman town; but Baxter maintains, that it was where Sterling now stands. Alauna was also a town of Gaul, placed by M. d'Anville among the Ineili, north of Coffedia, and west of Crocia- tonum.

ALAUNI, a people placed by Prokny in Noricum and also in European Sarmatia; probably the same with the Alani.

ALAUNIUM, a town of Gaul, placed by M. d'Anville in the mountains between Sagunfero to the north-call, and Apta-julia to the south-call.

ALAUNUS, a river of Britain, which Horfley supposes to be the Tweed, but Camden and Baxter think it is the river Alne, in Northumberland; and their conjecture is favoured by the affinity of the names.

ALANUS mons, a name given by the ancient geographers to the Valayd mountains of Russia.

ALASA, or ALOSA, in Ichthyology, a species of clupea. See Snad.

ALAUSI, or ATUASI, in Geography, a town of South America, in the jurisdiction of Cuenca, in Terra Firma.

ALAVI, or ALI, a river of Turkey in Europe, which rises in the mountains that separate Moldavia from Tran- sylvania, and runs into the Danube near Nicopolis, in Bulgaria.

ALAY, denoting, in the Turkish language, "the triumph," in Modern History, a ceremony which accompanies the assembling of the forces of the Turks upon the breaking out of a war. It is described by Baron Tott, in his memoirs, as a kind of masquerade, in which persons of the several trades and manufactures prevalent to the spectators the implements and exercise of their respective occupations. The labourer draws his plough, the weaver handles his shuttle, the joiner his plane; and these persons are seated in cars, richly ornamented, and commence the procession; then follows the standard of Mahomet, which is brought out of the kragho, and carried to the army, in order to ensure victory to the Ottoman troops. An emir precedes this banner, proclaiming with a loud voice, "Let no infidel dare to profane with his presence the holy standard of the prophet; and let every mussulman who perceives an infidel, make it known, under pain of reprobation." From this moment, a religious fury seizes the people, and impels them to commit acts of the most shocking barbarity. No regard is paid to sex or age, and many fall sacrificial on the occasion.

ALAYA cape, in Geography, the easter extremity of Venezuela, or Little Venice, which extends to and from the entrance of the gulf of that name, 150 leagues.

ALAYMO, MARC ANTHONY, in Biography, a Sicilian by birth; in the year 1610, being then only 20 years of age, was made doctor in medicine. He then went to Palermo, where he was particularly celebrated for his success in treating the plague, which raged in that city, in the year 1629. He died in 1663, aged 72 years, and was buried in the church of St. Mary of the Agoulers. In whar-...
mountainous paffes, and secluded from all means of escape; and it was therefore chosen for the state-prison, to which the Romans configned captive princes, after having barbarously dragged them through the streets of Rome, at the chariot-wheels of a triumphant consul. Here Perseus, king of Macedon, and his son Alexander, terminated their career, after the triumph of Paullus Emilius. Syphax, the Numidian, and Bithynus, king of the Amorans, were also condemned to this gask, by the particular elemancy of the senate, which sometimes indulged its savage disposition, by putting its captives to death. The natural security of this place was augmented by artificial fortifications; the ruins of which prove, at this day, their ancient solidity. For the entertainment of the garrison, which was required in a place of such importance, an amphitheatre was erected, the flattered remains of which are still visible, as well as the foundations of a temple, and other buildings, of Roman times. Lucius Vetellius, brother of the emperor of the same name, had a villa near this place, famous for the variety and excellence of its fruit-trees, which he brought from Syria. His gardens were the nurseries, where several of the most delicious fruits that are now so common in Europe, were first cultivated and multiplied. Against the severity of this climate, in which the adjoining lake is frequently frozen over, it was necessary to shelter the trees transplanted from Asia, and to treat them with peculiar attention, in order to rear them to perfection. Swinburne’s Travels, vol. iv. p. 357.

Alba Helviorum, or Albagungula, i.e. Alba Augulia, a town of Gaul, in the provincia Narbonensis, was the capital of the Helvii, and situated at a small distance from the Rhone. Hence the Helvii were denominated Albenenses. This town was afterwards called Victuria, and it is now Viroiers.

Alba Julia, now Weissenburg, a town of Transylvania, on the river Maurinus or Marich, imposed to be called Alba Julia, after Julia Domna, the wife of Severus, and mother of Caracalla. There are several inscriptions, however, near this place, which bear Col. Apul. i.e. colonia Apulensis, without the least mention of Alba Julia, though they were inferred after the time of Caracalla. Besides, Ulpius, reciting the colonies of Dacia, calls this colony Alba Julia. The reason of these circumstances it has been inferred, that Alba Julia is a corruption of Apulium. It was also called Apulum Augustum. Cellarius, tom. i. p. 381.

Alba Longa, a city of Italy in Latium, south-east of Rome, founded by Alcæus, the son of Areus, and a colony from Lavinium, at the foot of mount Albanus, according to Blair’s Chronology, in the year 1152 before Chrill, or 359 years before the foundation of Rome; and selecled by him as the place of his residence, and the capital of his kingdom. It was called Alba, we are told, from a white fow found by Areus, which farrowed 30 pigs on that spot, and which afforded an omen, that a city would be built there within 30 years. See Varro, R. R. (l. xi. c. iv.) Aurelius Victor de origin. Rom. gentis, and Propertius, lib. iv. eleg. i. ver. xxxv.

“Et festict Alba potens, alba fuis omine nata.”

The epithet longa, was added to distinguish it from the Alba of the Marii, or to express its length, as it was extended along the lake near which it was built. Its situation was at an equal distance between the lake and the mountain; probably between the present city of Albano and the lake of Castel Gandolfo, and peopled by a mixed colony of Latii and Troians. The inhabitants of this city were called Albanii. It was 30 years after Lavinium was built, that Alcæus fixed his abode at Alba; and there he died, after a reign of about 38 years, 12 of which he pafted at his new settlement. Upon the death of Alcæus, the Latins resolved to unite Alba and Lavinium into one sovereignty, under Sylvia; and Sylvia was succeeded by 13 kings of the same race, who, for near 400 years, reigned at Alba. Pius, one of them, bequathed the throne to his eldest son Numitor; but he was displeased of the kingdom by his brother Amulius, who, in order the more effectually to secure himself, killed the son of Numitor, and consoled his daughter, Rhea Sylvia, to the worship of Vesta. Rhea, however, was delivered of the twins, Romulus and Remus; who, after having been rescued from the Tiber, to which they were thrown by order of Amulius, were suckled by Acca Laurentia, the wife of Faustulus, and educated by the Gabii, under the direction and order of Faustulus. Upon a quarrel between the herdmen of Amulius and those of Numitor, the two brothers took part with the former against the latter; and, in consequence of the fray that was thus occasioned, Remus was carried before Numitor to receive punishment. When he was questioned concerning his birth and parentage, his reply excited, in the mind of Numitor, a lively remembrance of his two grandsons, and his anger was changed into tenderness. The two brothers concurred at length in dethroning Amulius, and restoring their grandfather Numitor to the throne. They then, by the advice of Numitor, undertook to found a new colony on the lands near the Tiber, where they had been taken up, and which he granted them for this purpose. Romulus and Remus differed concerning the precise spot where the new city was to be erected; the latter declaring for the Aventine, and the former for the Palatine mount. Remus, as it is said, fell in the contest that was then occasioned, and Romulus prevailed, and laid the foundations of the new city, which was called Rome, after his name. Rome, in a little while, became the rival of Alba; and soon after the accession of Tullius Hostilius to the throne, a dispute arose between the Albans and the Romans, and preparations were made for war. In an interview that occurred between Tullius and Fufetius, or as others call him, Supplicius, the Alban general, Tullius, proposed to determine the dispute by a single combat between himself and Fufetius, which the latter declined. It was at length agreed, that the three captains should be selected out of each camp to decide the difference. The champions on the part of Rome, were the Horatii; and on that of Alba, the Curatii. Rome ultimately gained the victory over Alba, her mother city. When Tullius afterwards made war upon the Veientes, Fufetius joined him with the Alban troops, but afterwards proved treacherous and deserted him. This treachery being known, Tullius detached Horatius, who had conquered the three Albans, with a chosen body of horse and foot, to demolish Alba, as he had previously concerted the bullwinks with the senate. Fufetius was ordered to be fastened to two chariots drawn by horses, and to be torn asunder: his accomplices were put to the sword; but the rest of the Alban soldiers were carried to Rome with the citizens, and the chief men among them were even admitted into the Roman senate. Thus fell, A. U. C. 85, ante Chrill C. 54, the city of Alba, famous for its riches, the number of its inhabitants, and, above all, for being the mother of Rome. The temple only, says Strabo, was preserved. Dion. Hal. lib. i. p. 52. lib. iii. p. 152—165. tom. i. Ed. Oxon. Livy, lib. i. c. 3—7. c. 24—29. tom. i. p. 22—31. p. 101—124. Ed. Dres. u. 2. Plut.
ALB

Geog. tom. i. p. 350—353.
Alba Maritima, a city of Dalmasia.
Alba Pompeia, a city of Italy in Liguria, near the river
Ceno or Ceva, where the emperor Perinax was born. It
was a colony either established at first by Italy, or re-
formed, after having been first settled by the Albinus.
The inhabitants were called Altenae Pompeiani. It is now called
Alba, without any epithet.
Alba Regalis. See Stuhl-Wieslburg.
Alba Terra, in Albamy, one of the many names that
were anciently given to the philosopher's stone.
ALBACETE, or ALBAXTE, in Geography, a small
town of Spain, in the canton of La Sierra, in the eastern
part of New Castile, situate in a fertile vale not far from
the mountains that separate La Mancha from the country
called the Desert. W. Long. 17° 46'. N. lat. 38° 55'.
ALBACHSEN, or ALBASA, a town of Germany, in
the circle of Wetzlland, three miles north of Corvey.
ALBACK, a town of Perun, in the province of Aider-
beizan, 55 leagues south well of Paris.
ALBACE, is located on the western coast of Africa,
in N. lat. about 27° 15', and about 35 leagues south-west
from the river Niger. It has a bay so called, and a
cape denominated Capea.
ALBAN (Sr.), in Biography, the first Christian
martyr in England, and usually called the protomartyr of
Britain, was born at Verulam, of pagan parents, and flourished
in the third century. In his youth, he went to Rome, with
Amphilbas, a monk of Carlecon, and served seven years
in the army of Diocletian. On his return to England, he
was instructed by Amphibalus in the Christian faith, be-
came a convert, and lived in the profession of Christiani-
ty till the year 303, when the Diocletian persecution com-
enced; but being cited before the Roman governor, for
having afforded an asylum to his preceptor, who was a
Christian, and avowing his own conversion, he was ordered
immediately to be beheaded. The traditionary tales of
the times report many miracles which happened on occasion
of his death. Bede, and other ancient writers, relate, that
in his way to execution, a stream was miraculously divided
to afford a passage for him; and a thousand persons who ac-
companied him; that the executioner was converted by the
miracle; that a fountain opened at the feet of St. Alban,
which afforded water in answer to his prayer for allaying
his thirst; and that the eyes of the executioner dropped
out of his head at the instant of his giving the fatal stroke.
We learn from the fame authority, that many of the spe-
cators were converted by these miracles. But the testimo-
ny of those who report them deferves little credit; and they
seem to be duly appreciated by Milton, who, in his History
of England, speaking of St. Alban, says: "The story of
whole martyrdom, foiled and worse martyred with the fabling
zal of some idle fanatics, more foul of miracles than apprehen-
sive of truth, deferves no longer digression." When the
fall of the church of St. Alban's was repaired, in
1257, the labourers found four leaden chaffs, containing
tales; and on a plate of lead, the following inscription:
"In hoc manufo, inventum est venerabile corpus Sancti
Alban, protomartyris Anglorum!" i.e. "In this manu-
foleum i. found the venerable body of St. Alban, the pro-
tomartyr of the English." Part of the hymn formerly fung
on the festival of this saint, is as follows:
"Ave protomartyr Anglorum,
Miles regis angelorum,
O Alban, flos martyrorum!"

ALB

"Hail, protomartyr of the English,
Soldier of the King of Angels,
O Alban, flower of the martyrs!"
Bis. Brit.
See AMPHIBALUS.
Alban, John de St. fo called from the place of his
birth, and de St. Quintin, a church of that name in Pearsly,
where he was made a dean (doyen), taught philosophy and
medicine at Oxford, towards the end of the twelfth century.
In this station he acquired so much celebrity that he was in-
vited to Paris by Philip Augustus, and made his physician.
After residing some years at Paris, he went to Montpellier,
to hear the professors of that place, then famous for its school
of physic. Being distinguished for his great learning and
abilities, he was soon invited to fill a professor's chair. In
1223, he returned to England, Matthew Paris says, to at-
tend Robert Groffette, bishop of Lincoln. The time of his
death is not known. He was doctor and professor of theo-
logy, as well as of medicine, a junction at that time by no
means uncommon.
Alban, in Geography, a town of France, in the depart-
ment of Tarn, and district of Alby, 5 leagues E. S. E.
of Alby. The town contains 196, and the canton 6,234 inhab-
habitants. The territory comprehends 205 kilometres and 6
communes.
Albana, in Ancient Geography, a sea-port town of Al-
bania, on the Calpian sea: now called Bacha or Baka, whence
this sea is called mer de Bacha. N. lat. 40°. E. long. 49°.
Albanelia, in Geography, a town of Naples, in
the Principato Corvea, 20 miles south call of Salerno.
Albanenses. See Albignenses.
Albanesius, Guy Anthony, in Biography, taught
medicine in the University of Padua, from 1632 to 1657,
in which year he was afflicted by one of his pupils. He
published, "Aphorismorum Hippocratis Expeditio. Peripa-
tetica," Padavii, 1639, 4to.
Albani, in Middle Age Writers, denote strangers or
foreigners; corresponding to those whom we call aliens.
Albani, in Antiquity, a college of Salii, or priests of
Mars, instituted by Tarquin, and denominated from mount
Albanus, the place of their residence.
Albani, or Albano, Francis, or Francisco, in
Biography, an eminent painter, was born at Bologna, in
1578, and educated with Guido, who assisted his early
studies, first at the school of Dennis Calvata, and afterwards
under the Caracci. He completed his studies at Rome,
working after the best models, and became one of the most
agreeable painters of the Roman school. At Rome, where
he resided 18 years, he was employed in some great works,
and there he married his first wife, who died in child-birth.
From hence he removed to his native town, and married a
beautiful woman, by whom he had 12 children, who served
him for models in the practice of his art. Albani converted
his children, who were very beautiful, and who were placed
in different attitudes, into Cupids, and the mother into a
Venus or grace; but, graceful as were his models, by con-
stantly painting after them, he preferred too great a similitude
in his figures, and in the air of his heads. His man-
ner, however, may be thus easily distinguished. In
the summer months he retired to one of his country houses,
which was adorned with fountains and groves, and here he
was furnished with landscape scenery, in his favourite sub-
jects of love and grace, which he treated with an elegance
of design, harmony of colouring, and delicacy of form,
that are the characteristics of his pencil. All his pictures
indeed, have not the same force of colour, but though
some are weaker than others, they are all delicate and plea-
ing. His boys and female forms were lovely and graceful; but
but his figures of the other sex were usually lean and without masculine beauty, except in some of his heads. In his drawings he was sometimes hasty and incorrect. His pictures of the four elements in the palace of the Sardina, at Turin, are of an extraordinary beauty, and well preferred; the design is excellent, the draperies perfectly elegant, the colouring lovely, and the whole very correct. His other principal works are at Rome and Bologna; but as he was extremely industrious, and the productions of his pencil were highly esteemed, his cabinet pictures are found in all considerable collections. As an engraver, he made one small folio etching of Dido killing herself, in which he did not succeed; and in this art he did not add to the character which his other works have established. He was fond of Italian poetry, and lamented that his early education had not enabled him to read the originals of the Latin poets. In private life he was model, affable, unexceptionable, attached to his family, placid in conversation, confiding in his pupils, whose works he occasionally retooched and improved. His life and faculties were continued to old age; and he died at Bologna, in 1666, aged 82 years. Pilkington and Strutt. Gen Dict.

**ALBANIA,** Giovanni Battista, was the brother and disciple of the former, and became admirable in every style of the dandy, manner, and colouring of his brother. He excelled in landscape, which he designed in an exquisite taste, touching the trees with great spirit, and giving them a peculiar sweetness of colour. He died in 1668. Pilkington.

**ALBANIA,** John Jeron, was born at Bergamo, of a noble family, and devoted himself to the study of the civil and canon law. By the zeal with which he prosecuted fore of his own relations in the Inquisition, he recommended himself to Cardinal Alexandrinus, the inquisitor, who, upon his being advanced to the papal see, under the name of Pius V., conferred upon Albani a cardinal’s hat. He died in 1591. His works are a treatise *De immittante Ecclesia?* published in 1553; another, *De potestate Papae et Conciliis,* printed at Venice, in 1561; and a third, *De Carolibus, &c.* Nouv. Dict. Hist.

**ALBANIA,** in History, the inhabitants of **ALBANIA,** in Asia, who are said by some writers to have derived their name from their fair complexion. Potema mentions a people of this denomination on the confines of Macedonia. The Albanians, in Ancient Geography, a country of Asia, was bounded on the west by Iberia, on the east by the Caspian sea, on the north by Mount Causaceus, and on the south by Armenia. The cities which it contained, and mentioned by Strabo. Potema, and Pliny, were Telea, Thalbis, Gelda, Thauna, Thablica, Albana, Khadaca, Miha, Boziata, and Calabac, which last Pliny calls the metropolis of Albania. Its chief rivers were Cyrus, now Kurr, Albanos, Catus, Gerras, Soana, Cambyses, and Alazon, all of which discharged themselves into the Caspian sea. The whole country, now known by the names of Schirwan and East Georgia, is extremely fertile and pleasant. Strabo (tom. ii. p. 767.) describes the inhabitants as tall, robust, and graceful in their persons, excelling those of other nations in comeliness as well as in stature, and as very simple in their manners. He adds, that they were unacquainted with weights and measures, and the use of money; that they could not count above one hundred, and that they carried on trade by exchange. They chiefly devoted themselves to pasturage, and had some resemblance of the wandering tribes; they were not altogether unacquainted with the art of war, nor unused to the practice of it; their common weapons were bows and arrows; they defended themselves with shields, and bore on their heads helmets made of the skins of wild beasts. They excelled in hunting, and were famous for the dogs which they reared for this purpose. They respected age, both in their parents and others; they thought it wrong to take any notice of the dead; they buried their money with them, and lived in poverty, as they had thus no property. They worshipped, as gods, the sun, Jupiter, and the moon; and the priest was next in honour to the king. Pliny (H. N. tom. i. p. 371.) says, that they were of a white complexion, and that they could see by night as well as by day. Tacitus (lib. v.) and Pliny (tom. i. p. 311.) trace their origin to the Theliadians, who attended Jason in his expedition to Colchis, and settled in this part of the iilmus, between the Naxus and Baptistian seas. According to Justin (lib. xiii.), they were descended from the inhabitants of Alba in Italy; and Ammianus Marcellinus derives them from the Massagetae. Albania was an ancient divided into several small kingdoms; and Strabo (lib. i. p. 463.) says, that the country had 26 different languages, and as many kings and kingdoms as languages. But the Albanians, in process of time, overcame the other petty princes, and made themselves masters of the whole country. In the time of Pompey, as we learn from Strabo, they could bring into the field 70,000 foot, and 20,000 horse. Of other things we have no account before the reign of Alexander the Great, to whom the king of Albania is said by Ptolemy (tom. i. p. 164.), to have offered a dog of extraordinary size and faithfulness. The next king, mentioned in history, and named Orases, was defeated by Pompey, and obliged to retire to Mount Caucasus. Another king of Albania, named Pharamenes, committed great devastations in Armenia, Cappadocia, and Media, in the time of Adrian, and was summoned by the emperor to Rome. Instead of attending, he sent a number of such great consuls as were then worn, made of cloth of gold, in which the emperor, as an insult to the king, ordered 300 criminals to be clad, and in that attire to fight the wild beasts in the public theatre. Upon Adrian’s death, the Albanian king attended the funerals of Antoninus Pius, who received him with respect and distinguished him with presents. Two other kings are mentioned; one the contemporary of Vespasian, and the other of Constandinus. The son of Constandinus the Great. The Albanians continued to be governed by their own princes till the reign of H. who is laid by Zonaras and other writers to have subdued Albania by his general Lontius. Anc. Univ. Hist. vol. ix. p. 122—126.

**ALBANIA,** a city of Alia in Ail, was situated to the east of the country Titan. **ALBANIA,** in Modern Geography, sometimes called Armnaut, a province of Turkey in Europe, comprinsing the ancient Illyricum and Epirus, situated in the Adriatic, and bounded on the north by Dalmatia and Servia, on the east by Macedonia and Thessaly, on the south by Lacedaemon, and on the west by the Adriatic. Its length is about 50 leagues, and its breadth about 20. Its capital wa formerly Albanopolis; but it is now Durratz. The other principal towns are Scutari, Doliche, Antervari, Croya, Alcasta, Velona, Dataro, Dobra, &c. The most remarkable river is Delisch, formerly Acheron; amongst the lakes we may reckon Scutari, and to the cliffs of mountains we may refer the Acracrian, or mountains of Chimara. The soil of this province is fertile, and produces excellent wine. Its manufacture is chiefly carpets. Its inhabitants are robust and courageous, and make good soldiers, especially cavalry. In the Turkish army, they are distinguished by the name of armnauts. The religion of Albania is that of the Greek Church. This province was annexed to the Ottoman empire.
ALBANUM, in Ancient Geography, a town of Pannonia. 
Albanum Pompeii, a name anciently given to the present Alban.

ALBANUM morta, a name given by Pliny to that part of the Caubian sea which bordered on Armenia.

ALBANUS, Joanus, in Biography, was received Doctor in Medicine at Bologna, in the year 1616, where he taught the theory and practice of physic several years, and published a treatise on the regimen to be observed by convalecients.

ALBANUS, in Ancient Geography, a river of Albani, thought by M. d'Anville to be Saruma.

ALBANUS Moni, the mountain adjoining to Albis Longa or Alban; and also a part of the Alban Moni of Strabo, which the Ancients considered as forming the extremity of the Alps, and together with the Montes Balbi separating the further Liburnia and Dalmatia from Pannonia.

ALBANY, a county of America, on Hudson's river, in the state of New York, lies between Ullet and Saratoga. Its extent is 46 miles by 25. By the census in 1796, the number of electors in this county was 5887, and the number of troops 6021.

ALBANY, the chief town of the above county, is situated on the west bank of Hudson's river, 160 miles north of the city of New York, and 542 south of Quebec. N. lat. 42° 35'. W. long. 73° 30'. This town and the suburbs, in 1797, contained 6021 inhabitants. The situation of Albany is peculiarly favourable for residence and for commerce. It is at the head of a fleet navigation on one of the noblest rivers in the world; the air is salubrious; and by the improvements of roads and canals, which are contemplated, it is expected to increase and flourish. The public buildings in this town are a low Dutch church of ancient and curious construction, one for the Episcopalian, two for Presbyterians, one for Germans or Dutch, and one for Methodists; an hospital, city hall, and well-built brick gaol. The corporation consists of a mayor, recorder, six aldermen, and as many assistants. In the vicinity of this city there are extensive works, in which the machinery is moved by water, for the manufacture of Scotch and Rappee, fustian, and cut tobacco, chocolate, mulberry, flannel, hairpowder, split pease, and hulled barley.

ALBANY, a British fortres in New South Wales, in North America, situated on a river of the same name. N. lat. 52° 14' 40'. W. long. 81° 59' 58".

ALBANY River, a river of North America, which, after running in a north-east direction, and communicating with several small lakes, falls into James's bay, in N. lat. 51° 30'. W. long. 84° 30'.

ALBARI, in Botany, See CANNA.

ALBARI, in Ancient Geography, a town of Syria, on the borders of Phoenicia.

ALBARAZIN, or Albaracin, in Geography, a fortified town of Spain, in the kingdom of Aragon, on the river Guadalquivir, and near the frontiers of New Castile, is the site of a bishop, suffragan to the archbishop of Saragossa, and famous for its excellent wool, called by this name. It is 20 miles south-west of Saragossa, and 40 miles east of Madrid. N. lat. 40° 32'. E. long. 2° 16'.

ALBARDEOLA, in Ornithology, a name given by many authors to the spoon-bill.

ALBARI, in Antiquity, properly denoted those who gave the whitening to earthen vessels, &c. In which sense they flood contradiinguiished from dealbation, who whitened walls.

ALBARIUM opus, in the Ancient Building, the incrustation or covering of the roofs of houset with white plaster, made of mere lime. The workmen were called albin or albari. This
This is otherwise called *opus album*. It differs from *terre-rium*, which is a common name given to all roofing or ceiling, including even that formed of lime and sand, or even lime and marble; whereas Albarium was restricted to that made of lime alone.

**ALBAS**, in *Geography*, town of France, in the department of Lot, three leagues west of Cahors.

**ALBASANO**, a town of Albania, in European Turkey, 132 leagues west of Constantinople. N. lat. 41° 30'. E. long. 20° 15'.

**ALBASTRA**, an ancient town of Egypt, on the Arabian coast; the inhabitants of which are called by Epiphanius Albalrides.

**ALBATEGGI**, in *Biography*, a celebrated astronomer of the ninth century, was a native of Batan, in Mesopotamia, and hence called Al Battani, or Albateni. As Batan was one of the dependencies of Harran, he was also denominated Mohammed Ebn Jaber Ebn Seman Abu Abdallah al Harrani and Mohammed of Aractus. His astronomical observations were made about the years 882 and 883, at Antioch, and at Araca or Aractus, a town of Chalced; and Blair, in his chronology, dates the time of his death about the year 888. Dr. Halley highly commends him (Phil. Trans. for 1693, No. 204), as a man of admirable genius, and an excellent observer, though he detects many errors in the editions of his works. He observed the autumnal equinox at Aractus on September 19th, one hour and 15 minutes after midnight, A.D. 883; and he also observed, about 883, that the first star of Aires was 18° 2' from the equinoctial point; he notes the obliquity of the ecliptic at 23° 31', and the motion of the sun's apogee, since Ptolemy's time, as well as the motion of the stars, one degree in 70 years. He computed new astronomical tables, instead of those of Ptolemy, which were imperfect, and adapted them to the meridian of Araba or Raca; and they were long used as the basis among the Arabs. He also composed a work, entitled "The Science of the Stars," comprising all parts of astronomy, according to his own observations and those of Ptolemy. This work was translated into Latin by Plato of Tiber, and published at Nuremberg in 1537, with some additions by Regiomontanus; and reprinted at Bologna in 1645, with the notes of this author. The Alphonsine tables of the moon's motions were founded on the observations of Albategni. The original Arabic of this work, which was never published, is in the library of the Vatican. Blair's Chronol. No. 38. D'Herbelot Bibl. Orient. Hutton's Math. Dict. vol. 1. p. 59, &c.

**ALBATEL**, in *Geography*, a cape on the coast of Barbary, about 12 leagues north-east of Cape de Tenes, within which are several good roads, particularly at Marsolach, to the west of Cerelli island and point.

**ALBATENIUS**, an Arabian physician, lived towards the end of the 11th century, contemporary with Serapion. He translated the works of Galen into Arabic.

**ALBATI equi**, in *Antiquity*, was a denomination given to those horses in the games of the circus, which were distinguished by white cloths or furniture. In which sense, they are contradistinguished from ryfari, prafin, and veneti.

**ALBATROSS**, in *Ornithology*. See Diomedea.

**ALBAZIN**, in *Geography*, a town of Great Tartary, in the road from Pekin to Mofcow, situated on the river Amur, and defended by a good fortress against the attacks of the Chinese and Tartar Monguls. N. lat. 54°. E. long. 104° 14'.

**ALBE**, in *Commerce*, a small coin, current in Germany, valued at a French sol and seven deniers.

**ALBEC**, in *Geography*, a river of Switzerland, runs into the Rhine, near Furkellen.

**ALBECK**, a town of Germany, in the district of Ulm, which is the capital of a province of the same name, is situated on the river Alb, five miles north-east of Ulm, and eight miles west-north-west of Augsburg. N. lat. 48° 2' J. E. long. 6° 58'.

**ALBECOR**, in *Ichthyology*, the *Scomber thynnus* of the Linnaean system.

**ALBEGNA**, in *Geography*, a river of Tuscany, runs into the sea between Telamon and Orbittella.

**ALBEKIRK**, a town of Holland, 13 leagues south-west of Medemblick.

**ALBEL**, a river which rises in Mount Abel, in the country of the Gréans, and discharges itself into the Rhine near Bergun.

**ALBELDA**, a town of Spain, on the river Iregua, in the country of Rionca.

**ALBELEN**, in *Ichthyology*, called also *Albula, and remembering the farra*, caught in the German and other lakes, is a fish of a fine silvery white colour, and from five to fix to twelve pounds in weight.

**ALBELLA**, in *Conchology*, a species of *Helix*, with an umbilicated smooth shell, the under part gibbous, and a femicircular aperture; found on the rocks of Europe.

**ALBELEMARLE, AUMARLE OF AUMALE, in Geography*, a town of France, which gives the title of Earl to the noble family of Keppel. See Aumale.

**ALBELEMARLE, a county of America, in the latitude of Virginia, lies between the Blue Ridge and the Tide Waters, and contains 13,365 inhabitants, in an extent of about 35 square miles.

**ALBELEMARLE Port**, a spacious bay or harbour, on the southern coast of Falkland islands, is situated between Fox bay and Port Stephens, and may be known by a small island off the entrance.

**ALBELEMARLE Sound**, an inlet of the sea, on the coast of North Carolina, 60 miles long, and from eight to 12 broad. It communicates with Pamphio sound, and with Currituck inlet, and receives Roanoke and Mcherrin rivers. The passage into it from the sea is called Roanoke inlet. N. lat. 35° 50'. W. long. 76° 10'.

**ALBEN**, a town of Austria, in the inner Carniola, is environd on all sides with high mountains, large forests and deferts, and is distant two miles north-west from Cirknitz. There are mines of mercury in the vicinity of this town. From the mountain of the same name on which it is situated, called also *Monte del Corso*, the river Alben flows, which runs into the gulf of Venice, between Laubach and Capo d'Illria.

**Albenic**, a lake of Austria, 13 miles west of Windisch-Garten.

**ALBENGIA**, a small island on the coast of Genoa, opposite to the town of Albenga, and called also Gallinara.

**ALBENGUA, or ALBENCA, anciently *Albinum Inganum, or Albingaenum*, a sea-port town of Italy, in the territory of Genoa, is the see of a bishop, suffragan to the archbishop of Genoa. It was formerly a very considerable and well-fortified town, but has suffered by the wars, and is deferted on account of the insalubrity of the air. The vicinity abounds with olive trees, and produces great quantities of hemp. It was burnt by the Pisans in 1175, but rebuilt by the Genoese. It is about 15 leagues south-west of Genoa. N. lat. 44° 43'. E. long. 5° 13'.

**ALBENQUE**.
ALBENIQUE, a small town of France, in the district of Calvados, and department of Lot, distant 6 leagues from Montauban.

ALBEOLA, in Orimontology, the Anas albofus of the Linnean System of Gmelin, the quercus siberiana of Buffon, little black and white duck of Edwards, the spirit of the Arctic Zoology, and the white and black falcine or nun of Buffon, is specifically distinguished by a white colour; black back and wing-quills, bluish head, and back of the head white. Its white robe, and white band with a black cap and mantle, have given occasion for calling it religieuse, or nun. The back of the head is decorated with green and purple lute, and the white band encircles it behind from the eyes. The Newfoundland fishers call it spirit, as Edwards fugelists, because it is a very nimble diver, appearing at great distance, very soon after it has plunged. It is found in America, from Hudson's Bay to Carolina, and forages in trees near fresh water.

ALBERCHE, in Geography, a river of Spain, which runs into the Tagus, near Talavera.

ALBERDORF, a town of Austria, on the river Bulekau, seven miles call of Schirattental.

ALBERGOTTI, FRANCIS, in Biography, an eminent civilian, of the 15th century, studied under Baldi, and excelled in the profession at Arezzo, in the rate of Florence; but removing to Florence, he was there emulated. His character for integrity is no less applauded than his skill in the law; so that the appellation annexed to his name is, "folice veritas doctor," or the teacher of solid truth. He wrote "Commentaries on the Digest," and some other pieces in law; and died in 1526. Gen. Biog.

ALBERGIS, JOHN, a native of Mazaran, in Sicily, where he practised medicine with success, towards the end of the 17th century, published at Parma in 1725, "Summa Tractatuum Chirurgicarum praeceps, 12mo."

ALBERIC, or ALBERT, a French historian, was canon of the church of Aix in Provence, in the 13th century, and wrote a history of the first crusade, from the reports of those who attended it. His narrative extends from 1095 to 1129, and is contained in two distinct works, viz., "Chronicon Hierofoliensis," printed in 4to, at Helmanstadt in 1584; and "Gesta Dei per Francos," in folio, 1611. Gen. Biog.

ALBERIZZI, PETER JOSEPH, studied medicine at Pisa, and practised several years at Milan; where he died 1722, aged only 31 years. He published "Critologia Medica de causis his peliterie, ejusdemque cura, qua vermiculii, de quibus faminiarii nonnulli, exploduntur."

ALBERNUO, in Conmune, a kind of cambric brought from the Levant, by way of Marailles.

ALBERONE, in Geography, a town of Naples, in the province of Casilinata, eight miles south-west of Volturara.

ALBERONI, CARDINAL, in Biography, a celebrated statesman, was born at Placentia in Italy, in 1604, and employed till the age of 14 in the occupation of his father, who was a gardener. Having received M. Campbell, secretary to the duke of Vendome, when he was robbed near the village where he lived, he was recommended by him to his general, who took him into Spain. From this menial low state he rose by several gradations to the dignity of cardinal and archbishop of Valencia, and to the office of prime minister, in the court of Spain. For both these honours he was indebted to the patronage of the princes of Parma, whose marriage with Philip V. he had projected and accomplished. His disposition was intriguing and enterprising: and not content with effecting some domestic reforms and arrangements, he formed the design of an expedition against Sarum and Sicily, and in order to prevent the interference of other powers, he made an alliance with Czar Peter, Charles XII. of Sweden, and, as some say, with the Ottoman Porte. He also proposed exciting the Turks to make war on the emperor, to advance the Pretender to the throne of England by means of Peter and Charles, to dethrone the duke of Orleans in the regency of France, and to annihitate the German power in Italy. But an union between England and France was the result of the discovery of this plan; and both these powers concurred in declaring war against Spain in 1719, and the condition of peace was the removal of Alberoni, and his abandonment from the kingdom. Having received an order in Dec. 1720, to quit Madrid in 24 hours, and to leave Spain in a fortnight, he retired with great wealth; nor was it discovered before he had been two days on his journey, that he had taken with him the tell-tale of Charles II. of Spain, which appointed Philip universal heir of the monarchy. The infringement was wrested from his possession by force, and purifying his journey to Genoa, he was then arrested by order of the popes, on the charge of negotiating with the Turks. On his execution, and subsequent liberation from the convent of the Jesuits, to which he was confined for a year, he engaged in new intrigues, and particularly in an unsuccessul enterprise against the small republic of St. Marino. A bon mot of Benedict XIV. on this occasion was very generally circulated: "Alberoni is like a glutton, who, after having eaten a large salmon, cannot help calling a wishful eye at a minnow." His views were more hostilely directed to the establishment and encouragement of a seminary of education for poor felhalls in his native city. Alberoni professed his health and vivacity to old age; his conversation chiefly turned on the recall of his own exploits, and was instructive and amusing; though in his temper he was irascible and impatient of contradiction. He died in 1750, at the advanced age of 87; and left behind him the character of "a great politician, as daring as Richelieu, and as simple as Mazarin, with as little principle as either." His life, to the year 1711, has been published by John Roulet, translated from the Spanish. A pretended "Political Tell-tale," in the name of cardinal Alberoni, printed in 1753, is considered as impious. Nouv. Dict. Hist. Gen. Biog.

ALBERSTROFF, in Geography. See Alberstroff. ALBERT, I., duke of Austria, and emperor, was the son of the emperor Rodolphus, and a competitor for the Imperial crown with Alphonsus of Naples, whom he deposed and killed in battle. Before this victory, he had been elected king of the Romans; but, when his election would be contested, he obtained the confirmation of it, and was solemnly crowned at Aix-la-Chapelle, in the year 1298. He began his reign with renewing the ancient leagues between the emperor, and with forming a treaty of marriage between his son Rodolphus and Bacche, the daughter of Philip the French king. The alliance with France was protested against by the three ecclesiastical electors, and upon the emperor's appeal to pope Boniface, with a demand that he would ratify his election, the pope declared that it was null and void, and that Albert ought to be treated as a murderer. Boniface proceeded, upon the complaint and remonstrance of the electors, to prohibit the subjects of the empire from acknowledging the claims of Albert, and to release them from the obligation of their oath of allegiance. The emperor, incensed at the conduct of the ecclesiastical electors, declared war against them, and inward complicity on his part to sue for peace. In 1299, the pope having quarrelled with Philip the Fair of France, made advances to Albert,
Albert, confirmed his election, invited him to Rome to receive the Imperial crown, and exhort him to declare war against Philip, whom he had excommunicated. The conditions, however, were humiliating; but the emperor acquiesced, and agreed to take the oath of allegiance to the pope, after acknowledging that kings and emperors received the power of the temporal sword from the holy see, and confining to perform all the promises made by Rodolphus and his predecessors, and to defend the rights of the holy see against all its enemies. Before this reconciliation between the pope and the emperor took place, Albert had engaged in an unsuccessful war with John d'Aves, next heir to John count of Holland, who had lately died, under a claim of his dominions, as feifs reverible to the empire. The war terminated with a stipulated condition that John d' Aves should enjoy the countries of Holland, West Friesland, and Zeeland, in consideration of doing homage to the emperor, from whom he accordingly received the investiture of those dominions. Albert, likewise, in 1302, invaded Bohemia, but was obliged to retreat with loss. But upon the death of Wenceslaus the younger, who was affiliated by his subjects, and who died without issue, the emperor feized Bohemia, and placed his son Rodolphus on the throne; but Rodolphus dying suddenly, Albert could not secure the crown for his next son, Frederic. His next object was to support Philip of Nassau, brother of Adolphus, the late emperor, in an unjust attempt to recover Mina and Thuringia from the rightful possessors; but this exploit terminated in a disgraceful defeat. In another instance he was no less mortified, but the event proved singularly important. The three cantons of Uri, Switz, and Underval, though they do not seem to have been in any respect dependent upon the house of Austria, had voluntarily fought the protection of Rodolphus; and he treated them with great indulgence, and defended their rights and privileges, without ever considering them as feifs of the house of Austria. But the conduct of his son Albert was directly the reverse: he wished to govern them as an absolute sovereign, and had formed a scheme for converting Switzerland into a principality for one of his sons. By his own infatuation and oppression, and the similar conduct of the governor whom he appointed, they were so aggrieved and incensed, that the three cantons above-mentioned formed a confederacy for the purpose of emancipating themselves from the Austrian yoke. They succeeded in their efforts, and retrieved that liberty which they have since enjoyed. The other cantons soon engaged in the confederacy, and thus was laid the foundation of the Helvetic republic. Albert was uniformly influenced by a spirit of rapacity, and an unwarrantable desire of aggrandizing his own family; and he at length fell a sacrifice to his ambition and avarice. Having refused to put his nephew John, duke of Sabaia, in possession of his paternal estates, which, it was thought, he desired for one of his own sons, the nephew formed a conspiracy against him. With this view, he engaged three confederates who contrived to meet Albert on his progress from Bali to Rheinfelden, after he had crossed the river Rhees, near Schaffhausen; and John, having stabbed him in the throat, his accomplices completed the Amurer in the fight of his son and their attendants, who were incapable of affording him any succour. In the place where the emperor was slain, A.D. 1308, a cloister was built, and called Koningsfelt, from whence his body, after having been deposited there for some time, was carried to Spirx, and kept among his predecessors. His character has been differently appraised by different writers. Some represent him as a Prince of a brutal disposition and manners, and of the most fordid ava-

rice; whilst others describe him as a prince of singular courage and address, and distinguished by an excellent understanding, and an inviolable attachment to truth. All agree, however, in charging him with an infatuable degree of avarice. It is said, that he equally abhorred flattery and flattery; and that there were three sorts of persons for whom he had a particular regard, viz. women of honour, men of courage, and pious ecclesiastics. He was called 'the Triumphator' on account of his generosity and valour, and the many victories he obtained over his enemies; and the 'encouraged,' because he had often, by the operation of poison, which was given to him at his own palace in Vienna, about three years before he was elected emperor. Albert by his wife Elisabeth, daughter of the duke of Carinthia and Gorycia, had six sons and five daughters. By his eldest son Albert, succeeded the 'Counterfeit,' the male issue of the family is derived. Mod. Un. Hist. vol. xxvi. p. 130. 14.

Albert II. duke of Austria, and emperor, succeeded the 'Grave and Magnanimous,' was the son of Albert of Austria, called the 'Wander of the World,' and married Elisabeth, daughter of the emperor Sigismund. By his wife he conducted he re-established the security of his Austrian subject, which had been for a long time interrupted by intestine wars and rapine; and if his life had been prolonged, he would probably have been the greatest prince that ever sat upon the Imperial throne. In one year, he was honoured with three crowns. To the Hungarian throne he was advanced in consequence of the will of Sigismund, whose daughter and heir he had married; and he was elected king of Bohemia, in consequence of a convention between the two families, which stipulated, that when the lawful heir male of the house of Bohemia should chance to fail, the crown should devolve upon a prince of the house of Austria. The throne, however, was disputed by Cemir; but after a successful struggle secured by Albert, who was crowned at Prague. During his conflict with Cemir, he was elected emperor at Frankfurt. After his election and coronation at Aix-la-Chapelle, it was his chief care to reform the administration of justice, and to abolish the tribunal, called the secret or Welphalia judgment, which condemned without trial, or even public accusation. He also conformed the neutrality which had been adopted by the German electors and princes, with regard to pope Eugenius and the council of Bâel, and by the mediation of the pope and council he concluded a peace between Hungary and Poland. When Bulgaria was invaded by Amurath, the Turkish Sultan, Albert took arms in its defence, and marched to Buda; but being there feized with a violent dysentery, he was under a necessity of returning to Vienna; and in his way thither the disorder proved fatal, A.D. 1439; and he was interred at Weissenburg. He left a pithomous son, and two daughters. In one of the diets which were held at Nuremberg during the short reign of this prince, Germany was divided into four circles, viz. Bavaria and Franconia, the countries about the Rhine together with Allemnia, Welphalia and the Low Countries, and Saxony. In another diet, it was proposed to divide the empire into six circuses, and this division was established by the emperor Maximilian I. Albert was of tall stature and great strength, liberal and just in his disposition, and of a virtuous character; he cherished a warm affection for his people, a great zeal for religion, and an uncommon esteem for learned men. Mod. Un. Hist. vol. xxvi. p. 273-278.

Albert the Great, so called on account of his great erudition, in Biography, was born at Lawingen in Sabia, about the year 1195, or, as some say, 1205. He
ALB was educated at Pavia, and in 1236 he was made doctor in medicine at Paris; where having heard father Jourdain, the Dominican, preach, he was induced to take the habit; and on the death of Jourdain, was made vicar-general, then provincial of that order. He taught philosophy, medicine, and theology, at Cologne, and at Paris, to numerous auditories. At Cologne St. Thomas Aquinas was his pupil. In 1260, he was made bishop of Ratibison; but at the end of three years he resigned that dignity, and retired to Cologne. From hence he went to Germany and Bohemia, to preach the crusade; and in 1274, he attended the council of Lyons. Allowing for this occasional absence, he continued to instruct the religious of his order in this city, till the 15th of November 1280, the time of his death. His works, which were very voluminous, were collected by father Jami, a Dominican of Grenoble, and published at Lyons in 1615, in 21 volumes in folio; but many of them are supposed to be spurious. The treatises "De secretis muliebrum, item de virtutibus hierbarum, lapidum, et animalium," published under his name, were written by Henry of Saxony, one of his pupils. He was undoubtedly the author of several works on the mathematical sciences; as arithmetic, geometry, perspective or optics, music, astrology, and astronomy; under the titles,—"De Spheera, de Altiris, de Altronomia, item speculum Astronomicum." As he was a man of genius and knowledge superior to his contemporaries, and particularly devoted to mathematical disquisitions, he was charged, according to the cant of the times, with being a magician. He is said to have contrived a kind of android, or machine in the human form, which he had brought to such perfection, that it could speak; and of this machine many tales are related, but they are not worth recording. It is not at all incredible, that by his knowledge of mechanics and acoustics, he might have contrived a machine which, by means of the air and certain springs, produced sounds, resembling those of the human voice; and that he might apply his knowledge in chemistry to the production of artificial flowers and fruits. Some have, without foundation, ascribed to Albert the invention of fire-arms. The chief object of his investigation was, probably, the philosopher's stone, as this was the "ignis fatuus" of the age. Gen. Dict. Dupin cent. xiii. Brucker's Hist. Philos. by Ensfeld, vol. ii. p. 371-372.

Albert of Aix, or Albertus Aquensis, was a canon of Aix-la-Chapelle, in the 12th century, who travelled into the Holy Land, and wrote in Latin "A History of the Expedition to Jerusalem, under Godfrey of Boulogne, and other leaders." This history comprehends a period of 24 years, terminating in 1126, and is esteemed accurate. It was printed by Reineccius, in 1584. Cave. H. L. tom. ii. p. 236.

Albert, Erasmus, a German divine of the 16th century, was born at Frankfurt: from a book entitled, "The Harmony between Jefus Christ and St. Francis?" and highly valued by the Franciscans, he collected many abridgments in a book which he entitled—"The Alcoran of the Cordeliers." To this boook Luther, of whom Albert was a disciple, prefixed a preface, and it has passed through a great number of editions. The author wrote other works in Latin and German, and died in 1551.

Albert, Kranz, an historical writer, was professor of divinity at Hamburg, in the beginning of the 17th century. His works are—"Metropolis," or, A History of the Churches estabhlished or reformed in the reign of Charles I.;—"A History of Saxony?"—"A History of the Vandals;" and "A Chronicle of the Affairs of the North, from the time of Charlemagne to the year 1504." He died in 1517. He is said to have collected facts with diligence, and to have related the truth with fidelity and freedom. Volf. de Hist. Latt. Cave. H. L. tom. ii. p. 247.

Albert of Stade, a benedictine monk, flourished about the middle of the 13th century. He wrote "a Chronicle," comprehending the whole period, from the beginning of the world to the year 1256, which was published with notes, by Reineccius, in 1587. Cave.

Albert of Strasbourg, or Albertus Argyreus, flourished in the 14th century, and published in Latin, "A History or Chronicle of Affairs from the Reign of Rodolphus I. in 1270 to the death of Charles IV., in 1378." This work, which is faithfully written, was edited by Urtifius, in a collection of authors, who wrote on the affairs of Germany, Vol. II. Cave.

Albert, Solomon, a pupil of Fabricius ab Aquapendente, a learned and ingenious anatomist, studied medicine at Wittemberg, where he was several years professor. He is said to have discovered the valve of the colon, first in a calf, afterwards more distinctly in the body of a man, and to have made many other improvements in anatomy. Haller Biblioth. Anatomic. vol. i. p. 251. His works are—"Histories, &c. human corporis partium in usum Tyronum edita, figuris illustrata," Wittemberg, 1583, 8vo. The plates, with the exception of two, are from Vafius. This work has passed through several editions. "Tres orationes, quarum tertia agit de sibi prima anatomica, quo orbe cepit, &c. tum de Galen libro qui de offitus infebruit. Annexum est thema de hachymaram usitate in levando animo affecto." Noimbergae 1555, 8vo. This Discourse on the efficacy of Tears, in allaying the Aftections of the Mind, is inserted in Haller's collection of dissertations. "Oratio de furitdtate et mutatis," Norimb. 1591. "Orationes passiones saepe rellagantae, notis indure cruento, &c." ibid. 1592. He died March 29th, 1690. His age is not known.

Albert, in Geography, a town of France, in the department of Somme, and district of Peronne, five leagues north-east of Amiens, and four north-west of Peronne. The town contains 1,936, and the canton 12,858 inhabitants: the territory includes 165 square autions, and 27 communes.

Alberti Borgheciano, Cherubino, in Biography, an eminent painter and engraver, was born at Borgo S. Sepulcro in 1552, and died in 1615. The rudiments of historical painting he acquired from his father, Michael Alberti; and in this art he made very considerable progress. His early works are in fresco at Rome; and there are also paintings in oil, which are admired for their judicious disposition, lively and beautiful colouring, and fine expression. His superior merit, as an engraver, is also acknowledged; and in this respect his best style of execution seems to have been founded on the prints of C. Cort and Agostino Carracci, whilst in his frescoes and other lighter plates, he was indebted to the works of Francesco Vigna, whose freedom of handling the graver is justly admired. He worked entirely, like these artists, with the graver, and seems never to have called in the assistance of the point. His engravings are never highly finished, or powerful in effect. The great fault of his time was the little attention paid to the chiaro-earmo. The lights are scattered and left unintoned, as well upon the distances, as upon the principal figures of the fore ground, which destroys the harmony, and prevents the proper gradation of the objects. The drawing of the naked parts of the figure, in the works of this artist, is rarely incorrect: the extremities are well marked; and the characters of the heads generally very expressive; but his drapeyoes are apt to be rather stiff and harsh. His prints
prints may be considered as very extraordinary efforts of a great genius; whilst the art was at a considerable distance from perfection. The number of plates engraved by Alberti amounts to nearly 180; of which 75 are from his own compositions, and the rest from Michael Angelo, Buonaroti, Raphael, Poldorado, Andrea del Sarto, &c. Of these we shall enumerate the following, viz.—A large nativity; a dead Christ, supported by an angel; St. Jerome seated in a landscape, meditating upon the cros; the resurrection of our Saviour; a holy family; creation of Adam and Eve, their expulsion from paradise, their subjection to labour; and the miracle of St. Philip Berlingo, where the men who defiled the exhortations of the faint are struck dead with lightning, which is esteemed one of the most excellent prints of this master. Pilkington and Strutt.

Alberti, Domenico, a Venetian dilettante, gifted with genius and an exquisite taste. He was of the corps diplomatique, and secretary to the Venetian ambassador at Madrid. At a time when there was little melody in harpsichord lefions, he brought about a revolution in the style of playing that instrument, by giving a singing treble to a rapid bass, composed of chords broken into groups of femiquavers, which it was so easy to imitate, that composers and players soon grew tired and ashamed of it. Jeriz at Paris, and Vento in London, glutted the public with whole volumes of lefions upon Alberti's bass, but none ever composed such elegant treble parts for keyed instrumen
ts; the melody of which fluttles its ground, through all the vicissitudes of 60 years—a prodigious longevity for a musical production in point of taste! There is a little history, belonging to the publication of Alberti's lefions in England, worth recording, as a beacon to plagiarists. The first time these lefions were heard in London, was at Hickford's room, when they were admirably performed by Jozzi, the second finger at the Opera, at his own benefit; who, not only passed them off for his own compositions, but printed them, and had the courage to affix his name to the title-page, and the confidence to sell them for a guinea a book, equal at least to two guineas now. Unluckily for the author of this fraud, but not before many copies were fold, a gentleman, just returned from Venice, being pos
sessed of a MS. copy of these fonatas in Alberti's own hand-writing, made Walsh, the music-feller, a present of the book, on purpose to expose the tranflation. Walsh, having the MS. upon such easy terms, fold the eight charming sonatas for six shillings a book. The style being new, and so much more within the power of gentle
men and ladies to execute, than the rich and complicated pieces of Handel, and wild original legendarian of Scar
latti, had a prodigious sale, and soon obliged Jozzi to make a precipitate retreat to Holland, where he practiced the same trick, but not with equal profit.

Alberti, Durante, flourished in 1590, and died at Rome in 1613, at the age of 75. He, and his two brothers, Cosimo and Giorgio, who were painters and engravers, were natives of Borgo S. Sepolcro. The two first engraved upon copper and wood; the last upon copper only, and died young in 1597. They are not supposed to have artificed of any great note. The son of this artist, viz. Pietro Francesco Alberti, was born in 1724, and died in 1768. He was an historical painter, and we have a print, called the "Academia de Pittori," and containing many figures slightly etched, but with spirit and in a style that indicate much of the master.

Alberti, Giovanni, a painter of perspective and history, brother of Cherubino, was born at Florence in 1538, and died in 1601. After receiving early instruction from his father, he went to Rome, where he studied geometry, and the works of Buonaroti and other great masters. His principal attention was devoted to perspective, in which he arrived at great eminence. He was distinguished by the elegance of his composition, the firmness and delicacy of his pencil, the grandeur of his thoughts, the judicious distribution of the parts, and the spirit visible through the whole. Pilkington.

Alberti, John, a learned German lawyer, was born at Wilmontstadt, and flourished in the 16th century. He was well acquainted with the oriental languages, and wrote "An Abridgment of the Koran," published at Nurem
berg in 1543. In 1546, he published in 4to. at Vienna, at the expence of the emperor Ferdinand I. A New Testament in the Syriac character and language, for the use of the Jacobite sect, in which book are omitted the second epistle of Peter, the second and third of John, the epistle of Jude, and the Revelation. Alberti also wrote a Syriac grammar, with a preface, tracing the progres of the oriental languages among the Latins. Nouv. Dict. Hist. Gen. Biog.

Alberti, Leoni-Battista, an eminent architect of Italy, was born of a noble family at Florence in 1528, and pur
sued his studies at the University of Bologna with such succ
ces, that at the age of 30 he composed a Latin comedy, inti
tled "Philoideas," under the name of Lepidus, which Aldus Manutius conceived to be antique. Here he took the degree of doctor of laws, and was ordained priest. However he chiefly devoted himself to the study of design, and to the examination of ancient edifices; and at Rome he was employed by pope Nicholas V. in several works of architecture. He also planned several considerable buildings at Mantua, Rimini, and Florence. Alberti was a painter, and a good mechanic; and invented an instrument for the practice of perspective; but he is principally known as a writer. His Latin work "On the Art of Architecture," in 10 books, was printed in 1481, much esteemed, and translated by Bartoli, into Italian, in 1549, and afterwards into French. He also wrote, in Latin, "On the Fruits of Architecture," in three books, which was translated by Domenichi. He lived to an advanced age, and died at Rome in 1480, as some say, but according to Tiraboschi, in 1473. His funeral oration was pronounced by Angelo Poliziano, and he was celebrated by the contemporary Italian poets. Gen. Biog.

Alberti, Michel, professor of medicine at Hall, in Saxony, and member of the Royal Academy at Berlin, a strenuous defender of the principles of Stahl, against the me
chanical physicians, particularly against Heister, was born at Fribourg, November 13th, 1682; he published "Epistolae qua Thermarum et Acidularum idolum medicum debuit," Halle 1714, 4to. "Introductio in Universam Medicinam," ibid. 1718, 1719, 1721, 3 vols. 4to., containing a multi
tude of theses on different parts of medicine. For the titles of these, see Haller's Bibliotheca Medicinae Pratice, vol. iv. p. 356, &c. "Systema jurisprudentiae Medice Schlesienerg," 4to. 1725. Haller gives a particular account of this work, which he highly commends. See as above; also for accounts of the remaining works of the author, who died at Hall, May 17th, 1757.

Albertini, Francis, a Calabrian, resigned a rich abbey in order to become a Jesuit. He died in 1619. In his "System of Theology," two vols. fol. he attempts to reconcile
recusate divinity with philosophy; and in a treatise "De Angulo Cudolo," he endeavours to prove, that brutes have their guardian angel.

ALBIPINUS, Mussius, an historian and poet of Italy, was born at Pædus, and flourished in the ninth century. He wrote concerning the reign of emperor Henry VII., 12 books on the affairs of Italy after Henry VII., and a third part of the history of Lewis of Bavaria; and he has been esteemed a judicious, faithful, and for the time in which he lived, an elegant historian. He also wrote a tragedy on the tyranny of Accision, which, with other poetical prodigies, gained him distinguished honours in the University of Padua. Petrarch mentions him with respect, as a diligent and accurate inquirer into facts. He died in 89. Volesius, Gen. Boig.

ALBERTISTS, a sect of Scholastics, were thus denominated from their leader Albertus Magnus.

ALBERTO, Bazos de, in Geography, a town of rocks before the city of St. Salvador, in the bay of All Saints, on the coast of Brazil. On one of them is a strong fort which commands the road, and between them and the city is a very good harbour, where ships may ride with safety.

ALBERTON, or Port Albert, a sea-port town of Africa, in the kingdom of Barca, on the confines of Tripoli, 50 leagues from Alexandria.

ALBERTUS, in Commerce, a gold coin, worth about 14 French livres, which was struck during the reign of Albertus, Archduke of Austria.

ALBESIA, in Antiquity, a kind of fluid used by the ancient Athenians, a nation of the Mæri.

ALBESTROFF, in Geography, a town of France, in the department of the Meurthe, and district of Châtillon, 3 leagues N. N. E. of Deuze. The town contains 651, and the canton 15,566 inhabitants; the territory includes 1973 kilometres, and 26 communes.

ALBERTROSS point, a rocky prominence on the coast of New Holland. Lat. 38° 4'. W. long. 18° 43'.

ALBI, a town of Italy, in the province of Abruzzo Ultra. See ALBA Furensis.

Albi is also a town of Savoy in the Genevois, 9 miles N. N. E. of Aix.

Albi, or Aley, Albige or Civita Alberbium, a city of France, in the department of the Tarn, and chief place of a district, situate on the river Tarn, was, before the revolution, the capital of a small country called the Albigens, in Upper Languedoc. It has been the residence of a royal tribunal, and since 1677, the see of an archbishop. Its cathedral is dedicated to St. Cecilia, and has one of the finest choirs in the kingdom. The archbishop was metropolitan of five bishoprics, and they reckoned 30 cardinals, who had been bishops of this see. The diocese contained about 347 parishes, and produced about 9,000 livres. It stands upon an eminence, and the number of inhabitants has been estimated at 96,499, of these the canton are 18,407; the territory comprehends 195 kilometres, and 18 communes. In the cathedral was a valuable silver shrine, of the Mosan kind, and of exquisite workmanship, which contained the relics of St. Chir, said to have been the first bishop of this city. There is a pleasant walk, called La Lice, a little above the city; and the archepiscopal palace is very magnificent, and the small town of Chatauvenux serves as a suburb. The river washes the walls of the city, and serves both for an ornament and a defence. It is 35 miles north-east of Toulouse, and 250 miles south of Paris. The territory of the Albigeois is about 10 leagues long and seven wide, is well peopled, and produces abundance of grapes, corn, wood, fawn, and sheep. It has also coal-mines. The trade of this district consists of dried prunes, grapes, wine, and a coarse kind of cloth. N. lat 43° 55' 44". E. long. 2° 30'. See ALBIGENSES.

ALBI, in Ecclesiastical History. See White Preface

ALBIANI, in Geography, a town on the Styx coast of Africa, 6 miles south of Inius.

ALBANIA, Gope, lies on the north-west point of the island of Cyprus, near the easter extremity of the Mediterranean. N. lat. 35° 20'. E. long. 32° 18'.

ALBANIA, a small town of France, in the district of Quercy, divided into two parts by the river Aveyron.

ALBICILLA, in Ornithology, a species of Falco, in the Limnaeus Cyphus, the aquila albicia of Brillou, the pygargus, albica bianunaria of Bonn. Gesser and Ray, the grand pygargue or great crou of Buffon, brown hooded crou of Finch, white-tailed eagle of Willoughby, and cinnereous eagle of Pennant and Latham. Its specific characters are, "that its eye and feet are yellow, the tail feathers white, and the intermediate ones black at their vertex." It is of the size of a peacock, being two feet nine inches long; its head and neck are of a pale ash colour; the iris and bill pale yellow, and the bill elongated at its base; the front between the eyes and the nuchal naked, with small scoured bristles, and of a carunculate base. The body and wings are cincereous, intermixed with dun; the tail white; the legs woolly below the knees, and of a bright yellow; the claws black. It inhabits Europe, particularly Scotland, and the adjacent islands, and preys upon large fih. Arifotole (Hist. Anim. lib. ix. c. 38. tom. I. p. 937.) gives this species the epithet of Hinnulnlan, denoting that it preys upon fawn, that is, young flags, deer and roe-bucks; and he represents it haunting the plains, groves, and towns; and also retorting to the mountains and forests.

ALBICILLA, in Conchology, is a species of the Nerita, with a frilated shell, subdentated lips, the interior turberated. It is found at the Cape of Good Hope and in the Indian sea.

ALBICUS, in Biography, an archbishop of Prague, was raised to that dignity by Sigismund, kind of Bohemia, and distinguished by the liberality of his sentiments. His character has been reproached by the papists on account of the indulgence which he exercised towards John Hus and the other disciples of Wickhiff. He composed three medical treatises, viz. "Praxis Medendi," "Regimina Sanitas," and "Regimen Pefidentes," printed at Leipše, in 1484, 5vo. long after his death.

ALBIGAUNUM, or Albium Inguanum, in Ancient Geography. See ALBENGUA

ALBIGENSES, in Ecclesiastical History, a sect or party of reformers, who appeared about Toulon and the Albigois, in Languedoc, in the 12th century; and who derived their name, not from Alg's being the place of their birth, or residence, or the seat of their principal assembly; but from their having been condemned in a council held in that town, in the year 1176. Their origin may be traced to the Paulicians, who, with a view of propagating their opinions, or of escaping oppression and persecution, retired from Bulgaria and Thrace, and formed settlements in other countries. Their first migration was into Italy, whence, in course of time, they sent colonies into almost all the other parts of Europe, and gradually formed a considerable number of religious assemblies of persons who adhered to their sect, who were severely persecuted by the Roman pontiffs. About the middle of the 13th century, many of the Paulicians settled in Lombardy, Italy, and from hence they migrated to France, Germany, and other countries, where by their piety and zeal they captivated the admiration and esteem of the multitude. In Italy,
they were called Paterini, and Cathari or Gazzari; in France they obtained the appellation of Albigenenses, from the circumstance already mentioned; and they were also denounced by Pope Innocent III., who, by his Bull 

"La Convension", the agreement, that at the end of life they should be received into their feet; for this reception they were prepared by confessors or friaries; and the admission, called spiritual baptism, was believed to save the soul of the perforn admitted, and was delayed to the last sickbed, when there were no hopes of recovery. Those who were thus received were commanded to make use of the endura, i.e. falling themselves to death, and even to hasten their death by opening a vein and bathing.

Of the manieheim of the Albigenenses, and other opinions and practices, which have been charged upon them by inquirors and popish writers, they have been exculpated by protestant authors; and the charges have been ascribed to that malignant zeal, which has induced persecutors to vindicate their own conduct, and to inveigh against those who have been deemed heretics. The errors and crimes of individuals have been not unfrequently hazarded upon the whole bodies of men; and we have reason to think, that this has been very much the case in the present instance. However this be, the Albigenenses became so formidable, both by their number and zeal, that a holy league, or crusade, was agreed upon among the Catholics; and pope Innocent III. exhorted all princes to oppose them as much as possible, and to expel them from their dominions. Raymond, earl of Toulouse, afforded them temporary protection and favour; upon which the pope ordered him to be excommunicated as a favourer of heretics. He also sent his legate, with letters to many of the prelates, commanding them to make inquisition against the Albigenenses, and to destroy them. He also engaged Philip, king of France, to concur in this work of extirpation. The pope's legate was accompanied by 12 abbots of the Cistercian order, preaching the cruces against the Albigenenses, and promising, by the authority of Innocent, a plenary remission of all sins to all who took upon them the crusade. To thefe Dominick joined himself, and in that expedition invented the inquisition; and he deputed those who were denounced cross-bearers to unite their efforts for suppressing these heretics. When these deputes of Dominick and the pope were suspected of being lefs zealous than they wished them to be, a plenary indulgence was proclaimed, in order to engage a greater number of affitants in this warfare of intolerance and blood. The cruces-bearers on this occasion wore the cruces on their breasts, as those who took it up against the Saracens bore it on their backs or shoulders. Raymond, who was still forbearing and indulgent, was excommunicated by a bull of Innocent, his subjects were absolved from their oath of allegiance, and power was given to any catholic, not only to act against his person, but to take possession of his country. The Earl was at last overcome, promised obedience, and fought reconciliation with the church. After the reconciliation of the earl, the crus'bearers were busily employed in attacking the heretics, feizing their cities, filling all places with slaughter and blood, and burning many whom they had taken captives. In the year 1209 Biterre was taken, the inhabitants without distinction put to the sword, and the city burnt. Carcassone was also destroyed; and Simon, earl of Montfort, made governor of the whole country, for the purpose of extirpating heretics, which he faithfully fulfilled. In the next year a new expedition of the cruc'bearers was undertaken against the Albigenenses. They feized Albi, and other towns, and either hanged or burnt those heretics whom they captured. The earl of Toulouse was alarmed by the delusive progress-
The progress of Simon Montfort, and fearing for himself, and for his country, raised a large army, and received succour from the kings of England and Aragon, to whom he was related. Having been deprived of his dominions by Montfort, he appealed, for redress, to the council of Lateran in 1213, but without avail. The synod decreeing him for ever exiled, he went to Spain, and his son Raymond to Provence, in order to collect auxiliary forces; and with these he recovered part of his dominions, and the city of Toulouse itself. Montfort was killed at the siege in his endeavours to retake it. The Earl died in 1221, and was succeeded by his son, who was unable to procure Christian burial for his father. When Raymond had recovered his father’s dominions, the Inquisition was banished from the country of Toulouse; but pope Honorius III. used every effort to render him obnoxious, and earnestly urged King Lewis of France to take up arms against the Albigenes. The French king undertook the expedition against Raymond and the heretics, and laid siege to Avignon; where he and many of his army died of a dysentery and other diseases. Avignon was at length taken by treachery, and Toulouse was compelled to surrender. Raymond obtained peace upon very humiliating conditions; being required to abjure his heresy, and to be for ever subject to the see of Rome, to expel all heretics, and not to advocate in their defence; to pay a fine of 2000 marks, and to surrender a considerable part of his dominions to the king and the church. He was then led to the high altar, in a linen garment, and with naked feet, and abdoluted from the sentence of excommunication. Opprified afterwards by a series of misfortunes, he bowed his neck to the papal yoke, and signified to the pope his desire that hereby might be wholly extirpated from his dominions. Soon after this act of tervile humiliation, viz. in 1249, he died, and was the last earl of Toulouse of that line. In confinement of these events, the Albigenes were dispersed, and they were little known or heard of till the time of the Reformation, when those who remained fell in with the Vaudois, and conformed to the doctrine of Zuinglius, and the discipline of Geneva. Limborch’s Hist. of the Inquisition by Chandler, vol. i. p. 42-70. Mofheim’s Eccl. Hist. vol. ii. p. 350. 8vo.

ALBINO, in Geography, a town of France, in the department of the Aveyron, six leagues north-west of Rhodes.

ALDINA, in Conchology, a species of Helix, with a smooth perforated white shell, gills below, and quadrangular aperture. It resembles the Albeila.

ALBINALI, in Geography, town of Aisa, in Arabia Felix.

ALBINATUS. See Aubaine.

ALBINE. See Assine.

ALBINELLA, in Entomology, a species of Phalena Tinea, with brown wings, and a single golden line, arched on the fore part, found in the groves of the northern part of Europe.

ALBINE, or Albien, in Geography, a town of Switzerland, in the Valais, 22 miles east of Sion.

ALBINGAUNUM, or ALBION INCIAGAUM, a town of Italy on the north-east side of Liguria. See Albenga.

ALBINI, in Antiquity. See Albarum Opus.

ALBION, in Zoology and Geography, a denomination given to the white negroes of Africa, who have light hair, blue eyes, and a white body, resembling that of the Europeans, when viewed at a distance; but, upon a nearer approach, the whites are pale and lind, like that of leprous persons, or of a dead body. Their eyes are so weak that they can hardly see any object in the day, or bear the rays of the sun; and yet, when the moon shines, they see as well, and run through the deepest shades of their forests, with as much ease and activity, as other men do in the brightest day-light. Their complexion is delicate; they are less robust and vigorous than other men; they generally sleep in the day, and go abroad in the night. The negroes regard them as monsters, and will not allow them to propagate their kind. In Africa this variety of the human species very frequently occurs. Wacher informs us, that there are white Indians of the same general character among the yellow or copper-coloured Indians of the Ithimums of Darien; and the Chacrelas of Java, as well as the Bidas of Ceylon, seem to be of the same description. M. Buffon observes, that this variation of nature takes place from black to white only, and not from white to black; and that all the people in the East Indies, in Africa, and in America, among whom these white men appear, he under the same latitude; the Ithimums of Darien, the Negro country, and the island of Ceylon being under the same parallel. It has been a subject of inquiry, whether these men form a peculiar and distinct race, and a permanent variety of the human species, or are merely individuals who have accidentally degenerated from their original stock. Buffon inclines to the latter opinion, and he alleges in proof of it, that in the Ithimum of America a husband and wife, both of a copper colour, produce one of these white children; so that the singular colour and constitution of these white Indians must be a species of disease which they derive from their parents, and the production of whites by negro parents, which sometimes happen, confirms the same theory. According to this author, white appears to be the primitive colour of nature, which may be varied by climate, food, and manners, to yellow, brown, and black; and which, in certain circumstances, returns, but so much altered, that it has no resemblance to the original whiteness, because it has been adulterated by the cauless that are alligned. Nature, he says, in her most perfect exertions, made men white; and the same nature, after suffering every possible change, still renders them white; but the natural or specific whiteness is very different from the individual or accidental. Of this we have examples in vegetables, as well as in men and other animals. A white rose is very different, even in the quality of white, from a red rose, which has been rendered white by the annual fruits. He deduces a farther proof that these white men are merely degenerated individuals from the comparative weakness of their constitution, and from the extreme feebleness of their eyes. This last fact, he says, will appear to be less singular, when it is considered, that, in Europe, very fair men have generally weak eyes; and he has remarked, that their organs of hearing are often dull: and it has been alleged by others, that dogs of a perfectly white colour are deaf. This is a subject which demands farther investigation. Buffon, Nat. Hist. by Smelle, vol. iii. p. 179—182.

M. Saussure, in his "Voyages dans les Alpes," gives an account of two boys at Chamouni, whom he refers to the chiefs of Albinos. One of them was about 20 or 21 years of age, and the other about two years younger. The elder had a dull look, with thickish lips, but his features in other respects were not different from those of other people. The younger was of a more agreeable figure, and more sprightly. Their eyes were not blue; the iris was rose-coloured; and the pupil, when viewed in the light, appeared red; whence he infers, that the interior membranes were deprived of the uva, and of the black mucous matter by which they should have been lined. In their infancy, their hair, eye-brows, eye-lashes, and the down upon their skin, were very fine, and of a perfect milk-white colour; but at the age above-mentioned, the hair was of a reddish cast, and more strong. Their fight was also strengthened, and, even in their infancy, was not much opposed.
offended by the light of the day. They were unable to labour with persons of their age, and were maintained by the charity of a relation. Although they had not the thick lips and flat noses of the white negroes, this difference is owing, as M. Sauffre thinks, to their being Albinos of Europe, and not of Africa. The malady that affects the eyes, the complexion, and the colour of the hair, enfeebles also their strength, without altering the conformation of their features; and of this malady, he apprehends, there are different degrees; so that it produces, in various instances, different effects. He at first ascribed it to an organic debility; in consequence of which, a relaxation of the lymphatic vessels within the eye, might admit the globules of the blood in too great abundance into the iris, uvea, and even the retina, and thus occasion the reduction of the iris and of the pupil. This debility, he supposed, might account for the intolerance of the light, and for the whiteness of the hair. But M. Blumenbach, professor in the university at Gottingen, attributes it to a different cause. He has observed the same phenomenon in brutes, in white dogs, and in owls; and he says, that it generally occurs in the warm-blooded animals, and that he has never found it in those with cold blood. This ingenious physiologist is of opinion, that the redness of the iris, and of the other internal parts of the eye, as well as the extreme sensibility that accompanies it, is owing to the total privation of that brown or blackish mucus, which, about the fifth week after conception, covers all the interior parts of the eye in its round flates. He observes, that Simon Pontias, in his treatise, "De coloribus oculorum," long ago remarked, that the interior membranes of blue eyes are lefs abundantly provided with this black mucus, and are therefore more sensible of the action of light. He adds, that this insensibility of blue eyes is very conformable to the situation of northern people, during their long twilight; and that, on the contrary, the deep black in the eyes of negroes enables them to bear the strong glare of the sun's beams in the torrid zone. As to the connection between this red colour of the eyes, and the whiteness of the skin and hair, he says, it is owing to a similitude of structure. This black mucus is formed, as he affirms, only in the delicate cellular substance, which has numerous blood-vessels contiguous to it, but contains no fat, like the inside of the eye, the skin of negroes, the spotted palate of several domestic animals, &c. and the colour of the hair generally corresponds with that of the iris. Galette Litt. de Gottingen. Oct. 1784.

M. Buzzi, surgeon to the hospital at Milan, published, at the same time, in the "Opusc. Scelti de Milan, 1784, tom. vii. p. 117," a very interesting memoir, in which he demonstrates, by dissection, the hypothesis of M. Blumenbach. Having an opportunity of dissecting the body of a paifant, who died at the age of 30 years, in the hospital of Milan, of a pulmonary disorder; and who was remarkable for the uncommon whiteness of his skin, hair, beard, and all the other covered parts of the body; he found the iris of the eyes perfectly white, and the pupil of a rofe-colour; and the eyes were altogether delirious of that black membrane, called the uvea, which was not discernible, either behind the iris or under the retina. Within the eye, there was only found the choroid coat, extremely thin, and tinged of a pale red colour, by vessels filled with discoloured blood. The skin, when separated from different parts of the body, appeared to be a thin wholly divested of the rete mucosum, nor was the least trace of it to be discovered by maceration, even in the wrinkles of the abdomen, where it is most abundant and most visible. The

whiteness of the skin and hair is ascribed by M. Buzzi to the absence of the rete mucosum, which, in his judgment, gives the colour to the cuticle, and to the hairs that are scattered over it. In proof of this opinion, he alleges a well-known fact, that the skin of the blacker horse is accidentally destroyed in any part of the body, the hairs that afterwards grow on that part are always white, because the rete mucosum, which tinges those hairs, is never regenerated with the skin. M. Buzzi having assigned the probable proximate cause of this phenomenon, it still remains to determine, what is the remote cause of it, or how the rete mucosum is destroyed in such subjects. It seems to be a fact, very generally admitted, that persons of this description do not form a distinct species, as they are produced from parents with dark skins and black eyes. This was the cause with respect to the Albinos of Chamouni, M. Buzzi relates a fact, cited by M. Sauffre, which seems to throw some light on the subject. A woman of Milan had seven sons, of whom the two eldest, and the two youngest had brown hair and black eyes; the other three had white skins, white hair, and red eyes. During the pregnancies that produced these Albinos, the woman had a constant and immoderate appetite for milk, which she took in great quantities, but when she was pregnant with the other four, she had no such desire. But it does not appear, that this preternatural appetite was not the effect of a certain heat, or internal diece, which destroyed the rete mucosum in the children before they were born. M. Sauffre observes, that this faulty conformation is more rare among women than among men; and it does not seem to be owing to the air of the mountains; for though he travelled the greatest part of the Alps, and the other mountains of Europe, he met with no other individuals of this kind.

ALBINOVANTES, Pedro, in Biography, a Latin poet, to whom Ovid addreft his 10th epistle, "Ex Ponto." Oper. tom. iii. p. 876. Ed. Burmann. There are extant of his writings, his Elegy on Dufus, and another on the death of Mccenas, published by Le Clerc in 1703, 5vo. and in 1715, 12mo. at Amsterdam, with a prolix commentary.

ALBINEMELIUM, or ALBIUM INTEMELIUM, in Ancient Geography, now Finameliga, a town of Liguria, or the present territory of Genoa. See Vintemiglia.

ALBINUS, Bernard, called Weiss or White, in Biography, was born at Deflaw, in the province of Anhalt, in Saxony, January 7th, 1653, and studied medicine at Leyden. In 1676, having taken his doctor's degree, he returned to his own country, where he soon distinguished himself for his sagacity and learning. In 1680, he was nominated professor of medicine at Frankfurt on the Oder, and became so celebrated for the pertinacity of his lectures, that pupils flocked to him from all parts of Germany. In 1694, Frederic, elector of Brandeburgh, appointed him his physician, with a pension of 600 florins, and soon after gave him a canonry at Magdeburg. In 1702, he was chosen professor of medicine at Leyden. Having filled that office 19 years with the highest reputation, he died on the 7th of September, 1721, aged 69 years.

A large collection of Thesae is published under his name, the titles of which may be seen in Haller's Bibl. Med. Prac.}

ALBINUS, Bernard Sigefred, son of the former, prosecuted his studies with so much zeal and success, that on the recommendation of Bierhaue, he was appointed professor of anatomy and surgery at Leyden, in 1718, when he was only 20 years of age. This office he continued
continued to fill by an uncommon fidelity, Haller says, for 53 years, and acquired a greater degree of reputation, as teacher, or demonstrator in anatomy, to which he exclusively dedicated himself, than had been enjoyed by any of his predecessors. He died, in May, 1777, aged 75 years. His first work, entitled, "Anatomia infantum in utroque genere," 4to, appeared in 1734. In composing this, he took great pains to measure and describe all the insertions of the muscles in the body, and to mark them in with aqua fortis, which he afterwards caused to be drawn by an excellent artist. In 1757, he gave some coloured plates of the arteries and veins of the intestines, and some elegant figures of the bones of the face. An anatomical examination of the plates of Enphony in, with a new edition of the plates themselves, was published by him in 1751; and republished with improvements in 1761. His own large tables of the skull and muscles appeared in 1747; and about the same time, seven tables of the grand uterus. His great tables of the bones was edited in 1753; and again, in an improved state, in 1762. Eight volumes, 4to, of "Anatomical Annotations," reprint with curious matter, but too much occupied with controversy, appeared successively from 1754 to 1769.

Besides his original works, which are numerous, and highly illustrative of the science, he published in 1757, an edition of the works of Vesalius, with an account of his life; in the same year, "Index libri quindecim Ravaiana"; and in the year 1777, "Guadalupe Nobelis Opera, et Hieronymi Fabritii ab Aquapendente." See Haller's "Biographia Anatomica, vol. ii.

Albinus, Christian, Bernard, though eclipsed by the superior fame of his brother, was so much esteemed for his skill and diligence, as to be raised to the chair of professor of anatomy, at Utrecht. He died April 5, 1752, aged 50 years. He published, in 1722, "Specimen Anatomicum, exhibens novum sermonem humanorum specificationem," 4to.; and the next year, "De anatome errores detegentes in Medicina," also in 4to.

Two other authors of the same name are noticed by bibliographers; James, a native of Hamburg, who published in 1720, a "Disquisition on the Scyry;" and Eleazer, who published natural histories of birds and of insects.

Albinus, Peter, or Weiss, a celebrated historian and good poet of the 16th century, was born at Saebeck in Minden, and became professor of poetry and mathematics in the academy of Wittemberg, and then secretary to the elector at Dresden, where he published a second enlarged edition of the "Chronicles of Minden," which he had printed at Wittemberg in 1580. His other works, principally historical, were much esteemed. Biog. Dict.

Albinus, Decimus Claudius, was born at Adrumetum in Africa, and called Albinus, on account of his fair complexion at his birth. In his youth he was infatuated in the Greek and Latin languages, and he is said to have written a treatise on agriculture, and a collection of Miletian tales, which was a licentious performance; but his prevailing taste inclined to a military life, and he was accustomed at school to repeat frequently, and with peculiar pleasure, the following verses from Virgil:

"Arma amens capio, nec fat rationes in armis,"

Æneid, ii. v. 314.

"With frenzy seiz'd, I run to meet the alarms;"

"Resolv'd on death, resolv'd to die in arms!"

DRYDEN.

He commenced his career under the emperor Antoninus, whose einzem he acquired; and after some previous grada-

tions of advancement, he commanded the army in Bithynia, when Avidius Cassius revolted against Marcus Aurelius. On this occasion he distinguished himself by his fidelity to his prince, and by his active service, for which he was rewarded, as it is said, with the consulship. Under Commodus he accompanied him in his expedition, and in the year 1754, was made a senator, and at length appointed commander of the legions in Britain. Whilst he governed Britain, Commodus, by the act of Capitonius, which is not generally credited, insulted him with permission to assume the title of Caesar, with all the ensigns appropriate to that dignity. However this be, Severus, as we are informed by Dion Cassius and Herodian, footed his ambition and engaged his attachment, by giving him this title. Albinus was deluded by this honour, and by the expectation which the emperor led him to entertain of sharing with him in the imperial government. Severus also appointed him his colleague in the consulship in the year 191, ordered statues to be erected to him, and conferred upon him other distinctions, which afforded an opportunity ultimately of destroying him. Having defeated and killed Niger, whom had assassinated and deceived by the same kind of dissimulation which he was practising on the credulous Albinus, he determined to get rid of this rival, whose character, contended with his own, induced the senate to exchange one rather for another. Some say that, before he had recourse to open force of arms, he tried the base perfidious means of assassination; but Dion Cassius's account is more probable, who says, that Severus, after his victory over Niger, deprived Albinus of the title and prerogatives of Caesar; and that Albinus, on the other hand, pretended even to the title of Augustus. Accordingly Albinus was proclaimed under this appellation, engaged Gaul and Spain in his interest, and betook himself to a powerful force to meet Severus who had proclaimed himself a public enemy. The two rivals, after some previous skirmishes, decided the contest for the empire in the plain between Lyons and Treves. Their two armies were equal in number, each of them consisting of 150,000 men, and they were led by the two emperors. The troops on each side fought with great valor. The British legions under Albinus were not inferior to those of Illyricum; but Severus was thought to be an able general than his competitor. The victory was long doubtful, but at length Severus prevailed; and Albinus was compelled to fly with the shattered relics of his army, first to Lyons, and then to a house near the Rhone, where he either destroyed himself with his own sword, or made one of his fives perform the fatal office for him. He was not quite dead, when a detachment of the enemy arrived, cut off his head, and carried it to Severus. His wife and children were at first pardoned; but afterwards inhumanly massacred, and their bodies thrown into the river. The whole family of Albinus, all his friends, and most distant relations, without distinction of age or sex, were, by the orders of Severus, barbarously slaughtered, and their effects confiscated. Most of the great men of Gaul and Spain, who had manifested any attachment to Albinus, underwent the same fate. By means of these murders and confiscations, Severus amassed an immense treasure, enriched his foilers, and, at his death, left incredible wealth to his children. This event happened on the 19th of February, according to Tillymont, A. D. 197, the 4th year of Severus's reign.

Of the character of Albinus, different accounts have been given. Capitonius, on whose report we cannot much depend, represents him as level, revered, unaffected, rigid to cruelty in his discipline, glutinous, and brutal. But this account is not very credible, when it is considered that his soldiers...
soldiers were attached to him, and that he was exceedingly beloved by the senate, and applauded for his justice and humanity. He seems, however, to have been a brave warrior, who had the art of making himself beloved; but who had not cunning enough to guard against the treachery of his enemy, and this was the cause of his ruin. Crever, Hist. of the Emperors, vol. viii. p. 65—66. Anc. Un. Hist. vol. xiii. p. 374—593. Albineus, A. Pothamus, the colleague of Licinius Lud-
cullus in the consulship, in the year before Christ 151, wrote a History of the Affairs of Rome, in the Greek language. He is mentioned by Cicero in his Brutus (Op. tom. i. p. 399. Ed. Olivet.) as a man of learning and eloquence. Upon
his making an apology, and interchanging pardo for the improprieties of expression that occurred in a work written in a language so different from that of his own country, Cato fa-
cetiously asked, “Why did you chuse rather to follicit par-
don for a fault than not to have committed it?” His conduct however in this respect needed no apology, as the Greek language was known to almost all nations, whilst the latter
was almost wholly confined to the Roman territory, and
therefore his history would be more extensively read. See
Albion, or Albice, in Ancient Geography, called also Reif Apollinis, from their worship of Apollo, and Cir-
vitias Regumus, was a Roman colony of Gallia Narbon-
enis. It is now Riez or Rieu, in Provence.

ALBION, a name formerly given to the island of Britain, comprehending England, Scotland, and Wales, by way of
contradiction from Hibernia, and the other British islands.
Thus Agathæmenus, (lib. xi. c. 4.) speaking of the British
islands, says, they are many in number; but the most consider-
able are Hibernia and Albion; and Ptolemy (lib. ii. c. 3.) calls
Albion a British island. Phiny also (H. N. lib. iv. c. 16.
tom. i. p. 222.) observes, that the island of Britain, so much
celebrated by the Greek and Latin writers, was formerly called
Albion; the name of Britain being common to all the islands
round it. The etymology of the name is uncertain. Some
derive it from the Greek ελβοιν, albon, signifying white, in
reference to the chalky cliffs on our coasts; others pretend
that its name was borrowed from a giant, the son of Ne-
ptune, mentioned by several ancient writers. Some of our
etymologists have recourse to the Hebrew tongue, and fome
to the Phoenician; albon in the former signifying white, and
alp or alpin, in the latter, denoting high and high mountain, the
land appearing so as you approach it from the continent.
The derivation from the Greek or Hebrew word signifying
white, seems to be countenanced by the British poets, who
call Britain Inis Wen, i. e. the White Island. Selden’s notes
on Polybalbon, p. 20.

ALBION, New, in Geography, the name given by Sir
Francis Drake to California, and part of the north-west coast
of America, when he took possession of it in 1578. Captain
Cook discovered the coast of New Albion, March 7, 1778,
and landed in a place fituate in N. lat. 44° 33’. E. long.
235° 5’. He describes the land as abounding with moun-
tains, the summits of which were covered with snow; but
the valleys that lay between them and the sea-coasts, high
as well as low, produced a great number of trees, which ap-
ppeared like a large forest. The inhabitants at first seemed
to prefer iron to every other article of commerce; but they
afterwards showed such a predilection for brass, that scarcely
a fragment of it was left in the ships except that which be-
longed to the necessary instruments. They were also ob-
served to be much more tenacious of their property than
those of the other savage nations which the voyagers had
met with, so that they would not part with wood, water,
grain, or even the most trilling article, without a compen-
sation; and they were sometimes very unreasonable in their
demands. The place in which the Resolution anchored was
called by captain Cook, St. George’s Sound; but he after-
wards understood that the natives gave it the name of
Nootka. Its entrance was situated in the eait corner of
Hope bay, in N. lat. 49° 32’. E. long. 233° 12’. The
clime seemed to be much milder than that on the easternd
limit of America, in the same parallel of latitude; and the ther-

ometer, even in the night, never fell lower than 45°; and
in the day-time frequently rose to 65°. The trees of this
country are chiefly the Canadian pine, white cypress, and
some other kinds of pine. The birds were few, and much
harassed by the natives, who use their feathers as ornaments
for their drefs, and their flesh for food. The people are ac-
quainted with the ufe of metals, having many iron tools;
and two silver spoons were procured, which were similar in
their construction to those feen in some Flemifh pictures,
and were worn by one of the natives as an ornament round his neck.
These metals had probably been conveyed to them by the
way of Hudson’s bay and Canada, or fome of them might have
been introduced from the north-western parts of Mexico. See
California.

On the 18th of April, 1792, Captain Vancouver, em-
ployed in an expedition for completing the survey of the
western coast of North America, from the latitude of 30° N.
to 65° N., fell in with the coast of New Albion in N. lat.
39° 27’. E. long. 236° 25’. As he approached the land,
the shore seemed to be perfectly compact, formed, generally
speaking, by cliffs of a moderate height and nearly perpen-
dicular. The inland country, which arose in a pleasing di-
vercity of hills and dales, was completely clothed with forest
trees of considerable magnitude, and thofe spots, which
were deftitute of wood, were beautifully green, with a luxuriant
herbage, interrupted by thicks of natural earth. This part
of the coast abounded with whales, noif of which were of
the tribe called the Greenland finners. In directing their
course along the coast northward, they paffed Cape Men-
docino, in lat. 40° 16’, long. 235° 53’. This Cape is the
highest on the fca-fhore of this part of New Albion. The
mountains behind it are confiderably elevated, and form a
high flep moat, composed of various hils that rife abruptly,
and are divided by many deep clafs. Dwarf-trees were
thickly scattered in the clafs and on the ridges of the hils;
and the general surface was covered with vegetables of a dull
green colour, occasionally interfeied with perpendicular frata of red earth or clay. As they advanced further north,
the diftant inland country was composed of mountains of
great elevation, before which were perceived hils and dales,
with woodland and clear fpoons, as if they were in a flate
of cultivation; but they could difcern neither houses, hats,
smoke, nor any other figns of its being inhabited. On the
coast to which they next approached, and which was formed
by rocky precipices, the moft projecting part, fituate in lat.
41° 8’; long. 236° 5’, was called Rocky Point. Near this
point the colour of the fca changed to a light river-coloured
water, which gave reafon for concluding that fome consider-
able river or rivers were in the neighborhood; but purfuing
their course they arrived again in oceanic-coloured water,
in lat. 41° 36’. long. 235° 58’. The land in this part formed
a conspicuous point, which was denominated Point St. George’s
bay. The inland mountains were much elevated, and clothed
with a variety of trees, chiefly of the pines, and some
spreading trees of confiderable magnitude were obferved.
Proceeding further along the coast they cafl anchor in lat.
3 Y 42°
A L B I O N.

42° 35', long. 235° 44': a cliff which projected into the sea near their station, and terminated in the form of a wedge, was called Cape Orford, int. 42° 5', long. 235° 35'. Some canoes came from the coast to visit the ships, and approached alongside of them with the greatest confidence. The people were distinguished by a peculiar dress, and a uniform deposit of blackness; their countenances indicated nothing ferocious; their features, partook of the European character; their colour was a light olive; and besides being punctuated nixi: that of the footst-

sea islanders, their skin had many other marks, which were either the effects of injury in moving through the forests with thin clothing, or purely ornamental. Their stature did not exceed five feet six inches; they were well-humoured, but fender in their persons, bore little or no resemblance to the people of Nootka; nor did they seem to have the least knowledge of their language. They preferred canelinos to the painting of their bodies; in their ears and noes they had small ornaments of bone; their hair, which was long and black, was clean and neatly combed, and generally tied in a club behind, and some of them had it thus tied in front. They were dressed in garments, nearly covering them, made principally of the skins of deer, bear, fox, and river otter. Their canoes, capable of carrying about eight people, were rudely wrought out of a single tree, resembling in shape a butcher's tray, and appearing to be unfit for either a sea voyage or any distant expedition. They brought but a few articles to barter, and they anxiously solicited in exchange iron and beads. In their traffic they were scrupulously honest in fixing their bargain with the first bidder, and in refusing any presents without an equivalent in return.

In their progress from their last station near Cape Orford, they discovered a point of land which they considered to be the Cape Blanco of Martin d'Aguilar, in lat. 43° 23', long. 235° 50', and the Cape Gregory of Captain Cook; and they fought for the river or straits, which are said to have been discovered by this navigator. They next arrived at a promontory, which Captain Cook calls Cape Perpetua, in latitude 44° 12', longitude 236° 51'; and pursuing their route, they passed Cape Footwater, which is a conspicuous promontory, in latitude 44° 40', longitude 236° 31'. They next proceeded to Cape Lookout, in latitude 45° 32', longitude 236° 17', which is a small projecting point, that had been seen by Mr. Mears, and off which are four rocks, one of them being perforated as he has described it. They afterwards passed Cape Disappointment of Mr. Mears, in latitude 46° 10', and longitude 236° 6', and the opening to the south of it called Deception Bay. The country before them presented a luxuriant landscape; the interior parts were elevated and diversified with hills, and the whole had the appearance of a continued forest, as far as the eye could reach. They wished to find a bay in the vicinity of a country that presented so delightful a prospect of fertility; but they were under a necessity of pursuing their course; and having passed the Local Point of Mr. Mears, and his Shoul-water bay, they arrived at Point Gravine, in latitude 45° 20', longitude 235° 58'. The coast from hence northward rose regularly in height, and the inland country acquired a considerable degree of elevation; and here they saw that land, called by Mr. Barclay, Disjuction Island, in latitude 45° 37', longitude 235° 40'; which is the largest detached land that they had observed on the coast, and presented a very barren aspect. A canoe or two were seen paddling near the island. "It is a fact," says Mr. V. "not less singular than worthy of observation, that on the whole extentive coast of New Albion, and more particularly in the vicinity of those fertile and delightful shores we had lately passed, we had not, excepting to the

southward of Cape Orford, and at this place, seen any inhabitants, or met with any circumstances, that in the most distant manner indicated a probability of the country being inhabited." Since they had passed Cape Orford, they had a constant current, setting in the line of the coast north-easterly, at the rate of two and a half leagues per hour. In the north part of the coast the most remarkable feature which they had seen, presented itself; its summit covered with perpetual snow, was divided into a very elegant double fork, and rose conspicuously from a base of lofty mountains clothed in the same manner, which declined to hills of a moderate height, and terminated in low cliffs, falling perpendicularly on a sandy beach. This was considered to be the mount Olympus of Mr. Mears, in latitude 47° 10', though the latitude of the observers was 45° 38', and the mountain was north of them. Pursuing their course further northward, they distinguished the south point of entrance into De Fuca's straits, and on the opposite side of the straits an opening of considerable extent. They perceived that this coast, like that which had been explored from Cape Mendocino, was firm and compactable, without any opening into the Mediterranean sea, as fitted in latitude 47° 45', or the least appearance of a secure harbour, either in that latitude, or from it southward to Cape Mendocino: although, in that space, geographers have thought it expedient to furnish many. They now saw several villages scattered along the shore, whose inhabitants came off, as it was suppos'd, for the purpose of trading. Having passed between Tatooche's Island, and a rock, called Rock Duncan, along the southern shore of the supposed straits of De Fuca, they anxiously looked for the point which Captain Cook had designated Cape Flattery; and at last concluded, that Claffit, a projecting and conspicuous promontory, at the south entrance of the inlet, is the point with an island lying off it, which Captain Cook called Cape Flattery. The village of Claffit is situated about two miles within the cape, and appeared to be extensive and populous. The few natives, who came off to the ship, resembled in most respects the people of Nootka: their persons, garments, and behaviour, were very similar; but instead of the ornamental crestant at the nose, used by the inhabitants of Nootka, they wore straight pieces of bone; their canoes, arms, and implements, were the same, and they spoke the same language. They anchored about eight miles within the entrance, on the southern shore of the supposed straits of De Fuca. The shores on each side of the straits are of a moderate height; those on the south side are composed of low sandy cliffs, and from the top of these the land appeared to ascend gently, and to be covered with trees, chiefly of the pine tribe, until the forest reached a range of high craggy mountains, the summits of which were covered with snow. The northern shore did not appear quite so high, nor were the mountains, which formed a compact range, so much covered with snow. Steering to the east, along the southern shore, their latitude was 48° 19', and longitude 236° 19'; and the variation of the compass 1° 45' easterly. The north promontory of Claffit was situated in latitude 48° 23', longitude 235° 38'. Proceeding forward, they came to anchor in 14 fathoms water, about three miles from a low sandy point of land, resembling Dungenes in the British Channel, and called New Dungenes: whence they discovered a lofty mountain, which they called Mount Baker, apparently at a very remote distance. "We had now," says Mr. V. "advanced further up this inlet than any other person from the civilized world; although it should hereafter be proved to be the same which is said to have been en-
tered by De Fuev; in support of which, oral testimony is the only authority produced, a tradition rendered still more doubtful, by its entrance differing at least 46° in latitude. This difference of latitude, however, is not sufficient altogether to differ the traditional accounts to which Mr. V. refers; and as a refrain, with a considerable extent of sea, has been actually found, and to the north of the isle many islands, or an archipelage of islands, it is much more reasonable to suppose that some error has been introduced into the old accounts, or that the situations may have originally been erroneously described, than that an alteration of the existence of a strait and of an archipelago of islands should have been the mere result of random conjecture.

It must be considered as a very singular circumstance, that in so great an extent of sea coast, as 257 leagues, to which the inquiries of these navigators have been directed, they should not till now have seen the appearance of any opening on its shores, which presented any certain prospect of affording shelter; the whole coast forming one compact, solid, and nearly frait barrier against the sea. The huts observed to the eastward of Claflet, were built exactly like the hovels at Nootka; and were composed of a few mats thrown over crows flickeys, and plainly indicated the residence of the natives to be merely temporary. The inhabitants viewed their European visitors with the utmost indifference; they traded with them in a civil and friendly manner; but did not appear to understand the Nootka language. Their next remove was to a harbour called Port Discovery, where they moored about a quarter of a mile from the shore under a kind of promontory, which afforded them shelter; and which they called Protection Island. The entrance of Port Discovery is situated in lat. 43° 7', long. 237° 20'. The country in its neighbourhood is bounded on the west side by mountains covered with snow; the soil is generally a light sandy loam, which being mixed with decayed vegetables, forms a rich fertile mould. Iron ore was generally found here, and appeared tolerably rich. Quartz, agate, the common flint, and a great intermixture of other flinty matter, with some variety of calcareous, magnesian, and argillaceous earths, were the mineral productions commonly found. The vegetables that grew most luxuriantly were the Canadian and Norwegian hemlock, silver pines, the Turamahac and Canadian poplar, arbor-vitae, common yew, black and common dwarf osk, American ash, common hazel, fycemore, furgar, mountain, and Pennsylvanian maple, oriental arbutus, American alder, and common willow. These, with the Canadian alder, small fruited crab, and Pennsylvanian cherry-trees, constituted the forests. Of excellent vegetables few were found; the white or dead-nettle, and famphire, the wild orache, and the vetch were the most common. Two or three forts of wild pears, and the common hedge mulberry were met with occasionally; they were excellent of their kind, and proved extremely agreeable and useful. The only living quadrupeds that were seen were a black bear, two or three wild dogs, as many rabbits, several small brown squirrels, rats, toads, and the flunk of a peculiarly offensive smell. The aquatic birds were few, and so timid that they could not be killed. About the shores and on the rocks were found some species of the tern, the common gull, sea pigeon of Newfoundland, curlews, sand-larks, flags, and the black sea-pye, like those in New Holland and New Zealand; but not in great abundance. In the woods they saw two or three spruce-partridges; few small birds were discovered, and of these the humming birds were the most numerous. At the out-skirts of the woods, and about the water-side, they saw a great number of the white-headed and brown eagle, ravens, carrion crows, American king-fisher, and a very handsome wood-pecker, and also a bird unknown to them, which they considered as a species of crane or leon, the eggs of which were of a bluish cast, larger than those of a turkey, and well tailed, with long legs and necks, of the size of the largest turkey, and with a light brown plumeage. Some blue, and some nearly white herons of the common size were also seen. The supply of fish was scanty, and confined in general of the common forts of small flat-fish, elkphant-fish, sea bream, sea perch, a large foot of sculpin, weighing fix or eight pounds, with a greenish colour about their throats, belly and gills, and affording coarse, but not unwholesome food, a few trout, and a small eel of a yellowish green colour, and well tailed. Of the reptile tribe they found a small common black snake, a few lizards and frogs, together with a great variety of common insects.

The country, in an agricultural view, seemed capable of improvement, though the soil was light and sandy. The spontaneous productions are nearly the same, and grow in equal luxuriance with those under the same parallel in Europe. The climate is mild, and every species of plants forward in its growth. Fresh water is very scarce; but sufficient for common domestic purposes. As for the inhabitants, they are thinly scattered along the shores. From New Dungenes to Port Discovery, our voyagers traversed near 150 miles of their fisheries without seeing as many inhabitants. Those whom they observed, nearly resembled the people of Nootka; but were not so fruitful in variety, nor so fitful in their habits. Their weapons, implements, canoes, and drufs nearly the same. Their native wooden garment was most fashionable, and next to this the skins of deer, bear, &c.; and some few wore dreffles manufactured from bark, which, like their woollen ones, were very neatly wrought. Their spears, arrows, fish-hooks, and other weapons, were shaped like those of Nootka; but none of them were pointed with copper or mufké shell. The three former were generally barbed, and those of their own manufacture were pointed with common flint, agate, and bone. Their arrows were pointed with thin flat iron; and their bows were of a superior construction, and made of yew, and the bow-string of the sinew of some marine animal. From the form and structure of their habitations, they seemed frequently to change them; and their deserted villages indicated their being migratory in their disposition and habits. Mr. V. supposes, however, that though the country seems to be thinly inhabited, it was once much more populous. In different excursions, they found the skulls, limbs, ribs, and back-bones or other vestiges of the human body, scattered about in great abundance; and hence it is inferred that there has been occasionally, and not at any very remote period, a great waste of human life. Several skeletons were found deposited in caves, and suspended on the branches of trees about 12 feet from the ground; these were probably the remains of the chiefs, priests, and leaders of particular tribes, to whom they paid particular respect. Baskets, containing the skeletons of young children, were also found in the same situation; and in other places, dead bodies were discovered in holes, which were flightly covered over, and in different states of decay. But the skeletons found in canoes and bails were a very small proportion to the skulls and other human bones indiscriminately scattered about the shores. Whether these were the result of epidemic diseases, or of recent wars, our navigator does not determine. From the character of the people, he thinks the latter cause not to be probable; for he represents them as uniformly civil and friendly, without manifesting the least sign of fear or suspicion at the approach of strangers, or any indication of their having been injured to hostility.
small-pox seemed to have been very fatal amongst them. The present depopulation, it is apprehended, may have arisen in some measure, from the inhabitants of this interior part having been infected by their former abode, and the small-pox having spread from the coast to the interior, for the convenience of obtaining in the intermediate mart, with more ease and at a cheaper rate, those valuable articles of commerce that within these late years have been brought to the seacoasts of this continent by Europeans and the citizens of America, and which are in great estimation among these people, and possessed by all in a greater or lesser degree."

From Port Discovery, our navigators pursued their route up the inlet, viewing in their progress a very picturesque and fertile country, and seeming to require only inhabitants and cultivation; having found a convenient road-lead, they anchored near a village in which the inhabitants were employed, in their temporary huts, in curing, by the smoke of the fire, clams, muscles, and a few other kinds of fish, which seemed to be intended for their winter's subsistence. Several of them were busily engaged, like swine, in rooting up a beautiful verdant meadow, in quest of a species of wild onion and other roots, for the sake of which they appeared to be attached to this spot. One of these roots resembled the Saranne, and was gathered with great industry and activity, for the purpose of making a paste with which they filled small boxes, placed in the baulks containing the skeletons of their children. In their manner, these people were friendly and hospitable, and very thankfully received the presents that were given them. They also bartered for any articles that were offered them; but they chiefly preferred copper. Bows and arrows, woolen and linen garments, and a few indifferently otter skins, composed the whole of their affortment for trading: and these they exchanged, in a very fair and honest manner, for copper, hawk's bells, and buttons, articles that greatly attracted their attention.

The dogs belonging to this tribe of Indians were numerous, and resembled those of Pomerania, but were larger in size. They were all shorn close to the skin, like our sheep; their fleeces were compact, and composed of a mixture of a coarse kind of wool, with very fine long hair, capable of being spun into yarn. It was conjectured that their woolen clothing might be formed partly of this material, mixed with a finer kind of wool from some other animal, which, though it must have been very common, was not discovered.

Here was discovered a narrow passage, which seemed to communicate with an opening of some extent; and to this harbour was given the name of Port Orchard. In their present situation, they were preoccupied by some of their Indian friends with a whole deer, in the chase of which and another they and their dogs had been busily engaged for almost a whole day. It was found that these people had a great aversion from human flesh; for conceiving that some pieces of the deer that were offered them were of this kind, they threw them away with gestures of great displeasure. Hence it was inferred, that the character given of North-west America does not attach to every tribe; but though these people were not in this respect savages, they were not wholly exempt from the general failing attendant on a savage life; for one of them secreted a knife and fork under his garment, and when detected gave them up with the utmost good humour and unconcern.

Our navigators, having advanced into an opening, situate in lat. 47° 10', and long. 237° 41', halted on an island about a mile from the escaped shore, which was one of the most extensive islands discovered in the examination of this coast; and which they called 

Vabon's Island. In one inlet which they examined, they found a tribe of Indians, who manifested hostile dispositions, and prepared their bows and arrows for an attack. Upon the ringing of a gun, though they expressed no alarm, or fear of our men, they而是

their bows, and commenced a friendly traffic. The village point near their present station, situate in lat. 47° 30', long. 237° 46', was called Restoration Point. Their next anchorage was in an excellent harbour, sheltered from all winds, in lat. 48° 23', long. 237° 57'. The inlet, which they had spent a fortnight in examining, they denominated Admiralty Inlet. On the 5th of June, they quitted this inlet, falling down Pequosha Sound, and proceeded northward; the north point of this inlet, lat. 48° 16', long. 237° 31', they called Point Paradise; and the west point, lat. 48° 10', long. 237° 31', they denominated Port Wilfin. On the west side of Strawberry Bay, where they anchored, there was an island, which producing abundance of upright cypress, they called Cypress Island, lat. 49° 36', long. 237° 34'. It was also found, that the easterly shore of the gulphs, from the passage into Port Gardner, called Deception Passages, in lat. 49° 27', long. 237° 27', to the north point of the entrance into Pequosha Sound, in lat. 47° 55', long. 237° 47', was an island about 10 miles wide in its broadest part; and it was distinguished by the name of Whidby's Island. In pursuing their investigation, they denominated a point in lat. 48° 57', long. 237° 20', Point Robert; another in lat. 49° 5', long. 237° 6', Point Grey; a third, about a league distant, Point Akinfon: an island which they passed, Passage Island; and a canal near it Bur-ward's Canal; and another island, in lat. 49° 36', long. 237° 5', Avail Island, from the shape of the mountain which composes it; a found to the southward, Howe's Sound; and a point in lat. 49° 23', long. 236° 51', Point Coon, near which is an extensive group of islands of various sizes. In their return to their flaps, they reached the north point of the inlet, which producing the first Scotch fir that had been seen, was called Scotch-fir Point, in lat. 49° 42', long. 236° 17', and to the arm of the sea they gave the name of Fer-站点: Canal. The fourth point of the land which they passed in lat. 49° 28', long. 236° 24', was called Point Upland; and a shoal, near which they purchased of the natives some excellent sturgeon, weighing from 14 to 200 lb. each, they called Sturgeon Bank. Near a cluster of islands, in lat. 48° 36' to 48° 48' and long. 237° 50', at its eastern extremity, they found an extensive bay, which was distinguished as Bel-lingham's Bay. In their progress northward, the forests were composed of a much less variety of trees, and their growth was less luxuriant. Those most common were pines of different sorts, the arbor vitae, the oriental arbutus, and some species of cypresses. On the islands were seen some few small oaks, with the Virginian juniper; and at the place where their flaps were last stationed, the Weymouth pine, Canadian elder, and black birch, which gave it the name of Birch Bay, situate in lat. 48° 53', long. 237° 33'. From this bay they sailed northward, June 24th, directing their course through the channel del Neultra Signora del Robario, in ex-tent about ten leagues from Point Upland to Point Marshall, the north-west point of the island of Fveida, in lat. 49° 48', long. 235° 47', near which is another island, called Har-wood Island, and not far off, in lat. 49° 57', long. 235° 54', Scawon's Island. In lat. 50° 41', long. 235° 25', was a point which they called Point Sarah; and the opposite point, about half a league distant, they called Point Mary. In a canal denominated Batte's Canal, they found an Indian village on the bank of a deep river, they landing on lat. 52° 34', long. 235° 8', containing about 150 of the natives, who plentifully supplied them with fresh herrings and other fish.
in barter for nails. Before the entrance into this canal was a round island, three or four miles in circuit, which obtained the name of *Stuart's Island*. Quitting *Desolation Sound*, in lat. 50° 11' long. 233° 21', they passed through an affembly of islands and rocks, and in the midst of whales and seals, to more pleasant shores, from which the friendly Indians came to visit them, with young birds, mortal fea-fowl, fish, and some berries, which they bartered for trinkets; and they anchored about half a mile to the northward of *Point Bluff*, in lat. 50° long. 233° 59', where was a large village of the natives, which conducted themselves with great civility and respect, and who were not fewer in number than 200 persons. Near Johnstone's Straits was a point, called *Point Chatham*, in lat. 55° 13', long. 234° 45'. About ten miles from this point they anchored under a narrow island, distinguished by the name of *Thurlow's Island*. To a snug and commodious port, to which they afterwards arrived, they gave the name of *Port Neville*; near which was a large village, the inhabitants of which understood the language of Nootka, and who bartered with the skins of the sea-otter of excellent quality, for fea-copper and blue cloth. Here they found the fabrication of mats for various purposes, and a kind of basked, wrought so closely as to contain water without the least leakage; and this in manufac-ture the women were chiefly employed. They next proceeded by *Call's Canal*, in lat. 50° 42' long. 234° 53', *Knight's Canal*, in lat. 51° 1' long. 234° 13', and *Deep-sea Bluff*, a point of land in lat. 50° 52' long. 233° 29', through an extensive cluster of islands, rocky inlets and rocks, called *Broughton's Archipelago*, to a flat in lat. 50° 35', long. 233° 19'. Afterwards they entered a channel called *Fife's Passage*, and found its caulkern point, named *Point Scott*, to be in lat. 50° 46' long. 233° 10'. Passing *Point Phillips*, at the distance of eight miles from Deep Sea Bluff, they reached the base of a remarkable mountain, in lat. 51° 12' long. 233° 20', called *Mount Stephen*, which is thus marked in the author's chart, and may seem to an excellent guide to the entrance of the various channels with which this country abounds. The next place of their meeting was named *Point Byrde*, in lat. 50° 51' long. 234° 52', near the well point of a channel called *Wellis's Passage*. Having pursed their course through a channel not more than half a mile wide, bounded on one side by islands, rocks, and breakers, which appeared almost to give the continental shore on the other, they anchored in lat. 51° 24' long. 232° 25'. They afterwards proceeded through a channel about two miles wide, between rocks and rocky isles, which seemed to be connected with the southern broken shore, and reached that part of the coast that had been visited and named by several of the traders from Europe and India. The inlet through which they had lately paddied was called *Queen Charlotte's Sound*, so called by Mr. S. Wedgeborough, in August 1786; an opening on the continental shore had in the same year been named *Smith's inlet*, by Mr. J. Hanna; a high distant mountain that appeared to be separated from the main land, formed part of a cluster denominated by Mr. Duncan, *Calvert's Islands*; and the channel between them and the main land had been called by Mr. Hanna, *Fitzhugh's Sound*. Their estimated latitude in this situation was 51° 24', and long. 232° 25'. They next fell across *Charlotte's Sound* for the entrance of Smith's inlet; afterwards steering along the eastern side of Calvert's island, they sought for *Port Safety*, laid down in Mr. Duncan's chart, or some other convenient anchorage. A cove within the fourth entrance of Fitzhugh's Sound, afforded them a secure and comfortable retreat from the dangers to which they had been expe-ced, and called it *Safety Cove*. Determining to abandon the northern survey of the continental shore for this season, they made the best of their way towards *Nootka Sound*, at which post they anchored on the 28th of August 1792. In this survey, they had traced the western continental shore of America, with all its various turnings, windings, numerous arms, inlets, creeks, bays, &c. from the lat. of 39° 5', long. 236° 36', to point *Menzies*, in lat. 52° 18'. long. 233° 53'; and they found that none of the channels which they explored extended more than 100 miles to the eastward of the entrance into the Strait of Juan de Fuca; they also found that the land forming the north side of that Strait is part of an island, or rather of an Archipelago, extending nearly 160 leagues in length from south-east to north-west; and on the side of this land most distant from the continent is Nootka Sound. In October 1792, our navigators left Nootka Sound, and proceeded to re-examine the coast of New Albion to the southward, and particularly a river and a harbour discovered by Mr. Gray, commander of the Columbia, between the 46th and 47th degrees of north latitude. They directed their course to-wards *Cape Claffet*, to which they restored Captain Cook's original appellation of *Cape Flattery*. One of the most conipicuous promontories southward from this cape was *Point de Reys*, as it is called by the Spaniards, in lat. 38° 0' long. 233° 8'. Southward of this point, the shore forms the north point of a bay, in which, according to the Spaniards, Mr. Francis Drake anchored, in the vicinity of which is a port called by the Spaniards *Botella*. They next proceeded to port *St. Francisco*, a Spanish settlement, in lat. 37° 48' 30", and long. 234° 52' 30". The mean variation of the compass was 12° 48' east. Leaving this port, they failed to *Monterey*, another Spanish Settlement. From hence they sailed towards the Sandwich islands. In April 1793, our navigators again visited the coast of New Albion; they first saw the coast at Cape Mendocino, and anchored, on the 2d of May, in *Port de la Trinidad*, so called by the Spaniards, who discovered it in 1775; but they found it a less convenient harbour than they had been led to expect from the description given of it in the journal of Don Francisco Maurel, translated by the Honourable Daines Barrington. The inhabitants of an Indian village in this neighbourhood, visited the ships in their canoes, fishing like the other Indians as they drew near, and traf-ficked with bows and arrows; inferior feathers, skins, small herring, and flat fish. They were likewise used to hunt a lower stature than any other Indians on the coast. Their persons were mutilated or disfigured, either for ornament or from a regard to some religious inclination, or for some other unknown purpofe. All the teeth of both sexes were, by some proccess, ground uniformly down, horizontally, to the gums; the women especially, carrying the fathion to an extreme, had their teeth reduced even below this level; and ornamented their lower lip with three perpendicular columns of punctation, one from each corner of the mouth, and one in the middle, occupying three-fifths of the lip and chin. The latitude of the ship's station was 41° 3', and that of *Rocky Point*, five miles to the north, 41° 8'; and the longitude of Trinidad bay 236° 0'. From Trinidad, pursuing their course to latitude 47° 55', longitude 233° 17', they saw the coast of the island of *Quadra* and *Vancouver*, and were within a league of *Ponta de Ferron*; and passing along the shore of the island de Ferron, they proceeded to Nootka, and anchored in Friendly Cove. From hence they failed to *Fitzhugh's Sound*, and recommended their exa-mination at the part where it had been discontinued in the preceding year. The survey now made, in most of its cir-cumstances, resembled the former. They found the same kind
A L B I O N.

kind of broken coal, with inlets and channels almost innumerable, and the finest extraordinary depth of water close to the shore, and in places included within the land. In the space of four months, devoted to this northern survey, they advanced little more than four degrees northward, leaving off between the 50th and 51st degree of north latitude. In a place near the entrance of the Harbour, they called the Port of Neufchatel, they found a deep sound. The natives offered for sale the skins of the animals whose wool was manufactured into the garments worn by the inhabitants of north-west America. They were large to belong to any of the canine race, as our navigators had formerly supposed. Exclusively of the head or tail, they were 50 inches long, and 35 inches broad, exclusively of the legs. The skin afforded but little wool in proportion to its size; and it is chiefly produced on the back and towards the shoulders, where a kind of creel is formed by long bristly hairs, protruding themselves through the wool, and the same part of hair forms an outer covering to the whole animal, and entirely hides the wool, which is short; and of a very fine quality. The skins were cream-coloured, the pelts was thick, and appeared to be of a strong texture; but they were too much matted for ascertaining the animal to which they belonged. The females of this part adopted a singular ornament. An horizontal incision was made about three tenths of an inch below the upper part of the under lip, extending from one corner of the mouth to the other, entirely through the flesh; this orifice was then fleshted sufficiently for admitting an ornament of wood, of an oval form, and hollow on both sides; which was confined closely to the gums of the lower jaws, and whole external surface projected horizontally. The clothing of the natives was formed either of outer skins or of the pine bark, and ornamented with woolen yarn, very fine, well spun, and dyed with a very lively and beautiful yellow. As to their dispositions and manners, they seemed to be civil, good humoured and friendly; and they manifested a considerable degree of vivacity and humour. They approached and left the ships with songs; they appeared to be happy and cheerful, and to live in the freest harmony and good fellowship with one another. They were well versed in commerce. In examining some of the openings, which presented themselves in the continental shore, which Mr. V. traversed in boats for 23 days, through a distance of 700 geographical miles, he was attacked by a party of Indians, under the direction of an old woman, who seemed to be their leader. In this survey they discovered a river, in 55° N. lat. on a bay, in the eastern side of the entrance of an arm of the sea, named by Captain V., Observatory Inlet. This small river, and another in Port Effington, were the only two streams that had yet been discovered to the north of the river Columbia. In September our navigators returned from between 56° and 57°, the highest latitude to which they advanced in this voyage, towards the south, keeping at a distance from the continent, and to the westward of Queen Charlotte's Islands. Having finished their survey of the coast of north west America, from the 50th to the 56th degree of north latitude, they concluded that no navigable communication exists between the north Pacific, and north Atlantic oceans; nor between the waters of the Pacific, nor any of the lakes or rivers in the interior part of the continent of North America.

In a third voyage, in 1794, Capt. Vancouver and his associates surveyed the higher latitudes of the north-western coast of America. Their first object was Cook's Sound; but they proceeded to examine Prince William's Sound; piling some points and capes of land, they sailed southward from Cape Fairweather, in N. lat. 58°
Gepidæ, A.D. 566. The skull of Cunimund, who fell in battle, was fashioned into a drinking cup, either to satiate the hatred of the conqueror, or to comply with the savage custom of the country; a custom which was common, as we are informed by Strabo, Pliny, and Ausonius Marcellinus, among the Scythian tribes. In consequence of this event, the nation of the Gepidæ was dissolved, the Avars took possession of their country, comprehending Walachia, Moldavia, and Transylvania, and the parts of Hungary beyond the Danube; and Alboin, besides his moiety of the spoil, perfused or compelled the fair Rofamond to acknowledge the rights of her victorious lover. The fame of Alboin being thus establifhed, he extended his views to the conquest of Italy, and he contrived by various artifices to gain an accession of strength from the adventurous youth of Germany and Scythia. The Lombards retained only that portion of their wealth, which was portable, and which would serve the occasions of their expedition; but they relinquished their lands to the Avars, who promised to relieve them if they failed in the conquest of Italy. Narfes, who had been offended by the Byzantine court, which had recalled him from Italy, contributed to excite and encourage the Lombards in their present undertaking; but he did not live to witness its termination. In 568 Alboin crossed the Alps, and without a battle or a flagon, the inland regions of Italy, from the hills of Trent to the gates of Ravenna and Rome, became the lafting patrimony of the Lombards. Before Pavia, however, the royal camp was stationed for three years; famine at length compelled the besieged to surrender; and the conqueror, more influenced by superstition than by humanity and honour, was prevented from fulfilling his vow of maflacing the inhabitants without distinction of age, sex or dignity, by a regard to the omen of his horse's fall as he entered the gates. This circumstance induced Alboin to pause and relent; and to proclaim to the trembling multitude, that they should live and obey. In this city he fixed his seat of empire, and Pavia, during some ages, was reffected as the capital of the kingdom of Italy. "The reign of the founder," says an elegant historian, "was splendid and tranfient; and before he could regulate his new conquests, Alboin fell a facrifice to domelick treason and female revenge. "In a feaft prepared at Verona for his companions in arms, the cup formed of the skull of Cunimund was introduced, and it was fent by the brutal favage to Rofamond. She touched it with her lips, and at the fame time formed the solemn purpofe, that the infult fhould be washed away in the blood of Alboin. With a view to the accomplishment of her purpofe, she engaged Helmichris, the king's armour-bearer, with whom she had a criminal correfpondence, to be the minifter of her vengeance. But Helmichris trembled in the precipft of perpetrating fuch a deed; and Rofamond was under the neceffity of procuring the affiilance of a lefs timid and more daring accomplice. Peredus, one of the bravest champions of the Lombards, was felected; but he had scruples, which it required some art to remove. The licentious and revengeful queen secured Peredus by a stratagem. Supplying the place of one of her female attendants to whom he was attached, and contriving some excuses for darknefs and silence till her intention was accomplished, he then told her deluded companion, that, as lie had indulged in criminal intercourse with the queen of the Lombards, his own death, or the death of Alboin, must be the conquence of fuch treasonable adultery. In this alternative he chose rather to be the sacrifice than the victim of Rofamond, who, availing herfelf of Alboin's afternoon fummers, when he retired from the table for repofe, introduced the conspirators, and urged them to the execution of the deed. Upon the first alarm Alboin flarted from his couch and attempted to draw his fword, but Rofamond had taken care previously to fallen it to the foabbard. He faw some time defended himfelf with a fword, the only instrument of holliftry or of defence to which he had access; he was foon, however, overpowered and dispatched by the spears of the affifants. "The daughter of Cunimund flamed in his fall; his body was buried under the ftrain-cafe of the palace; and the grateful polfibility of the Lombards revered the tomb and the memory of their victorious leader." The ambitious Rofamond, having procured the death of the king, A.D. 573, afpired to fecceed him; but neither the nor her daughter occupied the throne, which was filled by Clepho, one of the noblest chiefs, in conquence of the free fuflmage of the nation. Having poisoned Helmichris by a cup of liquor which he prefented to him, he was compelled to drink of the fame cup by her difcorded faver, as foon as he perceived its fatal operation on himfelf; and the death of the one was in a few minutes succeeded by that of the other. In the character and exploits of Alboin we fee favage valour combined with military talents, and a confiderable degree of proficiency in the art of government. He is faid to have been the invenior of feveral inftruments of war, that were in use long after his time. Un. Hist. vol. xvii. p. 337-342. Gibbon's Hist. vol. viii. p. 117-132.

ALBOLODUCY, in Geography, a small town of Murcia, in Spain, fitate at the confluence of two rivers, which flow from the mountains called Los Alpujarras, between Almeria and Guadix. N. lat. 35° 55'. W. long. 3° 16'.

ALBON, JAMES D', in Biography, Marquis of Fronsac, was one of the greatest generals of the 16th century, and rose to high military eminence, in the reigns of Henry II. and Charles IX. of France. By the former he was made Marshal of France in 1547, and he was chosen to carry the collar of his order to Henry VIII. of England, who decorated him with that of the garter. He acquired great reputation in the wars of 1552 and 1554, and in 1557 he was made prisoner at the battle of St. Quintin. After the death of Henry II. he was one of the triumvirate who governed the kingdom four or five years in fpite of Catharine of Medicis. He was killed in 1562, at the battle of Dreux, by a perfon whose conflicated effate he poftessed. The Huguenots, who did not love him, used to call him "the Harquebeuf of the world." He had the qualities of a folider and a courfier; was addicted to every kind of pleafure and luxury, excelled in politeness and the amiable accomplishments, and on the day of battle was distinguished by his prudence and his courage. His daughter and heirfs is faid to have been poisoned by her own mother for her property. Gen. Biog.

ALBONA, in Geography, a town of Itria, belonging to Venice, fitate at the foot of a mountain, near the gulf of Carnaro; 16 miles east of Rovigo.

ALBO is a river of Italy, which runs into the Po, nine miles south-south-east of Lumello.

ALBONAL, a town of Spain, in the province of Granada, fix leagues south-north of Motril.

ALBOR, or Alvor, a mountain of Portugal, in the province of Algarve, one league west of Lagos. In a cave on this mountain, John II., king of Portugal, died in 1495.

ALBORAK, in the Mahometan Theology, the beft on which the prophet is faid to have rode in his extraordinary aerial journeys. It is repreffented as of an intermediate shape and fize between an afe and a mule; and many fabulous
fabulous accounts are given of it by the Arabian commentators.

ALBORAN, in Geography, an island in the Mediterranean, near the coast of Fez. N. lat. 36°. W. long. 2° 32'.

ALBORNOS, Giles Alvarez Carillo, in Biography, cardinal and archbishop of Toledo, and one of the most celebrated statesmen of the 14th century. He was born of noble parentage at Cuenca, in New Castile; having studied canon law at Toulouse, he took orders and became almoner to Alphonso XI., king of Castile, and gradually rose to the primacy of Spain. As soon as he was created cardinal by pope Clement VI., who refided at Avignon, he resigned his Archbishops. Having been sent to Italy as legate by pope Innocent VI., he brought all the revoluted states to submission to the holy see. Upon his return to the succeeding pope Urban V., and upon being questioned with regard to the disposal of the large sums of money with which he had been entrusted, he caused a carriage, laden with locks and keys, to be brought under the windows. "There," said he to the pope, "is my account of the money. I have made you master of all the towns, the keys and locks of which you see in that carriage." The pope embraced him, and warmly expressed his obligations. Albornos retired to Viterbo, and spent his remaining days in acts of piety. He died in 1367, and was buried at Toledo. He founded a magnificent college at Bologna. Gen. Bigg.

ALBRO, in Ichthyology, a name by which the Erhythmus, a small red fish, caught in the Mediterranean, is commonly known in the markets of Rome and Venice.

ALBOURG, in Geography. See AALBERG.

ALBOURS, a volcanic mountain, near mount Taurus, eight leagues from Herat.

ALBOUZEME, a town of Africa, on the coast of Barbary. Before it is a bay formed by Cape Mourou, or Befancour on the Weft, and Cape Quiline on the east. It is otherwise called Buzemar, or the bay of Burema. N. lat. 34° 10'. W. long. 2° 54'.

ALBRECHTSBERG, a town of Germany, in the archduchy of Austria, nine miles west from S. Potten.

ALBRECT, John William, in Biography, born at Erfurt, in Upper Saxony, the 11th of August, 1703, was several years professor of anatomy, surgery, and botany, at Gottingen. The late Baron Haller, who succeeded him in those offices, in January 1736, speaks very favourably of his talents, and gives the following hint of his works; "Observa-

ALBREDA, in Geography, a town of Africa, in the country of Senegal.

ALBRET, or LARBIT, a small town of France, in the late province of Gascony, and duchy of Albit. It is situated in the department of Landes, in a sandy territory, 15 leagues south from Bordeaux. N. lat. 44° 10'. W. long. 16'.

ALBRICCIUS, in Biography, an English philosopher and physician of the 11th century, studied in the Universities of Oxford and Cambridge, and travelled for further improvement. He excelled in polite literature, and was eminently distinguished for his natural genius and acquired knowledge. Baile mentions the following works, viz. "De Origine Deorum"; "De Ratione Venerii;", "Virtutes Antiquorum:" and "Canonies Speculativi." He wrote other books Vol. I.

of philosophy and physic, which are dispersed in several libraries of England. Gen. Dict.

ALBUCA, formed from albus, white, in Botany, a genus of the hexaspria monogynia class and order, of the natural order of hita or hitice, the coronaria of Linnaeus, and the alphabete of Jussieu; the characters of which are, that it has no calyx; the corolla has six oblong-oval permanent petals, the three outer spreading, and the three inner converging; the flamina have filaments shorter than the corolla; three opposite to the inner petals, linear-fu-
bulate, complicate a little above the base, then flat, three opposite to the outer petals, thicker; anthers on the former oblong, fixed to the inflex tip of the filament below the middle, uprightly on the latter, similar but effete, or none; the piliation has an oblong, triangular germ, fyle three-fded, stigma a triangular pyramid; the pericarpium an oblong, obtuse, triangular, three celled, three-valved capsule; the seeds numerous, flat, lying over each other, and widening outwards. There are eight species, of which the first five have only three flaments fertile, and the others have all the flaments fertile. 1. A. alfijima or tall, with interior petals glandulose and bent in at the tip, leaves subulate, channelled, convolute, flowers in April and May, and was introduced about 1780, by Meffrs. Kennedy and Lee. 2. A. majus, with interior petals, glandulose and bent in at the tip, leaves linear-lanceolate, flat-tish, flowers in May, and was introduced about 1767, by Mr. W. Malcolm. 3. A. minor, with interior petals, glandulose and bent in at the tip, leaves linear-fabulate, channelled, flowers in May and June, and was cultivated by Mr. Miller in 1768. 4. A. costarata, or channel-leaved, with interior petals vaulted at the tip; leaves smooth, linear-fabulate, channelled, peduncles the length of the bractes; flowers in May, and was introduced in 1774. 5. A. Florian, or spiral-leaved, with interior petals vaulted at the tip, and leaves spiral. 6. A. fuligiiata, or upright-flowered, with interior petals vaulted at the tip, leaves smooth, peduncles very long, flowers in May, and was introduced in 1774. 7. A. viejoa, with interior petals vaulted at the tip, leaves hairy-glandulose, flowers in May and June, and was introduced about 1779, by Dr. J. Potherigil. S. A. abyssi-
nica, A. aiba of Lamack, with leaves linear, channelled, and smooth. To the above species Wildenow has added A. fasciculata, with interior petals glandulose, and bent in at the tip; peduncles spreading at right angles, leaves lanceolate-linear, and obliquely bent. A. viridiflora, with interior petals like the former, scape erect, flexuous, flowers hanging downwards, leaves linear-fabulate canadilulate, and externally hairy. A. cudata, with petals like the last, leaves linear-lanceolate, convolute at the margin, shorter than double the scape, peduncles very long and spreading at right angles, and straight flowers. A. feloea, with petals as before, leaves linear-lanceolate and smooth, peduncles rectangularly patent and erect flowers. A. aurea, with petals and leaves like the last, peduncles very long, erect and spreading, and erect flowers. A. frig-
gravus, with interior petals vaulted at the apex, leaves linear-lanceolate, channelled, panicules spreading of the length of the nodding flower, and very short bractes. All the species are brought from the Cape of Good Hope. They may be cultivated by keeping the roots in pots, filled with light earth, and sheltered under a hot-bed frame in winter, in which case they will thrive and produce flowers; but the bell method is to have a border in the front of a green-house or flow, where the roots of most of the bulbous flowers may be planted in the full ground, and screened in winter from frost; in such situations they thrive much better,
better, and flower stronger, than when kept in pots. Mar- 
yan’s Miller.

**ALBUCASIS, in Biography, an Arabian physician and** 
**surgeon, of singular merit.** At what time he lived is not pre-
cisely known; but as he describes the art of surgery, as greatly 
degenerated in his time, and gives proofs of the ignorance of 
many of his contemporaries, it is thought he could not be 
earlier than the middle of the 11th century; that is, 
about an hundred years after Avicenna, when surgery 
was successfully cultivated. It appears by a MS. in the 
Escurial library, (Bib. Ar. Hifp. toii. p. 136.) that 
he died in 1106. Much of what he has left on the subject 
of his art, is copied from Rhazes, from Paulus Aegineta, 
and other preceding writers; but there are also many or-
iginal observations; and although in the present improved 
state of surgery, little can be learned from him, yet by those 
who love to see the first dawnings of improvement in science, 
his works will be still turned over with pleasure. 
He insisted on the necessity of a surgeon’s being skilled 
in anatomy, to enable him to operate with success; he also 
hold it to be equally necessary that he should be acquainted 
with the Materia Medica, or the properties of the medi-
cines employed in curing diseases; and inveighs against 
those who undertake for gain the cure of diseases, of the 
nature and causes of which they are unacquainted. It 
appears from his writings, that he extracted polyph from 
the nostrils, performed the operation of bronchotomy, and 
used a preparation similar to the lapis infernalis, as a caustic. 
He made great use of the actual cautery, and is extravagant 
in his elogia on its properties. He is the first writer who left 
distinct descriptions and delineations of the instruments used 
in surgery, and of the manner of employing them. His 
works, which have been translated into Latin, at fatis bar-
bare, Haller says, have passed through several editions; 
the most esteemed is that published 1541, under the follow-
ing title:— Medendi Methodus cura, clara et brevis, pler-
que que ad Medicine Partes omnes, praecepit quique ad 
Chirurgiam requiruntur, Libris tribus exponens.” Vaillanc, 
1541, folio, “Cum Chirurgia Guileonis de Chaullaeo.”

“Haller has given a detailed, and pretty extended account 
of the subjects treated of in the volume.” Vid. Bibliotheca 
Chirurgica, vol. i. p. 177.

Mr. Channing has published an edition of Albusis, in 
Arabic and Latin, from the Clearedon press: “Albucasis de 
Chirurgia, Arab. et Lat. cura J. Channing.” Oxon. 1778.

**ALBUCINEA TUNICA OCULI, in Anatomy, has been** 
**faid to be the expansion of the tendons of the four straight 
muscles of the eye, on the front of the sclerotics. Modern 
anatomists, however, do not speak of a tunica albucineae; 
the whites of part of the eye-ball being owing to the 
coarler of the tunica conjunctiva, where it covers the front of 
the sclerotics. See Conjunctiva.

**ALBUCINEUS is applied by some, to denote the** 
aqueous humour of the eye.**

**ALBUGO, or ALB. ocull, the fame with albuginea,** 
**or the scutis of the eye.**

**ALBUGUS in Surgery, otherwise called LEUCOMA,** 
**is a whitish opaque speck, on the transparent part of the eye.** 
It is denominated by popular writers, a fear, film, bow, 
pearl, dragon, &c. The transmision of the rays of light 
through the cornea being obstruted by this densify of its 
casts, is followed by a partial or total blindnese, according 
to the extent of the disease. There are different stages 
and causes of the albugo, accompanied with more or less inflam-
mation. The cure will be difficult in proportion to the 
degree of opacity, and the concomitant circumstances. 
Sometimes it entirely baffles the skill of the surgeon; and 
at other times, it disappears without any attention. 
When the disease is accompanied with much active in-
flammation, leeches should be applied on the temples or un-
der the eye. If a superficial turgid blood-veil he observed 
goong into the affected part, and keeping up the disorder, 
it may be safely divided by the point of a lancet. But when 
there is no inflammation, and especially, if there be a fluid 
interposed between the anterior membranes of the cornea, 
lightly inflammation applications should be employed; such 
as a dream of elecric effusion, drawn from a wooden point; 
or the vapour of warm camphorated spirits, or oil of tur-
pentine; or a composition of pulverized sugar, aloes, and 
linely levigated glafs, blown through a quill. Great cau-
tion, however, should be observed in the use of these 
remedies; for, by injudicious management, the cafe may 
be much aggravated, and even rendered incurable.

Some perons advise us to excite the absorbents of the eye 
by collyria of alum, nitrated silver, vitriolated zinc, vitro-
lated copper, or a very weak solution of muriated mercury; 
accompanied with repeated small doses of calomel and cin-
chona; but it too frequently happens that more harm 
good is done by strong irritating applications to the tender 
an organ. The cutting of an issue in the arms, or a felon in 
the neck of the patient, has been also recommended in 
albugo; although we think their efficacy is very problematical.

It has been supossed that Tobs’s blindnese, mentioned 
in the second chapter of that apocryphal book, was the 
disease of which we have here treated. Vide Tobis Leuc-
comata Differ. med. dilucid. Prof. Macbeath, &c. Tu-
bing. 1748; in Haller, Diffp. chirurg. vol. i. p. 366, 410.

**ALBUHAZAN-BUB-NHAIDOR, in Biography, a** 
**philosopher, physician, and alterooger, at Fez, in Barby, 
physician to several of their kings, died of the plague in 
1415, and left a treatise on the cure of that disease.” Eloy. 

**ALBULAE, in Ancient Geography, a town of Maur-
tania, in Africa.**

**ALBULA, in the Linnean system of Ichthyology, a** 
**species of Salmo.** It is also the name of a species of M W C I, 
with the anterior dorsal fin quadriliated, the alula Bala-
menfes de Catesby, and the leffer silvery mug of Brown 
(Jam.), with the anterior dorsal fin composed of four rays. 
It is found in America.

**ALBULA Indica, the name of a small fish, resembling a** 
**hering, caught about the shores of the East-Indies, and 
called by the Dutch, the Wt-fish. Ray.**

**ALBULA nobilis, of Willughby and Ray, the Lavorinus** 
**Salmo of the Linnean system, and the Gwilad of the**
**British Zoology.**

**ALBULA, is also the name given by some writers to the** 
**Luefens Cyprius of the Linnean system, and the Dace** 
**of English writers.**

**ALBULA is also the name of a species of Nerita, called** 
**mammula, in the Linnean system of Zoology.**

**ALBULA, is also a name given by some naturalists to** 
**mineral waters of the luminous kind, ended with an** 
**attringent quality, and of use in wounds.**

**ALBULUS, in the Linnean system of Zoology, a** 
**species of Turko, with an imperforate smooth shell, and spires** 
**rotundated and flared; found, rarely, in the deep seas of**
**Greenland.**

**ALBUM, in Antiquity, denotes a white table, or regis-
ter, in which the names of magistrates, public tranactions,** 
**&c. were to be inscribed or entered.**

Hence
Hence we meet with album pustoris, album decurionum, album judicum, &c.

Album decurionum was the register of the Decuriones, called also matriculatio Decurionum.

Album judicum contained the names of those persons of the decuriae who at certain times performed the office of judges.

Album prætoris was a register of the formula of all actions, and the names of such judges as were appointed by the prætor for certain causes.

Album senatorum contained a list of the names of senators first introduced by Augustus, and renewed yearly. The high-priest entered the chief transformations each year into an album, or table, which was hung up in his house for the public use.

Album, among chemists, is used for white lead, popularly called cerusia.

Album, is also used among Alchemists, for a tincture pretended to transmute metals.

Album, in Ancient Geography, a promontory of Palestine, to the north-west of Upper Galilee, south of Tyre, and near Alexandria.

Album was also the epithet of a promontory of Africa, situated in the straits of Hercules or Gibraltar, east of Ampelus, west of mount Abila, and opposite to Mellaria, on the coast of Spain.

Album, in Literary History, is used to denote a kind of table, or pocket-book, wherein the men of letters with whom a person has conversed, inscribe their names, with some sentence or motto.

This is called by divers names and titles, as album amicum, repertorium amicum, &c.

The famous Algernon Sydney, being in Denmark, was by the university of Copenhagen presented with their album, whereupon he wrote these words:

"——— Manus hae inimica tyrannis
Enfe petit placidam fub libertate quietem."

Album is also applied in Pharmacy, as a title, or epithet, of divers compound medicines. Thus we meet with unguentum album cum camphora, &c.

Album gracum, dogs white dung, a medicinal drug, formerly used with honey, to cleanse and detersify, chiefly in inflammations of the throat; and for the most part outwardly, as a plaster; but, as Dr. Quincy observes, seldom to any great purpose. See Ncumanus’s Works, p. 583.

Some speak of its use internally, in the angina, and other inflammations; as also in the dysentery, colic, &c. and to prevent burns from rising into blisters.

Medicines of this kind have long since sunk into disuse.

Album gracum is in much request among the leather-dressers, for softening down the leather after the application of lime.

Album nigrum is used, among Medical Writers, for micedung, by some also called mierarda.

Album osse, among Anatomists, denotes the tunic acidata; sometimes also called album; popularly the white of the eye.

ALBUMAZAR, or ALBUBSSAR, Al Abu Mahsar, the father of Mebaan, in Biology, a celebrated Arabian philosopher and alchemist, who lived, according to some writers, in the 9th or 10th century; but, according to others, at a much earlier period. The time of his death is not mentioned in the Euficarian catalogues, but he is said to have lived to the age of 100 years; and if he died, as it is supposed, in the year 883, his birth must have been 15 years prior to the date affixed by Herbelot. Some have represented him as one of the most learned alchemists of his age. He wrote an astrological work, entitled, "De magnis conjunctionibus annonrum revolutionibus, ac eorum perfectionibus," printed at Venice in 1515; and "Introductio in Alcronomiam," printed in 1489. It is said, that he observed a comet above the orb of Venus. Hutton’s Math. Dict. Russell’s Aleppo, vol. ii. p. 100.

ALBUMEN, in the Linnaean System of Zoology, a species of Nerita, with a convex shell, subcorrupted umbilicus, and a distinct lobe. It is found very rarely at the Cape of Good Hope, and on the shores of the islands of Nicobar and the Moluccas.

Albumen, Albinumous matter, Albumine. Fr.—This word, which in the Latin language whence it is borrowed, signifies the white of an egg, is at present introduced into the modern chemical nomenclature, as the name of a peculiar substance, which, though existing in the greatest purity and abundance in the white of eggs, is to be found in various natural compounds, both of animal and vegetable origin.

Pure albumen is a fluid of a somewhat viscid consistence, perfectly soluble in pure water at the common temperature; but when exposed to a heat above 134 Fahr. it coagulates, and is then no longer soluble in water.

Animal albumen, in its purer natural state, constitutes the white of all birds’ eggs, and the ferum of blood: the vitreous and crystalline humors of the eye, the liquor that fills the abdominal cavity in cases of dropsy, and the fluid contents of the lymphatic vessels also contain a considerable portion of this substance. In the vegetable kingdom, it is produced principally in the tetranydious or cruciferous plants, in the farinaceous seeds, and in the young succulent shoots of trees and shrubs.

Albumen, Animal, has a slight sublinal taint, and never fails to turn the blue colour of syrup of violets green, thus indicating the presence of difengaged or carbonated alkali. When heated to about 133 Fahr. a number of white fibres begin to make their appearance, and these rapidly increasing, the whole mass is in a short time converted into a white opaque concrete solid, considerably elastic, and of a smooth compact fracture. By exposure to a dry heat, not exceeding that of boiling water, the coagulated albumen loses the gelatinous part of its moisture, shrinks in consequence in its volume, becomes hard, transparent, and very similar to horn; and when broken, exhibits a bright polished surface, and vitreous fracture. The application of a stronger heat destroys the equilibrium of its elementary parts, and produces the difengagement of ammoniacal gas, of carbonated ammonia, of a fetid epymenamic oil, and sulphurated hydrogen; there remains behind in the retort a spungy coal, from which may be obtained by lixiviation, muriat, phosphen, and carbonat of soda.

Liquid albumen is completely soluble in fresh distilled water, but if this last is charged with atmospheric air, the mass upon mixture becomes in some measure turbid, and a flocculent precipitate is by degrees deposited. The action of acids, more especially of the three mineral ones, causes an immediate coagulation; and the same effect is produced by all the metallic salts. Caustic alkalis, on the contrary, hold albumen, whether liquid or coagulated, in permanent solution. The addition of lime water occasions a precipitation, but the substance thus deposited, being phosphen of lime, shews that this is not so much a chemical action on the albumen itself, as a decomposition of the phosphenate of soda which it contains.

There has been a considerable diversity of opinion among chemists respecting the cause of the coagulation which is observed to take place in liquid albumen. Scheele, in his admirable Essay on alkalis, attributes it to a combination with carolic; this is chipped in the simplest way by the direct
addition of heat; and during the process, there does not appear to be any increase or diminution of weight. In further confirmation of this method of accounting for the fact, the following ingenious experiments were invented by the Swedish chemist. Having mixed one part of white of egg with four parts of water, he divided the mass into two equal parts, and added to one a solution of caustic alkalii, and to the other the same quantity of carbonated alkalii; the liquor in both cases, remained perfectly clear; then, upon dropping into the first a little muriatic acid, an immediate coagulation took place, while a like quantity of acid produced no effect on the latter solution. This is accounted for by Scheele in the following manner. By the combination of acid with caustic alkalii, the heat given out is absorbed by the albumen which thus coagulates, but when the acid is added to the carbonated alkalii, the whole of the caloric is taken up by the difgaged carbonic acid, and in consequence no coagulation is the result.

According to Fourcroy, the coagulation of albumen is owing to an aborption of oxygen, and the facts which appear to him to prove this are the following: If the red oxyd of mercury is triturated with albumen, it is reduced to the state of black oxyd, at the same time that the albumen becomes opaque, thick, and in some degree coagulated. The white of a fresh laid egg is incapable of being reduced by boiling to so firm a coagula as that of an egg which has been kept several days.

On the other hand, Carradini has shewn that albumen is coagulable by heat without the access of air, and even that when this effect takes place in oxygen gas, there is not the smallest portion of air absorbed.

It was the opinion of Buechet, that albumen is a kind of natural soap, and that its coagulation by acids was merely owing to their combination with the soda which it contains.

These differences between chemists of acknowledged ability, founded also upon undisputed facts, appear to arise from a mistaken necessity of considering coagulation as the constant effect of some one uniform cause, when a little consideration cannot fail of convincing us of the very equivocal nature of this phenomenon. Albumen certainly concretes by the mere action of heat unabated by any other substance; and this is probably owing in part to the fixation of caloric, and in part to the distribution of sulphurized hydrogen, as is manifest from the tarnishing of silver, and the blackening of acetated lead, by the white of a newly boiled egg; that the extraction of sulphurized hydrogen from albumen, is obvious also from certain other facts; thus coagulated albumen is soluble in a very dilute acid, and upon the addition of a few drops of a more concentrated one, is immediately precipitated, at the same time that a strong smell of sulphurized hydrogen is manifested. Again, nitrated silver instantly coagulates albumen, and black streaks at the same time begin to appear, owing to the formation of hydrophururet of silver. The coagulation produced by the red oxyd of mercury may be occasioned by the aborption of oxygen, if indeed the blackness of the mercury is not rather produced by combination with sulphurized hydrogen; and this is the more probable, as even metallic mercury undergoes a similar change. The thickening produced by metallic salts, is neither caused by the mere communication of heat nor of oxygen, since the coagu- lurn is an impossibl combination of the albumen with the metallic oxyd. In like manner a coagulation is formed by the combination of albumen with tannin, which has also a specific chemical action. Lastly, pure alcohol will coagulate albumen, probably by the mere abration of the water necessary to its liquidity, since the curd thus obtained is resoluble in water, without any remarkable change of properties.

Besides the general effect of acids on albumen, some of them produce peculiar changes which require notice. By concentrated sulphuric acid it is blackened and charred, ex- haline at the same time a nauseous odour; while, by the same acid diluted, it is merely coagulated and preferred from further change. Strong muriatic acid gives a violet tinge to the coagulum, and by long contact effects a partial de- composition, so far as to become faturated with ammonio. Nitrous acid, at the temperature of about 70° Fahr., causes a plentiful disengagement of azotic gas; if further heated, a quantity of pruflic acid is formed; and this change is immediately rendered sensible, by the peculiar odour of this acid, similar to that of bitter almonds; this is succeeded by the separation of carbonic acid and carbonated hydrogen; and as soon as this change comes on, the residue in the retort is found to consist of little cile than water, covered with a lemon-coloured fat oil, and holding in solution oxalic acid, which may be afterwards separated by crystallization. If dry caufic potash or foda be triturated with albumen, either liquid or folid, ammoniacal gas is feret at liberty; and the calcination of the residue yields a puri- fied alkalii, capable of producing a blue precipitate with the farts of iron.

The neutral farts appear to have little or no action, ex- cept that of preferring the albumen from putrefaction.

By spontaneous decomposition in the open air, albumen paffes rapidly, and probably without first becoming acid, into the putrid fermentation; in this state it exhaltes a qui- sid odour, allusnes a brown colour, gives out ammonia, and remains a considerable time before the decomposition is completed.

**Albume, Vegetable.** The discovery of albumen in vegetables is due to Fourcroy. This chemist having ob- served that the clarification of the expressed juices of the antileboratic plants was effected by the spontaneous coagula- tion of their colouring matter, at the temperature of boil- ing water, was induced to examine whether this property did not depend on the presence of albumen. For this pur- pose, having obtained the juice of two pounds of young cresses, he filtered it while cold, through blotting paper, and by this means separated the greater parts of the colouring fecla: the liquor was, however, full of a bright green, but upon being exposed in a broad shallow vessel to the air, at a temperature of about 80° Fahr., in two hours it became turbid, and deposited a greenish matter, becoming itself almost colourless; in this state it was exposed to the heat of boiling water, and in a few minutes there separated a large quantity of whitish flocculent matter. Another por- tion of the same clarified liquor being exposed to the air, deposited at the end of two days a similar coagulum; and the same effect was produced on the third portion by the addition of sulphuric acid. The substance thus obtained being first repeatedly washed in cold water, exhibited all the properties of animal albumen. It wasasily and quickly difolved by any of the alkalies; it experienced no change in boiling water, except that of becoming more solid; it converted the purple juice of mallows to green, and by distillation, yielded a notable quantity of ammonio: when
when exposed with a little water to a warm air, it swelled considerably, exhaled a fetid ammoniacal odour, and gave all the usual signs of active putrefaction; hence explaining the reason of the rank disagreed smell that characterizes the spontaneous decomposition of all the crucifom plants. When dried, by pressure between two pieces of paper, it exhibited a considerable degree of ductility and transparence, like glue.

Albumen was afterwards found in the roots of various vegetables, epecially of the rumex-patentia; also in wheat and the farinaceous seeds; and in general in all the green and succulent parts of plants. The acid pulps of fruits are totally detitute of this substance, but abound with jelly; and it is the opinion of Fourcroy, that in all these cases there is a conversion of albumen into jelly, by the gradual evolution of the acid, and consequent fixation of oxygen. Dict. Method. Art. Alummen Vegetal. Fourcroy Syll. des Conn. Chim. vol. viii.

ALBUNELAS, in Geography, a town of Spain, in the province of Granada, four leagues east of Alhama. ALBUQUERQUE, a town of Spain, in the province of Elremadura, on the frontiers of Portugal, situate on an eminence, and defended by a strong castle. It has a considerable trade of wool and woollen manufactures. N. lat. 38° 52'. W. long. 6° 6'.

ALBUQUERQUE, Alphonso, in Biography, a Portuguese governor of the Indies, contributed more than any other to extend the territories and to establish the power of the court of Portugal in that country. The first exploit which he performed, after being appointed governor, was the reduction of Calicut; which he attacked at once by land and sea, with such fury, that he soon became master of the town, which he burnt; and of the fortresses, which he demolished. As soon as he recovered from an accidental injury which he received on this occasion, he proceeded against Goa, and took it. This city, in 1599, became the residence of the governor, and the see of an archbishop and primat of the Indies. His next object was Malaccas, which he attacked by sea and land, took by storm, and delivered to the pillage of the Portuguese soldiers. The clear fifth referred for the king, amounted in value to 200,000 pieces of gold. The last enterprise of any moment in which he was engaged, was the siege and capture of Ormuz. He had formed other great projects, which, however, he did not live to execute. One of these was the revival of the trade of Alexandria, in which he knew the Venetians would have supplied the Turks, or any other persons, for their own emolument. He proposed, therefore, to the emperor of Ethiopia, that for his own security, he should divert the channel of the Nile, by cutting a passage for it into the Arabian sea before it reached Egypt; and by so doing, he would have rendered the greatest part of Egypt uninhabitable; and at the same time made it impracticable to renew the old mode of transporting East India commodities from the Red Sea to Alexandria, which was the object he had principally in view. Another project was to transport 300 horse from the island of Ormuz to the opposite coast of Arabia, and thus to plunder the tomb of Mahomet at Mecca, which he conceived would be beneficial in a variety of respects, and chiefly in reducing the trade of the east out of the hands of the Turks and other Mahometan nations. But death prevented the accomplishment of his various purpoaes; for after his return to Goa, he was seized with a distemper which in a few days proved fatal; so that he died, Dec. 16, 1575, at the age of 63. He was called by the Mahometans, Alberquerque Maiandy, because he was born at Melinda in Africa; but, by the Portuguese, he was justly denominated Alberquerque the Great. He was the ablest statesman, and the most consummate general they ever had in India, and left their affairs in the best situation; and yet he performed his numerous exploits with a very inconceivable force. With 30 ships he took Clicuit, with 21 he became master of Goa; with 23 he surprized Malaccas; and he had no more than 42 in his expedition against Ormuz. His funeral was performed with great solemnity, and his body interred in a chapel built by him at Goa, and dedicated to the blest Virgin, which chapel was much enlarged by his son, Alphonso Alberquerque, who lived to the age of 80, and wrote a large book of Memoirs, in which he recorded his father's actions.

He studied the disposition of the people among whom he lived, and conformed in outward pomp and magnificence on public days to the habits of the Indians; though in his private mode of living, he was frugal and abstemious. In exacting the dues of the crown, he was severe; but as to his personal fortune, he had scarcely anything which he would call his own. His officers were his children, to whose infatuation he was as attentive as the most affectionate parent is to the education of his sons. Whilst he overlooked trivial faults, he punished treachery or neglect of duty with inexorable severity. He was liberal in bestowing recompense and applause on those officers who distinguished themselves by any great actions; at the same time he was not only silent as to his own, but would not permit others to commend them. It was a maxim which he often repeated, "that he was afraid of nothing but flattery;" and it was observed, that he never preferred any who attempted to gain his favour in that way.

Some of the Portuguese historians have observed, that the vanity of his predecessor Almeyda, made him affect thestate of a prince when the Portuguese power was very imperfectly established; whereas the modelly of Alberquerque was most conspicuous when his victories left him nothing to fear, and when the greatest princes of the east sent ambaassadors to solicit his friendship. Alberquerque, however, was well born by humble ambition; and his extravagant desire of extending the dominions of Portugal, made him regardless of the measures which he adopted for this purpose. In private life, he was a man of the strictest honour; but in his public character, liable to just reproach and cenure. After serving his prince and country with singular zeal and success, he had the misfortune to die in disgrace. His ambition, austerity, and strict regard to justice, had raised enemies, who were aribidious in their endeavours to prejudice the king against him; and as he had solicited with a view to the preservation of Goa, the grant of it, together with the title of a duchy, as a reward for his services, this was made a pretence for exciting and increasing the jealousy of the king; and thus, before his death, he was displaced from the office of governor, and another perfon appointed in his room. When Alberquerque heard of this appointment, he is said to have exclaimed: "I incurred the hatred of many by my love for the king, and am disgraced by him through his prepossess- sion for other men. To the grave, unhappy old man; it is time thou wert there; to the grave!" His letter to the king,
king, recommending his natural son to his favour, close with these words: "I lay nothing of the Indies; they will speak for themselves, and for me." Mod. Uni. Hill. vol. viii. p. 43-50.

Albuquerque Coelho, Edward, marquis of Baixo, count of Terrambuco in Brazil, and gentleman of the chamber to Philip IV. King of Portugal, was distinguished by his valour in the Portuguese army, against the Dutch at Bahia. He wrote a "Journal of the War," from the year 1530, which was printed at Madrid, in 1620. He died at Madrid, in 1638. Gen. Biog.

Albure, or Auburn colour, a whitish-brown, or a mist colour, partaking of red and white. Skinner derives the word, in that sense, from the Latin, albus, white; and the Italian, burro, from brown, brown.

Alburnum, in Phystogy, denotes the white, soft sub stance that lies between the inner bark and the wood of trees, composed of layers of the former, which have not attained the solidity of the latter. In this state, dealers in timber call it the sap.

Alburnus, in the Linnean sytem of Zoology, a species of Alcyonium, white, very malleable, attenuated, and subdivided, with terminal tubulous pores. It is found in the Indian seas.

Alburnus, in Ichthyology, a species of the Cypri nus of Linnaeus, and the bleak of Ray and Pennant.

Alburnus, is also a species of the Perca.

Alburnus Portus et Muros, in Ancient Geography, lay to the north of Pauly, in that part of Magna Graecia, called Lucania.

Albus Pugus, or Picus, a village of Arabia, mentioned by Strabo, and called, according to the Greek idiom, Albus pugus.

Albus pificus, in Ichthyology, the white fish, a name by which Sylvan has distinguished the fish, more usually called the capito-lactis, and seeming to be the same with the blue chub; or, as it is more generally called, the jenling. It is the Cyprinus festus of the Linnean system.

Albuseira, in Geography, a small town of Algarve in Portugal, containing two parishes, and containing about 1000 inhabitants. It is situated on the sea-coast, between Lagos on the south, Faro on the east, and Sylves to the north. N. lat. 37° 09' W. long. 3° 21'.

Albuseira is also a lake in the island of Majorca, in the Mediterranean.

Albutius, Silis (Caier), in Biography, an orator of some celebrity at Rome, in the time of Augustus, was born at Novara, and advanced to the office of Edile; but receiving a public infilt, by being dragged from the tribunal, in consequence of a judgment he pronounced, he left his native place and settled at Rome. Here he formed a friendship with the orator Munatius Plancus, and afterwards became his rival. In his public pleadings he was too free in the use of rhetorical figures, and sunk into disrespect, so that he renounced the bar. In advanced life he returned to Novara, where he laboured under an ailment, and having delivered a discourse in justification of suicide, he flaved himself to death. The elder Seneca commends him as a man of eminent probity, for not knowing how to offer or to bear an injury. From a passage in Quintilian it appears that he was the author of a tract on rhetoric Suetonius de Clar. Orat. c. vi. Quinct. Inf. lib. ii. c. v. Gen. Diet.

Albutius, Titus, a Roman philosopher of the Epie curan sect, flourished about 100 years before Christ. Having been educated at Athens, he became so attached to Greek manners, that he preferred being regarded as a Greek rather than a Roman. According to Cicero, (De Finibus, lib. i. c. 3. and De Oratore, lib. iii. c. 43.), Scevola often rallied him on account of this affectation. Thus, he compares his style to a kind of inlaid or mosaic work.

"Quam lepide lexis compolte, ut ttferculas omnes Are pavimento, atque emblemate vermiculatu."

"How neatly are his polish'd words inlaid! Not nicer skill the artist has display'd, Whole patient hand, on smooth mosaic ground, Figures that live and speak, has strew'd around."

Whilst he was propror of Sardinia, he celebrated a kind of triumph in his province; and this arrogance induced the senate to refuse him a "supplication," or public thanksgiving to the gods in honour of his exploits. On his return from Sardinia he was accused of peculation in his office, and sentenced to exile. He withdrew to Athens, and devoted his remaining days to the study of philosophy. Although so possessed of talents for oratory, they were of the inferior kind; and he had no claim on the character of a Flate-man or a philosopher. From the farcical appelation of "Grecus Homo," bestowed upon him by Cicero (in Brut.) he appears to have been an affected trifler. Gen. Diet.

Albutius, Aegrius, Calpextatus, and Rubrius, four physicians, all lived in the time of Augustus, and acquired considerable wealth by practising medicine at Rome. Haller, Bibl. Med. vol. i. p. 166.

Albutius, John Peter, a celebrated philosopher and physician of the 16th century, taught medicine at the University of Padua, for forty years, where he also practised, we are told, with great reputation and successes, particularly in the plague which raged in that city, in the year 1577. He died February 14th, 1583, aged 75 years. His son, John Francis, who succeeded him in his practice, procured him to be buried at the church of St. Cuflorga, at Milan, where a handsome monument was raised to his memory, with an inscription, at once celebrating his talents, and virtues, the pity of his son, and the gratitude of his fellow-citizens.

Albuiziska, in Geography, a fortress which the Czarsa polleched on the river Amur, in Mongolian Tartary, about 1300 leagues from Moscow.

Alby. See ABL.

Alca, a small and very fertile island in the Capfin sea, on the coast of Tabritan.

Alca, Aul, in Ornithology, a genus of the order of Anfert, in the Linnean sytem, and of the Palmipedes, in the distribution of Latham; the characters of which are, that the bill is without teeth, short, compressed, convex, frequently furrowed transversely; the inferior mandible is gibbous before the base; the nostrils are behind the bill; and the feet generally have three toes. This genus comprehends 12 species, vid. 1. A. tosa, with four furrows on the bill, and a white line on each side running from the bill to the eyes. This is the alca of Clufins, Wormius, and Brilon; the plautus tonor of Klein; the pingouin of Buffon; and the razor-bill, an, or murr of Pennant, Roy, Willoughby, Albus, Edwards, and Latham; the Falk of Martin, and the marrot of Sibbald. This species weighs about 22½ ounces; its length is about 18 inches, and alar breadth 27; the bill is two inches long and black; the grooves of the upper mandible are four, and of the lower three; and the width of them is white; the inside of the mouth is of a fine pale yellow; the head, throat, and the whole upper side of the body are black; the wings are of the same colour, except the tips of the leaver quill-feathers which are white; the tail consists of 15 black feathers, and is sharp pointed; the whole under side of the body is white, the legs are black. The female, says Buffon, wants the white streak between the bill and the eye, but
but its throat is white. These birds, in company with the guillemot, appear in our seas in the beginning of February; but do not settle in their breeding-places till they begin to lay, about the beginning of May. When they take pos-

session of the ledges of the highest rocks that hang over the sea, they sit close together, and in rows one above another, and form a very grotesque appearance. They lay only one egg at a time, which is of a large size, in proportion to that of the bird, being three inches long, either white, or of a pale sea-green, irregularly spotted with black; if this egg is destroyed, both the auk and the guillemot will lay another, and if this be taken, a third; as they make no nest, they deposit the egg on the bare rock. Posing it in such a manner as no human art can effect, and fixing it by means of the viscous moisture that bedews its surface on its ex- 

clusion; and though such multitudes of eggs are contiguous to each other, each bird distinguishes its own. These eggs serve as food to the inhabitants of the coasts which the birds frequent, and are procured with great hazard by persons let down with ropes, held by their companions, and who for want of fable footing are precipitated down the rocks, and perish together. These birds are found in the northern parts of America, Europe, and Asia. They come to breed on the Ferroe islands, along the west of England, and on the Isle of Wight, where they add to the multitude of sea-

fowl that inhabit the great rocks, called the Needles. Their winter residence is not positively ascertained. As they cannot remain on the sea in that season, and never appear on shore, nor retire to southern climates, Edwards supposes they pass the winter in the caverns of rocks, which open under water, but rise internally as much above the level of the flood as to admit a recce, and here, as he apprehends, they remain torpid, and live upon their abundant fat. The pace of this bird is heavy and flagellip; and its ordinary posture is that of swimming or floating on the water, or lying stretched on the rocks or on the ice.

2. A. piuca, A. minor of Briff. mergus of Bellon. Aldrov. Johnft. Will. and Ray, alca unifcata of Brunn. and Mullcr, and black-billed auk of Pennant and Latham, has its bill smooth and compressed, the whole under side of the body, and the tips of the posterior wing-quills, white, and its legs red. This species weighs 18 ounces, its length is 17½ inches, and breadth 25 inches; the bill is of the same form with that of the preceding, but is entirely black. The cheeks, chin, and throat, are white; in all other respects it agrees with the former species. It has been found on our coasts in winter, when the other fort has left them. It is very common in Greenland, where it breeds on the cliffs, feeds on marine insects, and grows very fat. In winter these birds pass the day in the bays, and in the evening retire to the sea. The Greenlanders eat their flesh half putrid, suck their raw fat, and clothe themselves with their skins. When this bird is dressed with its entrails, it is esteemed by those people a great delicacy. Some have doubted whether these birds migrate far southward as the Mediterranean, whilst others affirm that they have been found on the coast of Canda; and Mr. Latham says, that they are common in the bay of Gibraltar, where they have been particularly noticed on account of the adroitenfs and activity with which they plunge into the water, and move through it in pursuit of their prey. The A. baica of Brunnick, with black tail and wings, is a variety of this species.

and great auk of Pennant and Latham, has its bill com-

pressed and furrowed on both sides, and has an oval spot on each side before the eyes. Its length to the end of its toes is three feet; the bill to the corner of the mouth is 4½ inches; part of the upper mandible is covered with short, black, velvet feathers; the head, neck, back, tail, and wings, are of a glossy black; the tips of the lefier quill-

feathers white, the whole under side of the body white, and the legs black. The wings are so small as to be useless for flight, their length, from the tip of the longest quill-feathers to the first joint, being only 4½ inches; and these birds are therefore observed by sailors never to oander beyond foundings, and by the fight of them they are able to ascertain the nearness of the land. They can fearfully even walk, and of course continue on the water, except in the time of breeding. According to Mr. Martin, they breed on the isle of St. Kilda, appearing there in the beginning of May and retiring in the middle of June. They lay one egg, six inches long, of a white colour; and if the egg be taken away, no other is laid in the same sea. Some eggs are irregularly marked with purplish lines crossing each other, and others are blotted black, and ferruginous about the thicker end. Mr. Macaulay, in his history of St. Kilda, p. 156, observes, that this bird does not visit that island annually, but sometimes keeps away for several years together; and that it lays its eggs close to the sea-mark, as it is incapable, by the shortness of its wings, of mounting higher. Birds of this species are said not to be numerous; they seldom appear on the coasts of Norway. They are met with near Newfoundland and Iceland. They do not resort annually to the Ferroe islands, and they rarely descend more to the south in the European seas. They feed on the cyclooperus, and such 

fifth, and on the rock-root and other plants. The skins are used by the Equisauus for garments. The aika of the Greenlanders, which is about the size of a duck, with the back black, and the belly white, and which can neither run nor fly, is supposed by M. Buffon to be this bird. These birds live in flocks at sea, and never approach the land, except in very severe cold; and in this case they are so numerous, that they cover the water like a thick dark fog. The Greenlanders drive them on the coast, and catch them with the hand, as they can neither run nor fly. At the mouth of the Bell river, they afford subsistence to the inhabitants in the months of February and March, and their down serves to line winter garments.

cula of Briffon, bowler of Martin, pufinus anglicus of Gefner, macareus of Buffon, and pufin of Pennant and Latham; has its bill compressed, channelled on each side with four furrows, the orbits and tempiks white, and its upper eye-lid pointed. For a further account of this spe-
cies, see PUFFIN.

5. A. alca, uria minor of Briffon, mergus melanoleucus, with a short sharp bill of Ray, small black and white diver of Will. and Edwards, Greenland dove or fea-turtle of Albin, rotges of Martin's Spitzb. and little auk of Pennant and Latham, has a smooth conical bill, the whole under part of the abdomen, and the tips of the posterior wing-quills white, and the legs black. The bill is short, strong, and black; the cheeks, throat, and under side of the body white, the crown of the head, hind part of the neck, back, tail, and wings black, the inner coverts of the wings grey, the specula feathers black and white; the legs and feet covered with dirty greenish white scales; the webs black. The size of the bird, from which this description was taken by Pennant, was not superior to that of a blackbird. Mr. Edwards describes another
another varying very little from this, which he imagines differs only in sex; the head and neck are wholly black and the inner covert of the wings barred with a dirty white. Gmelin mentions two varieties, viz. A. candida, or white of Brunnick, and the A. with a red breast. This species inhabits America and Europe, especially in the arctic sea, is found sometimes among fragments of ice, about nine inches long, as to the disposition of its legs, neck, food, and manners resembling the other species, but more capable of walking, laying two bluish white eggs, flying swiftly, and becoming fat in flurried weather, in consequence of the small fish that are brought within its reach; whilst at rest on the water or swimming, it is perpetually dipping its bill in the water. In Greenland it is called the ice-bird.

6. A. labradorica, or Labrador auk of Pennant and Latham, has a keel-shaped bill, its lower mandible angulated, the linear noltrils covered with an obscure membrane. The bill is narrow, the upper mandible of a dark red colour, the lower whitish, spotted with black, the temples dull white, the throat, wings, and short tail of a dark colour: and the legs red. It is about 12 inches long, and found in the country of Labrador.

7. A. trisetata, or crested auk of Pennant and Latham, has its bill somewhat ascending, conoidal, crimmon-coloured, white at the tip, with a furrow running on each side of the lower mandible from the throat, and a crested front. It is about the size of the thrush, 13 inches long, and found in the islands adjacent to Japan, and in Bird island, Situate between America and the northern part of Asia, in the day swimming on the sea, and at night in the rabbit holes of the shore and the crefts of rocks.

8. A. tetragula, or dufty auk of Pennant and Latham, has an ascending bill conoid, of a dingy brown colour, the lower mandible triangular, and the front somewhat crested. It is 11 inches long, and found in the sea of Kamtchatka, on the sea by day, and in the night concealed in the rabbit holes, caves, and fissures of rocks, where it forms its nest; it walks and flies very indifferently, stands erect, swims swiftly on the water, and dives well.

9. A. phoebaca, or peregrin auk of Pennant and Latham, has its bill fubovated, compressed and crinmon-coloured, with a single furrow in each mandible, with a white spot in the middle of the upper eye lid, and below the eye. The head and upper part of the body are dufty, the lower whitish, varied with black edges; from the remote corner of each eye a tuft of white feathers hangs down the neck; the tail is very short, the legs of a dirty yellow, and the membrane connecting the toes brown. This species is about the size of the little auk, is found in the sea that lies between the northern parts of Asia and America, sometimes by day in flocks swimming on the water, though not very far from land, unless driven out by storms, and in the night harbours in the crevices of rocks. About the middle of June they lay upon the rock or sand a single egg, about the size of that of a hen, of a dirty white or yellowish colour, spotted with brown, which is esteemed good. These birds, like others of the same clafs, are stupid, and are mostly taken by the natives, who place themselves in the evening among the rocks, drenched in garments of fur with large open sleeves, into which the birds fly for shelter as the night comes on, and thus they become an easy prey. They sometimes at sea take a flip for a roosting-place, and thus warn navigators of their being near the land at the accots of night, or on the approach of storms.

10. A. impavida, or macareux of Kamtchatka of Buffon, or tufted auk of Pennant and Latham, is entirely black, has four furrows in its bill, the fides of the head, the space about the eyes, and the corner of the throat white, and a yellowish longitudinal tuft from the eye-brows to the nape. This tuft is white near the head, and afterwards of a buff-yellow; the bill and legs are crimson. It resembles the puffin in its appearance and manners, but is somewhat larger, being about 18 inches long; swimming about for whole days in the sea, where it dives well, and occasionally flies swiftly, but never departing far from the rocks and islands; and feeding on flounders, crabs, and shell-fish, which it forces from the rocks with its strong bill; in the night it comes to shore, burrows about a yard deep underground, and makes a nest with feathers and sea-weed, in which it lodges with its mate, being monogamous. It lays one egg in May or June, which is fit to be eaten and used for food, but the flesh of the bird is hard and insipid. This species inhabits the shores of Kamtchatka, the Kurile islands, and those that lie between Kamtchatka and America. The young women of Kamtchatka form an ornament of the glutton's skin, in the shape of a crescent, which they suspend behind each ear, remembring the tufts of this bird; and a present of this kind from a lover to his mistress is in high estimation. The bills mixed with those of the common puffin, and the hairs of the tail, were formerly regarded by these people as a powerful amulet: they are now used as an appendage to their drefs, and the skins of the birds are fewed together as garments. This bird is called by the natives, monichagatine, or mitchagatchi, and iglina.

11. A. antiquus, or ancient auk of Pennant and Latham, has a black bill white at the base, covered with down, a small whitish crest, on each side of the head, and another long white one on the neck. The crown of the head and throat are black; the back, wings, and tail are fuliginous. This species is somewhat larger than the little auk, being almost 11 inches long, and is found near Kamtchatka, and the Kurile islands.

12. A. pygmea, or pygmy auk of Pennant and Latham, has a black bill white at the base, covered with down, a small whitish crest on each side of the head, and another long white one on the neck. The crown of the head and throat are black; the back, wings, and tail are fuliginous. This species is somewhat larger than the little auk, being almost 2 inches long, and is found near Kamtchatka, and the Kurile islands.

ALCAEUS,
ALCÆUS, in Classical Biography, a famous Greek lyric poet, was born at Mytilene in the island of Lesbos, and flourished in the 44th olympiad, about 604 years before Christ, and was contemporary with Sappho, to whom it is said he was affectionately attached. A verse, intimating his passion to Sappho, with her answer, is preferred by Ariotete, (Rhet. lib. i. c. 9.), thus translated:

Alcæus.—"I faint to Sappho would a with impart,
But fear locks up the secret in my heart."

Sappho.—"Thy down-call looks, respect, and timid air,
Too plain the nature of thy with declare;
If lawless, wild, inordinate deire,
Did not with thoughts inspire thy bosom fire,
Thy tongue and eyes, by innocence made bold,
Ere now the secret of thy foul had told."

The invention of lyric poetry is by some attributed to Alcæus, and it seems to be implied by Horace (Od. xxxii. lib. i.), unless he only intimates that he invented the barbizon, or harp. From him, however, the lyric measure, called "the Alcaic verse," derived its name. He was no less a votary of Minerva than of love and the muses. He strenuously opposed the liberty of his country against tyrants who usurped dominion, and particularly against Pittacus; and took up arms in its defence. But his courage failed him in the day of battle, and he attempted to save himself by flight, when his party was defeated, but was taken prisoner by Pittacus, who generously granted him both his life and liberty. He was afterwards sentenced to exile; but what was the issue of his conflicts, and how and where his life terminated, history does not inform us. Horace seems to intimate, that he became a confair. His poetical talents have never been disputed. His poems, of which only a few fragments now remain, collected by Neandrus, H. Stephens, and Urfinus, were written in the Æolian dialect, and in the measure of his own invention. The subjects of them were various, sometimes amatory and bacchanalian, but more generally grave and political. They are described by Horace in the following verses:

"Et te fonantem plenius aureo,
Alcae, pléctro dura navis,
Dura fugax mala, dura belli!
Utrunque facro digna silentio
Mirantur umbrae dicere: fed magis
Pognas, et exaëlos tyrannos
Denfum humeres bibit aure vulgus."

Od. xiii. i. ii.

"Alcæus strikes the golden strings,
And seas, and war, and exile lings:
Thus while they strike the various lyre,
The ghosts the sacred sounds admire;
But when Alcæus lifts the brain,
To deeds of war and tyrants fleet,
In thicker crowds the shadowy throng,
Drink deeper down the martial song."

FRANCIS.

Quintilian (Inst. Orat. lib. x. c. i. tom. ii. p. 896. Ed. Bu man.) says, that his style was concise, sublime, and accurate, and much resembling that of Homer; but that his pieces of the lighter kind were inferior to his other poems.

There were other ancient poets of this name (see Fabr. Bib. Græc. ubi supra); such as an Athenian tragic poet, who is said by some to have been the first composer of tragedies; and who, according to Suidas, is different from Alcæus, the son of Mecren, a comic poet, the fifth author of the ancient comedy. One of his pieces, entitled Psiphis, was produced in his dispute with Ariiphanes in the fourth year of the 97th Olympiad. Plutarch (in Flamin. Oper. tom. i. p. 357.) mentions another Alcæus, who lived in the 147th Olympiad. A. U. C. 555. B. C. 199, and who ridiculed Philip, king of Macedonia, on account of the battle which Titus Flaminus gained over him in Thebaly. An Alcæus of Mestia also lived in the time of Vespasian and Titus, of whose epigrams some are preferred in the Anthology. One of these is topped with having suffered a singular kind of death for his lewdness; which was the punishment laid to have been inflicted by means of a radifh, or the fifth called a mullet, on adulterers, and referred to by Juvenal, Sat. x. v. 295. Ed. Cafaub.

"—quodiam mœcelos et mugillis intrat:" and also in the menace of Catullus, epig. 51, ad Aurelius:

"Ah tum te miserum, malique fati
Quem adaequatis pedibus, patente porta,
Percurrunt ranhique, mœgalique."  
"Ah wretched thou, and born to lucklefs fate,
Who art discover'd by the unhut gate!
If once, alas! the jealous husband come,
The radifh or the sea-fish is thy doom."  

ALCÆUS, in Mythology, the son of Perucus and Andromeda, the father of Amphiryon, the supposed father of Hercules; hence called Alcides.

ALCAI, in Geography, a high and fertile mountain of Africa, in the kingdom of Fez, about 12 leagues from the capital. It is inhabited by many rich and powerful peasants.

ALCAEIS, in Ancient Poetry, a name common to several kinds of verses; so called from the poet Alcæus, the inventor of them.

The first species of alcæus consists of five feet, of which the first may be either sponde, or iambic; the second is an iambic; the third, a long syllable; the fourth, a dactyl; and the fifth, a dactyl, or amphimacer: as thefe of Horace.

"Omnes eodem cogitur, omnium
Verfatur urna, ferius, ocus,
Sors exitura."

The second species of alcæus consists of two dactyls, and two trochees; as,

"Exfilium impofitura cymbæ."  
Besides these two kinds of verses, which are properly called dactyllic alcæus, there is a third fort, called simply alcæus; whereof the first is an epitrete, the second and third are iambicambiæs, and the fourth a bacchæus; as,

"Cur timet flæ? cum Tiberim | tangere? cur | olivum?"

ALCAE Odes, consists of four strophes, each of which contains four verses; the two first are alcæus verses of the first kind: the third an iambic dimeter hypercatalectic, i.e. of four feet and a long syllable: as,

"Sors exitura, et nos in æternum."  
The fourth is an alcæus of the second kind.—The entire alcæ strophe is as follows:

"Omnes eodem cogitur, omnium
Verfatur urna, ferius, ocus
Sors exitura, et nos in æternum
Exfilium impofitura cymbæ."
The following is also of this species which Horace calls 
imacres Alcali comunes

"Non possidendem multa vocavere,
Recebatium; rectius occupat
Nomen buati, qui deorum
Museribus sapienter utti," &c.—Od. ix. lib. iv.

ALCAID, in matters of Polity, an officer of justice
among the Moors, Spaniards, and Portugaluese.
The word is also written alcaide, alcald, and alcaiz; sometimes also alcaide.

It is originally Arabic, compounded of the particle al, and the verb kad, or akad, to rule, govern, administer.
The emperor of Morocco's court confides chiefly of seven or eight alcáids, his devoted slaves.

The alcaide, or governor of a city or castle in Barbary, hath sovereign jurisdiction in civil and criminal concerns; and all fines and punishments are inflicted at his pleasure.

In some places the alcáids are much the fame with the emperors' tax-gatherers.

Alcaide, among the Spaniards, &c., is a kind of inferior judge, or minister of justice, who takes cognizance of causes in the first instance, and answers in good measure to the French procureur, and an English justice of peace.

They had also their alcáide of the wards, who took cognizance of cases of whoredom and adultery. This officer was otherwise called alcaide of honour. Du-Cange.

ALCALA de los Gazules, in Geography, a very ancient town of Spain in Seville, situated on a mountain, and surrounded by a fertile plain, 10 miles east and west from Medina Sidonia.

ALCALA de Guadaira, a small town of Spain in Seville, on the river Guadaira, two leagues south-east from Seville. N. lat. 37° 22'. W. long. 6° 6'.

ALCADE de Henares, in Geography, a town of Spain, in New Castile, situated on the river Henares, in a beautiful plain, and confining of well-built houses, which form handsome streets, and which are disposed in a kind of oval figure. N. lat. 40° 35'. W. long. 4° 20'. It is surrounded by piazzas, where the tradesmen keep their shops, which are well supplied with a variety of goods. The adjoining land, watered by the Henares, is fertile and well cultivated, and yields plenty of grain, good mustewine, and excellent melons. Near the town is a spring, the water of which is preferred, on account of its peculiar purity, for the king's use, and conveyed to Madrid. This town belongs to the archbishop of Toledo. It has a collegiate church, and a celebrated university, which was restored in 1549, by Cardinal Ximenes; and in the church belonging to it this Cardinal was buried. This university possessed a very considerable library, and many curious manuscripts. Gomez says, that they owed 4000 aurei, and that among them were seven of the Hebrew Bible. Here, it is probable, were deposited, the Greek manuscripts used for the Complutian edition of the Greek testament. Professor Moldenhawer went to Alcala, in 1784, with a view of discovering these manuscripts; but, to his extreme astonishment, he found that about 35 years before that time, a very illiterate librarian, who wanted room for some new books, sold the ancient vellum manuscripts to one Toryo, who dealt in fire-works, as materials for making rockets. Martinez, a Greek scholar, as soon as he heard of this savage act, hastened to save these treasures from destruction; but they were actually destroyed, except a few scattered leaves, which are now preserved in the library. It is added, as a circumstance of aggravation, that the number of manuscripts was very considerable. However, as rockets are not made of vellum, a learned writer confides himself with the reflection, that the manuscripts were written on paper, and therefore of no great antiquity. Michael's Intro. to the New Test. by Mart. vol. ii. p. 241. vol. iii. p. 544.

ALCALA del Rio, a town of Spain in Cordova, lies in a hilly country, but produces fine fruits and good wine. It is 13 leagues south-east from Cordova. N. lat. 37° 18'. W. long. 4° 17'.

ALCALA de la Selva, a town of Spain in Seville, on the Guadalquivir, two leagues above Seville.

ALCALI and ALCALIZATUM. See ALCAI and ALCALIZATION.

ALCAMENES, in Biography, a flautist, the scholar of Phidias. Pliny, xxxvi. 5. Cicero de Nat. D. i. 32.

ALCAMO, in Geography, a considerable town of Sicily in the valley of Mazara, about 25 miles south-west from Palermo. It is situated on high ground, in a fine open cultivated country, and well sheltered by large woods of olive trees. The number of inhabitants is about 8,500. It derives its name from Adaleam, the caliph's lieutenant, who, in 837, conquered Sicily, and who erected a fortress in Monte Bonifati; but Frederick of Swabia, having dispossessed the Saracens, destroyed the fort, and erected the borough of Alcamo at the foot of the mountain. Having passed through several Spanish families, it now belongs to the duke of Ferrandina, heir to the poffessions of Toledo, duke of Alba. The church is adorned with some good pictures by Pietro Novello, commonly called the Raphael of Sicily; and with altos relevos of great merit by Gigini. The streets of the town command a superb view: the belt land in the vicinity is town with corn, the next is planted with vines, and the whole is cultivated with myrtle-leaved furmace, the leaves and flowers of which are dried and pulverized, and exported in bags, for the purpose of tanning fine leather. N. lat. 38° 2'. E. long. 12° 56'. Swinf. Trav. vol. iii. p. 346.

ALCANDRO, a town of Spain in Old Castile, situated on the Ebro; four leagues from Calahorra.

ALCANI, or ALCAN, a town of Africa in Egypt, on the western branch of the Nile, 30 miles N.N.W. of Cairo.

ALCANITZ, or ALCANIS, a town of Spain in Aragon, on the river Guadaloupe, and the frontiers of Catalonia, 15 leagues south-east from Saragossa. It was formerly the capital of the Moors, but now belongs to the order of Catrabua. It has a collegiate church and a fortresses, and is surrounded with gardens and fruit-trees. A fountain in this town throws up water through 42 pipes. N. lat. 41° 10'. W. long. 3° 0'.

ALCENIZOS, a town of Spain in Leon, on the frontiers of Portugal, four leagues west from Zamora.

ALCANNHA, or ALKANKA, in Commerce, by the Turks called knab, a dying drug, brought from Egypt and the L. vant, being the leaves of a plant called longiflorum Egyptian, the Egyptian privet, or the Lawsonia inermis of the Linneas sy. The tree is also called elkanna, tamarindo, potvenec to Rheed, and grows in the East Indies, as Malabar and Ceylon, in Egypt, and also in Cyprus, and in all parts of Syria. The colour drawn from these leaves is either red or yellow, according to the mode of preparing it; yew, when steeped in common water; and red, when infused in vinegar or alum water. The people of Cairo make a considerable traffic of these leaves, which they reduce to a powder, called archenous, much used by the women to dye their nails, hands, hair, and other parts of the body of a golden yellow hue. They apply it also for the same purpose to the manes and tails of their horses.

This cullera
A

L

cultor amongst the oriental nations is very ancient, and has generally prevailed. This powder has been also used as an astringent, for the purpose of drying ulcers of the gums, and for removing the festid smell of the feet; and many other virtues are ascribed to it by Rumphius. It is seldom met with in the shops, but may be used without injury.

The root of the Anomusa tinctoria is utilised for it, principally for giving a red colour to inks, decors, and ointments. Murray, Mat. Med. vol. ii. p. 172, 173.

From the berries of Alcanna an oil is extracted of a very agreeable smell, and which has been of some use in physic, as a colom, called oil of Cyprus, a name which is sometimes also given to the plant. Phill. Trans. abr. vol. x. pt. ii. p. 731.

ALCANTARA, in Geography, a small but strongly fortified town of Spain in Lérida, situated on a fertile country on the banks of the river Tagus. It takes its name, which figures a bridge, from an old bridge erected in the time of the emperor Trajan over the Tagus, at the expense of several Lusitanian nations. This bridge was 250 feet high, 670 in length, and 29 broad; and on account of the bridge the Moors built the city. A chapel hewn out of a rock at the entrance of the bridge, was dedicated by the ancient Pagans to Trajan, and by the Christians to St. Julian. It was taken from the Moors in 1158, by Alphonso IX. King of Castile, and given to the knights of Calatrava, who afterwards assumed the name of Alcántara. In April, 1766, it was taken by the Portuguese and the earl of Galloway, and taken by the French in the November following. It is 45 leagues south-west from Madrid, and 38 west from Toledo. N. lat. 40° 32'. W. long. 7° 12'.

ALCANTARA, or Alcantarilla, a town of Spain in Andalusia, near the Guadalquivir, five leagues from Seville.

ALCANTARA, a district of Portugal, about a league from Lisbon. On a hill in this district there is a remarkable mine of faltpetre.

ALCANTARA, one of the most considerable rivers of Sicily, rises on the north side of mount Etna, and marks out the boundary of the mountain for about 60 miles. In many places its course has been interrupted by the eruptions of the volcano; and in others, its current, which is very rapid, has worn down the solid lava to the depth of 50 or 60 feet. Its rise is attributed to the melting of the snows on the mountain; as its waters resemble, by their whitish colour, those that run from the Glaciers amongst the Alps. Bydone's Tour, vol. i. p. 119.

ALCANTARA, Order of, an ancient military order of Spain, which took its name from the city above-mentioned. The precise year of its institution is not settled among antiquaries.

The knights of Alcántara make the same vows as those of Calatrava, and are only distinguished from them by this, that the cro^s fleur de lis, which they bear over a large white cloak, is of a green colour: they possess 37 commanderies.

By the terms of the surrender of Alcántara to this order, it was stipulated, that there should be a confraternity between the two orders, with the same practice and observances in both; and that the order of Alcántara should be subject to be visited by the grand-master of Calatrava. But the former soon released themselves from this engagement, on pretence that their grand-master had not been called to the election of that of Calatrava, as had been likewise stipulated in the articles.

After the expulsion of the Moors, and the taking of Granada, the sovereign of the order of Alcántara, and that of Calatrava, was settled in the town of Castile, by Ferdinand and Isabella.

In 1549, the knights of Alcántara sued for leave to marry; which was granted them.

The history of this order was chiefly taken up in expeditions against the Moors, and battles with their neighbours. See Calatrava.

ALCARAZ, in Geography, a town of Spain, in the canton of la Marcha in New Catalonia, situated on a promontory near the river Guadalquivir, in a very fertile country, defended by a strong castle, and remarkable for an ancient aqueduct. It is famous for a breed of small horses that are very fleet and doughty. It is ten leagues north of the confines of Andalusia, 45 south of Cuenca, and 55 south-east of Madrid. N. lat. 38° 27'. W. long. 3° 37'.

ALCARRIZO, a town of Spain, in the province of Gallicia, on the river Arnoz, eight miles south of Ourense.

ALCARRAZAS, in Pottery, are a kind of vessels used in Spain for coining water. What distinguishes them essentially from other kinds of earthen ware is their porosity: this is so considerable as to allow the liquor to ooz slowly through, and stand in small drops on the outside; hence there is a constant evaporation from their surface when immersed in a current of warm air, by which means the water remaining in the jar continues at a temperature much lower than that of the atmosphere around it.

These vessels appear to have been first introduced into Spain by the Saracens; and their use has since been extended into all the Spanish colonies in America and India. They have also been known from time immemorial in China, Hindostan, Persia, Arabia, Egypt, and Syria.

The most celebrated manufactory of this kind in Spain, is at Anduzar in Andalusia, the belt earth for the purpose being found in the neighbourhood, on the bank of the little river Tamunzor. This is a kind of white marl, consisting principally of carbonated lime, with about 30 per cent. of fels, and a little alumine, and oxd of iron.

The procés of the manufacture is very simple, and is as follows. The fresh dug earth is first dried in the sun till it becomes pulverizable: and when beaten to powder, it is passd through a fine sieve, in order to separate with accuracy all the flones and coarse sand that may be mixed with it; being then put into a wooden or copper vessel with water, it is tempered by hand to the confidence of a soft uniform paste. In this state it continues twelve hours, and is then spread upon bricks, previously covered with wood ashes, till the appearance of cracks upon its surface, owing to the draining off of part of the moisture.

This firll preparation being completed, the tempered earth is weighed, and put into a broad shallow vessel, where it is trodden with the naked feet, and at the same time mixed with salt, in the proportion of seven pounds for every 150 of earth, to be made into large jars, and of half the above quantity of salt for the manufacture of jugs and other small articles. The reason of this difference is obvious: the greater the vessel is, the thicker must its sides be, to give it the necessary strength; but as its porosity would be diminished in the same proportion, a greater quantity of soluble matter must be mixed with the earth. After this, a sufficient mass of the mixture being put on a potter's wheel, it is shaped in the usual manner into a jar or other vessel and, being then gradually dried, it is baked in a common pottery oven for 10 or 12 hours, according to the heat, care being taken that the salt be not so far decomposed as to become insoluble in water.

There is scarcely a house in Spain where Alcarrazas are not in constant use. Being filled with water, and exposed for a few hours to a current of air, a very small portion of the fluid is lost by evaporation, and the remainder will...
have acquired a degree of coolness very grateful in that warm climate.

The manufacture of large red jars called bucaras, which are applied to the same purposes as the true Alcarras, but are much inferior, in being less porous, and communicating to the water an unpleasant earthy taste.

Another use to which these vessels are applied in Portugal, is that of moistening snuff or tobacco. For this purpose, the jar being filled with snuff is placed in water, which filtering through its sides very slowly, gives, in a few hours, to the included powder, the requisite humidity. Journal des Mines, vol. vi. p. 791.

The editor of the Journal de Physique is of opinion that the mixture of foist meal with common potters' earth might afford an useful sublimate both for the Alcarras and the filtering stones. The foist meal is that earth of which the floating bricks of Tucany are made; and, according to the testimony of Plato and Strabo, was anciently found in great plenty both in Alba and Spain. To the proposed use, however, of this sublimate, the earthly flavour which it would communicate to the water is a radical objection.

Alcassar, Louis de, in Biography, a Spanish feal, was born at Seville in 1554, and was at first a teacher of philosophy, and afterwards of divinity at Cordova and at Seville for about 20 years. He directed for so many years his chief attention to the study of the book of Revelation, and his work on this subject, entitled, "Vegetatio artami fenuis in Apocalypsi," is much esteemed among the Catholics, and has been printed several times. Grotius is said to have borrowed many of his ideas from this book. His works, comprehending a commentary on such parts of the Old Testament, as had in his judgment any relation to the Apocalypse, and including a treatise "On Sacred Weights and Measures," and another, "On Bad Physicins," form two folio volumes. Heyddegger in his "Mysterium Babylonis magnum," published at Leyden in 1657, has examined some of his apocalyptic hypotheses. Alcassar died at Seville, June 16, 1615, at the age of 60 years. Gen. Dict.

Alcassar, or Alcazar, in Geography, formerly César al Cabiros, a city of Africa, on the coast of Barbary, in the kingdom of Fez. It is said to have been built by Jacob Almanzor, about the year 1180, during his war with Spain, and intended as a depot for the immense fleets that were collected for this purpose. It was formerly the residence of a governor, and a town of good trade, till the Portuguese made themselves masters of it in 1458; but, though it was not long in their possession, it gradually sunk into decay, and lies now in a ruinous condition. Its situation is so low, that it is overflowed with water in the winter, and moldeled with heat in summer. The rocks of this place are so numerous and so familiar, that they occupy the tops of the houses and mosques without molestation; the inhabitants festooning them sacred birds, and thinking it lawfull to disturb them. The bay of Tétuán now appoints a governor for this town, which is the seat of his dominions towards Mecquinez. In the vicinity of this town, there is a ridge of mountains running towards Tetuan, whose inhabitants are a band of robbers, whom it has not been possible to restrain or extirpate, as they find an inaccesible shelter in their mountainous forests. It was near this town, on the river Elma-hassan, that a famous battle was fought in 1578, when three kings were slain, viz. Abdemelech king of Morocco, Mahomet the uffurer, and Sebastian, king of Portugal. The Portuguese indulge a fanciful notion, that Sebastian was transported to an enchanted island, and they expect his return to establish their power, and to render their kingdom the first on the globe. This city, N. lat. 35° 15'; W. long. 12° 35', is called Alcázar gubri, or the great castle, to distinguish it from the Alcázars of the next article.

Alcassar Zeguir, or Cegueir, q. d. the little palace, a town or fortress of Africa, in the kingdom of Fez, between Tangiers and Ceuta. It was taken by Alphonso king of Portugal, in 1458, but soon after abandoned to the Moors. It lies on the south-edge of the ruins of Gibraltar, and a shallow bay between two points of land, affords anchorage for ships, and on the west of this are two long narrow islands, parallel to the coast. N. lat. 35° 49'; W. long. 5° 36'.

Alcassar de Guete, a town of Spain, in New Castile, almost between Cuenza and Guete, with which it forms nearly a triangle. N. lat. 40° 10'. W. long. 2° 10'.

Alcassar de Sal, a town of Portugal, in Estremadura, fixed leagues from the sea, on the confines of Alentejo, guarded by a castle which is said to be impregnable. The salt-work in this town yields very fine white salt, and gives it the name. Of the rushes that are gathered in the adjoining fields, mats are made for exportation. N. lat. 35° 18'; W. long. 5° 10'.

Alcatile, a town of India in the Carnatic, well of Madras.

Alcatraxes, an island in the Pacific Ocean, about 21 leagues from Acapulco; and half a league from the continent. N. lat. 15° 50'; W. long. 102° 30'.

Alcatraz, in Ornithology, a name given by the Spaniards, also by Fernandez, Hernandez, and Nieeremburg, to the Pelican of Mexico; and erroneously by Clibus and others after him, to the Indian horn-bill, or Buceros-Hydrocorax.

Alcava, in Politcs, a tax upon transferrable property, imposed by the Spanish government. It was at first 10, afterwards 14, and at present it is only 6 per cent. upon the sale of every sort of property, whether moveable or immovable; and it is repeated every time the property is sold. The levying of this tax requires a multitude of revenue officers, sufficient to guard the transportation of goods, not only from one province to another, but from one shop to another. It subjects not only the dealers in some sorts of goods, but those in all sorts; every farmer, every manufacturer, every merchant and shopkeeper, to the continual visits and examinations of the tax-gatherers. Through the greater part of a country, in which a tax of this kind is established, nothing can be produced for distant sale. The produce of every part of the country must be proportioned to the consumption of the neighbourhood. It is to the Alcava accordingly, that Ullariz imputes the ruin of the manufactures of Spain. He might have imputed to it likewise, says a very competent judge, the declension of agriculture; as it is imposed not only upon manufactures, but upon the rude produce of the land.

In the kingdom of Naples, there is a similar tax of three per cent. upon the value of all contrats, and consequently upon that of all contracts for sale. This is both lighter than the Spanish tax, and the greater part of towns and parishes is allowed to pay a compensation in lieu of it; which compensation is levied in any mode they please, and generally as to give no interruption to the interior commerce of the place. The Neapolitan tax is therefore not nearly so ruinous as the Spanish one. Smith's Wealth of Nations, vol. iii. p. 381.

Alcaude, in Geography, a beautiful town of Spain, in the province of Andalusia and district of Cordova, between
between Cordova and Jaen. N. lat. 37° 35'. W. long. 3° 26'.

AII.CAZAR, or AlcAçAR, ANDREW, of Guadalaxara, in New Calily, in Biography, a celebrated physician of the 16th century, published in 1575, at Salamanca, "Chirurgie libris sex, in quibus multa antiquorum et recentiorum habitationes localis habentus non declarata interpretatur," fol.

In the fifth book he treats, "De pudendiagrav vel menstruag vel lichenis. vulgo Galileo." He contends this disease was known to the ancients, and cites Pliny, and various other writers in proof of this position; but admits, that in certain stages of the disease, it is only to be cured by mortal instrumentation. See a full account of this work, and a refutation of his opinion of the antiquity of the lues, in Altrnue's treatise, De Morbis Venereal, vol. ii. p. 702.

ALCE, in Ancient Geography, a town of Peloponnesus, mentioned by Plutarch, in his life of Cleomenes. Alce is also, according to Livy, a town of Spain, belonging to the Celtiberians. It is likew ise a name given by Pliny to a river of Bithynia.

A16C, in Ornithology, a species of auk of Alca.

A16C, in Zoology, a species of Cervus. See Elk.

ALCEA, Holly Mallow, Malva of Tournesol, in Botany, a genus of the monandria polyanthra clavis, and order of the natural order of collectiones, and the malacce of Julliet. Its characters are, that the calyx is double, each one-leaved; the outer cut half-way into fix parts, permanent and very spreading; the inner cut half-way into five parts, larger and permanent; the corolla consists of five, obcordate, emarginate, spreading petals, coalescing at their bases; the flamine are filaments uniting into a sort of five-angled cylinder at bottom, loose at top, and inflated into the corolla; the anthers almost kidney-shaped; the pistillum has a germ orbiculate, style cylindric, short, stigmatic almost 20, stigmaticus, of the length of the style; the pericarp is composed of many jointed airs, in a ring round a columnar flattened receptacle, parting and opening on the inside; the seed is one, flat, kidney-shaped in each air. Schreber and Julliet join this genus to Althaea.

Profesor Martyn enumerates three, and Gmelin five species; viz. 1. A. robus, common hollymallow, with leaves inanite-angular. 2. A. funefis, with corbed, rough, cre- nated, angular leaves, and flem below ramose. 3. A. acanthis, with numerous corobed rotundato lobated leaves, floccis flowers, and a flem thick and very small. 4. A.quamandela, with a subtriangular crenated obtuse quinquever- tate leaves, and foliaries flowers. The A. Africana or African H. of Martyn, is described as having leaves three- lobed crenate, flowers solitary axillary, both calyces fxt- parted. 5. A. deaefida, ffig-leaved H. with inferior palmerred seven-lobed crenated leaves, the superior halfted. Linneus doubts, whether the first and fifth species, above enumerated, are distinct, and seems to think that the last is a variety of the first. But Prof. Martyn observes, that the difference in the form of their leaves always continues. Both these sorts were cultivated by Gerard in 1597. Allione says, that the holly- hock grows wild in the county of Nice. The colour of the flowers is accidental, and the double flowers are only varieties proceeding from culture. The various colours that have been noted are white, pale, red, deep-red, blackish-red, purple, yellow, and flesh-colour. Prof. Martyn informs us, that he has seen some plants with variegated flowers, raised from seeds which were brought from China. Although these varieties of double hollyhocks are not constant, the greatest number of plants, produced by seeds carefully saved from the most double flowers, will arise nearly the same with the plants from which they were taken, provided they are kept separate from single or bad coloured flowers.

The first species grows naturally in China, the fifth in its native land, and has also been brought from Madras. Linneus refers it to Siberia. A dwarf sort, with beautiful double variegated flowers, has been for some years in great esteem, under the name of Chinese hollyhock. These plants, though natives of warm countries, are sufficiently hardy to thrive in the open air in England, and have contributed much to the ornament of gardens towards the close of summer. In large gardens, they make a fine appearance; a succession of spikes arising on the same stem for two months. The flowers on the lower part of the spike appear in July, and new flowers will be produced till the end of September. In good ground the stalks will often rise to the height of eight or nine feet, and near fxt feet of each will be garnished with flowers. The African hollyhock is a native of the eastern shore of Africa; and the alcea indica of Burm. ind. p. 149, agrees with this in having three-lobed crenate leaves; but differs from it in having the flowers terminating and yellow; with the inner calyx five-eflift. The hollyhocks are propagated by seeds, which should be sown of plants of the best colours and of the most double flowers, and they should be grown in a bed of light earth, about the middle of April, and covered over half an inch deep. When the plants have put out six or eight leaves, they should be transplanted into nursery-beds, at a foot distance from each other, watering them till they have taken root, and afterwards keeping them clean from weeds till October, when they should be removed to the situation where they are to remain.

ALCEA. See Hibiscus and Malva.

ALCEA Floridana. See Gordonia.

ALCEAE, in Entomology, a species of Papilio Plceus, with diversicated wings, of brown and cinereous colour, the primaries marked with points, and the posterior cinereous underneath; found in the southern parts of Russia.

ALCEDO, king-fisher, in Ornithology, a genus of the order of Pice. The characters are, that the bill is three- fided, thick, straight, long and pointed; the tongue is fleshly, very short, flat and sharp, and the feet are for the most part gregary. The species enumerated by Gmelin, besides several varieties, amount to 41. These birds are dispersed over the whole globe; inhabiting chiefly the water, and living upon fish, which they catch with surprizing alertness and swiftness, rejecting afterwards the undigested parts; though their wings are short, they fly swiftly; their prevailing colour is blue; their nostrils are small, and generally covered. 1. A. crista, A. abomina, crisiata of Seba, flipida philippianis crista of Britton, with of Buffon, and crossed king-fisher of Latham, is short-tailed, sky-blue above, rufous beneath, and has its crest undulated with black. The bill is black, crest greenish, on each side of the neck is a bluish streak beginning from the eye; the shoulders, the upper coverts of the wings, and the margins of the wing-feathers and tail feathers, and the whole of the intermediate tail-feathers are violet, the chin rufous, the throat rufous, and white, the wing-feathers brown, and the legs with the claws reddish. It is about five inches long, and found in Amboyna and the Philippine islands. The flipida indica crista, or A. crista elegantiuima pica of Seba is a variety. 2. A. irida, spotted king-fisher of Edwards and Latham, is short tailed, greenish, yellow beneath, with a nebulous pectoral fascia. The bill is black, the line above and below the eyes yellow, the wings punctuated with white, and the feet red. It is seven inches long, and found in Guiana. 3. A. spisida, flipida of Gefner, Ray, Olf.
Olin, Aldr. and Briff, aecyon of Gref. and Aldr., martini- 
pecheur or aecyon of Befflon, king-fisher of Albin. and Will. 
European king-fisher of Pennant, and common king-fisher of 
Latham, is short-tailed, sky-blue above, fulvous below, and 
it's drapery are rufous. This bird is seven inches long and 11 
broad of a clumsy shape, the head and bill being very large, and 
the legs disproportionately fmall; the bill is two inches 
long, the upper mandible black, and the lower yellow; and 
the sides are red; but the colours of its plumage amply 
compensate for the inelegance of its form. The crown of 
the head and the covers of the wings are of a deep blackish 
green, spotted with bright azure; the fcapular feathers and 
covers of the tail are also of a refulgent azure; the whole 
underfide of the body is orange-coloured, and a broad mark 
of the fame paffa from the bill beyond the eyes; beyond 
that is a large white spot; the tail is short, and conflits of 
12 feathers of a rich deep blue; the feet are of a reddish 
yellow; the three lower joints of the outer toe adhere to 
the middle toe, and the inner toe adheres to it by one joint.

The king-fisher frequents the banks of rivers, and feeds 
on fish. It takes its prey somewhat in the manner of the 
oprey, balancing itself at a certain distance over the water 
for some time, and then darting below the surface, brings 
the prey up in its feet. When it remains fuspended in the 
air, in a bright day, the plumage exhibits a molt beautiful 
variety of the molt dazzling and brilliant colours. To this 
attitude the ancients refer; for lycois, quoted by Athenenius, 
(Dieop. lib. ix. p. 358,) calls thefe birds alcedo; mandarin, 
the halcyons with expanded wings. It makes its neft in 
holes in the sides of the cliffs, which it scoops to the depth 
of three feet, and lays from five to nine eggs, of a molt 
beaufiful demi-transparent white. The neft is very folid, on 
accounts of the refe of fish with which the young are fed. 
It begins to hatch its young early in the feafon; and ex- 
cludes the first brood in the beginning of April. Whilf 
the female is thus employed, the male is unmeaning in 
his attention, furnishing his mate with fish in fuch abundance 
that he is found at this feafon plump and fat. He eafons 
totwitter at this time, and enters the neft as quietly and 
privately as poifible. The young are hatched in about 20 
days, but difce in fize in fpace and beauty. The ancients 
believed that the halcyons were fo amorous, that the male died 
in the embrace, and Arilotle a£erts (lib. ix. c. 14.) that 
they begin to breed when only four months old. The species 
now defcribed is the alcedo, or male halcyon of Aril. 
(Hift. An. S92. 145,) which he defcribes with a precifion, 
to which he is not accustomed. His defcription of the bird 
is followed by that of the neft; which, he fays, refembled 
fofne confequences that are formed by the fea-water; that 
it was like the long-necked gourd, hollow within and having 
a narrow entrance, fo that if it overfet the water could not 
cater; that it refiitd any violence from iron, but might 
be broken with a blow of the hand; and that it was com- 
pofed of the bones of the Baken, or fea-needle. The neft 
was called halcyoneam, and medical virtues were attributed 
to it. Mr Pennant mimes to credit part at leaf of Arilotle's 
account, as to the form of the neft, which agrees with the 
deffcription given of it by Count Zimmah; and as to the ma- 
terials of which it is composed, and the fragments of bones 
and scales of fish that were found in it, he adds, that thofe 
who will not allow this to be a bird that frequents the sea 
should recollect that Arilotle made his observations in a 
milder climate than our's, and yet from Zimmah we learn, 
that even in Italy the king-fisher breeds in May on banks of 
Arfams that are near the sea, and the ancient Stagiircle 
allows, (Hift. An. 1859.) that the halcyon fometimes ar- 
cended rivers, poifibly to breed. M. Buffon is of opinion,
that the halcyon, of which Pliny (lib. xxxii, 3.) 
reckons four kinds, and which fome have supposed to be the 
nefts of king-fihers, are only clufhers of fea-reeds; and 
with regard to the nefts of Tonquin and China, which are 
feem'd fuch delicacies, and have also been afcribled to the 
halcyon, they are the indisputable productions of the defcent 
swallow. On the precarions foundation laid by Arilotle, 
very abfurd and incredible tales have been formed by 
subsequent writers; and the poets, indulging the powers 
of imagination, have added many fictitious to the account of 
the philofopher. Acordingly the neft has been reprefented as 
a floating one:

"Incubat halcyone pendentibus square nidos."  
OVID. Met. lib. xi.

It was therefore neceafary to place it in a tranquil sea, and 
to supply the bird with charms to allay the fury of a tur- 
bulent element, during the feafon of incubation. At 
that time it flid, therefore, control over the seas and the 
mlinds:

"X alcedon; oritum teneum utque balatae  
Te me tene, te tuum, de exarhima cyma num.  
Alcedo, glatentis Nereis tenet melius  
Ovid. Epod. 1."—Theocrit. Idyll. vii. 87.

"May halcyons smooth the waves, and calm the seas;  
And the rough south-call link into a breeze;  
Halcyons of all the birds that haunt the main,  
Moll lov'd and honour'd by the Nereid train."  
FawkES.

These birds were equally favourites with Thefis, as well as 
the Nereids:

"Dilecta Thetidæ Halcyones."  
VIRG. Georg. i. 899.

As if to their influence these deities owed a repose in 
the midst of the storms of winter, and by their means we 
were freed from those winds that disturb their submarine 
retreats, and agitation even the plants at the bottom of the 
sea. Such are the accounts given by the Roman and Sicilian 
poets. Arilotle and Pliny tell us, that this bird is most common in 
the seas of Sicily; that it fat only a few days, and thofe in 
the depth of winter; and during that period the mariner 
might fall in full fcurity; for which reafon they were afcribed 
Halcyon-day. By the poets the king-fiher was also made 
a bird of fong. Virgil ranks it with the honet

"Litouraque Alecyonem renouant, Acanthidæ dumæ."  
Georg. iii. 388.

And Silius Italicus celebrates its music, and its floating neft:

"Cum fonat halcyones cantu, nidioque natantes  
Immota gelafl, fopitis flufibus, undâ."  
lib. xiv. 275.

But these poets have probably transferred to this species the 
powers of song that belonged to the alecyo of the philo- 
fer (Hift. An. 892.), which was vocal and perched upon 
meadows of granaries, and coniferous among reeds; but Mr. Pennant differs from 
his opinion, because the colours of the latter are very plain, 
and conceives that the alecyo vocalis of Arilotle is one of 
the loft birds of the ancients. Some have even doubted, 
whether the king-fisher of the moderns and the alecyon 
of the ancients are the fame bird. But the defcription of 
Arilotle sufficiently identifies them. The alecyon, says that 
philosopher,
philosopher, (lib. ix. 14) is not much larger than a sparrow; its plumage is painted with blue and green, and lightly tinged with purple; these colours are not distinct, but melted together, and shining variously over the whole body, the wings and the neck; its bill is yellowish, long and slender. The habits of these birds also resemble one another. The alcyon is solitary and penive; and the king-fisher is almost always seen alone, and the pairing season is of short duration. The former was not only an inhabitant of the sea-shore, but haunted the banks of rivers, and the latter has also been found to seek shell-fish and large worms, that abound on the shore of the sea, and in rivulets that flow into it. Alcyon was fickle-feen and rapid in its flight; it wheeled swiftly round its limbs, and instantly retired into its little grot on the shore. The same character belongs also to the king-fisher. The alcyon and the king-fisher have the same mode of taking their prey, by diving vertically upon it. The king-fisher is the most beautiful bird in our climates, as to the richness and luxuriance of the colours of its plumage. It has, says Buffon, all the shades of the rainbow, the brilliancy of enamel, and the glossy softness of silk; and Géner compares the glowing yellow red, which colours the breast, to the red glare of a burning coal; and yet the king-fisher has shone from those climates where its repulsive and glowing colours would appear to the greatest advantage. There is a species that is common all the islands of the South Sea; and Forster, in his observations in Capt. Cook's second voyage, has remarked, that its plumage is much more brilliant between the tropics than in the regions fruited beyond the temperate zone, in New Zealand. In the language of the Society islands, the king-fisher is called Erenor, and at Otaheite it is accounted sacred, and not allowed to be taken or killed. King-fishers were found not only at Otaheite, but in Huahine and Ulieti, and in the islands that are scattered over the South Sea, though they are more than 1,500 leagues distant from any continent. These king-fishers are of a dull green, with a collar of the same about their neck. The islanders entertain a superstitious veneration for them. The chief at Ulieti intreated Capt. Cook's companions, in a very serious tone, to spare the king-fishers and heroes of his island, giving permission to kill all the other birds. There are 20 species in Africa and Asia, and eight more that are known in the warm parts of America. The European king-fisher is scattered through Asia and Africa; many of those sent from China and Egypt are found to be the same with ours, and Belon has met with the same in Greece and in Thrace. This bird, though it derives its origin from the hottest climates, bears the rigour of our seafarers. It is seen in the winter along the brooks, diving under the ice, and emerging with its prey. The Germans have called it Cifogel, or ice-bird; and it has been found even among the Tartars and Siberians. The Tartars and Oliacs use the feathers of these birds for many superstitious purposes. The former use them as love-amulet; pretending that thofe which float on water will induce a woman who is touched with them to fall in love with the person who thus applies it. The Oliacs take the skin, the bill and the claws of this bird, and enclose them in a purée; and whilst they preserve this amulet, they think they have no ill to fear. Credulity has admitted and reported many other familiar tales concerning the extraordinary powers and virtues of this bird; but it is needless to recite them. Its flesh has this odour of bashful bird milk, and is unpalatable food. Although these birds are found in cold as well as warm climates, they are often found dead under the ice. M. Daubenton has preserved some of them alive for several months, by feeding them every day with young fry, which is their only proper nourishment; for they reject every other kind of food; and they may be kept in rooms for some time, provided that they are placed near basins of water full of small fish. Olina describes the method of taking them, at day-break, or in the dusk of the evening, by fitting a trap at the edge of the water; he adds, that they live four or five years. 2. A. erithaca, ifipida bergalensis turquata of Buffon, martin-pecheur a front jaune of Buffon, Bengal K. ef Asin, and red headed K. of Latham, is short-tailed; its back is blue, its abdomen yellow, its head and rump purple, its throat and nose white. The bill and the feet are red. This bird is about the size of the last species, somewhat more than five inches long, and is found in Bengal. There is a variety called A. maroni, or red-headed K., of Brown, with a head and neck of an orange-red colour. 3. A. madagascariensis, or the pecheur de Madagasca, Burford's K. of Latham; has a short tail, rufous body, white throat, blackish tail feathers; the bill and feet are red. It is five inches and a half long, and inhabits Madagascar. 6. A. fuper«elosus, ifipida Americana viridis of Buffon, martin-pecheur vert and orange of Buffon, little green and orange K. of Edwards, and supercilious K. of Latham; is green above, white below, with a green band, and yellow eyebrows. It is about six inches long, and found in America. Buffon had it from Cayenne. 7. A. alcyon, ifipida cristata cardinalis of Buffon, alvenon of Ray, king-fisher of Catesby, and belted K. of Pennant and Latham; is long-tailed, crested and bluish, with a white abdomen, ferruginous breast, and a white spot before and behind the eyes. There are three varieties, viz. ifipida holovenisa, martineur pecheur de Louisinna of Buffon, or crab-catcher of Slome; ifipida Dominicensis cristata of Briffon, martin-pecheur hope de St. Domingue, and jaquacati-guen of Meargrave, Ray and Willughby. This species inhabits America, and feems to migrate from Hudson's Bay to Mexico, where it is eaten, though it has a rank fishy taste. It is about 13 inches long, feeds on fish, nests in high banks, into which it penetrates in a horizontal direction, lays four white eggs, and hatches in June. 8. A. torquata. See Achatallacta. 9. A. capensis, ifipida capitis bona of Buffon, martineur a gros bec of Buffon, martineur a pecheur a gros bec of Buffon; is short-tailed, ash-blue, below fulvous, its breast brick-colour, and bill red. It is 14 inches long, and found at the Cape of Good Hope. 10. A. senegalensis, ifipida Senegalensis major of Buffon, A. africana of Forst., martineur pecheur a tete grise of Buffon; is long-tailed, sky-blue, below-white, with a hoary head, and coverts of the wings black. There are three other varieties, viz. A. bluish green, and below yellowish, the crabeating K. of Latham; the A., with the head and neck obviously white; and A. above sky blue, below rufous yellow, and white throat. This species inhabits Arabia and Africa, and particularly the banks of the Senegal, where they are numerous; and the name of the K. is, in the language of the country, Aboueard. The second variety is found in St. Jago and Abyssinia. 11. A. Smyrnensis, Smyrna K. of Albinus and Latham; is long-tailed, ferruginous, with green wings, tail and back. It is found near Smyrna. There are two other varieties, viz. the great Gambia K. of Edwards, found in Gambia and Madagascar, 10 inches long; and the great Bengal K. of Albinus, found in Bengal, and on the coast of Malabar; 9 and 10 inches long. 12. A. rubra, ifipida ex albo et atro varia of Buffon, martin-pecheur pe of Buffon, black and white K. of Edwards and Latham; is short-tailed, black variegated with white, and below white. It is 11 inches long, and found in Asia and Africa. This bird is about the size of the Roylton crow, and its cry is not unlike that.
that of the common crow. 13. A. deal, isipida ternatana of Briffon, martin pecheur à longs brins of Buffon, Ternate K. of Latham; has the two tail-quills very long, attenuated in the middle, its body dark bluish, and its wings greenish. Seba calls this bird, on account of its beauty, the nymph of Ternate; and he says, that the feathers on the tail are one third longer in the male than in the female. It is 13 inches long, and inhabits the island of Ternate.

14. A. paradisia, galbula longicircum of Briffon, jacamar à longue queue of Buffon, swallow-tailed K. of Edwards, and paradise jacamar of Latham, has the two intermediate tail-feathers very long, the body greenish-gold, and the feet scapulur. The bill of this species is quadrangular, acuminate and black, the legs are black, and plumose as far as the toes, the head is violet brown, the throat, neck, and lower coverts of the wings are white; the two middle tail feathers are longer than the others by an inch; the plumage is generally of a dull, deep green, in which are distinguished some orange and violet reflections. The female is distinguished from the male by the two middle quills of the tail, which are much shorter, and by its plumage being deficient of the brilliant and violet reflections. These birds inhabit Surinam, live on insects, fly to great distances, and perch on the tops of trees, go in pairs, not being so solitary and fo sedentary as the other jacamars; nor have they the fame warble, but a cry or soft whistle, which is heard only at a small distance, and seldom repeated. 15. A. galbula, galbula of Briffon, jacamairi of Marcgrave, Ray, Willughby, and Edwards, jacamar of Buffon, green jacamar of Latham; has a wedge-shaped tail, body gold and green, rufous below, and its feet scapulur. The bill is quadrangular, two inches long, acuminate, black, with nostrils ovated at the base, deep blue irides, white chin, sometimes yellowish. Short weak plumose legs, of a greenish yellow colour, and black claws; the plumage is of a very brilliant gold-green with red copper reflections. The size is about that of a larger bird, and its length scarcely nine inches; it inhabits the thick forests and damp situations of Guiana and Brazil; it is solitary, and prefers the most secluded and obscure coverts; it perches on the middle boughs, and remains there alone, and at rest, for the greater part of the day and night; its flight is quick, but short; it lives on insects; it has a feeble broken warble, which is tolerably pleasant; and Piso says, that its flesh, though hard, is eaten in Brazil. The savages of Cayenne call this bird vescoton; and the creoles denominate it colibri des grands bois. 16. A. orientalis, isipida Indica of Briffon, eastern K. of Latham, is green, below rufous, head, throat, band of the eye, and tail-feathers fly-blue. The bill is red; the feet and claws black. It is four and an half inches long, and inhabits India. 17. A. Surinamensis, Surinam K. of Latham, is rufous-tailed and blue, whitish below, with a rufous breast, greenish black head, and transverse grey spots. Its bill is black, and the back marked with black spots. It inhabits Guiana, nesting in holes near the waters, laying five or six eggs, and living on fish. 18. A. purpurea, purple K. of Latham, is below of a reddish-gold colour; the head, rump, and tail are rufous-gold; the back and coverts of the wings bluish-black, the tail-feathers black, and the throat white; the tail and feet are red; a narrow line pales from behind the eyes towards the back, terminated by blue. It is about the size of the fourth species, and inhabits India. Of all the kingfishers, M. Buffon says, this is the handsomest and the richest in colours. 19. A. caruleo-phala, blue-headed K. of Latham, is of a blue colour, rufous below, with a white throat and blackish tail-feathers. The bill and feet are red; and the crown of the head of a bright blue, flained with waves of a lighter blue. It is four inches long and inhabits Madagascar. 20. A. Bengalensis, little Indian K. of Edwards, and Indian K. of Latham, is bluish-gold, rufous below, with brown tail and tail-feathers, and the head marked transversely with blue streaks; the bill is black. It is four and an half inches long, and inhabits Bengal. The little Indian K. of Edwards is a variety, which instead of the rufous occular band of the former, has two rufous spots. 21. A. lucorynchus, isipida Americana carneolea of Briffon; A. Americana or apatafa of Seba, martin pecheur à bec blanc of Buffon, and white-billed K. of Latham, is of a bluish-green colour, yellowish below, with the head and neck bay-coloured, the tail-feathers cinereous, the tail above blue, and below cinereous. The bill is whitish. It is scarcely five inches long, and inhabits America. 22. A. Briliifrons, rip-gip of Buffon, and Brafilian K. of Latham, is rufous variegated with bay, brown and white; below white, with the greater tail-feathers and tail rufous, marked transversely with white spots. The bill and eyes are black, the ocular band, feet, and claws are brown. It is about the size of the larck, and inhabits Brazil. Its cry, rip-gip, resembles the calling of a long-tailed turkey. 23. A. americana, white and green K. of Latham, is blackish-green, white below, spotted with green, and the space of the breast and throat rufous. The bill is black, a white line pales from its base below the eyes to the occiput; the feet are red; the female has no rufous space at the breast and throat, but the throat is white. It is six inches long, and inhabits Cayenne. 24. A. bicolor, rufous and green K. of Latham, is green, rufous-golden below, with a zone waved with white and black on the breast, distinguishing the male, and wings and tail dotted with white. It is eight inches long, and inhabits Cayenne. 25. A. malacota, isipida Brasilifrons mivia of Briffon, mutati of Ray, Willughby, and Buffon, Brafilian spotted K. of Latham; is brown spotted with yellowish, below white spotted with brown, with yellow throat. The bill is red; the feet and claws cinereous. It is of the size of the flave, and inhabits Brazil. 26. A. Cayennensis, taparara of Buffon, Cayenne K. of Latham, is blue, below white, with a transverse black band below the back of the head. The upper mandible is black, the lower red, the rump azure, the tail, and tail-feathers with a blue margin, the feet red. This species is numerous, solitary, lays its eggs in holes on the river-banks, is nine and an half inches long, and inhabits Cayenne and Guiana. The time of its incubation is September, and its cry is, carac, carac. 27. A. atricepsilla, black capped K. of Latham, is violet blue, below white, with the head, neck, shoulders, and tips of the wings black, and reddish abdomen. The bill and feet are red. It is ten inches long, and inhabits China. This bird is one of the most beautiful of the king-fishers. There is a variety, viz. A. Luminosa, found in the island of Luzon. black above, white below, with a ferruginous abdomen. 28. A. tuta, refactet K. of Latham, is long-tailed, olive above, white below, with white eye-brows and greenish-black collar. The bill is black, with the inferior mandible white, and the feet are black. It is eight and an half inches long, and inhabits Ortech, where it is held sacred by the inhabitants. 29. A. surba, venerata K. of Latham, is brown, pale below, with a roundish tail; and the margin of the tail-feathers, wing-coverts, and wing-feathers green. The bill is black, and the feet dusky. It is nine inches long, inhabits the Friendly islands, particularly Apye, and is deemed sacred. 30. A. siola, sacred K. of Latham, is white-blue, green, below white, with pale ferruginous eye-brows, and the tail and tail-feathers blackish. There are four other varieties, viz. A. with white eye-brows, A. with head greenish black, pale ferruginous below, and on the nose; A. with black head, blue crown, dirty yellow eye-brows, head and abdomen, and
and blue wings and tail; and A with a white collar. This species inhabits the Society Islands; the third variety is found in New Zealand; and the fourth, in the Philippine Islands. It is nine and a half inches long, and reckoned sacred by the inhabitants. 31. A. chlorops, green-headed K. of Latham, is green, with a white neck and black collar, the wings and tail of a sea-green. The bill, under part of the tail, and feet, are bluish black. It is nine inches long, and found in Bouvo, one of the Molucca islands. 32. A. cerulea, white-collared K. of Latham, is blue, rufous below, with white eye-brows and collar. It is almost seven inches long, and inhabits India. 33. A. fulica, great black K. of Latham, is crested, olive-coloured, below whitish obscurely fringed, with the tippets and back of the head dingy white; the tail roundish, of a rufly fulvous, crossed with black waves, and white at the end. The upper mandible is black; the lower white, and black at the base; the female has no crest. The crown of the female and the sides of the chin and neck of both sexes blackish brown; the collar of the female white, and the back olive; that of the male, at its lower part with the rump, pale sea colour, with a spot of the fame in the middle of the coverts of the wings; the tail feathers of the female greenish brown; the exterior margin of those of the male blue, but black within, and at their tip, sometimes white at the base, yellow feet, and black claws. This bird is the largest of the kind, its length being 15 inches, and inhabits New Guinea. 34. A. maxima, great African K. of Latham, is sub-crested, lead-black colour, pointed with white, with white throat, black neck, and fangunous breath and abdomen. The bill is black, with linear nostrils, and the feet very black. It is about the size of a crow, and inhabits Africa. 35. A. truscophala, white-headed K. of Latham, is blue-green, with its head, neck, and under surface white, and wing-quills brown. It is 12 inches long, and inhabits Java. 36. A. flavicollis, is yellowish below, with the head and back green; the bill red, and the tail blue. It inhabits the island of Ceylon, where it is called by the natives, ten-rou-joulon. This bird is peculiarly dextrous in catching its prey: when it sees the fish in the river it darts upon it and seizes it with its bill, transports it to its nest, subflits a day or two upon the tipoll, and spends the whole time in fishing. 37. A. None Guineas, New Guinea K. of Latham, is black spotted with white. 38. A. Aegyptia, Egyptian K. of Latham, is brown, with fagginous spots, and whitish below with cinerous spots. The bill is blackish; the throat fagginous-white; the upper coverts of the tail wholly white; the tail affy, the feet greenish, and the claws blackish. It is about the size of a crow, nits in the fycamore and palm-trees, feeds on frogs, lizards, and insects, and is found in Egypt. Haffelguiff has particularly described this bird. 39. A. grandis, great jacobin of Latham, is copper-gold coloured, below fagginous, with the head and limbs green-gold, and the feet ferruginous. 40. A. tridactyla, three-toed K. of Latham, is rich and brilliant in its plumage; the upper side of the head and back is of a deep lilac, the feathers of the wings are of a dull indigo, heightened by a border of vivid and shining blue that surrounds each feather; the under side of the body is white; the bill and legs are reddish. It is about 40 inches long, and inhabits Surinam and India, and the isle of the Indian ocean: Sonnerat found it in the island of Lucon. 41. A. frons, is short-tailed, with the hind part of the back, the tail, and middle of the wings blue, the shoulders black, the head and breast cinerous, and the belly fagginous. The bill and feet are vermilion. This bird is found near Yemen in Arabia, and is about 3 feet long. "Linneus by Gmelin. Latham. Buffon."
ALCHEMY.

extract of it had been found effectual in milder cases of a
similar kind. The root is more aulter than the herb, and
the virtues are communicated alike to water and spirit of
wine. It does not rank among the more powerful altrigents,
nor does it deserve that high commendation which has been
befieled upon it in hemorrhages, diarrhoeas, the florid fever,
and the healing of wounds. Murray Mat. Med. vol. iii.
11. There is a variety of this species, which is the A. minor
of Hudson, and the A. alpina subtlytis minor of Pluknet,
in which the leaves are more silky, smaller, and whiter; and
the stems leaf branching, and the flowers in leaf clusters.
2. A. alpina, cucquefoil or alpine ladies' mantle, with digitate
ferate leaves, under silky, grows naturally on the mountains
in Yorkshire, Cumberland, Westmorland, North Wales, and
the Highlands of Scotland. It is also a native of Sweden,
Denmark, the Alps, and other cold parts of Europe; and
is admitted into gardens on account of its elegance. It
is perennial, and flowers in July. 3. A. aphanoidea, with
many parted leaves and stem erect, is found in New Granada, by
Matis. 4. A. pentaphylla, with leaves quinate, multiform,
smooth, grows naturally on the high Alps, as Gothard,
Furca, &c. and is only found in some few curious botanical
gardens in this country. It was cultivated by Mr. Miller
in 1748. These species may be propagated by parting the
roots, for which the best time is Autumn. They should have
a moist soil, and a shady situation. When they are
propagated by seeds, they should be sown in Autumn, on a shady
moist border, and when the plants come up, they will only
need to be kept from weeds.—Martyn's Miller. Dr. Smith
(Flor. Brit. vol. i. p. 192.) has added to this genus the
aphanes amrns of Linnaeus.

ALCHEMIST, a person who professes ALCHEMY.

ALCHEMY, ALCHEMIE, Fr. The subject of alchemy occupies
so large a space in the humiliating history of the
misapplication of brilliant talents, and the wanderings of
the human understanding, as to justify, and indeed demand a
particular enquiry into the causes of its origin, the grounds of
its continuance, and the reason of its gradual decline, and
at length total retirement from public notice. Indeed,
therefore, of merely quoting the concise and farceful
definition given of it by Harris, 'Ars fine ars, cujus princi-
pium elit mentiri, medium laborare, fines mendicare,' (an
art without art, originating in falsehood, and proceeding
through labour to beggary), we shall treat of it at some
length, considering first, the origin of the application; fe-
cordly its history; thirdly, the theory and arguments
that are alleged in its support; and fourthly, the facts upon
which it professes to be establised.

1. The word alchemy occurs for the first time in the
writings of Julius Firmicus Maternus, who lived in the
fourth century, under the reign of Constantine. This,
however, is rather the date of the separation between
chemistry and alchemy than of the origin of either. The fact
seems to be, that a considerable quantity of real chemical
knowledge, but abundantly mixed, as the cullum was, with
fable and hypothesis, was posseffed by the priests of Egypt;
and by thele it was communicated, mostly under a promise
of secrecy, to the Alexandrian Greeks. It is probable also
that as there were several orders of initiation into their sacre-
rices to be passed through in succession by the aspirant before
he was enthriled with their highest mysteries, so there might
be a similar rule observed with regard to the communication
of the different subjects of the Hermetic philosophy; thus
the lowest secrets might be the preparation of the commoner
chemical menstrua; the next in order might be the composi-
tion of glafs, and the art of dying, both of which appear,
even in the time of Pliny, to have been chiefly practised in
Egypt, and contain at the present day more secrets than any
other of our chemical arts; the knowledge of the most
efficacious medicines would be esteemed as a proof of still
higher confidence; and from the love of mystery inherent in
the human mind, the most valuable communications of all
would be that mixture of astrology with medical and chemic-
tal theories, which, appearing to unfold the secret con-
nection between the great powers of nature, flattered the
imagination with the hope of performing things wholly
impossible to other mortals. The actual posseffion and exertion
of much lucrative knowledge, and the reputation of still
more valuable secrets, would naturally attract the notice of
the credulous, the interested, and, if any fish existed at
that period, of the philosophers, the real disinterested
enquirers after science. In those of time, as the influence
of the Egyptian priesthood declined by the consequences of
the Roman conquest and from other causes, when too the per-
sons enfrilled with the secrets of chemistry were considerably
increased in number, and were diffeminated through all the
great cities of the empire, it would necessarily happen that
many from choice or necessity would advance to further in
the study than was immediately conducive to their profit, by
the finding of metals, and the preparation of chemical com-
pounds of general demand and utility, while the more theo-
retical and mysterious parts of the science would remain in
possession of a few. The complicated economy of the
Egyptian hierarchy being broken up, and there existing no
longer any acknowledged heads of the science, the distinc-
tion between chemicg and alchemy would immediately
commence. The chemists, or artists in chemistry, having no other
object in view than pecuniary emolument from the sale of
chemical articles, would confine their attention to the
improvement of the particular manufactures in which they
were engaged. The theoretical chemists or alchemists, on the
other hand, having in view a certain mysterious unattainable
and probably unattainable object, would look with contempt
on the occupations of the chemist, and would consider them-
elves as in possession of the only liberal part of the science;
their language, partly from policy and partly from the want
of clear ideas on the subject, would become more and more
obscure, and knaves and impostors would creep in among
them, who would endeavours to indemnify themselves for the
ill success of their experiments by frauds and impostions on
the unwary. The original difference therefore between che-
metry and alchemy seems to have been that the former was
a mere art confining in the preparation of substances by known
procceses, while the latter, proceeding from general principles,
either affirmed gratuitously, or taken up on very inadequate
proof, was always aiming, through the medium of new and
uncertain experiments, at the discovery of those powers which
were supposed to be characteristic of the sublimer parts of
the Hermetic philosophy.

II. It appears certain, from the uniformly concurrent tes-
timony of ancient history, that Europe was originally in-
debted to Egypt for its knowledge of chemical science.
This knowledge, however, was but sparingly dealt out to a
few of the Greek philosophers, at the expense of much
felicitation, and many years of study by the Egyptian priests,
as long as that country retained its independence. After-
wards, when by the victorious expedition of Alexander, a
race of Greek monarchs was placed on the throne of the
Pharaohs, and the foundation of the university of Alex-
andria, there was effectually a coalition between the arts of
Greece and the science of Egypt, chemistry being rendered more
accessible, and the study in general, and with increafed
adour. The same spirit, however, which pervaded their
researches into metaphysics and theology, appears to have
animated
ALCHEMY.

animated their enquiries into the various branches of experimental philosophy; a certain mysterious sympathy was imagined between the metallic substances then known, and the heavenly bodies of our solar system; they were designated by the same names and represented by the same characters. The great intrinsic value also of metals, and their still greater conventional importance, especially of gold, silver, and copper, by being adopted as the general representatives of property, naturally engaged a great portion of the attention of chemists; they were submitted to the action of all the known menurins, they were combined with each other in all proportions, and as lead and copper often contain silver, and silver is found naturally alloyed with gold, but in such proportions as not to be rendered feasible without the aid of chemical analysis, there would often happen in the results of processes an unexpected remainder of one or other of the precious metals. Such an occurrence, flattering at the same time to the two dominant passions of the mind, the love of scientific discovery and the desire of gain, would be eagerly received as a proof of the mutual convertibility of the metals, and would at once cause all those entranced with the secret to confine their attention to this fingle object. The fame circumstance would also induce a still greater obscurity of language and affection of mysticism, in order to conceal their processes from the knowledge of those who were engaged in similar pursuits; and all confidence in each other being thus interdicted, the science would become re- trograde, and much valuable knowledge would entirely perish. The first ages of alchemy produced few writers of reputation; their works are for the most part unpublilshed, and confilt of treatises in Greek by Chirilian ecclesiastics, of which the following are the principal. "Synecis, on the philosopher's stone." "Zofimus of Panapolis, on the sacred and divine art of making gold and silver," in 24 books. "John, the high priest in the holy city, concerning the holy art." "Theophrastus, on the divine art." "Archelaus, on the fame." "Hierotheus, the philofopher, on the philopho-pher's stone." And "Ifaac, the monk, on the discovery of the method of making silver."

The golden age of alchemy most ominously commences with the conquests of Arabian fanaticism in Asia and Africa, the destruction of the Alexandrian library, and the subjeclion of Europe to the barbarian superstition, and the most profound ignorance. The Saracens lively, fable, credulous, and nurtured in an unknown system of alchemy, the celestial influences, adduced with eager faith the wonders of alchemy, and condoned to receive instruction from the slaves whom they had conquered; the rage of making gold spread through the whole Mahometan world, and in the splendid courts of Almanzor, Haroun al Ralchid, and Abdala Almamn, the professors of the Hermetic art found patronage, disciples, and emolument. Geber, Rhazes, Alfarabius and Avicenna, the most celebrated physicians and chemists of the Arabian school, were deeply tingecl with the prevailing infancy. From the 10th to the 13th century little is known concerning the state of alchemical studies; the descendents of the Arabian warriors had begun to acquire a taste for science when their thrones were shaken by the Crusades, and finally overthrown by the defeating deluge of the Turkish barbarians. The arts again retiring from Egypt and Syria, relided for a moment in Constantinople, and then withdrew to the western provinces of Europe. In the 13th century, Albertus Magnus, Roger Bacon, and Raymond Lully, appeared as the great revivers of alchemy and chemistry; for from this time, although alchemical pursuits were esteemed the noblest and most important, yet they ceased to occupy entirely the attention of experimental philosophers. The writings of these able men raised the study of alchemy to a degree of credit which it little merited, especially among the ecclesiastics, who professed at that time almost all the learning of the age; and even a pope John XXII. was weak enough to affect in his treatise on the art of transmutation, that he had himself made two hundred ingots of gold, of the weight of an hundred pounds each. The 15th century exhibits the fame combination of chemistry with alchemy, but in which it is pleasing to discover a great diminution of reverence with regard to the processes of common chemistry, which are for the most part told in insufficiently plain language by the very men who, when treating of alchemy, are utterly unintelligible. The great authors during this period are Ifaac and John Ifaac Hollandus, George Rupley, and Basli Valentine.

Hitherto alchemy had been confined to the fingle object of changing the baser metals into silver and gold, and, the materia medica confiling wholly of vegetable and animal preparations, there existed little or no connexion between the chemists and physicians. The prevalence, however, of the leprosy, and the rise and rapid progress of the venereal disease, rendered it necessary to have recourse to more potent remedies. The Alfatik practice of phyllic with regard to the use of mercury was introduced with the happiest effects by Carpus; antimony found an able advocate in Basli Valentine, whose "Curus Triumphalis Antimonii," is a curious mixture of enthusiasm and knowledge. The credit of the Galenists began to be shaken, and chemistry, by thus associating to itself the most philosophical of the three learned professions, acquired an immense accession of abilities.

The unexpected success which attended the first medical use of chemical preparation, awakened a new hope in the minds of the chemists; and this was not less than the discovery of an universal medicine, which should heal all disorders, and prolong the duration of human existence to an indefinite period. The great authors of this sect were Paracelius and Van Helmont, who, by their vigorous use of opium and mercury, effected a number of important cures, imposible to the common Galenical practice of the age. About the same time flourished Henry Conclusius Agrippa, and George Agricola, the first of whom, half knave and half enthusiast, belongs decidedly to the alchemical party; but the latter, though bewildered in youth, by the facile philosophy of his time, made ample amends to the cause of true science in his maturer years, by his admirable treatises on metallurgy and mineralogy.

From this time we meet with few authors of reputation who wrote professedly on alchemy, though a kind of half belief in the thing still clung about even the most eminent chemists, and may be clearly traced in their writings. A bold attempt to support the failing cause was made in the beginning of the 17th century by the Rosicrucians, a sect society which originated in Germany, and attracted the attention of the rest of Europe for 25 years. By pretending however to too much, even to more than the ancient chemists, when in the plenitude of their power and influence, ever arrogated to themselves, the fraternity made few converts, and speedily sunk into total discredit. The first philosophical society, for the express purpose of improving natural and mathematical knowledge, was formed at Naples, by Baptista Porta in 1560; and the noble example was followed by most of the other Italian states. The liberal spirit of free inquiry then pervaded the Alfatik established similar societies in England, France, and Germany; the experimental method of philosophizing was introduced by Bacon; public lectures in chemistry began to be instituted; and the principles and facts of alchemy underwent
and underwent a severe examination, from the Jesuit Athanasius Kircher, which it never afterwards recovered. The most eminent chemists now abjured altogether the researches of alchemy; and it left ground daily, as well by its own want of evidence, as by the frauds and ignorance of the cheats into whose hands it had fallen. Thus, rapidly declining, it was at length wholly lost to the view of the scientific world, and at present is rarely detected, even by the officers of public justice, to whose care it fell, with its ancient associate, astrology, has been commended in all the civilized nations of Europe.

III. According to the present theory, each metal is considered as a peculiar chemical element, perfectly indecomposable by any known method, a necessary consequence of which is the utter improbability and hopelessness of all alchemical pursuits; since their object is the composition and decomposition of bodies which are either absolutely simple, or at least as yet incapable of further analysis. This formidable difficulty, at the very outset, may well diffuse from all modern attempts at metallic transmutation; but the great fathers of chemical philosophy ought not, in common candour, to be stigmatized as fools or impostors, for irremonably maintaining doctrines which are only, in the present advanced state of the science, self-evidently absurd. In the following summary of the leading theories relative to alchemy, the reader will scarcely expect to find a perfect uniformity and consistency of the several parts with each other; especially when it is considered that they are necessarily collected from a variety of authors differing in abilities, in communicativeness, and in the periods at which they lived.

It appears to have been admitted on all hands, that the metals were compounds of metallic earth and sulphur (by sulphur was merely understood any pure inflammable substance). This earth being supposed to exist in a larger proportion, and left mixed with sulphur in mercury than in any other metal, it came in time to be commonly known by the name of mercurial earth. Gold, as being the most fixed and unchangeable of the metals, was considered as an intimate combination of pure sulphur and mercurial earth, while the other metallic bodies were thought to contain, besides these two essential parts, various impurities. Of this opinion, Gerber, Roger Bacon, Ripley, Homburg, &c., were strenuous advocates; and it is especially to the latter of these chemists that we owe the development of this theory, together with a memorable experimental argument in its support. Having exposed regulus of antimony to the action of the great burning-glass of the duke of Orleans, he found that it increased in weight, and at the same time became more fixed; a similar effect was produced by exposing mercury to a digesting heat for some days; it was converted into a red powder of greater fixity than the original mercury had gained in weight, and upon exposure to a red heat was almost wholly volatilized and recovered into mercury, except a small portion of white hard ponderous metal which remained behind. From this experiment, Homburg deduces the following conclusions: that the pure sulphur of metals is solar light; that it unites with, and increases the weight of all metals that are exposed to its action, except gold; that it gives them a greater fixity; and that, although when loosely combined with mercury, it only changes it into a red powder of yet, by the further action of heat, a part of the mercury becomes saturated with this sulphur, and is converted into a hard fixed metal, while the rest is volatilized. To these experiments, important as they were supposed to be at the time of their invention, the superior accuracy of modern chemistry would object, that the gaseous products were wholly overlooked, and that the fixed metallic residue from the decomposition of the mercurial oxyd, is only a proof of the original impurity of the mercury employed, since no attempt was made by a repetition of the process to effect the fixation of the whole of the mercury. From these and similar experiments, however, the old chemists drew the inferences already mentioned; and by bearing this in mind, it is easy to discover the objects which they had in view, in such of their processes as they confedend to publish in intelligible language. There were supposed to be two methods of making gold, by synthesis and transmutation. The former of these was effected by the direct combination of the pure sulphur of metals and mercurial earth; hence we see the reason of the numerous distillations and digestions, and processes of all kinds for depriving sulphur of its impurities, and bringing it to the last state of rectification or exaltation: hence also the multiplied experiments on quicksilver, in order to give it fixity in the fire: this method, however, was generally acknowledged to be so difficult, that few alchemists have even pretended to be able to do more than fix the mercury. The art of transmutation was carried much further: it was taken for granted that the object of Nature, in producing metals, was the formation of gold, as being the most perfect of thee substances; and that the failure, in all cases, was owing solely to the interposition of certain impurities: it was known also, that the common methods of refining depended on the separation of the precious metals from the base ones, with which they were mixed and contaminated; the conclusion, therefore, did not seem, a priori, very extravagant; that, by an improvement in the art of refining, such of the cheaper metals as appeared the most to resemble gold, might be freed from these impurities in which the whole difference between them and gold consisted. Lead, from its specific gravity, and copper, from its colour, were the principal subjects of experiment; and when it is considered that arsenic was not yet discovered to be a metal, and the amazing effects of this substance in disguising the properties of gold, instead of being unfurprised at the accounts of transmutations, the principal wonder is, that they are not filled more numerous, and supported by more unexceptionable evidence. The substance capable of effecting this extraordinary change was called the elixir, or medicine of metals, the tincurie, the powder of projection of the philosopher's bone, a very small portion of which was adequate to the transmutation of a very large proportion of lead or copper; and by using a greater quantity than necessary of this powder, the gold resulting from the operation acquired the property of acting itself as an elixir. Such is the simplest and most confident theory of the great work, as delivered in the writings of the belial and most philosophical of the alchemists; nor when its real importance is considered in regard to chemical science, and many of the arts, when too it is remembered what numerous and unfurprised sources of error existed at that early period of chemical investigation in which it flourished, and the impolishing theory whereby it was supported, shall we lightly stigmatize tho those who honestly devoted much of their time to the pursuit, with the opprobrious appellation of pietinacious followers.

IV. If we were to enter upon a minute examination of the evidence, by which the principal inferences of transmutation are supported, it would extend this article beyond its due limits; the documents besides are so equivocal, and the witnesses so dubious and incompetent, that the enquiry would but ill repay the trouble: in the room of this, therefore,
fore, we shall lay down some general considerations, which by their agreement or disagreement with any particular cafe, will enable us to form a probable judgment of its truth or falsehood. Nor is this, although a summary way of treating the question, unfair or unallowed. In any sytle that is offered to our belief, if we can point out a fundamental error or contradiction, we may without inconvenience from diffusing the proofs adduced in favour of detached parts. With what strength of evidence are many stories of apparitions and witchcraft supported, how generally were they believed at the time of their occurrence, and how universally are they flighted and ridiculed at present, not from any new flaw discoverable in the evidence, but from their variance with general principles and experience?

That the philosopher's stone never existed, that no metal has ever yet, by human art, been produced or decomposed, is highly probable, from the convincing proofs which have been afforded by the progress of chemical philosophy, of the fundamental errors, both in fact and theory, to which even the ablest of the alchemists were subject. All chemical knowledge was anciently made a secret of; but, by the invention of printing, and the rise of a moneyed liberal spirit of communication, it may be added also, by the superiority of modern over ancient science, all nostrums and mysteries have in a great measure disappeared, and whatever was of sufficient importance to attract general attention, has been added to the stock of general information. In the mean time, alchemy has ceased to be an object of curiosity, not because its end was mean and trivial, but because all its supposed great facts have been resolved into mistakes. The value of the precious metals, instead of diminishing, has rather been increasing, the direct contrary to which would have been the case, had they been capable of being produced from any of the bolder ones. The professors of alchemy have been chiefly poor, and have in many cases even offered to divulge their secret for a sum of money; that is, being in possession of the art of producing gold ad infinitum, they have offered to communicate this wonderful knowledge for a few ounces of the very substance which they could manufacture by the hundred weight. Some of the alchemists in the dark ages, especially in Germany, who had the unfortunate reputation of possessing the philosopher's stone, were imprisoned by the princes of the country, and furnished with chemical apparatus, till they should have purchased their liberty, by producing a certain weight of gold, but not an ounce was ever procured by this method. It is remarkable too, that the most skilful and reputable of the alchemists, although they maintain the possibility of transmutation, and profess to know the method by which it is to be effected, are very far from affirming, that they have themselves actually succeeded in the attempt. Again, if from the bent attested instances of gold-making, we exclude those which depend on the fulsome testimony of the alchemists themselves, or the incompetent evidence of men entirely ignorant of chemical science, we shall find the remainder reduced almost to nothing. The royal academy of sciences at Paris, during the first years of its institution, was almost overwhelmed with applications from men who professed to be able to make or deteriorate gold at pleasure; either in this respect deceiving themselves, or in the hope of facilitating their attempts on the public credulity, by the sanction of that learned body: many experiments were in consequence made in their presence, all of which totally failed of success. These repeated detections, like those on the subject of witchcraft, appear to have decided the opinions of philosophers respecting the falsehood of alchemy; and though the wonder of the ignorant is still occasionally called forth on both these subjects, they are no longer considered as worthy of a serious refutation.

**ALCHIMELECH**, in Botany, the Egyptian melilot. Rav.

**ALCHINDUS, James**, in Biography, an Arabian physician, is supposed to have lived about the middle of the twelfth century. His work, "De Medicinarum compositarum gradibus investigandis," was published with the works of Mefue, at Venice, in folio, in 1561, and 1603.

**ALCHOLLEA**, a kind of food in use among the western Moors, being fleshly meat, pickled, dried, boiled, and potted.

**ALCHORNEA**, in Botany, a genus of the dioecia monadelphus class and order of professor Martyn, and monadelphus obtundia of Swartz and Gmelin, the characters of which are, that the calyx of the male is a three or five-leaved perianthium; leaflets ovate, concave, equal, and deciduous, no corolla; the flamina have eight flaments, a little shorter than the calyx, slightly connate at the base, anthers ovate and upright; the pistillum is a rudiment: the calyx of the female is a one-leafed, four or five-toothed perianthium, the teeth equal and small; no corolla; the pistillum has a germ twin, superior, styles two, very long and filiform, stigmas simple and acute; the pericarpium is a capsule bicorn, two-seeded, two-celled, two-valved; the seeds are solitary, large and oblong; there is one species, viz. A. latifolia.

**ALCIATI, Andrew**, in Biography, an eminent civilian, was born at Milan in 1492. Having studied the law in the university of Pavia, and in that of Bologna, he commenced the exercise of his profession at Milan in 1517, and became professor of civil law, in the university of Avignon, in 1518. Although his salary amounted to 600 crowns, and the number of his auditors was 800, he left this lucrative and honourable situation in difficult, because the city of Avignon was unable to make a regular payment of his salary in 1522, and refused his first profession at Milan. In 1530, he was invited by Francis I, the king of France, to promote the study of the civil law at Bourges; but impelled by avarice, he successively changed his situation to Pavia, Bologna, and Ferrara, in each of which places he had many scholars and clients, and received ample recompense for his labours. When he was cenured by his friends for his frequent changes, he vainly interrogated them, whether they blamed the fun for revolving to enlighten all nations; or, whether, when they admired the fixed stars, they found fault with the planets? But his predominant principle was avarice; and this principle induced him to decline accepting the offer of Paul III. to quit Ferrara and settle at Rome. "Why," said he, "should I, for the uncertain and empty hope of the purple, relinquish the honours of my profession, accompanied with the possession of a rich scrip?" From Ferrara, Alciati returned to Pavia, and in 1550, died a fruitful, occasioned by excess of eating. He professed, without doubt, distinguished talents, blended with a considerable degree of self-sufficing and meanness; and he very materially contributed to the improvement of his profession, introducing a taste for polite literature, and banishing that barbarous latinity, which had before his time prevailed in the lectures and writings of the cultivators. Erasmus bel lows upon him this high encomium: "The praise which Cicero divides between Scævola and Crassus, when
when he calls the latter the orator best skilled in law, and the former the lawyer who was the most eloquent, is, by the consent of the learned, united in Alciati." His full work was, "An Explanation and Correction of the Greek terms which are met with in the Digelis," first published in Italy and afterwards at Strasbourg, in 1515. This was followed by "Paradoxes of the Civil Law," "Difficulties and Preparations," published about the year 1517. His treatise "De Verborum Significatione," was printed at Bourges in 1520. These, and many other works on jurisprudence, were published in 1571, in six folio volumes. He also wrote notes on Tacitus, of whose style he says, that energy of language contains with elegance. He also wrote "Emblems" in verse; of which the elder Scaliger says, "that they are entertaining, chaste, and elegant, and not without strength!" and that "the sentiments are such as may be useful, even in civil life." These were published at Augsburg, in 8vo. in 1531; and in 4to. at Padua, with notes, in 1661; and they have been translated into various languages. Other works of Alciati, not included in the folio edition, are "Refutata," Lugd. 1561; "Historia Mediolanensis," Svo. 1625; "De formis Romani Imperii," Svo. 1559; "Epigrammata," Svo. 1629. A volume of his letters was published at Utrecht in 1697; and in 1695, appeared a letter, which he wrote to a friend who had become a friar, representing the imprudence of his conduct, and expostulating with great spirit, the abuses of monastic life. Gen. Dict. Gen. Biog.

ALCIATI. JOHN PAUL, a native of Milan, distinguished himself in the 16th century, among those prophets who receded to the greatest distance from the Catholic faith, by denying the doctrine of the Trinity, and asserting that Jesus Christ did not exist before he was born of the Virgin Mary. With a view of indulging his speculations and professing his inquiries without molestation, he removed to Geneva. Here he found prophets no less intolerant than papists. From hence the zeal of Calvin in the perfection of Servetus, and the demand of subscription to the formulary of the Italian church at Geneva, obliged him, and others denominated Socinians, to seek refuge in some other country. Accordingly they fled to Poland, where Alciati and Blandrata were very successful in disseminating their opinions. Towards the close of his life, Alciati was reproached with having renounced Christianity, and becoming a Mahometan; but this is probably a calumny, similar to that which has been alleged against others, because they have concurred with the Mahometans in maintaining the simple unity of the divine nature. Calvin and Beza have been very severe in their charges against Alciati, representing him not only as ignorant, but frantic; this, however, is one of those infinences in which allowance should be made for that vehemence and invective which are often the refult of difference of opinion. Alciati closed his life at Dantzic. In 1564, he published "Letters to Gregorio Pauli" against the pre-existence of Christ. Gen. Dict.

ALCIBIADES, an Athenian general, was the son of Clinias, the nephew of Pericles, and lineally descended from Ajax; and as much, distinguished by the comeliness of his person and the natural endowments of his understanding, as by his rank and fortune. In early life he manifested those talents and propenities, which, duly cultivated and directed, would have rendered him eminent and illustrious. But his accomplishments and connections betrayed him into many snares and dangers, which he wanted resolution to avoid. Nature, in him, says Cornelius Nepos, had exerted her utmost force; since, whether we consider his virtues or his vices, he was distinguished from his fellow-citizens. He was floudous and learned, eloquent, aspiring, and invincible in his pursuits; whatever were the object he had set on foot, his views were directed, liberal, magnificent, and affable; and he knew when to assume these virtues when they suited his purpose, and to accommodate himself to the times; but when he gave a loose to his passions, he was indolent, luxurious, diffident, addicted to illicit amours, intemperate, and profane. As he entered into life with many advantages, that are adapted to command attention and esteem, he became a very general object of that love, which among the Greeks was sometimes a pure, sometimes an ambiguous, and sometimes a scandalous attachment. It was his felicity to engage the honourable regard and friendship of Socrates; and to his instruction and influence, he was much indebted; and though his preceptor was less successful than he wished, in restraining his vicious inclinations, implanting in his mind good principles, and guiding him to laudable pursuits, his pupil seems never to have totally lost the benefit of his good counsel. Of his vivacity and resolution, when he was very young, the writers of his life have recorded several instances, which indicate his characteristic temper. When he wished to stop a waggon which was peeling along the road, and interrupting a play in which he was engaged, and his perturbation had proved ineffectual, he threw himself directly before it, and challenged the driver to measure the strength of his horses; and this sudden display of resolution frightened both him, and made him stop his horses. On another occasion he went into a grammar-school, and asked for a volume of Homer, which the master was unable to produce; he gave him a box on the ear and departed; intimating in this action, that a person who was not conversant with Homer was not fit to be a teacher of youth. As an act of frolic, and for the gratification of his companions, he committed the fame act of insolence on Hippopotus, a respectable man of rank and fortune; but early on the next morning he went to his house, and being admitted into his presence, flipp'd himself, and offered his naked body to any chastisement which Hippopotus might think due to him. By this humiliation he not only appeased Hippopotus, but conciliated his esteem, and afterwards obtained his daughter Hipparche in marriage. Alciabades, as he advanced in years, addicted himself to the chariot-races, and he is said to have been the first person who lent fever chariots to the Roman games; and this public display of revolution fritzed him, and made him stop his horses. On another occasion he went into a grammar-school, and asked for a volume of Homer, which the master was unable to produce; he gave him a box on the ear and departed; intimating in this action, that a person who was not conversant with Homer was not fit to be a teacher of youth. As an act of frolic, and for the gratification of his companions, he committed the fame act of insolence on Hippopotus, a respectable man of rank and fortune; but early on the next morning he went to his house, and being admitted into his presence, flipp'd himself, and offered his naked body to any chastisement which Hippopotus might think due to him. By this humiliation he not only appeased Hippopotus, but conciliated his esteem, and afterwards obtained his daughter Hipparche in marriage. Alciabades, as he advanced in years, addicted himself to the chariot-races, and he is said to have been the first person who lent fever chariots to the Olympic games. The magnificence which he displayed on these occasions, rendered him popular in the Grecian states; and at Athens in particular his conduct in various respects became the topic of very general conversation. In order to divert their attention from the more frivolous and faulty parts of his character, he is said to have cut off the tail of a very beautiful dog, which he much valued. The aspiring and active disposition of Alciabades led him at an early period to military service. His first campaign was in the war which Athens carried on against Potidea; Socrates attended him, and preferred his life, when, after fighting valiantly, he fell wounded in the field. In the battle of Delium, some years afterwards, he returned the obligation, by guarding Socrates in the retreat, and bringing him off securely. A treaty of peace having been established between the Athenians and Spartans, by the instrumentality of Nicias, who by this event had acquired popularity and influence, the jealousy of Alciabades was excited, and his ambition led him to overturn the pacific system which Nicias was anxious to preserve. With this view he encouraged the people of Argos to break with the Spartans, and promised them the succour of the Athenians; and he exerted himself in widening the difference that still subsisted between the Lacedaemonians and the latter. He also represented Nicias as more attached to Sparta than Athens, and by his eloquence contributed to
fulvior his popularity, and to make him odious to the people. When ambassadors arrived from Lacedaemonia, with full powers to terminate all differences, he contrived, by an artifice, to prepossession them in his favour; and to induce them to declare, though they were deputed to propose an accommodation, they were not empowered to bring matters to a conclusion. He then charged them with prevarication, and defeated the object of their embassy. Having so far succeeded, he immediately recommended the cause of the Argives, Mantinians and Eleusians, who fought the friendship of Athens; but before any resolution could be adopted, an earthquake happened, which of course dissolved the assembly. When Nicias returned from Sparta, without having succeeded in his negotiations, the Athenians concluded a league with the Argives and the other states above mentioned, for 100 years. Alcibiades was now become so popular, that he was appointed to the command of a fleet which was destined to affright the Argives, and to put an end to the disputes which prevailed in their capital. The disposition of the people with regard to Alcibiades is justly represented by Ariophanes, in his comedy of "The Frogs," (A. v. fc. 4.) "The hate Alcibiades," says he, "and yet cannot do without him." The misanthrope Timon formed a much better judgment of this conduct of Alcibiades. When he met him as he was coming from the assembly, and observed the respect with which he was treated, he took him by the hand and addressed him; "Go on and prosper, my son; thou dost right in pulling thy fortune, for thy advancement will be the ruin of all these people." The war of Sicily, which soon followed, proved that Timon was not mistaken. The Athenians had long been desirous of establishing themselves in this island. Their ardor was inflamed by Alcibiades, who encouraged the delusive hope, that Sicily would be only their place of arms and arsenal; and that they should proceed from hence to the conquest of Carthage, and make themselves masters of all Africa and the sea, as far as the pillars of Hercules. Nicias and Alcibiades had harangued the people on this subject; but the latter prevailed. A powerful armament was prepared for the expedition; and Alcibiades, Nicias, and Lamachus were appointed joint commanders. When every thing was prepared, and the fleet was ready for sailing, several unfavourable omens occurred, which excited in the minds of the people very disturbing apprehensions. One of these omens was particularly menacing to the fortunes of Alcibiades. The Heraean, or white flag of Mercury, which floats at the entrances of private houses and temples at Athens, were in one night mutilated and destroyed. Alcibiades was suspected of being concerned in this act of impiety, and he was actually charged with having defaced other statues and with having ridiculed some of the sacred mysteries. The fleet, however, sailed; but soon after their arrival in Sicily, Alcibiades was recalled; but having accompanied the messengers as far as Thurium, he absconded and withdrew to Peloponnesus. Being asked, on this occasion, whether he would not rely on his country with regard to the judgment it might pass on him, he replied, "I would not rely on my mother, lest she should mistake a black bean for a white one," referring to the use of beans in giving fables, in which a black bean denoted condemnation. On his non-appearance he was condemned, his property confiscated, and the priestesses and prieftesses were commanded to curse him. Among the latter was Theano, who opposed this decree, alling, "that she had been appointed prieftess, not to curse but to bless." When news was some time after brought to Alcibiades, that the Athenians had condemned him to die, he is said to have declared, "I will make them envious, that I am still alive." Alcibiades, in confluence of this event, abandoned the interest of his country, and induced the Spartans to susceur the Syracusians, and to declare war against Athens. At Sparta he assumed the Lacedaemonian discipline, and by his versatility of disposition and manners, gained universal esteem. He cut his hair short, bathed in cold water, fed upon coarse bread and black broth, and affected simplicity and gravity of demeanour. He was at the same time active in his exertions, induced several of the cities of Ionia to revolt from the Athenians, and engaged Tissaphernes, the king of Peria's lieutenant, to concur in a league with the Spartans. Whilst he was thus employed, he engaged in an intrigue with the wife of the Spartan king, Agis, with the vain ambition, as he pretended, of giving a line of kings to the Lacedaemonians; and Agis became his implacable enemy. He favored his life by taking refuge with Tissaphernes, and in this new situation, he conformed to the luxurious manners of the Perians, and practiced adulation to such a degree, as completely to ingratiate himself with the Satrap. By his counsell, Tissaphernes maintained an even balance between the Athenians and Lacedaemonians; and Alcibiades at length contrived to make the friendship of the Perians the means of his own return to Athens. The constitution of the government having been changed, partly by his counsel and agency, from a democracy to an oligarchy, he was recalled by unanimous consent. But before his return he determined to merit the honour to which he was aspiring by some illustrious exploit. Accordingly, in conjunction with the other Athenian commanders Theramenes and Thrasybulus, he took several places and gained several victories over the Spartans and their allies, and then set sail for Athens, with a fleet of 200 ships laden with rich spoils, together with the ships and flags captured from the enemy, A. M. 3597, B. C. 427. His reception was in a very high degree flattering and honourable; and in an assembly of the people, he deplored his misfortunes, which he ascribed to his own evil genius more than to the ill-will of his countrymen; and by his eloquent and pathetic speech so pleased his audience, that crowds of gold were decreted him; he was appointed general by sea and land with unlimited power; his fortunes were restored to him; and he was absolved by the Eumolpides and Ceryces from all the exactions that had been denounced against him. "As for me," says Theodore, one of the persons employed in revoking the imprecaions for, I have not curbed him, if he has done no evil to his country." When this pageantry was concluded, he set sail with 100 ships for the island of Andros, which had revolted; and having gained a victory, he departed for Caria in order to raise money, and left the fleet in the charge of Antiochus. Before his return, Lyfander, the Spartan commander, brought on a battle, defeated the Athenian fleet, and slew Antiochus. The confluence of this disafford was discontent at Athens, and the loss of his command. Instead of returning home, he collected a band of soldiers of fortune, and enriched himself by the booty which he took among the Thracian tribes; avoided the fate of the 10 new commanders appointed by the Athenians, most of whom lost their lives, on account of their ill success; and warned the Athenian commanders of the danger to which their fleet was exposed at Egos-potamos. When Athens was taken by Lyfander, Alcibiades returned to Bithynia, where he was plundered of part of his property, and from hence he went to Phrygia, and obtained the protection of Pharnabazus the Persian governor. The Athenians, suffering under the oppression of the 30 tyrants, directed their views to Alcibiades; and as soon as the tyrants
tyrants themselves were apprized of it, they determined upon his death. Critics, one of the number, and formerly an intimate friend of Alcibiades, was active on the occasion; and engaged Lyander to apply to Pharnabazus for concurrence in their purpose. Alcibiades refided at this time in a village of Phrygia, with his mother Timandra. The allusion turned upon his house, and let it on fire; having in vain attempted to extinguish it, he rushed forth, and fairly pulled through it; but the darts of his murderers were poured upon him from a distance, and dispatched him. Timandra wrapped up the body in her own garments, and burned it in a town called Meliphi, where the emperor Alexander long afterwards caused a marble statue to be erected to his memory, and a bell to be annually sacrificed on his tomb. His death happened about the 40th year of his age, Ante Chrift. 403. Some of his writings were extant in the time of Cicero, Orat. ii. 22.

"It is not easy to say," says Rollin, in describing the character of Alcibiades, "whether his good or bad qualities were most pernicious to his country; for with the one he deceived, and with the other he oppressed. In him distinguished valour was united with nobility of blood. His person was beautiful and finely made; he was eloquent, of great ability in affairs, infinuating, and formed for charming all mankind. He loved glory, but without prejudice to his inclination for pleasure; nor was he so fond of pleasure as to neglect his glory for it. He knew how to give into or abstain from itself, according to the situation of his affairs. Never was there ductility of genius equal to his. He metamorphosed himself with incredible facility, like a Proteus, into the most contrary forms, and supported them all with as much ease and grace, as if each had been natural to him. This convertibility of character, according to occasions, the customs of countries, and his own interests, discovers a heart void of principles, without either truth or justice. He did not confine himself either to religion, virtue, laws, duties, or his country. His sole rule of action was his private ambition, to which he reduced everything. His aim was to please, to dazzle, and to be beloved; but at the same time to subject those he loved. He favoured them only as they served his purposes; and made his correspondence and society a means of engrossing everything to himself. His life was a perpetual mixture of good and evil. His failings for virtue were ill sustained, and quickly degenerated into vices and crimes, very little to the honour of the instructions of that great philosopher, who took no small pains to cultivate him into a man of worth. His actions were glorious, but without rule or principle. His character was elevated and grand, but without connection and confidence. He was successively the support and the terror of the Lacedaemonians and Periages. He was either the misfortune or refuge of his own country, according to his declaring for or against it. In fine, he was the author of an universal destructive war in Greece, from the sole motive of commanding, by inducing the Athenians to besiege Syracuse; much less from the hope of conquering Sicily, and afterwards Africa, than with the design of keeping Athens in dependence upon himself; convinced that having to deal with an inconstant, fulsome, ungrateful, jealous people, averse to those who governed, it was necessary to engage them continually in some great affair, in order to make his services always necessary to them, and that they might not be at leisure to examine, confine, and condemn his conduct. He had the fate generally experienced by pertons of his character, and of which they cannot reasonably complain. He never loved any one, himself being his sole motive; nor ever found a friend. He made it his merit and glory to amuse all men, and nobody confided in, or adhered to him. His sole view was to live with splendour, and to lord it universally; and he perished miserably, abandoned by the whole world, and obliged at his death to the feeble services and impotent zeal of one only woman, for the last honours rendered to his remains." Plutarch in Alcib. Orat. tom. i. p. 191. Corn. Nepos. in Alcib. Thucydides, p. 316, &c. Ed. Duker, Dio. Sulp. tom. i. p. 502-647. Ed. Weisring, Xenophon, Hellen. lib. ii. Rollin's Anc. Hist. vol. iii. p. 164-503. Anc. Ur. Hist. vol. v. p. 293, &c.

ALCIBIAS, was the name of one of the martyrs at Lyons, A. D. 177. He came originally from Phrygia, and led a very austere life, living upon bread and water; but was afterwards persuaded, in order to avoid giving offence, to partake of all sorts of food promiscuously, and to give God thanks. Lardner's works, vol. vii. p. 432.

ALCIBIADES, in Entomology, a species of Papilio Eumes, with white wings, the anterior bounded by a black margin, the posterior marked below and at their tip with feringous black spots, found at Tranquebar.

ALCIBLUM, in Botany, a word used sometimes by the ancients in an epithet for a kind of echium, or viper's buglos, and sometimes as the name of a peculiar plant.

ALCIDAMAS, in Entomology, a name given by Cramer to the Papilio Turmae of Linnaeus.

ALCIDES, a species of Papilio plebejus, with cased black wings dotted with blue, ferruginous below, and marked with a yellowish streak; found in Sierra Leone in Africa.

ALCIDES, also a species of Scarabæus, with the horn of the thorax bent, bearded below, and undentated, and the head recurved and naked, found in India.

ALCIDES, in Mythology, the surname of Hercules. See ALCUS.

ALCIDON, in Ancient Geography, a river of Triphylia, which rose on the frontiers of Arcadia, and discharged itself into the Jardanus.

ALCIMEDON, a plain of Arcadia, north of Mantinea.

ALCINUS, in Biography and History, is represented by Homer as king of the Phæacians, in the island now called Corfu. His subjects were excellent mariners, and much addicted to the dance and song, and very kind of social pleasure; they were employed in conducting the shipwrecked Ulysses, who was hospitably received by Alcimus, to Ithaca. The tale of Alcimus for horticulture is much celebrated; and his garden, or orchard, is described by Homer as affording an abundance of fruit in quick succession, and also copious streams and pleasant shade. Homer Odyly, lib. vii. v. 108.

Hence we read in ancient geography, of the port, and also of the gardens of Alcimus, which pertained to this island.

ALCINUS, a Platonic philosopher, probably lived about the
the beginning of the second century of the Christian era, and wrote a perspicuous and elegant "Introduction to the Philosophy of Plato," containing a summary of his doctrine. It was published in Greek by Aldus, at Venice, in 1531 and 1532, 8vo; and with Ficinus's Latin translation, at Basile, in 1532; and at Paris, in 1532, 4to; by Charpentier, with a Commentary, at Paris, in 1573; by Heinsius, Gr. and Lat. 8vo, at Leyden, in 1657, and reprinted at Oxford in 1667, 8vo; and in English, by Stapley, London, in 1655, 1657, &c. Fabr. Bib. Græc. lib. ii. c. 23. vol. iv. p. 452, &c.

ALCIONIUS, Pietro, a learned Italian, contributed to the revival of letters in the 17th century. He studied the Latin and Greek languages with great diligence, and was for many years corrector of the press to Aldus Manutius at Venice. His learning advanced him to a professorship at Florence, under the pontificate of Adrian VI. He translated many Greek works into Latin, and his translations have been highly commended. He was also the author of many original productions, which prove him to be a man of talents. In his disposition and manners, however, he was chargeable with moroseness and ingratitude, and with intemperance and gluttony. Whilst he unduly valued himself on account of his own performances, he detracted from the merit of others. In the troubles excited at Rome by the Colonna's, he left his estate; and in the year 1527, when the emperor's forces took the city, he received a wound as he was going to join the pope in the castle of St. Angelo; but upon the raising of the siege, he defected his patron, and united with Cardinal Pompey Colonna, at whose house he fainted and died. His piece on exile, in the composition of which he was reported to have purloined a treatise of Cicero, "De Gloria," which he had found in the library of a monastery, and afterwards destroyed, his "Orations on the taking of Rome by Charles V. and on the knights who died at the siege of Rhodes," are all the original works which he left. The former was printed at Venice, in 1522, 4to. and again at Leippsia, in 1702, under the title of "Anealecta de Calamitale Literatorum." Gen. Biog.

ALCIPHRON, a philospher of Magnesia, mentioned by A. Antonius and Suidas, flourished in the time of Alexander the Great. He is different from Aleiphrhon, the sophist, whose age is unknown, who wrote epistles on various tòpi, of which an edition was published at Leippsia, in 8vo. in 1715. Fabr. Bib. Græc. lib. ii. c. 10. vol. iv. p. 492.

ALCIPHRON, in Etymologia, a name given to the Pha- lena morba carice, with cinquecent wings, white streaks and point in the middle, yellow at the base, and five black points, found in the Indian fig.

ALCIPUS, a species of Papilio Donas, with yellow entire wings, a black margin, and white points, the posterior having a white disc, and black points, found in America.

ALCIS, in Mythology, the name of a deity worshipped by the Naharvai, a nation of Germans; and a name given to Minerva by the Macedonians. Tacit. Germ. 43. Liv. 42. 51.

ALCKHAUSEN, in Geography, a town of Snabia, belonging to the grand-master of the Teutonic order, in the county of Weiringen.

ALCKMÆON, in Biography, a physician and philosopher, was born at Crotona, and probably flourished about 500 years before Christ, as he was a disciple of Pythagoras, and attend- ed his lectures. He is said to have been the first person who attempted the dissection of a dead body, and of various animals, in order to examine the structure of the parts, and to have discovered the cochlea, one of the bones forming the organ of hearing. Le Clerc, Hist. de la Medicine, p. 94. He is said by Calclusus, Holler observs. (Bib. Anat. vol. i. p. 106.) to have attempted a treatise on anatomy, which, however, is lost. The sum of his tenets, as far as they can be collected from scattered fragments, is this: "Natural objects, which appear multiform to men, are in reality two fold; intelligible natures, which are immutable, and material forms, which are infinitely variable. The sun, moon, and stars are eternal, and are inhabited by portions of that divine fire, which is the first principle in nature. The moon is in the form of a boat, and when the bottom of the boat is turned towards the earth, it is invisible. The brain is the chief seat of the soul, which is in perpetual action and immortality. Health consists in preserving a due mean between the extremes of heat and cold, dryness and moisture." Diogen. Laer. lib. viii. 88. Clem. Alex. Strom. lib. i. p. 305. Arift. Met. lib. i. c. 5. lib. v. c. 4. Januic. Vit. Pyth. c. 23. &c. 104. Cicero. de Nat. Deor. lib. i. c. 11. Stob. Ecl. Phys. p. 54, 60, 93. Plut. Phoc. Phil. lib. ii. c. 19. 27. lib. iv. c. 17. Fabr. Bib. Græc. lib. vi. c. 9. tom. xii. p. 49. Brucker's Phil. by Enfield, vol. i. p. 401.

ALCMÆER, or ALKMAER, in Geography, a town of the United Provinces in North Holland, about four miles from the sea, and 16 miles from Amsterdam. The streets are regular, the houses well built, and it is kept clean and neat by means of its canals. The land about the town was formerly full of morasses, but since it has been drained it is become exceeding good meadow-land, and the town is surrounded by productive orchards and gardens. The town, both within and without, has several beautiful walks. The noble canal that reaches from Alcmæer to Hoorn, was cut towards the beginning of the 17th century. This place was once very strong, and in 1573, obliged the Spaniards to raise the siege, after being encamped before it seven weeks. In the register of this town it is recorded, that in 1527, 120 tulips, with the offsets, sold for 90,000 florins. The butter and cheeses that are made in the neighbourhood are reckoned the best in Holland, and furnish considerable articles of trade. N. lat. 52° 38'. E. long. 4° 26'.

ALCMAN, in Biography, a Lyric poet, was born at Sardis, or at Sparta, and flourished in the 37th Olympiad, about 670 years B. C. He was the disciple of Pindar, and it is suspected that he was in his youth a slave at Sparta, and that by his genius and good qualities he obtained his freedom and a high degree of reputation in Lyric poetry. He was a performer on the cithara, and probably sung verses to the flute. Clemens Alexandrinus (Strom. lib. i. c. 16. tom. i. p. 364—365, ed. Peter.) makes him the author of music for choral dances, and according to Archytas Hermionicus, cited by Athenæus, (Deipn. lib. xiii. c. 8. p. 600.) Alcam was one of the first and most eminent composers of songs upon love and gallantry. Suidas says, that he was the first who excluded hexameters from the verses that were to be sung to the lyre, which afterwards obtained the title of Lyric poems, and Alcin tells us, that he was one of the great musicians that was called to Lacedæmon by the exigences of the state, and that he sung his airs to the found of the flute; by which Dr. Burney understands that he taught the Spartan army to perform their evolutions to the sound of his instru- ment. Alcam, according to Athenæus, was not more remarkable for a musical genius than for a voracious appetite, and Alcin charges him among the greatest gluttons of antiquity; and his intemperance was probably the cause of the particular diffece of which he died. The Spartans erected a monument to him, which subsisted in the time of 4 C Paufanias.
Panfasias. Of the many poems attributed to him by antiquity, nothing remains besides a few fragments furnished by citations in Athenaeus and other ancient writers, and preferred by Neandrus, H. Stephens, and Ulfius. The name of his mistress was Megalofrata, a poetess. Alcman used the Dorian dialect. Fabric. Bib. Græc. lib. ii. c. 15. tom. i. p. 366. Burney's Hist. Musifc. vol. ii. p. 385, &c. Some have confounded Alcman with Alemion, the son of Perithus, of Croton, who, as Clem. Alex. (ab epip.) informs us, was the first who wrote a book concerning nature. See also Menagius ad Laertium, viii. 73.

ALCMANIAN, in the Ancicnt Poetry, a kind of lyric verse, or metre, consisting of two dactyls, and two trochees. Such a gr. is

"Virginius paucisque cano."

The word is formed from Alcman, the name of an ancient Greek poet, in great esteem for his Erotes, or amorous compositions.

Some authors ascribe other Alcmanian verses, composed of three dactyls and a long syllable.

E. gr. "Minuere lethitiamque Deti."

Others give an Alcmanian, composed of a dactyl, spondee, and another dactyl, and a long syllable.

E. gr. "Ne dubita, nam vera fides."

ALCMEN, in Mythology. See Alcmenae.

ALCMENON, in Enotomology. See Alcmeone. A species of the Papilio Danaus, with rounded wings of the same colour, yellow at the base and white at the tip, found in Malabar.

ALCO, in Zoology, the name given to the Canis Americanus of Linnaeus, about the size of a squirrel, with a small head, pendulous ears, curved body, and short tail. There are two varieties, the fat also, yezzate-nzoltli, canis Mexicanus of Hernandez, or michuzcaneros of Fernandes, which is extremely fat, head very small, ears pendulous, with the fore part of the head white, and yellowish ears, short neck, arched back, yellow hair, white, short pendulous tail, large belly, spotted with black, white legs and feet, and the female with fix conspicuous paps; and the techich of Fernandes, which is like the small dogs of Europe, except that it has a wild and melancholy air. The first of these approaches the Iceland dog, and the second is perhaps the same animal with the hovara, or crab dog of Guiana, which in figure resembles the fox, and in his hair the jackal; and has been called the crab-dog, because it lives chiefly upon crabs and other tettaceous animals.

ALCOBACA, in Geography, a town of Portugal, 10 leagues from the sea, and surrounded by mountains, in a beautiful situation. It has a celebrated Cistercian abbey, built by Alphonso I. in 1148, which has been the general sepulchre of the kings of that kingdom. It is south-east of Lisbon, and 61 leagues north-east of Peniche. This town carries on various manufactures, the oldest of which is in the monastery, established by Pombal. Cambries and fine linens are made here, but the woollen manufacture, and that for spinning of wool, which is performed by machinery, are more important. Link's Trav. in Portugal, p. 278.

ALCOTT, in Biography, an English Divine, was born at Beverley, in Yorkshire, and educated in the University of Cambridge, where he took the degree of Doctor of Laws. His theological preferment was rapid, and he was successively bishop of Rochester, Worcester, and Ely. In 1462 he was appointed master of the arts; in 1470 a privy-counsellor, and one of the ambassadors to the court of Calyson; in 1471 a commissioner to treat with the commissioners of the king of Scotland; and in 1472 lord-chancellor of England. He is represented as a prelate of distinguished learning and piety, and also of singular affability and purity. He was not only a considerable writer, but an excellent architect, so that he was made comptroller of the royal works and buildings under Henry VII. He improved the palaces of his felicidie; founded a school, according to Fuller, at Beverley; and he was also the founder of Jesus College, in Cambridge, appropriating to this purpose a munificence, which was notorious for its sumptuousness, that the society was called a community of spiritual bailiffs. This college was first founded for 400 fellows, and his wife, but under the patronage of the bishops of Ely, it has much increased in buildings and revenues, and now confides to a matter, 16 fellows, and 30 scholars. Acock was famous for preaching long sermons; one of his sermons before the University lasted upwards of two hours. He wrote several pieces, as "Mons Perfections ad Carthusianos;" "Abbatia Spiritus Sancti in pura Confessione fundata;" "Penitential Psalms;" in English verse; "Homilies vulgares;" and "Spectacle of a Virgin to Christ." Besides these he wrote a treatise with the whifficad and punning title of "Galli Canones ad Confratres suis," or the crowning of the cock to his brethren; at the beginning of which is a print of the bishop preaching to the clergy, with a cock on each side, and having also a cock in the first page. This prelate died Oct. 1, 1520, at Wilcbach, and was buried at a magnificent chapel, which he had built for himself, and which, though now neglected, is a noble specimen of his skill in architecture. Biog. Brit.

ALCOER, in Geography, a small town of Spain, in New Cadiz, situated in a fine country, between the Tagus and the river Cyone. N. lat. 38° 56'. W. long. 4° 20'.

ALCOHOL, eudactyl spirit, spirit of wine. Alcool, Ejsprit de vin. Fr. Winzegift, Germ. Spiritus ardens, Spirit of wine. Acquaariente, Italian. The term alcohol is applied exclusively by modern chemists, to the purely spirituous part of all liquors that have undergone the vinous fermentation. As this substance bears a very high importance, both as a chemical agent and in its various combinations, we shall bestow upon it considerable attention.

Alcohol is in all cases the product of the faccinare principle, and is formed by the successive processes of vinous fermentation and distillation. All fermented liquors, therefore, agree in these two points; the one, that a faccinare juice has been necessary to their production; and the other, that they are all capable of furnishing an ardent spirit by distillation. Various kinds of ardent spirits are known in commerce, such as brandy, rum, arrack, malt-spirits, and the like; these differ from each other in colour, smell, taste, and strength; but the spirituous part, to which they owe their inflammability, their hot fiery taste, and their intoxicating quality, is the same in each, and may be procured in its purest state by a second distillation, which is termed in technical language, rectification.

We shall refer the reader to the articles of Fermentation (Vinous), Distillation, and the several species of distilled spirits, for an account of the progressive stages in the formation of alcohol; and we shall here take up the subject with the process of rectification or the second distillation, whereby alcohol is brought to that state of purity in
in which its chemical properties are the most conspicuous.

Alcohol, as well as ardent spirits of different kinds, is procured most largely in this country from a fermented grain-liquor, prepared for the specific purpose of distillation, from grain, malt, etc.; but in the wine countries, the spirit is obtained from the distillation of wine; whence the synonymous term, spirit of wine. We shall only take the example of brandy, which is the product of the first distillation of wine, and mention the method by which alcohol is procured from it by rectification.

Brandy is a compound of alcohol, water, a colouring extractive matter, and a small quantity of oil. It is to the two last that it owes its peculiar flavour, smell, and appearance, whereby it is distinguished from other distilled spirits. The object of the process of rectification is to separate the third from the other ingredients, and this separation is effected upon the principle that alcohol is the most easily volatilized when a gentle heat is applied, and therefore appears in the first product of distillation, whilst the extractive matter and much of the water remain behind. It is more difficult, however, to get rid of the small portion of oil which brandy contains, as this is soluble in alcohol, and will rise with it in distillation, unless prevented by the means which will be presently mentioned.

The observations of M. Baume, and his directions for the preparation of alcohol, are so judicious and accurate that we shall here mention them.

The following is the process given by this able chemist: "To procure rectified alcohol, put a quantity of brandy in the water bath of an alembic, and proceed to distillation. Set apart the first product of the distillation when it amounts to about a fourth part of the liquor put into the alembic. Then continue the process till about as much more is obtained, or till the liquor comes over white and milky. Then redistil the latter product, and mix the first half which comes over with the first part of the former distillation, and continue to distil as long as any spirit comes over. This latter portion may be again distilled, and the first product mixed with the former products, as before. After each distillation, there remains in the alembic a watery liquor which retains the small of brandy but is greatly deprived of inflammable spirit, and is thrown away as aleuks.

"Having thus procured all the spirit from the brandy, return all the reserved first products to the alembic, and distil with a gentle fire. When about half the liquor has come over, it should be kept apart as pure rectified alcohol; the remainder is to be distilled as long as it is inflammable, and may either be again rectified, or reserved for those purposes where a spirit of inferior strength is required."

The reason given by this judicious chemist for the above process is this: the spirit which first passes over in distillation is the purest, and contains the largest portion of gross essentrial oil; the latter portion, on the other hand, is almost saturated with this oil, and the difference between the two is easily distinguishable when rubbed on the hands; the first product leaves no smell of brandy, but the last gives an odour like the breath of drunkards, who digest their food imperfectly. The quantity of oil, however, varies according to the nature of the brandy; that which is made from wine alone containing the least oil, but that which is procured from wine lees being so full of it as to leave a fraction of the oil swimming on the watery extractive liquor left in the alembic, after all the spirit has been distilled off.

M. Dubuisson remarks concerning this oil, that the Languedoc brandies contain much more of it than the Cognac, and that after distilling a large quantity of the former, the head of the alembic was covered with expanded drops of the oil, which adhered to the wick. When collected together, and quite cold, they became as fluff as dust, had a cheetin colour, a strong disagreeable taste, and a smell like turpentine.

Various additions have likewise been made to the pure spirits in order to altit in the separation of this oil. This is simple, and one of the most efficacious is water. This, when added to the oily spirit, turns it milky (as is the case with any other solution of essential oil in alcohol), and by weakening the cohesion between the oil and the spirit, it enables the latter to rise in distillation, unmixed with the former. The chief inconvenience of this addition is, that it weakens the strength of the spirit so much as to require successive rectifications before it can be sufficiently deprived of its watery part.

Chalk, crumb of bread, bran, and other substanqces, are also added before distillation to the spirit, when eady and ill flavoured; and they all have a good effect in keeping down the matters which contaminate the alcohol, and render the distillation more effectual in purifying it.

Quicklime is still more efficacious, but it much lessens the product of alcohol, alters its nature to some degree, and makes it less penetrating. It would appear, however, that there are some kinds of wine in which the odorous particles are so intimately mixed with the spirituous part, that it is scarcely possible to separate them by simple distillation, however cautiously and skillfully conducted.

The common still with the worm-tube and refrigeratory, is very well calculated for the rectification of spirits, only allowance must be made for the readjucings with which ardent spirit, when heated, affinms the flatte of vapour, and the very great expansion which it then undergoes.

Alcohol, freed from all foreign ingredients but water, and already of considerable strength, may be brought to the specific gravity of 0.835, at the temperature of 60°, by a single distillation, where the heat is moderate and applied very gradually, and the condensation flow. When about a third or half of the spirit is distillated over, the strength of the preceding portion is diminished, the specific gravity increases, and it becomes more watery, and therefore the first product should be kept apart. This cannot be rendered stronger by any repetition of simple distillation, but it may be still further dephlegmated by means which will be mentioned hereafter.

We shall now proceed to the properties of alcohol.

Alcohol is a colourless transparent liquor, appearing to the eye like pure water. It poiffles a peculiar penetrating smell, distinct from the proper colour of the distilled spirit from which it has been procured. To the taste it is excessively hot and burning, but without any peculiar flavour. From its great lightness and mobility, the bubbles which are formed on shaking it subside almost instantaneously, and this is one method of judging of its purity. Alcohol is very easily volatilized by the heat of the hand, it even begins to be converted into a very expansible vapour at the temperature of 53° Fahr. and the quickness of evaporation always produces a cool salutary effect. It boils at about 165°, and the vapours when condensed return unaltered to their former state. It has never been frozen by any cold, natural or artificial, and hence its use in thermometers to measure very low temperatures.

Alcohol takes fire very readily on the application of any lighted body, the speedier in proportion to its purity. It burns with a pale flame, white in the centre and blue at the edges; this gives but a small degree of heat, and is so faint as to be scarcely visible in bright daylight. It burns without
out any smoke or vapour, and if strong, leaves no residuum; but if weak, it is extinguished spontaneously, and the watery part remains behind.

Alcohol mixes with water in every proportion. Heat is extricated during the mixture, which is sensible to the hand, even in small quantities. At the same time there is a mutual penetration of parts, so that the bulk of the two liquors, when mixed, is less than when separate. Consequently the specific gravity of the mixture is greater than the mean specific gravity of the two liquors taken apart. The alcohol may be again for the most part separated from the water by distillation with a gentle heat. See Gravity (specific).

Owing to the great affinity which sobills between water and alcohol, this latter has the power of precipitating from their solution various salts dissolved in water. Thus, if some strong alcohol be added to a saturated solutidn of Glauber's salt in water, a conglom of is immediately produced, consisting of the salt separated from the water in a very divided form, whilst the alcohol and water form a chemical union. This precipitation, however, only takes place in solutions of those salts which are insoluble in alcohol. This circumstance has been very ingeniously applied to the analysis of various saline solutions, and especially to the examination of mineral waters. The power of precipitating some of these salts extends to very dilute solutions. Mr. Kirwan, in his valuable work on mineral waters, has found by experiment that saline may be completely precipitated from water which contains only one-thousandth of its weight of this earthy salt, by any alcohol whose specific gravity is below 0.875. For further particulars on this subject, we must refer the reader to the article Waters (Mineral, analysis of).

Alcohol is capable of uniting with a great number of substances, a circumstance which renders its use very extensive in a variety of chemical processes and in analysis. Thee we shall enumerate.

Some of the weaker acids, such as the boracic and tartaric acids, are soluble in alcohol without any apparent decomposition, and may be again recovered by evaporating the spirit. The stronger acids, however, exercise a very powerful action on alcohol, and produce several very curious and important compounds, particularly that singular liquor called Ethei. See the articles Ether, Oil of Wine, and Oleifant Gas.

All the alkali, when pure, may be dissolved in alcohol, but the fixed alkali, when combined with carbonic acid, are not soluble in this menstruum. This affords a very convenient method of procuring the caustic fixed alkali in a state of purity, and by proper management they may be made to crystallize from their spirituous solution. The colour of a solution of alkali in alcohol is always somewhat red, however pure the alkali be, which is owing to a partial decomposition of the spirit. See the articles Potash and Tincture of Salt of Tartar.

Several of the neutral, earthy, and metallic salts, are soluble in alcohol. It is of some importance in chemical analysis to ascertain the degree of solubility of these salts, and many experiments have been made for this purpose.

The first of any importance are those of M. Macquer. He employed a spirit rectified so far, that a phial holding a Paris ounce of distilled water, at the temperature of $45^\circ$ Fah., would contain six gross and fifty-four grains of the spirit. The salts which he employed were previously dried with care, so as to expel their water of crystallization. He poured into a mattras upon each of the salts half an ounce of the spirit, and let the vessel in a hot sand-bath. When the spirit began to boil, he filtrated it while hot, and then left it to cool. He then evaporated the spirit, and weighed the saline residuums; and from these he inferred the quantity of salt which the spirit had dissolved.

This method, however, cannot be considered as accurate, as some of the spirit must have evaporated during boiling, and some of the salt must have been deposited in the pores of the filter. Neither would the errors produced in this way be uniform, since it appears that some salts are, in a greater proportion than others, more soluble in hot than in cold spirit.

Wenzel also published a series of experiments, in 1777, on this subject. He varied the heat which he employed, according to the solubility of the salt.

He has, however, been guilty of a great omission in not mentioning the specific gravity of the alcohol which he used, but it may be supposed to be nearly the same as that of Macquer.

Lastly, Mr. Kirwan, with that accuracy for which he is so justly distinguished, has given in his treatise on mineral waters, a table of the solubility of certain salts, in which alcohol of different densities is employed, and the temperature properly noticed.

Our readers will find the results of all the above-mentioned experiments in the following Table.

</table>

On examining the comparative results given in the above Table, we cannot consider them as very satisfactory, and in some instances we perceive a striking difference in the results, that it must depend on some more extensive cause than mere casual error. Probably the degree and continuance of heat employed, in drying the salt and expelling its water of crystallization, must have differed considerably in the respective experiments. It would be useless to attempt to explain the cause of difference in all the results, but this shews the great necessity of attending minutely to every particular in such experiments.

The most important of the salts insoluble in highly rectified alcohol are the following—all the sulphates, both of the alkalies, earths, and metals; some of the nitrated metals; some of the muriated metals; and the carbonated fixed alkalies.

A peculiar colour is perceived in the flame of some of these solutions in alcohol when set on fire. The solution of nitre gives a pale yellow flame, that of boracic acid is a faint green, all the solutions of copper burn with a beautiful bright green, and those of nitrated or muriated iron shone with a deep blood red.

Ammonia, both pure and carbonated, dissolves readily in alcohol. They are generally united by means of distillation, a moderate heat being sufficient to volatilize each. These combinations are principally employed in pharmacy.

Alcohol will readily unite with the carbonic acid gas, and will take up full its own bulk of it at a medium temperature.
A L C O H O L.

perature.—The gas, however, appears to have little or no action on the spirit, since it is expelled from it by heat unaltered.

Neither metals, nor metallic oxys, nor metallic acids, appear to be in any degree soluble in alcohol.

 Sulphur will not contract any union with alcohol by simple digestion either cold or hot; but when they are both reduced to the form of vapour, and then mixed, a true solution is effected, and the result is a very pungent spirit with a strong odour of liver of sulphur, and which becomes milky and depoits the sulphur on dilution with water.

Ardent spirit acts in a slight degree on Phosphorus, and dissolves so much of this inflammable substance as to become slightly luminous in the dark when the solution is dropped into water.

None of the pure earths are soluble in alcohol, and this latter has the power of precipitating lime, barytes, and frontain, from their watery solutions.

It is on the chemical substances belonging to the vegetable kingdom that alcohol exerts its most powerful action as a solvent, and herein commits its very extensive use in pharmacy, in preparing liquors for the table, in some of the arts, and in a very important part of chemical analysis.

Molt of the acids belonging to the vegetable kingdom are highly soluble in ardent spirit, such as the tartarious, the citric, the oxalic, and the gallic. In procuring the latter from the gall-nut, alcohol furnishes it with a very elegant and commodious method of separating the acid from the mucilaginous extractive matter with which it is naturally mixed.

The acetic acid, when of the usual strength, simply mixes with alcohol, without producing any decomposition, but chemicals have succeeded in forming an acetic Ether, by employing the acid in its most concentratd state.

Alcohol will readily dissolve Sugar. Wenzel estimates the quantity at about one-fifth of the spirit. In all the sweet native vegetable juices, such as the sap of the figar-cane and the maple, or the expressed liquor from the parnip and beet root, the sugar is mixed with a large quantity of a mucilage very little soluble in alcohol. This furnishes a ready method for separating the purely saccharine part, a method which is much employed in the analysis of various vegetables, for the purpose of ascertaining the comparative quantity of sugar which they may be expected to yield to the manufacturer. The solution, when left to spontaneous evaporation, yields minute crystals of sugar, which are at first brown, and require a further purification.

Ardent spirit is an excellent solvent for effiencing oils, and in general, for the molt odorous and inflammable of the vegetable productions. In the effiencing oil of a plant refides the Spiritus Rect, or the AROMA, that which gives the exquisite perfume to the rofe or jelfamine. When these odoriferous plants are diffiélied with alcohol, it rins strongly impregnated with their scent and flavour, and as it takes up no colouring matter it remains perfectly clear as before. Thus, the common lavender water is alcohol diffiélied off the lavender plant, and holding in solution the effiencing oil in which the scent refides. The Distilled Spiris in pharmacy, are finnlar preparations of alcohol, containing the flavour of fails, aromatics, or other substances with which it has been diffiélied. (See Oils ESSENTIAL).

All the Resins are highly soluble in alcohol, but scarcely, if at all, in water. These solutions have the peculiar colours, and acid taste of the resin which they contain. An addition of water renders them all turbid, and from the pure resinous solutions it precipitates almost the whole of the diffiélied contents in the form of thick flakes. The solution of guaiacum affords an example of this.

The Gum Resins, which are natural mixtures of gum and resin, yield their resinous part to pure alcohol and but little of their gum; but water on the contrary diffiélies the gum and leaves the resin, but a mixture of alcohol and water will hold both the ingredients in solution. These preparations are called Tinctures in pharmacy, and they are of considerable use in containing within a small bulk, the medicinal virtues of larger quantities of the ingredients employed.

Artificial resins, or Resinous Extracts, are also made by evaporating to dryness solutions of the resinous parts of several vegetables in alcohol.

Camphor is readily and largely soluble in ardent spirit. This solution, when saturated, will fall almost the whole of the camphor on the addition of water. Camphor also remarkably affords the solution of the resins.

Solutions of resinous substances in alcohol form the basis of the spirit VARNISHES, which when applied in thin layers over any substance, soon dry from the evaporation of the spirit, whilst the resin remains behind furnishing a smooth thin coating to the surface which they are intended to protect.

The fixed oils, when in their simple state, are entirely insoluble in alcohol, but they may be rendered soluble in this menstruum, either when they have been converted into drying oils by the action of metallic oxys, or when they are united with alkalis in the form of SOAP. A solution of fine soap in alcohol is perfectly colourless and transparent, and will bear dilution with water without becoming turbid. It is employed in medicine as an external application, and is also a good reagent in the analysis of mineral waters to discover the presence of earthy faults. These decompose the soap by double affinity, and produce curdling.

The effect of alcohol on animal substances bears a considerable resemblance to its operation on the vegetable kingdom.

Mucular fibre and the coagulum of blood are not soluble in this menstruum, but are rendered by it hard, contracted, and incapable of putrefaction.

Albumen is equally insoluble in alcohol and is coagulated by it, probably owing to abturation of the water which held it in solution. Milk is speedily curdled by ardent spirit of every kind.

Alcohol will diffiélied WAX, Spermaceti, Biliary Caculi, and the strong scented animal resins or resinous extracts, such as Musk and Ambergris. This menstruum, however, does not appear to be so extensively applicable to the analysis of animal substances as of those from the vegetable kingdom.

We have already mentioned that alcohol well rectified may be brought to the specific gravity of 0.825 (at 60° temperature) by a simple distillation, where the procces is slowly and carefily conducted, and when only the first third, or half of the spirit which comes over is taken. Chemicals have, however, been able to bring it to a higher state of depuration, and consequently a less specific gravity. This is done by adding to the spirit the alumbine or still a quantity of a salt which is itself insoluble in alcohol, and which has such a greedy attraction for water as to be able to separate it from the spirit. Boehmde recommends for this purpose common salt, hot, dry, and dehydrated. He allows the salt and the spirit to stand together for twelve hours, and then to be heated in a water-bath so as to distil off the spirit by
by a very gentle warmth. The flat is left moist in the still, and contains much of the water of the spirit employed. Some recommend burnt alum in the room of flat, but the belt addition is very dry, hot, carbonated alkali. A highly dephlegmated alcohol may be prepared in this method without the intermediate process of distillation; only then the spirit will be of a reddish colour, and will contain that small portion of carbonic alkali which is always mixed with common carbonated potash, which is soluble in ardent spirit. The following is Boerhaave's process:—

"Take a clean glass body containing common spirit of wine, and add thereto one-third of its weight of pure and dry potash, (carbonated potash), which immediately falls to the bottom. Shake the glass, and the flat directly grows moist and begins to dissolve at the liquid, whilst a thin liquid floats above it; the more the vessel is shaken, the more liquid is the lower part of the flat, and the more distinctly separated from the upper liquid, nor is it ever possible to mix them together, but upon a still they will immediately separate into two layers."

1. If the vessel be then continued, he adds, by decanting carefully the upper of the two liquors, (which is the alcohol rendered by a little carbonic alkali that it holds distilled) and adding to it more carbonated alkali, till the portion left added will no longer become wet on shaking, a sign that the alkali is as fully deprived of water as it is capable of being made by means of alkali. As a proof of the high dephlegmation of the spirit by this method, it may be observed, that if a drop or two of water be added to alcohol in which flat of tartar has long remained dry, the alkali immediately becomes moist, and appears to run unceasing from the sides of the vessel.

2. If the alcohol be distilled off the alkaline flat with a gentle heat, the first part which comes over will be about the specific gravity of 0.819 to 0.815; at the temperature of 63°, and this is as high a degree of purity as it has been brought to in the accurate experiments made in this country, by Dr. Blagden, and others, for the purpose of ascertaining its specific gravity. (See Gravity for this.)

M. Lavoisier, however, affirms, that he has brought alcohol to the specific gravity of 0.791, chiefly by adding, before distillation, a very large quantity of alkali to as almost entirely to abolish the spirit.

After distillation, the wet alkaline flat which is left may be dried, and again used for the same purpose; but Boerhaave affirms, that after repeating the use of the same alkali for a number of times, it becomes changed in its nature, and unfit for the purpose. This would imply a decomposition of the alcohol, which deserves to be further examined.

Various tests have been devised for ascertaining the purity of alcohol, and the proportion of water which it contains. A spirit, which is very free from water will, when first free to burn away without leaving any residue; if it is of moderate strength it will burn for a certain time, and then become extinguished, and leave a portion of water more or less considerable, according to the degree of dephlegmation; if, on the contrary, it is very weak and watery, it will not kindle at all. This test, however, is by no means accurate, since the heat of the burning spirit will drive off part of the water which should be left in the retortum. Another test is, to drop a small quantity of spirit on a small heap of gunpowder and kindle it. The spirit burns quietly on the surface of the powder till it is all consumed, and the last portion leaves the powder if the spirit was pure, but if watery, the powder becomes too damp and will not explode. This test, also, is very inaccurate; for if the powder be drenched with even a strong spirit, it remains too damp to be kindled; and if it be only barely moistened, any spirit that will burn will flame it. A better test is, as we have mentioned, to shake the spirit in a phial with some dry carbonated alkali; but the most accurate of all is to ascertain its specific gravity, and compare it with the density of known quantities of alcohol and water, previously mixed for the purpose of giving a standard of comparison. The very extensive and accurate labours on this subject, conducted by Beaumé, Blagden, Gounenain, and other eminent scientific men, belong with more propriety to the subject of specific Gravity.

It remains for us to mention the chemical nature of alcohol, and the apparatus which attend its decomposition. The remarkable circumstance of a vegetable product burning away, without the smallest trace of smoke or fulminating vapour of any kind, had long engaged the attention of chemists. Juncker and Boerhaave threw much light on the subject by remarking, that the product of the combustion of alcohol was always a quantity of pure water; and this fact was more fully illustrated by the experiments of the illustrious Lavoisier. The ready evaporation of alcohol, and the case with which its vapour will fill a large vessel, renders it a dangerous experiment to submit a considerable quantity at once to combustion, in oxygen gas confined in any vessel, but this difficulty was surmounted in an ingenious manner. His first experiment was simply to ascertain the quantity of water yielded by the combustion of a given weight of alcohol. This was performed in the following apparatus, contrived by M. Meunier. See Plates of Chemistry, fig. 10.

E F is a worm, contained in the cooler A B C D. To the upper part of the worm E, the chimney G H is fixed, which is composed of two tubes, one within the other, the inner of which is a continuation of the worm, and the outer one is a case of tin-plate, which surrounds it at about an inch distance, and the interval is filled with sand. At the inferior extremity K of the inner tube, a glass tube is fixed, to which is adapted the argand lamp L M, for burning alcohol.

Things being thus disposed, and the lamp being filled with a determinate quantity of alcohol, it is set on fire; the water which is formed during combustion, rises in the chimney K E, and being condensed in the worm, runs out at its extremity F, into the bottle P. The use of the outer tube G H, and of the sand between it and the inner tube, is to prevent the latter which proceeds from the worm, from being cooled during combustion, which would occasion the water, formed by the burning, to fall back on the lamp instead of falling on into the worm.

This apparatus, though not perfect, has the advantage of enabling the chemist to operate with larger quantities than can be admitted in the more accurate experiments on combustion; and by it, the above-mentioned chemists were able to establish the important fact, that the quantity of water collected by the combustion of alcohol very feebly exceeds the quantity of the alcohol which is consumed. The product of water must vary according to the strength of the alcohol, and the care of conducting the experiment; but it is so considerable, that from sixteen ounces of ardent spirit, Lavoisier obtained eighteen ounces and a half of pure water. There is besides, however, a large quantity of carbonic acid produced in this experiment which escapes, and cannot be eliminated by this apparatus. Some of this gas unites with the water which is collected, and causes it to precipitate lime-water.

Having thus ascertained in a general way the products of
of the combustion of alcohol, Lavoisier proceeded to repeat the experiment, in vessels which might determine the result with accuracy. He employed, for this purpose, a large bell glass, holding from 700 to 800 cubic inches, and inverted over a mercurial trough. A small lamp, filled with a known weight of alcohol, was introduced under the glass swimming on the surface of the mercury, and the wick was armed with a very minute portion of phlogphorus. The atmospheric air within the glass was sucked out by a syphon, till the mercury rose to a certain height which was noted; and the phlogphorus on the wick being then kindled by a hot iron, the spirit soon took fire. As the air within the glass were soon consumed, and the inflammation of the spirit stopped, a constant supply of oxygen gas was sent into the glass through a syphon tube, connected with a reference of this gas, and which passed under the mercury into the glass where the combustion was going on. Great precaution was required not to let in more oxygen than was barely necessary to keep up the combustion; otherwise the heat, volatilizing part of the spirit, would have filled the glass with vapour of alcohol, and this mixing with the oxygen, would have suddenly exploded by the combustion. In this, as in other respects, the combustion of alcohol strikingly resembles that of pure hydrogen gas. The experiment was at first stopped by the quantity of carboxic acid generated; and on examining the results, (proper corrections being made for pressure and temperature) it was found, that 93.5 grains of alcohol and 116.72 grains of oxygen had been consumed. The products of these were 97.8 grains of carboxic acid and 106.2 grains of water, which last therefore exceeded by 12.7 grains the quantity of alcohol employed. From these data, and from previous experiments (wherein Lavoisier climated, that 100 grains of oxygen take up 38.88 grains of carbon, for the production of carboxic acid; and that the same quantity of oxygen takes up 17.64 grains of hydrogen for the production of water), he concluded the composition of alcohol to be the following,

<table>
<thead>
<tr>
<th>Element</th>
<th>Grams</th>

</tr>
</tbody>
</table>

We may observe, however, that the result of this experiment can only be considered as an approximation towards the truth, since the estimation of the component parts of alcohol here given, does not agree with that which is deduced by the same chemist, from the result of vinous fermentation. Neither is there any light thrown on the mode of union between the component parts, and their degree of oxygenation as they exist in the spirit before combustion.

Alcohol has likewise been more directly decomposed without the accession of oxygen gas. Dr. Priestley procured inflammable air by paffing the electric spark through spirit of wine. But the most striking experiments on this subject, performed by this excellent philosopher, were the decomposition of spirit by paffing it through red-hot tubes, both of earth and metal. He first transmitted two ounce measures of alcohol, reduced to vapour by boiling, through an ignited porcelain tube, and procured 1020 ounce measures of air, "which was all inflammable without any mixture of fixed air in it," and which burned with "a blue lamont flame." (We here quote the very words of the author, which the writer of the article Alcool, in the Encyclopedie Methodique, has made to correspond with the experiments of Lavoisier, by adopting the following

*Alcohol.*

*Principal translation—M. Priestley, en faisant passer de l'alcool dans un tube d'argile rougi au feu, en a retire du gaz hydro-gene melé de gaz acide carbonique*.) Dr. Priestley's next experiments are full more curious, as they determine the existence of carbonaceous matter in spirit of wine. Having found interesting results from the transmutation of the vapour of water through a heated copper tube, he repeated the experiments, only substituting the vapour of spirit of wine for that of water. "In this case," he observes, "the vapour of the spirit had no sooner entered the hot copper tube, than I was perfectly astonished at the rapid production of air. It resembled the blowing of bell-lows. But I had not used four ounces of the spirit of wine before I very unexpectedly found that the tube was perforated in several places, and presently afterwards it was so far dilated, that in attempting to remove it from the fire, it actually fell in pieces. The inside was full of a black foamy matter, resembling lamp-black." He then varied the experiment by using carbon tubes, placing within them copper filings, and transmitting the vapour of alcohol. The copper was, as before, converted into a black friable sub stance, obviously produced by the addition of carbonaceous matter furnished by one part of the spirit, whilst the other part appeared in the form of a copious stream of inflammable air. It is however by no means the whole of the charcoal of the alcohol which is retained by the copper, for much of it escapes mixed with the inflammable air in the form of fine dust, giving the gas the appearance of a dense black cloud; and when the tube is strongly heated, this volatized charcoal will give an uniform black coating to any balloon or large vessel in which the gas is received. Dr. Priestley found some other metals to undergo a similar change by the vapour of alcohol, but none in so striking a manner as copper. On heating some of this charcoal of copper, as he calls it, in oxygen gas, he found it to burn very readily to a certain point, after which the remainder could not be again kindled. The gas produced by the combustion was pure fixed air or carbonic acid.

The excellent Dutch chemists, of the Tevlerian institution, Van Marum and colleagues, repeated Dr. Priestley's experiments with great accuracy, and found the same results in every essential particular. They employed, as well as Dr. Priestley, Wedgwood's porcelain tubes, which they injected with rain tubes to prevent the sudden accession of the fire which is apt to crack them. One extremity of the carbon tube received a small retort in which was put the alcohol, and the other entered a metallic serpentine tube, immersed in a refrigeratory, and provided at the further end with a bottle to receive the gaseous products. In the first experiment which was performed, an ounce and a half of alcohol in vapour had been transmitted through the heated copper, and had produced about fix cubic feet of inflammable air.

In the second experiment the heat was greater, and the production of the gas more rapid. In all, the copper was reduced to a black and very friable substance, which fell to pieces between the fingers. The proportion of charcoal added to the copper by the experiments, varied at different times apparently owing to the greater or less rapidity with which the process was conducted. Dr. Priestley had united 306 grains of charcoal to 28 grains of copper. In one instance, and 308 to 19, in another; but the Dutch chemists found a much less proportion of charcoal, being only an addition of 293 grains to 748 grains of copper in one case, and in another, 185 of charcoal to 612 of the metal. The great difference in the results is, however, of little consequence in attempting
ing to ascertain by these experiments the exact proportion of the component parts of alcohol, since a large part of the carbonaceous ingredient escapes the copper, and passes over into the vessels which receive the inflammable air, where it either appears in the form of a fine black foot, or remains permanently united with the hydrogen gas. M. Van Marum likewise collected in the bottle connected with the retort a quantity of nearly pure water, about equal to half the weight of the alcohol evaporated by boiling, and of the specific gravity of 0.996. He does not inform us of the strength of the spirit which he used. He confirmed the other part of Dr. Priestley's experiment by burning the charcoal of copper in oxygen gas, and procuring pure carbonic acid, whilst the remaining copper still retained a small portion of carbon which could not be consumed. It is worthy of remark, that the inflammable air produced in the experiments of both these eminent chemists was found to be not much more than twice as light as common air, and it probably bears a considerable resemblance to that species of gas, termed, with great propriety by Mr. Cruiknank, 

*Oxidous Oxyd of Carbon.*

The vapour of alcohol transmitted through earthen tubes forms, in particular circumstances, that singular air which has been named *Oleffiant Gas.*

The ufe to which alcohol is applied are numerous and important. In the arts, it is employed largely as a solvent for those refrinous gums which form the basis of numerous varnishes and similar applications.

It polishes in the highest degree the cordial, stimulat¬ing, and intoxicating qualities of all distilled spirits, and although the first powerful and more grateful of the spirituous liquors, such as rum, brandy, &c. are more peculiarly devoted to the use of the table, the purer ardent spirit, again sufficiently diluted with water, is employed as the basis of many of the artificial cordial spirits and liquors, to which a flavou¬r and additional tafte are given by particular admixtures. Similar to this is the ufe of alcohol in medicine, where it serves as a solvent for the more active parts of vegetables, under the form of tinctures, and it is also employed as an external application, often with considerable success.

The highly antiseptic power of alcohol renders it particular¬ly valuable in preserving particular parts of the body as anatomical preparations.

The gentle, ready, and uniform heat which it gives during combustion, and the absence of smoke or fuliginous vapour of any kind, make it often a most eligible material for burning in lamps.

As a fluid for thermometers, it has the advantage over mercury in not freezing in any known degree of cold, but from its ready volatility in a moderate heat it cannot be depended on with any accuracy, above 90 or 100 degrees.

The expansibility of alcohol is much greater than water; the former being, in a range of temperature from 30 to 100, \( \frac{1}{40} \) th of its bulk, and the latter only \( \frac{1}{100} \) th.

The ufe of alcohol in chemical analysis has been already mentioned. As a solvent for some of the early and metallic salts, and a precipitant of others, it is peculiarly fitted to af¬bit in the analysis of mineral waters, and saline substances in general; and in the chemical examination of vegetable and animal matter, it furnishes a solvent of very extensive power, poftelled of the valuable advantage to the chemist of produc¬ing but little decomposition in the substances which it holds in solution, and therefore enabling him to present them almost exactly with their native properties and distinctive characters.

Vol. I.

Alcohol is sometimes also used for a very fine, impalp¬able powder, which women in the East make ufe of as a kind of *fimb.* Kohol is a general term applied to a sub¬stance applied to the eye-ball, on the inside of the eye-lids, in the form of a powder finely levigated. That which is em¬ployed for ornament is called simply al kohol, or *ipphahany,* when other ingredients, as flowers of olibanum, amber, and the like, are added, on account of some particular disorders, the kohol is distinguished by some appropriate epithet. Dr. Shaw, in his Travels, speaking of the women in Barbary, says, that none of these ladies think themselves completely drested, until they have tinged their hair and edges of their eye-lids with *al-kahol,* the powder of lead-ore. Lady Mont¬ague (Letters, vol. ii. p. 52.) takes notice of this custom among the Eastern women; and in her sprightly manner, the fapphires our English ladies would be overjoyed to know this secret. This one ufed at Aleppo, called Stibium by the ancients, but very different from antimony, is brought from Perin, and is prepared by reducing it in a quine, an apple, or a truffle, then adding a few drops of oil of almonds, it is ground into a turpentine powder on a marble. Of late years the lead ore, brought from England, under the name of Arcifoglio, has been ufed instead of the *ipphahany.* The quantity of kohol confumed in the East is incredibly great. It has been paid by one of their poets, in allusion to the probe ufed for applying the powder, and the mountains where the mineral is found, "that the mountains have been worn away by a bodkin." This probe or bodkin, called meel, is made of ivory, silver, or wood; it is dipped in water, and when a little of the powder has been sprinkled on it, it is applied horizontally to the eye, and the eye-lids being flutt upon it, the probe is drawn between them, leaving the infide tinged, and a black rim all round the edge. The Roman Satyrill alludes to this custom, as well as that of blackening the eye-brows:

"Illa supercilium madida fuliginis taetum

Obliqua producit acu, pungente trementes

Attollens oculis.

*Juv.** Sat. iii. v. 67, and Casaubon's note.

The kohol is also ufed by the men for strengthening the fight, and preventing various disorders of the eye, for which purpose different ingredients are occasionally added. It is also ufed to the eyes of children, as soon as they are born, and is renewed at the interval of a few days through the several periods of their adolescence. The ufe of the kohol is very ancient. Passages relative to it, in sacred history, may be seen in Shaw, (Travels, p. 229.), Harmer, (Observations, vol. ii. p. 405.), and Lowth's Notes of Isaiah, chap. iii. v. 15. Harmer conceives that the red¬ness of the eyes, as it is in our version, which the dying pa¬triarch mentions in blessing Judah, (Gen. xliv. 12.), is to be explained by this ufage. Dr. Ruffell observes, on a passage in Xenophon referred to by Shaw, that blackening the eyes, though a custom among the Medes, was not at that time in ufe among the Persians; for Cyrus, among other things, seems to have been upripled at the painted eyes of his grandfather Atyages. *Cyp.** lib. i. p. 8. See Ruffe¬ll's Aleppo, vol. i. p. 111. p. 507. Ed. 1794. From this im¬palpable powder the name was transferred to other subtile powders, and afterwards to spirits of wine exalted to its highest purity and perfection. See Porphyration.

*Alcohol,* in the Arabian *Astrolony,* is when a heavy

4 D

flow-paced
flow-paced planet receives another lighter one within its orb, so as to come in conjunction therewith.

Alcohol Maris, filings of salt reduced to an impalpable powder, by burning it into ruff with urine, then levigating it, and mixing it with a large quantity of water; that is, about a gallon to two pounds and a half of filings. After it has stood a quarter of an hour, the upper part of the water is to be poured off, and evaporated to a dryness. The powder at the bottom is then to be put into a paper, in the form of a finger-leaf, and washed, by gradually pouring in hot water, till it is freed from the urinous salts. With regard to the remaining grofs powder, the same process is to be repeated.

Mugrave has a great opinion of this preparation, as a remedy to bring back the gout from the nobler parts to the joints. He prescribes it thus: take of alcohol maris from five to ten grains, thoritai Andromachi from half a scruple to one dram, mix these with as much syrup of clove-julyflowers, as is sufficient to make a bullis.

Alcoholization, in Chemistry, the rectification of a vinous spirit.

This is otherwife called alcoholization.

Alcoholization, according to Sturkey, denotes the circulation of a volatile spirit on a fixed alkali, till such time as out of the two ares one neutral body different from both the former. Alcoholization is one way of volatilizing alkalis.

Alcoholization is also used for pulvisication.

Alcol, or Ancol, in Geography, lies on the coast of Barbary, on the east side of the Cape de Taro, under which there is a small bay and good road, but open to the north and north-east; so that when a Levant gale is expected, ships should move round the cape to the west-side.

Alcola is used by alcinia, for the tartar of urine. Alceda is found in three different forms, viz. 1. Refolved, or reduced into an impalpable substance. 2. Sandy, or voided under the appearance of small grains of whitish or reddish sand. 3. Muscagious, or viscous.

Alcolea, in Geography, a small town of Spain, in New Castile, situated in a fine country, a few leagues north of Madrid. N. lat. 40° 40'. W. long. 3° 6'.

Alcolea is also a town of Spain, in Andalufia, on the banks of the Guadalquivir, fix miles north of Carmona.

Alcolea is also another town of Spain, in Aragon, on the confines of Castile, south of Barbastre, and north-east of the river Yzuela. N. lat. 41° 50'. E. long. 2° 14'.

Alcosenae was also a town of the island of Ithaca, whence Ulysses was called Alcmeuces.

Alcon, in Biography, a physician of great eminence in the first century of the Christian era, acquired considerable wealth in his profession, under the Emperor Claudius. He is said to have been expert in the art of reducing fractured, or luxated bones, and in curing hernias by incision. He is probably the person mentioned by Martial, in the following epigram, lib. xi. ep. 85.

Mitior implicitas Alcon secat enterocelas,
Fractaque fabrili dedat officia manu.

See more of him in Le Clerc's Hist. de la Medicine, p. 581.

Alcon, in Entomology, a species of Papilio Pilipes, with entire caruncle wings, brown margin, below crenaceous brown, and numerous occipital points; found in Austria.

Alcor, in Astronomy, a small star adjoining to the large bright one in the middle of the tail of Ursa major.

The word is Arabic.—It is a proverb among the Arabia, applied to one who pretends to see small things, but overlooks much greater, "Thou canst see Alcor, and yet not see the full moon."

ALCORAN, or Al Koran, the Mahometan Scripture or Bible, containing the revelations, doctrines, and prophecies, of the pretended prophet Mahomet.

It is vulgarly called Alcoran; but the first syllable of the word is nothing more than an article signifying the; and therefore the true orthography of the word is Al Coran, or Al Koran, that is, the Koran. It is derived from the Arabic word koran, to read; and signifies the reading; or what ought to be read. Thus Mahomet gave it this title by way of eminence, in imitation of the Jews and Christians, who call the Old and New Testament, Scripture; and the Bible, i.e. the Book; and al Diktar, the adoration.

Besides this peculiar name, the Koran is also honoured with several appellations common to other books of Scripture; as Al Farkan from the verb faraha, to divide or distinguih, denoting a fiction or portion of scripture. It is also called Al Mufaief, the volume, and Al Kitab, the book, by way of eminence.

It is the common opinion among us, that Mahomet, al

Ebn, fitted by one Sergius, a monk, composed this book; but the Musulmen believe it as an article of their faith, that the prophet, who, they say, was an illiterate man, had no concern in inditing it; but that it was given him by God, who, to that end, made use of the ministry of the angel Gabriel; that, however, it was communicated to him by little and little, a verse at a time, and in different places, during the course of twenty-three years;—"And hence," say they, "proceed the disorder and confusion visible in the work: which, in truth, are so great, that all their doctors had never been able to adjust them. For Mahomet, or rather his copyist, having put all those loose verses promiscuously in a book together, it was impossible ever to retrieve the order wherein they were delivered.

Thos twenty-three years which the angel employed in conveying the Koran to Mahomet are of wonderful service to his followers: insomuch as they turn them with an answer to such as tax them with the glaring contradictions of which the book is full: those contradictions they piously father upon God himself; alledging, that in the course of so long a time, he repeated and altered several doctrines and precepts which the prophet had before received of him.

The Mahometan doctors erubiate any objection deduced from these contradictory passages by the doctrine of abrogation; and they distinguish the abrogated passages into three kinds: the first, where the word and senfe are both abrogated; the second, where the letter only is abrogated, but the senfe remains; and the third, where the senfe is abrogated, though the letter remains. Of the first kind were several verses, which by the tradition of Ans Ebn Maleer, were in the prophet's life-time read in the chapter of repentance, but are not now extant. Another instance of this kind we trace from the tradition of Abdallah Ebn Mafud, who reported that the prophet gave him a verse to read which he wrote down, but the next morning looking in his book, he found it was vandished, and the leaf blank; upon acquainting Mahomet with this circumstance, he was affurred by the prophet that the verse was revoked the same night. Of the second kind is the verse called the verse of floning, which, according to the tradition of Omar, afterwards Khalif, was extant, while Mahomet was living, though it be not now to be found. Of the last kind are observed several verses, in 69 different chapters, to the number of 225; such as the precepts of turning in prayer to Jerusalem, falling
failling after the old custom, forbearance towards idolaters, avoiding the ignorant, and the like.

Mr. D'Herbelot thinks it probable, that when the heretics of the Nestorians, Eutychians, &c. had been condemned by eccenomical councils, many bishops, priests, monks, &c. being driven into the defects of Arabia and Egypt, furnished the impostor with passages, and crude ill-conceived doctrines, out of the scriptures; and that it was hence that the Koran became so full of the wild and erroneous opinions of those heretics.

The Jews also, who were very numerous in Arabia, furnished materials for the Koran; nor is it without some reason that they boast twelve of their chief doctors to have been the authors of this work.

The Koran, it is to be observed, while Mahomet lived, was only kept in loose sheets; his successor, Abubeker, first collected the contents into a volume, not only from the palm leaves and skins on which they had been written, but also from the mouths of those who had committed them to memory; and when the transcript was completed, entwined the keeping of it to Haphsa, the daughter of Omar, one of the widows of Mahomet, in order to be consulted as an original; and there being a good deal of diversity between the several copies previously dispersed throughout the provinces, Ottoman, or Othman, successor of Abubeker, in the 35th year of the Hegira, procured a great number of copies to be taken from that of Haphsa; at the same time suppressing all the others not conformable to the original.

The chief differences, in the present copies of this book, consist in the points, which were not in use in the time of Mahomet, and his immediate successors, but were added since, to ascertain the reading; after the example of the Masoretes, who added the like points to the Hebrew texts of scripture.

The Koran is divided into 114 suras, or chapters, of very unequal length; which, in the manuscript copies, are not distinguished by their numerical order, though they are actually numbered in Sale's edition, but by particular titles, which, except the initial chapter, are taken sometimes from a particular matter treated of, or person mentioned therein, but usually from the first word of note. Some chapters have two or more titles, occasioned by the difference of the copies. Some of the chapters having been revealed at Mecca, and others at Medina, this difference is noted in the title. Several of them are said to have been revealed partly at Mecca and partly at Medina; and as to others, it is not agreed among commentators to which of these two places they belong. The suras are divided into little verses, in Arabic, called ayt, sign or wonder, which are all composed in a broken interrupted style, resembling prose rather than verse. Many of these have their particular titles formed in the same manner as those of the chapters.

Before the unequal divisions of chapter and verse, the Koran is divided into 60 equal portions, called abshab, each of which is again subdivided into four equal parts.—But it is more usually divided into 30 sections, named aya, each of twice the length of the former, and subdivided in like manner into four parts. Thse divisions are for the use of the readers of the Koran in the royal temples, or in the adjoining chapels where the emperors and great men are interred. Of these readers, there are 30 belonging to every chapel, and each reads his section every day, so that the whole Koran is read over once a day. Under the title, at the head of every chapter, except the ninth, is prefixed the following solemn form, called by the Mahometans the bif- millah; in the name of the most merciful God; which form, as well as the titles, are considered by some commentators of divine original; though others believe them to be human additions.

This form they constantly place at the beginning of all their books and writings in general, as a peculiar and characteristic mark of their religion; and it is deemed a sort of impiety to omit it. There are 9 chapters of the Koran, which have this peculiarity, that they begin with certain letters of the alphabet; some with a single one, and others with more. These letters are considered as peculiar marks of the Koran; and as concealing profound mysteries, the certain understanding of which, the more intelligent confess, has not been communicated to any mortal, their prophet alone excepted.

There are seven principal editions of the Koran; two at Medina, one at Mecca, one at Cufa, one at Basora, one in Syria, and the common, or vulgate edition. The first contains 6000 verses; the second and fifth 6574; the third 6281; the fourth 6293; the sixth 6225; the last 6226; but the number of words and letters in the name in all, viz. 77639 words, and 323015 letters.

The Koran is held not only of divine original, but eternal and uncreated, remaining, as some express it, in the very essence of God. The first transcript has been from everlasting by God's throne, written on a table of vast bigness, in which are also recorded the divine decrees, past and future. A copy from this table, in one volume, on paper, was sent down to the lowest heaven, by the ministry of the angel Gabriel, in the month of Ramadan, on the night of power: from whence it was delivered out by Gabriel to Mahomet, in parcels, some to Mecca, and some to Medina, though he had the confusion of seeing the whole once a year, and in the last year of his life twice. Some few chapters were delivered entire, the greater part only in separate periods, which were written down from time to time by the prophet's amanuenses, in such a part of any particular chapter as he directed. The first parcel that was revealed, was the first five verses of the 56th chapter, which the prophet received in a cave of mount Harâb, near Mecca.

Although the Sonnites or Orthodox believe that the Koran is uncreated and eternal, and Mahomet himself is said to have pronounced him an angel who affected the contrary, yet several have been of a different opinion; particularly the sect of the Montalzites, and the followers of Iba Ebn Sobech Abu Mafa. Son of the Mozdar, who accosted those who held the Koran to be uncreated, of infidelity, as affronts of two eternal beings. The dispute, which occasioned much warm contention, was at length compromised by Al Ghazzali, who maintained that the original idea of the Koran only is really in God, and consequently co-essential and co-eternal with him, but that the copies are created and the work of man.

The Koran is universally allowed to be written with the utmost elegance and purity of language, in the dialect of the tribe of Koreith, the most noble and polite of all the Arabsians, but with some mixture, though very rarely, of other dialects. It is considered the standard of the Arabic tongue; and as the more orthodox believe, and are taught by the book itself, inimitable by any human pen; and therefore infallible as a permanent miracle, greater than that of raising the dead, and of itself sufficient to convince the world of its divine original. Accordingly, Mahomet himself appealed to this miracle as the chief confirmation of his mission; publicly challenging the most eloquent man in Arabia, then abounding with persons whose folio
study and ambition it was to excel in elegance of style and composition, to produce even a single chapter that might be compared with it. However, there have not been wanting, even among the Mahometans themselves, those who have affected that there is nothing miraculous in this book with respect to style or composition, excepting only the prophetic relations of things past, and predictions of things to come; and that if God had left men to their natural liberty, and not restrained them in that particular, the Arabsians could have composed something not only equal, but superior to the Koran in eloquence, method, and purity of language. This was the opinion of the Mutazalites, and in particular of Al Mozar and Al Notham.

The style of the Koran is generally beautiful and fluent, especially where it imitates the prophetic manner and scripture-phraseology. It is concise and often obscure, adorned with bold figures after the eastern taste, enlivened with florid and fententious expressions, and in many places, especially where the majesty and attributes of God are described, sublime and magnificent. Although it be written in prose, yet the sentences generally conclude in a long continued rhyme, for the sake of which the sense is often interrupted, and unnecessary repetitions are too frequently made. But this kind of jingling delights the Arabsians; and they are fond of employing it in their most elaborate compositions; which they embellish with frequent citations from the Koran, and allusions to it. To this pomp and harmony of expression, some have ascribed the whole force and effect of the Koran, whilst others suppose, that the internal pleasures of paradise, which are so often displayed to the imagination of the reader, are the chief allurements to which it owes its efficacy.

"By the advocates of Mahometanisme," says a learned and ingenious writer, "the Koran has been always held forth as the greatest of miracles, and equally fabulous with the act of raising the dead. The miracles of Moses and Jesus, they say, were transient and temporary; but that of the Koran is permanent and perpetual; and therefore far surpass the miraculous events of preceding ages. We will not detract from the real merit of the Koran; we allow it to be generally elegant, and often sublime; but at the same time, we reject with disdain its arrogant pretence to any thing supernatural." "The real excellence of the work is to be referred to natural and visible causes." Besides the general impressions of admiration and astonishment, which the pretended prophet had produced on the minds of his followers, by the exterior faculties of his demeanour, and his long and splendid series of victories, Mahomet found, in the language of Arabia, a language extremely loved and diligently cultivated by the people to whom it was vernacular, "advantages which were never enjoyed by any former or succeeding impeller. It requires not the eye of a philosopher to discover in every land and country a principle of national pride; and if we look back for many ages in the history of the Arabsians, we shall easily perceive that pride among them invariably to have consisted in the knowledge and improvement of their native language. The Arabic, which has been justly esteemed the most copious of the eastern tongues; which had excelled from the remotest antiquity; which had been embellished by numberless poets, and refined by the constant exercise of the natives, was the most successful instrument which Mahomet employed in planting his new religion among them. Admirably adapted by its unrivalled harmony, and by its endless variety, to add painting to expression, and to pursue the imagination in its unbounded flight, it became in the hands of Mahomet an irresistible charm, to blind the judgment, and to captivate the fancy of his followers.

"Of that description of men, who first composed the adherents of Mahomet, and to whom the Koran was addressed, few, probably, were able to pass a very accurate judgment on the propriety of the sentiments, or on the beauties of the dictation: but all could judge of the military abilities of their leader; and, in the midst of their admiration, it is not difficult to conceive that they would ascribe to his compositions every imaginary beauty of inspired language. The shepherd and the forger, though awake to the charms of these wild but beautiful compositions, in which were celebrated their favourite occupations of peace or war, were yet little able to criticise any other works than those which were addressed to the imagination or the heart; to abstract reasonings on the attributes and dispensations of the Deity, to the comparative excellencies of rival religions, to the dispensation of any one religious system in all its parts, and to the force of its various proofs, they were quite inattentive. In such a situation, the appearance of a work, which possessed something like wisdom and confluence; which prescribed the rules, and illustrated the duties of life; and which contained the principles of a new and comparatively sublime theology, independently of its real and permanent merit, was likely to excite their admiration, and to become the standard of future composition.

"In the first periods of the literature of every country, something of this kind has happened. The father of Greek poetry very obviously influenced the taste and imitation of his countrymen. The modern nations of Europe all poise some original author, who, rising from the darkens of former ages, has begun the career of composition, and tinctured with the character of his own imagination the stream which has flowed through his posterity. But the prophet of Arabia had, in this respect, advantages peculiar to himself. His compositions were not to his followers the works of man, but the genuine language of heaven which had been sent them. They were not confined, therefore, to that admiration, which is so liberally bestowed on the earliest productions of genius; or to that fond attachment with which men every where regard the original compositions of their country; but with their admiration they blended their piety. To know and to feel the beauties of the Koran, was in some respect to share in the temper of heaven; and he who was most affected with admiration in the perusal of its beauties, seemed most fully the object of that mercy, which had given it to ignorant men. The Koran, therefore, became naturally and needfully the standard of taste. With a language thus hallowed to their imaginations, they were too well satisfied, either to dispute its elegance, or improve its structure. In succeeding ages, the additional function of antiquity or prescription was given to those compositions which their fathers had admired; and while the belief of its divine original continues, that admiration which has thus become the right and the duty of the faithful, can neither be altered nor diminished.

"When, therefore, we consider these peculiar advantages of the Koran, we have no reason to be surprized at the admiration in which it is held. But, if depending to a more minute investigation of it, we consider its perpetual inconstancy and absurdity, we shall indeed have cause for astonishment at that weakness of humanity, which could ever have received such impositions as the work of the Deity."
"The first praise of all the productions of genius is invention, that quality of the mind, which, by the extent and quickness of its views, is capable of the largest conceptions, and of forming new combinations of objects the most distant and unusual. But the Koran bears little impression of this transcendent character. Its materials are wholly borrowed from the Jewish and Christian scriptures, from the Talmudic legends, and apocryphal gospels then current in the east, and from the traditions and fables which abounded in Arabia. The materials, collected from these several sources, are here heaped together, with perpetual and needless repetitions, without any selected principle or visible connection. When a great part of the life of Mahomet had been spent in preparatory meditation on the system he was about to establish, its chapters were dealt out slowly and separately during the long period of 23 years. Yet thus defective in its structure, and not less exceptionable in its doctrines, was the work which Mahomet delivered to his followers as the oracles of God.

"The most prominent feature of the Koran, that point of excellence in which the partiality of its admirers has ever delighted to view it, is the sublime notion it generally imparts of the nature and attributes of God. If its author had really derived these just conceptions from the inspiration of that being, whom they attempt to describe, they would not have been surmounted, as they now are on every side, with error and absurdity. But it might easily be proved, that whatever it justly defines of the divine attributes, was borrowed from our holy scripture; which even from its first promulgation, but especially from the completion of the new testament, has extended the views, and enlightened the understandings of mankind; and thus furnished them with arms, which have too often been ineffectually turned against itself by its ungenerous enemies.

"In this instance particularly, the copy is far below the great original, both in the propriety of its images, and the force of its descriptions. Our holy scriptures are the only compositions that can enable the dim sight of mortality to penetrate into the invisible world, and to behold a glimpse of the divine perfections. Accordingly, when they would represent to us the happiness of heaven, they describe it, not by any thing minute and particular, but by something general and great: something, that without depending on any determinate object, may, at once by its beauty and immensity, excite our wishes and elevate our affections. Though, in the prophetical and evangelical writings, the joys that shall attend us in a future state are often mentioned with ardent admiration, they are expressed rather by allusions than similitude, rather by indefinite and figurative terms, than by any thing fixed and determinate. 'Eye hath not seen, nor ear heard, neither have entered into the heart of man the things which God hath prepared for them that love him.' Cor. ii. 9. What a reverence and astonishment does this passage excite in every hearer of taste and piety? What energy, and at the same time, what simplicity in the expression! How sublime, and at the same time, how obscure! Is it the imagery! Different was the conduct of Mahomet in his descriptions of heaven and of paradise. Uninfluenced by the necellary influence of virtuous intentions and divine inspiration, he was neither dexterous, nor indeed able to exalt the minds of men to sublime conceptions or to rational expectations. By attempting to explain what is inconceivable, to describe what is ineffable, and to materialize what in itself is spiritual, he absurdly and impiously desired to realignise the purity of the divine essence. Thus he fabricated a system of incoherence, a religion of depravity, totally repugnant indeed to the nature of that Being, who, as he pretended, was its object; but therefore more likely to accord with the appetites and conceptions of a corrupt and sensual age.

"That I may not appear," says the preacher, "to exalt our scriptures thus far above the Koran by an unreasonable preference, I shall produce a part of the second chapter of the latter, which is deservedly admired by the Mahometans, who wear it engraved on their ornaments, and recite it in their prayers.—'God! there is no God but he; the living, the self-lobbing: neither slumber nor sleep Kiveth him: to him belongeth whatever is in heaven and on earth. Who is he that can intercede with him but through his good pleasure? he knoweth that which is past, and that which is to come. His throne is extended over heaven and earth, and the preservation of both is to him no burden: he is the high, the mighty.' To this description who can refuse the praise of magnificence? Part of that magnificence, however, is to be referred to that verse of the psalmist, whence it was borrowed: 'He that keepeth Israel, shall neither slumber nor sleep.' Ps. cxii. 4. But if we compare it with that other passage of the same inspired psalmist, all its boasted grandeur is at once obscured, and lost in the blaze of a greater light. 'O my God, take me not away in the midst of my days; thy years are throughout all generations. Of old hast thou hid the foundations of the earth; and the heavens are the works of thy hands. They shall perish, but thou shalt endure; yea, all of them shall wax old, as doth a garment; as a vesture shalt thou change them, and they shall be changed; but thou art the same, and thy years shall not fail. 'The Koran, therefore, upon a retrospective view of these several circumstances, far from supporting its arrogant claim to a supernatural work, sinks below the level of many compositions confessedly of human original; and still lower does it fall in our estimation, when compared with that pure and perfect pattern which we justly admire in the scriptures of truth. It is then abundantly apparent, that no miracle either was externally performed for the support, or is internally involved in the composition, of the Mahometan revelation.' White's Sermons, containing a View of Christianity and Mahometanism, in their history, their evidence, and their effects, p. 250—271. Ed. 2.

The general aim of the Koran was to unite the professors of the three different religions, then followed in Arabia, Idolaters, Jews, and Christians, in the knowledge and worship of one God, under the function of certain laws, and the outward signs of ceremonies partly of ancient, and partly of novel institution, enforced by the consideration of rewards and punishments, both temporal and eternal; and to bring all to the obedience of Mahomet, as the prophet and amassador of God, who was to establish the true religion on earth, and be acknowledged chief pontiff in spiritual matters as well as supreme prince in temporal. The chief point, therefore, neucleated in the Koran is the unity of God, to restore which, the prophet pretended was the chief end of his mission; it being laid down by him as a fundamental truth, that there never was nor ever can be more than one true orthodox religion. The reft is taken up in preferring necessaries laws and directions, frequent admonitions to moral and divine virtues, the worship and reverence of the Supreme Being, and resignation to his will. One of the most learned commentators distinguishes the contents of the Koran into allegorical and literal; under the former are comprehended all the obscure, paradoxical, and ambiguous.
xiv.

enigmatical passages, with such as are repeated or abrogated; the latter, such as are clear, and in full force. See Mahometans.

Amongst the Mahometans this book is in the greatest reverence and esteem. The Mussulmen dare not so much as touch the Koran without being first washed, or legally purged; to prevent which, an inscription is put on the cover or label: "Let none touch it but they who are clean." It is read with great care and respect, being never held below the girdle. They swear by it, take oaths from it on all weighty occasions, carry it with them to war, write fencies of it in their ban-
ners, adorn it with gold and precious stones, and know-
ingly suffer it not to be in the possession of any of a different religion. Some say that it is punishable even with death in a Christian to touch it; others, that the veneration of the Mussulmen leads them to condemn the translating it into any other language as a profanation; but these seem to be aggravations. The Mahometans have taken care to have their scripture translated into the Persian, the Javan, the Malay, and other languages; though out of respect to the original, these versions are generally, if not always, interlined. It has been often published in Europe, in Arabic and in other languages. Maracci published it in Arabic and Latin, at Padua, in 1668, fol., with a partial and often faulty confession. The German translation of Boyvon was printed at Halle, in 1773; the French of Savary, at Paris, in 1782; and the English of Sale, at Lon-
don in 1734.

The number of commentaries on the Koran is so large that the bare titles would make a large volume.—Ben Ofehar has written the history of them, intituled Tarikb Ben Ofchair. The principal among them are, Rechacoor Thalakib, Zamahchfchari, and Bacai.

Beside the Koran, which is the basis of the Mahometan faith, they have also a book containing their traditions, which they call Sonna.

The Mahometans have a positive theology, built on the Koran and tradition; as well as a fcholastic one, built on reason.—They have likewise their canuils, and a kind of canon law; wherein they dilligently produce the laws of distin-
ction, and what of positive right.

They have their beneficaries too, chaplains, almoners, and canons, who read a chapter every day out of the Koran, in the mosques; and have prebends annexed to their office.

The kubh of the mosque is what we call the parson of the parish; and the fchoirs are the preachers, who take their text out of the Alcoran. See Sale's Translation of the Koran, preliminary discourse.

Alcoran is also used in a more limited sense, for a por-
tion or chapter of the Koran.

In which sense, the word is synonymous with fura.

Alcoran is also figuratively applied to certain other books full of impieties and impurities.

In this sense, we meet with the Alcoran of the Cordeliers, which has made a great noise; wherein St. Francis is extra-
vagantly magnified, and put on a level with Jesus Christ.

Alcoran, among the Persians, likewise signifies a kind of tower or belfry, very high and narrow, surrounded without by two or three galleries, one over another; whereby the Murrastes, a fort of pricks, repeat their prayers four or five days, with a very loud voice; making the town of the gallery all the while, that they may be the better heard all round.

Alcoranists, among Mahometans, those who adhere strictly to the letter or text of the Alcoran, from an opinion of its ultimate sufficiency and perfection. The Persians are generally Alcoranists, as admitting the Al-
coran alone for their rule of faith. The Turks, Tartars, Arabs, &c. besides the Alcoran, admit a multitude of traditions.

The Alcoranists, among Mahometans, amount to much the same with the Talmudists among the Jews. The Alco-
ranists can find nothing excellent out of the Alcoran; are enemies of philosophers, metaphysicians, and scholastic writ-
ers. With them the Alcoran is every thing.

ALCOUCHETE, in Geography, a town of Portugal, in the province of Estremadura, on the south coast of the Tagus, ten miles east of Lisbon. N. lat. 38° 55'. W. long. 8° 26'.

ALCOUTIN, a town of Portugal, in the province of Algarve, on the border of Alentejo, defended by a castle, and containing six parishes. It is situated on the Caluania, and six and one half leagues north-north-east of Tavira.

ALCOVE, in Architecture, a recess in a sleeping-room, made for the purpose of receiving the bed. It is also an arched seat in a garden.

The word is derived from the Spanish alcoba, which, ac-
cording to the older dictionaries of that language, signifies a vaulted cabinet in a chamber, open on one side, without window, and large enough to contain a bed. The Spanish word is derived from the Arabic al-kubba, the above, the place for the Lsq.; and all-kubba is probably from al-kubna the tent, or more probably from khab, steep, alkab, the bed, alkab the cave. The relation of these words is curious. According to the Spanish description, an alcove is not unlike a cave or recess in a rock, in which a wandering Arab might make his abode for the night.

Alcoves in ordinary rooms are square recesses conformable to the definition we have given, and are fixed in a style corresponding with the apartments to which they belong, and with flat or vaulted ceilings, as table may direct, or the height of the alcove may require. But in chambers of greater magnificence, and rooms of parade, they are not always recesses; but more properly a portion of a large apartment separated from the rest by an arch, or ballustrade, a screen of columns, or some other decorations, and elevated a few fteps above the general level of the floor. On this elevated platform, a date bed is usually placed, and sometimes seats and sofas to entertain company. This is what the French architec-
tes denominate an alcove. The recesss to which the English have appropriated the term, and which is conform-
able to its primary signification, the French denominate a niche, as may be seen in Blondel de la Decoration des Edi-
fores en general. (See Plate I. of Architecture.)

The authors of the Encyclopedic Methodique are of opin-
iou, that alcoves were in use among the ancients, and this would be indisputably true if we could receive the term in the lax fence in which they have explained it. But we cannot give the name of alcoves to the enclosures which they mention, confining of a kind of moveable ballustrade hung round with drapery, and placed in any part of a chamber at pleasure, nor to those draperies supported by terms, or affixed to the wall, which frequently occur in antique balsam-
reliefs. It must be confessed that we know very little of the private apartments of the ancients; yet if a recess for the bed to stand in had been a fashionable feature in a Greek or Roman bed chamber, it is probable that it would have been mentioned by Vitruvius, or others, and especially by Pliny, who is so minute and particular in the description of his Laurentine and Tuilcian villas. In each of these villas he describes a small elegant retired closet, surruffed with a bed, which by means of glasses folding doors and curtains, could be occasionally laid into or separated from the adjoin-

A L C

A L C
ing apartment. These closets appear to have been somewhat similar to alcoves, but they differ essentially from modern alcoves in having windows. The recesses discovered by the Abbé Winckelmann, in one of the chambers of Pompeia, in which he conjectures, perhaps rightly, that a bed had been placed, and these recesses which he found on the second story of Adnus's villa, at Tivoli, have better pretensions to the name of alcoves, but something more than a verbal description is wanting to enable us to determine whether they were formed for the express purpose of receiving a bed, or for some other purpose; or whether they were not such accidental recesses as are made by necessity in the arrangement of a building, which the architect turns to the belt uti in his power.

Be this as it may, alcoves, according to the modern manner, undoubtedly originated in Africa, or Asia, for we read of them perpetually in the Arabian stories, and in descriptions of Arabic palaces and gardens. From Arabia they were introduced among the Spaniards by their Saracen conquerors, and by the Spaniards, after the expulsion of the Moors, at the close of the fifteenth century, into Germany, France, and other nations, as the name they bear in every country sufficiently evinces.

At this time the Spaniards would fearfully have influence enough to make any thing fashionable north of the Pyrenees; but at the period we are speaking of they were held in high estimation, and many of their customs and manners were adopted in the other dominions of Charles the fifth. It is remarkable that in the designs of Palladio, and of several Roman architects of the same age, whose works have been confuted, we find no example of alcoves; from whence it may be inferred that they had not then become fashionable either in Rome or Venice. Whether they were more to be found in parts of Italy which were under the dominion of Charles might be an amusing subject of inquiry to an antiquary. It is said that alcoves are still frequent in the houses of the Spanish nobility, and Swinburne mentions two yet remaining in the Royal bed-chamber of the Moorish palace of the Alhambra, at Granada, which are probably the oldest in Europe, though it is uncertain whether their decorations are not of a more modern date, as the apartment was repaired for the use of Philip V. The beds were placed upon raised pavements of blue and white tiles, a fountain played in the middle to refresh the apartment in hot weather, and two small doors behind the alcove led to the royal baths.

In England, alcoves of every kind have been much in use, but the change in manners, in consequence of the general diffusion of wealth, has nearly banished the most magnificent kind with late beds, and the parade of which they were appendages. Even in private bed rooms they are now seldom considered except to obtain uniformity, or a communication to some other apartment, as they are found less convenient, and by confining the air, supposed to be less healthy to sleep in, than the uncontrasted space of the chamber.

ALCUDIA, in Geography, a small town of Spain, in Valencia, at the source of a river of the same name, which traverses the whole province from south-west to north-east. N. lat. 3° 45'. W. long. 0° 21'.

ALCUSAR, or Alcuezar, a town of Spain, in Aragon, upon the river Vero, north of Baldass, situated in a fertile country. N. lat. 42°. E. long. 1° 10'.

ALCUIN, or Albinus Flaccus, in Biography, flourished towards the close of the eighth century, and was famous for his genius and erudition. He was born in the north of England, and educated at York, under the direction of archbishop Egbert. Some say that he received part of his education in early life from Venerable Bede, but as he survived him about 70 years, others have disputed this fact. Egbert appointed him keeper of the curious library which he had founded at York; and he was also deacon of the church in this city, and abbot of Canterbury. In 793, he was sent on an embassy by Offa, king of Mercia, to the emperor Charlemagne, who conceived to high an opinion of him, that he solicited his bet to settle in his court, and to become his preceptor in the sciences, as well as to assist him in fettling some ecclesiastical disputes that agitated the country at that period. Accordingly he instructed the emperor in rhetoric, logic, mathematics, and divinity, and was in such high esteem at court that he was called, by way of eminence, the emperor's delight. Charlemagne likewise employed his learned favourite to write several books against the heretical opinions of Felix, bishop of Urgel, in Catalonia, who maintained that Jesus Christ was the son of God, not by nature but by adoption; and Alcuin accompanied the emperor in 794 to the council of Frankfort, which consisted of 50 bishops, and of which he was admitted a member. Although this council decreed, that Jesus Christ, as man, ought to be called the proper, not the adopted, son of God, the dispute was continued; and Felix being allowed to defend his opinion before an assembly of bishops at Aix-la-Chapelle, in 799, Alcuin was employed as his opponent, and performed the office to the entire satisfaction of the emperor and other attendants, and to the conviction of Felix and his followers, who were thus induced to abandon their errors and to accede to the opinion of the church. Alcuin performed other services on behalf of religion. He wrote commentaries for explaining the scriptures, but chiefly with a view to the investigation of their mystical meaning; he corrected the errors of the Latin translation in common use; and the first German translation of the scriptures has been ascribed to his direction and superintendence. He was also appointed, in concurrence with Paulus Diaconus, to compile, from the writings of the fathers, homilies or discourses upon select portions of scripture, which the ignorant priests of that period might commit to memory, and recite to the people. Alcuin, under the patronage and with the assistance of Charlemagne, contributed very much to the advancement of learning, by establishing public schools, particularly in France. Cave (Hist. Lit. tom. i. p. 67.) says, that France was indebted to Alcuin for all the polite learning of which it boasted in the eighth century and the following ages. The universities of Paris, Tours, Fulden, Soissons, and many others, were indebted to him for their origin and increase; those of which he was not the superior and founder, being
being at least enlightened by his doctrine and example, and
enriched by the benefits he procured for them from Charle-
magne. A German poet, cited by Camden, thus extols the
merit of Alcuin in introducing literature into France:

"Quid non Alcuino, facunda Lutetia, debo!
In tuatuar bonas ubi qui feliciter artes,
Barbarianque procul folus depeller, capit."

"Let Gallia's sons, nurtured in ancient lore,
To Alcuin's name a grateful tribute pay;
'Twas his, the light of science to restore,
And bid Barbaric darksas flee away."

Dr. Warton, however, (Hist. of English Poetry, vol. i.
diff. 2.) cautions us against forming "too magnificent ideas
of those celebrated masters of science, who were thus in-
vited into foreign countries to conduct the education of mighty
monarchs, and to plan the rudiments of the most
illustrious academies. Their merits are in a great measure
relative. Their circle of reading was contracted, their
syllabs of philosophy jejune; and their lectures rather
erred to stop the growth of ignorance than to produce any
positive or important improvements in knowledge." After
Alcuin had spent many years in the most intimate familiarity
with the greatest prince of his age, he obtained, at length,
with great difficulty, in 809, leave to retire from court to
his abbey of St. Martin's, at Tours. Here he kept up a
constant correspondence by letters with Charlemagne; from
which it appears, that both the emperor and his learned friend
were animated with the most ardently love to learning and
religion, and constantly employed in contriving and executing
the noblest designs for their advancement. The emperor of-
ten and earnestly solicited him to return to court, but no
arguments could induce him to quit this honourable retreat
where he was employed in the education of the youth
of the school which he had founded in this city; and where
he died on Whitsunday, in the year 804. He was a person
of distinguished piety and learning, and reckoned by William
of Malmesbury the best English divine after Bede and AId-
holm. He composed many treatises on a great variety of
subjects, in a style much superior with respect to purity and
elegance to that of the generality of writers in the age in
which he flourished. Besides his poem, "De Pontificibus
et Sanctis Eclefiae Eboracensis," first discovered by Ma-
billon, and published by Dr. Gale among his "Quindicem
Scriptores;" his other writings are extremely voluminous.
They consist of commentaries on the Bible, homilies, lives
of saints, theological and metaphysical discussions, epitaphs,
veres, and treatises on orthography, grammar, rhetoric, and
music; they are recited in the Biog. Brit. and by Cave,
(ubi supra) and amount in number to 53; and an edition
of them was published by Duchesne, at Paris, in folio, in 1617,
and at Ratibon in 1777. Some additional pieces are enu-
erated by Dupin. It has been said that Alcuin advised
Bede to publish his ecclesiastical history, and furnished ma-
terial for it; but the assertion is contradicted by chronology;
this work having been published in 731. There was another
Alcuinus, or Albinus, abbot of St. Aulnna's church at
Canterbury, the contemporary of Bede, who died three years
before him. By this Alcuin Bede was urged to publish his

ALCYON, or Alcyon, in Ornithology, a name given
by the ancients to the ipuda or king-fisher, and also a species
of the Alcedo.
of St. Dominica. 18. A. tuberosum, yellowish and tuberous, with the apices frequently subdivided, and tubulous pores, found adhering to rocks in the island of Mauritius. 19. A. gorgonoides, cincereous, fandy-flaky, with radiated watery cellules, found, with 12 rays of cellules, adhering to corals and rocks, in the island of Curaçao. 20. A. officinarum, with a roundish fhm, and oblong pores flattened over every part of it, found in the sea washing the American coast, very porous, white, and within rofe-coloured. 21. A. elaterum, white, very ramosus, attenuated and subdivided, with tubulous terminal pores, found in the Indian sea. 22. A. papillosum, cruffaccesus, with large papilla, thickly cut and convex, the boletus marinus of Marfglifo. 23. A. conglutinantum, gelatious, convex, with coniiierated lingus, and terminal mouths without teeth, found in the Cornith fcas. 24. A. officinarum, with many cylindric fflfus items, and an officeficated at the apex, found on the northern shore of Spitzbergen. 25. A. verticuli, green, ramosus, with cylindric obtufe pyramidal branches, found on the rocks of the island of Niufia, oppolite to Neapolis. 26. A. fdlatam, with two fettled terminal mouths. 28. A. coquilantium, with four fettled mouths, encompaffing a papilla, and four small erect terminal horns, found in the fea of Holland. Experiments made by Mr. Hatchett, on a few speciies of alcyonium, vis. abellium, ficus, and arbo- reum, he was led to conclude that they were all compofed of a fofl, flexible, membraneous fubfance, slightly hardened by carbonate, mixed with a fmall portion of fosphate of lime. Phil. Tranf. for 1800. P. 16. p. 564.

AcyUNUM is also a name given, with various epithets, to the Tufibora mystica of the Limnean fyltem, and also to several species of Millepora.

AcyUNUM is also a name given by Lloyd to a peculiar kind of foffle coral, of the Astrotites kind, found in Wales. It is very plentiful in that country, and puts-on the appearance of a fort of marble, being bedded in a marly matter for its matrix. Phil. Tranf. N. 252.

AcyUNUM Mare, in Ancient Geography, a name given to that part of the gulf of Corinth which fretched itself between the westen fhoft of Decjia, the northern coaft of Megafias, and a small part of Corinth, as far as the promon- tory of Olympia.

AcyUNUM was also the name of a lake in Corinth, of unfathomable depth, and which Nero attempted unsuccess- fully to found. Bacchus is faid to have defcended to hell through this lake to bring back Semple. Near this lake was a temple conftructed by the Oropians to Amphiaraurus, the forcer. Pafiamas. Ed. Kuhni, p. 200.

ALDA BARAM, in Ophiology, a name given by fome to the fefamoide bones of the great toe.

ALDAN, in Geography, a river of Siberia, which rifes in the mountains of Okhotic, on the borders of China, N. lat. 55° 50', and E. long. 135° 14', and taking a north-east course to lat. 63°, changes its direction to well-north-west, and at N. lat. 63° 25', E. long. 128° 24', joins the Lena.

AL DARU, in Botany, a name given by Avicenna, Se- ranion, and other Arabian writers, to the lenticel tree.

ALDOROUGH, in Geography, a fettled town of England, in the county of Suffolk, deriving its name from the river Ald, near it, and pleasantly fittuated between the fea on the east, and a high hill on the west, on which the church stands. The ifhery of this town in the feafon is consider- able, and near it there is a quay, with wareifoues for the fifh, and conveniencies for drying thofe of the North Sea. Herrings and fprats are the principal objects of attention; and it is faid that this is the only place for curing red fprats. The town is corporate, and fends two members to parliament. Its markets are on Wednesday and Saturday. It is 94 miles north-call of London. N. lat. 52° 10'. E. long. 1° 42'.

ALDOROUGH is also a market town in the Weft Riding of Yorkshire, on the river Otife, 15 miles north-west of York, and 208 miles north of London. N. lat. 54° 15', E. long. 1° 20'. It fends two members to parliament. It was formerly a Roman ftation, called Ifarium Brigantum, and probably the capital of the Brigantes. Its market-day is Wednesday.

ALDE, or Old, a small ifland on the north coaft of Norway. N. lat. 61° 25'. E. long. 4° 0'.

ALDS, Henry Van, in Biography, a painter who fhou- rified in 1650, and excelled in portraits.

AL.DEA Gallega, a d. Gallician village, a small market- town of Portugal, in Ef tremadura, fittuate in a kind of ifland formed by the Tagus, north of Sutault, and south- call of Lisbon. On an eminence, a league from Aldea Gal- lega, is a church dedicated to Nofta Senhora da Atelaya, our lady of the watch-tower; to which the negroes in Lisbon annually make a pilgrimage; and this black proceffion is attended by a great concourse of people. N. lat. 38° 45', W. long. 8° 31'.

ALDEB, or del Mar, or del Poco, a town of Spain, in Old Cattle, on the frontiers of Aragon.

ALDEA del Rio, a town of Spain, in the province of An- dalufia, and district of Cordova, fittuate on an eminence, to the south of the Guadalquiver; eight miles north-west of Cordova.

ALDEA river is on the coaft of Brazil, in about S. lat. 19° 52'. W. long. 45° 5', on which flands the town and port of Reys Magos. There is a large cape to the south of it.

ALDEA de Trinidad lies on the coaft of Brazil, called Paraguay, to the north-eaft part of the gulf of Santos, in S. lat. 24° 30'. W. long. 45° 30'.

ALDEAS Bay is about 16 leagues north-eaft from Cape Negro, on the southern part of the weft coaft of Africa, in S. lat. 15° 25'. E. long. 11° 25'. The bay is small but fercue; and Europeanhips, trading to the coaft for flavcs, frequently touch at it.

ALDEBAC, in the Materia Medica of the ancient Arabic physicians, the name by which they have called birdi- line, and which they reckoned among the vegetable poifons.

ALDEBARAN, in Astronomy, the Arabian name of a fixed ftar, of the firft magnitude, in the eye of the con- fellation Taurus, or the bull; and hence popularly called the bull's eye. For the beginning of the year 1800, its

ALDEBERT, or ADELBERT, in Biography, a native of France, who, in the eighth century, defcribed the people by pretended visions and revelations. He excercifed epifcopal dignity without the authority of Boniface, the pope's legate, and among other irregularities with which he was chargeable, both as to his principles and conduct, he forged a letter, addreffed to the human race, which he pretended to have been written by Jesus Christ, and to have been transmitted to him by the archangel Michael. He alfo remitted fines without confeffion, and required his followers to quit the churches, and to worship God in houses which he erected in the fields, and to kneel before crofles which he placed in woods and near fountains. His populariy was the caufe of feditiouf and tumult among the eaftern Franks. He was condemned at the intigation of Boniface by
by the pontiff Zachary, in a council held at Rome, A.D. 748, and thrown into pithon, where he probably ended his days. His forged letter was published by Stephen Bulcke, in the second vol. of the "Capitularia Regum Francorum," Mosleum's Eccl. Hist. vol. ii. p. 273.

ALDEGO, in Geography, a river of Italy, which rises near Montebello, in the Vicentia, and joins the Adige in the cañones of Venice, near Zerio.

ALDEGRETUS, or Andegheetus, in Biography, of a noble family at Padua, taught medicine at that university 34 years, and died of the plague in the year 1641, aged 58 years. He published "Lus Venetorum perfectionum tractatus ex ore Hercules Saxonum, Patavinii Medici clarissimi." 1597. 4to. See Alfric de Morbis Venetiorum, p. 417.

ALDEGREVER, Henry, a considerable engraver and painter, was born at Zoufft in Welfphalia, in 1528. He is said to have studied under Albert Durer, at Nuremberg, where style he copied. The mechanical part of his engraving is very neat, and executed entirely with the graver, in the style of Albert Durer. The light parts upon his steel are rendered soft and clear, by the addition of small long dots, which he has occasionally interfered with judgment. His drawing of the naked figure is more correct than that of the old German masters, and he has left of that flat taffle which appears in the belt of their works. It is observed, however, that his figures of men are more correct than those of his women. His heads are in general very expressive, and his other extremities well marked, but sometimes rather heavy. As a painter also, he is spoken of very highly, and considered as nearly if not altogether equal to his master, Albert Durer. His principal works are his own portrait, and several others, such as those of Knapperdallng, Melchizoch, &c.; the history of Sisathan and the two elders; Lives and Legends; the passion of Christ; the labours of Hercules; several Madonas; many historical subjects; a variety of Goldsmith ornaments, very beautifully engraved; and some few medals, amongst which is the society of Anabaptists. There is only one etching attributed to this master, which is Orpheus playing on a violin, and Euridice seated at the foot of a tree, dated 1528. It has been observed, that Aldegrever would have been very eminent in his profession, if in early life he had been introduced to a knowledge of the antique, and a more intimate acquaintance with the Roman masters. This artift has been erroneously called Aldegraft, and his Christian name has been Albert instead of Henry; but his name upon his own portrait is Aldegrever. The time of his decease is not known; but the last date which appears upon his prints is 1558. The number of his plates amounts to no less than 350. See Strat.

ALDEN, Fort, in Geography, is situate in Cherry-valley, in the state of New York.

ALDENAIIR, a small town of Germany, in the circle of the Lower Rhine, in a prefecture of the same name, and in the archbishopric of Cologne, situate on the river Ahr, eight leagues south of Cologne; Lat. 50° 35'. E. long. 6° 43'.

ALDENAU, a small town of the Lower Rhine, and archbishopric of Cologne, in a prefecture of the same name, 10 leagues south of Cologne. In the French distribution it is the chief place of a canton, in the district of Bonn, and department of the Rhine and Moeile; the place contains 1350, and the canton 7071 inhabitants, and the territory includes 20 communes. N. lat. 50° 25'. E. long. 6° 36'.

ALDENBERG, a town in the circle of Welfphalia and duchy of Berg, four leagues north-east of Cologne.

ALDENBURG, a town of ancient Rufus, now Old Ludoga, which lies in the government of St. Peterburgh.

ALDENBURGH, a town in the circle of Upper Saxony, and duchy of Anhalt Bernburg, two miles north of Bernburg.

ALDENHOVEN, a town of the circle of Welfphalia, and duchy of Juliers, three miles west-south-west of Juliers.

ALDER-tree, in Botany. See Butula.

ALDER, black. See Rhamnus.

ALDERAIMIN, or Alderainin, in Africology, the Arabian name of a star of the third magnitude, in the left shoulder of the constellation Cepheus, marked a by Bayer.

ALDERBURGH, in Geography, a considerable manufacturing village of England, in the county of Wiltts, two miles and a half south-east of Salisbury.

ALDERHOLM, an island of Sweden, at the mouth of the river Geble, in the gulf of Bothnia, formed, as is also Islandby, from the three branches of this river. This island is distant 80 miles north from Stockholm, and has a dock, arsenal, warehouses for deals, &c., and carries on a considerable trade.

ALDERMAN, among our ancient Saxon ancestors, was the second of the three orders or degrees of nobility. The word, in its original, is cadbarman; compound of old, old, or elder, elder, and man, q.d. elderman. Atelbing was the first rank of nobility, alderman the second, and thane the lowest.

It appears, says Mr. Hume (Hist. vol. i. p. 476, 8vo.), from the translations of the Saxon annals and laws, and from King Alfred's translation of Bede, as well as from all the ancient historians, that comes, in Latin, alderman; and earl in Dno-Saxon, were quite synonymous; and it also appears, (ib. p. 251.), that the aldermen or governors of counties, who, after the Danish times, are often called earls, were admitted into the witenagemot, or great council of the nation, and gave content to the publick statutes. The bishop, together with the alderman or earl, presided in the county-courts, or shiremeets, where all causes, ecclesiastical as well as civil, were decided; but they had no further authority than to keep order among the freeholders, and interpose with their opinion. The alderman received a third of the fines levied in these courts, and as most of the punishments were then pecuniary, this perquisite formed a considerable part of the profits belonging to the office. The alderman, or earl of a shire, appears to have been a person of the highest dignity and greatest power among the Anglo-Saxons; and therefore this office was commonly enjoyed by the thanes of the largest estates and most ancient families. Possessed both of the civil and military government of his shire, the alderman was a little king within his own territories, and assumed the titles of a king and prince in subfebrating charters, and other deeds. When he appeared at the head of the military forces of his shire in times of war, he was called a duke or heretegen, which signifies a general or commander of an army; and was indeed a high and potent prince. In the most ancient times of the Anglo-Saxon government, the aldermen, or earls, were appointed by the king; but towards the conclusion of this period, these great officers seem to have been elected by the freeholders of the shire, in the shiremeet or county-court. To enable them to support their dignity, they enjoyed certain lands, called the earl's lands, besides the fines above-mentioned, and several other perquisites. The office of earl was so far from being hereditary in the most ancient period of the Anglo-Saxon government, that it was held only during the good pleasure of the sovereign, and their own good behaviour. But towards the conclusion of this period, these great earls were most commonly, though not always, succeeded by their sons in their earldoms.
Alderman. This, however, was owing to the increasing power of the aristocracy, and to the prodigious wealth and influence of a few great families, rather than to any formal change in the constitution. Henry's Hist. vol. iii. p. 342.

It must be observed, however, that among our Saxon ancestors, there were several magnates who bore the title of alderman. Among them there were aldermannus tutor Anglie, aldermannus regis, comitatus, civitas, burgi, ecclesi, hundredi, sue waepentachii, &c. in Iocorum.

According to Spelman, the aldermannus tutor Anglie seems to have been the same office who was afterwards styled caputia justitiae Anglie, or chief justice of England; the aldermannus regis seems to have been an occasionalligimate, answering to our justice of assises; and the aldermannus comitatus, a magistrate who held a middle rank between what was afterwards called the earl, and the sheriffs' fat at the trial of caufes with the bishop; the latter proceeding according to ecclesiastical law, and the former declaring and expounding the common law of the land.

Alderman, in the English Policy, an associate to the mayor, or civil magistrate, of a city or town, for the better administration of his office.

The aldermen are an order of magnates, in our cities, and most of the municipal or incorporative towns, who form a kind of council, and regulate things relating to the policy of the place. They sometimes also take cognizance of civil and criminal matters; but that very rarely, and only in certain cases. Their number is not limited; but in some places is more, in some less, from five to twenty-five. Out of these are annually elected the mayors, or chief magistrates of places; who, at the expiration of their mayorality, return again into the body of the aldermen, whose delegates they were before. The twenty-five aldermen of London preside over the 26 wards of the city. When one of them dies or resigns, the wardmote chuse a successor, who is admitted, and sworn into office, by the lord-mayor and court of aldermen. All the aldermen are justices of the peace, by a charter of 15 Geo. II. The aldermen of London, &c. are exempted from serving inferior offices; nor shall they be put upon assizes, or serve on juries, so long as they continue to be aldermen. 2 C. 555. See Court.

Formerly there were also aldermen of the merchants, of hospitals, of hundred, &c. See Senator.

Aldersney, in Geography, a small island in the English channel, belonging to Great Britain, about four miles in length from east to west, separated from Cape la Hogue, on the coast of France, by a narrow strait, called the "Race of Alderney," and distant from it about three and a half leagues. This strait is very dangerous in stormy weather, more especially when two currents meet; otherwise it has sufficient depth of water for the largest ships; so that through this strait the French fleet made their escape after their defeat at la Hogue, in 1667. To the west-north-west are the dangerous rocks called the "Callacks," and the rocks called "Barrachies," are close to the west end of Alderney. On the east, for a mile, are several rocks, and a bank of sand at the distance of a league; east of this is Race, and round the rocks on the west is the passage to Jersey Island. Alderney, called by the French Aurigny or Orny, is a healthy island, fruitful in corn and pasture, and remarkable for a fine breed of cows. The inhabitants live together, for greater security, in a town of the same name; containing of about 200 houses, and their number is about 1000. The harbour, called Crabby, lies on the south side at some distance, and is only fit for small vehicls. Alderney, as well as the islands of Jersey, Guernsey, Sark, and their appendages, were parcels of the duchy of Normandy, and though united to the crown of England by the first princes of the Norman house, are governed by their own laws, which are for the most part the usual customs of Normandy, collected in the book intituled, "Le Grand Comteiner." The king's writ, or process from the courts of Westminster, is there of no force; but his commision is not bound by common acts of our parliament, unless particularly named. All caufes are originally determined by their own officers, the bailiffs and jurats of the islands; but an appeal lies from them to the king in council, in the last resort. Blackh. Com. vol. i. p. 107. N. lat. 49° 50'. W. long. 2° 15'.

Aldemey Cattle, a breed of cattle, probably first imported from the island of the same name, in general fine boned, but small and ill-made, and of a light red or yellowish colour. Cows of this breed are most frequently met with about the feats of the opulent, probably from their milk, though smaller in quantity, being more rich in quality than that of most other kinds, and yielding a larger portion of cream and butter from the same measure, which is of a beautiful yellow colour, and fine flavour. They are much inclined to fatten, and their heet has a fine grain and is well called, but rather more yellow or high coloured than that of some other perfect breeds. The author of the treatise on live-stock remarks, that they are a breed of cattle too delicate and tender to be much attended to by the British farmer, and not capable of bearing the cold of this island, especially the more northern parts of it, without being greatly injured by it. See Cattle.

Aldescus, in Antiquity Geography, a river which, according to the periphus of Dionysis Periegetes, discharged itself into the Euxine sea.

Aldhafera, in the Arabian History, denotes a fixed star of the third magnitude, in the Lion's main.

Aldheim, or Adelaide, Bt., in Biography, an eminent scholar and promoter of literature in the seventeenth century, and the nephew or near relation of Fyn, king of the Weft Saxons, was born at Caer-Bladon, now called Malmbury in Wilshire; and educated under Maudolphus, an Irish Scot, at the place of his nativity, as well as in France and Italy under Theobald, archbishop of Canterbury, and under Adrian, the most learned professor of the sciences, who had ever been in England, or under Albin, the pupil of Adrian. After the death of Maudolphus, who had instituted a school at Malmbury, Aldhelm succeeded him, and built a stately monastery, of which he himself was the first abbott. When the kingdom of the Weft Saxons was divided, upon the decease of Hella the bishop, into two dioceses, viz. Winchester and Shireburn, Aldhelm was promoted by Is to the latter, which comprehended Dorsetshire, Wilshire, Devonshire, and Cornwall. At Rome, whether he went to be consecrated by pope Sergius I. is said to have reproved the holy father for his incontinence; but Pope reproves him with not having discharged his conscience on this occasion. The monkish authors have recorded some extraordinary finances of his charity and Ed-mental; they have ascribed several miracles to him; and they report, that by his prayers he lengthened a beam in the church, which the builder had cut too short, and that he hung his garments to dry in the rays of the sun, which supernaturally supported them. It is of much greater importance, however, to contemplate his literary character and writings. It is evident, says Dr. Henry, from his works, which are still extant, that he had read the most celebrated authors of Greece and Rome, and that he was no contemptible writer in the languages in which these authors wrote. In the different seminaries, where he was educated, he had acquired a very uncommon stock of knowledge, and became famous for his learning, not only in England, but in foreign countries; so that several
several learned men sent him their writings, for his perceptual and correction; particularly prince Arciv, a son of the king of Scotland, who intended to give his pieces the last polish, by rubbing off the Scotch rut. Camden says, that he was the first Saxon who wrote in the Latin language, both in prose and verse; and he compiled a book for the instruction of his countrymen in the profuse of that language. Although another writer preceded him in Latin verification, it is certain, says Dr. Warton, (Hist. of English Poetry, vol. i. diff. 2.) that Aldhelm's Latin compositions, whether in verse or prose, as novelties, were deemed extraordinary performances, and excited the attention and admiration of scholars in all countries. A learned contemporary, who lived in a remote province of a Frankish territory, in a letter to Aldhelm, has this remarkable expression, "Vedra Latinitatis panegyricus rumor," has reached us, even at this distance. Venerable Bede gives the following character of him: "he was a man of universal erudition, having an elegant style, and being wonderfully well acquainted with books, both on philosophical and religious subjects." King Alfred the Great declared, that Aldhelm was the best of all the Saxon poets, and that a favourite song, which was universally sung in his time, near 200 years after the author's death, was of his composition. The character of Aldhelm is thus drawn by an ancient chronicler: "he was an excellent harper, a most elegant Saxon and Latin poet, a very skillful chanter or finger, a 'doctor egregius,' or doctor of singular merit, and admirably verified in the scriptures and the liberal sciences." It is related of him, that when he was abbot of Malmbury, having a fine voice and great skill in music as well as poetry, and observing the backwardness of his barbarous countrymen to listen to grave instructions, he composed a number of little poems, which he sung to them after mass in the sweetest manner; and by those means they were gradually instructed and civilized. William of Malmbury bears this testimony concerning him, that his style is left lively than may be defined by those who are more attentive to language than matter; but if you examine his writings attentively, you will find in them Grecian acuteness, Roman elegance, and English dignity. After Aldhelm had governed the monastery of Malmbury about 30 years, he is said to have retired to Shirburne, of which he had been consecrated bishop in 705, and where he died, May 25, A.D. 709. His treatise against the millakes of the Britons concerning the celebration of Easter, was the means of reconciling many of the Britons to the Catholic faith on this point. He also wrote several other treatises on various subjects, the titles of which are recorded in the Biog. Brit., some of which are lost, and others published by Martin Delrio, at Mentz, in 1601, in Svo, and by Cassius in the Bibliotheca Patrum. His book, written partly in prose and partly in hexameter verse, in praise of virginity, dedicated to Ethelburga, abbess of Barking, was published among Bede's Oeconomia. Biog. Brit. Henry's Hist. vol. iv. p. 10-13. Svo. Care Hill. Lit. fac. vi. vol. i. p. 757, ed. Oxon.

ALDHUN, ALTHWINUS or ALDWINUS, the first bishop of Durham, was promoted to the see of Lindisfarne or Holy Island, in 990, the 12th year of the reign of king Ethelred. The legends of the time say, that he was admonished by heaven to quit this station, in which he was harried by the incursions of the Danish pirates; and that he and the monks, who accompanied him, took with them the body of St. Cuthbert, which had been buried there 113 years, and after wandering about for some time, settled at Dunhelm, now called Durham, where he established a city and a cathedral church. Before this time, the town consisted only of a few scattered cottages, and the spot which he selected for the establishment of his colony was covered with wood, which was soon cleared away by the bishop and his followers. In three years the church was completed and dedicated to St. Cuthbert, whose bones were deposited within its walls. From this time the episcopal see was fixed at Durham. Alfred and Edward, the sons of king Ethelred, were educated by this prelate; and when their father was driven from the throne by Swain, king of Denmark, he conducted them, together with queen Emma, into Normandy, to duke Richard, the queen's brother, A.D. 1017. In the next year the bishop was so affected with the news of the defeat of the English by the Scots, that he died a few days after, having enjoyed the prelacy 19 years. Aldhun was of a noble family, but, according to Simeon of Durham, was more ennobled by his virtues and religious devotion. Biog. Brit.

ALDI, in Antiquity, servants who attended their masters in expeditions to the wars. They were otherwise called Aldmen, Aldon, and Alidona.

ALDPORT, in Geography, an ancient name for Manchester.

ALDRED, in Biography, an English prelate of the 11th century, was a man of an enterprising and ambitious spirit, and gradually rose from being a monk of Wincheffter and abbot of Tavillock, to the see of Worcefter and the archbishopric of York. Four years after he was promoted to the see of Worcefter, which he obtained in 1046, he took a journey through Hungary to Jerusalem, the first adventure of the kind which any Englishman had performed; and upon his return he was deputed by Edward, the Confessor, on an important embassy to the emperor Henry II. On his arrival in England, after some lay in Germany, where he acquainted himself with the church discipline, which he introduced into his own country, he procured the administration of the see of Wilton for three years, during the absence of its bishop, and that of Hereford for four years, after the death of its incumbent. In 1061 he was advanced to the archbishopric of York, and allowed, as it has been said, by means of bribery, to hold the see of Worcefter in commendam. Pope Nicholas II., having heard of his immoral practices, not only refused him the pall, for which he applied, but deprived him of his other preeminent places; but being robbed in his way home over the Alps, he was under a necessity of returning to Rome, and by the bold interference of earl Tosti, the pope was prevailed upon to grant him the pall, on condition of his resigning the see of Worcefter. Afterwards the king, considering the deprivations which the see of York had suffered by the incursions of the Barbarians, permitted Aldred to retain 12 towns, or manors belonging to the see of Worcefter for his own use. Others, however, say, that he detained them by violence and injustice. The following instance of revolution, and of prietly arrogance, is recorded by his panegyrist Stubbs. The high sheriff having intercepted some provisions, which the archbishop's servants were conveying to the palace at York, and feized them for the king's use, Aldred, instead of seeking legal redress, sent a deputation of clergy and citizens to demand restitution, and enforced the demand by threats of excommunication. Upon the sheriff's refusal, the archbishop, with a train of ecclesiastics, hastened to the king, who was then sitting in council at Withamster, and abruptly addressed him in this impetuous language. "Hear me, William! when thou wert an alien, and God had permitted thee, for our sins, and through much blood, to reign over us, thou displayed thy king, and placed the crown upon thy head with a blessing; but now, because thou defervest it not, I will change that blessing into a curse against thee, as a per-
a persecutor of God and his ministers, and a breaker and con
temner of those oaths and promisses, which thou madest unto
me before the altar of St. Peter;" The king was admonished
and terrified, threw himself at the feet of the archbishop, and
anxiously entreated to know what offence he had committed.
When the nobility who were present expressed their indigna
tion at the prelate’s infidelity, and at his suffering the king
to lie at his feet; "Let him alone," said the archbishop; "he
is not fallen at my feet, but at the feet of St. Peter." At length he raised the king and delivered his complaint: upon which an order was issued, that the goods
should be fully restored, and the prelate was sent away loaded
with rich presents.

Aldred’s veracity of principle was sufficiently manifested in
his conduct under the changes of government that occurred
during the latter part of his life. When his patron Edward
was dead, he assisted Harold in obtaining the crown. On the
arrival of William the Norman, when Stigand, archbishop of
Canterbury, refused to crown him, Aldred fell in with the
former, and performed the ceremony. Upon the Danish
invasion, when the citizens of York, and others, who were
of the court of King Edgar, took refuge in the church, the
archbishop fied them and went to the news, and died Sept. 13, 1069, just before the Danes landed;
and was buried in the cathedral church of York. Biog. Brit.

A L D R I C H , or A L D R I C H M O R E , Robert, was bishop of Car
lisle, in the reign of Henry VIII, Edward VI, and Mary,
and of course accommodated his principles to the changes of
the times. He was born at Barnham in Buckinghamshire,
educated at Eton school, and elected scholar of King’s col-
lege, Cambridge, in 1517, where he took the degree of master
of arts. At this time Erasmus styled him "blandez elo-
quentiae juvenis." Leland has also celebrated him for his
admirable parts and learning. In 1529 he was incorporated
bishop of divinity at Oxford, and in 1530 he was licencied
as doctor in the same faculty. He successively became
archdeacon of Colchester, canon of Windsor, and registrar
of the order of the garter, and at length, in 1557, bishop of Car-
lisle. He died March 28, 1585, at Horn-Castle, in Lincoln-
shire, which was a house belonging the bishops of Car-
lisle. He wrote several pieces, such as "Reflections con-
cerning the Sacraments;" "Answes to Queries containing
the Abuses of the Mafa;" "Various Epigrams;" and "Re-
olutions," of some questions relating to bishops and priets,
and other matters, tending to the reformation of the church,
begun by Henry VIII. Biog. Brit.

A L D R I C H , HENRY, an eminent divine and polite scholar,
was born at Wel-ton, in 1647, and educated in the col-
lege school, under the famous Balfy. In 1662 he was ad-
mitted into Christchurch college, Oxford, where he continued,
in the several situations and with the appropriate commenda-
tions of a diligent student, useful tutor, and excellent master,
to the day of his death, Dec. 14, 1710. Having passed
through the gradations of bachelor of arts in 1666, and master
in 1669, he took degrees, and became an eminent tutor in his
college. In 1683 he was installed canon of Christ church,
and in the same year accumulated the degrees of bachelor
and doctor in divinity. During the reign of James II, he
bore a conspicuous part in the controversy with the papists,
and published several tracts; ranking, according to bishop
Burke, (Hist. of his own Times,) among those eminent
English clergymen, "who examined all the points of popery,
with a solidity of judgment, a clearness of argument, a depth
of learning, and a vivacity of writing, far beyond any thing
that had before that time appeared in our language." Soon
after the Revolution, viz. in 1689, Dr. Aldrich was invested
dean of Christchurch, in which high station he behaved in the
moral worthy and exemplary manner, and exerted himself
in promoting learning, virtue, and religion. By his skill in
architecture he improved the buildings of the college; and
under the part of it called Peckwater quadrangle, so deftly
designed, was designed, was designed, was designed, by him.
The parish church of All Saints, in Oxford, and the chapel of Trinity College, which he designed, are further instances of his architectural
knowledge. In order to excite and cherish a taste for po
literature, he annually published some piece of an ancient Greek
author, as a new year’s gift to the students of his house.
The works of this kind which he edited were "Xenophonis
Memorabilia," Gr. and Lat. Oxon. 1690, 8vo.; "Xen
ophontis Sermo de Angelfso," Gr. and Lat. Oxon. 1691,
8vo.; "Arilliis Historia LXXII. Interpretum," Gr. and
Lat. Oxon. 1692, 8vo.; "Xenophontis de re equellibrb." Gr.
and Lat. Oxon. 1693, 8vo.; "Epicetus et Theophraste-
tus," Gr. and Lat. Oxon. 1707, 8vo.; "Platonis, Xen
ophontis, Plutarchii, Luciani Symplosia," Gr. Oxon. 1711,
8vo. He wrote likewise a system of Logic, intitled "Artis
Logicae Compendium," Oxon. 1695, 8vo.; and "Elements
of Geometry," in Latin, never published. He was also con
cerned in Gregory’s Greek Testament, printed at Oxford in
1705, fol. He wrote likewise anacreontic verses, an
account of his own life, and some other pieces of是有。
The candour of Aldrich's temper, and the moderation of his principles, may be inferred from his having been appointed by William III, in 1689, one of the commissioners for preparing matters towards introducing alterations in the service of the church, and accomplishing a comprehension with the dissenters; but the dread of innovation has always prevented the execution of this design. Besides the preferments above recited, Dr. Aldrich possessed the living of Wem, in Shropshire, and in 1702 he was chosen proctor of the convocation. In 1710 he died at his college, leaving an order to be buried, without any memorial, in the cathedral. "His modesty and humility, his calm pleasantries, his attention to academic business, and to the credit of his college, his exertions for the encouragement of learning, and the proofs which his memoirs afford of reputable talents, various accomplishments and amiable qualities, units to transmit his name with honour to posterity." Biog. Brit. Burney's Hist. of Mufic.

ALDROVANDA, in P. tany, a genus of the pentadria pentagynia class of order; the characters of which are, that the calyx is a five-parted, crested, equal, permanent perianthium; the corolla has five petals, oblong, acuminate, of the length of the calyx, and permanent; the stamens have filaments of the length of the flowers, and filiform anthers; the pistillum has a globosiform, stigmas very short, and obtuse stigmas; the pericarpium is a globosiform capsule with five valves, single seeds from which are longish, fixed to the inner wall of the pericarpium. There is one species, viz. A. recondita, kuttica of Flucknet, and bucarda of Aublaine, which is found in marbles, both in Italy and India, with bladders like utricularia, but in bunches. Martyn.

ALDROVANDI, Ulysses, in Biography, a celebrated naturalist, sometimes called the Modern Pliny, was born of a noble family, at Bologna, in 1522, and pursued his studies partly at his native place and partly at Padua. The truth of his religious opinions having been suspected, he travelled to Rome in 1550, for the purpose of vindicating himself; and there he took the advantage of studying the antiquities of the place, and drew up a treatise on the ancient statues, which was published in the work of his friend Lucio Mauro, on Roman antiquities. On this occasion he likewise became acquainted with Rondeletio, whose researches into the history of fishes gave him a taste for the knowledge of nature. Upon his return to Bologna he engaged in the study of botany, and went to Pisa to obtain instruction from professor Ghieri. Having graduated in medicine at Bologna in 1555, he was in the following year appointed to the chairs of philosophy and logic, and to the lectureship of botany, and by his interest the botanical garden of Bologna was founded in 1567. The duties of his profession, to which he sedulously attended, did not prevent his devoting his time and property to the important objects of collecting books, conducting an extensive correspondence, and taking journeys, with a view to obtain information concerning every branch of natural history. He also expended large sums, and involved himself in pecuniary difficulties, in the design of forming a museum of rare and curious productions, and in employing the best artists in delineating them. He not only cau ted to be delineated the external face of the objects he describes, but frequently gives anatomical accounts of their internal structure, with the use of the parts; more especially of the birds, in which he made some valuable discoveries. As the result of this labour and expence, he published four folio volumes with plates: three on ornithology, and one on insects. One volume on bloodless animals, and another on fishes, were likewise composed by him. The rest, making the whole number 13 volumes, and treating on serpents, quadrupeds, mollusks, metals, and trees, were compiled after his death, principally from the materials which he had collected. For the titles of the several treatises, see Haller's Bib. Botanica, Anatomica, and Medica, under the art. Aldrovandus. Notwithstanding the liberal allowance which he received in the execution of his extensive and magnificent plan, the expense of it ruined his fortune, and exhausted all his resources incompletely, that he died, in 1705, after having lost his fight, as it is said, at the hospital in Bologna, at the advanced age of 83 years. Haller says, that he quarrelled with the apothecaries and physicians at Bologna, and was expelled the college of physicians. To his country he bequeathed his immense collection, and it formed the basis of the museum now existing at Bologna, where his memory is held in great and deserved honour. Although his industry and zeal seem to have exceeded his judgment, and his works are defective in arrangement, and abound with superfluous and dubious matters, yet natural history is greatly indebted to his diligence and liberality. Buffon calls him the most laborious and learned of all the naturalists, and commends the plan and distribution of his work, and the exactness of his descriptions. Bayle observes, that antiquity does not furnish us with a design so extensive and laborious as that of Aldrovandus with regard to natural history. Pliny, he says, has treated of a greater number of subjects, but he only touches them lightly, and says but little upon any thing, whereas Aldrovandus has collected all he could meet with. His Hortus Siccus, or collection of dried specimens of plants, which filled sixteen large folio volumes, was existing, Haller says, near a century after the collection was formed. Besides his manuscripts in natural history, he left various writings in almost every other department of the arts and sciences. His philae are celebrated by Barcini, afterwards pope Urban VIII. in the following epigram:

"Multiplices rerum formas quas potest et aether
Exhibit, et quicquid promit et abdit humus,
Mens haerit, spectant oculi, dum cuncta fagaci
Aldobardeus teus digerit arte liber.
Miratur proprios folios industria factus
Quoque tuiti mai fegret effer parem,
Obiunt ipfa finitum rerum sequenda creatrix,
Et cupit eflc fuum quid visid artis opus."

"The various forms that swim the watery plains,
Whate'er the earth's capacious womb contains,
The trees and herbs that on her face appear,
And all the wing'd inhabitants of air,
In thy stupendous work collected lie,
To rear the foul, and strike the skies e'er eye,
Her own productions industry no more
Dares own, but wonders at the fruit the bore;
And fruitful nature at thy deeds amaz'd,
Wifhes her own those works thy art has rais'd."

Gen. Dict.
ALE, a popular fermented drink, made from malt and hops; and chiefly distinguished from beer, another potable liquor made from the same ingredients, by the quantity of hops used therein; which is greater in beer, and therefore renders the liquor more bitter, and fitter for keeping. For the method of brewing ale, see below. The brewers also distinguish pale, or fine ale, brown ale, &c. Their several properties, effects, &c. see under MALT-LIQUOR.

The art of making an infusion of corn, and particularly of barley, similar to our ale, seems to have been known and practiced in very ancient times among those people who lived in climates that did not afford grapes. It seems to have passed from Egypt into those western nations, which were settled by the colonists that migrated from the east. The zythum and curmi, mentioned by Tacitus, as the beverage of the ancient Germans, are supposed by Matthiolius to correspond to our ale and beer, Diodorus Siculus says (lib. iv. c. 6. tom. i. p. 350.) that the Gauls, who lived in a country that produced neither grapes nor olives, made a strong liquor of barley, which they called Zythum. The natives of Spain, the inhabitants of France, and the aborigines of Britain, used this liquor, under the different names of curmi, zythum, and curmi, in the first, and of curmi in the second, and of curmi in the last; all which names literally denote the strong water.

After the introduction of agriculture into this island, ale or beer was substituted for mead, and became the most general drink of all the British nations which practiced that art, as it had been of all the Celtic people on the continent. "All the several nations, (says Pliny. H. N. xiv. 29. tom. i. p. 729.) who inhabit the west of Europe, have a liquor with which they intoxicate themselves, made with corn and water, fruge madida. The manner of making this liquor is somewhat different in Gaul, Spain, and other countries, and it is called by many various names; but its nature and properties are everywhere the same. The people of Spain, in particular, brew this liquor so well, that it will keep good for a long time. So exquisite is the ingenuity of mankind in gratifying their vicious appetites, that they have thus invented a method to make water itself intoxicating." The manner in which the ancient Britons, and other Celtic nations, made their ale is thus described by Diodorus, (Orig. lib. xx. c. 2.) and Orosius, (lib. iv. p. 259.) cited by Henry (Hist. of England, vol. ii. p. 264, 8vo.) "the grain is steeped in water, and made to germinate, by which its spirits are excited and set at liberty; it is then dried and ground; after which it is infused in a certain quantity of water; which, being fermented, becomes a pleasant, warming, strengthening, and intoxicating liquor." This ale was most commonly made of barley, but sometimes of wheat, oats, and millet. Gesoon lib. vii. c. 34. p. 263. This liquor is of such antiquity in England, that we find mention of it in the laws of Ina, king of Wessex. Ale was the favourite liquor of the Anglo-Saxons and Danes, as it had been of their ancestors, the Germans. Tacitus, de Mor. Germ. c. 23. Before their conversion to Christianity, they believed that drinking large and frequent draughts of ale was one of the chief felicities which their heroes enjoyed who were admitted into the hall of Odin. Amongst the liquors provided for a royal banquet, in the reign of Edward the Confessor, ale is particularly specified. In Scotland and Wales they had two kinds of ale, called common ale and spiced ale; and their value was thus ascertained by law: "if a farmer hath no mead, he shall pay two casks of spiced ale, or four casks of common ale, for one cask of mead." By this law, a cask of spiced ale, nine palms long, and 18 palms in diameter, was valued at a sum of money equal in effect to £7. 10s. of our present money; and a cask of common ale, of the same dimensions, at a sum equal to £1. 15s. Hence it appears, that common ale was at this period an article of luxury among the Welsh, and that it could only be obtained by the great and opulent. Wine at this time seems to have been unknown even to the kings of Wales, as it is not mentioned in their laws; though Gwalas Cambrensis, who flourished a century after the conquest, informs us, that there was a vineyard in his time at Monmouth, near Newbridge, in South Wales. Henry's Hill. vol. iv. p. 297. By a statute of 35. Henry III. in 1274, mentioned by Hume (Hist. Eng., vol. ii. p. 224.), a brewer was allowed to sell two gallons of ale for a penny in cities, and three or four gallons for the same price in the country. But the first office of ale was fixed by the famous Stat. 51 Henry II.

The following method of preparing ale from turning four in long voyages, was first published by Dr. Stubs (Phil. Trans., 1697.), and experience has evinced its utility. To every gallon of five gallons, after being placed in a cask on shipboard not to be flirred any more, put in two new laid eggs whole, and let them be in it. In a fortnight, or a little more, the egg-shells will be entirely dissolved, and the eggs become like wind-eggs enclosed only in a thin skin; after this the white has been pressed on, but the yolks are not touched or corrupted by the juice, and the ale has been well preserved, that it was found better in January than in December.

The duties on ale and beer make a considerable branch of the revenue in England. They were first imposed in 1643, when the excise was first established, again by Car. II. and have been continued by several subsequent acts of parliament. By 7 Geo. III. c. 79, for every barrel of beer or ale, above 16 shillings a barrel, (exclusive of the duty hereby imposed, and not being two-penny ale, or table beer, (the brewer shall pay ten shillings; and for every barrel of table beer, or beer or ale of 12s. the barrel, or under (exclusive of the duty), two shillings; and for every barrel of two-penny ale, (described in the seventh article of the Union with Scotland) four shillings and two-pence. The allowance for waffe shall be three gallons out of 35 gallons, which shall be reckoned a barrel of beer or ale made by common brewers.

The saccharine matter extracild from the farinaceous foods, of which ales are made, and subjected to fermentation analogous to that of wine, imparts to our ales a quantity of alcohol; and they have, therefore, in general, the cordial, exhilarating, intoxicating, and sedative qualities of wine. But their effect in these respects, depends partly upon the quantity and condition of the saccharine matter that is employed, and partly upon the management of the fermentation to which they are subjected. Barley is chiefly employed for the purpose of making ales, though it might be prepared from any of the cereals; and this selection is very properly made, because its germination is most easily conducted, and under its germination it gives out its spirit most readily, and in greatest quantity. Ales, made in the ordinary manner, will be stronger or weaker according to the quantity of the saccharine matter that is used; and this will be greater or less according to the quantity of well-packed barms in the barley that is employed, according to the mode in which it is malted, according to the proper and complete extraction of the saccharine matter by water, and according to the diffusion in a greater or less degree, of a quantity of the superfluous water. The other qualities of ales, build their strength or weakness, will depend upon the conduct of the fermentation. As the infusion of malt or wort is not so well dispelled to fermentation as the juices of fruits, it will require the addition of a ferment; and afterward the conduct of the fermentation will be very much the same with that of wines; at first very active, and then slowly protracted for a long time; but, however ale is made, its fermentation is not so complete as to being rendered
to complete and perfect as that of wine. In most ales there is probably a large portion of unaffinamrate of matter, which of course renders ales more nourishing than wines, and they are, ceteris paribus, more liable to accepy in the stomach than wines. It has been commonly supposed, that the vividness of words is never entirely corrected by the fermentation; and therefore that ales are more apt than wines to fill the vesels of the human body with vitific fluids; but Dr. Cullen thinks that this circumstance deferves little attention, as it is probable that the power of the galtic fluid, and of the fermentation which happens in the stomach and intestines reduces the whole nearly to an equality in respect of fluidity. Cullen’s Mat. Med. vol. i. p. 418, &c.

Ale, cerovusia, is also a denomination given to divers medicated liquors, or diet-drinks, of which ale is the basis or vehicle. The medicated ales make a large article in our old dispensatories. Such are the cerovusia oxoidesia, for the eyes; cerovusia anti-arthritica, against the gout; cerovusia cephalis, for the head; cerovusia epilipsis, &c.

Ale, pottle, is prepared by infusing the dry leaves of gill or ground-ivy, in malt-liquor; which hereby becomes impregnated with the virtues of that plant; and is therefore reputed abortive and valerianary, good in disorders of the breast, and against obstructions of the uveae.

Ale, Dr. Butler’s purging, is prepared of polypody, fena, farfarpalliis, azureus, febrif, graz, agrimony, and maidenhair, put up in a bag, and hung in a vessel of ale.

We also meet in some dispensatories with a mixture of ale, made by boiling that liquor with a confidence; which has been used against obstructions in the kidneys, and the fluxus albus.

Ale-beer. See Beer.

Ale-berry, is ale boiled with bread and mace; sweetened, strained, and drank hot.

Ale-conner, an officer in the city of London, whose business is to inspect the measures of the public houses. There are four of them: and they are chosen by the common-hall of the city.

Aleshouse must be licensed by justices of the peace, who take recognizances of the persons licensed, viz. 10l. each, and of their security, 5l. each, that they will not suffer unlawful gaming, or other disorderly practices in their houses. By 35 Geo. III. c. 115, every person, excepting those who fell ale in fairs, who shall fall by retail ale or beer without licence, or who those fell beer or ale in cells containing not less than fifty gallons, or in bottles, not less than two dozen quarts, not to be drank in his own house; out of alehouse, &c. (38 G. III. c. 54.), is liable to a penalty of 20l. for the first offence, and for the second shall moreover be incapable of being afterwards licensed to keep an alehouse, with all costs. The licence is granted on the first of September, or within twenty days after, at a general meeting of the justices for the division to which he belongs, upon his producing a certificate to his character, unfeis, by living in a city or town-corporate, and if he be a subscriber, he is liable to a penalty not exceeding 40l. and not less than 10l., and likewise to a fine of 10s. for permitting tipping, &c. 1 Jac. c. 9. 26 Geo. II. c. 41. 29 Geo. II. c. 12. 5 Geo. III. c. 45. 30 Geo. III. c. 38. and 32 Geo. III. c. 59. By the last act no person can fell wine by retail to be drank in his own house, who has no an ale-licence.

Ale-measure. See Measure.

Ale-flour, a rust, or tributary, nearly paid to the lord-mayor of London, by those who fell ale within the city.

Ale-taster, is the officer appointed and sworn, in every court-leet, to take heed that there be a due size, and goodneat of bread, ale, and beer, sold within the jurisdiction of the leet.

Ale is used by some of our ancient English writers, and particularly in composition with other words, for festival. Thus, bridal or bride-ale is the feast in honour of the bride or marriage; leet-ale in some parts of England denotes the dinner at a court-leet of a manor for the jury and county tenants; lamb-ale is used for an annual feast at lamb-hagerng; Whitsun-ale is the name by which in the midland counties the rural feasts and feasting at Whituncture are denominated; and church-ale was a feast established for the repair of the church, or in honour of the church-fant, &c. See Warton’s Hist. of English Poetry, vol. iii. p. 128.

Church-bills, as they are described by Pierce, bishop of Bath and Wells, in his answer to the inquiries of archbishop Land, are when the people go from afternoon-prayers on Sundays to their lawful sports and pastimes in the churchyard, or in the neighbourhood, or in some public-house where they drink and make merry. By the benevolence of the people at these palesmies, many poor parishes have call their bells, and beautified their churches, and rared stock for the poor.

Clerk-ales, or lesser church-ales, were so called because they were for the better maintenance of the parish-clerk; and there is great reason for them, says his lordship, for in poor country parishes, where the wages of the clerk are but small, the people thinking it unfit that the clerk should duly attend at church, and not gain by his office, lend him in provision, and then come on Sundays and feast with him, by which means he feels more ale, and takes more of the liberality of the people, than their quarterly payment would amount to in many years; and since these have been put down, many ministers have complained to me, says his lordship, that they are afraid they shall have no parish clerks. A hid-ale is when a poor man, decayed in his inutility, is set up again by the liberal benevolence and contribution of his friends at a Sunday’s feast. The people were fond of these recreations, and the bishop recommends them, as bringing the people more willingly to church, as tending to civilize them, and to compone differences among them, and as serving to increase love and unity. But the justices of the peace were of a different opinion, and signed a petition to the king, in which they declare that these revels had not only introduced a great profanation of the Lord’s day, but riotous tippling, contempt of authority, quarrels, murders, &c. and were very prejudicial to the peace, plenty, and good government of the country, and therefore they pray that they might be suppressed. Two judges in the western circuit, in 1653, made an order for suppressing them; but Land complained to king Charles I. of their invading the episcopal jurisdiction, and they were summoned before the council, reprimanded, and enjoined to revoke this order at the next assizes. Neal’s Hist. Puritans, vol. i. p. 457, 440.

ALEA, in Roman Antiquity, signifies, in general, games of chance. They were forbidden by the Roman laws, and Titian laws, except in the month of December. Hor. Od. iii. 24. 58. Martial, iv. 14. v. 85. xiv. 1. These laws, however, were not strictly observed. The character of gamesters, alkulators or alaeus, was held infamous. Cicero. Cat. ii. 16. Pliny, ii. 27.

ALEA, in a more limited sense, is applied by Roman writers to a particular game played with dice, in a pair of tables, somewhat after the manner of our back-gammon, or trick-trac. Instead of our men, they played with white and black bones, which were moved this way or that, as the dice directed. In this game appears to have been the game with what the Greeks called petra and elias; the Romans sometimes tabula, tellania, and XII. spiga, in the game of Minerva, given to her by Auleus king of Arcadia.

ALEA, in Ancient Geography, a town of Arcadia, south-east of Styrmus. It was founded by Lecus, and had three
three considerable temples, viz. those of the Ephemian Diana, of Minerva Alea, and of Bacchus. The feast of Bacchus, called Strenna, was celebrated every third year; and Paufanias relates, that on this occasion they privately scourged the women at the altar of this deity. 

ALEA was also a town of Thessaly, and another of Spain, where Steph. Byz. places the Carpentani.

ALEANDER, JEROME, in Biography, was born in 1480, and distinguished himself in the 16th century by his violent opposition to Luther and the Reformation. Luther says he was a Jew, probably on account of his accurate acquaintance with the Hebrew language; but Bayle shows that he was defended from a Catholic family of distinction in Fria. His memory was singularly retentive, and enabled him to acquire not only the Hebrew, Greek, and Latin, but also many modern languages. According to Luther, who is contradicted by Bayle, he was at Rome in the pontificate of Alexander VI. and was secretary to the infamous Cazan Borgia. It is acknowledged, however, that he was invited to France by Lewis XII. in 1508, to teach the Belles Lettres in the university of Paris. In this situation he was so much esteemed, that he attracted the attention of Leo X. and by the recommendation of this pontiff he became secretary to the cardinal de Mediæ, and afterwards succeeded Aczialio as librarian of the Vatican. In 1519 he was sent by Leo as his nuncio into Germany; and in the diet of Worms he declared for three hours against the doctrine of Luther. Although he declined the contest to which Luther challenged him, he had influence sufficient to obtain an edict, which he himself drew up, for burning his books and proscribing his person. In 1531 he was again nuncio in Germany and attempted, though unsuccessfully, to diffuse Charles V. of making a truce with the Protestants in this country. Having been created cardinal by Paul III. in 1537, he was sent a third time into Germany, where, as the pope's legate, he exerted himself in checking the progress of the Reformation. Upon his return to Rome he died in 1542, in consequence of taking too many unseasonable medicines, and just as he was finishing a large work against all the professors of literature, which was never published. The works which he has left are a Greek and Latin Lexicon, printed at Paris in 1521, fol. and a Greek Grammar, printed at Strafsburg in 1517. Svo. Luther represents Alexander as a man destitute of principle, of violent passions, infatiable avarice, and licentious conduct; but he was an adverary, and allowance should be made for the feelings and language of resentment. Erasmus speaks with respect of his learning, but complains of his unkindness as a friend, of his want of veracity, and of the injury which he suffered from his accusations. Alexander's mortification at checking the progress of heresy, notwithstanding his utmost efforts to restrain it, is emphatically expressed in the epitaph, which he composed for his own tomb.

"Nam situm est a Diophanes, / In Julijs ostinae statu ; / Quo fidele quidem, ut ille loquor, / Nominem in conspectu mortis." 

Not unreluctant I reign my breath, 
For to behold life's ills is worse than death."

Gen. Dict.

ALEANDER, JEROME, the Younger, the nephew of the former, was by profession a civilian, and a writer of some distinction in the 17th century. He was secretary first to Benedict, and afterwards to Barberini at Rome, and a member of the literary academy denominated the Accademia, for which he wrote several pieces, and one on the device adopted by the society. In the way of his profession he wrote "Commentaries on the Institutes of Caius," and as an antiquarian he wrote a piece intitled, "Explicatio antiquae ta

buke Marmorex Soli efficie exculpant," &c. printed in 1452 at Rome, in 1516, and at Paris in 1517. He also wrote Italian and Latin poems, and some pieces on ecclesiastical affairs. His death, which is laid to being owing to excess of eating, happened in 1634 and his funeral, which was magnificent, was conducted and attended by his associates of the academy. Gen. Dict.

ALEATORIUM, in Roman Antiquity, was the place where they played at alea.

The aleatorium was near the spherylyium; that the sportsmen, when tired with the pila, or more robust exerceses, might refresh themselves in the aleatorium.

ALEBECE, in Ancient Geography, a town of Gaul, supposed to be the same with Albaceae.

ALEBVS, a river of Spain.

ALEC, in Ichthyology, a name given by Gaza, in his commentaries on Aristotle, to the fish called by that author maenies, and by Ovid, menecles. It is of the sparus kind.

ALECOST, See Tamarctum.

ALECTO, in Mythology, one of the three Furies, daughter of Acheron and Night, or of Pluto or Proserpine; she is represented with vipers about her head and wings, and armed with vipers, scorpions, and torches. The name denotes envy, or that which has no rest; being derived from a priv. and κεφαλή, I refl. See a fine description of this Fury in Virgil. An. vii.

ALECTO, in Entomology, a species of Sphynx, with the fore wings grey above, and the posterior red, with a black bafe and margin; found in India.

ALECTORIA, in Ornithology, a species of Crax, with a yellow cere, black body, and white belly.

ALECTORICARDITES, compound of the Greek alexere, cock, and καρδία, heart, in Natural History, a name given by Plutarch to a bird resembling a pullet's heart, with the fat near the heart of it, and the corvine feathers defcended from it.

ALECTORIUS lupis, is used for a small species of lyson, or disjoint segment of a palate of a fhy, approaching to the nature of the cheloniadus lupis.

ALECTOROLOPHUS, in Botany. See Bartsia, Pedicularis, and Rhinanthus.

ALECTOROMANTIA, from alexere, a cock, and μαντεψ, divination, in Antiquity, an ancient kind of divination, performed by means of a cock.

This art was in use among the Greeks; and the usual manner of it was this: A circle was made on the ground, and divided into twenty-four equal portions, or spaces: in each of which spaces was written one of the letters of the al phabet, and upon each of these letters was laid a grain of wheat. This done, a cock was turned loose in the circle, and careful observation was made of the grains he pecked. The letters corresponding to those grains were afterwards formed into a word; which word was to be the answer defined.

It was thus that Libanius and Jamblichus fought who should succeed the emperor Valens; and the cock answering to the spaces ΕΟΔΥ, they concluded upon Theodore, but by
ALEC, in Geography, a genus of the didynamia angiospermia class and order: it characters are, that the calyx is a perianthium, one-leaved, two-lipped, upper lip two-cleft, lower three cleft; the clefts ovate, obtuse, shorter than the tube; the corolla one-petalled, tubular; the tube gradually widened; the border expanding, five-parted; the parts broad-lanceolate, obtuse, the filaments, four filaments, inserted into the tube, filiform, bearded, of the length of the tube, two of them a little shorter, others two; the pistil, a gland ovate, filiform, of the length of the filaments, stigma incurved, a little thicker than the style, and of the same length, solitary on both sides; the pericarpium, a capsular, ovate, obtuse, twin, smooth, two-celled, and two-seeded; the seeds solitary and ovate. There is one species, viz. A. Capena, a native of the Cape of Good Hope, in the very near place near rivers, flowering in November and December, and growing black in drying. Martyn.

ALECRUONURUS gramin. See Festuca.

ALEEI, in Geography, a river of Walia, in Denbighshire, which runs into the Elwy.

A-LEE, in Sea Language, the situation of the helm, when it is pulled down to the lee-side of the ship, in order to put the ship about, or lay her head to the windward. See Hand-over.

ALEFCHIMO, in Geography, a ball or district of the island Corsica, situated on the coast, containing 28 villages, and 10,000 people.

ALEGAMBE, Philip, in Biography, a learned Jesuit, was born at Brufels in 1592; and having finished his education, entered into the service of the duke of Olfm in Spain, and accompanied him to Sicily. After he assumed the habit of a Jesuit at Palermo in 1613, he taught philosophy at Grat in Austria, and became professor and doctor of divinity in 1659. During this period he travelled through Germany, France, Spain, and Italy, as tutor to the son of the prince of Egemberg, a favourite of the emperor Ferdinand II. and attended him as confesser, in 1638, in his embassy to pope Urban VIII. When this mission was finished, he was retained at Rome by the general of the Jesuits as secretary of the Latin diplomatics to Germany, and afterwards appointed president of spiritual affairs, and auditor of confessions in the professed house. He died of the dropsy in 1672. His chief work was a "Biography of Antwerp Jesuits," printed at Antwerp in 1643, and at Rome, by Subod, in 1672. Gen. Dict.

ALEGER, a name given to an inferior sort of vinegar, made of ale, or malt liquor, instead of wine. Power has given a description of the case in aleger. V. Power, Exper. Philol. Ob. 3. p. 32.

ALEGRANZA, in Geography, one of the smaller of the Canary islands, situated at the north-east side of the Lancelrota, one of the larger. lat. 29° 25'.

ALEGRE, or Allegra, a town of France, in the department of the Upper Loire, and district of Puy-en-Velay, 5 leagues E. of Brioude, and 4 N.E. of Puy-en-Velay. The place contains 886, and the canton 5690 inhabitants; the territory comprehends 170 kilometres and 8 communes.

ALEGRETE, a town of Portugal in Alentejo, upon the river Caua, with the title of a marquisate, and containing about 500 inhabitants; 2 leagues south-east of Pont-Alegra. N. lat. 36° 6'. W. long. 6° 36'.

ALEGRINUS, John, in Biography, cardinal and patriarch of Constantinople, was a native of Albayle in Picardy. He was legate a latere in Spain and Portugal, and died in 1240. His works were formerly in estimation, but are now disregarded.

ALEHOOF, in Botany. See GELECHOMA.

ALEI, in Geography, a river of Ruffia, which runs into the Ohy on the left side of it.

ALEIPHA, from αΙλαπα, I amoint, in the Materia Medica of the ancients, a word used for all fatty bodies whatever. The oils of vegetables, and the fat of animals were all called by this general name. But these simple substances were not the only ones called by it, for it is very frequently used to express any sort of medicated oil impregnated with aromatic vegetables; but its general acceptation in this sense, was for such compositions as were intended to nourish the body; and therefore they were properly only vegetable or animal fats impregnated with the lighter parts of plants, and not clogged with an addition of powders, or with wax, or any thing of that kind, which might have given them the confidence of ointments. The ancient physicians were very fond of these compositions, which they applied either to some diseased part only, or to the whole body, and after they had made the patient use the warm bath to relax and open the pores.

ALELUS CAMPO, in Ancient Geography, a plain of Cilicia, placed by Strabo to the east of Sarus, between Adana and the sea. It is so called from Bellerophon's wandering and perishing there, after being thrown off Pegusus.

ALEKSEISKI, in Geography, a town of Ruffia, in the government of Simbirsk, 36 leagues S.S.E. of Simbirsk. N. lat. 55° 15'. E. long. 50° 14'.

ALEKSIJEPSKOIE, a town of Ruffia, in the government of Saratov, 37 leagues N.E. of Saratov.

ALEKSK, a town of Russia, in the government of Tul', on the Oka, 9 leagues N.E. of Kaluga. N. lat. 54° 44'. E. long. 36° 44'.

ALEMA, a city of Gilead, beyond Jordan, mentioned in Maccab. v. 26; and perhaps the same with Helmon-Debitaim.

ALEMAN, Louis, in Biography, was born in 1592, and advanced rapidly through several gradations of ecclesiastical preferment to the archbishopric of Arles. He was much respected by Louis III, king of Naples, who, on his account, confirmed the privileges granted to the city of Arles; and he was honoured by pope Martin V. who had employed him in several services, with the dignity of cardinal. After the death of Martin V. he embroiled himself with pope Eugenius IV. by holding the council of Bails, of which he was president, in contradiction to his wishes; and he was excommunicated by this pontiff. He was again restored to his communion and dignities by pope Nicholas V. and sent as his legate to Lower Germany. On his return to his diocese, he was usefully employed in reforming the clergy, and instructing the people. He died at Salon in 1450, and was canonized. With the virtues of an ecclesiastical he united the talents of a humanist. Now. Diet. Hist.

ALEMAN, Louis Augustin, was born at Grenoble in 1653, where he followed the profession of an advocate. His works were, "Remarks of M. de Vaugelas on the French Language," with a preface by himself; "New Observations, or a Civil War in France upon Language," 1 vol. Paris 1683; "Monastick History of Ireland," 1 vol. Paris, 1650; "Historical Journal of Europe for the year 1654." Now. Diet. Hist.

ALEMANNI, Allemanni, or Alemani, in Ancient Geography,
A L E

Geography and History, the denomination of a body of Suevi, who appeared on the banks of the Men, and in the neighborhood of the Roman provinces, itself either of food, of plunder, or of martial glory, about the year 214, or the 4th of the reign of the emperor Caracalla. Dion. Cauf. lib. Ixvii. p. 1350. Abinius Quadratus, an original Roman historian, cited by Agathias, (ib. i. c. 5.) informs us, that this hostile array of Volunteers, which coalesced into a great and permanent nation, was composed of many different tribes, and on this account, affixed the name of Alennani, or Allennani, i.e. men of all nations, to denote at once their various lineage, and their common bravery. They confided chiefly of Suevi, who, in process of time, were joined by several other German nations and some Gauls; for we are told by Tacitus, that a considerable number of Gauls, abandoning their own country, went to settle beyond the Rhine, in that territory which had formerly belonged to the Suevi. Aurelius Victor, St. Jerome, and other writers, place them between the Danube, the Upper Rhine, and the Mein, in the present duchy of Wurttemberg. They were numerous and warlike, and were chiefly celebrated for fighting with great dexterity and bravery on horseback. Their abhorrence of slavery was so great, that even those who were taken prisoners by Caracalla chose rather to die than to be sold for slaves: for when they were actually sold, they not only destroyed themselves, but some of them dispatched also their children. Dion. Cauf. lib. Ixvii. p. 84. Their government was monarchical; and the objects of their worship were the same with those of the other German nations. Caracalla, in consequence of a victory which he gained over the Alemanni, in the year 214, was distinguished by the surname of Alennanicus. In 224, the 15th year of the emperor Alexander Severus, the Alemanni, accompanied with other German nations, passed the Rhine, took possession of the forts on the banks of the river, and ravaged Gaul. Alexander, returning from Peria, hastened to the banks of the Rhine, and, as the Alemanni had repassed the river upon the news of his approach, he ordered a bridge to be thrown over, proposing to attack them in their own country. But being affrighted by the mutinous soldiers, at the instigation of Maximinus, this buffoon devolved upon his successor. Accordingly Maximinus pursued them with great slaughter, and took many of them prisoners, with great spoil of corn and cattle; and the advantages he gained were thought to be so considerable, that the senate conferred upon him and his son the title of Alennanicus. In the year 256, the fourth of Valerian's reign, the Alemanni made an unexpected irruption into Gaul, and laid waste the country; whilst those who dwelt on the banks of the Danube, penetrated through the Rhetian Alps into the plains of Lombardy, advanced, as far as Ravenna, and displayed the victorious banners of barbarians almost in sight of Rome. A large army was suddenly convened, at the appearance of which the Alemanni were terrified, and retired into Germany laden with spoil. On another occasion, 30,000,000 of this warlike people are said to have been vanquished in a battle near Milan, by Gallienus, at the head of only 10,000 Romans. Whether we give credit to the relation of this victory or not, Gallienus seems to have formed an alliance with the Alemanni, and protected Italy from their fury, by marrying Pipa, the daughter of a king of the Marcomanni, a tribe of the Suevi, often confounded with the Alemanni. A party of them was defeated by Claudius in 265, and compelled to fly before a precipitate flight into their own country. As soon, however, as they heard of the death of Claudius, they prepared for again invading Italy; 40,000 horse appeared in the field, and the number of the infantry doubled that of the cavalry. Their first objects were a few cities on the Rhzian frontier; but as they proceeded they enlarged their views, and they traced a line of devastation from the Danube to the Po. Aurelian, A. D. 270, having collected an active body of troops, marched with silence and celebrity along the skirts of the Hercynian forest; and when the Alemanni, laden with the spoils of Italy, arrived at the Danube, the Roman army, which lay concealed, intercepted their return. The dismembered barbarians, enclosed by the Roman legions, and reduced to a condition abject and disdained, fled for peace. Their ambassadors were received by Aurelian with every appendage of dignity; and when they were ordered to rife and allowed to speak, they attempted to extenuate their conduct, and demanded a large subsidy, as the price of the alliance which they offered to the Romans. The emperor's reply was fierce and imperious. He treated their offer with contempt, and their demand with indignation; and dismissed them with the choice only of submitting to his unconditional mercy, or awaiting the utmost severity of his resentment. Aurelian, being suddenly called away into Panonia, committed the destruction of the Alemanni, either by sword or by famine, to his lieutenants. But the barbarians made their escape, and returned towards the mountains of Italy. As soon as the emperor heard that they had liberated themselves, and were ravaging the territory of Milan, he hastened to march to the relief of Italy. The Alemanni, in the mean while, had spread themselves from the Alps to the Apennines; and, by a defultory war, the force of the enemy remained unabated. Three considerable battles are mentioned, in which the principal force of both armies was equally engaged. In the first battle, fought near Piacentia, the Romans received a severe a blow, that the immediate discomfiture of the empire was apprehended. But the firmness of the emperor restored in some degree the honour of his arms. The second battle was fought near Fano in Umbria; and here the Alemanni were totally and irresistibly defeated. The flying remnant of their host was exterminated in a third and last battle near Pavia; and Italy was rescued from the inroads of these barbarians. During the alarm which preceded the decisive battle of Fano, the Sibylline books were consulted, A. D. 271; and the ceremonies which were enjoined were punitively observed. "These superstitious arts," says Mr. Gibbon, "however pernicious in themselves, were subverted to the success of the war; and if, in the decisive battle of Fano, the Alemanni fancied they saw an army of spectres comba ng-them on the side of Aurelian, he received a real and effectual aid from this imaginary reinforcement." The emperor Probus, A. D. 277, delivered Gaul from the invasion of the Alemanni by discovering 70 flourishing cities, which had been oppressed by those barbarians, who, since the death of Aurelian, had ravaged that great province with impunity. Probus purified his Gallic victories, passed the Rhine, compelled nine of the most considerable princes of Germany to repair to his camp, to fall prostrate at his feet, and to accept such conditions as he thought proper to dictate: and, in order to raise a bulwark against their future inroads, he constructed a stone wall of considerable height, and strengthened it by towers at convenient distances. From the neighbourhood of Newlaut and Ratibon on the Danube, it stretched across hills, vallies, rivers, and morasses, as far as Wimpfen on the Neckar, and at length terminated on the banks of the Rhine, after a winding course of near 290 miles. Within a few years after the death of Probus, this wall was overthrown by the Alemanni. In 287, they made another incursion into Gaul, but were defeated by Maximian, who, in the following year, passed the Rhine, and laid their country waste wherever he came with fire and sword. Diocletian also, at the same time, entered Germany through
through Rhaetia; and is said to have extended the confines of the empire to the source of the Danube. In the year 291 the Burgundians seized on part of the country belonging to the Allemanni; and in 301 Conflantius the father of Conflantine the Great, gained a brilliant victory over them, on which account the Allemanni are said to have lost 60,000 men. Notwithstanding this loss, they did not long remain quiet; for in 310, they again crossed the Rhine and ravaged the neighboring provinces: but Conflantine marching against them, defeated them in a battle, and obliged them to quit theirbooty and repossess the Rhine. Some say he was called Maximus on account of this victory. In the 18th year of Conflantius's reign, the Allemanni again attempted to make an invasion into Italy; and having advanced as far as the lake of Conflance, the emperor marched against them, and put them to flight. In the course of the same year, another body of them, breaking into Gaul with the Franks and Saxons, took and plundered above 40 towns on the banks of the Rhine, and among these was the city of Cologne, which they almost entirely ruined. They were at length driven out of Gaul by Julian; but affembling near Strasbourg, he marched against them, A.D. 357; and after victory had remained for some time in suspense, the Allemanni were entirely defeated, and driven completely out of Gaul. Julian ravaged the countries of the Alemans and their allies for some time, and granted them a truce for ten months. When the truce expired, he passed the Rhine on a bridge of boats, entered their country, and compelled them to sue for peace. Upon the death of Julian they again ravage Gaul; defeat the Romans in a pitched battle, but were afterwards defeated by Jovinus in three battles, A.D. 366. In the cloze of the following year they again rally, and pass the Rhine; but Valentinian gains a signal victory over them. In 369 Valentinian invades their country; and in 374 concludes a peace with their king Maximarun. In 378 they again pass the Rhine, and ravage the neighboring provinces, but are defeated with great slaughter by Gratian. In 388 they submitted to Maximus, who had usurped the empire in Gaul, and agreed to pay him a yearly tribute. In the reign of Honorius a colony of the Allemanni was allowed to settle in that part of the present Switzerland, which is separated by mount Jura from the Franche Comté, and by the lake of Geneva and the Rhine from the present Savoy and province of Vienne. About the year 411 the country bordering on the lake Lemanus, or the lake of Geneva, was, according to Servius, inhabited by the Allemanni. In 477 Audocras, king of the Saxons, and Childeric, king of the Franks, marched against those who had settled among the Alps, and put many of them to death. Upon the destruction of the western empire, the Allemanni subdued that part of Gaul which is now known by the name of Alsace, where they settled. They were joined by their countrymen in Germany, and those who dwelt between Mount Jura and the lake of Geneva; and in 496 entered Germania Secunda, and wasted the country; but they were overcome by Clovis, king of the Salian Franks, and dispersed. Those who settled in Alsace, and near the lake of Geneva, acknowledged him for their king. Others took refuge in Rhaetia and Noricum, where they were allowed by Theodoric, king of Italy, to reside. Many of them were transplanted by the same prince into Italy, and the rest were permitted to settle between the Alps and the Danube. From this time the Allemanni had no king of their own; but continued, although for a time they were dispersed in several countries, chiefly partly to the Ostrogoths, who were masters of Italy, and partly to the Franks, who had dominion in Gaul. When the Ostrogoths ceded their territories out of Italy to the children of Clovis, the Alemanni, those excepted whom Theodoric had transplanted into that country, submitted to the Franks. Gibbon, History of the Decl. and Fall of Rom. Emp., vol. i. p. 417, &c. Vol. ii. p. 21, &c. A.D. Un. Hist. vol. xvii. p. 288—299.

ALEMANNIA, or ALEMANIA, in Ancient Geography, a name given to Germany, which was not known before the time of the Antonines, and then applied only to a part of it. The appellation is derived from the Alemanni.

ALEMBERT, John le Rond d', in Biography, an eminent mathematician and philosopher, and an elegant writer, was born at Paris, November 16, 1717. His surname De le Rond was derived from that of the church near which he was exposed as a foundling by his mother, who is said to have been Mademoiselle Tencin, sister of the Abbe, afterwards Cardinal, Tencin. His father Delouches Caron, hearing of his situation in the house of a glazier, with whose wife he was put to nurse, yielded to the impulse of affection and duty, and took measures for his future sublimity and education. In acquiring the first rudiments of education among the Jansenists, he manifested signs of those extraordinary powers, by which he was afterwards distinguished. At the age of 10 years, his schoolmaster declared that he had nothing farther to teach him; and during his attention to theological studies, he composed at a very early period, "A Commentary on the Epistles of St. Paul to the Romans," which led the Jansenists to expect, that he would be an able champion in their cause, and become a second Pascal. But pursuing his education at the college of Mazarin, he transferred his attention from theology to mathematics, in which he found greater satisfaction, and in the knowledge of which he afterwards excelled.

Upon leaving the college, he retired to the house of his nurse, for the purpose of enjoying a tranquil retreat, and of prosecuting his studies without interruption. He hoped likewise to tell him his gratitude for her former kindness by sharing with her the means of sublimity with which he was provided, and thus contributing to the increase of her domestic comfort. In this obscure situation he lived for many years, with the greatest simplicity, and derived satisfaction to himself from administering to the happiness of those with whom he was connected. His bookish had no just conception of the extraordinary talents of her guest; and she could not help occasionally considering him as an object of compassion. "You will never," said the one day to him, "be any thing but a philosopher; and what is a philosopher but a fool, who toils and plagues himself, that people may talk of him after he is dead?" With a view to the improvement of his fortune, or rather of the means of comfortable sublimity, he followed the advice of his friends in directing his attention, first, to the law, in which he took his degrees, and afterwards to medicine; but his attachment to mathematics prevailed over every other consideration, and induced him to decline the advantage which he might reasonably expect to derive from any other lucrative profession. At the age of 24, in 1741, he attracted notice by correcting the errors of Reyneau's "Analyse Des Monuments," which was a work of high estimation in the department of analytics; and he was admitted a member of the Academy of Sciences. He then incessantly examined the path in which a body moves in passing obliquely from a racer into a denser fluid; and this investigation, which he commenced after having closely pondered whether the mind rapidly or gradually moved him in extending his views to the forces of moving bodies. The result of his speculation was, his "Treatise on Dynamics;" (Traité de Dynamique, 4to, Paris, 1743. Ed. 2. 1758.) in which he separates into two parts the action of the moving powers, and
and considers the one as alone producing the motion of the body, in the second instant, and the other as employed to destroy that which it had in the first. This principle had been applied by M. d'Alembert, so early as the year 1744, to the theory of the equilibrium, and the motion of fluids, (Traité de l'Equilibre et du Mouvement des Fluides, Paris, 1744. Ed. 2. 1750.) and the discovery of it was succeeded by a new calculus, the first essays of which were published in a "Discourse on the General Theory of the Winds," (Réflexions sur la Cause General des Vents, Paris, 4to. 1747.) which the academy of Berlin honoured with the prize-medal in 1746; and at the same time the author was elected an honorary member. This work was dedicated to the king of Prussia, who was terminating a glorious campaign by an honourable peace, in the three following Latin verses:

"Hec ego de ventis, dum ventorum ocyor alis
Palantes agit Autrrias Fredericus, et orbis
Insignia lauro, ramum pretendit olivae.

"Swifter than wind, while of the winds I write,
The foes of conquering Frederic sped their flight;
While laurel o'er the hero's temple bends,
To the tied' school the olive branch he fends."

The numerous and valuable productions above recited, entitle d'Alembert to rank among the most celebrated mathematicians of the age. But he is no less distinguished by his genius, judgment, and taste, than by his mathematical knowledge; and he is deservedly regarded in France as one of the first writers of that nation. To him the original design of the French Encyclopedia has been generally ascribed; a work which was begun in 1750 by d'Alembert, Diderot, Voltaire, and many other learned men, and which has contributed in a very eminent degree to the diffusion of knowledge. Many of the most valuable articles in mathematics, history, and polite literature, were composed by M. d'Alembert; and the preliminary discourse, concerning the state, progress, connections, and affections, of the various branches of human knowledge, will be ever considered by the best judges as the evidence of a well informed and comprehensive mind, as a specimen of judicious arrangement and correct criticism, and also as a model of just thinking and good writing. Beside the valuable store with which he furnished this treasure of universal science, his talents were displayed in many separate publications on subjects of classical and polite literature. His "Translation of select parts of Tacitus, ("Traduction de divers morceaux de Tacite," in 2 vols. 12mo. affords, says one of his biographers, an elegant specimen of his learning; and his "Memoirs of Chriltiana queen of Sweden," is a masterly piece of biographical writing, in which the author evokes his acquaintance.
